**Citizenship:** A status that individuals have within a community, such as a nation-state, that is a right of birth or is granted by the state, which guarantees particular rights and entitlements (e.g., the right to vote, a right to education and healthcare) to such individuals who also have obligations to the community of which they are a part.

**Digital Divide:** A term that refers to inequalities of access to networked information and communication technologies (ICTs) based upon factors such as personal income, race, ethnicity, or geographical location and how such inequalities of access impacted upon the life chances of individuals, as networked ICTs became increasingly central to how the economy and society operates.

**Fourth Estate:** A term used to identify a role for the media and, particularly, the news media as the watchdogs of how power and authority are used on behalf of the public. The term has its origins in France prior to the French Revolution of 1789. The other estates are the executive, the parliament, and the judiciary.

**Intellectual Property:** Original ideas, concepts, or designs that have been registered legally as copyrights, patents, or trademarks that entitle their owners to receive economic revenues in the form of royalties for the reproduction or use and which give their owners rights over the reuse or modification of these copyrighted, patented, or trademarked forms of intangible property.

**Open Source:** A term derived from software development that refers to source code that is made available to all on an open, public, and non-proprietary basis. Open source software is distributed with its source code and can be reproduced and modified freely by other users.

**Public Sphere:** A forum that is independent of the state, where uses of public authority can be debated among informed citizens and where public opinion is thus formed through rational debate. The German philosopher Jürgen Habermas, saw the media as playing this role in early modern Europe (the bourgeois public sphere). Habermas, however, was pessimistic about the impact of commercial mass media upon the possibility of maintaining such an autonomous forum.

## INTRODUCTION

Geoinformatic surveillance for spatial and temporal hot-spot detection and prioritization is crucial in the 21st century. A hot spot may be any unusual phenomenon, anomaly, aberration, outbreak, elevated cluster, or critical area. Government agencies require hot-spot delineation and prioritization for monitoring, etiology, management, or early warning. Responsible factors may be natural, accidental, or intentional, with relevance to both infrastructure and security.

This article describes multidisciplinary research based on novel methods for hot-spot detection and prioritization, driven by a diverse variety of case studies of interest to agencies, academia, and the private sector. These case studies concern critical societal issues, such as public health, ecosystem health, biodiversity and threats to biodiversity, emerging infectious disease, water management and conservation, carbon sources and sinks, persistent poverty, environmental justices, crop pathogens, invasive-species management, biosurveillance, biosecurity, disease biogeoinformatics, social networks, sensor networks, hospital networks and syndrome surveillance, video mining, early warning, tsunami inundation, remote sensing, and disaster management.

Our approach has involved an innovation of the popular circle-based spatial scan statistic. In particular, it employs the notion of an upper level set (ULS) and is accordingly called the upper level set scan statistic system, pointing to the next generation of sophisticated analytical and computational systems, effective for the detection of arbitrarily shaped hot spots along spatiotemporal dimensions. It also involves a novel prioritization scheme based on multiple indicators and stakeholder criteria without having to reduce indicators to a single index using Hasse diagrams and partially ordered sets. It is accordingly called the poset prioritization and ranking system (see Patil & Taillie, 2004a, 2004b).

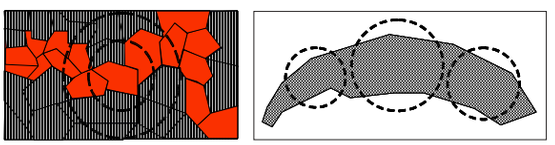
## UPPER LEVEL SET HOT-SPOT SCAN STATISTIC SYSTEM

Patil and Taillie (2004a, 2004b) introduce an innovation of the health-area-popular circle-based spatial and spatiotemporal scan statistic. It employs the notion of an upper level set, and is accordingly called the upper level set scan statistic, pointing to a sophisticated analytical and computational system as the next generation of the present-day popular SaTScan (Kulldorff, 1997, 2001; Kulldorff & Nagarwalla, 1995; Kulldorff, Rand, Gherman, Williams, & Defrancesco, 1998; Mostashari, Kulldorff, & Miller, 2002; Waller, 2002).

*Figure 1. Limitations of circular scanning windows. (Left) An irregularly shaped cluster—perhaps a cholera outbreak along a winding river floodplain. Small circles miss much of the outbreak and large circles include many unwanted cells. (Right) Circular windows may report a single irregularly shaped cluster as a series of small clusters.*



## Background Theory of Scan Statistics

The spatial scan statistic concerns the following situation: A region $R$ of Euclidian space is tessellated or subdivided into cells, which will be denoted by the symbol $a$. Data is available in the form of a count $Y_a$ on each cell $a$. In addition, a size value $A_a$ is associated with each cell. The cell sizes $A_a$ are regarded as fixed and known, while the cell counts $Y_a$ are independent random variables. Two distributional settings are commonly studied:

- **Binomial:** The size $A_a=N_a$ is a positive integer and $Y_a$~Binomial $(N_a,p_a)$, where $p_a$ is an unknown parameter attached to cell $a$ with $0<p_a<1$.
- **Poisson:** The size $A_a$ is a positive real number and $Y_a$~Poisson $(\lambda_a A_a)$, where $\lambda_a>0$ is an unknown parameter attached to cell $a$.

Each distributional model has a simple interpretation. For the binomial, $N_a$ people reside in cell $a$ and each person contracts a certain disease independently with probability $p_a$. The cell count $Y_a$ is the number of diseased people. For the Poisson, $A_a$ is the size (e.g., area or some adjusted population size) of the cell $a$, and $Y_a$ is a realization of a Poisson process with intensity $\lambda_a$. In each scenario, the responses $Y_a$ are independent; it is assumed that spatial variability can be accounted for by cell-to-cell variation in model parameters.

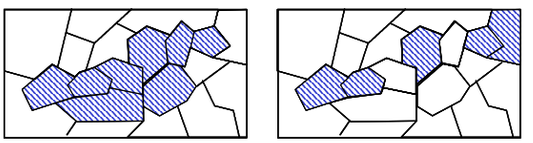
The spatial scan statistic seeks to identify hot spots or clusters of cells having an elevated response with respect to the remainder of the region. Elevated response means large values for the rates (or intensities),

$$G_a=Y_a/A_a,$$

instead of the raw counts $Y_a$. The scan statistic easily accommodates other adjustments, such as for age or gender.

A collection of cells from the tessellation should satisfy several geometric properties before it can be considered as a candidate for a hot-spot cluster. First, the union of the cells should comprise a geographically connected subset of the region $R$ (Figure 2). Such collections of connected cells will be referred to as zones Z and the set of all zones is denoted by $\Omega$. Second, the zone should not be excessively large. Otherwise, the zone instead of its exterior would constitute the background. This restriction is generally achieved by limiting the search for hot spots to zones comprising of less than, say, 50% of the region.

*Figure 2. A tessellated region. The collection of shaded cells in the left-hand diagram is connected and, therefore, constitutes a zone in $\Omega$. The collection on the right is not connected.*



The notion of a hot spot is inherently vague and lacks any a priori definition. There is no true hot spot in the statistical sense of a true parameter value. A hot spot is instead defined by its estimate, provided the estimate is statistically significant. To this end, the scan statistic adopts a hypothesis testing model in which the hot spot occurs as an unknown zonal parameter in the statement of the alternative hypothesis.

The traditional spatial scan statistic uses expanding circles to determine a reduced list $\Omega_0$ of candidate zones Z. By their very construction, these candidate zones tend to be compact in shape and may do a poor job of approximating actual clusters. The reduced parameter space of the circular scan statistic is determined entirely by the geometry of the tessellation and does not involve the data in any way. We propose a scan statistic that takes an adaptive point of view in which $\Omega_0$ depends very much upon the data. Furthermore, $\Omega_0$ induces a tree structure useful for visualization and expressing uncertainty of hot-spot clusters in the form of a hot-spot confidence set on the tree.

Although the traditional spatial scan statistic is applicable only to tessellated data, the ULS approach has an abstract graph (i.e., vertices and edges) as its starting point. Accordingly, this approach can also be applied to data defined over networks, such as subway, water, or highway systems. There is complete flexibility regarding the definition of adjacency. For example, one may declare two cells as adjacent if (a) their boundaries have at least one point in common, (b) their common boundary has positive length, or (c) in the case of a drainage network, the flow is from one cell to the next.

## ULS Scan Statistic

The ULS scan statistic is an adaptive approach in which the reduced parameter space $\Omega_0=\Omega_{ULS}$ is determined from the data using the empirical cell rates:

$$G_a=Y_a/A_a.$$

These rates determine a function $a\rightarrow G_a$ defined over the cells in the tessellation. This function has only finitely many values, and each level g defines an upper level set:

$$U_g=\{a:G_a\geq g\}$$

Since upper level sets do not have to be geographically connected (Figure 3), we take the reduced list of candidate zones $\Omega_{ULS}$ to consist of all connected components of all possible upper level sets. The zones in $\Omega_{ULS}$ are plausible as potential hot spots since they are portions of upper level sets of the response rate. The number of zones is small enough for practical maximum likelihood search; in fact, the size of $\Omega_{ULS}$ does not exceed the number of cells in the tessellation.

A ULS tree can be defined on the reduced parameter space $\Omega_{ULS}$. Its nodes are the zones $Z\in\Omega_{ULS}$ and are therefore collections of vertices from the abstract graph. Leaf nodes are typically singleton vertices at which the response rate attains a local maximum. The root node consists of all connected vertices in the abstract graph. Figure 4 shows the tree structure for the surface from Figure 3.

*Figure 3. Schematic response surface with two response levels, g and g'. The upper level set determined by g has three connected components, $Z_1$, $Z_2$, and $Z_3$, that determined by g' has $Z_4$, $Z_5$, and $Z_6$ as its connected components. The diagram also illustrates the three ways in which connectivity can change as the level drops from g to g': (a) Zones $Z_1$ and $Z_2$ grow in size and eventually coalesce into a single zone $Z_4$, (b) zone $Z_3$ simply grows to $Z_5$, and (c) zone $Z_6$ is newly emergent.*

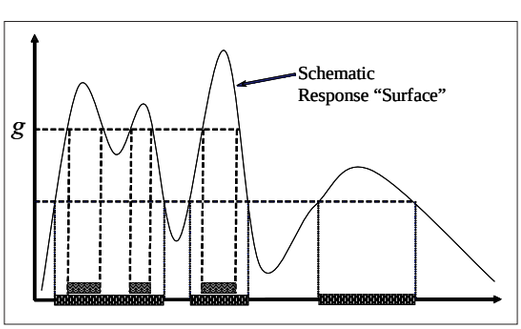


*Figure 4. ULS connectivity tree for the schematic surface displayed in Figure 3. The four leaf nodes correspond to surface peaks. The root node represents the entire region. Junction nodes (A, B, and C) occur when two (or more) connected components coalesce into a single connected component.*

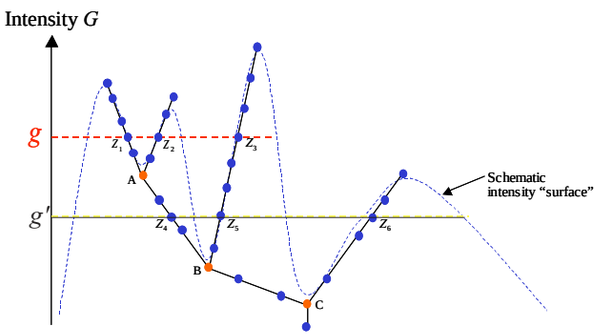

A consequence of the adaptivity of the ULS approach is that $\Omega_{ULS}$ must be recalculated for each replicate in a simulation study. Efficient algorithms are needed for this calculation. Several generic algorithms are available in the computer-science literature (Cormen, Leierson, Rivest, & Stein, 2001, Section 22.3 for depth-first search; Knuth, 1973, p. 353; Press, Teukolsky, Vetterling, & Flannery, 1992, Section 8.6 for transitive closure).

## Hot-Spot Membership Rating

Zonal estimation uncertainty is visually depicted by inner and outer envelopes, where the outer envelope consists of all cells belonging to at least one zone in the confidence set. Cells in the inner envelope belong to all of the zones in the confidence set. In other words, the outer envelope is the union of all zones in the confidence set while the inner envelope is their intersection (Figure 5 and Figure 6).

*Figure 5. Estimation uncertainty in hot-spot delineation. Cells in the inner envelope belong to all plausible estimates (at specified confidence level); cells in the outer envelope belong to at least one plausible estimate. The MLE is nested between the two envelopes.*

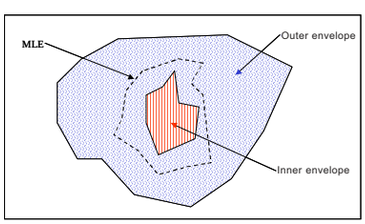

*Figure 6. A confidence set of hot spots on the ULS tree. The different connected components correspond to different hot-spot loci, while the nodes within a connected component correspond to different delineations of that hot spot—all at the appropriate confidence level.*

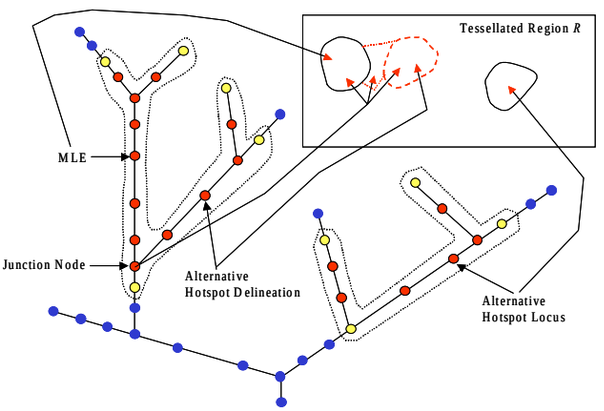

A numerical rating may also be assigned to each cell for inclusion in the hot spot. The rating is the percentage of zones in the confidence set that includes the cell under consideration. The inner envelope consists of cells receiving a 100% rating while the outer envelope contains the cells with a nonzero rating. A map of these ratings, with the superimposed MLE, provides a visual display of uncertainty of the hot-spot delineation.

## Typology of Space-Time Hot Spots

Scan statistic methods extend readily to the detection of hot spots in space and time. A space-time version of the circle-based scan statistic employs cylindrical extensions of spatial circles, but cylinders are often unable to adequately represent the temporal evolution of a hot spot (Figure 7). The space-time generalization of the ULS scan statistic can detect arbitrarily shaped hot spots in space and time (Patil & Taillie, 2004b). This lets us classify space-time hot spots into various evolutionary types, a few of which appear on the left-hand side of Figure 8. The merging hot spot is particularly interesting because, while it comprises a connected zone in space and time, several of its time slices are spatially disconnected. The diagrams in Figure 8 are motivated by a study on trajectories of persistent poverty in the United States being conducted by Amy Glasmeier of Penn State University.

*Figure 7. Temporal evolution of a spatial hot spot is represented by the shape of the hot spot in space and time. Cylinders may not adequately capture this shape.*

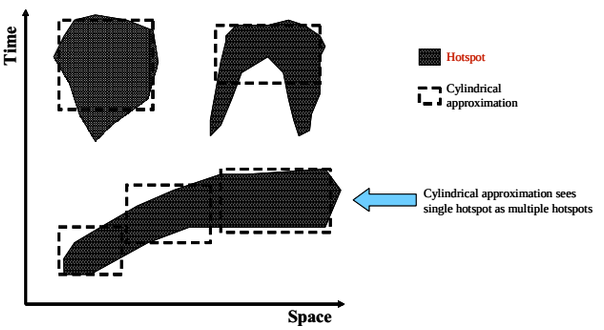

*Figure 8. The four diagrams on the top depict different types of space-time hot spots. The spatial dimension is represented schematically on the horizontal axis while time is on the vertical axis. The diagrams on the bottom show the trajectory (sequence of time slices) of a merging hot spot.*

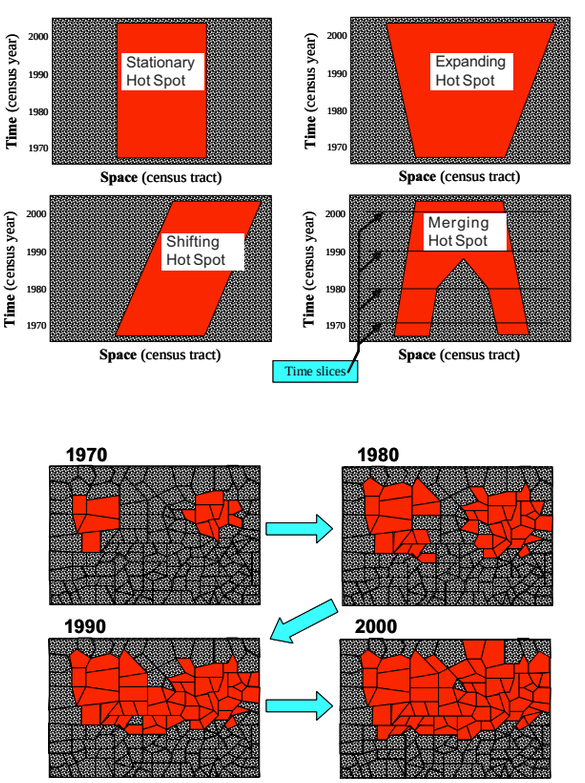

## PARTIALLY ORDERED SET HOT-SPOT PRIORITIZATION SYSTEM

The prioritization system of hot-spot geoinformatics is concerned with the ranking of a finite collection of objects when a suite of indicator values is available for each member of the collection. The objects can be represented as a configuration of points in indicator space, but the different indicators typically convey different comparative messages, and there is no unique way to rank the objects while taking all indicators into account. A traditional approach is to assign a composite numerical score to each object by combining the indicator information in some fashion. Consciously or otherwise, every such composite involves judgments (often arbitrary or controversial) about trade-offs or substitutability among indicators.

Rather than attempting to combine indicators, Patil and Taillie (2004a) take the view that the relative positions in indicator space determine only a partial ordering, and that a given pair of objects may not be inherently comparable. Working with Hasse diagrams of the partial order, they study the collection of all rankings compatible with the partial order. In this way, an interval of possible ranks is assigned to each object. The intervals can be very wide. Noting, however, that ranks near the ends of each interval are usually infrequent under linear extensions, a distribution is obtained over the interval of possible ranks. This distribution, called the rank-frequency distribution, is unimodal, is log concave, and represents the degree of ambiguity involved in attempting to assign a rank to the corresponding object.

*Figure 9. Hasse diagram and corresponding linear extension tree. The linear extension tree enumerates all admissible linear extensions of the poset. Dashed links in the dimension tree are not implied by the partial order and are called jumps. If one tries to trace the linear extension in the original Hasse diagram, a jump would be required at each dashed link.*

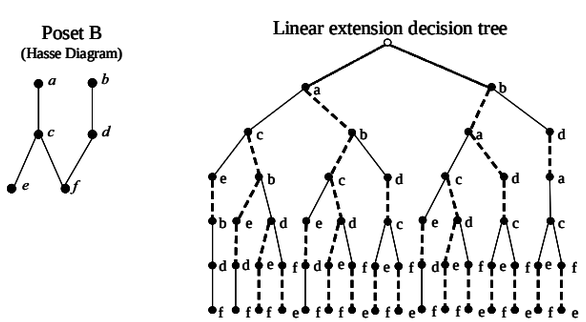

*Figure 10. Cumulative rank-frequency distribution for the poset in Figure 9*

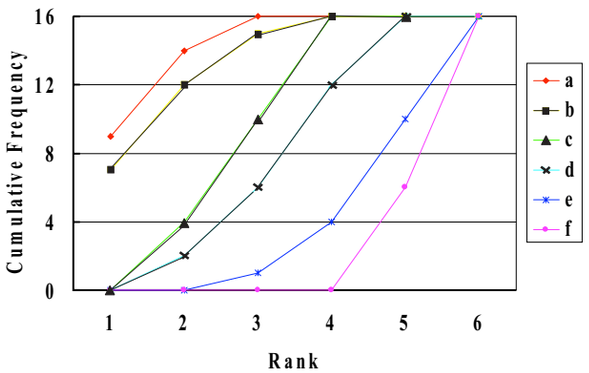

The stochastic ordering of distributions imposes a partial order on the collection of rank-frequency distributions. This collection of distributions is in one-to-one correspondence with the original collection of objects, and the induced ordering on these objects is called the cumulative rank-frequency (CRF) ordering, extending the original partial order. For example, Figure 9 shows the Hasse diagram for a small partially ordered set (poset) with six objects, labeled a through f. The decision tree on the right enumerates all possible linear extensions of the poset, where each path through the tree determines a linear extension. In this example, there are a total of 16 linear extensions. Object a is assigned Rank 1 by nine of those extensions, Rank 2 by five of the extensions, and Rank 3 by the remaining two extensions. The cumulative rank frequencies for Object a are thus 9, 9+5=14, and 9+5+2=16. These determine a cumulative rank profile for Object a as shown in Figure 10 and similarly for the other five objects.

For this example, the six profiles are stacked one above the other, thus determining a linear ordering of the objects. The CRF operator treats each linear extension as an equal voter in determining the CRF ranking. It is possible to generalize to a weighted CRF operator by giving linear extensions differential weights either on mathematical grounds (e.g., number of jumps) or empirical grounds (e.g., indicator concordance). Explicit enumeration of all possible linear extensions is computationally impractical unless the number of objects is quite small. In such cases, the rank frequencies can be estimated using discrete Markov chain Monte Carlo (MCMC) methods.

The resulting prioritization system has the following innovative features.

- Ability to rank and prioritize hot spots
- Utilizes multiple indicator and stakeholder criteria without integrating indicators into an index

- Employs Hasse diagrams, partially ordered sets, and Markov Chain Monte Carlo computations leading to several key applications, including the following.
- Early warning systems
- Identification of critical areas for focused investigation

In the areas of health policy, health statistics, and disease etiology, the prioritization component may be combined with a hot-spot detection component to yield a three-stage surveillance system:

- **First-Stages Screening:** Identification of significant clusters (hot spots) by a ULS version of the scan statistic
- **Second-Stage Screening:** Rank and prioritize significant hot spots using likelihood values and other attributes such as raw intensity values, remediation-feasibility scores, and socioeconomic and demographic factors
- **Third-Stage Screening:** Follow up hot spots for etiology and/or intervention

For more details, see Patil and Taillie (2004a).

## SELECT CASE STUDIES

In response to an ever-increasing volume of georeferenced data, government agencies require a new generation of decision-support systems for the early detection, surveillance, and prioritization of hot spots. A decision-support framework for geographic and network surveillance, using systems involving upper level sets and partially ordered sets, is applicable to a variety of important case studies, such as the following:

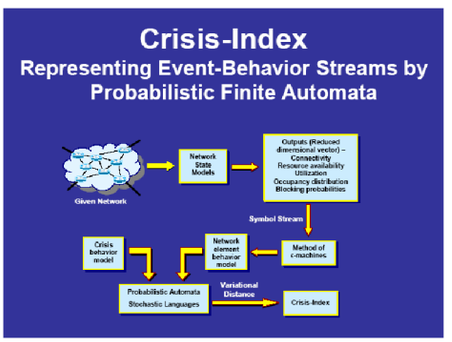
1. Cyber security and computer network diagnostics
2. Tasking of self-organizing surveillance mobile sensor networks
3. Drinking-water quality and water utility vulnerability
4. Surveillance network and early warning
5. West Nile virus
6. Crop pathogens and bioterrorism
7. Disaster management such as oil spill detection, monitoring, and prioritization
8. Network analysis of biological integrity in freshwater streams

The framework can be applied to irregular networks, such as those formed by streams (Figure 11), political units, social networks, and the Internet. When applied to data collected over both space and time, the ULS scan statistic system may be used to detect shifting poverty hot spots (Figure 11), the coalescence of neighboring hot spots, or their growth.

Protecting the nation's computer networks from cyber attacks is an important homeland security priority requiring diagnostic tools for detecting security attacks and infrastructure failures. A probabilistic finite state automaton (PFSA), describing a network element, is obtained from its data stream output. The variational distance between the stochastic languages generated by normal and crisis automata may be used to form a crisis index. The ULS scan statistic is then applied to crises indices over a collection of network elements for hot-spot detection. These hot spots and their prioritization can be used to detect coordinated attacks geographically spread over a network. Additional applications of PFSA include the tasking of self-organizing surveillance mobile sensor networks, geotelemetry with wireless sensor networks, video-mining networks, and syndrome surveillance in public health.

The National Tsunami Hazard Mitigation Program (NTHMP) is the first systematic national effort for the production of inundation maps essential for tsunami

*Figure 12. Framework for probabilistic finite state automata (top), and a metric for measuring the distance between two finite state automata*



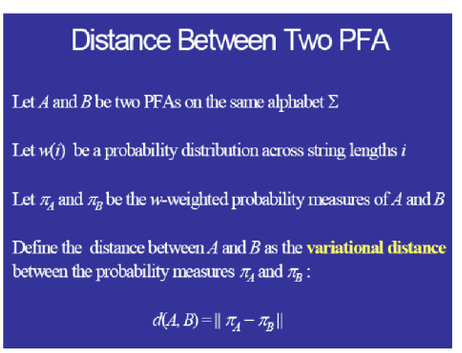


*Figure 13. Portion of a community projected to be inundated by a tsunami as predicted under a tsunami inundation model for a given earthquake scenario (region on the left). Two typologies expected under tsunamis of increasing severity (right).*

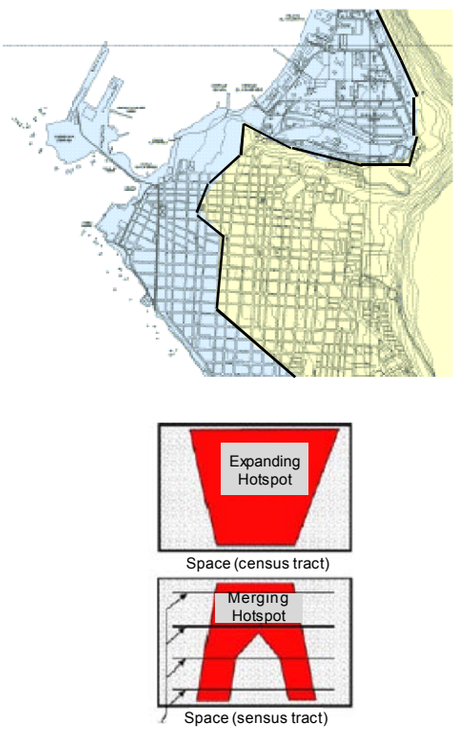


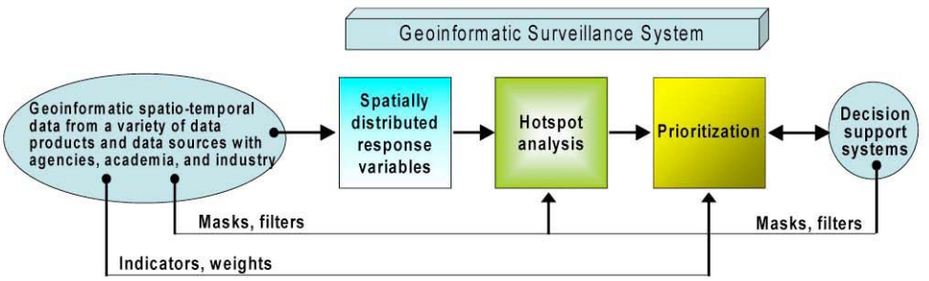
hazard planning and mitigation. Without a clear understanding of what areas are most at risk, it is not possible to develop effective emergency response plans involving population and infrastructure vulnerability and evacuation routes (Gonzalez, 2001). Inundation maps enable the construction of tsunami risk maps, where risk is the hazard multiplied by the exposure; for example, the probability that a particular grid cell is struck by a tsunami times the number of people occupying that cell. These form risk surfaces defined over tessellations of grid cells in regions under consideration. For purposes of optimal disaster management planning, it is essential to have the capability to recognize priority high-risk areas with minimal false alarms. Tsunami disaster management triggers research, expanding its scope to geospatial continuous-response risk variables with skewed distributions, and to hot-spot trajectories representing changing spatial patterns of inundated areas with increasing tsunami severity. Understanding the latter typology may impact the planning of evacuation routes. Under an expanding hot-spot scenario, traffic is always directed outward from the hot spots, but under merging hot spots, a portion of the traffic may be directed through regions between hot spots when the tsunami is predicted to be small. Another significant contribution to tsunami disaster management will be to prioritize and rank risk hot spots detected at specified confidence levels with respect to multiple criteria, stakeholders, and indicators without reduction to a single index. Examples of such criteria may include the number of people at risk and the economic value of infrastructure, buildings, and their contents.

## CONCLUSION

Government agencies often require concise summaries of georeferenced data to support their decisions regarding the geographic allocation of resources. Geoinformatic surveillance for spatial and spatiotemporal hot-spot detection and prioritization is a critical need for the 21st century. A hot spot can mean an unusual phenomenon, anomaly, aberration, outbreak, or critical area. Hot-spot delineation and prioritization may be required for etiology, management, or early warning.

This article briefly describes a prototype geoinformatic hot-spot surveillance (GHS) system for hot-spot delinea-

*Figure 14. Framework for the Geoinformatic Hotspot Surveillance (GHS) system.*



tion and prioritization (Figure 14) in a variety of case studies of critical societal importance. The prototype system is comprised of modules for (a) hot-spot detection and delineation, and (b) hot-spot prioritization.

## NOTE

This research was supported by the National Science Foundation Digital Government Program Award Number EIA-0307010. Partner federal agencies include DOD, DOT, EPA, NASA, NCHS, NCI, NIEHS, USFS, and USGS with USGS as the coordinating agency. The contents have not been subjected to agency review and therefore do not necessarily reflect the views of the agencies and no official endorsement should be inferred.

## KEY TERMS

**Digital Government Case Studies:** Investigations of interest to society demonstrating the efficacy of proposed digital informatic approaches to handling government databases.

**Early Warning:** Alert to a pending disaster.

**Hot Spot:** A connected subset of the study region with statistically significant elevated rates of disease, poverty, accidents, or any other relevant georeferenced phenomenon.

**Hot-Spot Rating:** Confidence level that a given cell belongs to a hot spot.

**Poset Prioritization and Ranking System:** Nonparametric approach to ranking objects using multiple indicators based on cumulative rank functions constructed from Hasse diagrams and linear extension trees.

**Typology of Space-Time Hot Spots:** Classification of the trajectories of hot spots over time when the upper level set scan statistic system is applied to space-time data.

**Upper Level Set Scan Statistic System:** Adaptive system for hot-spot detection and delineation based on upper level sets in georeferenced data.

# How Business Changes Government in the Information Age

**Jurgen van der Heijden**
*University of Amsterdam, The Netherlands*

## INTRODUCTION

EzGov is a leading company providing online solutions for governments. Ed Trimble, EzGov CEO, states, "He's doing something that's changing government, that's changing the world, that's really making a difference" (Diana, 2004). This article is about changing government. Considered as the main agent to change government are politics. Mainstream studies of public administration also consider government itself, judges and citizens as change agents. This fits with the classical, liberal vision on the public domain, wherein these parties are the only known subjects (see Howlett & Ramesh, 1995, pp. 52-59; Stone, 1997, pp. 351-372). In this vision companies are considered to be citizens. Problem then is to see clearly the profound influence business has on governmental change.

With increasing velocity information technology products appear on the market that are especially designed to change government. Also with other products the government buys its own change, for instance with management consultancy. In the study of public administration a good view lacks on the importance business has here in changing government. That's the focus of this article, what's its purpose? First purpose is to give an explanation of the way business changes government with the products it sells. Second purpose is to come up with ideas on how to deliberately accept change of government by way of business products. How to do that in a way that both government and business will function better and present society with legitimate solutions for physical and social problems?

## BACKGROUND

The market is acknowledged as an instrument that changes the physical and social environment (Howlett & Ramesh, 1995, p. 86). Often the market is placed in a system of three factors that change the environment, the two others being government and civil society. In order to function at their best government, market and civil society each needs to solve those problems it can solve best, and leave other problems to one of the other two (Stone, 1997, pp. 66-79). For instance fighting crime is a task for government, making cars is what the market does, and organizing a soccer match is something of civil society. However, certain soccer matches do concern both the market and government, so the division of tasks is not sharp.

Scholars of public administration have only distinguished three factors (Stone, 1997, pp. 259-262), but there is one more factor that changes the physical and social environment, design (Howlett & Ramesh, 1995, p. 160; Lessig, 2004, pp. 139-173; Murray & Scott, 2002). Think of cars and how they have changed the lives of people, both physical and social. The design of cars is an example of a social and physical co-evolution (Nelson & Nelson, 2002; Nelson, Bhaven, & Sampat, 2001). For instance, safety measures are a physical reaction to the physical and social damage that car accidents can bring. It's this very co-evolution that brings to the fore how the relations change between government, market, civil society, and also design. Cars can give prove of that: the market supplies them, the government regulates that, civil society is important to give voice to the interests being harmed by cars, like health and nature, and design is used to give answers to new regulation and the pressure from civil society.

This picture of the interference between these four factors explains how the market is one factor that changes government. Therefore, parties that change the market do change government. Those can be parties like business, consumers, courts, special interest groups, and even the government that changes the market and thus itself. Theory of public administration takes account of the influence these parties have on the market, and the market has on government. What lacks is a good view on the influence that products and their design have. In this view business as the main supplier of products is a major change agent of the government.

## BUSINESS AS CHANGE AGENT OF GOVERNMENT

Domotica stands for home automation. The market supplies most domotica products, for instance remote control

of heating, lighting, curtains, and even doors. The government can make it obligatory that all domotica products comply with technical standards, but often that's something the market can organize itself. An important group of Dutch domotica companies not only discuss technical standards amongst themselves, but also involve civil society. They have an open eye for especially patient groups that are important in the process of defining products and their technical standards. In fact, the organization of these companies can also be considered as a phenomenon that belongs to civil society. Together with other representatives of civil society, patient groups, it regulates both the market, and defines design. This is a task the government could execute, and it will want to control how these parties perform. Reason to do so is that domotica takes out of the hands of the government important parts of health care, when it results in patients living in their homes longer.

The replacement of care to homes diminishes the demand for care in hospitals, that in many countries is financed by the government. This also has consequences for civil society. Elderly and sick people living in communities longer demand citizens to organize care amongst each other more. All this proves how the information technology, that domotica consists of, changes the relations between government, market, civil society, and design. This is a socio-physical co-evolution wherein innovations in technological design of domotica both change government, market, and civil society, and change themselves under the influence of these three. Part of this picture of changing relations is the relation between business and government. As an important supplier of technological products, business incites many changes in the relations between government, market, civil society, and design. Business is therefore a change agent of the government. How to take control of that?

## PRACTICAL IDEAS ON HOW TO CHANGE GOVERNMENT BY WAY OF BUSINESS

In the Netherlands, roads are the responsibility of municipalities, water boards, provinces and the state government. In the region of The Hague, a process has started in 2003 wherein these parties handed over their responsibility to a regional mobility manager. This would never have happened without preceding technological innovations enabling to really manage traffic on a regional basis: especially video monitoring, computer programs for the analysis of traffic and the possibility to send one to one text messages to mobile phones of traffic users. At the moment mobility managers are looking for ways to cooperate with commuters and the managers of sites where many work. Therefore they're in need of new technologies and have asked the industry to come up with custom made designs to manage traffic in cooperation with commuters and these managers.

What becomes apparent is a co-evolution of governmental organization and technology (Van Est, 1999, pp. 283-284, 337, 341-342): first technology enables municipalities, water boards, provinces and the state government to hand over responsibility, and now new cooperative practices are in need of further technological innovations. What also becomes apparent is how the government has an instrument in asking the industry for new products (Hajer & Kesselring, 1999, pp. 17-25). How to make use of this instrument to take control over the way these products will change government? If indeed business is an important change agent of the government, then purchasing and giving assignments is the way for the government to influence its own change. It can do so for instance by getting involved in the process of designing the products it will buy. In that dialogue government can challenge designers to come up with an assessment of what the products they make will mean for government and the way it functions. At the same time, the designers can challenge the government to order that very technological innovation it dares to take responsibility for. Thesis here is that government can respond to business as a change agent by looking at the way is buys and gives assignments, for instance by way of organizing this dialogue with its suppliers.

An instrument the government can work with is public procurement. This is certainly not unknown, but not acknowledged as an instrument that should fit in somewhere with well known governmental instruments like legislation, communication, finance and governance. It should however fit in because with the help of public procurement the government initiates very large projects like building roads, city renewal and the installation of information technology. On the one hand, this is often done with scrutiny, meaning that the government takes good care to select the best supplier and not to pay too much. On the other hand it's not standing practice to assess what chain of events will follow from for instance building a road. The causes and effects following from that can have a huge impact on the physical and social environment, and also on the government itself. Trying to influence those causes and effects is only now getting to governments as something they should do. An example is green public procurement (European Commission, 2004). There it can become an important instrument to protect the environment.

What change of itself does a government buy? It should demand from companies to make it aware of all the causes and effects that can be expected from a product

when the government buys and uses it. Important to assess those causes and effects is a dialogue that could also include representatives of civil society. Idea is that only the most challenging dialogue develops the best products. In this dialogue the impact of a product on the social and physical environment is assessed, and amongst that the impact on the functioning of government itself. At such a moment a so-called constructive technology assessment takes place (Rip, 1997). The results of that should be included in the assignment the government finally gives to a company. Does that guarantee that the governmental change will also be legitimate?

## LEGITIMACY

Implementing spatial plans can have huge consequences for the physical and social environment. Therefore, in most countries parties representing an involved interest have the right to give voice and comment to the government before it permits implementation. In more than one country companies supply information technology that both presents the plans and is a means to give voice and comment by way of the internet. This is a service that makes life much easier for parties representing involved interests. However, their communication changes significantly when they give voice and comment electronically. Even if they're not obliged to do so, and still have the chance to meet people from the government in person, the relationship has changed, because they may feel the need to explain why the electronic alternative has been ignored.

True advocates of people's rights give ample warning for all the dangers of information technology (e.g., Lessig, 2004, p. 173), but have an open eye of course for all the benefits. Each innovation of a product has to be good and at the same time right. Good meaning that a product has more effect and is more efficient, right meaning that the involved people and interests are being treated in a fair way (Richardson, 1995, p. 115). Government is a guarantee in society that both actions from the government itself, and from companies, citizens, and citizens groups are legitimate. Any change of the government therefore has to be legitimate, but what is that, and how to assess that?

Formally a change of the government is legitimate when the government itself agrees, and can successfully defend this change before elected representatives of the people. Material legitimacy means that after the change the physical and social environment are better of, and people and their interests have been treated fairly. Of course representatives have the primacy to assess that, and questions concerning fairness can be fought over in court (Dworkin, 1986, pp. 52-65, 176-184). However, in modern society it often falls short to leave that all to parliament and courts. Companies more and more have to ask beforehand if the effects of their products on the government are both good and right. It's wise to do that in dialogue. Without the help of the government, citizens and citizen groups' risk can be too high that a company on its own gets it wrong.

All these parties have discovered how they all benefit from dialogue. Therefore product innovation more and more takes place in close cooperation, like in the example of domotica. Product innovation in cooperation with governments and citizens groups takes place in dialogue wherein also government policy and the policies of citizens groups develop. Idea is that in many cases this leads to more efficacy, efficiency, and also fairness. When for instance the new product of a company is developed under these circumstances chances are better that government and citizens will accept it (Bijker, Hughes, & Pinch, 1993). Is this a product that as a consequence changes government, than chances are better that this happens in a legitimate way.

## FUTURE TRENDS

Do we need a new perspective on companies in a society looking for legitimate solutions, and wherein information technology gains importance every day? This question belongs on the agenda of not only scholars of public administration. If it turns out to be an important question than also politicians and citizens should ponder it. Another question is how elected officials both in executive and parliamentarian positions should overlook governmental agencies purchasing products and giving assignments to design products. One more question is whether the above-mentioned dialogue can be organized in such a way that citizens that will be affected by the product can have a part in the process of design. Does this improve products and make them really competitive? This opens up a whole new point for discussion if it's taken into account that underneath the use of dialogue lies a world of cultural evolution and differences, for instance between the United States and Europe (Rifkin, 2004). Is the one society better fit than the other to have dialogue and thus innovate products?

Will companies that alter the government put emphasis on characteristics that appeal to them, but that the government traditionally does not really value? Will they for instance regard the citizen more as a client instead of an object of policy like the government often is used to? If so then governmental service might improve, but at the same time a client is expected to come and ask for what he wants. Objects of policy instead often get what the government has in store for them, whether they like it or

not (Alejandro, 2001). For some people however that's preferable since they have difficulty to know what they can ask for. What's good and what's right? An answer will not follow here (see Lessig, 2004, pp. 7-11), but it's important to know that characteristics of companies will permeate in government once companies change the government.

## CONCLUSION

In the classical, liberal vision on the public domain subjects are the legislature, government, courts and citizens. Each in its own way can change the government. So citizens can do that by way of voting, going to court, and organizing themselves in citizens groups. Companies are not acknowledged as a subject. They are considered to change government the same way as citizens and their groups can, but not as companies as such (Howlett & Ramesh, 1995, p. 66). That doesn't give companies a place at the same level as the legislature, government, courts and citizens. Should companies have that place, or should their role in the formal state remain that of a citizen? Or should the role the citizen traditionally has in the study of public administration be seen in a different light? There are good reasons to understand the citizen and its entrepreneurship as maybe the most important factor of change in society. He is the consultant, the supplier of information technology, and the builder of roads with profound influence on society.

Especially consultants are in the market of selling products to change government. Until about fifteen years ago, this used to be a market for social products only. Social products being methods mainly for organizational change designed to alter the behavior of people working within governmental agencies (Rainey, 1997, pp. 333-336). With increasing velocity technological products enter the market that are especially designed to change government. Does for instance the one municipality buy a product to help citizens give voice and comment regarding its policies then what should the other municipality do? For how long can it lag behind, and when it decides to also buy such a product, what will be on the market then? Ed Trimble: "Another big factor in government's decision to move forward with this is that the state next door or the country next door may be providing a service, and that government's constituents begin expecting that service" (Diana, 2004). This gives the market a position in changing government that is unprecedented and not accounted for in ethics, politics and science. How to understand this development and how to respond to it?

Socio-physical co-evolution is in this article pivotal to understand the way the market changes government, and also gives a guideline how to work as governmental agencies and companies with that. Guideline is to establish a dialogue between government and companies, and wherein also citizens are involved (Grin & Van der Graaf, 1996). From that dialogue should follow the assignment from the government to a company to make products and take account of the effects it will have on the government itself. This dialogue is best organized when a constructive technology assessment takes place wherein government, companies, and citizens participate. The idea is that the effects that the product will have on the government will then be legitimate.

## KEY TERMS

**Civil Society:** The whole of citizens and their groups that pursue interests of the physical and social environment.

**Constructive Technology Assessment:** Assessment of the physical and social impact of the implementation of a technology in dialogue between involved parties.

**Domotica:** Home automation.

**Environment, Physical:** The environment as far as it consists of natural and cultural phenomena.

**Environment, Social:** The environment as far as it consists of what people think, follow, agree upon, talk about and remember.

**Modern Governance:** The design and implementation of governmental policy in cooperation between governmental agencies, citizens, companies, and interest groups.

**Public Procurement:** Governmental agencies purchasing goods, services, and public works.

**Socio-Physical Co-Evolution:** Transition of social and physical technologies wherein innovation of the one sparks innovation of the other.

**Study of Public Administration:** Scientific discipline pointed at the study of decision-making and organization in the public domain.

**Voice and Comment:** The right of the citizen to give its opinion about a governmental policy beforehand, and ask for a review when it's fixed but not set.

# How People Search for Governmental Information on the Web

**Will Berkheiser**
*The Pennsylvania State University, USA*

## INTRODUCTION

People are now confronted with the task of locating electronic information needed to address the issues of their daily lives. The Web is presently the major information source for many people in the U.S. (Cole, Suman, Schramm, Lunn, & Aquino, 2003), used more than newspapers, magazines, and television as a source of information. Americans are expanding their use of the Web for all sorts of information and commercial purposes (Horrigan, 2004; Horrigan & Rainie, 2002; National Telecommunications and Information Administration, 2002). Searching for information is one of the most popular Web activities, second only to the use of e-mail (Nielsen Media, 1997). However, successfully locating needed information remains a difficult and challenging task (Eastman & Jansen, 2003). Locating relevant information not only affects individuals but also commercial, educational, and governmental organizations.

This is especially true in regards to people interacting with their governmental agencies. Executive Order 13011 (Clinton, 1996) directed the U.S. federal government to move aggressively with strategies to utilize the Internet. Birdsell and Muzzio (1999) present the growing presence of governmental Web sites, classifying them into three general categories, (1) provision of information, (2) delivery of forms, and (3) transactions. In 2004, 29% of American said they visited a government Web site to contact some governmental entity, 18% sent an e-mail and 22% use multiple means (Horrigan, 2004). It seems clear that the Web is a major conduit for accessing governmental information and maybe services. Search engines are the primary means for people to locate Web sites (Nielsen Media, 1997).

Given the Web's importance, we need to understand how Web search engines perform (Lawrence & Giles, 1998) and how people use and interact with Web search engines to locate governmental information. Examining Web searching for governmental information is an important area of research with the potential to increase our understanding of users of Web-based governmental information, advance our knowledge of Web searchers' governmental information needs, and positively impact the design of Web search engines and sites that specialize in governmental information.

## BACKGROUND

There has been limited large-scale research examining Web searching for governmental information. Croft, Cook, and Wilder (1995) present analysis of the use of THOMAS, a governmental system that makes U.S. legislative information available to the public. The researchers report that searchers used very simple queries and appeared to have trouble locating specific bills. The researchers also noted that was some dissatisfaction with the relevance of returned results. Marchionini and Levi (2004) present an on-going study of the Bureau of Labor Statistics, reporting that user interfaces to governmental Web sites require special attention

Hargittai (2003) reports that users look for governmental information in a variety of ways with considerable temporal variance for task completion. The manner in which content is presented often confuses searchers. Hargittai reports that the two major sources of confusion concerned the uniform resource locator and the page design layout. Ceaparu and Shneiderman (2004) investigated alternate ways of organizing governmental statistics, reporting that users were more successful in finding answers when the information was organized into categories rather than an alphabetical listing.

There is a body of research focusing on general Web searching (Jansen, Spink, & Saracevic, 2000; Spink &

Jansen, 2004). Spink and Jansen (2004) report that searching for governmental information on the Excite search from 1997 to 2001 was about 1.5% to 3% of all queries. Jansen and Spink (2005) report that searching for governmental information on AlltheWeb.com, a Norwegian-based search engine, was about 2.0% of all queries in a study of datasets from 2001 and 2002. Jansen, Spink, and Pedersen (2005) report that searching for governmental information on AltaVista in 2002 was about 1.6%. Overall, few Web queries are related to government information; however, as a stand-alone category, governmental queries are a sizeable percentage.

Although these studies provide important insights into Web searching, further research is needed that validates these results for the searching of governmental information on Web search engines. This is especially important as Web searching systems are continually undergoing changes and governmental entities are moving more services to the Web (e.g., http://usgovinfo.about.com/library/news/aainternet.htm).

We address this need in the present study by examining a set of queries representing governmental-related information needs to analyze how people are searching for governmental information, including what information they are seeking. We also classify a sub-set of these queries to develop a taxonomy that can asset in the development and organization of governmental Web sites.

## FUTURE TRENDS

### Research Questions

The research questions driving this study are:

1. What are the characteristics of governmental Web searching
2. What types of governmental information are people searching for on the Web
3. How effective are these queries in locating governmental information

### Research Design

#### Data Collection

To address the first research question, we obtained, and qualitatively analyzed, actual governmental-related queries submitted to the AltaVista Web search engine. For this research question, we are interested in examining the characteristics of the governmental-related queries, investigating areas such as the number of terms in queries, the number of queries in a session, and the use of query operators, among other aspects. Our analyses of searching behavior addressed the following approaches to Web searching behavior.

a. **Query Length:** The query length is defined as the length, measured in terms, of the entire search query. This may include Boolean operators
b. **Session Size:** A session is the total amount of queries submitted over a period of time. A session may include only one query, or may extend over a longer period of time and include multiple queries
c. **Result Pages Viewed:** Result pages viewed is the number of pages returned by the search engine based on the query submitted that were actually visited by the user

The third research question involved classifying a sub-set of these queries with a controlled hierarchal vocabulary. This has implications not only for searchers using the Web to locate governmental information but also search engines and Web sites that serve these users.

To investigate our research questions, we gathered data from the AltaVista search engine. In 2002, Alta Vista was the 9th most popular search engine (Sullivan, 2002), had a content collection of 550 million Web pages (Sullivan, 2000), and approximately 5.6 million unique visitors per month. Overall, AltaVista offers a full range of searching options, has an extremely large content collection, and millions of unique visitors per month. After being an independent company for several years, Overture Services purchased AltaVista in 2003 (Morrissey, 2003).

We recorded the queries examined for this study on the AltaVista server on Sunday, September 8, 2002 and span a 24-hour period. We checked news stories from this day to see if any looked as if they may have influence the investigation, namely the term analysis. There did not appear to be a major news stories occurring on this date. However, the date is near the anniversary of the 9-11 attacks.

We recorded the queries in a transaction log that represents a portion of the searches executed on the Web search engine on this particular date. The original general transaction log contains approximately 1,000,000 records. Each record contains three fields:

1. **Time of Day:** Measured in hours, minutes, and seconds from midnight of each day as recorded by the AltaVista server
2. **User Identification:** An anonymous user code assigned by the AltaVista server
3. **Query Terms:** Terms exactly as entered by the given user

## Data Analysis

From the complete transaction logs, we were interested in only those queries that were governmental-related. We therefore culled a subset of queries pertaining to government-related information using a modified snowball sampling technique (e.g., Patton, 1990). More specifically, we started with several seed terms (i.e., government, Congress, taxes, license, etc.) that are central indicators of government-related searching. Using this set of terms, we extracted all records from the transaction log that contained these terms.

We then reviewed the extracted records identifying other terms that frequently appeared. These new terms were then combined with the set of original terms, and from the original transaction log we extracted all records that contained these terms. The process was repeated until the addition of new terms to the set added less than ten new and unique queries. This data set permitted us to address our first research question.

For the third research question, we chose 4,000 queries to classify according to a controlled hierarchal vocabulary. We derived this taxonomy from (Brodie, 2002) and organized a five-level hierarchy, which is:

- Level of government (cf., state, local, federal)
- High-level request (cf., forms, information)
- Applicable to (cf., business, citizen)
- Mid-level request (cf., organization of government, aspect of government, tax service)
- Low-level request (cf., information about government, courts, taxes).

With this controlled vocabulary, we were able to classify the queries and then conducted data analysis on the classified queries in order to find any unique relationships or trends within the classification. A complete list of codes within each category is provided in Appendix A.

# Results

## Searching Characteristics

We first address research question one, which is: What are the characteristics of governmental Web searching?

Table 1 presents overall descriptive data for the governmental-related queries.

The number of governmental sessions was 0.8% of the 369,350 sessions in the entire dataset. The number of queries was 0.4% of the 1,073,388 queries in the data set. The set of governmental queries contained 1.3% of the unique terms in the complete transaction log and represents 0.6% of all terms.

*Table 1. Aggregate results of searching characteristics*

| | | | | | |
|---|---|---|---|---|---|
| **Sessions** | 3,021 | 0.8% of all session | | | |
| **Queries** | 4,694 | 0.4% of all queries | | | |
| **Terms** | | | | | |
| *Unique* | 3,867 | 1.3% of all unique terms | | | |
| *Total* | 18,873 | 0.6% of all terms | | | |
| | **Mean** | **Max** | **Min** | **Mode** | **SD** |
| **Mean terms per query** | 4.02 | 20 | 1 | 3 | 2.06 |
| **Terms per query** | **Occurrences** | **%** | | | |
| *1 term* | 221 | 5% | | | |
| *2 terms* | 802 | 17% | | | |
| *3+ terms* | 3,671 | 78% | | | |
| *Total* | 4,694 | 100% | | | |
| | **Mean** | **Max** | **Min** | **Mode** | **SD** |
| **Mean queries per user** | 1.55 | 16 | 1 | 1 | 1.19 |
| | **Occurrences** | **%** | | | |
| **Users modifying queries** | 938 | 31% | | | |
| **Session size** | **Occurrences** | **%** | | | |
| *1 query* | 2,083 | 69% | | | |
| *2 queries* | 588 | 19% | | | |
| *3+ queries* | 350 | 12% | | | |
| *Total* | 3,021 | 100% | | | |
| | **Occurrences** | **%** | | | |
| **Boolean Queries** | 343 | 7% | | | |
| | **Occurrences** | **%** | | | |
| **Terms not repeated in data set** | 2,384 | 13% | | | |
| | **Occurrences** | **%** | | | |
| **Use of 100 most frequently occurring terms** | 10,337 | 55% | | | |

*Figure 1. Percentages of queries within level of government categories*

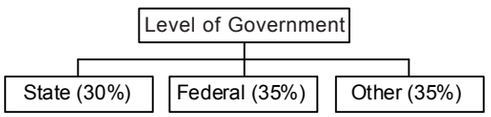

*Figure 2. Percentages of queries for type of high-level request*

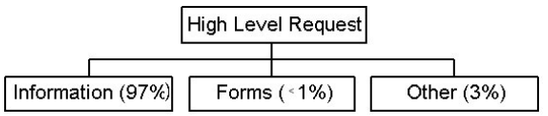

*Figure 3. Percentages of queries at applicable to user types*

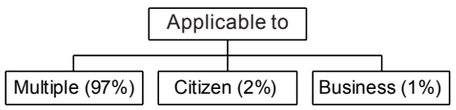

*Figure 4. Percentages of queries for type of mid-level request*

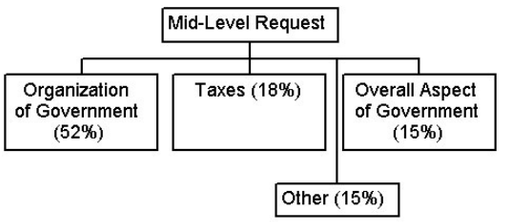


The number of queries in a session and the number of terms in a query are indicators of the complexity of the searcher's information need, with the greater number of queries and terms indicating the greater complexity. The number of terms per query (4.02 terms) is substantially higher than for Web searching in general, which is about 2 terms (Spink & Jansen, 2004). This may indicate that governmental information is more difficult to locate than general Web information or that these searchers have a more refined information need.

The number of one query sessions (69%) is much higher than the entire transaction log, at 47.6% one query sessions (Jansen, Spink, & Pederson, 2005). The percentage use of Boolean and terms not repeated in the data were comparable to the entire data set. The percentage use of the 100 most frequently occurring terms (55%) was higher than the entire data set (14%), but this may be expected due to the tighter topic domain.

## Types of Governmental Information

To address research question two, (i.e., What types of governmental information are people searching for on the Web?), we took 4,000 of the governmental queries and classified them using our five-level hierarchy. The first level of classification is level of government. This category includes federal, state, local, city, county, and so forth. Figure 1 presents an overview of the results for this category.

Queries in the Other category were typically searches for local, city or county related governmental information. The other two main levels of government searched for, state and federal, accounted for 65% of all government-related queries.

The next level of classification is high-level request. This level includes requests for information, forms, services, and so forth. Figure 2 shows the breakdown of the results for this category.

From Figure 2, we see that 97% of the requests were for information, with only 1% for forms. There were very few queries seeking governmental services. This distribution may be because of the preponderance of information of the Web and a lack of awareness of governmental services that are available.

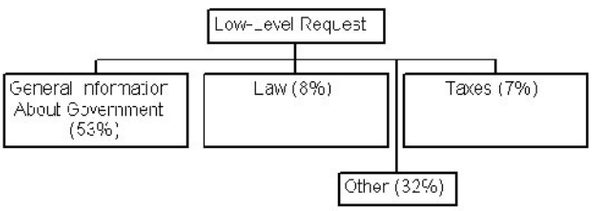
The small percentage of forms at first was surprising, but this may be due to the use of the AltaVista search engine for data analysis. Searchers may be using the search engine to locate the overall government site (i.e., Internal Revenue Service). Once at the site, they may be searching for the particular form or specific information.

The next category we examined is not necessarily a request level, but an applicable to level. This level includes multiple parties, citizen, business, and so forth. Figure 3 shows the breakdown of the results we found for this category.

This classification attempts to address who would be searching for information and could lead to creating an accurate taxonomy or Web site for the user's interest. Unfortunately, when we look at the results of the counts, the largest percentage of the searches is applicable to multiple parties. That is, the query was not specific enough to say who exactly was searching for the information. The other two categories that make up the remainder of the counts are citizens and businesses.

We then classified queries at the mid-level request. This level includes requests for information about orga-

*Figure 5. Percentages of queries for type of low-level request*



nization of government, taxes, some overall aspect of government, and so forth. Figure 4 illustrated the breakdown of the results we found for this category.

The mid-level request attempts to classify further what exactly is the information need of the query. For example, we can now say that a citizen is looking for basically information about an organization of government. This information is vital when creating accurate taxonomies.

Looking at the percentages in Figure 4, we see that a large percentage of the requests were for an organization of government such as an agency or branch of government. Requests for tax related information is the second largest percentage, followed by a request for some overall aspect of government. Finally, requests for some overall aspect of government was a popular one mostly due to people wondering about general government of the U.S. and policy issues about how government operates.

The fifth level we chose to look at is the low-level request. This level includes general information about government, law, taxes, and so forth. Figure 5 shows the breakdown of the results we found for this category.

At this level we come as close as we can to pinpointing what exactly a query was searching for. The percentages again show a strong favoring of general information about government, information about some aspect of government, and so forth. This illustrates that mostly what government related queries are after is general information. This is very helpful because a taxonomy is created to organize information.

Other categories that come up as noticeable percentages in the low-level requests are law and taxes. These are both very important aspects of government that deserve to be separated into their own unique categories in order to be further broken down to help direct users to the proper information source.

## Effectiveness of Governmental Queries

To address research question three (i.e., How effective are these queries in locating governmental information?), we took the top ten governmental queries and submitted them to Google. We submitted the queries on October 26, 2004 using an automated process. The total submission time was approximately 25 seconds. We downloaded the top 20 results for each of these 10 queries, resulting in 200 results for evaluation. Our criterion for relevance was straightforward, "Was the resulting uniform resource locator (URL) within the gov domain (including U.S. state and mil domains)?" If the URL was in the gov domain, than we considered that result relevant. If the URL was not in the gov domain, than we considered that result no relevant. The results are displayed in Table 2.

For our 200 results, 64 (325) were relevant and 136 (38%) were not relevant.

## CONCLUSION

From our analysis, it appears that searching for governmental information requires more terms relative to general Web searching. There are also predictable categories of

*Table 2. Aggregate results of effectiveness of governmental queries*

| Query | Relevant | % | Non-relevant | % |
|---|---|---|---|---|
| Florida department of revenue | 7 | 35% | 13 | 65% |
| "White House" | 10 | 50% | 10 | 50% |
| Estate taxes | 8 | 40% | 12 | 60% |
| +government +"people's party" | 1 | 5% | 19 | 95% |
| California Department of Social Services | 13 | 65% | 7 | 35% |
| North Dakota State Departments "North Dakota department" | 5 | 25% | 15 | 75% |
| Clinton, Pentagon speech, 1998 | 3 | 15% | 17 | 85% |
| San Bernardino sheriff "sheriff's department" | 7 | 35% | 13 | 65% |
| GA census +1880 | 4 | 20% | 16 | 80% |
| Washington State Department of Motor Vehicles Seattle | 6 | 30% | 14 | 70% |
| | 64 | 32% | 136 | 68% |

searching for government information on the Web, with most queries applicable to multiple types of searchers. Searchers appear primarily interested in information about government rather than services. It may be difficult to try and isolate particular information objects to sets of users, as queries tend to transcend multiple groups. The relevance of governmental queries is about 32%, with even generous criteria of relevance. This may indicate that governmental agencies have a ways to go to push their information and services to the general population.

Results of this research may lead to better organization of governmental Web information and increase the availability of government service, making them easier to locate. This type of research can lead to the creation of more effective government portals.

As governmental agencies continue to push information, forms, and services to their citizenry, it is imperative that they continue to account for the role that search engines have in the process of getting this information to the general population. It is apparent that any categorization will be of limited value to the multitude of users. So, a reliance on indexing and searching will be needed.

## INTRODUCTION

News reports do not frequently mention many problems or accidents caused by human error. The specialty of human factors seeks to avoid human error by making certain that computers and all other equipment are designed to be easy to understand and use; costly human errors are thus minimised. This article provides a basic overview of the subject of human factors as it pertains to problem and error avoidance in computerised public information systems. When computer/system design does not adequately consider human capability, the performance of the computer/system and the user will be below desired levels.

## BACKGROUND: HUMAN FACTORS, THE DISCIPLINE

Human factors has helped to make information systems less costly and easier to use. Some background on this discipline will help to show the relationship it has with information systems.

Human factors is the science of the relationships between humans, their activities, and the context in which those activities take place. The specialty of human factors came into being during WWII when it was found that the sophisticated equipment being designed did not perform as expected; there was a strong and immediate need to understand why many humans were unable to effectively use equipment and/or systems. Teams of researchers learned that the design strategies used did not consider human performance limitations—for example, some designs presented too much information at the same time or in the wrong order for humans to be able to successfully operate controls. Or, the arrangement of controls made them difficult to reach quickly and easily. From this discovery came the concept that *human* users, their work *activities,* and the *contexts* of the activities had to be thought of as different parts of a whole system and that each depends upon the other for successful operation (Bailey, 1996).

After WWII the discipline of human factors became a specialised knowledge area as it became apparent that the human element of any system had to be considered if the capabilities of new technologies were to be efficiently exploited. The older strategy of modifying designs over a long period of time through user experiences was inadequate; rates of change had become so rapid that products were obsolete before improvements could be added. Now, the strategy often used by successful design environments is to include human factors in design and development. When properly managed, products or systems that use human factors knowledge are more efficient, safer, and more pleasing to use because they are designed to accommodate human performance capabilities (Norman, 1988).

Human factors is an extremely broad technical and scientific discipline; founders of the first national and international human factors organisations came from such diverse fields as engineering, design, education, computer technology, psychology, and medicine. Through its diversity human factors is able to draw upon and combine knowledge from any area when working with human and system performance issues. Due to the complexity of human behaviour, human factors specialists emphasise in their work an iterative empirical approach. First, an initial recommendation or interface design is made and then laboratory or field studies are conducted to test this initial design (the prototype). Changes are made when deficits are identified; modifications are made; and further testing is then performed. This process continues until significant problems are no longer found. Finally, validation is achieved through observation in the field after system deployment.

This emphasis on empirical work tends to shape how human factors specialists perform their roles. Irrespective of the specific methodology chosen for gathering data about tasks, users, and the use of products, human factors work tends to result in product improvements likely to be economical, easy, and efficient to use from the beginning of use; the cost of and need to go back and fix problems when human factors is not used is avoided.

Human factors can also be called ergonomics. As the term “human factors” is in more common usage in the computer field, it is used for this article.

## Human Factors and Computers

As with other technologies, WWII helped to stimulate the development of computers. The first models of computer used to manage information were primitive in comparison to the computers of today. They were designed by scientists and engineers to be used by scientists and engineers. These computer systems were difficult to operate and had to be closely watched during operation; users had to understand the technology for successful operation and tolerate problems, as technology-advanced computers became easier to operate. With today's systems, the typical user does not need to understand technology; what is important is that a user understands how to tell a computer exactly what information is needed.

This progress in computer technology means that average users of computers and information technology (IT) are no longer just scientists or engineers; instead, they can be anyone who understands how to operate the computer information system they are using. While computer and IT systems are much easier to use, this does not mean that there are not challenges faced. When working with information stored electronically or operating something with the help of a computer, problems can occur when a user misunderstands information presented to them, or they fail to correctly tell the computing system what is wanted. Literature on computers and electronic technology describes instances where there were serious negative consequences when information presented by a computer was misunderstood or systems were mistakenly told to do something different than what was wanted. The shooting down of Korean Airlines flight 007 in 1983 demonstrates some of the problems that can occur between the operator and a computer. Before take-off a crew member entered wrong data into an on-board computer. A warning was ignored as it appeared to be caused by another factor other than the entry of incorrect data. Subsequently the incorrect data caused the pilot to fly off course and into a sensitive area where the aircraft was shot down by a missile. Had the system been designed differently, so that the human activity context was better considered, then it would be likely that a tragic chain of events would not have been started.

To prevent such events from occurring, an emphasis on understanding how to design systems, where it is difficult for people to make mistakes or misunderstand, has emerged as a specialty within the field of human factors. The concept of *human-computer interaction,* or HCI, as a specialty within human factors emerged. In simple terms, HCI is the search for ways to make computers and complex information services accessible, usable, and acceptable to the non-specialist user.

At first, the emphasis of HCI was on physical aspects such as the size, location, and qualities of computer screens and controls. How people think when using computing and IT systems was added as it became more and more evident that how users think and understand is extremely critical in computer design. The subspecialties of *cognitive engineering* and *usability* followed—the former concerns understanding how people think when understanding systems, and the latter concerns how well people can understand and use systems.

Human factors and its related disciplines are now recognised as an important part of the computing system design process. Most computer and related system design approaches try to consider the needs and capabilities of users. With new products and technologies constantly entering the market, new problems are continually encountered—this underscores a continuing need to address human factors when designing computers and computing systems (Cooper, 1999).

The migration of paper-based forms to computer-based public information systems is the type of problem now faced. Work currently in progress in Sweden has found that the way a form looks on paper cannot be used on a computer screen. A computerised system had been developed that used exact copies of paper forms on computer screens. User error rates were extremely high, and the computer system was more costly to operate than its paper-based predecessor. The computer system had been designed without involvement of human factors specialists. Human factors specialists were asked to help correct system problems. The initial results of the human factors assessment reduced error rates and costs; work continues to bring performance to a desired level. The human factors specialists questioned and observed users. From those, it was possible to identify simple solutions to performance problems.

## Public Information Systems, Computers, and Human Factors

Since public and private information systems use the same technology and function to exchange information between users and systems, is there any difference between the two? Should they be treated differently? Do the two have different needs?

Questions about difference and how human factors is connected are perhaps best answered by looking at the populations served and the reasons for the creation of any particular system. Private information systems generally serve segments of entire populations (exclusive) and make little or no attempt to accommodate those who lack needed skills. In contrast, public systems must at least have the goal of being usable by every member of a population (inclusive). The exclusive nature of private information systems means that during development and

design there is a focus on meeting the needs of a target group that is part of an entire population. In contrast, public information systems generally must be developed and designed to at least have the goal of accessibility to an entire population. A second major difference between the two is that private information systems are oriented towards generating at least enough revenue to meet expenses, while public information systems are oriented towards providing service (which may or may not generate revenue).

While these differences may be subtle in some circumstances (e.g., a system used by a private, non-profit organisation or a system used by a fee-based public entity), it can be argued that, in some form, an inclusive or exclusive orientation is present.

How is this difference important with respect to human factors and public information systems? It is important because public information systems must be designed to be usable by the public—which includes everyone in a population. The goal of accessibility to an entire population means having to design for all levels of computer skills, education, and ability. A private information system is designed to be used by persons who are already familiar with computers and, if specialised knowledge/skills are needed, training is provided.

Any entity responsible for a public information system benefits from incorporating human factors knowledge and skills into any information system development or operation. The multiple levels of needs of users make understanding this diversity essential. Without human factors there is a much higher risk that the best design alternatives will not be found and selected—such as trying to move from paper forms to computer-based forms without considering the differences between entering data on paper and entering the same data onto a computer screen. As described in greater detail in the following section, human factors practices make certain that people can easily understand and use a system.

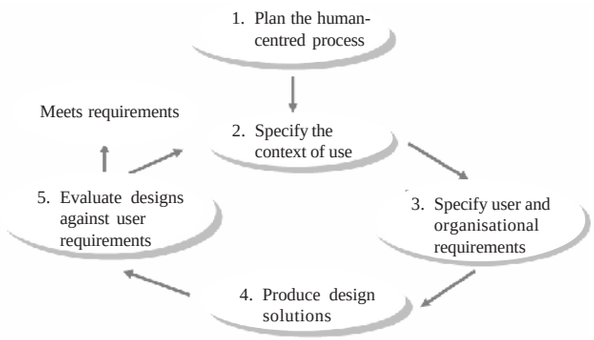
## HUMAN FACTORS AS A KEY ELEMENT IN PUBLIC SYSTEM DESIGN

Including human factors in the earliest stages of any design process ensures that a product is defined in terms of user needs. Human factors input at these stages also helps project management to redirect resources to approaches that are most likely to have the greatest user benefit. Human factor specialist involvement throughout design processes results in catching problems early on; thus helping to reduce overall project costs. Finally, the ability to anticipate user responses continues to improve as successive prototypes more closely approximate the final product and actual field conditions. During design and development processes, human factors specialists base user interface and system design recommendations on an understanding of user needs, goals, characteristics, and expectations. Systems designers then work with human factors specialists to translate these stated needs into specific technical design requirements that may be implemented within cost targets. As noted earlier, the human factors specialist can work with public information system development and design processes to balance usability requirements with user constraints, system requirements, and development costs. The result can be that the final product functions as desired and in ways that are easily usable (Bailey, 1996).

## PLANNING FOR HUMAN FACTORS DURING PUBLIC INFORMATION SYSTEM DEVELOPMENT

Information systems' planning is a common problem for organisations, and planning for human factors is a particular problem within the overall problem of design (Kuark, 1996). The traditional approach to planning IT systems is called the systems development life cycle (SDLC) method (Davis & Olson, 1985). This approach can be summarised as a linear checklist of activities undertaken in a series of phases that begins with planning and ends with system termination. To put it another way, SDLC is a planning process that separates an IT system problem into its constituent parts, treats each step separately, and then unifies the parts into a whole at the end (Langefors, 1973). This approach has been criticised as too concentrated on technology at the expense of users and product performance (e.g., Noyes et al., 1996). To keep the valuable parts of the SDLC method there is a movement to integrate human factors into SDLC (Zhang, Carey, Te'eni, & Tremaine, 2005). Whether integrated in with SDLC or another methodology, HCI development and design is the process of creating quickly all or part of a system in the form of a simulation or prototype (e.g., on paper or a nonworking sample displayed on a computer screen). The advantage of this method is that it allows user feedback early enough to accommodate major structural changes before extensive development investments are committed. This use of prototyping is a team process which helps to overcome the limitations SDLC. The early SDLC model has been described as too linear, lacking a group planning orientation and not an actual reflection of real world conditions (e.g., Wanninger & Dickson, 1992). Now the emphasis is on using the systematic features of SDLC

*Figure 1. UCD process model (from ISO 13407, 1999)*



from a human factors perspective; technical decisions are based on an understanding of human needs and capabilities (e.g., Zhang et al., 2005). The following section on user-centred design describes the most commonly used model promoted by human factors professionals and user-oriented designers.

## USER-CENTRED DESIGN

User-centred design (UCD) refers to the design of interaction between users and the system, called *interaction design* (Preece, Rogers, & Sharp, 2002). It models a system from a user perspective and focuses on the usability of an interactive software system. The core objective is to effectively support users in executing their tasks (Earthy, 2001).

*Usability* is recognised as one of the most important quality characteristics of software intensive systems and products. Usability gives many benefits including "increased productivity, enhanced quality of work, improved user satisfaction, reductions in support and training costs and improved user satisfaction" (ISO13407, 1999).

The prevailing paradigm of developing *usable* products and systems (or UCD) is that usable products are created through processes of user-centred design. The UCD process model is illustrated in Figure 1. Achieving quality in use requires this type of user-centred design process and the use of appropriate usability evaluation techniques. Usability is defined as a high level quality objective: to achieve effectiveness, efficiency, and satisfaction. This requires not only ease of use but also appropriate functionality, reliability, computer performance, satisfaction, comfort, and so on.

### UCD and Usability

The role of UCD in a development effort is to deal with user needs in a way that highlights potential problems and ensures that products, systems, and services will succeed because they are based on appropriate UCD and usability. The applied discipline of cognitive engineering leans heavily on the knowledge and methods developed by human experimental psychology and, to a lesser extent, on applied physiology and related human sciences to carry this goal out.

### Usability Facilities

Usability laboratories have become an important tool. These laboratories, together with appropriate field-kit evaluations, enable us to meet the growing number of requests for usability support, chiefly user-based evaluations of development prototypes and competitors' products. Together with the appropriate development processes, laboratory studies help predict and deal with specific usability problems during product development. Such a laboratory also provides an extremely powerful tool to identify and publicise general usability issues that affect overall product use. Rubin (1994) describes usability testing in detail and gives examples of typical usability laboratories.

## IMPLEMENTATION ISSUES

Although improved technology will always have a critical role in system design, it is often the case that human factors considerations will take up the majority of the time of IT designers and managers. Much is known about the nature of human error, the conditions that encourage error, and hardware/software designs that are error resistant (Norman, 1990), and much of this is now well recognised in IT training literature (Salvendy, 1997). While human factors is recognised and used by many information system developers and designers, there are those who take the perspective that users who want access must accommodate themselves to an information system.

The attitude of the employees' response for administering a public information system is also critical for success. New users or those with problems may need to ask an employee (a human-human interface) for help. Employees who have a negative attitude will too often give the user a negative attitude towards the system (Cialdini, 1993). Including employees in processes will help to avoid the problem of employees undermining the operation of a

public information system; following are some points to use in the avoidance of employee resistance.

## Cognitive Aspects of Implementation

Overcoming employee resistance is a problem in cognitive change. Human factors texts and reference books describe how computerisation alters the flow and content of information, changes job content, or affects relationships between organisational members (e.g., Bailey, 1996; Dix, Finlay, Abowd, & Beale, 1998; Helander, 1997). A key finding was that the primary issue was not computing itself, but rather perceptions of the method of implementing it. It is precisely in this area that human factors become important by including assessment of organisations during public information system changes.

## Cognitive Perception

In IT projects there are four common cognitive perceptions that must be overcome by employees: (1) automation is mandated arbitrarily; (2) the new computer system will be unreliable; (3) the new system will increase rather than decrease the work burden; and (4) they (employees) will neither understand a system nor be able to operate it. Free and open communications throughout an IT implementation process is an important avenue for reducing employee resistance coming from these issues. Negative perceptions regarding the introduction of IT may be overcome to a significant extent through the encouragement of employee decision making during an IT introduction process.

## Attitudes

Although user attitudes tend to be against change, once new technology is seen as bringing desired benefits, attitudes will begin to adapt. In particular, acceptance is much more likely when computing is presented as complementary to human skills, enhancing rather than replacing them (Petheram, 1989; Rosenbrock, 1981). Changing employee attitudes is all the more important since word of mouth is a critical aspect of the process by which technological innovations are spread (Czepiel, 1974). Dickson, a pioneer in the study of human relations and IT noted that, when it comes to management information systems, it is essential to involve people as a component, knowledge of their behaviour as a part of the system is important to the success of the entire field (Dickson, 1968).

The human factor in IT involves both teamwork and leadership. If a leader attempts to bring about IT change in an authoritarian manner, the result may be resistance, lack of effectiveness, and even outright failure. On the other hand, if a leader is able to mobilise the cognitive pressure of professionalism in favour of IT change, then an organisational culture of acceptance is possible (Prasad & Prasad, 1994).

# FUTURE TRENDS

When considering the future of human factors in public information systems, it is useful to first recognise that an astonishingly rapid rate of technological change has been and is the norm for computing systems. Whole buildings and highly trained teams were once needed for a single computer; in contrast, more powerful systems can now be found on the top of the desk of the least-skilled person in an organisation. Given this rapid and dramatic pace of change and development, it is challenging to predict future directions.

Despite this dramatic pace which defies the imagination it is possible to observe that whatever technology may bring the core emphasis of human factors will remain unchanged. For any technological change to be effective, it must be readily understandable and usable by an average user. For example, while nearly instantaneous processing and presentation of data is becoming the norm, that data are of no value if confusing or overwhelming.

Any future system, regardless of any technological advance it may achieve, must include in its design consideration how humans comprehend, manage, and process information. For example, Miller (1956) reported that the average person is unable to remember more than seven pieces of information at one time. A computing system that requires that a user remember eight pieces of information to successfully complete an operation will therefore have high rates of user error. It is this kind of simple, yet critical, understanding of human capability that must always be included in design.

Thus, technologies and designs of the future will always need to include recognition of human limitations in any interface design. Toolkits that contain information about human capabilities will make it possible for researchers and designers to consistently include consideration of the human user in any final product.

# CONCLUSION

New technologies are often seen as an ultimate solution. While this is essentially correct, it is also necessary to recognise that improved technology does not change human capability. Computers and computing systems, as with public information systems, can only be as effective as users are capable. Designs that expect users to learn to perform beyond usual capabilities ignore the reality that

humans are limited and unlike technology, cannot be improved or upgraded. For this reason it is essential that the concept of user-centred design be part of any public information system design process.

As implied, the introduction into IT system development of user-centred design procedures ensures that success stories associated with usability engineering will continue. Advanced development projects that examine psychological factors underlying consumer reactions and expectations include user-centred evaluations of prototypes and match human capabilities with system designs. These are most likely to result in public information systems that are accepted by both the public and governmental employees.

The inclusion of human factors into public information system development and design processes will, over the life of a system, reduce costs through the avoidance of the need to correct problems caused by errors or through difficultly in using the system. To successfully achieve this integration strong leadership that requires human factors elements in a system is necessary. Strategies such as specifying ISO 13407 (1999) as the standard during development and design are recommended as a way to be sure that human factors will be included.

## KEY TERMS

**Cognitive Engineering:** Understanding and predicting how changes in a task environment will influence task performance.

**Human-Computer Interaction (HCI):** The study of people, computer technology, and the ways these influence each other (Dix et al., 1998).

**Human Factors (or Ergonomics):** The scientific discipline concerned with the understanding of interactions among humans and other elements of a system, and the profession that applies theory, principles, data, and methods to design in order to optimise human well-being and overall system performance (IEA, 2005).

**Interface:** A point in any human-computer system where information is exchanged. Interface designs that do not take into consideration human capabilities will likely have higher than desirable rates of human error.

**Usability:** The effectiveness, efficiency, and satisfaction with which specified users can achieve specified goals in particular environments.

**User-Centred Design:** During the design of systems or products the capabilities of end users (humans) are considered so that the final system or product is readily usable and designed so that the likelihood of error is minimised.

**User Interface:** The way that a human and computer system exchange information. Both hardware and software are part of the user interface. The screen, keyboard, and mouse are the most common hardware combination; any other hardware design that can be used to exchange information is also a user interface. The software arranges the information (e.g., sequence, quantity, manner requested, etc.). Human factors focuses on making certain that information is presented in a way that facilitates understanding.

# ICT as an Example of Industrial Policy in EU

**Morten Falch**

## INTRODUCTION

A substantial part of the economic growth that has taken place within the past 2 decades is related to information and communication technology (ICT). First, the ICT sector itself has achieved very high growth rates. Second, productivity gains in other sectors have been achieved, to a large extent, through implementation of ICT-related innovations. It is, therefore, no surprise that ICT plays an important role in virtually all industrial policy programs. Policies stimulating e-government are one of the ingredients in such programs.

In 2000, the leaders of the European Union (EU) adopted the Lisbon strategy to make the EU the most dynamic and competitive knowledge-based economy in the world (CEC, 2000). ICT was seen as a key component in achieving these goals[1], and a special program—eEurope—has been designed to realize the Lisbon goals in the ICT area. This program is, however, also a continuation of a wide range of ICT initiatives taken by the EU Commission since 1984.

## BACKGROUND

In the eEurope program, the Commission mentions three types of benefits stemming from ICT:

1. The ICT sector itself accounted for 6% of employment in the EU in 2000
2. ICT improves productivity in other sectors
3. ICT boosts citizenship and quality of life (CEC, 2004a).

Although the third point may, in part, be outside the scope of industrial policy, as it does not directly address the economic sphere, the three points reflect very well the dual aspect of the EU ICT policy, which has been inherent from the early beginning:

- **International Competitiveness:** Telecom is considered to be a high-tech sector of strategic importance with regard to the generation of employment and economic growth. In addition, telecom is a sector in which the EU has a relatively strong position compared to the United States (U.S.) and Japan.
- **The Information Society:** Telecom networks constitute an essential infrastructure for the information society. Cheap and ubiquitous access to advanced telecom services is, therefore, important for the generation of employment and economic growth in any industry.

The first point is typical for sector-specific industrial policy. The objective is to strengthen an industrial sector deemed to be of particular importance to maintain or even improve the EU position in the international division of labor. The major reason is a high growth potential with regard to employment and contribution to GDP.

The second point is somewhat more related to horizontal industrial policy aiming at improving the business environment in general. Here, ICT is seen as a part of the overall infrastructure used by all industries. It should be noted that this distinction is not completely clear-cut. The argument for industrial policies directed towards a specific sector will often be that a particular sector possesses important spillovers to other industries. For instance, one of the arguments used as justification for the support to the agricultural sector is that agricultural production generates employment in food-processing industries.

The telecom sector itself has often used its importance for the entire economy as an argument for support. This argument has also been widely used by other sectors if they had an interest in affecting political decisions. However, with regard to telecom, there has also been a strong pressure from users—in particular, business users—depending on access to more advanced communication services.

A strong ICT sector may support the development of an information society, and an advanced information society will benefit the ICT sector as it stimulates demand and innovation of ICT products and services. Still, the two objectives are addressing two different groups—users

and producers of ICT—and these groups often have contradicting interests.

## THE EU RESEARCH PROGRAMS

The first initiative taken by the Commission was the introduction of a number of European-wide research programs. The ESPRIT program supporting IT research was commissioned in 1984 and the first phase of the RACE program, supporting telecom research, was commissioned the year after. Both programs offered support for so-called pre-competitive research. In this way, any accusations of industry subsidies could be avoided, and it was easier for competing companies to exchange information. The core of the RACE program was to develop technologies for developing a broadband in Europe (a distant goal at that time), and the focus was mainly on providing the basic infrastructure, although very few applications justifying the need for huge investments in optical networks were available. An important objective of the program was also to create an international forum for discussions and cooperation between European telecom companies to establish a common vision for the future European telecom networks and, thereby, facilitate integration of a market fragmented along national borders.

The RACE program was extended and followed by a series of other telematic research programs. However, there has been a gradual shift in focus from development of basic technologies towards development of applications. This reflects a trend towards more application-oriented research as well as a shift towards more focus on the demand side. Also, the kind of participants in the research programs has changed. From the beginning, telecom operators were very active in the programs, but following a reorientation of the telecom operators towards more commercial—and more limited—research and development activities, they have restricted their participation. On the other hand, a large number of small- and middle-size consultancy firms and information technology (IT) companies have engaged in the programs.

## STANDARDIZATION

A related activity was the establishment of a European standardization body, ETSI. The creation of this body moved a part of international standardization from ITU into the European framework. In addition, it enabled a more direct involvement from industry partners in the standardization process. Many of the EU-funded research projects participate directly in ETSI so that the research made through cooperation between European industry actors can result in common European standards.

The establishment of a European-based standardization body is not only a way to contribute to the development of a common internal market within the EU. It also contributes to strengthening the role of the EU-based industries in the formation of global standards, and thereby it contributes to an improved international competitiveness of the European telecom industry.

## SECTOR REFORM

Another line of EU policy has been related to the market reform of the telecom sector. This reform was initiated by the Green Paper issued in 1987 (CEC, 1987) and followed by a series of directives that have been revised a couple of times. The latest major revision was made though the issuing of the new telecom framework directives in 2002. The vision behind the market reform is to change the telecom sector from being a public utility provided by publicly owned—or at least publicly controlled—monopolies into a "normal" industry sector, where private companies compete for market shares and without any sector-specific regulation.

Although the sector reform should be seen in the context of an ongoing reform of public sector activities in general, the primary objective is to initiate a more dynamic development of the telecom sector itself through a complete restructuring and to remove barriers set by former public involvement. It should, however, be noted that the objective of "normalization" of the sector was not clearly defined from the beginning. The first step, which was suggested in the Green Paper, was the liberalization of terminal equipment, creating a common market in this area. The Green Paper of 1987 also suggested a liberalization of other telecom services than telephony, while telephony, which at that time was by far the most important service, as well as the physical network, should be reserved for the incumbent monopoly operators.

A further point is that not all member countries agreed on the proposed liberalization. In particular, France, together with countries from Southern Europe, were very reluctant to liberalize the telecom market, and many countries were concerned about how their own incumbent telecom operator could survive in a liberalized market. A good example of this is Denmark, where the market was divided between four regional operators in limited geographical areas. The Danish government wanted to create a strong Danish actor on the telecom market and merged all operators into one (Tele Danmark). In addition, a substantial part of the revenue raised through the subsequent privatization was given to Tele Danmark, enabling the company to invest in telecom companies abroad.

A more recent line of policy actions is related to the stimulation of demand and development of content. These types of initiatives dominate the eEurope program initiated for realizing the goals set by the Lisbon agenda with regard to ICT. The objectives of the program do not include anything about the ICT sector itself, but focuses on making ICT available to everybody and stimulating entrepreneurship.

## eEUROPE

The eEurope program was initiated in 2000 as a Commission initiative for the special European Council of Lisbon (ECE, 2000). The program has later been followed by the eEurope 2005 program (CEC, 2002a), and the successor of this program—i2010—has just been announced (CEC, 2005).

The eEurope plan 2000-2002 had three overall objectives: Cheaper, faster and more secure Internet, investment in people and skills and greater use of the Internet. In the eEurope 2005 plan, these aims were replaced with: Modern online public services, dynamic e-business environment, widespread availability of broadband access and secure information infrastructure (CEC, 2003). Both plans include actions stimulating network as well as content development.

This dual perspective is most clearly formulated in the 2005 plan, where the mutual dependence between network development and content development is recognized and public action is recommended to correct this market failure: "Funding more advanced multimedia services depends on the availability of broadband for these services to run on, while funding broadband infrastructure depends on the availability of new services to use it. Action is, therefore, needed to stimulate services and infrastructure to create the dynamic where one side develops from the growth of the other" (CEC, 2003, p. 2).

This is the typical market failure argument used for implementing industrial policy: To achieve the most favorable development, it is necessary to help the market to take the right decisions.

Both plans include a large number of action points, but none or very few of these points include initiatives that would be termed as industrial policy in the supply-oriented, traditional sense. However, they include the development of a wide range of e-government applications, such as e-learning and e-health, and the provision of broadband access to public institutions. Development of such applications enables both cost saving and service improvements in the public sector. But maybe even more important is the impact on other sectors. Development of e-government services stimulate development of similar service in the private sector and lead to further growth in the demand for infrastructure facilities, such as broadband. eEurope also includes a large number of initiatives involving the private sector. These initiatives include support to research and development in telecom networks as well as applications like e-business. The objective of many of these initiatives is to develop pilots, which can inspire other parts of the private sector. Finally, the plans include a continuation of the telecom reform process and measures for improvement of legislation to facilitate e-business.

Although the 2005 plan states the importance of the supply side, the only really new initiative, in addition to a continuation of the telecom reform process, is a suggestion to finance network development in less favored regions; for example, by the use of structural funds. This initiative is maybe the one most in line with the old-type industrial policy subsidies.

In addition to initiatives at the EU level, most member countries have defined their own national broadband strategies as a part of eEurope. National programs within the ICT area are far from a new phenomenon. In the early 1990s, it became fashion for each country to develop its own plan for how it could become global champions in ICT (Henten, Falch, & Skouby, 1995).

The national programs fit very well with the EU programs, as they basically use the same type of remedies: Support for research and development and pilot projects, e-government initiatives, and demand stimulation through demand from public sector institutions. Very few countries have discussed direct subsidies for network development. Sweden has had programs for public funding of broadband networks, and in Denmark, broadband access receives substantial taxation subsidies, as companies are allowed to offer broadband connections to their employees as a tax-free fringe benefit.

## FUTURE TRENDS

The eEurope and iEurope programs tend to emphasize more on content development and stimulation of demand than previous ICT programs. The same trend can be observed in other countries; for example, in the Japanese U-Japan program. One reason for this is that the major parts of telecom reform now have been implemented and the supply of network infrastructure no more is seen as a major bottleneck for development of the information society. Therefore, more attention is given to development of content. In this context, e-government plays a major role, as development of public content can stimulate development of content in the private sector as well as the demand for ICT network facilities, such as broadband.

## CONCLUSION

During the process of creation of the EU internal market, it has been important to remove all barriers for international trade between member states. This includes national subsidies as well as other measures favoring domestic industries. On the other hand, it has been important to ensure development of the European industry in competition with the U.S. and Japan. This has led to a strategy with policy goals that are not very different from those set by traditional national industrial policy; but at the European level, many of the traditional remedies are replaced by a new set of initiatives with focus on stimulation of ICT-based innovations and applications. In this context, e-government plays a crucial role, as development of public e-services stimulates the overall use and demand for ICT. The impact of such policies on the entire economy is difficult to assess. But there has been a clear, positive impact on the penetration of ICT technologies in the countries being most active in this policy area. In particular, policies securing more competition on national ICT markets led to a much faster introduction and higher penetration of new ICT services, such as broadband access and mobile communication.

## KEY TERMS

**eEurope:** The eEurope program was initiated in 2000 as a part of the Lisbon Process to ensure that the EU will fully benefit from opportunities of the information society. The objectives are to make communication services including broadband widely available, to stimulate content development and improve e-literacy—all in a way that strengthens social cohesion.

**ETSI:** ETSI is a European standardization body established following an initiative set by the European Commission. ETSI prepares common standards for telecommunication systems for fixed and mobile networks and services, TV broadcasting as well as for information technologies. Both European and non-European companies can be members. Today it has 688 members from 55 countries.

**EU Research and Development Programs in ICT:** European research activities are structured around consecutive 4-year programs, or so-called Framework Programs. The Sixth Framework Prograe (FP6) sets priorities —including the information society technologies (IST) priority—for the period 2002-2006. While the first cycles mainly focused on the basic technology, later programs include a wide range of applications as well. The current program includes a project line on ICT research for innovative government.

**Industrial Policy:** State policies conducted with the aim of strengthening the industrial base of a country or region. General macroeconomic stabilization policies are not considered part of industrial policies; however, industrial policies can encompass a broad range of supply-and-demand-oriented policy initiatives.

**International Telecommunication Union (ITU):** An international organization within the United Nations system where governments and the private sector coordinate global telecom networks and services.

**Lisbon Process:** At a summit in Lisbon in March 2000, European leaders set the goal of the EU becoming "the most dynamic and competitive knowledge-based economy in the world" by 2010. The target was a 3% average annual economic growth and the creation of 20 million jobs by 2010.

**Telecom Sector Reform:** A reform that has transformed the telecom sector from national monopolies controlled by governments to a sector with competition and private ownership. The telecom market was in principle liberalized in 1996 within the U.S. and in 1998 within the EU, although public ownership of telecom operators still persists in some European countries.

# ICT Considerations for a Municipality in South Africa

**Udo Averweg**
*eThekwini Municipality and University of KwaZulu-Natal, South Africa*

**Siyabonga Manyanga**
*eThekwini Municipality, South Africa*

## INTRODUCTION

The availability of publicly accessible Internet networks and services are the first prerequisite in ensuring that all citizens and nations can benefit from information on the World Wide Web (UNESCO, 2003). Information and communication technologies (ICT) are playing an increasingly important role in the daily lives of citizens, revolutionising work and leisure and changing the rules of doing business. ICT encompass all technologies that facilitate the processing and transfer of information and communication services (United Nations, 2002). In the realm of government, ICT applications are promising to enhance the delivery of public goods and services to citizens not only by improving the process and management of government but also by redefining the traditional concepts of citizenship and democracy (Pascual, 2003). The spread of ICT brings hope that governments can transform (Pacific Council on International Policy, 2002).

This article is organised as follows:

- Background to the research is given
- ICT adoption in the eThekwini Municipality in South Africa is described
- The research goals, method, data gathering, and results are discussed
- Management implications towards implementing a successful e-government strategy are given
- Future trends are then suggested and a conclusion is given

## BACKGROUND

Electronic service delivery (ESD) is a method of delivering services and conducting business with customers, suppliers, and stakeholders to achieve local government developmental goals of improved customer service and business efficiency. The eThekwini Municipality in South Africa sees the e-government strategy (Ethekwini Municipality Integrated Development Plan 2003-2007, 2003) and its Web site at URL http://www.durban.gov.za as important management tools for improved citizen service delivery and communications. The ultimate objectives of this Web site are to make most of Durban's over-the-counter services available online, assisting people to find a wide range of information about local governance online and marketing the city to tourists and business people (eThekwini Municipality Portfolio of Sustainability Best Practice, 2004).

An editorial in the *South African Business Day* on August 26, 2003 reports that the City of Durban on the east coast of South Africa in the eThekwini Municipality Area (EMA), is quietly installing one of the largest networks in the country to link up scores of municipal centres all over greater Durban. The more technologically savvy can already access a wealth of city information via the Internet, by browsing the Web site either from home personal computers (PCs) or an increasing number of Web-linked computers at municipal libraries. The editorial states that Durban "is also pumping tens of millions of rands into promoting the local technology sector." It is against this background that research was conducted to glean a clearer understanding of the implication of ICT for e-government adoption in the EMA.

## ICT ADOPTION IN THE eTHEKWINI MUNCIPALITY AREA (EMA) OF SOUTH AFRICA

eThekwini Municipality's population is 3.9 million citizens (Statistics South Africa, 2001). The population is an amalgamation of racial and cultural diversity. The black African community is comprised of 68.3%, coloured citizens 2.8%, Asian citizens 19.9% and white citizens 9% (Statistics South Africa, 2001). Thirty-eight percent of the population is under 19 years of age (Ethekwini Municipality Integrated Development Plan 2003-2007, 2003). Ethekwini Municipality has a capital budget of ZAR2.70

billion (approximately U.S. $0.40 billion) and an operating budget of ZAR9.64 billion (approximately U.S. $1.45 billion) for the 2005/6 financial year—visit URL http://www.durban.gov.za. Durban is South Africa's major port and the second largest industrial hub after Johannesburg. The EMA's gross geographic product income is ZAR25,529 (approximately U.S. $3,838) per person, per annum which is higher than the South African average of ZAR17,756 (approximately U.S. $2,670) per person, per annum.

Erwin and Averweg (2003) report that there is a need for organisations to adapt to constantly changing business conditions. The Ethekwini Municipality: Quality of Life Household Survey 2002/2003 (2003) reveals the needs and problems impacting the quality of life of EMA citizens. Some issues raised include new housing requirements, water and sanitation supply and lack of recreation facilities (Ethekwini Municipal Area Development Profile, 2002). This survey reveals that there is also a growing need for information in the EMA. Among the solutions to fulfil this need, ICT is seen as an effective mechanism to access municipal information in particular and development information in general. As reflected in the "Results and Discussion" section in this article, most EMA citizens receive municipal information via a municipal magazine (*MetroBeat* publication which is published monthly by the Communications Department, eThekwini Municipality) delivered to their post box. However, from the authors' survey, EMA citizens indicate that they would like to receive information via the electronic information exchange mechanism in the form of the Internet.

There is a growing number of EMA citizens accessing the eThekwini Municipality Web site through other initiatives (e.g., Carnegie E-Community project aims to improve the quality of life of municipal citizens and access to information by placing computers in municipal libraries). South African Web sites, which seek a local and global reach, have to cater for the digital divide which exists between the technological "haves" and "have nots" (Averweg, Barraclough, & Spencer, 2003). The mere existence of gaps in levels of ICT practices between rich and poor across and within countries is not an automatic reason to argue that ICT should be placed near the top of the development agenda (Manyanga, 2002). In looking at the difference in access between developed and developing countries, Gumucio-Dagron (2003) notes that the "divide has never been only a 'digital' or technological divide. It is a social, economic, and political fracture." The authors suggest that a comparable situation exists (in microcosm form) in the EMA. Bridging the digital divide in the EMA is not the end in itself. It is not even the beginning of the end. The authors suggest that perhaps it is the end of the beginning to bring positive changes in the development of a municipal information society.

## E-Government and E-Governance

E-government is about transformation that helps citizens and businesses find new opportunities in the world's knowledge economy (Pacific Council on International Policy, 2002). Governments have not been immune to the impact ICT have in society (Rivera-Sanchez & Sriramesh, 2003). Governments that define e-government as simply moving services online "miss larger opportunities which [will] determine competitive advantage in the long run" (Caldow, 2002). Definitions of e-government range from "the use of information technology (IT) to free movement of information to overcome the physical bounds of traditional paper and physical based systems" to "the use of technology to enhance the access to and delivery of government services to benefit citizens, business partners and employees" (Deloitte & Touche, 2003). Ultimately, e-government aims to enhance access to and delivery of government services to benefit citizens (Pascual, 2003). E-government needs to find a positive developmental role. Without this, e-government runs the risk of being a 21st century "rusting tractor," cast aside as it fails to fulfil its promise (Heeks, 2003). E-government services focus on four main customers: citizens, the business community, government employees, and government agencies. The focus of this article is on citizens in the (local government) EMA.

E-governance refers to a local government's inventiveness to electronically govern areas under its jurisdiction (Manyanga, 2002). This effectively means the public sector's use of innovative ICT (e.g., Internet) to deliver to all citizens improved services, reliable information, and greater knowledge in order to facilitate access to the governing process and encourage deeper citizen participation.

## Research Goals

ICT can be defined as electronic means of capturing, processing, storing, and communicating information (Heeks, 1999). E-readiness can be defined in terms of availability of ICT infrastructure, the accessibility of ICT to the general population and the effect of the legal and regulatory framework on ICT use (Manyanga, 2002). In building a model of ICT, two separate elements exist: the technology itself and the information on which it operates. Heeks (1999) suggests that in order to make this model useful, two further processes should be added: processes of purposeful activity and the people to undertake those processes. Together these constitute an "information system," such as a support system that helps citizens interact with their local municipality. The authors suggest that the harmonious development of a

municipal information society is only possible if the availability of multilingual and multicultural information is encouraged.

Ethekwini Municipality embarked on an initiative to understand the needs of its users and non-users in utilising ICT as a tool to improve service delivery and establish effective communication between itself and its constituencies. Prospective techniques help practitioners work on an e-government project that is still at the planning stage (Heeks, 2003). This article reports on these initiative findings from a survey conducted and suggested management implications that relate to the adoption of an e-government strategy in the EMA. With the high failure rate of e-government projects, Heeks (2003) notes that it carries direct and indirect financial costs, it damages morale, credibility, and trust, and it prevents the benefits of e-government from being delivered. The focus of this article is on citizen's capabilities to use ICT to acquire or share information with the municipality and general community development in the EMA. The primary objective of this research article are to gauge (1) e-readiness of the citizens to use ICT as a communication medium; (2) the technological capabilities of ICT end-users and non-users; and (3) obstacles and barriers which may impact e-government implementation (social, cultural, etc).

## Research Method and Data Gathering

A survey instrument developed gauges EMA citizen's ICT needs and capabilities. This survey tool attempts to obtain a snapshot of the current ICT status of EMA citizens. The authors' rationale is that social, cultural, and other contextual factors are often ignored in the development of ICT strategies. In order to overcome this shortcoming, it was considered important to bring these factors "on board" for planning the eThekwini Municipality's e-government strategy. The survey instrument comprises two sections:

- **Section 1: General Information:** Section 1 contains three subsections: (1) citizen personal information; (2) experience in using a computer and access to the Internet; and (3) focus on the eThekwini Municipality Web site.
- **Section 2: Citizen's Information Needs:** Section 2 contains three subsections: (1) how citizens currently receive and would like to receive information about eThekwini Municipality; (2) how citizens currently interact and would like to interact with eThekwini Municipality; and (3) identify areas where the citizens would prefer eThekwini Municipality to provide access to PCs.

During May 2003, the questionnaire was administered face-to-face to 465 EMA citizens by the second author and seven temporary staff members. The duration of each interview was approximately ten minutes. The sample was selected at random basis. Both quantitative and qualitative data were collected. Interviews were conducted at EMA municipal (customer service) offices and municipal libraries. The requirement for effective e-governance requires a good understanding of the cultural or social background of its end-users (citizens in its communities). The citizen survey thus focused on the e-readiness of EMA citizens to "tap" into the new methods of communication for e-governance.

## Results and Discussion

ICT survey results are the reflection of e-readiness of EMA's citizens to use ICT as a communication medium with eThekwini Municipality and among themselves. Using SPSS software, the race grouping (Table 1) and computer experience (Table 2) were weighted to actual population composition of the EMA.

Table 1 shows the number of participants with household PCs by race.

Table 1 indicates that white citizens had the highest percentage (76.7%) household PCs. A significant percentage (89.5%) of black citizens surveyed did not have household PCs (Ethekwini Municipality: Quality of Life Household Survey 2002/2003, 2003). The average percentage of respondents surveyed that had PCs in their household is 21.7%.

Table 2 reflects the computer experience of respondents by race grouping. On the average, 58.7% of respondents reported that they had some computer experience. Computer experience by white citizens was relatively high (85.7%) followed by Asian citizens (77.5%). Black citizens reported the least (46.8%) computer experience.

Table 3 reflects employed respondents had the highest percentage (49.6%) of computer experience. This percentage was followed by respondents who were studying (21.4%).

Table 4 reflects matriculated respondents had the highest percentage (51.3%) of computer experience. It is interesting to note that those respondents surveyed who have no education, did have some computer experience (1.1%). Inadequate computer literacy and the lack of access to ICT are widely recognised as an increasingly daunting obstacle to the economic, civic, and political development of Africa (Badshah & Thumler, 2003).

The concept of e-government involves using ICT (e.g., Internet) to deliver public services (Rivera-Sanchez & Sriramesh, 2003). Table 5 reflects the age-grouping of respondents surveyed that had Internet access. Respondents with the highest percentage (43.2%) were those in

*Table 1. Race grouping of EMA respondents with household PCs (Source: Ethekwini Municipality: Quality of Life Household Survey 2002/2003, 2003)*

| Race Grouping | Percentage (%) of respondents who have a household PC |
|---|---|
| Black | 10.5% |
| Asian | 39.5% |
| Coloured | 28.6% |
| White | 76.7% |
| **Average** | **21.7%** |

*Table 2. Computer experience of respondents surveyed by race grouping*

| Race Grouping | Percentage (%) of respondents who have some computer experience |
|---|---|
| Black | 46.8% |
| Asian | 77.5% |
| Coloured | 64.3% |
| White | 85.7% |
| **Average** | **58.7%** |

the "21-30" age-grouping. The second highest age-grouping "31-40" reflects that 21% of respondents surveyed have Internet access. This tends to suggest that EMA citizens surveyed receive Internet exposure during their post-matriculation studies and in their employment environments.

Table 6 indicates that of the respondents surveyed with Internet access, 16.7% reported that they had visited the eThekwini Municipality Web site at URL http://www.durban.gov.za. See Table 6.

Table 7 reflects current delivery mechanisms that EMA citizens received information about eThekwini Municipality. A significant number (69.6%) of the respondents surveyed received municipal information (*MetroBeat* publication) delivered to their post boxes.

Table 8 indicates that 47.9% of respondents surveyed reported that they were satisfied with the current manner in which they received information from eThekwini Municipality about eThekwini Municipality. Heeks (1999) cautions that as an aid to entrepreneurs in the developing world, "poor entrepreneurs need more than money, skills, and infrastructure to make use of the data delivered by ICT." E-government must be about meeting the needs of citizens and quality of life (Pacific Council on International Policy, 2002).

Table 9 reflects respondent's preferred information delivery mechanisms for receiving information about eThekwini Municipality. About two-thirds (63%) of respondents surveyed reported that they would like to continue receiving information via the South African Post Office. It is interesting to note that only 5% of respondents surveyed reported that they would like to receive information via the Internet. On the contrary, when respondents surveyed were asked whether in future they would like to interact with eThekwini Municipality specifically via the Internet, 64.3% of them reported positively.

The aim is not simply to deliver services electronically in the EMA but to encourage its citizens to start learning about the Internet via its Web site and thereafter make use of the Internet for other services. The success of the Internet should be measured in terms of accessibility and contribution to social progress, rather than in terms of numbers of connected individuals (Kamel & Hussein, 2000). Evidence suggests that countries that have experienced the most rapid diffusion of ICT have also experienced the most rapid rates of employment and output growth (Baily & Lawrence, 2001). The Ethekwini Municipality Integrated Development Plan 2003-2007 (2003) states that its strategic commitment is to develop a smart city as part of the process of economic development and "a shift to service and knowledge-based activities."

In response to the question regarding the preferred location where respondents surveyed would like to have PCs installed, 51% of the respondents surveyed reported that it should be installed in municipal libraries, 20% in schools and 13% in shopping centres/malls (see Table 10). Some respondents stated, "the idea of computers in libraries and shopping centres is good, they take their time to resolve queries," "timing bad sometimes" and there is

*Table 3. Proportion of participants who were experienced with computers by occupation status*

rather a need to "upgrade township services." Research shows that to implement public access centres extensively, is a big challenge (Fernández-Maldonado, 2003).

In summary, the authors' survey focused on establishing a better understanding of how ICT can contribute to eThekwini Municipality's citizen service delivery and development communication. The main objective was to establish how EMA citizens perceive new technology and their willingness to "try out" ICT as a new form of communication (e-readiness). This survey also analysed the social factors related to the eThekwini Municipality's progressiveness with e-government and some future challenges for governance using ICT within EMA. Some management implications for consideration are now suggested.

## Management Implications

From this study, the authors suggest the following criteria serve as important management implications for implementing a successful e-government strategy in the EMA:

- **Physical Access:** Access to communications and the Internet is a cornerstone of a municipal information society. Digital inclusion cannot be achieved without providing all EMA citizens access with affordable ICT appliances to the information highway. Citizens should be able to access public and government records including all the information they require in a modern democratic society (UNESCO, 2003). The findings of the authors' re-

*Table 6. Proportion of respondents with internet access who visited the Thekwini Municipality Web site*

| Percentage (%) of respondents who visited theThekwini Municipality Web site | Percentage (%) of respondents who have NOT visited the eThekwini Municipality Web site |
|---|---|
| 16.7% | 83.3% |

*Table 7. Current delivery mechanisms for receiving information about eThekwini Municipality*

| Delivery mechanism | Percentage (%) of respondents |
|---|---|
| Telephone | 4.3% |
| Post Office | 69.6% |
| Municipal office | 7.6% |
| Municipal publication | 13.3% |
| Community meeting | 4.4% |
| Internet | 0.1% |
| School/Tertiary | 0.7% |
| **Total** | **100%** |

*Table 8. Level of citizen's satisfaction regarding the manner they received information about eThekwini Municipality*

| Satisfaction Level | Percentage (%) of respondents |
|---|---|
| Not satisfied | 9.2% |
| Average satisfaction | 37.1% |
| Satisfied | 47.9% |
| Don't know | 5.8% |
| **Total** | **100%** |

*Table 9. Preferred delivery mechanisms for receiving information about eThekwini Municipality*

| Delivery mechanism | Percentage (%) of respondents |
|---|---|
| Telephone | 9% |
| Post office | 63% |
| Municipal office | 3% |
| Municipal publication | 11% |
| Community meeting | 5% |
| Internet | 5% |
| E-mail/SMS | 4% |
| **Total** | **100%** |

search shows that citizens surveyed prefer access to PCs installed in municipal libraries.

- **Appropriate Technology:** Establishing the appropriate method of interaction must be identified to ensure that technology reaches all EMA citizens. The challenge is to chart an appropriate course which does not perpetuate Gumucio-Dagron's "new apartheid" syndrome (Gumucio-Dagron, 2003).
- **Affordability:** The communication mechanism, whether in regional centres or via PCs, should be affordable to EMA citizens (end-users)
- **Human Capital:** Training and re-skilling will be necessary. As many EMA citizens lack ICT skills, "digital literacy" and/or do not have access to PCs, demonstrations on how to effectively utilise ICT technology (e.g., e-mail/SMS) must be provided. Help should be

*Table 10. Preferred locations for PC installation and associated percentage*

| Preferred location for PC installation | Percentage (%) of respondents |
|---|---|
| Municipal library | 51% |
| School | 20% |
| Municipal office | 8% |
| Clinic | 8% |
| Shopping centre/mall | 13% |
| **Total** | **100%** |

given to people to learn how to use a computer and access information and services on the Internet (UNESCO, 2003). Furthermore attention must be afforded to the training of teachers to adapt to the new learning environment. ICT demands that citizens be perpetually in a learning environment.

- **Relevant Content:** The content developed must be locally relevant to its constituency, especially in terms of language. Language is the foundation of communication between people and is also part of their cultural heritage (UNESCO, 2003). Averweg, Barraclough, & Spencer (2003) suggest that a Web site must facilitate access by end-users not familiar with Internet norms and whose home language is not English. Nowadays the priority is the creation of bridges between linguistic communities to facilitate the circulation of texts in more than one language (UNESCO, 2003). To bridge the digital divide through e-government, e-government must be relevant to citizens. The motivation for using ICT should stem from citizens having their needs addressed (Pascual, 2003). For these citizens' needs, the authors suggest community-focused applications, content management, and knowledge sharing. There is a need to strengthen the political and cultural will to offer Internet users a wider choice of languages (UNESCO, 2003).
- **Political Will:** Nothing is more critical to the success of e-government than political will (Pacific Council on International Policy, 2002). The political will of EMA citizens, eThekwini Municipal councillors, eThekwini Municipal officials, social groups and the business community will need to be secured to facilitate a successful e-government implementation project.
- **Integration:** ICT must not act as a further burden to EMA citizen's lives. ICT should be integrated into priority sectors of the EMA economy and into citizen's daily lives. This should be coupled with efforts to de-mystify and de-demonise ICT for people to accept it as an everyday tool and not an end to itself (OleKambainei & Sintim-Misa, 2003). The authors suggest that the challenge will be to balance the demands of a few very literate and demanding citizens with a majority who may probably never move to the electronic world. One suggestion is to focus on ICT-based trade as a precursor to fully-fledged e-commerce. Kamel & Hussein (2000) report that with continuous developments in ICT, there are "remarkable contributions to the growing global environment with implications on individual and societal aspects of life".
- **Socio-Economic Factors:** The South African government has a responsibility for the well-being of its employees that cannot be ignored as new technologies are introduced. There is a need for capacity building in the acquisition and application of new technologies for the information poor (UNESCO, 2003). The socio-economic status of EMA citizens (end-users) should be considered. By evaluating their e-readiness, this will determine the usability of e-government tools. Innovations in ICT have had remarkable effects on socio-economic development (Kamel & Hussein, 2000). The socio-economic status of Web site users determines their requirements (Averweg, Barraclough, & Spencer, 2003).
- **Legal and Regulatory Framework:** Government regulations affecting technology use and changes that need to be made to create an environment that fosters ICT usage must be considered. The effect of legal and regulatory framework on ICT use should be geared to facilitate the growth of the digital age.

Successful e-governance should be able to not only attract citizens who are already connected online but also to move citizens who are not already there. Therefore, e-governance is not only about reforming work processes within and among governmental institutions but is rather about improving government services to and in collaboration with citizens and business organisations. This will foster the development of a municipal information society. Some future trends for the acceptance of e-governance are now given.

## FUTURE TRENDS

Given the changing role of technology in government, the authors suggest four contextual factors that are primary to the future acceptance of e-governance in the EMA:

- **Usefulness:** EMA citizens must be convinced of the relevant advantage of using ICT. Embracing ICT should be perceived as easier, faster, and less expensive than current processes. ICT needs to be understood and considered to be useful by EMA citizens.
- **Ease of Use:** EMA citizens must be comfortable with the use of ICT. If the appropriate skills and understanding of ICT are in place, then the use of ICT will be easier thereby making its acceptance in the EMA more likely.
- **Intention:** EMA citizens must intend embracing ICT and have a positive attitude towards it. Citizens who view ICT which has no potential in what they are doing are unlikely to accept the potential of ICT.
- **External Variables:** These are factors affecting EMA citizen's acceptance of ICT, which are beyond the individual's control.

It is important that innovative ICT be adopted by EMA to deliver to all its citizens improved services, reliable information, and greater knowledge in order to facilitate the e-governance process by encouraging citizen participation. This will serve to improve information flows in a municipal information society.

## CONCLUSION

Public participation is an important element in the stages of the e-government process, from defining a society's vision and priorities for e-government to determining e-readiness and managing e-government projects (Pacific Council on International Policy, 2002). E-government is not just about municipal Web sites, e-mail, and SMS. It is not about service delivery using ICT via the Internet. It is not about digital access to eThekwini Municipality information. It is about how EMA citizens change in relating to their eThekwini Municipality and the degree to which e-governance changes citizens relating to each other in a municipal information society.

This research suggests that possibly South African local governments need to assess their respective e-readiness to adopt e-government strategies or implementation plans. While there is a drive for e-government in South Africa, this needs to be tempered especially in terms of the considerable obstacles to rolling out e-government in South African municipalities. Research needs to be conducted by South African municipalities regarding issues that may impact their e-government development strategies. This will facilitate an appropriate ICT infrastructure being made available. To seek building an ICT capacity without a solid foundation of research and development is nothing but building a skyscraper in quicksand (Okpaku, 2003). It will also identify skills gaps required to use ICT effectively and some social and cultural barriers for an effective e-government strategy within each South African municipality. Should the appropriate research be undertaken, South African municipalities will be able to ensure they adopt an appropriate ICT infrastructure for their citizens thereby improving ESD and narrowing the digital divide.

## ACKNOWLEDGMENT

An earlier version of this research was presented at the World Forum on Information Society (WFIS), Geneva, Switzerland, 8-10 December 2003.

## KEY TERMS

**Digital Divide:** At the broadest level, term refers to the gap between those individuals who own, access and effectively utilise information and communication technologies and those who do not. However, since the it involves a complex Web of interconnected social, economic, and cultural factors that cannot be fully captured by a definition that focuses solely on access or ownership, "Digital Divide" is defined as a social, economic, and political fracture in a knowledge-based global economy.

**Electronic Service Delivery:** Electronic Service Delivery (ESD) is a method of delivering services and conducting business with customers, suppliers and stake-

holders to achieve local government developmental goals of improved customer service and business efficiency.

**E-Governance:** E-governance refers to a local government's inventiveness to electronically govern areas under its jurisdiction.

**E-Government:** E-government refers to the use of technology to enhance the access to and delivery of government services to benefit citizens, business partners, and employees.

**E-Readiness:** E-readiness may be defined in terms of availability of ICT infrastructure, the accessibility of information and communication technologies (ICT) to the general citizen population and the effect of the legal and regulatory framework on ICT use.

**Municipal Information Society:** Municipal Information Society is defined as the innovative use of information and communication technologies (ICT) to improve the internal operation of a municipality as well as its communication and collaboration with citizens and business organisations in a municipal region.

**Quality of Life:** The ability to integrate a fulfilling and productive work life with a fulfilling personal and family life.

# ICT in the Islamic World

**Fatimetou Mint Mohamed-Saleck**
*Nouakchott University, Mauritania*

## INTRODUCTION

A priori, the Islamic Republic of Mauritania was not prepared for the information and communication technology (ICT) revolution. This vast West African desert country, whose 2.8 million inhabitants are strongly imprinted by Islamic culture, is still firmly rooted in customs and social values that the "late and superficial" French colonization was hardly able to disrupt (Balans, 1979).

Under these conditions, one can easily understand the slow evolution of information and communication technology in the country as it appears in the Report of the ICT Thematic Group of the Poverty Reduction Strategy Paper (Cadre Stratégique de Réduction de la Pauvreté, 2000).

As a matter of fact, it was not until 1974 that the first institutional incentive for development of computer technology appeared through the creation of a computer division at the Ministry of Finances responsible for the automated management of public spending. The first PCs appeared in the mid-eighties in some administrative departments, in particular the customs department through the SYDONIA project, designed to manage customs operations and the provision of certain statistical data (Cadre Stratégique de Réduction de la Pauvreté, 2000).

In 1990, the government founded the National Data Processing Commission, a body for strategic analysis entrusted with the broad mission of designing, implementing, and monitoring the national data processing policy. The Commission also aimed to computerize some administrative departments, such as Civil Service, the Central Bank of Mauritania, or the taxation authority (Cadre Stratégique de Réduction de la Pauvreté, 2000).

In general, computer use remained very scarce for a long time throughout the Mauritanian administration. In 1999, there were 446 micro-computers, seven mini-computers, and only 20 local networks of 10 machines, which correspond to a ratio of two computers for every 100 agents. Local software production is insignificant, with only two development platforms in the private sector (Cadre Stratégique de Réduction de la Pauvreté, 2000).

Concerning the Internet, main indicators as of May 31, 2000 show an average rate of use of approximately 0.16% when one compares the total number of e-mail accounts in Mauritania to the total number of inhabitants. This rate is 0.46% in Nouakchott, the capital city. The rate of Internet use by telephone subscribers is 20% on average and 28.9% in Nouakchott (Cadre Stratégique de Réduction de la Pauvreté, 2000).

In the field of telecommunications, it was only by the end of the 1970s that the telephone appeared in some regional capitals; as of May 2000, the urban telephone network has more than 20,000 lines (Cadre Stratégique de Réduction de la Pauvreté, 2000).

Thus, in the year 2000, the ICT sector was in its preliminary stages, marked by a lack of infrastructure, equipment, and human resources.

On the eve of the new millennium, the Mauritanian government was truly committed to mastering ICT, considering it an invaluable developmental tool for the integration of the country into the "communication arena" which constitutes the "information society" (Levy, 1997). The national strategy for the development of new technologies adopted in 2002 is attributable to a strong ambition to promote Mauritanian society and economy using ICT.

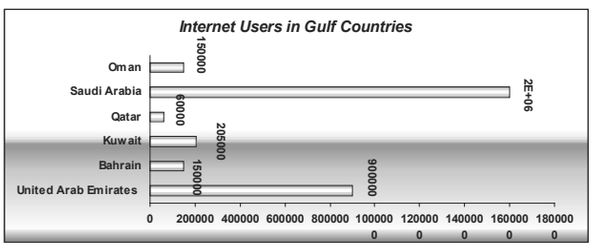
Being definitely in keeping with an e-government perspective, the strategy advocates, among other objectives, the use of information and communication technology by the administration in to improve services rendered to users in compliance with individual rights and freedoms.

As an Islamic republic, Mauritania has witnessed specific challenges to the development of new technologies. This study will examine the moral dilemma faced by Muslim countries regarding the evolution of ICT and e-government. Thus, the experiences of Mauritania will help to paint a broad picture of how these new technologies are being implemented throughout the Muslim world.

## THE INTRODUCTION OF ICT INTO THE ISLAMIC WORLD

Strangely enough, Islam, which is often depicted as obscurantist by a generally ill-informed opinion, did not at all challenge the new information and communication technology considered as a symbol of freedom, modernity, and progress. In other words, the emergence of ICT did not stimulate a debate in the Islamic world, even if

*Figure 1. Internet use in the Arabic Gulf countries (Source: Information Society in the State of Qatar, 2003, WSIS—Geneva 2003)*



historically "some sort of hesitation" was observable at first in this respect, particularly in the Arab Gulf countries. Hence, in Saudi Arabia, the government signed a memorandum of understanding in 1999 with a company for the installation of Smart Filter software, designed to prevent access to subversive sites or sites whose contents could conflict with principles Islam. In Kuwait, the department of information announced openly on its official Web site that censorship (on the Internet) was one of its prerogatives!

But in general, these hesitations have been more or less overcome, probably largely on account of the sustained infatuation of Muslim populations for the Internet, as illustrated by Figure 1.

Generally speaking, as reported by two studies sponsored by the Islamic Organization for Education, Sciences, and Culture (ISESCO); Muslim countries are actively engaged in promoting ICT, which is perceived as a factor of development (Bennani & Mrabet, 2003; N'Diaye, 2003). The ranking based on the digital access index of the International Telecommunications Union (ITU) shows that several Muslim countries are highly ranked as indicated by Table 1.

Today, it can be said that new information and communication technology is accepted in the Muslim world as supported by the declaration adopted by the Islamic Conference Organization (OCI) during its 10th Summit in Putrajaya (Malaysia, October 11-17, 2003) which states, "We acknowledge that in the knowledge based society in which we live today, Information and Communication Technology is a powerful and necessary tool of political, economic and social development …"

In reality, it could not be otherwise because Islam, to start with, is meant to be a religion of knowledge and science. Accordingly, the first verse of the Koran glorifies knowledge in the following words, "Read in the name of your Lord! He the creator; (…) who taught man what man did not know before" (Ould Bah, 2003).

*Table 1. 2003 ranking of countries according to ITU index (excerpts)*

| | Rank | Country | ITU Index |
|---|---|---|---|
| Excellent | 1 | Sweden | 0.85 |
| | 11 | United States | 0.78 |
| Good | 34 | United Arab Emirates | 0.64 |
| | 38 | Bahrain | 0.60 |
| | 46 | Malaysia | 0.57 |
| | 48 | Qatar | 0.55 |
| | 49 | Brunei Daressalam | 0.55 |
| | 60 | Kuwait | 0.51 |
| Medium | 70 | Turkey | 0.48 |
| | 82 | Saudi Arabia | 0.44 |
| | 87 | Iran (R.I.) | 0.43 |
| | 98 | Egypt | 0.40 |
| | 99 | Tunisia | 0.41 |
| | 118 | Morocco | 0.33 |
| Weak | 126 | Syria | 0.28 |
| | 129 | Pakistan | 0.24 |
| | 157 | Mauritania | 0.14 |
| | 158 | Senegal | 0.14 |
| | 163 | Côte d'Ivoire | 0.13 |
| | 178 | Niger | 0.04 |

However, one must refrain from considering the Muslim world as now totally and definitively in favor of ICT. In fact, Resolution # 4 of the OCI Summit states that "*rather than be an end per se*, the development, assimilation, and application of information and communication technology (ICT) in the member states are the main instruments targeting the achievement of global and sustainable development and ensuring access to the information society." The expression "*rather than be an end per se*" underlies a quite well thought-out reservation expressed by the Prime Minister of Malaysia, Muhammad Mahatir (2003) who said in an interview in December 2003 with the Journal *Choix*,

*the Internet does not only produce good information, but it also produces obscenities. There are those who think that they can decide for themselves whether they have moral values, but trying to instill good values in them is not the easiest thing in the world. We should try to find a means to filter obscenities. Presently, technology does not provide us with the ability to means of selectively screen access. But the time will come when software will help to eliminate obscene and morally subversive material.*

With respect to this matter, Muslim states feel a need to protect their societies against some of the material that can circulate freely on information networks, especially data that undermine order and morality. However, these

concerns are not specific to Muslim countries. Quite similar concerns led the U.S. Congress to adopt the Communication Decency Act in February 1996 designed to fight indecency on the Internet. But this Act, which was declared unconstitutional by the Federal Court of Philadelphia on account of the right to freedom of expression, was also criticized on rational grounds: Is it really possible to censor the Internet? These concerns, now obsolete in the West, led P. Nicoleau (1996) to recommend the creation of an international authority in charge of fighting immorality on the Internet!

In Mauritania, ICT must first be perceived in relation to the recurring debate on authenticity symbolized by Islamic values and the modernization that the country has experienced since independence. In this respect, and in an effort to provide a strong synthesis, the Preamble of the Constitution of July 20, 1991 states that the people of Mauritania desire to begin "creating the conditions for a harmonious social evolution that is *respectful of the principles of Islam, the only source of righteousness*, and that is open to *the requirements of the modern world* …" (Ould Bouboutt, 1994). In other words, Mauritania is clearly seeking to open up to the world, taking its place in the information society while remaining faithful to its Islamic ties!

Thus, the highest Mauritanian authorities consider the incorporation mastery of ICT as a requirement of globalization and encourage the public to use this technology. In this context, the creation of a department in charge of developing ICT as of September 2000, and assigned to a woman, was regarded as a pioneering (and audacious) initiative in the Muslim world, and is attributable to a deliberate choice in favor of modernity.

Additionally, and like other Muslim countries, the Mauritanian authorities have not eluded the difficulties likely to emerge because of inappropriate use of ICT, especially consequences deriving from such use with regard to the (vulnerable) Mauritanian social fabric. The national strategy for the development of new technologies clearly foresees these concerns "as Mauritania believes that *if new technologies are adapted to the context of the country*, they can contribute significantly to reducing poverty and underdevelopment."

This is why the Secretary of State for New Technology truly involved religious scholars in the design, validation, and implementation process of the national strategy for the development of new technologies. Religious scholars became involved in the governance process of ICT "in order to support its good use … and assess any issue addressing ICT. The government will create a framework for a national debate on ICT (including religious scholars, civil-servants, experts, economic operators, and associations) …"

For those who drafted the strategy, there is a need to "communicate to the general public the legal and *ethical* principles as well as the technical choices based on which the government plans to lead the society as a whole on how to use ICT properly." In this context, appealing to religious scholars was necessary for two reasons: obtaining the support of the people because the participation of the religious scholars is per se a guarantee of authenticity for the population; and reassuring religious authorities in general about the scope of the strategy in regards to religious principles.

## E-GOVERNMENT IN MAURITANIA

Administration cannot be cut off from its environment. The introduction of new technologies in the Mauritanian administration remains largely dependent upon the general situation of these technologies in the country. To this effect, a general trend for reform was experienced by Mauritania in ICT development as part of the Sector Policy Declaration for Postal Services and Telecommunications (1998), which liberalizes the sector, and especially the Poverty Reduction Strategy Paper (2000), which advocates an extensive use of ICT as a factor of development and economic growth.

As part of this framework, the first mobile phone licenses were awarded by the Regulation Agency, an independent administrative authority founded in 1999.

In order to facilitate access to ICT, computer hardware and equipment were exempted from all duties and taxes in 2000, and the Agency for the Promotion of Universal Access to Services was founded in 2002.

Accordingly, the creation of the Secretary of State for New Technology (SSNT) in 2000 marked an important turning point. This department reporting to the Prime Minister—an indication of its importance—has "a broad mission of promoting the use of computers and associated technology by the *administration*, the private sector, and civil society."

The National Strategy for the Development of New Technologies was approved in 2002. This public policy, which was designed by the SSNT as part of a participatory process in collaboration with the targeted administration, the private sector and the civil society; is a global strategy aimed at helping Mauritania become a member of the information society. It is based on eight main axes including the development of infrastructures, the valorization of human resources, the modernization of the state thanks to digital tools, the adaptation of the legal framework, the promotion of ICT in the private sector, and the visibility of Mauritania on the World Wide Web.

The implementation of the strategy had an unquestionably positive impact on the sector of ICT in Mauritania. The ratio increased from 0.5 phones per 100 inhabitants

*Figure 2. Use of technological material in the administration (Rapports de l'OTIM 2003, 2004 et du CSRP—Groupe thématique NTIC, Mai 2000)*

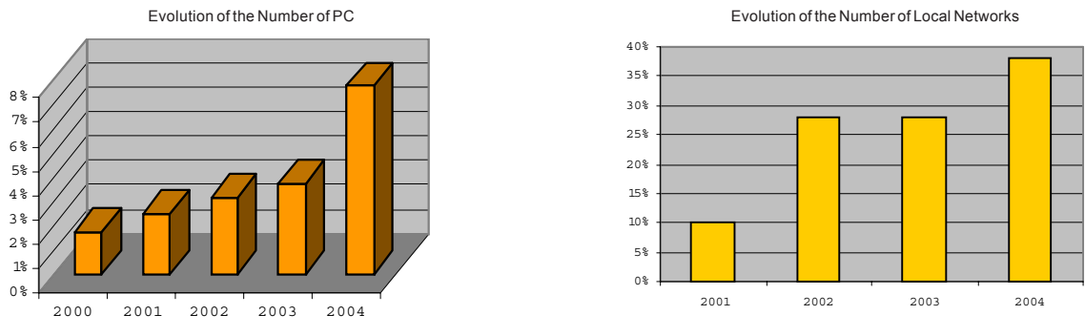


*Figure 3. Evolution of Internet use by the administration (Rapports de l'OTIM 2003, 2004 et du CSRP—Groupe thématique NTIC, Mai 2000)*

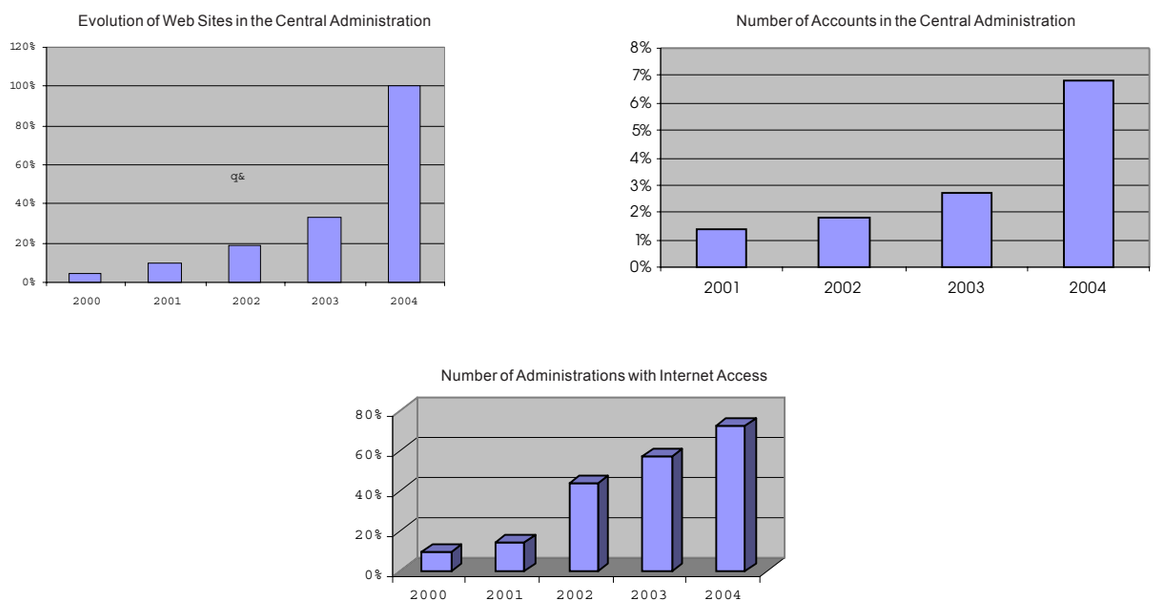


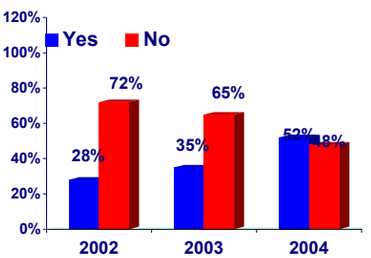
in 1998 to more than 20 as of December 2003; the Internet access bandwidth increased from 256 Kbps in 2000 to 45 Mbps in 2004, and a significant increase in the use of the Internet and associated technology developed in the administration, the private sector and civil society.

With respect to the administration, the third priority axis of this strategy (modernization of the administration through the use of digital tools) assigns a key role to e-government, which is a system of government involving a wider scale use of information and communication technology in the work of the administration and its relation with the public.

In this regard, the strategy shows that "the insufficient level of introduction of computers and new technologies into the administration might penalize the effort to modernize this administration." Based on this acknowledgment, the strategy provides for "increasing the role of computers and associated technologies at all levels of the administration and *ensuring the development of an online public service,*" which marks an indirect but definite reference to e-government.

The implementation of the measures pertaining to the third axis of the strategy started in 2002; Figures 2, 3, and 4 show the evolution of the main indicators on this issue.

*Figure 4. Proportion of administrations using databases (Rapports de l'OTIM 2003, 2004)*



Thanks to the National Program for Good Governance (Pouillaudes, 1999) and to its component, the Civil Service Modernization Program, the government adopted the Administration Computerization Scheme in May 2004. This computerization scheme aims at achieving a *first stage of e-governance* for the central and local administration in early 2006; it is based on four objectives constituting the *pillars of the modernization of the Mauritanian administration*:

- Development of infrastructures and equipment
- Development of Web based contents
- Development of human resources
- Adaptation of the legal and institutional framework

With respect to *infrastructures and equipment*, the scheme provides for the acquisition of technical means (support and transportation) to help service and public agents communicate with each other, with the outside and with the users in particular to modernize administrative work and automate certain procedures based on a secure intranet and access to the Internet using a bandwidth of 50 Mbps at least (fiber-optic equipment, VSAT and BLR for the territorial administration).

Additionally, the scheme aims to set up a local area network (LAN) for each administration, providing every service therein with at least one computer, and a package of software and standard applications. To this effect, the computing needs of the administration were identified and assessed, mainly through computer technology development plans designed for several departments.

Several important steps to achieving these goals have already been or will soon be undertaken, such as the first phase of a high-speed administrative intranet scheduled for commissioning in December 2004. Other projects scheduled for 2005 include implementing an administrative data center for the management of infrastructures, providing intranet and Internet access to the administration, networking the departments, and upgrading the administration's Internet bandwidth from 1 to 2 Mbps.

Actions relating to *Web-based content* are at the center of the e-government process through the design of a full system of information for the administration, including the creation of Web sites and online public service indexes, several of which were or are about to be designed at the departmental level.

Additionally, a contract signed with Microsoft (2003) tentatively provides for the online hosting of two public services in 2005. The following full involvement of the Mauritanian people in the process is expected, their show of interest in online the publication of the electoral lists since 2001 and in the computerization of the civil registry service, both intended to guarantee transparency in the presidential and legislative elections.

At present, the SSNT has already implemented a telemedicine project aimed at putting ICT at the service of the health sector to promote better patient care and personnel training through national and international interconnection of Mauritanian hospitals. Similarly, another project contributed to the creation of Internet centers in secondary schools.

With respect to *adaptation to the legal framework*, a bill drafted by the SSNT attempts to define the conditions for the creation and use of computer systems and public internet sites.

This bill, which will constitute the charter of e-government in Mauritania considers that ICT "*must contribute to improving administrative work and facilitating contacts between the administration and the public.*" Referring to the policy of modernizing civil service, the bill states "the need to improve information and services rendered to the public and the need to increase the efficiency of the administration."

Article 2 of this bill identifies the responsibilities of each administration in matters of e-government. These responsibilities specifically consist of:

- Improving the management of computer hardware and other associated technological equipment
- Specifying the types of information to be disseminated and the types of services to be developed on the Internet
- Organizing the digitalization and the dissemination of data
- Ensuring compliance to regulations related to the security of information systems, the protection of personal data and recognition of intellectual property rights

The plan also provides for an online official journal because "in order to be usable, legal information must be

known and published and, as a matter of fact, new technologies provide unequalled possibilities for the dissemination of legal information" (Coutrot, 2004).

These various initiatives will be supported by an original and efficient *training* policy in ICT. This policy, which is already engaged mainly through the national program for the training of public decision makers (ministers and members of parliament), was followed up in 2004 through a vast training program for civil servants and government agents in ICT for the benefit of advisers, directors and heads of services of the central administration. Therefore, about one fourth of the administrative personnel were trained in the use of office automation and the Internet. This effort will be completed by a plan to retrain the technical personnel of the administration in ICT (at least two computer specialists per department) through training workshops and seminars for the benefit of technicians, engineers and network administrators and, of course, through distance learning techniques.

Finally, in order to reinforce this mechanism, diverse supporting measures are planned. These measures deal in particular with reducing the costs of and promoting universal access to ICT through the development of infrastructures, with a vast movement for the dissemination of ICT among people who are the ultimate target of e-government.

## CONCLUSION

The governments of Muslim countries, like other countries in the world, cannot and do not want to remain cut off from the digital revolution, even if the impact of ICT varies according to the wealth and rigor of the system of social value in each country.

In Mauritania, supporting ICT and, in particular, e-government is clearly a priority for the state as important steps were made, *in a short period of time*, to introduce as part of clearly stated public policies a digital *component* to administrative procedures and work. This is indeed a successful evolution, and in view of recent favorable oil prospects, Mauritania will now have the means to set up an e-government, which appears today an urgent necessity.

## KEY TERMS

**BLR (Boucle Locale Radio: Radio Local Loop):** Telecommunication network system helping to link telephone (or Internet) subscribers using a hertz radio link instead of copper wires.

**E-Government:** Institutional system in which the administration uses information and communication technology to manage its relations with its public, to improve public services and to reinforce public policies.

**Intranet:** Computer network designed for the exclusive use of an institution and using the same protocols and techniques as the Internet (TCP-IP).

**Online Public Services:** Services (information, provision of services) provided by the administration to users from an Internet site.

**Retraining:** Training operation aiming at providing the technical staff of the administration, in lieu of its initial training, with training in ICT so that it can carry out administrative tasks pertaining to the domain of ICT.

**VSAT (Very Small Aperture Terminal Satellite):** Satellite communication system which receives information transmitted from a geostationary satellite toward which a central earth station is pointed.

## INTRODUCTION

The present fourth period, the network period, is characterised by a convergence of three main technologies (computer technology, telecommunication technology, and media technology) into information and communication technology (ICT). ICT are embedded in many things and the invisible microcomputerisation that once took off with the chips is enhanced through nanotechnology, biotechnology, and wireless technology—often entitled ubiquitous computing. The author presents ongoing changes in work life and presents a rtheoretical model: The convergence theory on ICT and psychosocial life environment. The convergence model reflects some main ongoing processes in the network society encompassing various spheres of life (professional, private, and public). Sociological theories on the Information Society are discussed in this context as well as theories from the information systems (IS) community. In the Future Trends section the new international collaboration is addressed where research and policy (including politics) develop goals and strategies to deal with societal and psychosocial changes related to the development, introduction, and use of ICT.

## BACKGROUND

The area, Information and Communication Technology and its interaction with social changes on organisational, individual, and societal levels, has in the 2000s received growing attention, due to the depth and wide use of it. This article is mainly based on my latest two books. The first one, *Humans on the Net: ICT, Work Organization, and Human Beings* (Bradley, 2001) was presented at the first European Union (EU) conference, *Work Life 2000*, during the half year when Sweden chaired EU. The second book, *Social and Community Informatics: Humans on the Net* (Bradley, 2006), summarises and updates the authors research over 30 years. It will hopefully serve as a source for people to better understand and contribute answers to questions such as: How will people live, learn, and work in the future ICT society? In short, key issues within the organisational change/psychosocial life environment, and their interaction with the use of information and communication technology are analysed.

Some sections were presented at the *World IT Forum* (WITFOR 2003) in Vilnius in August 2003 addressing "Social and Ethical Aspects of the Information Society" and at the conference, "E-society" in Avila, Spain in 2004.

Empirical experiences show that it is important to keep a balance between pure technical research and development in software and hardware technologies, new fields such as nanotechnology and the behavioural and social science disciplines, for example, psychology, sociology, cultural anthropology, and ethnography.

The ICT-related disciplines have so far been focused too much on the "technology push" instead of on human needs and requirements in the development, introduction, and use of ICT. New universities, sometimes called IT universities, are appearing in many European countries trying to bring together disciplines from the traditional university and disciplines from the technical university to facilitate a necessary rethinking and reorientation of research and development (R&D), sometimes resulting in new centres directly entitled "Humans in the ICT Society" focusing on the human, organisational, and societal aspects of ICT use.

## THE NETWORK ERA: CONTINUOUS AND ACCELERATED CHANGES IN THE DESIGN OF ORGANISATION, WORK TASKS, AND MANAGEMENT

The main changes during the network period are summarised in the next five sections and are mainly based on Bradley (2001) and further developed in Bradley (2006). They are primarily derived from our research in the developed countries.

### Accelerated Changes at Work in the Net Era

More flexible work processes have appeared regarding both the professional role itself and leadership. Further, the professional role, the learning role, and the role of citizen are becoming more and more integrated. Repetitive

jobs and physically strenuous jobs, including routine work, are disappearing and a total upgrading of qualifications has occurred. In parallel with this, the organisation has become flattened out. In an international perspective more work tasks are becoming similar because software programs are sold world-wide and the work tasks are carried out in a more and more similar way.

Organisational structures as networks have become more and more common. Psychosocial and organisational aspects of networking have come into focus in recent research.

## Network Organisations are Like Crocheted Table Cloths

- A crocheted lace cloth is a good model for the developing and future structure of how the world—social systems, organisations, and official authorities—will look. The network era has been established and networks interact more and more wirelessly. It is possible to crochet all the time: each new loop (computer) is connected to another loop through the same yarn (tele-technology).
- Power can both be centralised and decentralised in the network structures, but the process is invisible.
- The distribution of power is now possible in quite a deep sense as competence transfers to the periphery, out to the production level.
- The hierarchical structures of companies that mirrored industrialisation and industrial technology during the mainframe period of the computerisation era are fading away.

The present trend toward the flattening of hierarchies can, according to Aulin's law of requisite hierarchy, be explained by the increasing regulatory abilities of individuals and organisations, due to such factors as better education, management, and technological support (Heylighen & Joslyn, 2001). Another way to express this is that hierarchical regulation and hierarchical organisations are built into information systems and ICT.

## Network Organisations: New Communication Patterns

Some examples of what characteristics the network organisations have and how people are affected are:

- direct communication between the various levels of the organisation
- barriers between idea and execution are disappearing
- reallocation of power in the organisation
- continuous changes of structure and roles
- openness to the surrounding world
- multidimensional virtual culture

## Decreasing Core Workforce in the Flexible Company

At the centre there is a core workforce of permanent full-time employees who enjoy a wide range of employment rights and benefits; however, the core workforce is decreasing. The other growing part is the peripheral workforce. It consists of part-time staff, self-employed consultants, subcontracted and outsourced workers, and temporary and agency employees. Some of these "knowledge workers" are key resources, while others are exchangeable. Through the network organisational structure they might have very strong positions in the company because of their expertise or social contacts, although this is unseen. Power is invisible in these new forms of organisations: power has no outward manifestation and is not reflected to the same extent as before in properties and gadgets linked to leadership.

Hence more and more organic organisational structures are developing, with a focus on flexible work processes, including dynamic networks for capital and human resources (compare the network organisations above). Economic systems are being created where the present boundaries are increasingly becoming eroded. Advanced ICT support is used for various forms of collaboration. More and more individuals function as self-governing company units.

## Reflections

There are both positive and negative impacts on the individual. One critical point is that too much responsibility is put on the individual who:

- loses permanent employment
- has to manage his/her own competence development
- has to market himself/herself
- is expected to take on any position and swallow job enlargement
- is expected to be creative – with little compensation
- is a unit in a competitive world market

One might ask if this means the freedom from paid work in a traditional sense. Other questions are: Should our school system prepare for fostering free agents or portfolio individuals? Should school and learning prepare young

people for acting proactively in meeting the ongoing unhealthy development? From an ethical point of view individual responsibility is "a word of honour". People need a basic security as (employees) citizens. Regarding the role as workers and citizens, there is a need for balance between a strong society and strong individuals. Few persons are strong throughout life. The importance of thinking in terms of sustainability both regarding environment and sustainable human beings is becoming clear.

### The Home Becomes a Communication Sphere

The big challenge in the near future is the home in a broad sense, as many human roles are converging to one life role, and the home is more and more understood in terms of virtual space as well as physical. Driving forces are converging embedded technologies. The following trends are enforcing the home as a communication sphere, where the home could be regarded as an extended family centre, a care centre, a multimedia centre, a centre for democratic dialogue, a marketplace, a learning centre, and an entertainment centre.

### The Occurrence of an Accelerated Tempo

Research shows that there are reasons to talk about ICT stress or Internet stress. Certain ICT stress is related to the fact that there is an increased dependency on computers and networks and an increased expectancy that these technologies are functioning well. Stress phenomena in the Internet world are information overload, contact overload, demands for availability, lack of organisational filters, and difficulty of separating noise from essentials, changing level of expectations, and an altered perception of time and space in general.

## THEORIES ON ICT AND ORGANISATIONAL AND SOCIETAL CHANGE

Theoretical models on "Computer Technology and Changes and Work Life" were developed by the author (Bradley, 1977, 1986/1989) and were empirically tested in three large work organisations in Sweden, representing three main historical periods of computer technology (from mainframe computers to microcomputerisation). The psychosocial work environment was considered in terms of the following perspectives: three levels of analyses (individual, organisational, and societal), objective and subjective work environments, interplay between the levels of analysis, interplay between objective and subjective work environments, interplay between working life and private life, and a life-cycle perspective.

The roots are in social psychology and organisational theories the way these disciplines were interpreted in the Nordic countries at the time. A main perspective is that the environment/structure on various levels is affecting the individual, but she/he can also impact the society on these levels. The concepts of the model include structural factors, our perception of these, and intervening variables that explain reactions but also have to be focused at the use and introduction of ICT.

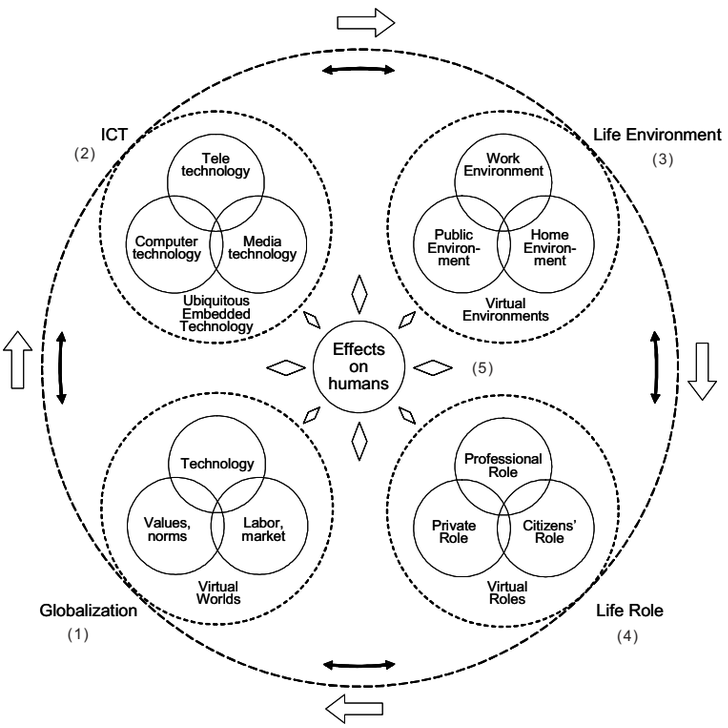
Psychological variables were used as general terms covering a number of intermediate, psychologically relevant variables such as the level of aspiration, weight attached to specific work-environment areas. *Psychosocial environment* referred to the process involving the interaction between the objective environment and the subjective one and, essential concepts within the psychosocial work environment included factors such as contact patterns and communication, organisational structure and design, work content and workload, participation in decision making, promotional and development patterns, salary conditions and working hours. Theories, methods, and results from the RAM programme were summarised in "Computers and the Psychosocial Work Environment" (Bradley, 1989) and appear also in "Social and Community Informatics" (Bradley, 20066), since the measures and tools are still relevant for studies of the social and organisational impact of ICT, but now are applicable in the broad life environment.

The present network period is based strongly on the convergence and integration of three main technologies: computer technology, tele-technology, and media technology. The convergence process (see Figure 1) is enforced all the time by smaller, cheaper, and more powerful components. ICT is more and more being used in almost every activity and embedded in more and more places (ubiquitous computing). Converging circles are reflecting graphically the ongoing process.

Both convergence and interactions are important features in the model. Convergence here means a move towards a common content. Interaction means that technology interacts with the social world with values and beliefs. There is also an ongoing interaction between the "clusters of circles".

The convergence model on "ICT and the Psychosocial Life Environment" is a graphical illustration of ongoing changes in the Net Society. It is presented in detail in Bradley (2006). Some comments concerning the model in Figure 1 will follow, and the description of structures with reference to concepts (1-5) in the outer circle in the figure.

*Figure 1. Convergence model on ICT and psychosocial life environment (Bradley, 2005, in press)*



1. **Globalisation*:*** A convergence is occurring between technology, economy, norms/values, and labour market and is entitled globalisation. The geographical span is changing. At present our work life is mainly based on national and international trade which will be more and more without limits in the future and will take global forms. Electronic commerce and electronic marketplaces are creating a strong change factor behind the structure of work life. The geographical space in the future is both global and beyond—including virtual reality (VR).
2. **ICT:** A convergence of computer technology, telecommunication technology, and media technology is occurring to become what is entitled ICT. Knowledge is managed in new ways. In the 2000s there are multiple channels to choose from: word of mouth, writing, audio visual, and electronic. In the future metachannels, for example, metamedia of VR and controlled reality environments (environments that are manipulated and managed in VR) will become more frequent. In the latest wars it has sometimes been unclear what could be "manipulated reality".
3. **Life Environment:** A convergence of work environment, home environment, and public environment are converging to a life environment, where the public issues tend to merge into our homes. A new emphasis on certain dimensions in the psychosocial environment occurs. New dimensions are appearing in the psychosocial environment. Openness for unforeseen implications is required.
4. **Life Role:** Professional role (work life) and private role (private life) and citizen's role (public life) converge to become a Life Role. Role and role formation are central concepts in social psychology and represents a level between structures and the individual. The concept "role" is a system of social norms that is directed to an individual as a member of a group or as belonging to a limited category of people. The concept "role" appears where psychology and sociology meet. It is also important that individuals can influence and form their roles.
5. **Effects on Humans:** Effects on the individual become more multifaceted and complex. This is valid both regarding the psychological and the physical effects on the individual. The way humans handle their situation can roughly be categorised as active or passive reactions. In the Figure 1 this is represented by the circle in the middle, "effects on humans", with two-way arrows around as a flower showing an interaction. In consequence, the individual is affected by ICT, the Life Environment with its three subenvironments, the Life Role with its

three subroles, and globalisation with its three components of values, technology, and labour market. But as an individual, that person can also influence the technology, the environment, and his/her own role and phenomena on the organisational and societal level, and the new virtual reality (see the following).

Four circles representing VR are marked with dotted lines and surround the four clusters of converging circles. These circles reflect our participation in cyberspace on various levels. In the lower left part in Figure 1, Virtual worlds is a concept that refers to the global level. Within the concept of ICT, the step taken by applied embedded and ubiquitous technology make the technology more hidden for the individual and in the society as a whole. Virtual environments in the upper right part of Figure 1 is already a common concept. Finally, virtual human roles are appearing, which in a more extreme form could be another personality that people play, for example, avatars.

The thin double-directed arrows represent interaction, and the broader one-directed arrows represent the main direction for the movement and the process described in the circle model. Transferred to actions people can, in the professional role, private role, and citizen's role influence our life environment on various levels of analyses (see also Future Trends section).

How do the convergence theory on ICT and the psychosocial life environment relate to other theories on the information society? What do other theories conclude about the information and communication society (ICTS)?

Frank Webster (1995), in *Theories of the Information Society*, provides a point of departure of an interrogative and sceptical view of the concept of an information society (IS). His approach is to start from contemporary social theories instead of social impact approaches. The following are categorised as pro-IS theories: post-industrialism, postmodernism, flexible specialisation, and the information mode of development. The following are against IS theories: neo-Marxism, regulation theory, flexible accumulation, the nation state and violence, and the public sphere. Webster brings forward five definitions of IS which represent criteria for the new society, by its own or combined: technological, economical, occupational, spatial, and cultural. References to some main theories are given in the following: Anthony Giddens (1990, 2000), Herbert Schiller (1993), Jurgen Habermas (1989).

Webster raises the question whether what dominates now is a break or continuity and his conclusion is that there are still features of a capitalist continuity, but also a shift in orientation with some novel form of work organisation and some change in occupational pattern. But there is no system break witnessed so far (Webster, 1995). However a group of theorists categorised as postmodernists (Barthes, Baudrillard, Vattimo, & Lyotard) point out that the information society contains a quite new type of society—a paradigm shift. Jensen (1999) has identified four various directions that for him seems to be plausible for the future: the dream society; the green society; a world of conflict; a world with no changes. He argues that the dream society encompasses the end of human kind's multi-millennium epoch of material domination and the beginning of the first postmaterialistic era. This is very much in contrast with the view that for a long time people will fight towards the so called digital divide.

The most quoted research during the latest years has been Castells' book on the Network Society. In his latest book (Castells, 2001), he analyses the digital divide from a global perspective.

From the convergence theory (Figure 1) and associated empirical research together with the sociological theories mentioned above on ICT and societal change, the conclusion can be made that up to the beginning of year 2000 there is a continuity as well as new paradigm shift. In other words there are opportunities to influence the direction that will dominate in the future. The question is rather if people are able and willing to engage themselves on various levels of actions.

Theories in the field of this article come from many academic disciplines, academic communities, and cultures which have different perspectives and focus. What are the contributions from the IS community? For many years the focus was in development and design of information systems, and later on, the introduction and use of information systems. The tele-technology and media technology parts of the concept ICT were not addressed for many years. Some contributions after 2000 are as follows.

Melville, Kraemer, and Gurbaxani (2004) have developed a model of IT business value and thereby chose the resource-based view of the firm, which is often used in management literature and international business. They applied the integrative model to synthesise research about IT business value and developed propositions for future research in the field. The principal finding from their analysis was that IT is valuable, but the extent and dimensions are dependent on internal and external factors, including complementary organisational resources of the firm and its trading partners, as well as the competitive and macroenvironment.

Their conceptual model is comprehensive and shows the complexity of the field. It is integrative but is not interactive in the sense that interactions between theoretical levels of analysis are discussed. The following main concepts are of IT resources, technological IT resources, human IT resources, and complementary organisational resources. The other concepts are business processes and performance with focus on competitive environment: industry characteristics, trading part-

ner resources, and business processes. Within a macroenvironment are country characteristics and similar concepts.

Schulze and Orlikowski (2001) have explored the discourse on virtual organising and identified a number of metaphors which characterise various aspects of vitality. They examined the various metaphors in the practitioner-directed literature on virtual organising and concluded that the discourse contained a multiplicity of different metaphors. The identified metaphors were virtual organising as a platform, as existing in space, as composed of bits, as operating as a community, and as engaging in a network of relationships. They suggest that due to the absence of experiences to guide practice, these images are shaping people's views of and actions towards virtual organising. They then analysed these metaphors with regard to aspects of organising, meaning, source, examples, affordance, and challenge. From the conclusion that metaphors are powerful tools of social constructions, they mean that researchers and practitioners should be aware of the critical implications and of unintended consequences.

Another strand of research in the IS literature is user acceptance theory (Davis, Bagozzi & Warshaw, 1989). Van der Heijden (2004) discusses the differences in user acceptance models for productivity-oriented and pleasure-oriented information systems, hence emphasising various values.

In response to the criticism of IS research different types of approaches have been applied, for example, grounded theory, use of the discipline ethnography, structuration theory, and activity theory to study the design, development, and use of ICT.

Networks of various ICT related academic schools sharing some common perspective form world-wide networks, for example, Network for Value Sensitive Design, Community Informatics Research (CIRN), The International Conference on the Social and Ethical Impacts of Information and Communication Technologies (ETHICOMP).

In summary, critical research has been more common outside the IS community, but this is changing. Walsham (2005) argues the need for IS research which is critical and aimed at making a better world with technology. He draws implications for actions in terms of research agenda, teaching activities, publishing, and institution building. A better world with ICT should not mean better in purely economic terms, but also related social and spiritual welfare globally. A critical approach is, according to Walsham, a perspective that includes, for example, the social construction of "truth", historical and cultural contingency, and power relations. He concludes that global futures in general, and the IS field in particular, are not predetermined, but result from our own efforts and actions.

## FUTURE TRENDS

People are living in a society deeply and broadly affected by the new technology. It might be harder to identify both risks and opportunities at present and for the future. A new generation exists, which has grown up in the digital environment. There are reasons today to go back to classics in research; for example, there are no more work environments in the traditional sense – they are dissolving, although phenomena identified in research in working life, in which the Nordic Countries were very active for many years, have to be reviewed with a new perspective. How are the human needs of influence, belonging, and meaning met in the new structures and communication patterns?

Regarding "Effects on Humans" (compare Figure 1), important questions for the future are: how is ICT changing our identity and self-perception, social competence, creativity, integrity, trust, dependency, balance between emotional and rational components, balance between female and male, and involvement and alienation?

One way to summarise the discussion on the ICT society and the individual is to address psychosocial processes. These could be formulated as research questions or policy statements. By now there are reasons to start up normative research which later on could be discussed across wider cultures. It concerns the classic question if research is value-free, which at an early stage was challenged by many scholars and with strong arguments.

- Normatively, ICT should contribute to enrichment in the social contact between people and should be used to prevent social isolation and facilitate integration.
- ICT should contribute to a greater autonomy for the individual and prevent stress reactions. Control or freedom is a classic issue often described in the terms of "privacy, integrity".
- ICT should facilitate information access for all and support individual learning, but at the same time prohibit various kinds of overload, for example, information overload and contact overload.
- ICT should contribute to the deepened development of true human qualities and be used to provide time for people to develop themselves as human beings.
- ICT should contribute to both environmental sustainability and human sustainability.

- E-conflicts must be avoided. E-cooperation and peace is a major goal.

In the Vilnius Declaration at the *World IT Forum,* the major goals are seen as:

- *Bridging* the digital divide between rich and poor in the world, urban and rural societies, men and women, and different generations
- *Ensuring* the freedom of expression enshrined in Article 19 of The Universal Declaration of Human Rights and other such instruments
- *Reducing* poverty through the use of education and ICT
- *Facilitating* the social integration of excluded segments of societies
- *Respecting* linguistic and cultural diversity
- *Fostering* the creation of public domains with full respect of intellectual property rights
- *Supporting* communities in fighting illiteracy
- *Encouraging* e-governance and e-democracy initiatives
- *Improving* the quality of life through effective health service systems
- *Protecting* the local and global environment for future generations

There are academic discourses on most of the concepts embedded in the main goals above, for example, digital divide, sustainability, integration, quality of life, and e-democracy. Theories and empirical research in the field have to be balanced with action-oriented, value-oriented research.

WSIS (World Summit on the Information Society) is an opportunity for a wide range of actors to develop principles and prioritize actions that would lead to democratic, inclusive, participatory, and development-oriented ICT societies at the local, national, and international levels. Meetings will continue.

## CONCLUSION

With distributed computer power, strong telecommunication (for example, the Internet) and mobile equipment, there is an inherent opportunity for deepening democracy and strengthening individuals and their influence on society. However, there is also an increasing risk of enforcing centralisation and misuse of power. Issues on organisational design and management—especially classics in participation design—are now important areas for R&D, and are valid not solely for the working life and professional role. The organisation and management of our role as private persons and as citizens are becoming crucial.

Within disciplines such as Informatics a discussion of focus in research and development is taking place. Both analysis and design need to address not only the work process and management connected to the sphere of production life, but also people's life environment and the psychosocial life environment. Not only professional roles, but also our roles as citizens and private persons are going through a deep change. Community research in a broad sense comes to the fore, with respect to both physical and virtual communities. Analysis and design of ICT and societal systems at the local level and globally become important. There is also a need for new and additional actors at the deeper and broader integration of ICT in the society (children, elderly, and consumer organisations). Educational programs on community informatics and social informatics are appearing in many academic institutions.

Many academic communities are addressing the complex issue of "ICT and Work Organisation and Society", for example, ODAM within IEA (Organisational Design and Management), ETHICOM, CIRN, CSCW society, and subtracks within HCII (Human Computer Interaction International), and Working Groups within IFIP (International Federation of Information Processing). ECIS (European Conference on Information Systems) and the correspondent international ICIS (International Conference on Information Systems) are becoming more open to these issues during the latest years. Research becomes easily fragmented and hard to overview. However, new journals are appearing with a broad cross-disciplinary perspective. New centres are established, and widening definitions of disciplines are occurring in parallel with a harder specialisation, especially within electronics and hardware. Hopefully this article will serve as opening the door to a field of research with accelerated speed of change and complexity. There is a need for a much stronger support internationally for cross-discipinary, cross-cultural, and action-oriented research on the topic, "ICT for Deepening of Humane and Societal Qualities".

## KEY TERMS

**E-Society:** A coherent term referring to a society where information and communication technology deeply and broadly have penetrated and become integrated in the society and its substructures, for example, workplaces, homes, authorities, communities with use of the present terminology, which in the next step could be changed. The prefix "E" refers to electronic communication and/or electronics. Other similar terms used are ICT society, digital society, information society, and computer society. Electronic society or e-society can involve societies that use electronic communications technology over a broad spectrum, for example, the Internet, extranet, e-mail, e-books, databases, and mobile phones.

**Convergence:** Convergence here means a move towards a common content.

**Net, The:** *Net* may mean fibers woven in a grid-like structure, as in fishing net or crocheted cloth. It most often refers to the network (see Network) or Internet (see Internet). In this article it mainly refers to a virtual place where digital information is transmitted and stored and where digital communication has taken place. The term is used for the hardware, software, and structure.

**Network Organisation:** A computer network is a system for communication between computers. These networks may be fixed (cable, permanent) or temporary via, for example, modem. To network is to interact socially for the purpose of getting connections or personal advancement. Many people network for jobs and information. To get a job in the present economy, it is important to have a strong network. The Internet is the largest of the existing networks. The term network has been transferred to organisational theory and refers to organisations characterised in this article.

**Psychosocial:** Psychosocial environment refers to the process involving the interaction between the objective environment and the subjective one. Essential concepts within the psychosocial work environment include factors such as contact patterns and communication, organisational structure and design, work content and workload, participation in decision making, promotional and development patterns, salary conditions, and working hours.

**Role:** The position, task, or function a person has in a certain context and the norms and expectancies which are associated with this position or task. Every person has a set of roles which is played in various contexts, for example, professional role, private role, citizen's role.

When various roles are hard to combine, a role conflict appears.

**Software:** Computer software (or simply software) is that part of a computer system that consists of encoded information as opposed to the physical computer equipment (hardware) which is used to store and process this information. The term is roughly synonymous with computer program but is more generic in scope. Software has historically been considered an intermediary between electronic hardware and data. As computational science becomes increasingly complex, the distinction between software and data becomes less precise. Software may at present be considered an interface between hardware, data, or software.

**Stress:** Medically speaking, stress is a combination of adjustment measures that is the organisms' reaction to frustrations and other sources of irritation in its surroundings. Stress in everyday speech normally refers to the harmful reactions, even if stress also can be a positive reaction. Stress often refers to the concepts of over-stimulation and under-stimulation. Stress occurs when an individual sees a situation as threatening and cannot reduce his/her frustration by means of socially acceptable and generally appropriate behaviour.

**Work Organisation:** Refers to the structure of a working place and includes the methods used to allocate work, the basis for decision making and organisational aids. Work organisation is also a part of the social and psychosocial work environment.

# ICTs and Governance in Africa

**Wole Michael Olatokun**
*Africa Regional Centre for Information Sciences (ARCIS), Nigeria*

## INTRODUCTION

Information and communication technologies (ICTs) comprise a range of technology products and activities that enable the recording, storage, processing and retrieval, transmission, and reception of information. These products include computers, basic telecommunications services, e-mail, satellite communications, microelectronics, and the Internet. Arguably, these products and activities have found pervasive "functional inclusion" in virtually all sectors of any economy. Their use can help improve the quality of life for citizens, especially in the health, education environment, and agriculture sectors (Mansell & Wehn, 1998). IDEA (2000) asserts that ICTs and the phenomenal growth of the Internet also create new opportunities and challenges for the process of widening and deepening the process of good governance. For example, electronic communications through the use of ICTs offers the potential for greatly enhancing the transparency, efficiency and ease for sustainability of good democratic governance (IDEA, 2000).

It is apparent that though ICTs have emerged as the major engine of economic growth and international competitiveness in certain developing countries (mostly in Southeast Asia) and some of the larger developed economies, applications and developments of these technologies, however, are still at a minimal level, starting to make very small beginnings in African countries. Although there are some noticeable applications of ICTs to governance in some African countries, most of the countries are yet to grasp the underlying dynamics of ICT contribution to economic development. Of particular concern are those countries that lack the technology capacity and legal policy frameworks. The implications and importance of ICTs in different countries, thus, vary considerably in complexity, and this can be argued to be a function of the national level of technological capabilities (NLTC) available, as well as the governance regimes to guide and coordinate the efficient use of ICTs (Oyeyinka, 1997). Many of the less-developing countries (LDCs), especially in Africa, were by-passed in the earlier technological development train … largely as a result of the historical antecedent of lack of assets and technological capabilities and good governance. Rather than being further left behind, these countries have started to appreciate the fact that ICTs can present opportunities to allow them join in the new economic order, and help reduce some of the technological gap between the developed and less-developed economies (Dzidonu, 2001). Much research would seem to have gone into understanding the component of NLTC with very little done on the governance component. This article attempts to consider the application of ICTs in governance in Africa.

.

### Defining Governance

Governance is sometimes viewed as the process by which a constituted government practically exercises its statutory power and authority towards achieving its set goals for society. Such perception, however, tends to minimize the importance of the role that the citizenry, as the governed, must be allowed to play in setting the dynamics and direction of governance. Accordingly, a more inclusive notion of governance is that it is the process by which people in a community govern themselves towards achieving the goal that they mutually set for themselves. This notion was aptly expressed by the Deputy Secretary-General of the United Nations, Louise Frechette, who said that governance is "the process through which institutions, businesses, and citizens' groups articulate their interests, exercise their rights and obligations and mediate their differences" (UNECA, 1999, p. 1).

According to Tiamiyu (2000), governance in society is about the communication, articulation, and sharing of vision, and the synchronization of action among various stakeholders or socio-economic groups in the society. In other words, governance is not just about the relationship between a governor and the governed, nor the mere exercise of authority by one group over others. It is the aggregate of the participation of all stakeholders and groups in the society in the economic and socio-political life of that society. According to UNESCO (2005a), governance refers to the exercise of political, economic and administrative authority in the management of a country's affairs, including citizens' articulation of their interests and exercise of their legal rights and obligations.

In developing world areas, such as in Africa, where satisfying basic necessities of life is still a challenge, the definition of governance must be inclusive. Good governance must include effective participation in public deci-

sion making and management by citizens, accountability, legitimacy, transparency, the rule of law, and an open and enabling environment for addressing socioeconomic problems. This requires participatory democracy and capacity by governments to respond to the demands of development. The capacity aspect must be emphasized, as "… a more open, participatory government is not a sufficient condition for good governance. Expression of citizen demands, whether for services, accountability, or transparency, is futile without a government willing and able to listen and respond. A democracy without effective administrative capacity is an empty shell" (Lal, Gaumer, & Manhica, 1999). As such, good governance is not only about providing an open and free political atmosphere, it also requires a government with the capacity to raise the standards of living and quality of life of the people.

## WHAT ROLE FOR ICTS IN GOVERNANCE?

E-governance may be understood as the performance of governance via electronic medium to facilitate an efficient, speedy, and transparent process of disseminating information to the public and other agencies, and for performing government administration activities. E-governance is generally considered as a wider concept than e-government, since it can bring about a change in how citizens relate to governments and to each other. The idea of adopting ICTs is to move beyond the passive information-giving to active citizen involvement in the decision-making process. E-governance can bring forth new concepts of citizenship, both in terms of citizen needs and responsibilities. Its objective is to engage, enable, and empower the citizen.

The purpose of implementing e-governance is to enhance good governance. Good governance is generally characterized by participation, transparency, and accountability. Recent advances in communication technologies and the Internet provide opportunities to transform the relationship between governments and citizens in a new way, thus contributing to the achievement of good governance goals. The use of ICTs can increase the broad involvement of citizens in the process of governance at all levels by providing the possibility of online discussion groups and by enhancing the rapid development and effectiveness of pressure groups. Advantages for the government include that the government may provide better service in terms of time, and governance may be more efficient and effective. In addition, transaction costs can be lowered and government services become more accessible (Ningo, 1999).

The fields of implementation of e-governance are:

- **E-Administration:** Improving of government processes and of the internal workings of the public sector with new ICT-executed information processes.
- **E-Services:** Improving delivery of public services to citizens. Some examples of interactive services are: requests for public documents, requests for legal documents and certificates, issuing permits and licenses.
- **E-Democracy:** Creating greater and more active citizen participation and involvement enabled by ICTs in the decision-making process (Heeks, 2001).

According to Coleman (2003), e-governance offers the prospect of at least 10 major administrative and democratic improvements:

1. Cheaper and more effective management and processing of information
2. A freer flow of information between departments, agencies and layers within government
3. More professional administrators, supported by standardized, electronically embedded decision-making systems
4. The routine provision of services according to impersonal rules, as opposed to client list arrangements
5. Transparency, particularly in relation to the procurement of government services
6. Opportunities to work in partnership with the private sector in modernizing governmental processes
7. A freer flow of information between government and citizens
8. The strengthening of intermediary democratic institutions, such as parliaments, local government, civil-society organizations (CSOs), and independent media
9. Opportunities for citizens to participate more directly in policy development
10. Opportunities to combine traditional and modern methods of accountability

## African Governance and ICTs: Some Reference Points

According to Coleman (2003), successful e-government initiatives can have demonstrable and tangible impacts on improving citizen participation and quality of life as a result of effective multi-stakeholder partnerships. There are many examples of successful African e-governance

projects, often implemented in isolation from broader strategies for sustainable e-governance. According to Coleman (2003), the strategic programs for e-governance have been established recently in countries such as Egypt, Kenya, Senegal, Mozambique, and South Africa. These strategic initiatives indicate that African e-governance is moving beyond the stage of novel experimentation. As in Europe and North America, African governments are proceeding pragmatically and incrementally towards e-governance, but they are increasingly doing so within a framework of established good practices and strategically articulated objectives (Coleman, 2003). Some examples of the wide range of relatively successful African e-governance projects are highlighted next.

The Information Technology Standards Association (ITSA) of Kenya launched an Electronic Graft Management pilot project, whose aim is to increase public awareness and encourage public participation in fighting corrupt practices. According to Onunga (2004), the pilot project intends to use the Internet and e-mail as the channel for communication by the public for reporting. The idea is to introduce the use of an Internet hotline, popularly known as an online reporting mechanism. For the pilot project, the existing Internet infrastructure that currently covers six major towns will be used. Existing Internet cafés and e-touch centers in these towns are to be used by the public for reporting, at no cost. In addition, two remote locations, which do not have the required infrastructure, will also be set up to test the feasibility of connecting larger rural areas. The EGM Centre will filter information electronically and forward/channel it to relevant authorities for action. The partnerships are currently being formulated between ITSA and the relevant authorities. The greatest challenge facing the implementation of the project is how to make the public report genuine corruption voluntarily (Onunga, 2004).

Nigeria has commissioned a new Online Project of the Corporate Affairs Commission (CAC). The project was informed by the need to transform the Commission into a more efficient and effective companies registry (UNESCO, 2005b). Also, in Nigeria, there is the Nigeria Congress Online, a Web site that is a fusion of all issues of interest relating to and impacting all aspects of governance, namely the presidency, state/local government administration, the legislature, and the judiciary. It also serves as an interactive forum for interface between the Nigerian government and other stakeholders of democracy (The Nigeria Congress Online, 2004). The objectives of the site are: the promotion and sustenance of democracy; promotion of transparency in government; facilitation of awareness and interaction between the government and the people; encouragement of basic constitutional, human rights and freedoms; and service as a repository of knowledge and parliamentary history data. In Ethiopia, there is the establishment of distance learning for civil servants. There are approximately 350,000 civil servants in the Ethiopian government, of whom 14% have PCs and less than 1% have e-mail access. The World Bank's Global Development Learning Network has established a peer-to-peer video-conferencing and distance learning center in Addis Ababa to train civil servants in the use of ICTs (Coleman, 2003). Zambia has developed the Zamlii—an online Zambian legal information portal, which is a comprehensive online collection of documents and research relating to Zambian legal and constitutional issues, intended as a legal network for lawyers, judges, academics, students, and citizens. Also, there is the Parliamentary Technical Assistance Project in Uganda, which was introduced in 1998 to assist the Parliament of Uganda with its own modernization process so elected members can better represent the interests of their constituents, make better laws and provide more effective oversight of the executive.

Another e-government project is the Kubatana Trust of Zimbabwe, which aims at strengthening the use of e-mail and Internet strategies in Zimbabwean NGOs and civil society organizations. Kubatana hopes to make human rights and civic education information accessible to the general public from a centralized electronic source. The objectives of the project are to develop a central Zimbabwean development and human rights portal. The portal will contain editorial material highlighting the work of the organizations hosted on the portal, develop an electronic fact sheet for each organization hosted on the portal, develop an e-activism page for online campaigns, and link existing Zimbabwean NGO and civil society Web sites to the portal. By focusing solely on Zimbabwe and being committed to the regular updating and development of the portal, it is believed that Kubatana will become the most important source of Zimbabwean human rights and development information on the Internet.

Furthermore, in South Africa, there is the Cape Gateway portal, which provides Web-based information about government services and departments, structured according to users' life events. There is also the Independent Electoral Commission voter registration system, which is a satellite-enabled network that allows the Commission to register voters, collect and verify ballots, and relay election results across the country. According to Adesida (2001), Ghana is a success story in its efforts toward applying ICTs toward reducing poverty and improving governance. There is the Environmental Information Network, a project that aims to strengthen effective networking between various environmental agencies and NGOs in Ghana (Coleman, 2003). Finally, the urban information system in Senegal allows free Internet access to people in a Dakar neighborhood, with special services that make it easier for residents to communicate

*Table 1. Internet penetration in Africa and rest of the world (www.internetworldstats.com, 2004)*

| World Regions | Population % of World | Internet Usage, Latest Data | % Population (Penetration) | World Users (%) |
|---|---|---|---|---|
| Africa | 14.0 % | 13,468,600 | 1.5 % | 1.5 % |
| Asia | 56.3 % | 302,257,003 | 8.4 % | 34.0 % |
| Europe | 11.4 % | 259,653,144 | 35.5 % | 29.2 % |
| Middle East | 4.0 % | 19,370,700 | 7.5 % | 2.2 % |
| North America | 5.1 % | 221,437,647 | 67.4 % | 24.9 % |
| Latin America/Caribbean | 8.5 % | 56,224,957 | 10.3 % | 6.3 % |
| Oceania/Australia | 0.5 % | 16,269,080 | 48.6 % | 1.8 % |
| WORLD TOTAL | 100.0 % | 888,681,131 | 13.9 % | 100.0 % |

with local government agencies. It also generates local content. Another program using ICTs to improve governance also originated in Dakar. It was designed to improve the quality of parliamentary debate on ICT policy, plus, it educated members of the Senegalese Parliament about the implications of ICTs for development and opened possibilities for members of Parliament to access information on other subjects.

Having the above reference points of ICTs' use in governance in Africa in mind, we discuss in the next section some of the challenges and future trends of the application of ICTs to governance in Africa.

## CHALLENGES AND FUTURE TRENDS

We assume in this article that ICTs could play a significant role in improving governance in Africa by enlarging the democratic space, enhancing dialog, facilitating inclusiveness and providing governments the tools to better perform their administrative and management functions. However, despite the capacity of ICTs to facilitate communication and bring people together, they also have become another dividing factor. In Africa and much of the world today, there is a "digital divide" between and within nations. Africa is at the bottom of the ladder of the information society compared with other continents. Within African countries, a major divide is emerging between the relatively "information-rich" and the abjectly "information-poor." This division is probably more pronounced, as only a very few can afford to be linked to the global information highway. Reasons vary, but the most important are: poverty and lack of education. The cheapest Internet computer today is about $300 (United States (U.S.) dollars) in the U.S. In Africa, despite the fall in prices and market liberalization, the cheapest computers retail for about $1,000, which doubles the average per capita income for most Africans. In addition to a computer, one needs a telephone line and Internet Service Provider (ISP) to participate in the information society. For the majority of Africans, telephone is a luxury, which is either not affordable or not available. Waiting time to get a telephone line in Africa could run up to 10 years at a cost of more than $1,000 per line. Even when the line is available, the charges are the highest in the world. African ISPs are also scarce, expensive, and unreliable.

From Table 1, it is obvious that the rate of access for each of the regions does not match global population figures. Sub-Saharan Africa, which has 13% of the world's population, has only just more than 1% of Internet users, whereas 5% of the world's population, in North America, constitutes almost one-third of total Internet users. Literacy rates are low in Africa, also, with too many people unable to read or write. Even when one can read, ICTs require training to be able to use them effectively. Despite novel ways of providing access through community centers and sharing of access, these factors conspire to keep the financially poor from joining the information society. For the most connected country in Africa, South Africa, less than 5% of its population has access from home to the Internet (The Economist, 2000). Also, the infrastructure necessary for globalization is inadequate in Africa, while financial resources are becoming more and more limited. As pointed out by Mansell and When (1998), "the most basic telecommunication infrastructure is still absent, unreliable and/or very costly" (Mansell & When, 1998). In addition, power supply is a major problem. In many cities where there is electricity, power supply is unreliable, and in most rural areas it is simply not available.

According to Aiyepeku (2005), with regard to ICTs and its application in government business, the uncoordinated status of "ICTs for governance" in Africa may be characterized as follows: Africa has been essentially at the receiving end of well-meaning, largely exogenous initiatives aimed at mainstreaming ICTs in the region's development processes; most African ICT-in-the-development-process initiatives, so far, have been little more than pious hopes and random "success stories," with rare empirical evidence of long-term applications in specific

African development environments. In addition, critical resource inputs—intellectual, technological and financial—into most ICT-for-African-development projects have invariably followed a rather predictable, uniform model, irrespective of the widely differing infrastructure, cultural, and political contexts of beneficiary African states. Aiyepeku (2005) submitted further that the commitment of most African states to the cause of mainstreaming ICT into governance and indeed the development process has been typically long on words and resolutions, but painfully short on *a comprehensive package of systematic actions, with measurable indices of progress towards the attainment of discernible objectives/goals.*

While the barriers to creating the information society in African countries are high, the opportunities for connection are growing. In telecommunications, a substantial increase in the rate of expansion and modernization of fixed networks is taking place, along with the explosion of mobile networks. The number of main lines grew about 9% a year between 1995 and 2001; however, this is off a very low base—the overall fixed-line teledensity as of 2001 was still only about 1 per 130 inhabitants in Sub-Saharan Africa (excluding South Africa). Overall, the number of fixed lines increased from 12.5 million to 21 million across Africa between 1995 and 2001. North Africa has 11.4 million of these and South Africa another 5 million, leaving only 4.6 million line for the rest of the continent. The sub-Sahara thus contains about 10% of the world's population (626 million), but only 0.2% of the world's 1 billion telephone lines. Comparing this to all of the low-income countries, (which house 50% of the world's population and 10% of the telephone lines), the penetration of phone lines on the sub-continent is about 5 times worse than the "average" low-income country (Jensen, 2002). It should be noted that there is a high level of variability between countries and regions, even within the sub-Sahara.

## CONCLUSION

In this article, we explored the role of ICTs in governance in the continent of Africa and submitted that its use in governance offers the potential for greatly enhancing the transparency, efficiency, and ease for sustainability of good democratic governance. Also, we pointed out that ICTs are not an end, but are means and tools that offer opportunities to improve governance in Africa, especially by enlarging the democratic space, enhancing dialog, facilitating inclusiveness, and providing governments the tools to better perform their administrative and management functions. Some reference points of the application of ICTs to governance in some African countries were highlighted, as well as the challenges inhibiting the successful application. This article noted that although there are some noticeable applications of ICTs to governance in some African countries, most have not yet fully grasped its underlying dynamics. We conclude that by applying ICTs to governance, African governments have a lot of opportunities to avail themselves of and, indeed, the future of ICTs' application in governance is very bright, provided African governments take drastic steps targeted at surmounting the challenges highlighted above.

## KEY TERMS

**Africa:** Africa is the world's second-largest and second most populous continent, after Asia. At about 30,360,000 km (11,722,000 square miles) including its adjacent islands, it covers 5.9% of the Earth's total surface area, and 20.3% of the total land area. With more than 840,000,000 people (as of 2005) in 57 territories, it accounts for more than 12% of the world's human population (Wikipedia, 2005).

**E-Governance:** E-governance implies the use of ICT channels to change the way citizens and businesses interact with government to enable citizens' involvement in decision making, increased access to information, more transparency and civil society strengthening (Schware & Deane, 2003).

**E-Government:** E-government refers to the use of technology to enhance the access to and delivery of government services to benefit citizens, business partners and employees.

**Good Governance:** Good governance refers to governance that is participatory, consensus oriented, accountable, transparent, responsive, effective, and efficient, equitable and inclusive, and follows the rule of law. It assures that corruption is minimized, the views of minorities are taken into account and the voices of the most vulnerable in society are heard in decision making. It is also responsive to the present and future needs of society.

**Governance:** Refers to the process of decision making and the process by which decisions are implemented (or not implemented). Governance can be used in several contexts, such as corporate governance, international governance, national governance, and local governance.

**Information and Communication Technologies (ICTs):** Encompass all forms of technology used in processing and disseminating information.

## INTRODUCTION

Official procedures usually require that the citizen is unmistakably identified. This may be needed to ensure that the person approaching the authority is the one that has filed an application such as tracking the status of a request, for exercising certain rights such as representing a company or being a party in a proceeding, or for ensuring that the person is eligible to receive certain information such as her penal record. We define identification as the process necessary to validate or recognize identity.

In addition to identification, authenticity of a declaration of intent or act is needed in order to establish assurance of the purported identity. In conventional paper-based processes with personal appearance identification is usually carried out using identity cards, deeds, or witnesses. Authentication is provided by handwritten signatures.

When in e-government official processes are carried out electronically, both identification and authentication remain important aspects and need to be supported electronically. This may be provided by introducing electronic substitutes of paper-based official documents and handwritten signatures. At first glance, electronic signatures, digital certificates, and public key infrastructure (PKI) are such means. The legal basis for electronic signatures exists, for example, at the E.U. level (Signature Directive, 1999) or by national signature laws such as (Signature Law, 2000).

However, some issues need to be considered when introducing identification models for e-government on the regional or national level. These issues include scalability, durability, sustainability, and last but not least data protection and privacy. In this article we discuss these issues on identification in e-government. Therefore, the requirements on identification are sketched in section "Requirements of an Identification Model." Section "Identification vs. Electronic Signatures" continues by highlighting what shortcomings an identification model solely relying on electronic signatures and PKI faces. Section "Approaches to Electronic Identification" gives an overview of what solutions have been proposed and section "Fragmented Identifiers to Preserve Privacy" deepens one approach by introducing the model that has been followed by Austria (E-Government Act, 2004).

## REQUIREMENTS OF AN IDENTIFICATION MODEL

When introducing an identification model for e-government usually a number of considerations are being made. Irrespective of whether the identification model is being introduced on a national, regional or municipality level, unique identities shall be supported as this is needed by many official processes. The model also should support permanent, preferably lifelong identifiers that resist changes of names and so forth. This ensures that a citizen can be identified within a certain process irrespective when the identification is needed. Land registers are an obvious example where identification may be needed for quite a while.

In particular on the large scale, establishing the identity based on features such as name and date of birth is not sufficient, as widespread names may lead to digital twins. Thus, scalability is a further issue. Related to scalability, an aspect that shall not be underestimated is that systems that work well with early adopters that usually are technology-educated may turn out to not scale when the technology is taken up generally. An example—aside from security considerations—are usernames and passwords that tend to become costly on the large scale, as forgotten passwords and helpdesk costs become an issue. This particularly holds for e-government, as most citizens have official business rarely—in many cases once a year or less.

When obtaining an electronic identity linking to a physical person might require personal appearance to proof the identity by conventional means, such as identity cards. It however is hard to argue that a registration needs to be done with every authority that aims for introducing e-government. A single registration requiring personal appearance should suffice. Moreover, an identification system should be interoperable between

*Table 1. Overview of identification requirements*

- Unique identification: Citizens shall be unmistakably distinguished from others
- Durability: Permanent identifiers should be supported
- Scalability: Digital twins shall be avoided even in large scale environments
- Maintainability: The system shall, for example avoid forgotten identifiers if rarely used
- Single registration: A single show-up to obtain an electronic identity suffices
- Interoperability: Identification shall work in various administrative domains
- Privacy: Data protection shall be maintained

administrations, preferably taking cross-border processes into account, so that the citizen can use his electronic identity with different authorities.

Interoperability and cross-administrative usage of electronic identification comes with a connotation putting privacy at stake, as unrelated cases might be linked. This raises data protection concerns, in particular with nation-wide identifiers.

Table 1 summarizes the requirements that have been identified above.

## IDENTIFICATION vs. ELECTRONIC SIGNATURES

For unique identification an identifier of the person is needed. This unique identifier needs to be linked to the electronic signature to allow the relying party—usually the public authority in case of e-government processes—to verify that an electronic signature has been created by the claimed identity. If considering electronic signatures as the sole means of identification, the link between the physical person and the electronic signature is provided by the digital certificate.

However, data that is usually included in digital certificates—if using qualified certificates following the E.U. Signature Directive (Signature Directive, 1999) at least the name or a pseudonym—are not sufficient for uniquely identifying a person, as there might be digital twins, that is, two persons holding the same name. Even when amending the name by the date of birth and the place of birth, the digital twin problem isn't necessarily avoided. Even in a relatively small country such as Austria with a population of about 8 million several hundred citizens having the same name and date of birth exist. Moreover, the name may change over time such as due to marriage, thus processes started under the former name no longer can be identified solely relying on a certificate. Further problems that arise are that the spelling of names may not be consistent which affects the data quality that can be gained.

An option alleged useful might be to use the serial number of the certificate which per definition should be unique. Still several problems exist: First, a citizen might have several certificates each having different serial numbers that need to be linked to one person. Secondly, the certificate might expire or be revoked and thus no permanent identifier is given.

## APPROACHES TO ELECTRONIC IDENTIFICATION

Unique personal identification numbers (PIN) are a tool of choice to avoid the digital twin problem. However, data protection is a concern, as, for example, the E.U. (Data Protection Directive, 1995) explicitly refers to national PINs when asking the Member States to determine "the conditions under which a national identification number or any other identifier of general application may be processed." The solutions followed by Member States vary significantly—also depending on culture and historically grown approaches: Using the national PINs within E-Government processes is accepted in some countries. Similarly the tax numbers or social security numbers may be used in others. For data protection reasons, such an approach is however considered unacceptable in several countries.

When linking unique identifiers to the electronic signature for authentication purposes, several options exist: From a theoretical perspective, this can either be done explicitly by holding the PIN with the data needed to create the electronic signature—the digital certificate or the signed document—or implicitly by defining a separate record that establishes the link.

Summarizing, the following approaches are worth investigating when introducing unique identification, have been proposed or even been implemented by countries, respectively:

- Introducing a permanent identifier into the certificate has been investigated by the IETF PKIX group

(Pinkas & Gindin, 2004). An example of introducing a permanent identifier into the certificate is the Italian "InfoCamere" signature card of the Italian Chamber of Commerce where the tax number is stored in the certificate.

- Even if a unique identifier has already been introduced by a country, adding this to electronic identity media such as citizen cards might have been avoided for data protection reasons. For example, although people from Finland have personal identification numbers issued at birth, the Finnish FINEID card does not store that number, but a unique electronic ID (Partanen, 2003) that does not reveal information of the holder. The unique electronic ID however might be argued as a unique identifier stored in the certificate.
- Data could be added to the certificate that eases unique identification, for example, the gender, the date of birth, the name of birth, maiden names, or the name of the parents. The proposals in many cases follow the data that also is given in national identity cards. When changing to electronic identity this however raises data protection concerns, as directory services of certification service providers are usually public data.
- Using a separate record to establish a link between the unique identifier and the electronic signature has been chosen with the Austrian citizen card concept (Leitold et al., 2002) which is discussed in more detail in the following section.

## FRAGMENTED IDENTIFIERS TO PRESERVE PRIVACY

As one example of using unique identity and at the same time taking data protection aspects into account the Austrian identification management model is sketched in this section. The legal basis of this model together with the basis of the Austrian citizen card has been enacted as (E-Government Act, 2004).

Austria has introduced a national Central Register of Residents (CRR) in 2001. This forms a basis for electronic identification of residents. Together with registers for legal persons—the Register of Company Names and the Register of Associations—a data basis for natural and legal persons falling under registration obligations is provided. To cover citizens that are not registered in the CRR, for example, cross-border commuters or expatriates, a Supplementary Register has been introduced to which citizens or foreigners may apply for inclusion.

The identification model followed is based on the idea that within a certain sector of state activity no immediate data protection problem exists due to the introduction of unique identifiers. This is common practice as, tax numbers provide unique identification within the tax system or similarly social security numbers provide unique identification within the health insurance or social security system. Data protection concerns arise when data is exchanged between sectors of state activity where the cases are not related. Thus, such communication should be controlled—still basing the identification model on single sources is useful.

To provide that goal, the Austrian model introduces a so-called identity link where a base number is cryptographically derived from the before mentioned registers and stored on the citizen card. The identity link is a data structure signed by the public authority that asserts that a permanent identifier—the base number—relates to a certain certificate. By using a separate structure, the identity link is under control of the citizen and can be kept confidential. The citizen may also possess various citizen cards—having different certificates but linking each to the citizen's unique base number via a dedicated identity link.

The model defines a set of sectors of state activity where a single unique identification number may be used from a data protection perspective—some 30 such sectors have been defined in Austria (e.g., tax, health, etc.). When a citizen identifies herself in one sector of state activity, her citizen card combines an identifier of the sector with her base number in the identity link and applies a cryptographic one way function. This results in fragmented PINs where the citizen is uniquely identified in a certain sector, but the identification in one sector cannot be used in a different sector to identify the same citizen. Where such interadministrative relations need to be established, this can be either done with assistance of the citizen who is in control of the identity link, or where legally admissible the Data Protection Commission is authorized and technically enabled to establish such a link via the source registers (e.g., the CRR).

Summarizing the approach, Austria has implemented a system where the citizen controls her identification data stored in the citizen card. Fragmented PINs that are derived from various central registers are used in a way that cross-relating unrelated databases is inhibited by cryptographic means.

## CONCLUSION

The article has discussed the importance of unique identification when carrying out administrative processes electronically, that is, when advancing to E-Government. A number of requirements have been defined that are

worth considering when establishing a nationwide identification system. Provisions and shortcomings when using electronic signatures as sole means of identification have been addressed.

Data protection and privacy have been identified as a major challenge. While the introduction of electronic identification and e-government promises benefits for the citizens, privacy should not be at stake.

A number of approaches to unique identification have been discussed. Among these, one model actually implemented has been introduced as an example of how a putative contradiction between unique identification and privacy can be met.

## KEY TERMS

**Authentication:** The provision of assurance of the claimed identity of an entity.

**Certification Service Provider:** An entity who issues digital certificates.

**Digital Certificate:** An electronic attestation which links data such as public keys to a person and confirms the identity of that person.

**Electronic Signature:** Data in electronic form which are attached to or logically associated with other electronic data and which serves as a method of authentication.

**Identification:** The process necessary to validate or recognize identity.

**Identity**: Designation of a specific person by means of data which are particularly suitable to distinguish persons from each other, such as, in particular, name, date of birth and place of birth but also, for example, company name or (alpha)numerical designations.

**Qualified Electronic Signature:** An electronic signature that fulfills the requirements to have legal equivalence to a handwritten signature (e.g., an electronic signature as defined in article 5.1 of the E.U. Signature Directive).

**Unique Identity:** Designation of a specific person by means of one or more features enabling that data subject to be unmistakably distinguished from all other data subjects.

# Immigration and Digital Government

**Constantine E. Passaris**
*University of New Brunswick, Canada*

## INTRODUCTION

The information age of the 21st century has transformed the economic, social, and political landscape in a profound and indelible manner. It also has changed the role and functions of government and redefined the scope and substance of good governance. Never before in human history has the pace of structural change been more pervasive, rapid, and global in its context. The information age has precipitated profound structural changes in the economic landscape and has given birth to the new economy. The new global economy is composed of a trilogy of interactive forces that include globalization, trade liberalization, and the information technology and communications revolution. Globalization has melted national borders, free trade has enhanced economic integration, and the information and communications revolution has made geography and time irrelevant (Passaris, 2001). Immigration has taken on a new perspective in the context of globalization. There is no denying that the spread of Internet-based technologies throughout society has become the dominant economic reality of the 21st century. E-economy—the use of information and communication technologies for product and process innovation across all sectors of the economy—has emerged as the primary engine of productivity and growth for the global economy. In large part due to advances in information and communications technologies, the role of international borders in this globalized economy has been transformed from the traditional geographical frontiers to virtual economic communities.

Innovations in transportation and information and communications technology also has impacted immigration flows and made the world, in the phrase coined by Marshall McLuhan (1988), truly a "global village". Borders have become less relevant for digital content communications and transactions. Cyberspace has no natural demarcations or border patrols. Indeed, knowledge-based products, such as software, games, and music, cross borders without impediment and with relative ease (Passaris, 2003).

The advent of the information age has had a profound impact on the nature and scope of e-government and has given birth to the digital government of the 21st century. In particular, the interface between government and immigration management has been redesigned and restructured in terms of access to immigration information and application forms, the processing of immigration applicants for admission, enforcement of security measures and the prevention of terrorist infiltration, and the time line for adjudicating immigration applications, to name just a few of the significant changes to the contemporary process by which the governments of immigrant-receiving countries enforce their immigration policies.

## BACKGROUND

There is no denying that the information age has resulted in a significant restructuring between the interface of government and immigration. Furthermore, the new economy has altered the microeconomic and macroeconomic dynamics in the pattern and flow of immigration in the 21st century. Indeed, the most important factor driving the changes in immigration is economic globalization (Burstein & Biles, 2003). In this context, economic migrants are driving the immigration agenda in the information age.

In this borderless world, financial capital travels the world, going to wherever it can earn the highest return. Human capital has become equally mobile, much like financial capital, pursuing the highest expected return in terms of employment opportunities and financial remuneration. The flow of human capital through migration has become an increasingly important issue in this context (Passaris, 1999).

Migration flows in the 21st century are taking place in the context of the new global economy. The advent of globalization, the preponderance of regional trading blocks, and the emergence of the knowledge-based economy are the signature marks of the new global economy of the 21st century. The industrial/agrarian economic model of the past that determined the scope and substance of immigration patterns has been replaced by the pursuit of immigration for the purpose of enhancing a country's technological capacity and optimizing its human and social capital endowment. In this regard, the importance of human capital has redefined the quantitative and qualitative parameters of the modern dynamics for immigration flows. Indeed, in the current context, the

economic wealth of nations is determined not by the quantity of a country's natural endowments and physical resources but by the level of technological skills and educational attainment of its labor force (Florida, 2002).

The new century has introduced significant changes in the geopolitical landscape, which is reflected in the economic disparity between developed and developing nations on the international landscape. It is also underlined in the emergence of national security and combating terrorism as a principal priority for governments through redefining public policy with respect to immigration. It also has heightened concerns regarding the magnitude of illegal immigration.

The pattern of global migrations experienced a fundamental restructuring toward the end of the 20th century and the beginning of the 21st century. An economic realignment has taken place as a consequence of globalization, which has redefined countries of emigration and countries of immigration. This was precipitated by the profound structural changes in the economic landscape and the emergence of a new pattern of pull-and-push forces impacting migration flows. In particular, the traditional delineation of immigrant-receiving and emigrant-sending countries has been altered significantly. In this context, the leading source countries of emigration are currently the transition countries in Europe as well as the developing countries in Asia, Africa, and South America. Furthermore, countries of southern Europe such as Spain, Italy, and Greece, who until recently were countries of emigration, have been transformed into countries of immigration. It is also worth noting that the structural transformation of the national economies of developed countries and especially immigrant-receiving countries has had an indelible impact on the economic profile of recent immigrants.

## INFORMATION DISSEMINATION

A central feature associated with the microeconomic foundations of the migration process is the accumulation and dissemination of relevant and reliable information. Indeed, a necessary prerequisite regarding the decision to emigrate is the process of acquiring accurate knowledge and data that are essential precedents for an effective evaluation and assessment of the costs and benefits related to migrating (Passaris, 1989). The advent of the information age and new digital technologies have enhanced the information axiom that is relevant to the flow of immigration. There is no denying that the magnitude and quality of the economic, political, social, and cultural information and data to which prospective migrants have access forms an important component of the decision-making process leading to emigration. It is in this context that digital government has had the most profound impact.

Text in many languages and personal experiences are the two major catalysts for transmitting information and knowledge. Prospective migrants are likely to garner the information they need for a comparison between conditions and prospects in their country of origin with those in their country of destination from books, articles, pamphlets, interviews with immigration officers, holiday visits to the country of intended destination, contacts with residents of the country of destination, and correspondence with relatives and friends residing in that country of intended migration. Increasingly, this information is retrieved on the Internet from government Web sites, portals of immigration organizations, e-mails, and other forms of virtual connectivity.

## MULTICULTURAL IMMIGRATION

A feature of contemporary consequence with respect to immigration is the influx of a pronounced multicultural and multiracial flow of immigrant streams (Economic Council of Canada, 1991). It is anticipated that future immigration flows will be from non-traditional source countries and even more multicultural and multiracial in composition (Passaris, 1988). This underlines the need for a more vigorous assessment of the scope and substance of immigration information and the format of its electronic dissemination. In particular, digital government in immigrant-receiving countries will require a polyglot realignment in the immigration information provided on their Web sites, forms, and portals.

In many respects, an immigrant-receiving country's multicultural profile is a valuable economic asset and should be utilized strategically in the formulation of public policy. The presence of this multitude of cultures provides an opportunity to develop special economic relationships all over the world (Passaris, 1987b). The multicultural, multiracial, multifaith, and multilinguistic character of contemporary immigrant-receiving countries should become an important component of the scope and substance of digital government, especially in the area of immigration.

In the new global economy, multicultural immigration offers the receiving country a set of competitive strengths and enhanced economic development strategies. The multicultural skills and attributes of immigrant arrivals should be harnessed for competitive advantage in such areas of vital economic importance as enhanced international trade and export potential, building overseas business contacts, attracting foreign investments, tourist

appeal, and many other avenues of direct and indirect economic benefit. In short, the unique and valuable economic attributes of a country's multicultural human resources should become an integral component of a nation's economic development strategy and an important focus of economic growth initiatives (Passaris, 1985). On the other hand, the influx of immigrant labor from widely diverse geographical source countries raises some specific challenges related to the transfer of human capital across international boundaries. One such issue is the accreditation of overseas educational qualifications by immigrant-receiving countries and the recognition of transferable international work experience (Passaris, 1989a). All of those challenges and opportunities require a proactive approach in the development of government policy.

## INTERNETIZATION

Advances in information and communications technology of the 21st century have made possible the contraction of time and space and enhanced personal and institutional connectivity. The rapidity of change and the magnitude of the structural transformation are the hallmarks of this information revolution.

This structural transformation has had a compelling impact on the way we live, learn, work, invest, provide for our health care, entertain ourselves, access government services, exercise our democratic responsibilities, influence the formulation of public policy, and communicate with each other. Public services, banking, education, health care, and electronic commerce are at the forefront of the information revolution with the capability of accessing information, services, and products from around the world almost instantaneously (Passaris, 2001).

Internetization is a word that I have coined in order to capture the pervasive influence of the Internet and the World Wide Web in all aspects of human endeavor for our society in the 21st century. It is a process that is empowered by the information and communications technology in a borderless world with a tremendous capacity for virtual connectivity. The electronic prefix that appears before an increasing number of our daily activities, such as e-commerce, e-mail, e-learning, and e-government, is a tangible expression of the pervasive influence of the Internet.

## DIGITAL GOVERNMENT

Digital government, or e-government, refers to the use of computers and computer networks in order to improve government services and government interaction with citizens. The concept of a digital government is a recent innovation that has arisen from the widespread adoption of personal computers. While some governments have made use of computers for decades, the major impact of such use has been recognized only in the last few years. In the context of immigration, the role of e-government is multidimensional and multilayered. There is no denying that electronic connectivity has had an indelible impact on the scope, substance, and micro-dynamic elements of immigration. It also has been suggested that the use of the Internet for government services is likely to lead to greater rationalization, standardization, and the use of rule-based systems (Fountain, 2001).

The scope of digital government can be divided into several categories: (1) the personal use of computers by the public service for individual and administrative tasks such as communication, research, and word processing; (2) the use of databases to centrally store large amounts of information related to government and citizen activities; and (3) new private computer networks that connect databases and people in unprecedented ways, while government interaction with the public is facilitated by informative Web sites and by Web sites that offer the option to access government services electronically. In short, digital government can be used for two generic functions: to facilitate internal tasks and to enhance connectivity with the public.

By adopting electronic connectivity and digitalization, governments have improved numerous governance functions; in particular:

1. Government can facilitate the integration of government services across government departments.
2. E-government can help to change the delivery channels of public administration by responding to citizens' requests in a timely and efficient manner.
3. Public services can be accessed via the Internet through government portals with secure protocols. Furthermore, sophisticated e-government applications provide a citizen with the opportunity to determine the progress of his or her request through an online query.
4. Electronically mediated interaction, whether by way of e-mail, Web-enabled discussion threads, chat rooms, surveys, or yet-to-be-invented consultation mechanisms could have a significant impact on public consultations and could enhance citizen engagement in the democratic process.
5. Digital government has the potential of enabling the average citizen to become better informed about public issues and to make a more significant contribution to the public debate.

## IMMIGRATION INTERFACE

All immigrant-receiving countries have adopted extensive digital formats for the purpose of providing information and communicating with prospective immigrants. In those countries, government online has become the rule rather than the exception. Enhanced government electronic connectivity is driven by the objective of mainstreaming the immigration process and speeding up the decision-making time line. It is intended to implement a secure infrastructure and to sustain the transformation in service and business practices. It facilitates partnerships between government departments and organizes immigration information by topic. This accomplishes the streamlining of information and services in an integrated, multi-service delivery network operating across programs, departments, and jurisdictions. The range of government immigration electronic connectivity includes gateways and clusters in order to attain the goal of a horizontal delivery of information. In short, the contemporary evolution of digital government is to eliminate the complexity and bureaucratic bent of internal government processes. More specifically, it is aimed at information technology homogeneity, process reengineering, information technology rationalization, and improved interdepartment cooperation. In most cases, this takes the form of a single window of service to clients, where all government services are available to the public through one Internet portal.

Digital government has endowed the immigration process with Web sites that can be viewed in several languages and can provide immigration information for a large number of immigration streams such as business immigrants, foreign investors, skilled worker immigrants, humanitarian or refugee admissions, employer-sponsored migration, the family unification category, international adoption, entrepreneurial immigration, and so forth. Furthermore, they provide information regarding immigrating and settling in the country of destination, including information about entry requirements, permanent residency status, and application forms and fees, and specifying the format of personal, financial, and medical documentation that is required.

In the context of the structural change precipitated by the information technology and communications revolution and the speed of change, the immigration process has had to conform to a reduced time cycle through digitalization. The interface between immigration and government digitalization has taken many forms and is in constant evolution and development. The following is a comprehensive list of the features of digital connectivity with respect to the immigration process:

1. Application forms that can be downloaded from the Web site.
2. An electronic online service for completing and transmitting applications via the Internet.
3. Some government Web sites that allow for e-payments in the form of an online administrative fee payment service, which allows immigrant applicants to pay their administrative fees online at their convenience.
4. An electronic format to check on the progress of a prospective immigrants application online.
5. An online service that allows clients to submit an address or a change of address notification online.
6. Some immigrant-receiving countries require certain economic and professional attributes prior to granting an immigration visa. Those Web sites provide an anonymous online test to check if prospective immigrants meet the requirements.
7. An online service to schedule or cancel a personal meeting with an immigration official.
8. All of this with due regard for client privacy, establishing a secure connection, and authenticating the client. With the significant increase in the use of online service, government immigration departments have recorded a reduction in other forms of government interaction, such as in-person meetings, regular mail, fax transmissions, and telephone calls.

It is worth noting that most government immigration Web sites include information to assist newcomers to integrate in the economic, social, and cultural life of their country of destination. This assistance may be in the form of language instruction for newcomers or tips regarding the immigrant's integration into society in the areas of life skills and job search. Furthermore, government immigration Web sites include contacts for non-governmental organizations and community volunteer associations that assist newcomers to adapt more quickly to their new social and economic environment as well as provide guidance for health and educational services.

An important component of government online is the availability of an electronic virtual library and a publicly accessible storage facility for immigration legislation, electronic databases, policy documents, booklets, and so forth for the purpose of disseminating reliable information and facilitating the immigration process. Access to reliable and accurate sources of information is a fundamental axiom and essential prerequisite for the completion of a successful cycle for immigration and the economic and social integration in a host country.

Despite significant accomplishments in the interface between digital government and the immigration process,

several challenges continue to exist. They include foreign language coverage, content management, and consistency of information across departmental Web sites. The ultimate goal is the digital development of all online-compatible administration services, which will require the central development of compatible basic components and standards for the public administration of the digital infrastructure as well as a coordinated approach in the implementation of all three tiers of government and between government departments and agencies.

## PRIVACY AND SECURITY

The nature and scope of digital interaction between government and prospective immigrants embraces issues of privacy, security, confidentiality, and human rights. One of the principal challenges of the information age is to build a level of personal trust and security in the digital environment of the 21st century. Indeed, it is vital to adopt the principles that will help to guide governments and public organizations in confirming the identities of online parties and in ensuring that electronic communications are kept confidential and secure (Passaris, Samuel, Stanford & Dabydeen, 2000).

Legislation protecting the privacy of individual migrants as well as a publicly adhered to policy on the use of encryption technologies and security protection measures developed and implemented within government are essential prerequisites for building trust in the process of digital interface. More specifically, the principles that can help to build trust and confidence in the digitalization of government services are that (1) the responsibilities of participants are proportionate to the degree of knowledge and control that rationally can be expected of them; (2) the risks for authentication processes should be identified, assessed, and managed in a reasonable, fair, and efficient manner; (3) all participants have a responsibility to contribute to the mitigation of risk through sound security practices; (4) for the purpose of ensuring privacy, the collection, use, and disclosure of personal information in authentication processes should be minimized; (5) the disclosure requirements for participants that require authentication services should disclose information to ensure that other participants are aware of the risks and responsibilities associated with participation; and (6) government organizations and public services implementing authentication processes should make available an efficient and effective complaint-handling process.

In practice, government immigration Web sites usually record and log in the virtual presence of a visitor for statistical purposes, which is used by the governemnt department to monitor the use of the site, to discover what information is most and least used, and to make the site more useful to visitors. The information recorded includes the visitor's IP or server's address, the date and time of the visit to the site, the pages accessed, the visitor's operating system, the Web browser version and type, the time taken to transmit information to the visitor, and the previous Internet address from which he or she came directly to this Web site. It is worth noting that no attempt is made to identify the visitor or his or her browsing activities except in the event of an investigation into apparent improper use of the government department's Internet facility or when a law enforcement agency exercises a warrant to inspect the Internet Service Provider's logs.

Most applications regarding immigration can be completed at the Web site. The Internet user is asked questions about his or her name, address, zip code, e-mail, birthdate, marital status, passport details, health status, profession, countries of residence during the last years, criminal history, financial situation, and credit card details to pay an application fee. Some of those questions may infringe on personal privacy and individual human rights.

Some immigrant-receiving countries do not permit the electronic transmission of immigrant applications. Forms only can be downloaded and printed. The prospective immigrant is subsequently asked to complete the form and to send it by fax or regular mail.

The progress of an immigrant's application can be viewed after the user submits his or her family name, birth date, country of birth, and other types of personal authentication. Information on this site is sent between the applicant's computer and the government server in an encrypted format. Those government Web sites emphasize the use of secure sockets layer (SSL) protocol with 128-bit encryption that enhances the privacy of the information passing between a visitor's browser and the government servers.

Some government Web sites allow for the electronic transmission of administrative fee payments by providing credit card details. However, failure to press the close button may result in personal or credit card details becoming available to third parties.

In short, either through personal negligence or purposeful hacking, the possibility of security breaches and the public disclosure of personal and private information continue to be a serious challenge.

## FUTURE TRENDS

The contemporary scope of multicultural immigration and the anticipated increase in cultural and linguistic diversity of source countries of emigration in the future renders

the multilingual capabilities of government immigration Web sites an important issue. Chinese and English are the two most frequently used languages on the Internet. The most common languages incorporated in government immigration Web sites are English, French, Chinese, Portuguese, Spanish, Arabic, and German.

The multicultural profiling of most government immigration Web sites raises the question of cultural symbiosis. By that, I mean the extent to which specific cultural connotations are taken into account in designing the architecture of the Web site. It is common knowledge that different colors, visual icons, literary expressions, images, cultural artifacts, and so forth do not have a uniform appeal and receptivity along the horizontal spectrum of cultures and linguistic groups. In particular, direct translations of the text on immigration information from one language to another may result in comprehension difficulties and may contribute to cultural barriers.

This also applies to the choice of colors, cultural artifacts, and illustrations, which may have unintended connotations. The extent of cultural receptivity depends in large measure upon the degree of success in incorporating textual and visual cultural symbiosis. In short, great care and cultural sensitivity must be exercised in the development of government immigration Web sites in order to appeal directly to the intended cultural groups and linguistic communities.

Finally, it is important to recognize the existence of a digital divide between countries of immigration and countries of emigration. Immigrant-receiving countries are economically advanced countries with the most avant garde information technology infrastructure and per capita personal computer ownership and use. On the other hand, emigrant-sending countries are primarily developing countries with low levels of digital connectivity and computer accessibility. This digital disparity between immigration and emigration countries, while narrowing over time, remains a serious obstacle for the most effective utilization of electronic connectivity in the context of the migration process.

## CONCLUSION

The advent of digital government in the domain of immigration poses unique challenges and opportunities. The wealth of information and resources that is available in digital format has enhanced the connectivity between governments and migrants. The 21st century has underlined the importance of issues of national security, combating terrorism, and preventing illegal immigration. There is no denying that open societies are more vulnerable to illegal infiltration and terrorist acts. Internetization and the scope of virtual connectivity have embraced a globalized perspective for immigration that is without precedent. The removal of barriers to human mobility and the more pronounced streams of multicultural immigration will be the defining features of the next few decades of the 21st century.

## KEY TERMS

**Asylum:** The granting of permanent or temporary residence for refugee movements.

**Economic Migrations:** Migration movements that are motivated by economic benefit and economic self-improvement.

**Emigration:** The movement of people out of a country of origin with the consequence of decreasing its population and labor force.

**Forced Migrations:** The forced movement of people out of their country of origin for compelling reasons of political, social, cultural, ethnic, or religious persecution.

**Globalization:** The growth of interdependence among world economies with enhanced trade liberalization and electronic connectivity.

**Illegal Migration:** Migratory movements that are not approved or sanctioned by immigrant-receiving countries.

**Immigration:** The movement of people into a country of destination with the consequence of increasing its population and labor force.

**Immigration Policy:** The overall direction of government's public policy on immigration expressed in legislation, orders-in-council, department of immigration memos, budgetary appropriations, and ministerial speeches.

**Internetization:** The important role of the Internet and the World Wide Web in all aspects of human endeavor. Internetization is the infrastructure and the medium of electronic connectivity in the information age and the new global economy.

**Migration:** The movement of people between countries.

**Migration Management:** The application of migration policies, procedures, and guidelines for the purpose of managing the numerical flow and qualitative aspects of immigration, such as the occupational composition and/or the education levels immigration flows.

**Refugees:** People who are forced to move out of their country or origin for fear of death or persecution.

**Source Country of Migration:** Countries of origin for migratory flows.

**Target Country of Migration:** Also referred to as a country of destination, it is the ultimate destination of migratory flows.

**Transition Country of Migration:** Countries that previously were under the Communist bloc and recently have embraced capitalism and a free enterprise economy.

**Voluntary Migrations:** The movement of people out of their country of origin, primarily with the purpose of economic advancement and improving their standard of living.

# Implementation of E-Government Systems in Developing Countries

**Rahul De'**
*Indian Institute of Management Bangalore, India*

## INTRODUCTION

The introduction of e-government systems in India started out in the late 60s and early 70s with an emphasis on computerising applications for defence services, for the economic planning department, for the national census, for elections and for tax collections and so forth. The government mainly did the spending and the development was entirely done by internal information technology departments. In the 80s the National Informatics Centre was established, whose main role was to implement and support large-scale computerisation projects in India. The 90s saw the emergence of a national IT initiative by the Government of India with corresponding plans in the states. External funding was sought from agencies such as the World Bank and external parties such as NGOs and private corporations were involved in the computerisation efforts. The focus also shifted to external e-government systems that could provide services to the public.

The 90s saw a spate of e-government initiatives in India, in various states, that addressed issues of land records management through digitisation, issue of government documents to public and collection of various dues via kiosk-based centres and the use of GIS-based services for assisting agriculture. Currently, in the year 2005, the government in India is poised to spend Rs 120 billion on e-government initiatives.

The results of such efforts are not very promising, though: most e-government systems that are implemented in developing countries around the world fail, with the failure rates at over 80%. Many reasons are attributed to such high failure rates, most of which have to do with a lack of direction and continued support by the responsible government department. Projects, apparently, are conceived of as a response to the push to "computerise" from the government without a clear understanding of the problem being addressed or the adequate design of such systems. Or, projects are conceived of to address certain immediate problems without analysing the deeper causes of the problem.

The argument put forth in this article is that e-government system implementations are hugely complex processes that involve a complex set of factors; factors that have to be in place for the project to succeed. Government departments and officials are only one set of stakeholders who ensure the success of such projects, whereas a whole other set, those who use the system, are often left out of the analysis both during the design of the system and during its deployment. Further, e-government systems provide government services via an electronic intermediary where a manual provider is either removed or displaced altogether. The removal of officials, or their reentry at different points of the service chain, is a point of contention and may lead to conflict between stakeholder groups. An analysis of this potential for conflict is essential for implementation success of e-government systems.

The rest of this article examines these issues in more detail. The next section discusses the background to this research. The following section examines the main findings related to the issues highlighted above. The last section concludes the discussion and outlines future work.

## BACKGROUND

External e-government systems or government-to-citizen systems in developing countries are embedded in public spaces and deliver services that are demanded by a significant and diverse population. Their implementation success is based on neither their technical merits alone (the systems view) nor on the aspects of change management and user acceptance alone (the user view) (Markus, 1983). Such systems are embedded in a Web of relations or in a Web of interactions within a particular socio-economic context and their design and implementation requires an understanding of this context (Sein & Harindranath, 2004).

Prior research in e-government systems and ICT (information and communication technology) for development provides a basis for arguing the above theoretical approach. Information technology (IT) is best seen as an institutional actor (Avgerou, 2003) with its own myths and visions that have captured the imagination of its participant actors and the ideas and regulations that

guide the behaviour of the actors including those of resistance and subversion. In a developing country like India the needs, aspirations, and understanding of e-government is derived from a failure, in part, of governance mechanisms (Kaushik, 2004). The role and content of e-government systems arises from this context. Some examples will help to make concrete these theoretical issues.

Consider the implementation of a system for managing a rural development project (Madon, 1992). The main challenge to the implementation and acceptance of the system was the institutionalisation of the technology in the "ongoing context of formal and informal work and decision-making processes." Counter posing the "rational" development model and planning process for which the system was designed against the "real" model that emerged showed the complex interaction of caste, community, and regional complexities along with corruption and gross inefficiencies.

The CARD system also shows the complex play of stakeholders goals that prevents a system's intended benefits from being fully realised (Caseley, 2004). The system automated the process of land registration in the state of Andhra Pradesh in South India. The system was initiated by the state government to address the problems of widespread red tape and corruption in all aspects of land records access and mutation. One of the main problems was that of the presence of document writers outside registration offices who acted as the agents for corrupt officials. The CARD system was implemented in many districts and a few years after the launch, the study concluded that the system had not made things any easier for citizens as they still had to employ document writers and also pay bribes to access the system (on the other hand it had made things easier for the employees who could now locate files easily and also update them, while maintaining their corruption incomes).

Stakeholder theory enables the categorisation of those persons who are impacted by or impact e-government systems (De', 2005). Stakeholders have a "salience" that is both determined by and determines their power, legitimacy and influence on the system (Scholl, 2004). The following section identifies stakeholders from the perspective of their participation in an e-government implementation and their influence on the system.

## STAKEHOLDERS AND IMPLEMENTATION ISSUES

It is useful to view the stakeholders that impact the eventual success of a system as belonging to the demand-side, those who will consume the services of the system, or to the supply-side, those who fund, design, implement, and maintain the system. Individuals, groups, and organisations belong to either stakeholder group according to their relationship to the system. These categories can overlap, that is, there could be individuals or groups who belong to both categories.

It will be observed that most e-government systems implementations in developing countries are driven by the supply-side, who design the services, the processes and the architecture of the system without consulting any demand-side stakeholders. Supply-side stakeholders dominate the implementation process and are mostly informed by their own ideological commitments or by the technological imperatives of their commercial partners. They have control over all the resources and deploy them according to their understanding of demand-side needs.

Demand-side stakeholders consume the services of the e-government system and, on occasion, provide the revenues that sustain the systems. There are instances where demand-side stakeholders such as citizen's groups and civil society groups have demanded that they be included in the implementation process but this is rarely achieved. They decide the eventual success of the system through use or non-use and are directly impacted by the service efficiencies achieved.

### Example of Bhoomi System

To understand the different stakeholder groups let us consider the Bhoomi system that was implemented in the state of Karnataka in South India, and was launched in all districts of the state in 2001 (De' & Sen, 2004). It essentially allows farmers to receive a record of their land holdings at a reasonable price and also enter requests for mutations into the system. Land records are maintained electronically and details about crops are updated thrice a year. Farmers may obtain a Record of Rights, Tenancy and Crop (RTC) certificate from the system for a nominal price (Rs 15, about USD 0.33). This system replaced a manual system that was maintained by village accounts and was reportedly hard to access owing to corruption and red tape.

Neither demand-side nor supply-side stakeholders, for the Bhoomi system, form a contiguous group, there are further divisions of the stakeholders depending on their interaction with the system (see Table 1). For the demand side the primary users are the farmers who have records in the system and who use the system extensively. Till October 2004, over 22 million farmers had accessed the system since inception. Farmers use the certificates mostly to access loans from banks, along with using it as a surety in courts, for checking the details of their data, and for use in selling or mutation. With the advent of a faster process

*Table 1. Suppy-side and demand-side stakeholders for Bhoomi system*

| *Supply-Side* | *Demand-Side* |
|---|---|
| Village Accountant<br>Revenue Inspector<br>Computer Operator (or new VA)<br>Case Worker<br><br>Shirestedar<br>Tehsildar<br><br>Chief Minister<br>Secretary of Revenue Department | Farmer<br><br>Banks<br>Courts<br>Police Stations<br><br>Agriculture Department<br>Revenue Department |

of obtaining the certificates, banks have an increased possibility of doing business (of giving loans to farmers) and they are the secondary demand-side users. Other secondary users are courts and police stations. On the supply side, the primary users are the kiosk-operators (new village accountants) who run and maintain the system at the local level, the old village accountants who provide update data, caseworkers who assist farmers and revenue inspectors who are required for mutations of records. At the secondary level are the Tehsildar and Shirestedar (district officials) who also participate in the mutation process. At the tertiary level are the owners of the system such as the Secretary of the Revenue department, the Chief Minister of the state and others who are the top management that championed the project and whose work is indirectly assisted by the system.

## Analysis

With this understanding of stakeholders, a complex e-government intervention like Bhoomi can be analysed along various perspectives. The first, and most common, point is that demand-side stakeholders are rarely included in the design of the system. None of the farmers or banks or other departments were included in the design phase of the implementation of Bhoomi. Design and implementation was carried out entirely by the Project Champion and the implementation team that consisted of a government agency and some private players. The design imperatives were on issues such as data protection, access protection, standardisation of the data format, and uptime guarantees of the system. What was left out of the design were the usage considerations such as difficulty or ease of the users in accessing the system, the reasons why the users buy the certificates from the system, the interconnections with banks and courts that could have been possible and the subtle nature of user access (the ability of farmers to come to district or sub-district headquarters to access the system). Information systems literature highlights the role of user involvement during the design phase of systems, however in most cases of e-government systems such a practice is not followed.

Most e-government initiatives in developing countries sustain the levels of intermediation on the supply side. For instance, in Bhoomi, the traditional role of the old village accountant (VA) is replaced by the new village accountant (kiosk operators) who, for a fee, enter data by the farmers and print out the RTC certificates. The old village accountants were people who lived in the villages (there was usually one VA for three villages) and were known to farmers. The new VAs are unknown operators who are also government employees but their kiosks are at sub-district headquarters which is usually a half-day journey away for a farmer. There was no attempt by the designers to remove the role of the VAs initially, by providing automated or private/commercial kiosk-operators, or to enhance their roles to increase functionality. Sustaining traditional roles is a deliberate political choice, apparently to reduce resistance to the systems, as in the case of the CARD system (Caseley, 2004). However, in both Bhoomi and CARD the designers have tried to change the systems after implementation and pressure from various demand-side stakeholders for reform.

In situations where the intermediation by government officials is changed by the introduction of a system, the attempt is to increase the role of high-level officials in transactions. For instance, in the Bhoomi system the district-level official, the Tehsildar, was introduced in the land record mutation process whereas in the prior manual system this official only had to consider escalation cases. This aggregates control and power at the level of the Tehsildar at the district-level, reducing the power of revenue inspectors, village accountants, and Shirestedars. This re-intermediation poses the problem of conflict that could arise owing to the redistribution of power amongst stakeholder groups (Markus, 1983).

*Figure 1. Stakeholder conflict*

| | Supply-side Stakeholder | Demand-side Stakeholder |
|---|---|---|
| Intermediation | Increase or keep same | Decrease |
| Design | Include | Exclude |
| Control over data | Increase | Decrease |

## FUTURE TRENDS

The framework of stakeholders developed above provides a means by which a careful analysis of the complexities of e-government systems implementation can be performed. Further research along these lines will have to analyse the basis of conflict amongst different stakeholder groups. Figure 1 depicts the possible bases of conflict among demand-side and supply-side stakeholders. Along the intermediation dimension supply-side stakeholders would want to increase (or keep same) the scope and power of the officials whereas demand-side stakeholders would want to reduce this influence. In both the Bhoomi and CARD systems, the role of supply-side stakeholders was maintained or increased, and there was subsequent pressure from citizens and the media to reduce this. Further research is required to establish whether the question of the level of dis-(or re-) intermediation can be framed at the design phase itself.

So far, supply-side stakeholders have always kept out demand-side groups from the design of system features and implementation of the system; the latter are included only after deployment. Research has to examine the scope and mode of demand-side inclusion in the design process. With the increasing awareness of technology and an informed citizenry, in developing countries, the exclusion of citizens in the design process could lead to debilitating conflict.

A third dimension that requires further study and that provides scope for conflict is the control over and access to data that invariably increases for supply-side stakeholders. With manual systems, the data records are physically stored closer to citizens or to the source of the data, but with e-government systems the data location is typically in centralised, remote servers. This leaves citizens in a position where they have to re-learn and re-negotiate the processes by which they could access their data. Conflict arises as there is a potential for misuse (or perceived misuse) of the data by supply-side stakeholders.

With implementation of large and complex e-government systems, the potential for conflict assumes significance and it plays out subtly through policies, media reports of particular aspects of problems with systems, project reports, case studies and public speeches by officials. That it exists is incontrovertible and yet it remains largely unexplored in the literature.

## CONCLUSION

This article espoused a nuanced reading of stakeholders in the context of e-government systems in developing countries. Demand-side and supply-side stakeholders are two broad categories of interested parties that impact the final implementation of e-government systems, however this distinction is rarely included in the theory or assessment of such systems. Supply-side groups play the dominant role in the implementation process as they define the entire life cycle of the project, whereas demand-side groups are included only marginally. With such an exclusion of demand-side groups, the main impact is on the (dis-) intermediation of officials in the system; where these officials could have been displaced in the new system, their roles and positions are usually maintained. Such differences in views leads to conflict along several dimensions and this remains as future work for this research.

## KEY TERMS

**Conflict:** Oppositional positions by two parties, such as stakeholder groups, arising from their views of what an e-government system should be.

**Demand-Side Stakeholder:** A person or agency who is desirous of the services offered by any e-government system and who will have an impact on it in a practical sense.

**E-Government:** Government's use of information technology to introduce efficiency and transparency in its own functioning and in its service offerings to citizens.

**Ensemble:** A view of information systems that includes the technology as well as the people and institutions that use the technology, and interactions between them.

**Implementation:** Analysis, design, and installation of a system on hardware and software.

**Intermediation:** The act of coming in between or intervention by electronic means; where e-government systems connect citizens to governments without intervening officials.

**Supply-Side Stakeholder:** A person or agency that is responsible for offering e-government services and who will have an impact on its design and functioning in a practical sense.

# Implementing E-Government Systems in Transition Economies

**Călin Gurău**
*Groupe Sup de Co Montpellier, France*

## INTRODUCTION

In the last 20 years, the explosive development of telecommunication and computer technology has transformed information in the most important economic and social asset. The information society has changed the rules of interactions between people and organisations, increasing the power of individuals. The specific characteristics of the Internet permit freedom of expression and interaction, to a level unmatched by the traditional channel of communications.

As the use of the Internet became more spread in the society, the governments understood that it is risky and ineffective to ignore the possibilities provided by online information and communication. Since the Internet cannot be controlled by any single institution, the only possibility to influence public opinion is to participate in online exchanges. From this perspective, the Internet can be defined as a highly democratic media channel, which allows not only one-to-one, one-to-many or many-to-many communication, but also the storage and retrieval of historical data.

On the other hand, Internet communication can improve the efficiency of various administrative operations and reduce costs. E-government tends to be multidimensional, impacting above all on economic, social and governance dimensions. The benefits of introducing online system in the area of government and public administration are many and varied, such as: cost-effective delivery of services, improved revenue collection on taxes and service levies; IT literacy and reduction of the internal digital divide; increased access to and quality of education; improved education management capacity; improved social security; improved social welfare; integration and coordination of social and economic policy; improved public safety and security; increased capacity for a rational distribution of public funds (geographically and among population groups); greater accountability and transparency in public administration; better coordination and cooperation among government agencies and among different levels of government; improved public relations and communications; increased awareness of rights of civil society and obligations of government; greater public participation in governments' affairs (United Nations, 2003).

The implementation and effective co-ordination of e-government systems is complex and difficult, requiring knowledge and substantial resources. The implementation process will be most probably influenced by the level of economic development of every country, as well as by the political agenda of the ruling party. From this perspective, there might be significant differences between the developed economies that have a stable democratic system, and the developing countries, or the economies in transition.

These countries, some of them with a fairly developed financial and technological infrastructure, experience specific conditions in terms of knowledge, technological abilities, IT market, telecommunication infrastructure, and regulations. Many of these countries are presently attempting to transform a traditional economy, into an e-society in which Internet communication and interaction pays a central role.

## BACKGROUND

As in the case of e-commerce models, the implementation of advanced e-government systems is a gradual process. A report prepared by the United Nations (2003) has defined the five gradual stages of e-government implementation: (a) emerging e-government—characterised by the establishment of an online presence—often an government Web site; (b) enhanced e-government, in which the functions of the e-government platform become more diversified and the information exchange between government and citizens becomes more dynamic; (c) interactive e-government, when the government online portal permits downloading of administrative forms and documents, sending e-mail messages to officials, or engaging in online discussion forums; (d) the transactional stage, when the Internet connection offers facilities to pay taxes or conduct public administration online transactions; and finally (e) seamless e-government, which is characterised by a full integration of e-services across administrative boundaries.

A country's social, political, and economic background correlates closely with its e-government program development (United Nations, 2003). However, some developing and transitioning economies succeeded to implement, in a short period of time, very advanced e-government systems. Key factors such as the state of telecommunication infrastructure, the strength of the human

capital, the political will, and commitment of the national leadership, play important roles. Each of these factors influence how decision makers, policy planners, and public sector managers elect to approach, develop, and implement e-government programs.

According to a 31-country survey of nearly 29,000 people by market research firm Taylor Nelson Sofres, 30% of the adult population around the world now accesses some aspect of government on the Internet (eGovernment, 2003a). However, the service adoption curve has displayed little variation; information searches and form downloads show fairly widespread and growing (though moderately) usage, while the percentage of users providing personal information to their governments over the Internet and those paying for government services online remains low and static.

These findings can hardly qualify the e-government systems as service oriented and citizen-centric, since they are not a medium to elicit useful feedback and an active participation of the population to the political decision making. E-government should increase citizens' involvement in the process of governance at all levels, by introducing new voices in the current political dialogue, and enhancing the system of e-democracy.

Despite the recognised importance of e-government in transition economies and developing countries, as an engine for economic and political change, encouraging sustained growth and interactive democracy, very few studies have concentrated on the pattern of e-government implementation and development in these countries. Most of the material available are reports and surveys initiated, and prepared by transnational institutions, such as the United Nations, European Commission, or by market research organisations—eMarketer or Taylor Nelson Sofres.

The transition economies from Central and Eastern Europe need to make a special effort in order to develop the information and telecommunication infrastructure, and to avoid the formation of an e-elite that controls information access and use in these countries. At present the importance of an information-based society is recognised by all the government in the region, and important initiatives have been taken to at political, legal, and social level.

## ELEMENTS DETERMINING AND INFLUENCING SUCCESSFUL DEVELOPMENT OF E-GOVERNMENT SYSTEMS IN ROMANIA

The following elements are essential for the introduction and development of effective e-government systems in transition economies (O'Brien, 2004):

- **Government:** Political orientation, priorities and will
- **Citizens:** Access to Internet, skills for interacting with a Web site, knowledge of e-government initiatives
- **Internet Penetration and Telecommunication Infrastructure**
- **Systems' Compatibility:** Supporting legislation, electronic payments, democratic ideology

Each of these four elements will be discussed in detailed in the following pages, presenting the existing situation in Romania.

### Government Initiatives

The implementation of an integrated e-government system is considered essential by the Romanian government, considering not only the needs of the population, but also the perspective of becoming a member of the European Union (Filip & Stoica, 2002; O'Brien, 2004). Romania began its e-government effort in late 2000, declaring its intention to move fully into the information age (Patterson, 2002).

The Romanian government established a series of strategic objectives for the implementation of efficient e-government services (Malacopol, 2002):

- To create the legal framework (predictable, simple, consistent)
- To facilitate the industry development (favourable, stable and highly predictable environment for business growth, ensuring fair competition, granting specific facilities and incentives)
- To promote the electronic services awareness, security and consumer confidence
- To generate national sustainable economic growth and foreign direct investment through the communications and information technology sectors
- To build up synergic co-operation for different industries using global communications systems
- To set up an example of development and a growth engine by the government involvement in building successful projects.

In September 2003, the Romanian government launched its e-government portal—www.e-guvernare.ro—providing a one-stop shop to public services online (eGovernment, 2003b). The portal, also called "Electronic National System," gives 24/7 access to information from central and local government institutions, official forms and interactive services. 164 official forms from 465 public institutions, and five interactive services are currently

available, such as VAT declaration and submission of statistical information (eEurope+, 2004). Additional initiatives were taken at governmental level for the development of e-procurement in public administration (Kablenet, 2002), and e-voting.

The Romanian government's e-procurement platform went live on March 4, 2002 and is now available to 947 public bodies and 7,800 suppliers (eGovernment, 2003c). The Romanian Ministry of Communications and Information Technology announced in May 2003 that the number of transactions conducted through the government's e-procurement platform had reached 100,000. More than 60,000 of these transactions were conducted since the beginning of 2003, signalling a growing take-up of the platform by public entities.

The Romanian government approved on October 2003 an urgent ordinance, allowing a test of e-voting methods during the referendum on constitutional changes held on October 19 (eGovernment, 2003d). The Ministry for Communications and Information Technology announced that members of the Romanian military and police currently in mission abroad (Iraq, Afghanistan, Bosnia-Herzegovina, and Kosovo) will be able to cast their votes electronically during the referendum. These votes have been submitted using digital certificates and registered through an electronic voting system managed by the Romanian Central Electoral Bureau.

## Citizens and Enterprises: Human Skills and Development

It is estimated that in Romania there are more than 4 million Internet users (ITU, 2004). From these, 34% have Internet access in their professional office, 25% access the Internet in schools or Internet Cafes, and the remaining 24% are home users (Paunescu, 2003). Most of the intensive Internet users (at least 2 hours every day) are young, having ages between 18 and 25 years old (36%), or between 26 and 36 years old (38%).

Unfortunately, a large proportion of the Romanian population does not have the necessary knowledge and skills to use a computer or to access the Internet. The study eEurope+(2004) outlines that in terms of skills, 21% of the interviewed people claimed that they do not know what Internet is, and 45% that they do not know how to use a computer. In terms of technical reasons for not using the Internet, 7% of the people answered that they do not have a computer at work, 7% that the Internet is too complicated, and 13% that they do not have an Internet access device at home.

Although the number and the profile of the Internet users is important for the design and implementation of specific e-government services (e.g., the large proportion of young Internet users indicate the need for a more flexible, interesting layout of the governmental Web sites), it is also important to assess the intensity of use of the existing e-government services, both for individual citizens and for enterprises.

The study conducted under the Program eEurope+ (2004) provided an insight into the intensity of use of e-government services in Romania, considering both individual citizens and enterprises. Only 2% of the interviewed citizens have downloaded official forms from the e-government site, and 3% have sent filled in forms using the online facility—these percentages represent the lowest among all the other countries from Central and Eastern Europe. The situation is similar for the interaction firms-e-government site: 3% of the interviewed firms used the "social contribution for employees" online service, 1% the "notification of VAT," 3% the "declaration of corporate tax," and 4% the "declaration of VAT."

These figures show that the human capital in Romania is still in a developing stage, and that much must be done to improve the Internet and computer skills, as well as the use of the existent e-government services by the population.

## Internet and Telecommunication Infrastructure

The development and the reliability of the Internet and telecommunication infrastructure are essential for the effective implementation and development of e-government systems. If the citizens do not have access to reliable and cheap Internet connections, the e-government system will be no more than political propaganda.

The statistical data presented in Tables 1, 2, and 3 show that although Romania has made continuous progresses in developing the Internet and telecommunication infrastructure, it is still far away from the European level of the same indicators.

If the e-government system wants to fulfil the ambitious function of implementing e-democracy and increasing public participation in political debates and processes, the level of infrastructure requires substantial development. This can be done simply by providing

*Table 1. Internet indicators—Romania 2000/2001/2002/2003 (ITU, 2004)*

| Internet Indicators | Internet Hosts (total) | Internet Hosts/10,000 inhabitants | Internet Users (000) | Internet Users/10,000 inhabitants |
|---|---|---|---|---|
| Romania 2000 | 41,523 | 18.51 | 800 | 356.67 |
| Romania 2001 | 46,283 | 20.67 | 1,000 | 446.63 |
| Romania 2002 | 40,971 | 18.90 | 2,200 | 1,014.71 |
| Romania 2003 | 47,428 | 22.59 | 4,000 | 1,905.27 |
| Europe 2003 | | 280.95 | | 2,388.30 |

*Table 2. PCs indicators—Romania 2000/2001/2002 (ITU, 2004)*

| PCs Indicators | Estimated PCs (000) (total) | Estimated PCs / 100 inhabitants |
|---|---|---|
| Romania 2000 | 713 | 3.18 |
| Romania 2001 | 800 | 3.57 |
| Romania 2002 | 1.800 | 8.30 |
| Europe 2002 | | 21.44 |

*Table 3. Telecommunication indicators—Romania 2000/2001/2002/2003 (ITU, 2004)*

| Telecommunication Indicators | Main telephone lines (000) | Main telephone lines / 100 inhabitants |
|---|---|---|
| Romania 2000 | 3,899.2 | 17.38 |
| Romania 2001 | 4,116 | 18.38 |
| Romania 2002 | 4,215.2 | 19.44 |
| Romania 2003 | 4,300 | 20.48 |
| Europe 2003 | | 41.00 |

the required supporting legislation, and creating the necessary market conditions for free competition. There are clear signs that the government has initiated measures for updating the legislation and increasing the competition in IT&C markets (Filip & Stoica, 2002).

## Systems' Compatibility

The success of e-government initiatives is also influenced by the compatibility of online systems with other social, economic, or financial systems functioning in the country. A good example is the system of electronic payment, which is absolutely essential to permit efficient online transactions on the government Web site. This system requires an appropriate legislative framework, and an "electronic currency" economy.

The Romanian market is still mainly based on a "cash culture," the credit or debit cards being virtually unknown 10 years ago. The successful introduction of digital banking channels therefore requires a gradual development of the market for electronic financial services. A recent study (eEurope+, 2004) has shown that only 2% of the people and 12% of the businesses included in the sample are using the Internet for banking or other financial services in Romania.

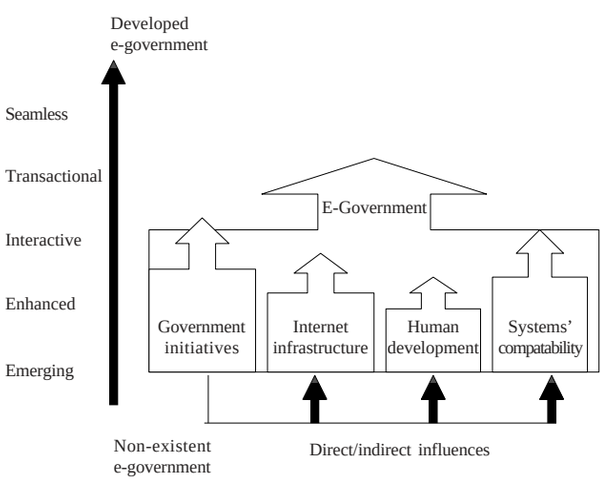
Recent governmental regulations regarding the payment of salaries by state enterprises directly in card accounts (since August 2003), and the introduction of electronic payment for all public services (since July 2003), will most probably encourage the extensive use of banks cards in the Romanian economy.

## FUTURE TRENDS

Despite the clear progresses achieved by Romania in the implementation of e-government systems, there is still much to be done. All the four major elements identified as essential for the effective functioning of e-government services should be developed and enhanced: government initiative, human capital development, improvement of Internet and telecommunications infrastructure, and the increased compatibility of various social, economic, and financial systems with the e-government services (see Figure 1). On the other hand, the institution responsible with the implementation of e-government projects should monitor the performance of these sites, and take concrete action for improving them. Analysing the present situation, it can be considered that the development of e-government systems in Romania is in the "interactive" stage, although elements of the "transactional" stage can also be identified (United Nations, 2003).

The Romanian government has already initiated a series of project for the future development of the e-government platform. One of the greatest challenges is the lack of Internet connectivity experienced by rural communities. In order to solve this problem, the Romanian Ministry of Communication and Information Technology and the World Bank have launched in January 2004 the "Knowledge-based Economy" project which will install 300 local virtual networks or telecenters in rural communities (Zamfirescu, Filip, & Brbat, 2005). These local telecenters will improve not only the link between citizens

*Figure 1. The situation of the four elements required for the effective implementation of e-government services in Romania*



and the government, but will also provide a better access to information and education (World Bank, 2004).

The USAID-funded Romanian Information Technology Initiative Project, in partnership with the Romanian Ministry of Communications and Information Technology, have organised in September 2005 an e-government forum on building local projects through public private partnerships. The participants to this forum have identified a series of priorities for the future development of e-government applications in Romania. Their conclusions outline that the government initiative should be multi-directional: firstly, it should train and motivate public servants to use information technology; secondly, the general policy framework and infrastructure for digital communications must be designed to support innovation, expand access, and generate trust in online systems; and thirdly, the e-government strategy must be connected to local communities and to the local administration. The next phase of e-government implementation should focus on interoperability, in order to open the wireless access to e-government applications to mobile phone users, at an European level (ITDC, 2005).

## CONCLUSION

In comparison with other countries from Central and Eastern Europe, the implementation of e-government systems in Romania has followed a particular model (O'Brien, 2004). Although the infrastructure, the human capital, and the compatibility with other systems was insufficiently developed, the government has taken important steps for the implementation of e-government services: the launch of the official Web site of the government with a directory containing administrative forms and information, and especially, the introduction of an online platform for e-procurement, which was supported by a clear legislation initiative.

One of the most important factors identified as crucial by the United Nations (2003) report, political will and initiative, is undoubtedly present in Romania. Unfortunately, the access to e-government services is drastically limited by the poor Internet infrastructure, the low Internet penetration, and the level of Internet/computer skills of the population. On the other hand, the existent e-government services are not effectively promoted by central and local administrative services, which creates an additional barrier to an intensive use of the e-government system (Popescu, 2002).

All these problems can be addressed, directly or indirectly, by the Romanian government, in order to harmonise the level of development of all the four elements that are necessary for the effective use of e-government services.

## KEY TERMS

**Citizen-Centric Systems:** E-government systems that are designed to enhance citizens' participation in the political and social environment, taking into accounts their profile, behaviour and needs.

**E-Democracy:** The use of information and communication technologies and strategies by democratic actors (governments, elected officials, the media, political organizations, citizen/voters) within political and governance processes of local communities, nations and on the international stage.

**E-Elite:** Social or political class that have preferential access to information technology, being able to control the information flows in a society.

**E-Government:** The use by government agencies of information technologies (such as Wide Area Networks, the Internet, and mobile computing) in order to transform their relations with citizens, businesses or other government agencies, and to increase the efficiency of their operations.

**E-Payments:** The use of information technology applications and devices to make payments in electronic format.

**E-Procurement:** The business-to-business or business-to-government purchase and sale of supplies and services over the Internet. The organisations implementing e-Procurement systems expect to be able to control inventory more effectively and reduce purchasing agent overhead.

**E-Voting:** An election system that allows a person to vote electronically, using online information technology applications.

# Implementing Enterprise Systems in the Public Sector

**Michel L. Ehrenhard**
*University of Twente, The Netherlands*

## INTRODUCTION

*Modernizing public administration requires a new approach to technology. You can no longer rely on rigid, monolithic service systems. You need technology that can increase efficiency, improve economic viability, enhance process transparency, and help you communicate with the public. You need a public sector solution that supports integrated processes, simplifies service-oriented administration and cost management, and distributes the information needed for judicious planning and decision making.* (SAP, 2003)

## BACKGROUND

Enterprise systems (ES), also known as enterprise resource planning (ERP) systems, appear to be a dream come true as they promise seamless integration of all the information flowing through an organization: financial and accounting information, human resource information, supply chain information, customer information, and so forth (Davenport, 1998). The market for ES has grown enormously during the nineties. Most of the Fortune 500 companies have already installed ES (Kumar & Van Hillegersberg, 2000). For government the promise of ES might even be larger as integrated information flows can support government's processes in numerous ways and help improve service delivery, accountability, and managing for results. As the implementation of ES has proven to be quite difficult due to far-reaching consequences for the organization as a whole, the growing number of government organizations choosing to implement an ES needs to learn from previous experiences. Unfortunately, the scientific literature on ES implementation is mostly limited to the private sector, and as such neglects a substantial part of the organized society. Furthermore, implementation is even more difficult due to the unique nature of government organizations.

The structure of the article is as follows. First, a description of ES is given, as well as the problems that generally surface during the implementation process. Then, public sector issues with information systems implementation are derived from literature on IT in the public sector. Subsequently, the scarce literature in the field of public sector ES implementation is synthesized and discussed. Based on the aforementioned two streams of research and the few studies already conducted, the emerging trends and research opportunities in the field of public sector ES implementation are put forward. Finally, the key findings are summarized in the conclusion.

## ENTERPRISE SYSTEMS AND IMPLEMENTATION ISSUES

What differentiates ES from other types of large information systems? ES are characterized by four main traits. First and foremost, ES integrate the information flows within the organization. Furthermore, ES are commercial packages (i.e., vendors release them). Third, ES consist out of best practices. And final, since every organization is in essence unique, some assembly will always be required; ES integrate the software, not the computing platform.

Due to the sheer size and reach of ES packages, complications during implementation quickly arise. Most notorious is the impact on the organization as a whole. Davenport (1998) points out that ES have profound business implications, and offloading responsibility to technologists is particularly dangerous as technical challenges are not the main reason ES fail. Companies often fail to reconcile the technological imperatives of the ES with the business needs of the enterprise itself. Also, the business often must be modified to fit the system (Davenport, 1998). This means the organizations' business processes need to be reengineered to fit the best practices that comprise the system, which considerably adds to the expense and risk of introducing ES (Kumar & Van Hillegersberg, 2000; Markus & Tanis, 2000). Moreover, vendors try to structure the systems to reflect best practices, but it is the vendor, not the costumer that is defining what "best" means (Davenport, 1998). This means the adopting organization is dependent on the vendor for updates of the package (Markus & Tanis, 2000). Furthermore, achieving full integration depends a lot on the

configuration of the system and the choice for installing just one system instead of modules from multiple vendors (Markus & Tanis, 2000). Still, in addition to having important strategic implications, ES also have a direct and paradoxal impact on a company's organization and culture. On one hand organizations are capable to streamline their management structures, creating flatter, more flexible, and more democratic organizations. On the other hand, they also involve the centralization of control over information and the standardization of processes, which are qualities more content with hierarchical, command-and-control organizations with uniform cultures (Davenport, 1998).

Next to these organizational impacts of ES, organizations also have good reasons not to adopt ES or even abandon ES implementation. Two reasons that are often mentioned is that the packages in the market lack fit with the specific needs of an organization, and that ES have the tendency to inhibit flexibility, growth, and decentralized decision making. Also important are the available alternatives, for instance sophisticated data warehousing or using middleware to change a system's architecture (Markus & Tanis, 2000). To sum up, the main reasons for not adopting a system also hold for ES: high cost, no competitive advantage, and resistance to change.

## INFORMATION SYSTEMS IMPLEMENTATION IN THE PUBLIC SECTOR

Next to the specific characteristics of ES implementation, information systems implementation in the public sector differs from information systems implementation in business. Numerous studies have been conducted to define the differences between the public and private sector, however, still one of the most influential in the field of information systems is the article by Rainey, Backoff, and Levine (1976). They distinguish three main characteristics in which public sector organizations differ from private sector organizations. Usually, public sector organizations are less exposed to the market, resulting in: less incentive for effectiveness, more legal and formal constraints, and higher political influences. Also, due to the unique sanctions and coercive power of government, demands on fair, honest, responsive, accountable, and honest behaviors by public managers are higher. And, public managers need to handle complex—possibly conflicting—criteria, while there is high turnover of politically appointed top managers.

Based on these distinctions Caudle, Gore, & Newcomer (1991) made a study on key information systems management issues for the public sector. Unique and paramount for the public sector is the linking of IS planning and budgeting as a replacement for the allocative mechanism of the market, and freely transferring a technology from one agency to another contrast sharply with private sector IS development. Issues that already have peaked in the private sector but are still on the rise in the public sector are the integration of technologies, end-user computing, and office automation. This lag is most probably caused by limitations by government red tape and accountability requirements (Caudle, Gorr, & Newcomer, 1991). The authors end with some theoretically derived potential issues. Public managers should be more inclined to develop new information technologies than their politically appointed superiors. And, the more red tape the organization has, the more flexible the information technology employed should be.

Even a decade later, Brown (2001) worries about the elementary level of issues mentioned in a UK government report on the delivery of government IT projects. The list of issues that need more attention in the UK public sector—but most probably in all Western governments–includes: commitment of senior management; identifying the end users and their needs; skilled and knowledgeable project managers; breaking down a project into manageable sub-components; adequate training; importance of IT contract definition, negotiation and management; contingency plans in place; and a post-implementation review (Brown, 2001). All these lessons can be found in basic handbooks on IT implementation. Another important lesson rings a bell: key decisions about IT systems are business decisions not technical ones (Brown, 2001; cf., Davenport, 1998).

## PUBLIC SECTOR ENTERPRISE SYSTEMS IMPLEMENTATION

Very few studies have been conducted on ES implementation in the government. After a search for combinations of the words "government" or "public sector," with "enterprise system," "enterprise systems"or"enterprise resource planning" in the "Web of Science" and "Business Source Elite" databases a number of scientific articles appeared. A further selection was made by reading these articles and removing those that included studies in which ES implementation in the government was not the main topic of the study (Ashbaugh & Miranda, 2002; Bannister, 2001; Boudreau & Robey, 2005; Yen & Sheu, 2004), and those that where conducted in a university setting (Scott & Wagner, 2003; Siau & Messersmith, 2003). We removed studies on academic administrations from our selection, as universities are not very representative for government organizations such as ministries,

municipalities, executive agencies, etc. Finally, four articles remained (Chang & Gable, 2002; Gulledge & Sommer, 2003, 2004; Kumar, Maheshwari, & Kumar, 2002). Most noticeable, besides the few studies conducted in total, is that all articles have been published after 2000. It appears that the study of public sector ES implementation is still in its infancy.

The two articles by Gulledge and Sommer (2003, 2004) report on an U.S. Department of Defense installation management enterprise implementation, and two U.S. NAVY implementations. The 2003 article differs from the other articles in the sample as the authors argue that there is nothing special about public sector business processes that insulate them from modern private sector management methods. However, in their more recent article they stress that in the private sector the implementing organization usually owns all of the business processes within its domain, while in the public sector this is not always the case. This can lead to a "split instance": multiple standard software solutions are implemented in a domain that requires a single instance. Gulledge and Sommer argue that this problem is political and driven by the desire of senior management to preserve organizational stovepipes. Bannister (2001) also emphasizes the importance of breaking down specialized vertical system to provide an integrated service to the citizen. Currently, for instance Gortmaker and Janssen (2004) are studying opportunities for business process orchestration in the public sector.

The other two articles (Chang & Gable, 2002; Kumar, Maheshwari, & Kumar, 2002) take a more factor oriented approach as they provide us with vast lists of (sub-) issues. Both studies used surveys to gather their data. Chang and Gable studied five Australian government agencies, while Kumar et al. focused on 10 Canadian government organizations. Chang and Gable choose to use a modified Delphi technique to derive major and sub issues and have respondents weigh the major issues. Unexpectedly, they found very scarce influence of organizational context, including politics. Next to problems with reporting functionality and security, mainly human aspects were problematic. Examples were that few people understood the system beyond a single module, inadequate training, and a lack of understanding between agency staff and implementation personnel.

Kumar et al. based their survey on three of the four phases in the ERP Experience Cycle of Markus and Tanis (2000). The onwards and upwards phase was not studied as none of the organizations in their sample had reached this stage (!). Kumar et al. provide the percentage of respondents that said they had encountered these specific issues. From their research, above all, cost escalation arises as a major issue, whereas human aspects, primarily in the form of training play an important role too. Also, modifying the software and developing add-ons countered a number of ERP limitations. Surprisingly, they found that very few organizations reported changes in organizational structures to support the new systems.

## FUTURE TRENDS

It is important to consider that ES are still evolving in functionality, service arrangements, terminology, and—perhaps most interesting—architecture (Markus & Tanis, 2000). Two future developments in the architecture domain stand out most. One is the evolution of extended ES towards including interorganizational processes such as supplier and customer relation management (Kumar & Van Hillegersberg, 2000). The other is a component-based strategy that would rely on a minimal ERP backbone together with a variety of domain-specific components (see Sprott, 2000). The organization is then responsible for the selection, design or development of their components. In this manner ES will become much more flexible than they are nowadays. Other future developments are the move from transaction data to other types of documents (e.g., multimedia documents, and the move from transaction processing to decision support, data mining, and executive information systems) (Kumar & Van Hillegersberg, 2000).

Additionally, a recent global study among different sectors found that the organizations that already adopted ES, have still fully obtained the promised benefits (Davenport, Harris, & Cantrell, 2002, 2004). The researchers emphasize the need to further integrate, optimize, and informate. Better integration can be achieved by unifying and harmonizing ES, data, and processes with the environment, and better connecting units and processes, as well as with customers and suppliers. Better optimization is reached by standardizing processes to fit best practices, and to fit processes with strategy and systems. And, organizations need to informate: using information to transform work, to support business analysis, and for decision-making needs. An example of an opportunity for government improvement found in this study, was that government organizations were ranked second-highest with management reporting and metrics functionality installed, but failed to utilize this information as they also have the lowest number of performance management functionality installed compared to the business sectors.

A lot of opportunities for public sector ES implementation research exist as the field is still in its infancy. The underlying dynamics of resistance to ES implementation need to be mapped to get past lists of major issues as present in two of the four articles. In the first place, studies in the public sector will add to the general ES implementation literature by contextualizing the findings of previous studies. Will these findings hold in a public

sector environment? Furthermore, there needs to be research into differences between specific governmental sectors. Additionally, the public sector can be fruitful ground for studies into professional or service-oriented organizations. Of course, the important venues Markus and Tanis (2000) mentioned, can just as well be studied in the public sector: financial costs and risks; technical issues; managerial issues; IT adoption, use and impacts; and integration. The Enterprise System phenomenon has strong conceptual links with just about every major area of information systems research. Yet, most rewarding might be the exemplary role government can play in pursuing a components-based strategy, due to the ease of technology transfer. Perhaps, components for government ES can be developed around the globe as open source software (see, Von Hippel & Von Krogh, 2003).

## CONCLUSION

A number of issues can be perceived as well in ES implementation as in public sector information systems implementation. Obviously, the implementation of any system must be seen in a broader perspective then solely technical. In addition, the integration of public sector IT is lagging compared to business. This might also explain the currently limited number of studies on ES implementation in the public sector. From the studies conducted specifically into ES implementation in the public sector we learn a number of things. Foremost, the problems encountered by government are quite similar to those encountered by business. However, a number of typical issues did arise in these studies. The integration of different information flows provided by ES might be terse due to the public sectors' organizational stovepipes. Also, the ES software needed to be modified in half the organizations, which meant that higher investments needed to be made and implementation became more complicated. Furthermore, very few organizations reported changes in organizational structure to support the ES, also the availability and retention of skilled staff was problematic, both possibly inhibited by red tape (see Bozeman, Reed, & Scott, 1992) or other public sector constraints. It is therefore important for public sector organizations to negotiate increased attention on government specific needs for ES (Kumar, Maheshwari, & Kumar, 2002).

Interesting is the statement that there is a theoretical relationship between the amount of red tape and the flexibility of the information technology used (Caudle, Gorr, & Newcomer, 1991). This would either mean that reengineering with ES could abolish vast quantities of red tape, or that public sector ES need to be flexible to adapt to rule-bound public sector organizations. Either viewpoint currently sounds quite utopian. Yet, the most promising future venue might be a component-based strategy, as government is usually more rule-bound and technology sharing should be easier than in business. In this way government can leave its lagging position and leap jump to become a frontrunner in the ES field.

## KEY TERMS

**Component-Based Strategy:** Strategy based on agreed standard interfaces that allow the disparate sets of parts to be assembled, to interoperate and to be upgraded with newer parts that conform to the same interface.

**Enterprise System (ES):** Configurable information system package sold by a vendor, which integrates information and information-based processes within and across functional areas in an organization based on best practices.

**ES Best Practices:** The standard templates for generic business processes instilled in an ES. These best practices may differ quite substantially from the way any particular organization does business and implicitly demand a certain level of process reengineering to reach cross-functional efficiency and effectiveness.

**ES Implementation:** The entire adoption process of an ES system: starting with the idea of introducing an ES, running the introduction project, stabilizing the system, and onward; maintaining the system, supporting the users, getting results, and upgrading.

**ES Functionality:** A business function supported by a software module in an ES. Examples of functions are finance and accounting, human resource, supply chain, customer information, and many more.

**ES Module:** A packaged functional assembly of software for use with other such assemblies within an ES. See ES functionality.

**ES Package:** A package purchased or leased from ES software vendors (like SAP, Peoplesoft, Oracle, Baan, JD Edwards, etc.) instead of being developed in-house from scratch. This means implementers of an ES often need to adjust the organization's ways of working to fit the package, they enter into long-term relationships with software vendors, and they depend on the vendor for continued enhancement of their package.

# Implications of FLOSS for Public Organizations

**Stefan Koch**
*Vienna University of Economics and BA, Austria*

## INTRODUCTION

In the last years, free and open source software (also sometimes termed libre software) has gathered increasing interest, both from the business and academic worlds. As some projects in different application domains like most notably the operating system Linux together with the suite of GNU utilities, the office suites GNOME and KDE, Apache, sendmail, bind, and several programming languages have achieved huge success in their respective markets, both the adoption by commercial companies, and also the development of new business models by corporations both small and large like Netscape or IBM have increased. Given this situation, it did not take a long time for the discussion surrounding this new phenomenon to reach public organizations. Especially the most prominent example, the choice between a free operating system like GNU/Linux or a commercial system like Microsoft Windows has sparked interest in this new form of software, its legal and economic implications, and its new model of software development.

In this article, these implications will be explored, explicitly not focusing solely on the Linux vs. Microsoft debate. To this end, an introduction to free/libre/open source software (FLOSS) and its concepts will be given, then different aspects of the relationship between FLOSS and public organizations, especially e-government, together with future trends will be discussed.

## BACKGROUND

### History of FLOSS

The history of FLOSS (Gonzalez-Barahona, de las Heras Quiros, & Bollinger, 1999; Raymond, 1999; Working Group on Libre Software, 2000) in fact started very early, as in the 1950s and 1960s the first large-scale computers from IBM and others came with software that was distributed with source code, could be modified, improved, and shared.

The history of the current free and open source movement is closely interconnected with the history of the Unix operating system, which after having been largely free, was commercialized following the AT&T divestiture in 1984. This led to the foundation of the Free Software Foundation and the GNU Project by Richard Stallman in 1983 (Stallman, 2002). The aim was to produce a free Unix-like operating system, but for the time being, mostly tools and compilers were produced. Besides this, Unix was also improved at the University of California at Berkeley, mainly funded by DARPA contracts, spawning both Sun Microsystems and the later BSD (Berkeley Software Distribution) family of free operating systems.

Another milestone in the FLOSS movement was the announcement by Finnish graduate student Linus Torvalds that he has been working on a Unix-like kernel for x386-microprocessors (Torvalds & Diamond, 2001), whose source he released and which was to be known as Linux. After this, the movement became known to a wider public, leading to other memorable events like Netscape releasing the source code of the Navigator browser in 1998 (Hamerly, Paquin, & Walton, 1999) thus founding the Mozilla project, the continuing support by corporations like IBM and the rise of new firms like RedHat or VALinux.

### Definition of FLOSS and Licenses

The area of FLOSS is surrounded by several terms, most notably open source software and free software (Dixon, 2003; Laurent, 2004; Rosen, 2004). The term open source as used by the Open Source Initiative (OSI) is defined using the open source definition (Perens, 1999), which lists a number of rights which a license has to grant in order to constitute an open source license. These include most notably free redistribution, inclusion of source code, to allow for derived works which can be redistributed under the same license, integrity of author's source code, absence of discrimination against persons, groups or fields of endeavor, and some clauses for the license itself, its distribution, and that it must neither be specific to a product nor contaminate other software.

The Free Software Foundation (FSF) advocates the term free software, explicitly alluding to "free" as in "free speech", not as in "free beer" (Stallman, 2002). A software is defined as free if the user has the freedom to run the program, for any purpose, to study how the program works, and adapt it to his needs, to redistribute copies and to improve the program, and release these improvements to the public. Access to the source code is a necessary precondition. In this definition, open source and free

software are largely interchangeable. Libre Software is the European term for free software and is used as a way of referring both to free and open source software. The GNU project itself prefers copylefted software, which is free software whose distribution terms do not let redistributors add any additional restrictions when they redistribute or modify the software. This means that every copy of the software, even if it has been modified, must be free software. This is a more stringent proposition than found in the Open Source Definition, which just allows this.

The most well-known and important free and open source license, the GNU General Public License (GPL), is an example for such a copyleft license, with the associated viral characteristics, as any program using or built upon GPLed software must itself be under GPL. To ease these limitations, the GNU project also advocates under special circumstances the use of the GNU Lesser (formerly Library) General Public License (GNU LGPL), which permits linking with non-free modules. There are a number of other licenses, some of which can be considered copyleft, like the X11 license or clarified versions of the original, vague Artistic License, and others which can be considered free or open source, like BSD, Apache or the Mozilla Public License and Sun Public License. Other licenses not considered free or open are for example the Sun Community Source License or Microsoft's Shared Source License.

### FLOSS Development Process

Not only is FLOSS unique in its licenses and legal implications, but also in its development process. The main ideas of this development model are described in the seminal work of Raymond (1999), "The Cathedral and the Bazaar," first published in 1997, in which he contrasts the traditional type of software development of a few people planning a cathedral in splendid isolation with the new collaborative bazaar form of open source software development. In this, a large number of developer-turned users come together without monetary compensation (Hertel, Niedner, & Hermann, 2003; Raymond, 1999) to cooperate under a model of rigorous peer-review and take advantage of parallel debugging that leads to innovation and rapid advancement in developing and evolving software products. In order to allow for this to happen and to minimize duplicated work, the source code of the software needs to be accessible which necessitates suitable licenses, and new versions need to be released often.

Possible advantages and disadvantages of this new development model have been hotly debated (Bollinger, Nelson, Self, & Turnbull, 1999; McConnell, 1999; Vixie, 1999). Critics admonish that the largely missing requirements engineering and design, together with the trend to search for bugs late in the life-cycle in the source code lead to high effort, which is just hidden by spreading it throughout the world, but this is countered with arguments of very high modularity, fast release cycles and efficient communication and coordination using the internet. Today, agile methods like eXtreme programming or the strict release processes in place in several open source projects (Holck & Jorgensen, 2004) give evidence to mixed forms of development. Currently, empirical research on similarities and dissimilarities between FLOSS development and other development models is still proceeding (Koch, 2004; Mockus, Fielding, & Herbsleb, 2002).

## IMPLICATIONS OF FLOSS FOR E-GOVERNMENT AND PUBLIC ORGANIZATIONS

### Overview

In this article, the possible implications of and interactions with FLOSS will be detailed from the viewpoint of public organizations. There are several main areas which are to be distinguished. The first case is a public organization adopting FLOSS, the most prominent example certainly being the choice between GNU/Linux and Microsoft Windows. It is to be analyzed what influences this decision in the general case of any organization, and what special considerations affect this decision for public organizations. In the second area to be considered, public organizations leave the role of passive users and become co-developers. Besides feeding back their own improvements to any project, public organizations might also act as sponsors of FLOSS projects or ideas out of various reasons. In the third and last area to be considered, public organizations interact with FLOSS as regulatory authorities (e.g., regarding software patents).

### Public Organizations as Adopters of FLOSS

The public sector needs to change over to communicating digitally, which is posing great demands on the IT systems on which e-government is based and on work processes in the public sector. This change, especially in the current situation of tight budgets, needs to be made as cost-effectively as possible. As the most obvious characteristic of FLOSS when selecting software is the price, or more correctly the absence of price in the form of license fees, many public organization facing a decision regarding procurement of software consider it. Most prominently this is embodied in the decision between a Microsoft

Windows operating system together with MS Office Suite and competing FLOSS products like GNU/Linux together with GNOME or KDE graphical user interface and OpenOffice.org suite.

But the absence of license fees does not present the whole story, and in addition makes any criticism by proponents of commercial products easy. Any decision in software procurement needs to be based, besides the functionality offered, on the costs over the whole lifetime of the software (Danish Board of Technology, 2002). This viewpoint, as exemplified by the term total cost of ownership (TCO) introduced by Gartner Group, calls for a more thorough analysis of cost factors, not only regarding initial costs of procurement. As there are several proprietary variants of this method available, the different cost categories are not generally defined, but using a generic set of different cost factors throughout the lifetime of a software (Working Group on Libre Software, 2000), possible advantages and disadvantages of FLOSS can be discussed. Naturally, any investment needs to be evaluated carefully on its own. While the pure costs for acquisition are lower due to absence of license fees, prior information gathering might incur higher costs due to decentralization and lower marketing (Golden, 2005). On the other hand, information found will in general be more objective. Regarding implementation of the software, no clear picture can be found, as on the one hand probably less sophisticated installation routines and lower penetration and therefore availability of personnel might hint at higher costs for FLOSS, while on the other hand generally more diverse options for configuration and even changes to the source code might decrease costs. Training might in some special cases benefit from access to the source code as well, but for some FLOSS availability of professional training services poses a problem. Costs for operation and maintenance might be reduced by the possibility for changes to the source code, the availability of a community of co-developers, absence of lock-in to a single supplier and thus increased lifespan, but again lower penetration with scarcity and thus increased price for experienced personnel might be problematic. The transition to a new technology will be eased in the case of FLOSS by availability of the source code and the adherence to open standards, both considerably reducing these switching costs (Shapiro & Varian, 1998). For the most prominent case currently discussed, GNU/Linux vs. MS Windows, a plethora of studies have been made available (Fink, 2003; Rosenberg, 2000), some having been sponsored by public organizations like the cities of Munich (http://www.muenchen.de/linux), Vienna (Gillich, 2004) or Paris, by independent bodies (Danish Board of Technology, 2002), and some inspired by business interests. From a scientific viewpoint, these are difficult to evaluate and compare due to different scenarios applied, and also sometimes secrecy regarding the methods used. The MigrationNavigator (http://www.migrationnavigator.org) tries to help in selecting an appropriate study on migration to GNU/Linux and open source based on an evaluation using a set of criteria including areas covered and focus of analysis.

But cost is not the only factor in IT investment decisions. Indeed, especially FLOSS offers to the user additional freedoms, and these freedoms might indeed have value (Danish Boards of Technology, 2002). For some of these, real options analysis (Taudes, Feurstein, & Mild, 2000; Trigeorgis, 1998) which aims at using option-pricing theory to value flexibilities, might be a possible way of expressing their possible financial return. The first advantage comes from the option to modify and enhance the software at will, in addition to thoroughly checking for any bugs. Some of this work can be relegated to the project's community and thus outsourced, but both direction taken and effort applied are difficult to predict. In general, this will increase the lifespan of a software, as it can be adapted to cope with new platforms or technologies. As a further freedom, the usage of the software is not restricted, so it could be used in other parts of the organization, for other business processes, or even to pursue some business models. Flexibility for the user is also increased or at least preserved due to the fact that there is no single supplier which can possibly terminate support or further development in order to induce switching to a new product.

The main risks currently associated with adopting FLOSS as voiced by organizations are of a legal nature. Naturally, these apply to public organizations as well (Suzor, Fitzgerald, & Bassett, 2004). The first of these is that there is no party who would assume liability, which although probably true when FLOSS is downloaded directly from the project's Web site, need not necessarily be true if a consulting company is involved, and also generally depends on the applicable legislation. Other legal concerns deal with issues of copyright and intellectual property, and are fuelled by SCO's campaign against Linux vendors and users.

Regarding the functionality, a general discussion of FLOSS vs. commercial products surely is not possible, and is even difficult for the case of MS Office and OpenOffice.org. On the other hand, the issue of security which might be, especially in some areas of e-government like e-voting, a primary issue and concern, is often disputed (Payne, 2002; Witten, Landwehr, & Caloyannides, 2001). Proponents of FLOSS argue that open source code allows for parallel review by many people, including in-house auditing, and faster patch releases when problems are found, as there is no dependency on a single vendor to do this, who might be motivated not by purely technical but also commercial considerations. On the other hand, possible attackers

also gain access to the source code and can thus probably more easily uncover loopholes. Currently, data seems to show that indeed FLOSS systems tend to be more secure, but most accounts currently are centered on the operating system field and are not yet conclusive (Payne, 2002; Witten et al., 2001). The fact that FLOSS generally supports open standards is also of high interest in the context of e-government and especially digital communication between the public sector and citizens, as it will allow for universal accessibility of all material produced.

For some public organizations, for example those active in development like the United Nations, the fact that even proprietary software offered for free creates dependencies and does not allow for further sharing, deeper understanding and thus technology transfer, modifications and maybe even pursuing respective business models might increase adoption or at least promotion (Yee, 1999).

Currently we already see some adoption, for example the city of Munich started the "LiMux" project, an evolutionary migration following long discussions also regarding legal risks. In Vienna, a soft migration is planned, in which users have the option of switching to FLOSS, resulting in the IT department charging them less money. Worldwide, for example the Brazilian government started an initiative to migrate 40 percent of its computers to FLOSS by 2006, a similar move being planned in Venezuela. Other countries very active in considering FLOSS adoption are Japan, drawn in by the security aspect, South Korea and China, which has expressed its commitment to building a domestic software industry around Linux, which is also an aim of the Indian government. This is but a small snapshot of current activities, and discussions are still proceeding, as most initiatives have not yet been passed or implemented.

## Public Organizations as Producers of FLOSS

At the heart of the FLOSS development model lies the idea that users abandon their passive stance and join the development team themselves. These contributions could be as small as reporting bugs found, joining discussions on the future directions, or could include fixing bugs or programming additional functionality. Naturally, this could apply to public organizations as well. As the adoption is still limited as described above, this effect is not yet seen to a large degree, but a cooperation having been announced between Munich and Vienna, including for instance for the development of a "public authority desktop" or of an open source groupware, can be seen as a first step. This can also be seen as the start of a new trend: Public organizations pursuing FLOSS business models. While some of the proposed models (Fink, 2003; Golden, 2005; Raymond, 1999; Rosenberg, 2000) are not applicable, cost-sharing, or risk-spreading by opening the code seem to be appropriate.

More than this, public organizations have other means at their disposal as well, especially sponsorship of FLOSS development. For example, Japan has reserved 1bn yen (EUR 80m) for a project that aims to build an inexpensive and trustworthy FLOSS operating system. Another example would be the POSSE project funded by DARPA, an agency which is part of the U.S. DoD, to develop a "trusted" operating system and generally increase security (Smith et al., 2004). The European Community is endorsing FLOSS in the IDA (Interchange of Data between Administrations) programme to co-ordinate the establishment of networks between administrations, and is also sponsoring several related projects in the Sixth Framework Programme for Research and Technology Development, as does the U.S. National Science Foundation.

In fact, one of the roots of the FLOSS idea is that software that has been developed using public funds should not be owned by a private company to gain profits from, but should be preserved as a public good. For example, the software that the X and BSD licenses originally covered was funded by monetary grants of the U.S. government. Since the U.S. citizens had already paid for the software with their taxes, they were granted permission to make use of that software as they pleased (Perens, 1999). Some U.S. states, including Massachusetts, have passed laws prohibiting commercial entities from making money off products developed by the government using taxpayer money. The European Environment Agency (EEA) has for many years made it a requirement that custom built software is supplied as open source.

Criticism voiced towards this point of view centers around the fact that especially software under GPL would also require further extensions to be under the same license, thus stifling innovation based on this research by commercial firms (Hahn, 2002). Naturally, this discussion leads to the more general issues of whether there is a market failure in software industry that warrants intervention, and whether protection of intellectual property is beneficial to innovation or not. These are addressed in the following paragraphs.

## Public Organizations as Regulatory Authorities

In their last role, public organizations face the FLOSS movement as regulatory authorities. Some governments including Germany, France, Spain, and Argentina are currently considering bills pertaining to FLOSS adoption

by public organizations (Hahn, 2002). In Brazil, several municipal governments mandate FLOSS to be given preference. Naturally, these initiatives face criticism as well, for example on the grounds that governments should not intervene in a free market environment but simply pick the best solution for the case at hand (Hahn, 2002). Therefore again, this comes to the question of whether there is a market failure in the software industry. While some authors argue that there is indeed a market failure in packaged software due to incomplete contracts and asymmetric information, and while it is possible that in markets exhibiting network externalities (Shapiro & Varian, 1998) inferior products might come to dominate, the fact itself is very much disputed (Hahn, 2002). In any case, FLOSS might increase competition even in markets with a dominant producer, and might play an important role in enforcing standards by providing reference implementations, thus again reducing possible lock-in of consumers by commercial firms (Shapiro & Varian, 1998; Working Group on Libre Software, 2000).

Even more importantly than this promotion of FLOSS adoption, governmental authorities are today facing decisions which will possibly change the course of this phenomenon and the software industry. The most prominent example is the case of software patents. The economic principle behind a patent is that it provides an incentive by offering a monopoly both to invent and to invest in invention. While copyright is granted on the implementation, the actual program, and is not opposed but in fact used by the FLOSS movement, patents are granted on ideas that could be implemented in software. Possible patent infringements of FLOSS therefore pose a substantial problem and might threaten the whole FLOSS movement (Hahn, 2002; Vemuri & Bertone, 2004). The issue of the patentability of software and its algorithms therefore has been and still is hotly debated, currently in the context of the European Union. After a draft directive was submitted by the European Commission in 2002, the European Parliament approved but only after introducing a number of significant amendments. In 2004, the Council of the EU reached a first political agreement on a compromise, which only includes a minority of these amendments. However, it has failed to formally adopt the revised draft, as several member states have expressed doubts about the agreement.

In this discussion, a general economic question is asked: Is the protection of intellectual property a necessary precondition for research and development? Will the software industry collapse, building no more new software products, if software patents are not passed? This issue of whether patents are beneficial or not is hotly debated (Hahn, 2002). For example, Beimborn and Hoppen (2004) used a simulation approach, showing that patent protection is globally efficient only in markets with a relatively low profit potential.

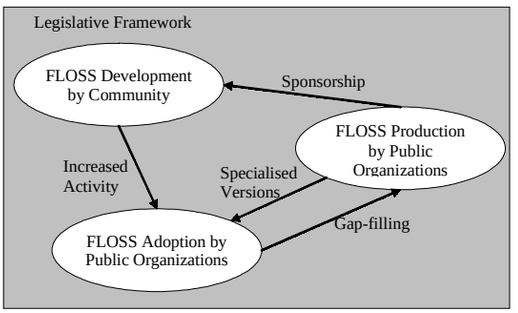
On a grander scale, the ideas of FLOSS are starting to challenge conventional wisdom in fields other than software development (Lessig, 2001, 2004; Perelman, 2002; Vaidhyanathan, 2001). For example, FLOSS-type licenses have been developed for written material, at first for software documentation, later on for scientific material and now in general. There are free academic journals, and whole books on the Web having been placed under such licenses. Even the Freedom of Information Acts, established for example in the U.S. and U.K., could be seen in this light.

## FUTURE TRENDS

Using the main areas of relations as previously defined, we see the following future trends that public organizations will have to face. In the area of adoption of FLOSS, the discussion will be prolonged, and will reach beyond the classical topic of GNU/Linux vs. MS Windows into functional areas in which FLOSS implementations are currently making considerable progress. These will include areas like groupware or content management but also increasingly facets of enterprise resource planning. These trends will lead to an increased number of consulters offering services for FLOSS implementation and support, alleviating some of the current problems. In this situation, choosing the optimal software is a challenging task for a public organization. Any decision-maker is advised to at least consider any FLOSS alternatives for the current situation. In the future, IT investment decisions also in public organizations will and should become more methodologically sound. This includes a thorough evaluation of costs throughout the whole lifecycle, and even a quantification of strategic flexibilities afforded by FLOSS, for example using real options analysis.

The production of FLOSS by public organizations is currently largely not pursued by the normal process of a user becoming co-developer by contributing his own modifications, but by other means including sponsorship. In the future, continuing efforts in sponsorship are to be assumed, as several governments and bodies like the European Union are considering FLOSS licenses for research based on their grants. Increased adoption will also put more pressure on public organizations to become producers of FLOSS themselves, in order to fill any gaps uncovered in the available software, which in turn will strengthen adoption by providing specialized software. This is presumed to take the form of partnerships in several cases, like the cooperation having been announced between Munich and Vienna for the development of a

*Figure 1. Relationships between FLOSS and public organizations*



"public authority desktop." Such initiatives can serve to reduce both costs and risks for the parties involved, and will present a worthwhile option for public administrations.

The regulation of FLOSS will certainly have the biggest effect, both considering policies for mandatory adoption in public organizations, and most notably landmark decisions in the future regarding especially software patents. Such decisions will surely shape the future of the software industry, if not even development of larger issues of intellectual property.

Following, all of these possible relations form a coherent picture for the future, in which the different areas have effects on one another. In particular, we see a positive feedback loop between adoption and production of FLOSS in public organizations, while all areas are deeply affected by the legislative framework installed. These relationships are depicted in Figure 1.

## CONCLUSION

In this article, the implications of FLOSS for public organizations and e-government have been discussed. As this issue of FLOSS and its development has been a hot topic for some years, it has also reached these organizations. As has been shown, FLOSS and public organizations currently interact on many levels, in the areas of adoption, production and legislation, and this situation is not likely to change for some time to come. Therefore an increased understanding of what FLOSS and its development process indeed are, and what the wider implications of this movement, even beyond the software industry, might be, is a necessary step.

## KEY TERMS

**Free/Libre/Open Source Software (FLOSS):** Software under a license which grants several freedoms to the user, most notably access to the source code, possibility for modifications and free redistribution.

**Free/Libre/Open Source Software Development:** A collaborative form of software development, which postulates that a large number of developer-turned users cooperate under a model of rigorous peer-review and take advantage of parallel debugging that leads to innovation and rapid advancement in developing and evolving software products.

**Free/Libre/Open Source Software License:** A license which grants several freedoms to the user, most notably access to the source code, possibility for modifications and free redistribution. Software under such a license is called free/libre/open source software.

**GNU General Public License (GNU GPL):** A FLOSS license advocated by the GNU project, which enforces copyleft. This means that every copy of the software, even if it has been modified, must be under GNU GPL.

**Network Externalities:** An economic term describing the effect that a product's value to a consumer changes as the number of users of the product changes.

**Real Options Analysis:** A modern investment appraisal strategy, which argues for including any flexibilities available to the management inherent in a project into the project's value using option-pricing theory. Possible real options in IT projects would be to defer investment, cancel the project or change their scope.

**Total Cost of Ownership (TCO):** In order to correctly assess the costs associated with a given software or other IT asset, the costs during the whole lifetime need to be evaluated. This includes the costs for purchasing, installation, maintenance and also termination or switching.

# Identity Management and Citizen Privacy

## INTRODUCTION

E-government systems aim to transition traditional paper-based systems to "paperless" digital information systems to automate and streamline government operations and services. This transformation to digital form raises daunting challenges related to protecting identity and privacy of the citizens. Electronic fraud and identity theft are among the biggest risks to an e-government system that may potentially undermine its success. The CSI/FBI 2005 (Gordon, Loeb, Lucyshyn, & Richardson, 2005) Computer Crime and Security Survey reports more than $30 million in losses attributed to theft of proprietary information and more than a $31 million dollars loss related to unauthorized accesses. According to the data collected by the Consumer Sentinel and Identity Theft Data Clearing House, identity theft accounts for almost 40% of the fraud complaints (FTC, 2005). It is estimated that billions of records are available in both private and government databases describing each citizen's finances, interests, and demographics. For instance, personal healthcare information about the diseases and health cases inflicting the general population are available in different places including insurance companies and pharmacies. While accessing such data is important for detecting epidemics and bio-terrorism, such accesses can easily encroach into citizen privacy. This demands a balancing act in dealing with issues related to privacy, accountability, national security, and/or good governance. Because of the heterogeneity of an e-government system, the task of protecting identity information as citizens interact with different sub-systems becomes exacerbated. Users typically may need to maintain multiple identities or complete anonymity while interacting with multiple interoperating systems raising severe privacy and identity management problems. For an e-government system to be reliable, and hence successfully deployed, the privacy and identity management issues need to be properly addressed and incorporated in its infrastructure design.

Privacy may be defined as *"the right of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated"* (Jajodia, 1998). Thus, unlike security, which is *organization-centric,* privacy is a *person-centric* concept and refers to the control that an individual has over the use of his or her personal information. One aspect of the privacy problem is the anonymity of the users, which is aimed at protecting the *identity* of the users. The *identity* of an individual is a collection of personal data associated with the individual that uniquely identifies him or her. Associated with each identity is a set of attribute-value pairs, also known as *credentials*, typically representing a user's qualifications and personal attributes including sensitive personal information such as name, age, and social security number. The capability to identify entities (subjects, objects, and resources) is essential in order to know what to protect from whom. Depending upon the context, a subset of the identity may be used to signify an individual. Such a "*partial identity*" is typically bound to the individual with a *pseudonym* (Köhntopp & Berthold, 2000), and may or may not uniquely identify the individual. Typically, multiplicity of identities for individual entities becomes necessary because of the requirements of anonymity, personal data protection, and controlled access to resources in multidomain e-government systems. Moreover, the notion of privacy and identity is inherently complex and may often be contradictory; furthermore, each stakeholder could have a different perspective on them. In large multidomain e-government system, identity management would typically aim towards providing mechanisms that ensure identity dependability to build and maintain trust and confidence between the interacting entities.

## E-GOVERNMENT PRIVACY AND IDENTITY MANAGEMENT ISSUES

An e-government provides citizens with services that involve processing their personal information. With more and more personal information being stored in multimedia format (text, image, audio, and video), much heightened socio-psychological concerns with regards to privacy can be seen. Privacy vulnerabilities arise even if data is available in statistical or aggregate forms, or that allow personal information to be inferred. Furthermore, the fact that the government can carefully monitor every transaction and resource accesses made by a citizen can discourage citizen participation, thus affecting successful deployment of e-government systems. Compared to the general e-commerce environments, the e-government systems have increased obligation/responsibility towards maintaining privacy of the citizens (Dempsey, 2003).

### Challenges

Several privacy and identity management related challenges exist that need to be addressed to ensure the success of an e-government environment.

#### Privacy Policy Specification

Development of a comprehensive privacy policy specification framework is a major challenge. There is a need for an expressive privacy policy specification and enforcement framework that supports flexible, fine-grained policy specification, and facilitates auditing and monitoring while maintaining scalability as well as cost-effectiveness. In particular, users' privacy preference could be very diverse, and could depend on the context and purpose of use of personal information. In general, natural language based specification would be immensely desirable but it can introduce severe problems in machine-readability, introducing difficulty in removing ambiguity and consistency in the policies. Formal, expressive languages are necessary and should be augmented with scalable correctness evaluation tools to facilitate proper administration and enforcement of privacy policies.

#### Active Content

One privacy challenge is introduced by Internet technologies such as Web browsers, whose vulnerabilities can be exploited to compromise privacy. For instance, cookies, the data stored on the client's machine and exchanged between the clients and the server to maintain connection information, can be used for the purpose of gathering user information. Use of executable content such as Java applets and ActiveX controls is another source of security vulnerability, that could be used to obtain personal information. Tools and techniques to ensure that such active content does not violate privacy requirements of users are crucial.

#### Multidomain Environment

Two characteristics of e-government services exacerbate privacy and identity management problems: (1) sharing of citizens' information among different government agencies and (2) differing privacy preferences of the citizens, heterogeneous privacy requirements of different e-government sub-domains, and potential use of identities to access different e-government sub-systems. While facilitating citizens' services, e-government domains may need to exchange users' information, including their identities and credentials. Further, the domains' privacy policies themselves may need to be integrated to provide transparency of the underlying privacy-preserving information sharing activities. Diverse privacy requirements of the citizens need to be addressed by the e-government infrastructure to ensure that all citizens feel safe to interact with the e-government systems. Further challenge is to facilitate unknown users to interact with e-government systems raising trust issues coupled with privacy requirements. A facility to establish trust between e-government systems and the users without unnecessarily divulging sensitive information is essential. To benefit from different applications one often requires multiple identities, which introduce multiple risks of exposure and fraud. If a user has to authenticate each time he accesses a different e-government sub-systems, it will involve multiple risks of identity theft.

#### Anonymity

Users often prefer anonymity during online transactions particularly when his or her activities can reveal sensitive information about him or her. A partial identity that cannot be used to uniquely identify an individual provides a degree of anonymity. Anonymity does not imply that no information is released; instead, the released information should not reveal the actual identity of a user (Damiani, di Vimercati, & Samarati, 2003).For example, a patient may collect/order medicine from a pharmacist anonymously. Here, the pharmacist should be able to associate the patient's partial identity to the prescription. Some interactions, however, cannot be conducted anonymously, for example when a doctor diagnoses a patient, his or her identity must be uniquely verified and his or her health records must be accessed.

### Information Inference and Privacy

Information inference makes privacy difficult in today's IT environments where different pieces of private information are stored in different sources. Given access to different sets of someone's personal data which are not sensitive, it may be possible to infer unauthorized, sensitive personal information about him or her (Thuraisingham, 2003). Emerging sophisticated data mining tools that can associate different pieces of personal information severely exacerbate the inference problem. For instance, mining of pharmaceutical purchases could indicate that a user is possibly suffering from a particular disease. At the same time, use of data mining tools may be useful for many purposes, such as detecting impending bio-terrorism or furthering discoveries. The key challenge is to ensure balanced use of such tools for privacy protection vs. other benefits.

## Approaches to Privacy and Identity Management

Several technologies that address privacy and identity management issues have emerged which are applicable to e-government systems.

### Privacy-Aware Access Control

A fundamental approach to privacy enforcement is data protection. Privacy can be viewed as contextualized and purpose based access control. Traditional discretionary and mandatory access control (DAC and MAC) have limited capabilities in capturing privacy requirements. Newly emerging advanced role-based access control (RBAC) models show better potential to address the privacy needs by defining roles with "*need to know*" constraints related to private information (He, 2003). Bertino (2005) proposes a *purpose based access control* that determines purpose when data is created and allowed to be accessed. In general, emerging context based access control approaches can be used to enforce privacy requirements.

### Privacy-Enhancing Technologies (PET)

PETs enhance personal privacy by either preventing unnecessary access to information or by allowing citizens to have control over the access to their personal information. Different PETs have been developed to enforce *pseudonymity, anonymity, unlinkability* (cannot link information pieces for inference), *unobservability* (cannot observe effect of an operation), *unlawful/unnecessary* processing of personal information (Borking, 2001). Some of these technologies are new and expensive for practical adoption. Several tools such as *Web anonymizers* and *remailers* currently provide support for achieving some level of privacy. However, there also are tools that offset these, such as *snoopware* that locate personal data on the Web, and *stealthware* that essentially monitors client behavior.

Rigorous guidelines and frameworks are being put in place as a result of the e-government strategies under the *Presidential Management Agenda* (OMB, 2002). Some of the enabling technologies such as *XML key management specification*, X.509 Certificates, Web services trust, Security Assertion Markup Language (SAML), eXtensible Access Control Markup Language (XACML), Service Provisioning Markup Language (SPML), Kerberos, and WS-SecureConversation provide credential, PKI, authentication, provisioning and authorization services that can support privacy enforcement. Existing solutions like IBM's Tivoli software, Microsoft password, Oracle's 10g Oracle Identity Management, Microsoft's Single-Sign-On system, among others, provide components for identity management and provisioning.

### Platform for Privacy Preferences

P3P is an emerging privacy solution that uses *privacy profile management*. P3P essentially allows users to set their Web browsers to read a Web site's privacy policies and set the user's privacy profiles accordingly. P3P is the most widely suggested tool for privacy enforcement (McIver, 2004), and has become the suggested standard in the U.S., Berthold and Kohntopp (2000) use APPEL (A P3P Preference Expression Language) for identity management, using privacy profiles defined by the users themselves. IBM's Enterprise Privacy Authorization Language (EPAL) is an extension of P3P.

### Privacy Assurance

Third party verification of privacy enforcement mechanisms is essential to build citizen's confidence in the system. Some approaches and tools towards this include privacy impact assessments (PIA), privacy commissioners, CPA WebTrust, BBBOnline, and TrustE. (Dempsey, 2003). PIAs should be performed by an agency external to the agency involved in the possible violation of privacy. Privacy Commissioners are the proposed agencies that oversee privacy protection for the nation.

### Policy Integration

An approach to privacy protection includes using sticky policies along with technologies like identity-based en-

cryption (IBE) and Trusted Computing Platform Alliance (TCPA) (Mont, Pearson, & Bramhall, 2003). Technologies such as X.509 Certificates WS-Trust, SAML, XACML, SPML, Kerberos, WS-SecureConversation facilitate policy integration in multidomain e-government environments.

### Inference Control

An approach to privacy is to modify personal data such that private information is not be revealed from the accessed data. For example, an initiative of IBM deals with non-personal demographic data of a group of data with no accesses to any private details. Another similar approach randomizes data such that aggregated information is comparably accurate to the actual data, but with the effect that individual private data cannot be accessed (Clifton, Kantarcioglu, Lin, & Zhu, 2002, Efvimievski, Srikanth, Agrawal, & Gehrke, 2004). Yet another approach is to selectively make data anonymous according to the needs of the uniqueness of the data. An approach used in database applications is to distribute the database such that no private data can be accessed from any one database. Privacy-preserving data mining techniques are commonly used to ensure that information is not inferred by using mining data sets. In particular, such tools aim at modifying or trimming sensitive raw data before mining tools can process them or the knowledge that can be inferred using data mining is excluded by applying some privacy-preserving algorithms (Clifton et. al, 2002).

## Usability, Standards, and Legal Issues

As privacy issue is inherently person-centric usability and human factors, as well as socio-legal and standardizations issues related to privacy need to be properly addressed to build a comprehensive privacy protection framework.

### Usability, Human-Factors

Technology, however good it is, may be wasted if it is not adopted by users, and this is particularly applicable to privacy. Hence, a privacy framework should emphasize the usability factors. Studies have shown that many users are unaware of privacy rights and enforcement tools. Others believe that privacy is not a big enough concern to worry about (Brodie, et al., 2005). The primary reason for this is the lack of awareness of the privacy enforcement solutions and the lack of proper interfaces for privacy policy specification. A recent study carried shows that usability aspects should address the following key features, (Cranor & Garfinkle, 2005):

- **Language of Specification:** Natural language or machine readable language depending on the proficiency of the user
- **Complexity of the Preferences:** Privacy preferences are context-dependant and privacy is sometimes traded because of the difficulty of specification
- **Presentation of Laws and Regulations:** Users should easily understand what privacy rights they have
- **Efforts and Learning Curve:** Users should be required to put in minimal efforts in learning privacy solutions
- **Visualization of the Policy:** Users should be able to view the policy they have specified, be it through use of icons, natural language statements or even graphics

### Standardization and Legal Issues

With the abundance and diversity of different systems, different standards have come to existence. For example, NIST SP 800-25 provides guidelines for PKI technology for digital signatures and authentication for federal agencies. E-authentication service component was established as a part of the E-Authentication Initiative by the General Services Administration (GSA) Office of Government-wide Policy (OGP) to enable trust and confidence in e-government transactions through the establishment of an integrated policy and technical infrastructure for electronic authentication. Through this initiative, citizens, businesses, and governmental entities are expected to have simpler access to multiple agency applications through the re-use of credentials and established identities. However, a major challenge still facing identity management remains one of uniformity between different standards and trust establishment mechanisms. Non-conformity between standards still exists due to dissimilarity of government agencies. A solution is to use standardized smart cards. In particular, auditing requirements for the identity management system that provides some degree of "*identity assurance*" is desirable. A solution proposed is that of using a federated identity management (FIM); however, it is limited to Web-services based infrastructure only (Shin, Ahn, & Shenoy, 2004). The emerging compliance requirements such as HIPAA, Gramm-Leach-Biley Act, Sarbanes-Oxley, EU Data Protection Directive, and California Bill 1386, have exacerbated the privacy problem.

Privacy policies are typically based on the country's privacy laws. For instance, in the US, the privacy policies are guided by *Section 208 of the E-Government Act of 2002.* Several guidelines, such as the *Principles of Fair Information Practices* have been defined for enforcing privacy policies. Other constitutional acts such as *Sec-*

*tion 208 of the U.S. E-Government Act*, 2002, the *EU Data Protection Directive*, 1995, and so forth, outline the privacy requirements expected of any information system service. Unfortunately, the 2004 Global E-Government report shows that only 14% of e-government systems implement privacy policies. A challenge to privacy policy development is its conformance to the country's legal, social, and ethical environment. Some countries do not provide citizen privacy at all (McIver, 2004).

## A Privacy Framework

Figure 1 presents a comprehensive framework for privacy and identity management.

### The Non-Technological Plane

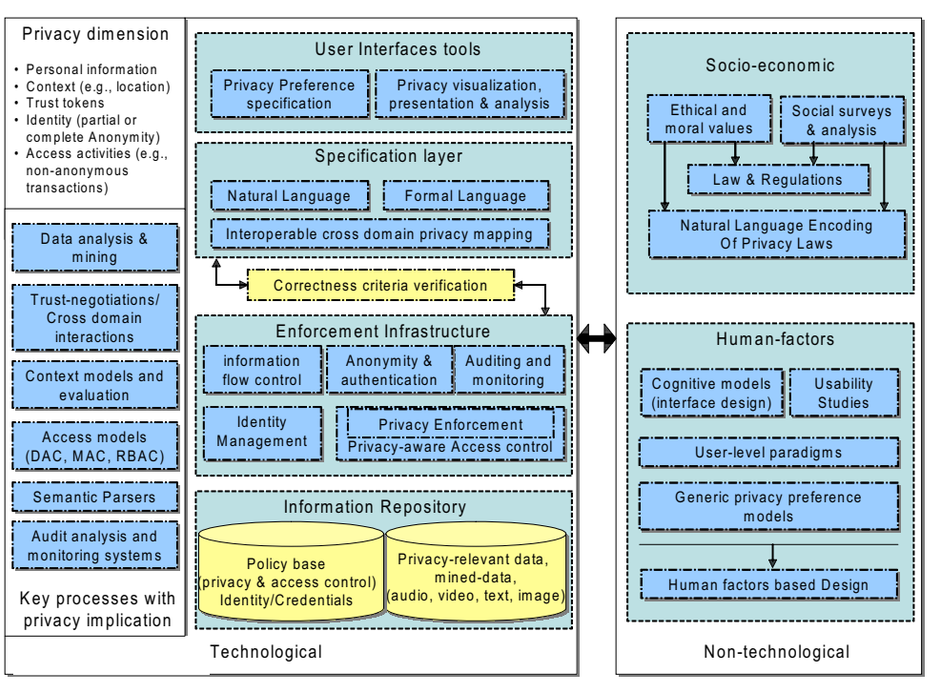
This aspect of privacy refers to the socio-economic and human factors that have significant privacy implications. A key issue is to capture the legal and socio-economic factors into the privacy policy guidelines. Similarly, cognitive models of user's perception of privacy and interface requirements, generic privacy preference models and usability studies should derive the human-factors based design principles that should be incorporated into the development of privacy solutions.

### The Technology Plane

The components of this layer are the technologies and technical concepts associated with privacy protection. Effective user interfaces are crucial for deploying usable privacy solutions. In particular, tools are needed to facilitate specification of users' privacy preferences, and their presentation (e.g., visualization techniques). The specification layer primarily contains language technologies (NL-based/XML/SAML) that provide efficient machine readable encoding of both the users' privacy preferences and the domains' privacy policies to ensure privacy-preserving interactions. Correctness verification of specified policies and policy mappings is essential and primarily includes static analysis of consistency and safety issues.

The enforcement infrastructure contains key components required to enforce privacy policies, auditing functions, identity management procedures, and anonymity/authentication functions. The information repository (IR) includes information that has privacy implications. Note that access control and privacy policies themselves are included in IR. For instance, revealing policies during trust-negotiation could also reveal sensitive private data. The correctness verification module supports the enforcement mechanisms to handle dynamic constraints.

*Figure 1. A comprehensive privacy framework*



Various mechanisms and processes that have privacy-implications are shown on the left block. Techniques to address privacy concerns raised by these need to be properly synthesized in the specification as well as enforcement layers. For instance, consider the inference problem associated with data mining. This can be addressed by the information a flow control module. Alternatively, as new information is mined, new access control policies could be dynamically generated to ensure that such inferred sensitive information is not allowed to be accessed.

The key privacy dimensions include: *privacy of personal information*, *anonymity*, *context privacy*, *trust token privacy,* and *access privacy*. First two deal with selective protection of personal information and identity. Context privacy deals with the privacy of a user's current context (e.g., location information). Trust token privacy is associated with trust negotiation mechanisms and refers to the privacy of the various credentials that are not involved in trust negotiations; these may include personal information as well as other profile information. Access privacy refers to privacy of access activities.

## CONCLUSION

In this article, we have discussed various challenges and existing solutions related to privacy and identity management. Solutions for these challenges are new, have not matured, and have not yet been synthesized into a comprehensive solution that is desirable for an e-government system. Identity management and privacy issues thus have the potential to pose a roadblock to the successful deployment of e-government systems. We have also presented a comprehensive privacy framework that integrates the non-technological and technological components. Such a holistic framework is essential to enable a high assurance privacy protection infrastructure for an e-government system.

## KEY TERMS

**Inference Problem:** Inference problem refers to the situation when different pieces of less sensitive information about some entity reveal a more sensitive piece of information about it.

**Privacy-Enhancing Technologies:** Technologies that enhance personal privacy by either preventing unnecessary access to information or by allowing users to have control over the access to their personal information.

**Privacy Impact Assessment:** A formal process to identify and assess privacy implications and its impact.

**Privacy:** The right of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated.

**Privacy-Preserving Data Mining:** A data mining mechanism that ensures mined data contain no sensitive personal information.

**Security Assertion Markup:** An XML standard for exchanging authentication and authorization data between security domains.

**Trust Negotiation:** A mechanism of establishing trust between strangers that involves selective exchange of sensitive credentials to establish mutual trust

**Usability:** The degree of user-friendliness and convenience or ease of use of a technological solution.

# Information and Communication Technology and Good Governance in Africa

**Godwin Onu**
*Nnamdi Azikiwe University, Nigeria*

## INTRODUCTION

The 20th and 21st centuries have witnessed major paradigm shifts in the conceptualization of development and governance. These phenomena are aided and propelled by a new "network intelligence" consummated in the introduction of information and communication technology (ICT). The world has also witnessed a reinvention of the whole process of governance that has impacted society in various ways. Through the Internet and digital connectivity, today's world has come to be closer than ever before. Efficiency and processes of governance have been improved through faster information flow in the governance chain. Bottlenecks and cost of labor have been reduced across the world. Furthermore, ICT has opened new possibilities, improved transparency and access to information as well as partnership and collaboration, leading to improved relationships between the citizen and state. While Europe and North America, as well as some countries of Asia and the pacific, have taken advantage of this development to improve their economies and governance process, Ningo (1999) observes that sub-Saharan Africa has remained either passive or in the periphery, often reduced to a consumer for reasons related to its history or its system of governance—or lack of one. This has led to a yawning digital divide (especially between Africa and developed states of the world.

What led to this divide and how can Africa, then, benefit from this revolution? What are the obstacles?

## BACKGROUND

Such historical factors as colonialism and associated exploitative orientations and, more recently, military dictatorship and neo-liberalism have dominated the literature of Africa's political economy as explanatory framework for underdevelopment. Little has been blamed on the problems of state interventionism that characterized the post-independence period and that appear to have exposed the weakness of the state in Africa to manage its resources and deliver services, thereby leading to underdevelopment and poverty. Even at that, the prognosis and taxonomy of the post-cold war developments in Africa still lean on such templates. In fact, African scholarship has continued to heap blames for underdevelopment on doors of liberalism, mercantilism and their "center-peripheral" characters. According to Bathily (Nnoli, Ed., 2000, p.49), "It appears clearly that the crisis of the post-colonial state is not directly caused by state intervention in the economy." To that extent, Bathily contends that the solution to this crisis cannot be generated by the mere restoration of the so-called macro-economic equilibrium.

The current Africa's problems have also been traced to corruption and bad governance (World Bank, 1989). Identification of these problems and their impediments to political and economic development have led experts, scholars, organizations and agencies to show concerted interests towards paradigm shift and reinventing governance. The move is borne out of the genuine conviction that there is a correlation between bad governance as witnessed in Africa and other parts of the world and over-centralization. This correlation also extends to governance and problems of war, poverty, corruption and human security. Consequently, these have led to various dimensions of inequality and growth below the world's minimum standards for economic development. According to Adedeji (2002), African performance in 1960-1975 was substantially below all the targets set by the United Nations (UN) Second Development Decade. Its GDP annual growth was 4.5% instead of the 6.0%; its export was 2.8% instead of 7.00%; its agricultural growth rate was 1.6% instead of 4.00%; while manufacturing grew at 6.0% instead of 8.00%. Import was 10.0% instead of 7.0%. This, according to Adedeji, reveals that Africa was faced with development crisis. Unfortunately, performance during the one-quarter of the 20th century (1975-2000) was more abysmal than that achieved during the first 15 years of independent Africa (1960-1975). It is postulated that if Africa has to exit from poverty and develop, it needs a growth rate of 7.0% per annum (Adedeji, 2002). The following data demonstrate Africa's growth rate and prospects from 2002 to 2006.

It is the contention of scholarship also that this bad governance could be averted if there is culture of accountability, transparency, as well as commitment of political leadership to deliver services to the governed.

*Table 1. Real GDP growth rate of developing countries (International Development Economic Associates, 2005)*

| | 2002 | 2003 | 2004 | 2005 | 2006 |

## STEPS TAKEN TO ACHIEVE GOOD GOVERNANCE

Various steps have been taken at the national, regional and global levels to address the problems of bad governance in Africa. At the global level, there is a general call for democratization and economic reforms that could entrench a regime of accountability, transparency and culture of trust. Institutions, such as the World Bank, International Monetary Fund (IMF) and donor nations, have not minced words on these virtues as conditions for granting any form of aid to Africa. They have even extended their definition of governance to include a redefinition of the state, the de-politization of public administration and involvement of non-governmental organizations.

At the regional level, there have been concerted efforts at political and economic integration as well as such programs as the New Partnership for Africa's Development (NEPAD), which is designed to use its Peer Review Mechanism and ICT as tracking tools against bad governance. Through this process, NEPAD will help eradicate poverty and empower African states to develop.

At national levels, states of Africa have various provisions in their constitutions and have introduced various institutional measures and anti-corruption agencies

to check bad governance. In spite of these efforts, corruption and bad governance continue to ravage the continent, leading to abject poverty. The main thrust of this article, therefore, is to establish how ICT can help achieve good governance in Africa and bridge the divide in overall development (but also the digital divide) between the advanced industrial countries and Africa.

## ICT AS A ROAD MAP TO GOOD GOVERNANCE IN AFRICA

While good governance could be achieved through efficient management of the nation's resources, entrenching a culture of trust, accountability and transparency, we argue that ICT could be a veritable tool of making the above factors possible. ICT in governance has been defined as "the use of Information and Communication Technology to support the act and process of governance through the provision of improved administrative systems within and without government" (Duncobe, 1999) in Emadoye (2002, p. 1). On the other hand, governance is an exercise of political, economic and administrative authority to manage a nation's affairs (UNDP, 1997). It is the complex mechanisms, processes, relationships and institutions through which citizens and groups articulate their interests, exercise their rights and obligations, and mediate their differences. This poses the concept of governance in two dimensions (good and bad). But we are concerned with good governance. This, the United Nations Development Program (UNDP) argues, has to do with effective management of public resources in response to the critical needs of the society. According to Cloete (2001, p. 4), good governance is "the achievement by a democratic government of the most appropriate developmental policy objectives to sustainably develop its society, by mobilizing, applying and coordinating all available resources in the public, private and voluntary sectors, domestically and internationally, in the most effective, efficient and democratic way". According to Cloete, this latter definition contains both empirical and normative utilitarian approach. It is also a reflection of the current academic state of public administration/management.

Having said this, it is important to note that no matter how defined, good governance must take care of the principles of responsibility, accountability, transparency, trust and efficient service delivery – all channeled towards the improvement of the welfare of the governed. It is being emphasized, because good governance provides an enabling environment for economic development, political participation, social inclusion, equity and quality of life of citizens. These issues generate broad consensus in society and reduce the problems of war and violence; it reduces poverty by creating employment opportunities through investment and guarantees human security. It creates an atmosphere of freedom, develops talent and ingenuity, reduces fear and throws open windows of opportunity to both domestic and foreign investors.

The above background suggests one basic question. In what ways can ICT be used to achieve this good governance? In other words, what is the instrumental utility of ICT to improveme peoples' welfare, hold government accountable and achieve a responsible, efficient and transparent public administration that could deliver services?

Backus (2001) writes that ICT can be involved in governance in two major dimensions: internally and externally. Internally, it facilitates speedy, transparent, accountable, efficient and effective process for performing government administration activities. Externally, it facilitates speedy, transparent, accountable, efficient and effective interaction with the public, citizens, business and other agencies.

Duivenboden (2002) agrees that ICT could create new ways of service delivery through multi-challenging information supplies. It could equally influence the behavior of governments in their relations with citizens to a certain extent. Duivenboden admits that electronic governance (e-governance) could lead to increased access of citizens to government information and increase the process of transparency. E-governance also saves time and money for both citizens and the state.

Cloete (2001) emphasized the importance of electronic management assessment tools and their use to improve policy outcomes and service delivery. He observed that the poor state of these tools have led to policy failures and poor policy implementation in most developing states. ICT, according to Uma (2004), enables the government to reinvent itself, get closer to the citizenry and forge closer alliances and partnerships with diverse communities of interest, practice, expertise, conviction and inter-dependence within the context of national agendas. Backus (2001) writes further that the objective of e-governance is similar to the objectives of good governance: Good governance is the exercise of economic, political and administrative authority to better manage affairs of a country at all levels, national and local. Many other ways have also been identified as roadmaps to good governance via ICT:

### Citizen Participation

The introduction of ICT (including the widespread use of the Internet across the world and its increasing use in Africa) has proven to be a major way of increasing public

participation in the governance process. E-governance through ICT is a major roadmap towards defining a society's vision and priorities for e-government. ICT facilitates electronic democracy—voting; public opinion polls; policy inputs; campaigns; payment of taxes; political contacts, especially with elected leaders; networking; as well as advocacy. According to the Pacific Council on International Policy (2002), participation requires collaboration, especially between the private sector and civil society groups that may possess the much-needed expertise and resources. Participation makes it possible for citizens to evaluate government services openly. This enables the government to make improvements in its services and policy process. Good governance in Africa could be facilitated through this process of participation, as it would enable the average African to make input into policy process and generate confidence and trust in the political system. The overall consequence may be political stability and economic development. Experiences from across the world reveal that ICT can be instrumental to community development, improved access to information and public-private partnership, and all of these can also be of tremendous benefit to Africa.

## Community Development

ICT in Africa could lead to information sharing, local administration, healthcare service delivery, and accessing information needed at localities without traveling to the state or nation's capitals. In Africa also, ICT could be used by civil society organizations to inform people in the localities about their rights and privileges, and so forth. The effect of this is the empowerment of the civil societies to checkmate their governments and hold them accountable for their responsibilities. This is a major way of guaranteeing transparency and good governance.

## Access

ICT in Africa can create access to information about the entire political process, services and choices available. Government agencies can equally use ICT facilities to advertise their activities, programs and plans, as well as achievements. It can also be used to announce jobs and opportunities on Web sites. Citizens can submit applications online and fill out forms. Though this access still follows the digital divide between developed and developing states, among African states as well as in their urban and rural centers, its benefits are numerous if made possible. The divide also has its gender dimension, since speculations are that women have less access to ICT worldwide.

## Partnership

Through ICT in Africa, a feeling of ownership of policy process, legitimacy, and sense of efficacy and patriotism will be generated. As states in transition, it can help in forging a closer and stronger partnership between public and private sectors.

It can also be possible to transact business and send messages faster than ever before in Africa. Though connectivity is still abysmal, such facilities as e-mail, fax and cellular telephones, digital television and radio have been of immense benefits. Cost-effective administration (through microelectronics, fiber optics, video compression, fast-packet switching and high-density storage technology, reduction in the volume of files and of the cost of labor) has been enhanced.

Finally, ICT in Africa, like in other parts of the world, has led to information gathering for intelligence, national security and ecological monitoring, not only to manage natural disasters but also for improvement of agriculture.

Having outlined how ICT can benefit Africa and improve governance, it is noteworthy to state that ICT is like the theory of the hammer, which the carpenter can use for good, bad and ugly. This understanding informs part of its special constraints. Ningo (1999) suggests that Africa should take advantage of the development of ICT, since it offers a dramatic opportunity to leap-frog into the future and break out of decades of stagnation and decline. In this regard, Hegener (1996) warned that if Africa cannot take advantage of the information revolution and surf this great wave of technological change, it may be crushed by it. This, he argues, will lead to greater marginalized and economic stagnancy in the future. Ronfeldt (1992) also suggested that governments that succeed in using the information revolution and its associated technologies to develop advanced information and communication infrastructures may leap ahead of others in terms of their capacity to deal with current issues, assert their presence, build cooperative networks and partnerships, and cope with competition and conflict at home and abroad.

# THE FUTURE OF ICT IN AFRICA: PROBLEMS AND CONSTRAINTS

The introduction of ICT at least brings the hope that if adopted and properly implemented, African states can transform from a culture of distrust, dishonesty and mismanagement to that of transparency and accountability that will encourage an efficient and cost-effective public administration and good governance. It will also enable the continent benefit from the present UN Millennium Development Goals.

While this is admissible, it is important to note that peculiar environmental factors may constrain the extent ICT will determine the roadmap to good governance in Africa. Though these factors are not peculiar to Africa, their presence is widely engrossed and their effect severe. The following factors could hinder Africa's dream and disrupt this roadmap to political and economic development.

## Problems

### Lack of Infrastructure

Infrastructure is essential to successful ICT procurement and sustenance. These include legal recognition and acknowledgement of electronic data as legal documents, electronic signatures, issues of piracy and intellectual property rights, and procurement policies. These require legal reforms and broad policy frameworks that are yet to be developed in most African states.

### Telecommunication

Most African states are still below the world minimum in accessibility to telecommunications. It was found out that Africa has only a 13% share of the world population. Out of this number, only 1% has total global telephone lines, 1% Internet users, 1.2% of total world Internet sites, and almost 0% of global ICT production. With an estimated 274,742 hosts in 2001, Africa has 0.19% of the total global Internet hosts, while its share of personal computers stood at 7,558,000, representing 1.53% of the world total (United States Internet Council, 2001). There is no gainsaying that without this facility, electronic governance, democracy and commerce will be hampered. While in many African states the telecommunication industry has been liberalized, still, the cost of access to these facilities are yet to be within the reach of majority, especially when telecommunication companies are constituting themselves into new monopolies, thereby defeating the essence of liberalization. Even at that, the distribution of the telephone is not only skewed in favor of urban residents, especially the urban elites, but the digital divide continues to increase between the urban and rural dwellers. This divide has also proven to be generational. While African youths appear to be more ICT literate, a greater percentage of elders appear to be behind this new technology.

### Lack of Knowledge Jobs

There is still a gross lack of technical manpower in the field of information technology (IT). This affects not only software maintenance, but also development of new ones and manufacturing of accompanying hardware. IT facilities need to be properly set up, computers repaired and serviced. To a large extent, trained manpower for these services are in short supply. In some offices, where computers are available, they serve the purpose of decoration. Even at homes, generational gaps also exist in their use. Older people feel it is not their business. Younger ones get more interested. Unfortunately, it is the older people that occupy most sensitive positions in the public and private offices.

### Poverty/Cost

Poverty is still a major handicap in access to ICT. Most Africans cannot access the Internet or own telephones or other digital receivers, because they are unaffordable. Because of this lack of access, most cannot benefit from various online facilities, such as information, education, e-commerce and so forth. This could endanger the future of ICT benefits for good governance in Africa. Computers are very expensive and, in many cases, unaffordable to the average person.

Another major effect of this poverty in Africa is the use of IT to achieve an inter-generational shift in corruption. The few cyber-cafes that are available are owned by private persons and are often filled with young men and women scamming to defraud – a technique unknown to the older generation and a more sophisticated form of corruption. Employing such people in government offices will offer opportunity for new forms of fraud in the future.

### Civil Wars

Available statistics show that many states in Africa are deeply engrossed in civil wars and political instability. The report of the UN Secretary General (April, 1998) shows that since 1970, more than 30 wars have been fought in Africa, most of them intra-state in origin. In 1996, 14 out of 53 countries in Africa were experiencing armed conflicts that accounted for more than half of all war-related deaths globally This creates environmental problems that are hardly ideal for the development of ICT. Mostly, these states are more committed to basic survival, containing insurgency and fundamentalism than development of ICT infrastructure.

### Electricity

In such countries as Nigeria, electricity supply is grossly irregular. In many cases, electricity supply is erratic. It comes on and off. This not only slows progress and development, but also inflicts serious damage to computers and their software. The future of IT development in Africa could be endangered by the poor energy sector existent in many states of Africa, coupled with the fact that many rural communities have no electricity.

Then, there is the lack of most governments' willingness to set up public information centers for cheaper and easy access to information and business transaction. This is not because the government policy makers do not acknowledge the benefits of these; but, lack of patriotism and corruption stand in their way, disposing them to be unwilling to invest where there are no direct cash rewards.

### Lack of Space for Open Comments

This might look minor or ignorable, but it is very important. In designing Web sites, most agencies and organizations hardly create open space for exchange of information and comments on government policies. What government and its agencies do is tell people what they want them to know. This channel is closed for the fear of criticisms arising from the public as well as challenge of policy options. The future of ICT in Africa faces an uphill task in the challenge of the above constraints.

### Policy Dichotomization

In some African countries, ministries of communications are separated from those of technology. This keeps IT and communication technologies as separate issues. In Nigeria, for instance, ICT understanding is narrowed down generally to just computers and Internet. There are three separate policies on IT. IT and Broadcasting have different regulatory bodies (Ya'u, 2001). According to Ya'u, this not only creates problems in terms of coordination between the various agencies and resulting duplication of efforts, but also does not allow the countries to tackle the issues of convergence that ICT represents. This dichotomous stance was exemplified when ministers responsible for economic planning were meeting with the Economic Commission for Africa (ECA) in May 1996 to conceptualize the African Information Society Initiative (AISI). That same month, the Ministers responsible for telecommunications were meeting in Abidjan to agree on the green paper outlining the Telecommunication Policies for Africa (Apeworkin, 2001). Again in Nigeria, while the Minister for African Integration was representing Nigeria in the African Development Forum (ADF'99), the Minister for Telecommunications was releasing the National Policy on Telecommunication in Abuja with no reference to what was going on in Addis Ababa (Ya'u, 2002).

## PROSPECTS OF ICT IN AFRICA

Leaderships have at least demonstrated some desires to embrace ICT. For instance, there have been numerous initiatives to embrace ICT and bridge the yawing gap at both international and domestic levels. The World Bank, UNDP and even the Group of Eight initiate some. These have led to modest improvement in connectivity in most African states. By 1995, only six African states had the Internet, but by 2002, virtually all had access to the Internet (Ya'u, 2002).

In spite of these modest improvements, the reports of the Organization for Economic Cooperation and Development (OECD, 2001) and the US Internet Council (UIC, 2000) showed that the divide between Africa and other developed parts of the world is still on the increase. This position leaves us with one major, disturbing question. Will Africa ever catch up and bridge the divide in IT? Mansell and Wehn (1998:25) said it will take at least a century. Cogburn and Adeya (1999, p. 12) sounded even more pessimistic. According to them, "it is an illusion to think that ICT-poor countries can 'catch up' or keep pace with advances in the most technologically advanced countries." Even the efforts through NEPAD did not seem to win the confidence of some scholars. According to Ya'u (2005, p. 8), "NEPAD is symptomatic. There is nowhere in the document in which the ways ICTs are reinforcing existing global inequalities or how the challenges e-commerce is posing to developing countries are factored in the discussion on bridging the development gap." He blamed Africa for taking the matter on its surface level without taking into consideration its historical roots and for thinking that the gap can be bridged just by promoting access for foreign investors in ICT industry by removing for them import duties, taxes and breaks as well as holidays, and reducing itself to consumerist status. The extent to which Africa can catch up therefore, will depend on the level of its leadership commitment to achieving good governance that will enshrine principles of transparency, accountability and service delivery. It is in realization of these virtues that words could be matched by action that could bring Africa nearer to actualization of digital technology and bridge its consequent divide.

## CONCLUSION

The World Bank (1994) had noted that the future of economic development and good governance are hinged on ICT. Africa needs to translate this prediction from mere expression of interest to concrete efforts at bridging the digital divide, not only between the continent and the rest of the world, but within Africa itself, between rural and urban dwellers. For instance, while 29 members of the OECD share 97% of Internet hosts, 92% of the market in production and consumption of computer hardware and software services and 86% of all Internet users, the whole of Africa contain only 2.5% Internet users, or less than 1%

of the world's online community (Norris, 2000). This calls for indigenous investment in the ICT sector, with the hope that it will positively impact on governance process. This is a major way of getting through the center-periphery model of development that has beset Africa since the period of colonization. It is equally important to note that the problem of governance does not solely lie in lack of technology. Effective use of technology calls for improvement in various governance infrastructures that will not only enable this technological acquisition but its productive usage. This, therefore, calls for the ICT knowledge society. It is observed that one of the fundamental reasons for the absence of good governance in post-colonial Africa is the sheer incapacity of its bureaucracy to discharge its duties (Chabal, 1992). With creation of a knowledge society and the positive use of IT, the bureaucracy may be better positioned to discharge its roles and deliver services. If Africans can see ICT as an innovation for the common good and adjust from the current culture of greed to that of using the new technology to track bad governance, then the benefits will be tremendous and the future bright. The problem of ownership of ICT may not even constitute an impediment.

## KEY TERMS

**Bureaucracy:** This refers to the personnel and administrative structure of an organization. Business, labor, religious, educational and governmental systems depend on a large workforce arranged in a hierarchy to carry out specialized tasks based on internal rules and procedures. The term is used mostly in referring to government administration, especially regarding officials in government and civil services. It is often used pejoratively to suggest waste, inefficiency and red tape (Encarta, 2003). In sociological theories, bureaucracy is an organizational structure characterized by regularized procedure, division of responsibility, hierarchy and impersonal relationships. The term can characterize either governmental or nongovernmental organizations.

**Cyber Café:** "Cyber" is anything related computers or networking. Cyber Café, though, used in exchange with Internet café, is expected to be a coffee shop that offers computer terminals for customers to browse the Internet while sipping coffee. It is a colloquial concept that is fast becoming an accepted formal language.

**Globalization:** The process by which markets and production in different countries are becoming increasingly independent due to the dynamics of trade in goods and services and flows of capital and technology (European Commission, 1997). Globalization involves much more than economic transaction and spans into political, social and cultural issues. Economic globalization has to do with a borderless global economy, in which the principal agents are the multi-nationals, which are disembodied from any national base. Political globalization refers to the withering away of the state. Cultural globalizing refers to the present global village that watches more or less the same television serials and videos, consumes or aspires to consume the same products. Social globalization refers to the homogenization of today's mode of life, which is based on an individualist and consumerist culture. As a result of globalization, social geography gains a planetary dimension. "Place" comes to involve more than local, provincial, country, regional and continental realms. With globalization, the world as a whole also becomes a social space in its own right (Encarta, 2003).

**Governance:** The term governance has not received any universal fit-all definition. The best we have are working definitions by international organizations, which in most cases lack underlying theories. The UNDP defines governance as "the exercise of political authority to manage a nation's affairs. It is the complex mechanisms, processes, relationships and institutions through which citizens and groups articulate their interests, exercise their rights and obligations and mediate their differences." In keeping with this, it defines sound governance as effective and efficient management of public resources and an adequate response to critical societal needs. It also denotes democratic forms of relationships between the governed and the governors, relationships that have inbuilt mechanisms for public participation, accountability and transparency. It is contended that systems that incorporate the above elements have been better able to satisfy broad societal needs, including sustainable human development (Economic Commission for Africa, 1988). It can also represent decision-making processes in the administration of an organization. Governance also refers to the process whereby elements in society wield power and authority, and influence and enact policies and decisions concerning public life, as well as economic and social development.

**Human Security:** Human security has been looked at from two primary perspectives. From the narrow perspective, it has to do with protection of individuals and communities from violent threats and internal conflicts. The broad perspective defines it to include threats of hunger, poverty, exclusion and natural disasters.

**Internet:** Internet is a collection of computer networks that operate to common standards and enable the computers and the programs they run to communicate directly. There are many small-scale, controlled-access "enterprise Internets," but the term is usually applied to the global, publicly accessible network, called simply the Internet or Net. By the end of 2002, more than 100,000 networks and around 120 million users were connected via the Internet. According to Encarta Encyclopedia (2003), Internet connection is usually accomplished using international standards collectively called Transmission Control Protocol/Internet Protocol (TCP/IP), which are issued by an organization called the Internet Engineering Task Force, combined with a network registration process and with the aid of public providers of Internet access services, known as Internet service providers (ISPs). This global communications network consisting of thousands of networks typically interconnected by fiber-optic ca-

bling had two parent networks whose joining began the ongoing evolution.

- U.S. Military (tactical communication in the event of telephone downtime during wartime)
- Academics (shared information between researchers).

**Poverty:** Poverty is an economic condition in which people lack sufficient income to obtain certain minimal levels of health services, food, housing, clothing and education, generally recognized as necessary to ensure an adequate standard of living. What is considered adequate, however, depends on the average standard of living in a particular society. Poverty could be relative or absolute. Relative poverty is that experienced by those whose income falls considerably below the average for their particular society. Absolute poverty is that experienced by those who do not have enough food to remain healthy. However, estimating poverty on an income basis may not measure essential elements that also contribute to a healthy life. People without access to education or health services should be considered poor even if they have adequate food (Encarta, 2003).

# Information in Electronic Government

## INTRODUCTION

Information and communications technology (ICT) is radically changing productive processes in both the private and public sectors. Institutions that are more efficient eliminate production diseconomies and enable a more functional market. Specifically, institutions can multiply the incentives for human capital accumulation both by reducing the endogenous uncertainty in social-economic relations and by providing additional input to human capital generation itself (think of schools, universities, and research institutes).

Mainstream economic thinking generally accepts the argument according to which the transaction and information costs that are inherent to policy-making are largely greater than those incurred by the private sector (Dixit, 1996). If this is true, then public sector intervention is denied the possibility of achieving more efficient results than those obtained by the private sector (Holstrom & Milgrom,1991). Yet, ICT is radically transforming the way government entities perform their activities, which makes a timely debate on public sector information, in all its forms, all the more crucial.

Public administrations are following the example of the private sector by harnessing the efficiency-boosting potential of these new technologies. This development goes under the name of "electronic government" (e-government) and it encompasses both the internal and external applications of ICT in the public sector.

The importance of this development is increasingly evident in many countries of the world. Experiments are underway in Europe, at all levels of public administration (local, regional, national, and supranational), to improve the efficiency of public services and to increase interactions with the external world. ICT not only facilitates the inner workings of administrative machinery, it also eases communication between different branches of the administration and its interaction with citizens and businesses. This latter aspect is one of the main advantages of e-government, as it brings public sector entities, businesses, and citizens closer together, as well as improving the standard of public services.

In September 2003, the European Commission issued a Communication on "The Role of E-government for Europe's Future": it stated that e-government "is an enabler to realise a better and more efficient public administration. It improves the development and implementation of public policies and helps the public sector to cope with the conflicting demands of delivering more and better services with fewer resources" (p. 7).

## BACKGROUND

In order to understand just how complex the impact of ICT on public sector information actually is, it may be useful to start with a clear definition of the scope of e-government.

E-government is defined in the literature as "the process of transforming public administration's internal and external relations through network-based activities, information and communications technologies, in order to: (1) optimize service delivery, (2) increase citizen and business participation, and (3) enhance government capability" (Di Maio, 2001). This is probably the most comprehensive of all of the different formulations suggested so far to mark out the contours of this process, in that it identifies two macro areas—increased internal efficiency in the public administration and improvement of external relations with all parts of society—in addition to setting the medium-to-long term objectives. The implementation of these strategies is part of a broader process of re-definition of the administrator-citizen relationship, in an effort to respond to the need for change in the mechanisms of participation in the democratic life of a nation and also to boost efficiency—in terms of quality and cost—of the public services delivered to the community and to business, enabling the largest possible number of individuals and businesses to enjoy the advantages of the emerging Information Society (Aichholzer & Schmutzer, 2000).

Many of the definitions advanced at an international level go much in the same direction. European Commission (2003) defines e-government as "the use of information and communication technologies in public administrations combined with organisational change and new skills in order to improve public services and democratic processes and strengthen support to public policies"(p. 7). EPAN (2004) and IDABC (2005) identify seven types of interconnected benefits: (1) improved quality of infor-

mation and information supply; (2) reduction of process time; (3) reduction of administrative burdens; (4) cost reduction; (5) improved service level; (6) increased efficiency; (7) increased customer satisfaction.

All definitions imply a rather broad vision of e-government, which is perceived not only as an evolution of the activities linked to the public sector, but also as part of a more generalized transformation of the State, through a deep re-examination of democratic practices and processes. For instance, in Zulfiqar et al. (2001) e-government is portrayed as a process that entails a complex and dynamic transformation of the entire state apparatus, at all levels, with ICT being used to involve citizens (C), businesses (B), administrations and governments—including foreign—(G), and public employees (E). These four categories represent the so-called "constituency"—the beneficiaries—of e-government strategies: in practice, it covers civil society and its democratic apparatus as a whole.

In a knowledge-based approach, a successful e-government plan hinges on the full-fledged participation of all of the categories of stakeholders in the process. The combined contribution of all of these agents is the only way to achieve the "dissemination of information and knowledge" which—together with a profound re-thinking of relations between social "communities"—may not only bring about a powerful infrastructural and conceptual evolution of the administrative apparatus, but also modify the way individual rights and duties are exercised (Lenk & Traunmuller, 2000).

The use of ICT in the implementation process of e-government closely reflects the two macro areas mentioned above. On the one hand, these new technologies contribute to an improvement of the internal efficiency of public administrations, by streamlining information and administrative process management—which will have an impact on relations between administrative apparatuses at both a horizontal level (between agencies, departments and ministries) and a vertical one (between central and local agencies). On the other hand, ICT enables better management of external relations—with the constituency—ensuring higher standards of service and information delivery to the public, as well as—at least potentially—enabling levels of democratic participation that were previously unimaginable (Caldow, 2001). Understandably, ambitious objectives such as the above require not only broad-based support, but also the implementation of a series of preliminary steps, including the following (Aichholzer & Schmutzer, 2000):

- Policies to facilitate access to information and public services (tax policies for the spread of screen-based technology, education and training policies, infrastructure endowment, services planned in a multi-media approach, so as to minimize the exclusion of potential users in a given country (digital divide)
- The reorganization of the internal structure of public administrations in a user-centered approach, more than based on an "administrative" allocation of competence

Figure 1 identifies 4 stages in the implementation of e-government, each of which might be broken down, in turn, on the basis of policies; measures concerning employees; processes underway; and the adoption of technologies including: (a) presence of the public administration on the web, (b) interaction with the public, (c) development of transactional services (enabling the full-fledged implementation of self-service applications, as well as the use of the web as a tool that is complementary to other communications channels), (d) complete transformation of the public administration's modes of interaction with its branches and with the citizens.

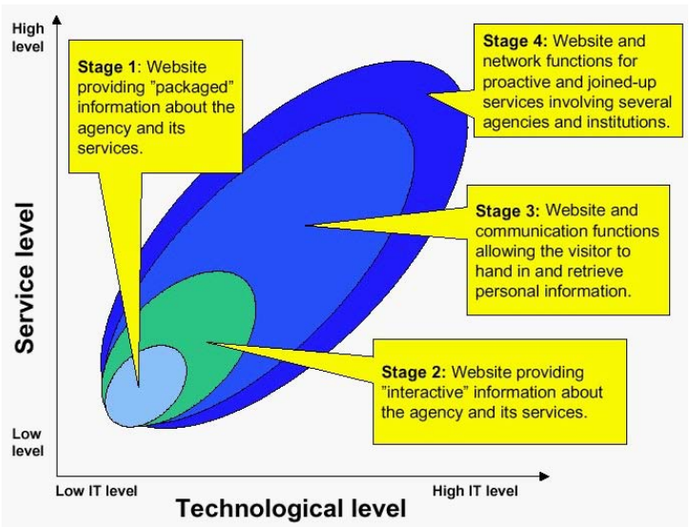
In a context in which e-government is fully implemented, public sector information management extends well beyond the straightforward supply of services to the public. It becomes the nerve center of all relations in the newborn Information Society. However, the somewhat embryonic state of the current "frontiers" of e-government appears (at least in Europe) to call for the need to kickstart the major shift forward that—alone—can transform e-government from a simple improvement in relations between public administrations and citizens to a new paradigm of government and growth in the future Information Society.

## SUPPLY AND DEMAND OF PUBLIC SECTOR INFORMATION

The expression *public sector information* is used to describe the depository of documentation that is produced, collected, and, to a degree, disseminated by the public administration. It does not cover the documentation regarding the public sector that is produced by the private sector.

This concise definition hides a far more complex classification. The wealth of public sector information and documentation may be categorized on the basis of distinctive and, partly, overlapping criteria, such as: type of entity generating the information; legal norms regulating its production and dissemination; different users and addresses; agents processing and managing the documentation; material and formal characteristics of information, etc.

*Figure 1. The four stages of e-government (Source: Swedish Agency for Administrative Development (2000), The 24/7 Agency–Criteria for 24/7 Agencies in the Networked Public Administration http://www.statskontoret.se/upload/Publikationer/2000/200041.pdf)*



Consider, for instance, the following:

- Legal documentation (laws, regulations, rulings, and general administrative provisions; at all levels of the administration: central, regional, and local)
- Statistical information
- Institutional communication
- Archival documentation (stored in current and historical archives)
- Scientific information (environmental, health care, etc.)
- Parliamentary documentation
- Official cartography

Each of the categories in the non-comprehensive list above comes under different legal schemes (relating, for instance, to consultability and access), and requires different processing methodologies, storage facilities, and user or recipient requirements.

The terms *public sector information* and *documentation from public sources* are used here as synonyms, though the term *documentation* (documents and data) is more precise, as it points directly to the link with digital media, whereas *information* is a more generic term, and may also cover oral communication. The availability of public documentation and the requirements of users have influenced each other mutually and changed in time.

The discovery of the Internet by public administrations, with its potential ease-of-use, has rapidly amplified both demand on the part of the various user categories, and the supply, not only of information, but also of services.

Technological innovation, the widespread demand for good governance, the emergence of general information and access-related rights, pertaining to information and access, and the evolution in administration-citizen relations are only some of the factors that have helped do away with many of the barriers to the consultation of documents by the general public.

For example, in Italy, in the early 1990s, Law 241 established the right of access to administrative documentation on the basis of an interest that needed to be demonstrated. Legislative decree No. 39, which was adopted on Feb. 24, 1997, transposing Community Directive No. 13 (June 7, 1990), provided that public authorities are under the obligation of making environmental information available to "anyone advancing the request for such information, without any need for a specific interest to be demonstrated."

This has led, on the one hand, to a shift from document accessibility to document consultability, and, on the other hand, to a shrinking of the domain of confidential documentation and an expansion of the documentation that is accessible to a non-differentiated public.

The trend allowing public access to administrative documentation, which has made considerable headway in all western countries, flows from an awareness of the fact that democracy as a principle is deeply influenced by

the way information circulates in a given society and by its availability to citizens. It can be argued that a good yardstick for assessing the degree of democracy in a system is the quantity and quality of information that circulates within the system and the number of potential users having access to it.

In Italy, the only relevant legislation on the dissemination of information by the public sector is Law No. 150 (June 7, 2000). For the first time in the Italian legal system, this provision specifically stated the objectives of public communication, namely to:

- Illustrate and promote knowledge of legislative provisions, to facilitate their implementation
- Illustrate the activities of institutions and the way they work
- Facilitate access to public services by making them more widely known
- Promote extensive and in-depth knowledge of relevant public and social issues
- Foster internal processes to simplify procedures and modernize institutions, and provide information on administrative procedures, their initiation and development
- Promote the image of the administrations, and the image of Italy, in Europe and throughout the world, by disseminating information and lending visibility to local, regional, national and international events

However, this legislation does not place any obligations on the various levels of administration with respect to the dissemination of information.

## CITIZEN'S RIGHTS

"La libre communication des pensées et des opinions est un des droits les plus précieux de l'homme, tout citoyen peut donc parler, écrire, imprimer librement, sauf à répondre de l'abus de cette liberté dans les cas déterminés par la loi": the spirit and the tone of Article 11 of the 1789 *Déclaration des droits de l'homme et du citoyen* readily shows that the contentious issue immediately at stake, at that time, was censorship and the first freedom guaranteed to citizens was protection against this threat. Owing precisely to these roots, the right to information has been generally conceived as the right of information professionals and when it did refer to citizens at large, it was usually understood to mean freedom of opinion and expression, and is still treated as such in many contemporary texts of constitutional law.

With the 1948 Universal Declaration of Human Rights—Article 19 of which explicitly states the right to "seek, obtain, and disseminate information"—the right to information has become a constitutional right of every citizen. It is no longer confined to the however vast area of the mass media, but instead applies to the full range of activities of any individual.

In particular, establishing the right to "seek and obtain information" has modified the relationship between citizens and government. For one, governments' obligations are no longer circumscribed to censorship, according to the classical pattern of negative freedom. Governments must open up to the demands emanating from their citizens, and abandon the entrenched privileges of any administration, as evidenced by the fact that several countries over the last few years have adopted laws on the rights of citizens to access government-held documentation (European Commission, 1999).

Before the advent of Internet, a vertical form of communication based on the pattern of free-to-air television prevailed almost exclusively. This meant that the recipients of communication were understood to be passive, much like readers, albeit of images rather than words; and it reproduced and perpetuated the distinction between producers and consumers of information, and the need for a category of mediators who would lend material substance to the notion of citizens' access to information. This was basically the case even in those situations in which laws were in effect granting access to information to all citizens, as in the late 18$^{th}$ century Sweden, where public documentation was, by way of principle, accessible to all citizens. However, since the exercise of this right meant that the individual had to travel to wherever the documentation was stored, journalists—who would obtain the information, make their selection, and convey it to public opinion—mainly used it. In practice, a mediator filtered the right of everyman.

Today, citizens can use networks and engage in horizontal modes of communication, which has substantially modified their position, doing away with dominant positions, pre-established agendas, or restricted speaking times. Once this new mode of access is recognized, with its manifold implications, all citizens are, in principle, on an equal footing, and they can all become agents of communication. This has undeniable democratic implications. Individual citizens are no longer simply information-retrievers: they are also information-suppliers, thereby breaking down the power that was exercised until only recently by a restricted group of professional mediators who selected the information to be circulated. The degree of democracy of a system is determined *inter alia* by the extent to which citizens may actually perform this new role.

The most significant innovation must surely be the elimination of the barrier that separates information sup-

pliers from information consumers. A new "communicating subject" has emerged, and this means that the issues at stake now extend well beyond the growing individualization of information and communication.

## CONCLUSION

The expanding potential of individuals as "communicating subjects" results directly in a change in the social quality of information. With all individuals acting as both producers and consumers of information, even the most marginal Internet user enjoyed a "power of speech" that may match that of governments or powerful corporations, if the information that is introduced to the network by that user is just the sort that the others would have done anything to suppress. Censorship, in all its dimensions, becomes much more difficult to apply, as those totalitarian regimes that are attempting to curb the penetration of the Internet know very well.

Nevertheless, this is not the only difficulty. A formally free environment is not enough, as the network can express its full potential only on condition that access to both the information supply and information search phases is truly free in material terms. In addition, this, in turn, requires a basic set of conditions, ranging from mass (computer) literacy to the availability of real "universal service" (in terms of geographical coverage, compatible telephone rate policies...).

The situation is hugely complicated today because: (1) it is no longer under the complete control of the traditional established powers, the nation states; (2) powerful entities, especially in industry, have the ambition to governing the world of information and communications technologies; and, (3) the network rhetoric means having to measure up to the hyperbole of every inhabitant of the planet being considered an agent of communication processes.

Basic values should be identified. For instance, what does equality mean in this context? Not to be content with consoling, albeit Utopian visions, means tackling more than the issues mentioned above: mass computer literacy and universal service. Another crucial issue is that of surfing tools, browsers and search engines, which should not be rudimental for some and rich versions for others, but should be research-enabling and not merely information filters (with the selection criteria set by others).

This is where public policies take center-stage: can the planning and development of the new nervous system of society be left to industry and the marketplace alone? Alternatively, is there instead a need for social demand, captured and interpreted by institutions, to orient supply so that it does not have bringing the products that guarantee maximum profits into the market as its only polar star?

Therefore, in the newest of worlds, the time-old question rises once again: State or Market? Of course, these two terms are not necessarily at loggerheads. But they may very well be so, if the (rarely disinterested) illusion that the two terms may be reconciled without enlightened policy-making is entertained.

## KEY TERMS

**Digital Divide:** Inequalities in access to ICT, computing skills, and electronic information content among inviduals, households, and communities within a country and among countries.

**Documentation from Public Sources:** Synonym for *public sector information. Documentation* (documents and data) is more precise, as it points directly to the link with digital media.

**Electronic Information:** Any sign, signals, writing, images, sounds, data, or intelligence of any kind store in whole or in part in electronic form.

**Electronic Government:** The process of transforming public administration's internal and external relations through network-based activities, Information, and communications technologies, in order to: (1) optimize service delivery, (2) increase citizen and business participation, and (3) enhance government capability.

**Electronic Government Constituency:** Citizens (C), businesses (B), administrations and governments—including foreign—(G) and public employees (E). In practice, it covers civil society and its democratic apparatus as a whole.

**Public Administration:** Government or other public entity, including public advisory bodies, at national, regional, or local level.

**Public Sector Information:** Depository of documentation that is produced, collected and, to a degree, disseminated by the public administration. It does not cover the documentation regarding the public sector that is produced by the private sector.

# Information Management in Kutch Earthquake

**Bharati Sen**
*SNDT Women's University, India*

## INTRODUCTION

The term digital governance refers to governance processes in which information and communication technologies (ICT) play a significant role. Digital governance uses ICT to induce changes in the delivery and standards of governance services and, more importantly, in the way citizens interact and participate in the governance sphere. The role played by ICT could be wide ranging: in delivery and standards of governance services, to how people access such services, and the participation of people in the governance sphere (Digital governance.org Initiative, n.d.).

Digital governance is not just another facet of governance or one more interface between citizens and government. Digital governance is a whole new opportunity, creating immense possibilities between citizens and government by redefining vision and the scope of the entire gamut of relationships (Bedi, Singh, & Srivastava, 2001). Two fundamental anchors of digital governance are local knowledge communities and citizen-centric governance.

## BACKGROUND

In 2001, an earthquake measuring 6.9 to 7.9 on the Richter scale struck the district of Kutch in the state of Gujarat, India. The day was January 26, celebrated as Republic Day in India. Damage to life and property was immense. The rescue, relief and rehabilitation work that followed heavily depended on information of various categories and at various levels of functioning. This is the story of transformation of a situation of crisis into a window of opportunity. The article is a development from the oral history recorded from individuals who were associated with the rescue relief and rehabilitation work in Kutch (Mukherjee, 2002). The author was one of the consultants for this project.

## ROLE OF INFORMATION

The importance of this information management came through right from the day of the earthquake. Numerous agencies came to work to provide succour; relief material came in truckloads. Coordination was needed urgently. Many times there would be mismatch of items. For example, a truckload of tea was available but there was no sugar. It was important to put into balance what was required and what was available. The need was felt for a composite demand chart. This was the beginning of collecting and collating information that ultimately resulted in creation of Setus, or bridges; that is, centers that not only catered to the information required for carrying out relief operations, but developed into nodes that would supply data to the government and CSOs about the ground-level requirements and inform the beneficiaries at the personal level of what was available. Later, the Setus coordinated the information required for developmental work so that the devastated region could become productive again.

The idea, according to a United Nations Development Program (UNDP) report (2001), was almost classical in its simplicity—a network of village-level centers that provide a trickle-up flow of data, feedback and information to influence policy and programs. A Setu was conceived as a nodal link between all the actors in relief and rehabilitation. Its stakeholders were government agencies and officials at different levels, CSOs, the donor community, the village community and the Setus themselves. Primarily intended to bridge the gap between the efforts and outcomes of the rehabilitation process, the Setus ultimately aimed to make people less vulnerable in a multi-hazard environment by harnessing local resources to optimal levels. To do this, the Setus had a wide-ranging set of activities. They facilitated coordination between government agencies and CSOs on the one hand and the village community on the other, to ensure a proper flow of benefits. They served as platforms for redress of grievances and transparency of procedures. All this was to be made possible through a two-way information flow.

### Information for Relief

By January 30, 2001, 33 sub centers, which later were renamed Setus, were established across Kutch for distribution of relief material. The main depot was in Bhuj. The decision was that volunteers would not go around in trucks distributing relief material. Instead, there would be few volunteers in each of the sub centers. These volunteers would set up "relief material distribution commit-

tees," establish the needs of the local people and then approach the depot with a consolidated list of requirements. This would affect people's participation as well as prevent wastage, as only the relief material whose need had been established would be distributed. The distribution at the local level would be through a committee. This arrangement went on for about 2 months.

Responses to large disaster events are likely to involve a large number of relief agencies and teams that create severe pressure on requirements for interoperability and cooperation. With numerous agencies wanting to help Kutch, coordination became essential. The CSOs and corporate houses did not know where to work, how to work. Some corporate houses did not know how to deal with local people or community. These agencies sometimes had special focus such as health, housing and so forth. Also, Kutch being a large district, had long distances to cover. Therefore, information and coordination was essential with relief distribution.

## Information for Rehabilitation

In the rehabilitation work, Setus influenced the decision of government by producing concrete data. Initially, the government had decided that villages more than 70% damaged would be relocated. Government had announced this policy. However, it was known that Kutch has a drinking water problem. Also, the agricultural land of the villagers would be disturbed, and people may not accept it.

The 33 Setus, within 48 hours, developed a program for facilitating village community, including village *gram panchayats* on relocation, explaining what relocation was, whether it would be acceptable to them, reasons for their opinions. It was a facilitation program for the village to take a decision about acceptance or rejection of relocation. Only 2%-3% of the villages were agreeable to relocation. The remaining wanted *in situ* reconstruction and rehabilitation. This opinion, with enough scientific and technical data, was provided to district government and state government.

This made government change its policy. The decision was made for *in situ* development. The government was also very happy, as this prevented a crisis. This made government decide to make Setus become an official body for reconstruction and rehabilitation of Kutch. A government resolution (GR) to the effect that the Setus are the earthquake rehabilitation support centers was released.

## Collaborating with Government Rehabilitation Programs

These support centers also took up the job of damage assessment, damage to shelter, damage to water structures—dams, wells—damage to hospitals, assessment of injuries of people. The assessments were to help determine the extent of damage and the commensurate assistance to be disbursed by the government.

The first survey in the rehabilitation phase was to determine whether people were getting their installments of assistance from the government. The installments were released when certain phases of construction was completed; for example, the first installment to build up to plinth level, the second installment after seismic safety features were incorporated, and so forth. Overall, the picture was that there was incongruence between government data and information available on the ground. In Bhachau Taluka, one of the worst affected areas, the government said that 70% disbursement had been done, whereas the actual figure of receipt was found to be 30%-40%.

Then it was realized that the government had disbursed the checks, but the problem was with local banks, which were not able to operate properly due to lack of staff and inadequate cash reserves, especially the village branches. Therefore, money transaction had hit a bottleneck.

At the village level, the community was also not very used to banking transactions. Without cash, construction work could not commence or continue. This information was conveyed to the collector, who immediately called all the banks and the chairmen of the banks and sorted out the situation.

## Information and Transparency

The Setus collected household data for the 360-370 villages, including the hamlets. This included category of damage; whether repair or reconstruction was required; if construction was necessary, was any CSO involved; if so, name of the CSO; the level of construction; and seismic safety measures.

The other utility of the survey was identifying spurious claims. For example, two brothers applied for assistance for the same house they had been occupying before the earthquake. Setus determined the number of houses that existed before the earthquake and the number of houses for which compensation was being given after the earthquake. After this, a flying visit would be made by a government surveyor.

In the beginning, this caused problems, as the community felt that though the Setus were primarily for the community, they were actually working against the community. This is where the importance of Setus vis a vis government machinery became evident. Since the Setu office bearers worked with the community, they could explain that because of a few people the village was

getting a bad name in the whole region. The people who had claimed their legitimate share realized that because of such occurrences, if their village gets a bad name, the government may actually withhold disbursement of compensation. Thus, a major crisis could be diffused.

### Government Policies and Feedback

Simultaneously, the government was forming policies that had to be understood by the villagers, and it needed feedback for smoother implementation. For example, the government had said that the second installment for construction of homes would be given after finishing the first installment's work, and that construction must be seismic safe. However, people did not understand what seismic safety meant. So such information had to be disseminated and awareness developed. Therefore, information collection and dissemination for coordination, policy advocacy with grievance redress and awareness building were major activities at this stage of rehabilitation.

However, Setus have not always been successful in policy advocacy. For example, the government had decided that for construction of temporary shelters, galvanized sheets and three bags of cement were to be distributed to each affected villager. Setus pointed out that Kutch was a cyclone-prone area, and the tin sheets could fly off during a cyclone and become a major hazard. Also, it is very hot in summer, sometimes reaching 48 to 50 degrees centigrade in the Rann area. In this situation, people could not live under tin sheets. However, the government still distributed the sheets.

## Information for Development

Availability of information that is reliable was a strongly felt need. Information was floating all around – with the government and the CSOs. Ordinarily, each CSO would carry out its own survey, and the data would remain with them, unavailable to others. Later, another CSO might have carried out a similar survey, unaware of the existing report. Such surveys cost time and money. In addition, the villagers did not get control of their own information. Hence, the communities do not become empowered to actively participate in decisions for development. This, according to Harris (1996), tends to stimulate social exclusion by failing to include local communities.

### Information for Empowerment

As the rehabilitation work came to an end, it was decided that work should continue for development. Among other activities, a databank needed to be organized, as information is power. Each agency trying to do any developmental work has to collect information from a government office, running from one table to another and spending 15 days doing so. This process has to be repeated by any other agency wanting the same data. Finding collated and accurate information at one place is well neigh impossible. Therefore, it was decided to set up a data/information bank. With a comprehensive database, every organization could immediately get the required information.

### Development of Databank

The critical importance of information flow in real time between the government, CSOs and the community underscored the need to electronically connect the central coordination cell in Bhuj with each Setu to enable speedy transfer of the voluminous data being handled by the district administration. With UNDP support (through USAID), the Kutch Rehabilitation Information Center (KRIC) was set up for the collection, processing and dissemination of information. KRIC developed rehabilitation information management system (RIMS) software to analyze village-level data generated by the Setus on progress in the shelter, health, schools and livelihoods sectors (United Nations Development Program, 2001).

A software company became a partner in the creation of the databank. Personnel from the software company and Setu jointly drew up the User Requirement Specifications (URS). The software professionals were entrusted with the job of structuring the data as per the URS, screen design and user interface, information retrieval tools and techniques, and so forth. Setu personnel started working on the questionnaires that would go out in the field, where the data gets collected. A snapshot of the village was to be constructed from the questionnaire. Information to be collected was extensive and diverse, such as whether there was a primary health center or who was the *Sarpanch* (village head) and the cast he belonged to. Occupation of the people was a major component of the database, especially whether there were handicraft artisans and their profiles of skills.

One section of the databank would provide information to donor agencies about requirement of schools, the number of paraplegics requiring help and so forth.

The other section of the databank contained government information, such as various government schemes, bank loan facilities, eligibility for applying for schemes or loans, methods for applying and so forth. The government was keen in providing information about schemes, as this would reduce the number of useless applications. This section was to help the community avoid schemes.

Government information is scattered across diverse departments. Also, different facilities are taken care of by various government levels. For example, within a state,

national highways are central government responsibility; other roads are state government responsibility but, at the district level, Zilla Parishad (or district administration) is responsible, whereas village roads are the responsibility of local government (or *Panchayat*). Therefore, comprehensive data on roads is not available anywhere, even if each individual department has its own set of data well organized. This databank would cut across departments and organizational structures to collate data from the user's point of view.

## Data Collation

Data was collated under 10 sectors, such as shelter, livelihood, health and education. Within each sector, the data was beneficiary-wise. Therefore, if any government policy was made, or a CSO intervention had to be organized, the focus could be on the actual number of beneficiaries, names of beneficiaries, their income and type of intervention required.

For vulnerable sections (widows, handicapped, paraplegics, orphans), where there were organizations and the government had very specific programs, data was organized by individuals' names. It was possible to know if a certain widow was getting her pension, the amount and so forth.

This primary data collected was to be used to complement and support the secondary sources, such as census data. The Setus are to supply both government-generated data where it is available and enrich it with local micro-level data. .

## Data Updating Frequency

The next requirement was to set the parameters for updating frequency. Some data was to be collected every 3 months, some once a year. The basic population and caste statistics—their residence and so forth—would be updated once a year, whereas data about the number of children attending a school, the number of days the teacher was present and so forth was to be collected every month to provide a status report to the government about the state of the schools.

## Report Generation

Special reports were also to be generated as required. For example, OXFAM had taken up work in two villages of laying pipelines that had been damaged by the earthquake. It required information on water availability and usage in that area, especially the social dynamics, such as whether the Rajputs and Harijans get an equal amount of water and so forth. The local Setu coordinator compiled an in-depth study of that locality on ownership of water and its usage, such as the total number of wells, the number of wells belonging to the different castes (such as Darbar, Koli), if there was a pond, whether the water was clean for washing clothes, were Harijan women allowed to use the pond and so on. This report ensured that the OXFAM project would take care of equitable distribution for the entire community and not get skewed. This type of in-depth report was possible because the Setus were part of the community; the Setu members were constantly interacting with village inhabitants.

## Village Gazette

Once the databank was developed, the next step was to develop a village gazette for every village of Kutch. The village gazette is to cover the history of the village, its socio-economic aspects, human resources and natural resources (like different species of vegetation, water, boundaries and so forth). A satellite map would also be provided for natural resources. There would be household survey data for every house and the physical plan of the village. The village gazette would become the one-stop information shop for anyone wanting to work in that area. By data aggregation of the villages, a regional planning tool, a data tool for policy advocacy, would be created.

## Problems of Connectivity

While essential hardware such as Dell servers and database software are available, the Setu centers have their own computers from where data is uploaded on the server through a dial-up facility. The problem remains with connectivity. Telephone is present only in a few places. The Setus that do not have telephonic connectivity yet send their data on floppies/CDs.

The state government has offered the connectivity through the Gujarat State Wide Area Network (GSWAN)—that is, a 2 mbps line to the districts and a 64 kbps line to the talukas. So far, the government has been using the network for teleconferencing and videoconferencing.

## Problem of Sustainability

The development of the database and regular updating requires funds. After the initial funding is over, resources have to be generated to continue the program. It has been envisaged that the users, whether individuals or organizations, will pay for the information, as they will not have to waste time and money for data gathering to commence their work.

## FUTURE TRENDS

After this experience in Kutch, during mid-term evaluation World Bank has recommended the government of Gujarat start Setus in non-Kutch areas. Gujarat government has funded CSOs to start these types of Setus in non-Kutch areas of Patan, Surendranagar, Rajkot and Jamnagar. When Tazakistan had an earthquake, it was eager to emulate Kutch's program. Setus have made empowerment through information for the people, of the people and by the people, possible.

The adoption and use of ICT has led to better community support and development, as explained by Taylor (2004). The civic empowerment through information and knowledge management has made the local community more demanding, a necessity in good governance. This, therefore, will lead to a more proactive government. The work of the Setus has been instrumental in raising awareness among the local citizens regarding the empowering nature of information, use of technology for better access to information and use of information as a potent weapon to fight bureaucratic obfuscation.

The future is in tapping into the cumulative information/knowledge facilitated by digital technology, building on processes and systems already in place and enhancing the role of the local communities in government decision-making.

## CONCLUSION

With advancement in ICT in the form of the Internet, GIS, remote sensing and satellite-based communication links, it is very much possible to plan and implement disaster risk-reducing measures. These technologies have been playing a major role in designing early warning systems, catalyzing the process of preparedness, response and mitigation. ICT tools are also being widely used to build knowledge warehouses using the Internet and data warehousing techniques. These knowledge warehouses can facilitate planning and policy decisions for preparedness, response, recovery and mitigation at all levels (Asia Pacific Telecommunity-International Telecommunication Union, 2005).

To reduce the risk and vulnerabilities in India, the Ministry of Home Affairs, being the Nodal Ministry for disaster management, is taking the lead on disaster management and mitigation in the country. The Ministry has drawn up a National Disaster Management Framework for India. This national framework covers prime sectors, such as institutional mechanisms at all administrative levels and disaster mitigation/prevention to be mainstreamed into the development process (Mohanty, Karelia, & Issar, 2005).

This is a top-down approach of the government at the macro level. The experiences of the Kutch earthquake has established that it is not the technical, but rather the social and cultural, aspects of digital revolution that provide the transforming force. Participation of community members, groups, and organizations is imperative for overcoming crisis. A shared value base between community and policy makers is crucial to the formulation of policies that build, develop and sustain communities (Day, 2004).

In fact, Mathen (2001), writing within 2 months of the earthquake, felt that the process of rehabilitation would not require experts except at the mapping and information-generation stage. Once that was done and shared with people, then their accumulated knowledge, collective wisdom and adaptive skills would work out the "best practices."

Knowledge and recognition of this set of knowledge by the decision makers and people alike are the pillars on which good governance rests. Digitization of this knowledge within a network, open to all individuals, opens possibilities for everyone to access and use this knowledge—paving the way for digital governance (or e-governance). Introduction of digital governance ensures that citizens can participate in and influence decision-making processes that affect them closely. Citizens no longer remain passive recipients of governance services provided to them, but can proactively decide the types and standards of governance services they want and the governance structures that can best deliver them.

## KEY TERMS

**Data Collation:** Data is documented information or evidence of any kind. In library and information science and computer science, collation is the assembly of written information into a standard order.

**Earthquake:** Shaking and vibration at the surface of the earth resulting from underground movement along a fault plane of from volcanic activity

**Information Management:** The administration of information, its uses and transmission, and the application of theories and techniques of information science to create, modify, or improve information handling systems.

**Rehabilitation:** The processes of helping a person achieve the highest level of function, independence, and quality of life possible. From the Latin "habilitas," which means to make able.

## INTRODUCTION

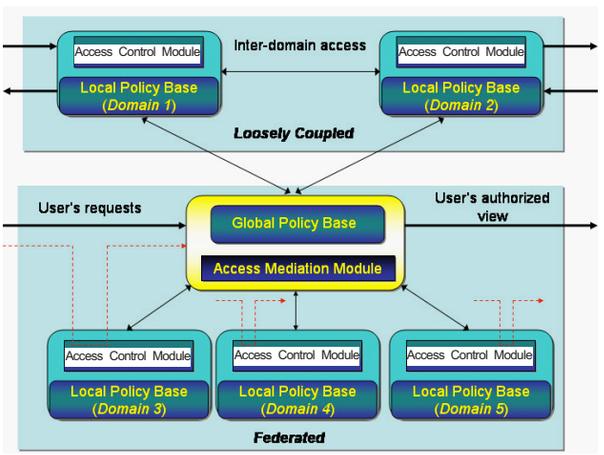
An electronic government (e-government) can be viewed as a large distributed information system consisting of interconnected heterogeneous subsystems through which government agencies, citizens, and public and private sectors interact to facilitate exchange and sharing of huge volumes of information. Such large scale information sharing and interoperation are geared towards streamlining decision-making processes through an efficient flow of information and execution of government's transactions to facilitate easy access to improved services. Key scenarios of system interactions in an e-government include: government to citizen/employee (G2C/E), government to business (G2B), and government to government (G2G), (OMB, 2004). G2C (or G2E) activities cover the interactions and information exchange between government agencies and citizens (or its employees), for instance, while filing government taxes. G2B refers to activities related to interactions between government and public and private sectors, for instance, when a government agency engages in a supplier-consumer or a buyer-seller relationship with a public/private sector business. G2G refers to activities involving interactions between two government entities. An interaction between a state office and a related federal office is an example of a G2G interaction. A critical issue related to these interactions is the need to integrate system components under disparate administrative domains with distinct policies and mechanisms. Crucial goals of an e-government infrastructure also include increasing *internal efficiency and effectiveness* (IEE) and streamlining *common lines of business* (CLoB) (OMB, 2004). For instance, if each of the federal agencies has its own payroll system, the IEE activities may involve consolidating the payroll function of multiple agencies into one system. This makes the payroll function a logical part of different agencies, thus, processing different sets of payroll information, under possibly different security policies. Similarly, if the agencies have CLoBs, the e-government infrastructure would need to remove unwarranted redundancy in service components and information processing activities.

Although emerging IT solutions provide intriguing opportunities for supporting the design and implementation of an e-government infrastructure, use of these technologies, the highly sensitive nature of information it maintains, critical transactions it processes, and the national security issues the government processes bring forth, create significant infrastructure security challenge (GAO, 2004; Joshi, et al., 2001b). The recent GAO report indicates that while interconnectivity of heterogeneous domains is a basic need for an efficient e-government system, it significantly raises the potential for unauthorized access to personal and confidential data and exposes the critical infrastructures to new vulnerabilities (GAO, 2004). A significant challenge is thus, to provide an integrated e-government infrastructure that ensures secure integration of services and information sources, fosters security assured partnerships among public and private sectors, and securely manage government resources.

## INFORMATION SYSTEMS SECURITY

Various goals of information systems security include *confidentiality*, *integrity*, *availability*, *accountability*, and *assurance* (Joshi, Aref, Ghafoor, & Spafford, 2001a). Primary mechanisms that provide the foundation for the security of information systems and infrastructures include *authentication, access control,* and *audit*. Authentication establishes the identity of an entity and is a prerequisite for access control. Access control limits the actions or operations that a legitimate entity performs. The audit process collects data about the system's activity. Once a user is authenticated, the system should enforce access control using an established technique such as a reference monitor that mediates each access by

*Figure 1. Example multidomain environment*



a user to an object. Several access-control models have been proposed to address the security needs of information systems. Traditional access control approaches fall into two broad categories: *discretionary* (DAC) and *mandatory* (MAC). DAC approach lets users grant their privileges to other users, whereas MAC approach uses a classification scheme for subjects and objects. User classification leads to several clearance levels for access control, whereas classification of objects can be established according to their sensitivity. To avoid the unauthorized flow of sensitive information, the MAC model—often known as the *multilevel model*—can enforce *no read-up* and *no write-down* rules with respect to the security levels (Joshi, et al., 2001a).

Several security technologies that are becoming indispensable for large distributed and networked heterogeneous systems, like an e-government, include *firewalls, intrusion detection systems, encryption techniques, public key infrastructure (PKI) technologies,* and *trust management techniques*. For an e-government infrastructure, designing and implementing various security mechanisms in an integrated manner poses a daunting challenge.

## SECURE INTEGRATION IN E-GOVERMENT SYSTEMS

An e-government system is essentially a multi-domain environment containing a number of independent security domains employing their own security policies, mechanisms, data models, and different architectures and computing platforms. A multidomain environment can be characterized as either *loosely coupled* or *tightly coupled* (Joshi, Bhatti, Bertino, & Ghafoor, 2004). Figure 1 depicts the two forms of multidomain interactions from an access control perspective. In a *loosely coupled* environment (e.g., domains 1 and 2), systems dynamically form transient partnerships. On the other hand, in a *tightly coupled* or federated multidomain environment (e.g., domains 3, 4, and 5), the domains form more or less a permanent partnership and their security policies are integrated to form a mediation layer or a metapolicy that mediates all accesses. Typically, a complex multi-domain environment, such as that formed by all the five domains in Figure 1, may contain several component multidomain environments that are either *loosely coupled* or *tightly coupled.* For instance, given a particular state in the USA, all state agencies can be either federated or loosely coupled with each other, depending on requirements. A *State Office* may be loosely coupled with the *Land Records Office*, but the *Land Records Office* maybe federated with the *City Electricity* department. But the components of the e-government associated with two different states may actually be acting as two loosely coupled domains. For instance, if the *Police department of Pittsburgh* wants to interact with the *Police department of New York City*, then the interaction could actually be between two independent multidomain components associated with *Pennsylvania* and *New York*, respectively.

Achieving secure integration in such a heterogeneous environment is a multifaceted problem. The key challenges include: *semantic heterogeneity, secure interoperation, risk propagation and assurance,* and *security management* (Joshi, Ghafoor, Aref, & Spafford, 2001b).

### Semantic Heterogeneity

Heterogeneity may exist in several forms (Hosmer, 1991). For example, it may be composed of diverse interacting constituent agencies with different policies, or the variations of the same set of security goals, and/or may have heterogeneous system components such as operating systems, databases, and so forth, each with different security goals and mechanisms. Integrating such heterogeneous systems within an e-government infrastructure requires powerful mechanisms to resolve semantic heterogeneity among the security attributes of the individual domains that span different layers and components. Policies can give rise to naming conflicts among similar security attributes, and structural conflicts among policy components such as user/role hierarchies and access rules.

## Secure Interoperation

*Secure interoperability* among partner domains in a multidomain environment is a crucial issue and can be achieved by enforcing the principles of autonomy and security (Gong & Qian, 1996): The *principle of autonomy* states that *if an action is permitted in an individual domain, then it should also be permitted during interoperation*; whereas, the *principle of security* states that *if an action is not permitted in an individual domain, then it should also not be permitted in interoperation*. It is possible that when two perfectly secure domains allow cross-domain interactions, the interoperation introduces security holes (Gong et al., 1996). For example, consider two systems $S_1$ and $S_2$, and assume that user *A* can access whatever user *B* can access in $S_1$, and user *C* can access whatever user *D* can access in $S_2$. Now, suppose we allow $S_1$ and $S_2$ to interoperate by allowing *D* to access *A*'s files and *B* to access *C*'s files. This results in the violation of the security principle, as B can now, because of transitivity, access *A*'s files, which was not permitted within $S_1$ alone. A crucial problem is related to the issue of the verification of the correctness of the integrated policies and the complexity issues related to it (Joshi et al., 2001b).

## Assurance and Risk Propagation

A multidomain environment is a single-point of failure system. In other words, if a single e-government component is compromised, the entire infrastructure could become vulnerable to attack. Hence, appropriate mechanisms need to be in place to ensure that system components are highly assured and that propagation of risks to unaffected systems from potentially compromised systems can be controlled in a timely fashion. Assurance indicates the confidence that the security goals are met by the enforcement mechanisms deployed (Joshi et al., 2001b). A related issue is the *cascading problem*. In general, information that e-government systems contain may use various security classifications in different domains. Consider two multilevel systems *X* and *Y* that classify information as *unclassified* and *secret*, and *secret* and *top secret*, respectively. When integrated, they will collectively process the information at the three levels and share them. If the two systems are individually compromised, that is, a malefactor can now downgrade *top secret* to *secret* in *Y* and *secret* to *unclassified* in *X*, then the *top secret* information can be easily made available as *unclassified* information in system *X*. Thus, in an e-government environment, each system should maintain a high level of assurance and be aware of the security assurances of the other systems. Determining the level of interconnectivity among e-government components based on risks that each poses is highly desirable but difficult to achieve because of the complexity of determining risk that each component may pose.

## Security Management

Security management is another significant challenge for an integrated e-government infrastructure because it contains a large number of administrative domains with huge pools of subjects, objects, and resources that need to be managed. In particular, these entities may not be known at policy design time. For example, a federal agency may not exactly know which types of users or private businesses it will be interacting with in the future. The entities that represent users, objects, policies, security domains, and other components may also be transient. This inherent dynamism makes the task of overall management and, in particular, security configuration management, and the management of metapolicies and policy evolution very difficult (Joshi et al., 2001b). Practical and efficient methodologies for security management will be crucial for the success an e-government. A challenge requiring significant national effort is that of creating efficient and effective nation wide plans for incidence handling, disaster recovery and business continuity.

A key technical problem in an organizational system is the insider attack that disgruntled employees can launch. In an e-government, this can pose a serious national security risk. Such a problem can exist because of inadequacy of systems to properly administer access policies and ensure their enforcement (Briney, 2000). Proper management of authorization policies, and policies related to the use of various software programs such as e-mails, browsers, and so forth and use of up-to-date virus protections can greatly reduce insider attacks that can often be considered accidental or unintentional. Such unintentional insider security breaches can largely be avoided through education and awareness, for instances, as advocated by the Human Firewall Council. Approaches using separation of duty and granting of least privilege to users can greatly reduce the misuse of resources by an insider.

The gravity of insider threat in an e-government environment accentuates the need for proper monitoring of not just the technical activities of employees with crucial knowledge of the working of the e-government infrastructure, but also their personal traits to detect any deviant behavior. Doing that requires a careful balancing act between monitoring employee activities and maintaining citizen privacy.

## Approaches to Secure Integration

The primary requirement for achieving secure integration of disparate systems is a generic and flexible policy specification framework that is expressive enough to specify a wide range of security policies and can provide a semantic basis for policy composition and modifications (Hosmer, 1991). Role-based access control (RBAC) has emerged as the most promising approach for the specification of diverse security policies, because of its policy neutrality and flexibility, that facilitates policy integration in multi-domain environments (Joshi et al., 2001b). Significant security administration benefit is provided by an RBAC approach through use of role hierarchies that define role-role relationships. RBAC based policy and metapolicy frameworks can be used to allow autonomy and transparency for the policies of individual domains and facilitate policies' continuous evolution.

Database schema integration techniques using data dictionary approach can be used to address the semantic heterogeneity problem (Batini, 1986). Additionally, emerging XML and Semantic Web technologies have shown significant promise for addressing the semantic heterogeneity problem while integrating diverse systems. In particular, use of ontology to assist in semantic mapping between security policies of different domains is becoming a possibility because of the tools such as *resource definition framework* (RDF), *DARPA Markup Language + Ontology Inference Layer* (DAML+OIL) and/or *Web Ontology Language* (OWL). Ontology can be defined as "*the specification of conceptualizations used to help programs and humans share knowledge*" (Gruber, 1993). Security "ontologies" may be used to capture the names used to indicate various security attributes and their intended semantics and relationships in different security domains (Qin, 2003). Similarly, the domain ontologies related to information in different security administration domains can provide a basis for identifying information objects and their associations that need to be protected against unauthorized access.

For a loosely coupled system, secure interoperation may be achieved (Joshi et al., 2004): (1) using pre-defined role mappings, which requires a specification of the level of sharing between the interoperating domains; and (2) using certificates for the arbitrary role-mappings, which involves an understanding of the kinds of accesses given to a principal depending on his credentials. This may require a *trust negotiation* and/or a *trust management* framework. Trust negotiation technologies facilitate willing partners to cautiously form a loosely coupled environment through controlled dissemination of sensitive policies by employing negotiation strategies to agree on the level of sharing of information, particularly in peer-to-peer environments. Several trust negotiation languages have been recently proposed, such as Trust-X (Bertino, Ferrari, & Squicciarini, 2004) and X-TNL (Bertino, 2004). An RBAC approach to trust management can be used to address security problems in decentralized multi-domain environments. One such language is RTML (Li & Mitchell, 2003). Some other proposed trust management solutions include TrustBuilder (Winslett et al., 2002). Other works related to the integration of multiple policies have been primarily in the context of multilevel security models (Bonatti, Sapino, & Subrahmanian, 1996; Gong et al., 1996). Recent work include trust based approaches and role-based approaches (Gavrila & Barkley, 1998; Piromruen & Joshi, 2005; Shafiq, 2005).

A promising new approach to achieving secure integration is using the newly emerging Web services based architecture, in particular for loosely coupled environment (Medjahed, Rezgui, Bouguettaya, & Ouzzani, 2003). Secure interoperation between Web services involves trust management, which can be handled through WS-Trust. Other architectural methods include common object request broker architecture (CORBA) and OSF distributed computing environment (DCE). CORBA and DCE do not have formal semantics for policy specification and thus make security mechanisms more or less ad-hoc (Joshi, 2001b).

For federated systems, the role hierarchies and constraints of the domains are integrated to ensure that the principles of autonomy and security are not violated. In the process, new role-relations may need to be created between roles of the different domains (Joshi et al., 2004). Traditional database federation approaches have been found very useful for implementing tightly coupled environment. Database integration is applied to policy integration, by which global authorization policies are mapped to the local rights (Jonscher & Dittrich, 1995). Besides RBAC, DAC and MAC, access control approaches based on credential certificates in multidomain system have been addressed (Joshi et al., 2001a).

Interoperability of workflows across different domains in e-government system will be a significant challenge, as it needs to integrate processes that span multiple transactions across multiple systems. Work related to security of workflow systems or task oriented systems are limited and remain a significant challenge (Atluri, Huang, & Bertino, 2000; Joshi et al., 2001b). Table 1 shows a comparison of various access control approaches.

To manage secure integration of multiple heterogeneous policies in an e-government environment, a multiphase approach, depicted in Figure 2 is desirable (Joshi et al., 2004). The pre-integration phase deals with the bookkeeping aspects of integration involving maintenance of detailed semantic information about policy entities, such as the roles and rules of the individual do-

*Table 1. Access control approaches and features compared*

| Approach | Features |
|---|---|
| DAC | Ownership based, flexible, most widely used, does not provide high degree of security, and hence low assurance |
| | Typed versions such as SPM, TAM and DTAC are expressive but have little or no experience base |
| | DTAC can handle dynamic changes and task based control |
| | Most cannot be used where classification levels are needed |
| | Typed versions have tried to include classification levels |
| MAC | Administration based |
| | Information flow control rules; uses classification labels |
| | High level of security, and hence high assurance, but less flexible |
| RBAC | Policy-neutral/flexible; Principle of least privilege |
| | Separation of duty; Easy administrative features |
| | Able to express DAC, MAC and user-specific |
| | Can be easily incorporated into current technologies |
| | Good potential for use in multidomain environments when policies are expressed using role hierarchies and constraints |
| Access control for Tasks or workflow Systems | Task-oriented authorization paradigm, RBAC for WFMS |
| | TBAC is at an initial stage of development |
| | Key for success of transaction intensive DG environment |
| Certificate-based | Utilization of existing PKI facilities |
| | Complements the host's access control model |
| | Can use trust centers in the WWW |

mains, and domain attributes that can assist in detecting semantic differences. Information maintained in this phase can also be used for managing incremental changes in domain policies. The policy comparison phase involves detecting semantic conflicts, including naming conflicts among domain roles, or structural conflicts among role hierarchies. Semantic conflicts among these entities can be detected by comparing the information obtained in the pre-integration phase about various domain entities. Developing techniques for automatic detection of semantic conflicts is a challenging task. The policy conformance phase focuses on resolving semantic and rule conflicts. A key challenge is to develop automatic techniques to synthesize mediation policies. The overall process of generating a correct and consistent mediation policy is typically an iterative process. In particular, considerable restructuring and refinement of the mediation policies may be needed. Such iteration, in conjunction with the policy conformance phase, is carried out by the merging/restructuring phase. The methodology can be augmented by assurance-based risk assessment of the domains engaged in cross domain interactions.

## CONCLUSION

A key challenge to e-government infrastructures is the secure integration of the disparate information systems associated with the different government agencies, public-private sectors, as well as individual citizens. In essence, the e-government environment is a multidomain environment that needs to facilitate intense inter-domain interactions. This raises serious concerns related to semantic heterogeneity, secure interoperability, risk propagation, and the overall management of the integrated infrastructure. Diverse sets of security models and mechanisms are available to address different issues such as access control, authentication, and auditing; however, a holistic approach is needed to address the system-wide issues and requirements. These challenges could pose a roadblock to the timely deployment and the success of the e-government infrastructures.

## KEY TERMS

**Cascading Problem:** The problem that exists among different domains employing different sets of multilevel security levels, such that the higher security level of one domain is a lower security level of the other. If both systems are individually compromised, the interoperation will allow sensitive information from the system with higher sensitivity levels to be leaked to the one with the lower sensitivity levels.

**Loosely Coupled:** When systems unknown to each other dynamically establish transient partnerships and facilitate cross domain interactions for a short period of time, they are said to have formed a loosely coupled environment.

**Ontology:** A classification of the concepts in a system and the relationships between these concepts.

**Role-Based Access Control:** The form of access control approach where users are made available permissions they require within a system based on their roles in the organization.

**Secure Interoperation:** When different security domains allow cross domain accesses, and these accesses conform to the defined local policies as well as the established cross-domain access policies, they are said to engage in a secure interoperation.

**Semantic Heterogeneity:** The differences between the meanings and concepts attributed to similar entities, and the similarities between the meanings attributed to different entities by different domains refer to semantic heterogeneity.

**Tightly Coupled:** When two systems, previously known to each other, tightly integrate their policies to maintain high degree of information sharing and cross domain interactions, possibly on a permanent or a long-term basis, they are said to have formed a tightly coupled environment.

**Trust:** A certain level of assurance an entity has on another system that it will act as it is supposed to.

# Information Security Management in Digital Government

## INTRODUCTION

Ensuring security for its information systems, including computers and networks, is a fundamental prerequisite for a digital government to function to the expectation of its people. The security problem can be "visualized" by projecting it onto a three-level hierarchy: management level, system level, and application and data level. The key elements of information security include integrity, confidentiality, availability, authentication and non-repudiation, which have to be taken into account at different levels within the hierarchy. Since there are specific articles in this encyclopedia to address the security issues at the lowest two levels, this article will focus on the management level at the top level of the hierarchy.

At the management level, the main emphases are to prevent security breaches from happening and to minimize the impact when security events happen. The decision of security investment and deployment requires clear identification of risks posed to the information systems and feasible cost analyses. In addition, to ensure that the investment and deployment are worthwhile, information security policies and procedures have to be thoughtfully devised and effectively enforced. Therefore, at the management level, *risk assessment*, *cost analysis*, *policymaking*, *procedure definition,* and *policy and procedure enforcement* have to be looked into.

## RISK ASSESMENT

Risk assessment is a systematic approach to identify critical risks, analyze the impacts of the risks and mitigate them. With limited resources for putting in place a security process, a digital government has to assess potential risks to ensure that resources are deployed in an optimal manner. Therefore, the following steps, namely *risk identification*, *risk impact analysis* and *risk mitigation*, have to be taken.

- **Risk Identification:** The objective of risk identification is to delineate those risks that can have significant impact on the functionality and credibility of the digital government. Aspects to be looked into include *technical source of risks*, *procedural source of risks* and *probability of security breach* (Rajput, 2000).
  - **Technical Source of Risks:** Weaknesses and limitations inherent in the employed techniques, such as the encryption, firewall and so forth, need to be identified. For example, as computing power keeps increasing, the strength of the data encryption standard (DES) (Stallings, 1998), which has been in widespread use for some 20 years, is pushed to its limit and no longer deemed as secure for critical processes.
  - **Procedural Source of Risks:** Procedural controls in administration processes and system access processes may also have some loopholes to be covered. Personal behavior and organizational culture may also have influence on procedure and practice.
  - **Probability of Security Breach:** Probability of the occurrence of potential risks needs to be studied so that risk impact can be objectively analyzed. A model for calculating the probability of a breach occurrence can be found in Coleman (2003).
- **Risk Impact Analysis:** With the potential risks identified, impacts on the following aspects need to be analyzed.
  - **Credibility of the Government:** "Visible" security breaches, physically significant or insignificant, can harm the credibility of the government and reduce its people's confidence in it. For example, the reputation of a government's ability to protect its information or even its people may be compromised if the

images of the national flag on its governmental portals are replaced by its rival nation with the images of the latter's national flag.

- **Information Availability and Service Continuity:** 24-hours-a-day/7-days-a-week information availability and service continuity are the key requirements and characteristics that distinguish digital governments from traditional governments. Unavailability and discontinuity of information services will certainly have prominent impact on the functionality of the government, and therefore need to be analyzed.

- **Risk Mitigation:** Risk mitigation is the process of using effective controls to minimize the impact of the risks to an acceptable level. This process enables the government to determine how much risk it is prepared to take and to what extent its assets and data should be protected. To mitigate the impacts of the potential risks on the digital government, essential technological security controls need to be put in place, and procedures and practice guidelines have to be drawn up.

The level of acceptable security is determined by weighing the probability of threat against the cost of putting up resistance against the threat. Within the level of acceptable security, identifying and attempting to mitigate the risks with low probability of occurrence have insignificant value. There is a wide spectrum of implications stemming from the need for risk mitigation, such as cost, policy formulation or even cultural change among the civil servants of the digital governments.

## COST ANALYSIS

Effective security mechanisms require a process that allows digital governments to determine informatively the acceptable level of security within which risks are mitigated to a minimum. Once the security level is determined, cost analysis aiming at reaching that level can then be carried out. Cost analysis includes:

- *Direct financial costs* incurred by the acquisition or lease of security assets and services, such as network monitoring devices, firewalls, encrypting routers and lease of Virtual Private Network (VPN) services. In addition to the hardware and software, a department charged with the responsibility of ensuring information security has to be established. External or independent audits also have to be involved regularly for reviewing the security practices and procedures, assessing unidentified risks, and making recommendations and reports. These all add up to a significant overhead.
- *Indirect performance costs* incurred by the incorporation of processes of authentication, administration, encryption, integrity verification, policy enforcement and so forth. Some of these processes will directly reduce the performance and efficiency of the IT systems. Some (e.g., policy enforcement, security controls and security audit) may result in rivalry between government agencies, which may cause ill effect on the performance of the government itself rather than on the information technology (IT) systems.

## POLICYMAKING

Security policy is a set of rules that regulate how a digital government manages the risks and protects its data and information systems. This has to take into account the management, uses and distribution of its information and IT assets. Aspects to be looked at when formulating security policies include:

- **Standards:** Any digital government committing to information security needs to look for guidance to achieve consistent, comprehensive and assessable security. Several standards providing useful guidance are now available. BS 7799/ISO 17799 (BS 7799 Part1, 2000) is one of the most prominent standards.
- **Data Classification:** Over-protection might have negative impact on the performance of the government, while under-protection may compromise the security. Data classification facilitates selective security enforcement.
- **Regulation of Use of Data and Assets:** For example, the use of live information for development and testing should be prohibited and the use of sniffers (i.e., software or devices monitoring data flowing over networks) has to be regulated.
- **Human Rights and Privacy:** Regulations governing the protection of human rights and privacy is the part of a digital government's commitment that has to be addressed in the security policy.
- **Response to Warnings:** Digital government agencies should set up pre-defined procedures and actions to take in response to security incidents of different levels of security concerns or warnings issued by security organizations, such as the Computer Emergency Response Team (CERT), so that the agencies could respond promptly.

- **Security Awareness Education:** Government employees and system users should be made aware of the security policies, practice codes and responsibility. Security training should be provided to all personnel involved in the design, implementation, maintenance and use of the information systems.
- **Liability:** Individuals subjected to the security policy must understand their responsibility and liability. Legislation governing information security should also be in place and up to date.

## PROCEDURE DEFINITION

While policies are rules describing *what* and *why* of information security within the digital government, procedures are more detailed and precise documents telling *who*, *when* and *how* of information security. These procedures should include:

- **Secure Backups:** Backup procedures should include:
  - Backups for configurations of information infrastructure.
  - Backups for servers that provide network/Web services.
  - Distributed off-site storage backups.
  - Regular verification of the integrity of the backups.
- **Assets Certification:** This to ensure that assets used in the information systems comply with specific security requirements.
- **Audit Trails:** Activities on the information systems should be noted, monitored and analyzed so that security events can be prevented or traced. Configurations of network infrastructure have to be verified to ensure their validity.
- **Plan for Disaster:** There is no such a thing as a 100% secure system. To ensure a digital government can still continue to function properly when the worst strikes, a contingency and recovery plan for crisis management is of paramount importance. This should include computer security incident response procedures (CSIRP).

## POLICY AND PROCEDURE ENFORCEMENT

Enforcing security policies and procedures is a constant endeavor of a digital government. Complying with standards is an effective way of policy and procedure enforcement. Two good sources of information to look to are BS 7799, which is a standard consisting of two parts (BS 7799 Part 1, 2000; BS 7999 Part 2, 2002) that set out the requirements for an information security management system (ISMS). They help identify, manage and mitigate the impact of risks to which information is constantly subjected. Part 1, divided into 10 sections and internationally adopted under the ISO reference ISO/IEC 17799, contains explanatory information and guidance. Part 2 suggests a model for organizations to build and run their ISMSs. Another useful resource is the Turnbull Report (Turnbull, 1999), which sets out how organizations should comply with the requirements for financial and operational controls to tackle the issues of risk management.

Another way of enforcing policies and procedures is regular audits, which help the government agencies review their systems and security practices, and identify overlooked risks.

## CONCLUSION

Information security can be visualized by projecting the security problem onto a hierarchy consisting of management level, system level, and application and data level. Policies and procedures determined at the management level set out the guidelines and rules that govern the security implementation at the other two, lower levels. To establish effective policies and procedures, the managerial staff at the top level needs to properly assess the risks. Risk assessment includes risk identification, risk impact analysis and risk mitigation. Complying with standards facilitates effective enforcement of security policies and procedures.

## KEY TERMS

**Audit Trails:** A chronological log keeping track of network traffics, system activities and abnormal behaviors that provide clue to security breaches.

**Computer Emergency Response Team (CERT):** An organization that provides services regarding security issues of computer systems and networks, such as technical assistance for responding to computer security incidents, raising public awareness of computer security issues and product vulnerability assistance.

**Computer Security Incident Response Procedure (CSIRP):** CSIRP is a procedure spelling out the actions an organization should take when information security breaches occur.

**Data Encryption Standard (DES):** A symmetric secret key cryptographic scheme operates on a 64-bit message block using a 56-bit secret key. The characteristic of symmetry means that encryption and decryption use the same secret key.

**Information Security Management System (ISMS):** ISMS is a systematic approach to managing and protecting sensitive information of an organization so it remains secure. It encompasses people, processes and IT systems.

**Risk Assessment:** A systematic approach to identifying critical risks, analyzing the impacts of the risks and mitigating the risks.

**Risk Mitigation:** A process of using effective controls to minimize the impact of risks to an acceptable level.

# Information Sharing as a Democratic Tool

**Thomas B. Riley**
*Commonwealth Centre for E-Governance and Riley Information Services, Canada*

**William Sheridan**
*Commonwealth Centre for E-Governance and Informetrica Limited, Canada*

*... the degree to which organization members at each level in an organization have a reason to be willing to share information is often the single most important factor in the design of any e-governance program.* (Perri, 2004, p. 39)

## INTRODUCTION

This section begins by looking at ways in which governments can facilitate better access to information in both the public and private sector. This is an important factor in the e-governance equation. Information sharing is an essential activity for government for any form of e-governance program to succeed, because information provides the evidence of a correspondence (or lack of correspondence) between policy and reality. The particular emphasis herein will be on the growing influence of the Internet and all the new, emerging communication technologies through which services can be delivered in all sectors of society. The role of the Internet and the growth of electronic democracy are briefly explored.

Part of the rhetoric of both information management and public consultation is the notion of information sharing. This concept is, in fact, one of the central tenants of knowledge management. Despite these good intentions, however, management gurus (Drucker, 1999) find themselves continually admonishing both organizations and knowledge workers of the need to share more information. Is there an information gap between colleagues, so that work is impeded or prevented because co-workers don't communicate with one another? And by the same token, is there an information gap between knowledge workers and the public, so that the public cannot make informed choices about important decisions?

### The Role of Government

Governments are particularly interested in the answers to these questions, because they are held to a higher standard of accountability than the private sector, and any suspicion that strategic information is being intentionally withheld is sure to further erode the sense of legitimacy people feel towards their governments. One can infer that some sort of information gap does occur, else there would be no need for continual injunctions to overcome it. Diagnosing why it occurs and how to cope with it has become a growth industry (Rumizen, 2001).

One reason for the existence of an information gap in governments is that neither the information holdings nor information management have been rationalized as computerization and digitization have grown (Milner, 2000). These sections of the bureaucracy have always felt both under-funded and understaffed, so they were struggling just to keep up with current requirements, never mind planning to do better. Professionals such as information and knowledge managers usually advocate that governments devote the resources and make the effort to be both more systematic and share more widely when it comes to the way information holdings are organized and the extent to which information outreach is practiced (i.e., keeping the public informed).

Data protection (also known as privacy laws in many countries) is currently the major information issue that covers both the public and private sector. In a very short period of time, we will likely see freedom-of-information expand from the conditions for access to government documents to encompass both the public and private sectors. Information best practices also need to be written to help the developing world. In an information-rich era, combined with the rise of the dominance of the Digital Age in many countries, great potential exists to democratize information at all levels of society throughout the world. Due to our new information technologies (ITs), information is not only a commodity to be bartered in the marketplace, but a potentially powerful democratic tool.

### The Context of Information Sharing

The wide variety of practices leads to an important question: Is there an objective (i.e., politically neutral) way of assessing the actual value provided by governments when they share information with the public? Unfortunately, at this level of aggregation, the question is both

too vague and too encompassing to elicit a meaningful answer. Nevertheless, the question can be deconstructed and dealt with in terms of its various aspects.

This is perhaps one of the most interesting times, given that we are undergoing an evolution as to how we live and operate as a society. We are witnessing a phenomenal rate of change in societies around the world in a very short period of time. Even as long as 11 years ago, a survey of IT showed that the global impact of computers and communications was already measurable and profound (Dordick & Wang, 1993). Both production and distribution in every industry are increasingly becoming mediated with electronic technologies. Access to information can enable both the tracking of processes already in motion and the altering of conditions about to unfold. Hence, the key to understanding and controlling social change is good information sharing.

Even while operating at less than full efficiency, the combination of computers and communications (i.e., the Internet) has transformed the quality of working life, social life and personal life to an extent that was probably never before experienced in human history (Buick & Jevtic, 1995). Everyone benefits through processes informed by more information and better information, even those individuals who do not personally use computers or have access to connectivity. So the information that supports the knowledge society has great potential to supply timely and correct evidence for both social and business policies. But the only way such benefits will actually accrue to society is if this knowledge is actually used to improve or change the conditions of peoples' lives. In other words, information must complement reform if things are going to improve for the better. Information by itself has no magical ability to stop pollution, prevent crime, create jobs or rectify injustice. Is the knowledge from the Internet used for these purposes? That can only be assessed on a country-by-country, community-by-community, case-by-case basis.

## INFORMATION SHARING AS A DEMOCRATIC TOOL

Many countries have adopted explicit programs to put "Government Online" so that the layout of documents and navigability of government Web sites are more user-friendly (Nielsen, 2000). The rationale for these programs has been that as more of the public goes online, users of government information will not be happy if they can't find material that was promised or is expected because it is hidden as a result of poorly conceptualized categories or poorly organized hyperlinks. Considerable progress has been made on this front to make document search intuitive so that average members of the public can navigate their way to whatever is available on government Web sites.

Whatever the opinions or views of individuals and governments in society, it is evident that we need a far deeper debate and discourse over the impacts of technologies. There are concerns over ensuring that all citizens have universal access to the Internet (and are free to use it or not use it as they wish); there are serious, abiding anxieties about the digital divide that is occurring throughout the world. One of Marshall McLuhan's lasting legacies is the recognition that the advent of technologies is not an unalloyed good—sometimes over-use can reverse the benefits that were intended.

### The Need for Policies

As the Internet takes hold in our daily lives and begins to take a new and ubiquitous shape and form, the need for governments to develop information policies to suit the changing nature of these technologies is becoming more evident. The direction to be given to these policies can come from the simple maxim that people are entitled to receive information about anything that has a bearing on their well-being. The World Wide Web is now so big that some Web sites are not even getting joined to the network of networks because there might be a connection problem in their local area. Also, government and private organizations over the past few years have Web sites that can only be accessed through their own Intranets, or by having a specific address for a Web site with a password to enter. Google is an excellent search tool, but is only as good as the information it can access in the public domain.

The world is at the fingertips of the citizen, but the new challenge is actually finding what is out there and getting access to the vast amounts of information that both government Web sites and departmental databases possesses. The government of Canada is working to find ways to merge its databases to enable the citizen to take advantage of information stored by government. Many technical problems are being faced. This attempt to find ways to provide more information to the citizen reflects the desire to respond to a growing information-aware society.

## THE SHAPE OF INFORMATION RIGHTS TO COME: DEMOCRACY'S BEST TOOL

Regarding the variety of information within government databases about existing policies and procedures, there

are often background papers or official pronouncements available on government Web sites that lay out in general terms what policies or directions the government is committed to or contemplating (Hunter, 2002). Policy experts, public interest groups, and business people or representatives usually find these materials useful but generally too vague or theoretical. More detailed information on these topics would assist those who will be affected to make the necessary adjustments, but that in turn can commit the government to alternatives it either hasn't thought through yet or wants to have some discretion with during implementation (Kettl, 2002). What has the potential to open this area to wider information dissemination and public participation is the growing practice of participatory rule-making (Kerwin, 2003).

In some American states, some federal departments and, increasingly, in other countries, stakeholders in a statutory/regulatory policy area are being invited to help write the rules that will implement the legislation. This requires participants who are well enough informed to actually contribute to the process, and to arrange that informative Web sites on every case are created (and supported in the back office). This way, all of the relevant material is continuously available, and responses and feedback can be e-mailed back during the lifetime of the project. Much more of this kind of information sharing would be helpful to anyone interested in a specific program, statute or regulation.

## Information Security

In the new digital environments, citizens are increasingly demanding more privacy rights to protect their personal information. However, there is also a contradiction here, because at the moment, citizens are sharing and using personal and aggregate information more than ever before. But in a cyberspace environment, the citizen is becoming increasingly sophisticated in understanding the impact that information can have on one's life. The individual wants to ensure that one's own personal information is not abused. The individual wants the ability to control his or her personal information environment in cyberspace. At the same time, the individual wants unfettered access to all manner of information. But the sheer amount of information available, the ability to communicate information and the value that individuals put on information is bringing a new understanding of the nature of information itself.

Thus, on the side of freedom of information, the public is starting to demand more information for all facets of its life. We see more data on labels of commercial products; shareholders demand more information about the activities of the companies in which they are investing (not just the usual hyped good news about the company's activities in the past year). Much of this trend has been driven by the alleged financial malfeasance of companies such as Enron and WorldCom in the United States (U.S.) and Nortel Networks in Canada.

## Democratic Accountability

Citizens want to share more information about many activities in society. The Information Age appears to be bringing more demands for accountability. In years to come, the public will expect more accountability in the form of enlightening information from private and public organizations alike. Much of this is being driven by the Internet, where there is now so much discourse, exchange of information and thousands of blogs. The Internet is an open network contributing to the development of open environments. This idea is now spreading into society as a whole, resulting in demands for more and more accountability from all our public- and private-sector organizations. In the face of such demands, those who manage information repositories are beginning to consider the possibility of offering voluntary sharing rather than being forced into mandatory disclosure.

Making available information about the future developments of policies and programs is the most problematic part of government information distribution. There are a number of reasons for this – one is the nature of representative government itself. Many public officials, both elected and appointed, see policy development as their prerogative in so far as it reflects a division of labor within governance (Rhodes, 1997). It is a role that many of them guard jealously and share only reluctantly (Cullen & Cushman, 2000). In this context, sharing more than a minimal amount of information about prospective policy development could be interpreted as the thin edge of the wedge that would eventually erode their role in policy-making itself. The other side of this coin is the firm belief by these same public officials that most people either do not want, or are not willing to take the time or give the effort necessary, to become effective participants in governance.

## Information Rights

We currently live in an age of individuals' rights developed in the late nineteenth and twentieth centuries. This will change, as the recognition dawns that it is also aggregate rights that strengthen the citizenry as a whole. As this idea flourishes, demands for information on a more sophisticated level will grow. Information rights will become a part of civil society's infrastructure. As the knowledge economy grows, and the knowledge professional comes to be seen as a continuing, powerful force

in our society, so will the demands for wider swathes of information grow. It might seem at the moment that we already live in a world with too much information. The change in this demand for information will be for relevant information that enlightens, not overwhelms, the citizen. These trends are creating increasingly new problems for governments. In the spreading e-democracy movement around the world, the major emphasis is on how governments can better provide information to the citizen and how the public can take advantage of what is available from government. Technology is the key driver in finding ways and means to allow the public to access public information.

Not everyone wants or will use more and better information if it is provided by governments on their Web sites. But a growing number do want it, and will use it, so the question really is whether governments will recognize the wave of the future and surf it willingly. In Canada, for example, 52% of citizens online go to government Web sites for a variety of usages.

The information issue now has a new form. Governments are also going to be subject to pressures from emerging information trends in society. For example, the secrecy of governments, at the moment, is defined by the degree to which information is shared with the public. The weakness of a freedom of information law is shown by the narrowness with which governments exempt withholding of information from the public. But governments need to do more than just pass or amend freedom of information laws. In our new environments, we have to look at information as the social force it has become. Changing environments are beginning to bring different attitudes.

## Responding to Public Demand

Once governments put content online, a policy issue immediately emerges. The private sector learned this in the early days of the Web. The growth of online marketing and e-commerce brought with it major privacy and copyright issues. For the citizen who is going online for government information, if a request is rejected, the issue becomes: Why can I not have access? Part of the answer to this is that government departments and agencies decide in advance what information can be public, based on their respective freedom of information laws, and only make documents publicly available very selectively.

Almost all policies, statutes and regulations will impact the public in terms of one or more of (a) taxes paid, (b) revenues spent, (c) actions required, or (d) actions prohibited. In addition, government programs usually also affect how the economy functions in general, and how companies operate in particular. The more such impacts can be known in advance, the more opportunity there is to begin the adjustment process as soon as possible, so that new requirements do not hit the public suddenly and traumatically. And for every option foreclosed, others are just as likely to open up, so planning can begin to take advantage of the new arrangement and either minimize losses or maximize gains. The new expectations for transparency now require that such information be made available to the entire public (Oliver, 2004).

In an information-intensive society, citizens might want more from both governments and the private sector alike. The above is simply an overview of the emerging issues and problems. Solutions need to be sought as these new technologies become even more persuasive forces in our society.

# POSSIBLE SOLUTIONS: INFORMATION AS A PRACTICAL TOOL

There is a good model to be followed not only by national governments but international organizations. If we are to handle the digital divide between those who have the opportunities to be online and the vast numbers of people who cannot necessarily afford the costs of going online, it is going to be essential to level the playing field. In any populist democracy, it is important that such initiatives embrace all the people**.** At the moment, it is estimated there are only between 150 and 200 million people online. These are small numbers, where our world population has exceeded 6 billion people.

More publicly provided connectivity, such as through libraries or community centers, could help disseminate more government information to the citizenry (Gurstein, 2000). More declassification of mundane information by government would also be helpful for that goal. The policy of cost recovery through the charge of fees on downloads could also be reviewed, since most of the cost with hard copy production and distribution previously was for printing and mailing, both of which are now dispensed with because of Internet availability and end-user printing. The actual cost of gathering, analyzing, reporting and posting the information is the kind of expense governments have previously borne as part of their mandate, and a return to that policy would also greatly assist information dissemination.

International organizations could also provide programs to educate people on usage of the Internet. Education then leads to individual usage. It usually will vary between individuals, but through knowledge of how to use the Internet people can be participants in this more encompassing form of democracy as they see fit. Such programs can embrace many people around the world and

ensure that the users who most benefit are not just those in the affluent, industrialized countries.

## Guidelines for Better Performance

National government should seek ways to engage its citizenry in the process of government. It can do this in such information-sharing ways as:

- Making more information available online from government itself to ensure there is an informed citizenry
- Providing Web sites that seek input from people on all manner of government programs and issues
- Developing listservs and discussion groups on important national issues and other means to engage the citizenry
- Providing grants to organizations seeking online democratic activities
- Developing local community projects that embrace all levels of society, from the academic world to businesses large and small to non-profit and volunteer organizations; this can encompass governments in developing countries
- Developing easy-to-use Web sites to facilitate seamless access by citizens
- Ensuring information on Web sites is easily attainable in a form understood by the citizen and can be easily downloaded
- Providing supplying search engines and hot links to ensure that citizens get what they want in the right format from the right agency
- Giving the populations of developing countries access to the Internet by developing information policies and policies to implement different communications technologies that will encompass all the citizens in the countrie.
- Designing programs to teach local leaders, public-minded citizens and volunteers in the communities to become information facilitators;

## CONCLUSION

The Internet is a medium that has allowed people to involve themselves in the democratic process in new and unique ways. Governments at all levels and international organizations will increasingly be impacted by these changes. Thus, there is also a need for awareness building within governments and international organizations of the changes that are occurring. This can be accomplished through educational and training programs. Disseminating information on a wide basis can improve conditions in a country. Information sharing from government is the lynchpin of the knowledge society. For such a society to evolve worldwide, it is incumbent on governments to do what they must to bring all its people into this new economy.

## KEY TERMS

**Accountability:** Making organizational proceedings transparent and explaining and justifying decisions and choices in terms of stated policies and procedures.

**Connectivity:** Linkage of computers to telecommunications networks so that users can access the Internet and the services on it (such as the World Wide Web and e-mail).

**E-Governance:** Digitizing government information and placing online document dissemination, information solicitation, workflow coordination, service delivery, consultation and voting.

**Freedom of Information:** Legislation and regulations that require public requests for information be granted in a timely fashion and when mandated, at a standardized price.

**Information Rights:** The public's right of access to organizational information, and policies and procedures assuring that the information is used only for the purposes specified when gathered.

**Information Sharing:** The exchange of information within and between governments and between governments and the wider society.

**Privacy Protection:** Provisions that assure that access to information on specific individuals and groups is limited to those with specific authorization, and that confidentiality is maintained.

## INTRODUCTION

In order to discuss e-government in the context of industrial policy, it is necessary to examine the industrial policy concept as such. Industrial policy is not a term often appearing in encyclopedias or handbooks of economics and there is no general understanding of the concept in the economics literature. Nevertheless, it is a concept which has played and continues to play and important role in discussions on the economic development of nations and regions.

## BACKGROUND

In some presentations on the issue of industrial policies, the concept is associated with policies to strengthen manufacturing industries as opposed to services. This was, for instance, a theme in the American discussions on deindustrialization in the 1980s and early 1990s, and it is also a theme in the presentations of the European Commission on industrial policy—for example, in the communications of the Commission on "Industrial Policy in an Enlarged Europe" (CEC, 2002, 2004). However, this is not the most common understanding of the term. Usually, the word "industrial" is not related to industry of the manufacturing kind alone but to business in general, encompassing manufacturing as well as services.

Another line of division in the different interpretations of the term relates to whether industrial policies are sector related or could be horizontal (cross-sector) as well. Laffont (1996), for instance, operates with a broad and horizontal understanding of the concept of industrial policy as does, for example, Cowling (1999) in *Industrial Policy in Europe*. In this perception of the term, industrial policies can very well be horizontal in the sense that public authorities of one country may want to promote all forms of enterprises in their own country. Industrial policies are thus considered as national policies to promote the industrial development of a country in the international setting (Cowling, 1999).

It has also been argued that there can be a close relationship between horizontal and sector related policies in the sense that the general goals can be of a horizontal character, while the means can include sector-oriented initiatives. In a paper on "Industrial Policy in the Economics Literature," Navarro (2003), for instance, writes: "Policy has to be tailored to specific sectors and develop competencies that are specific to the local/regional context. Getting the horizontal policies right is essential, but a narrow focus on horizontal policies alone will only have a mild effect" (p. 14). A close relationship between horizontal and sector related initiatives can be seen in the case of policies to promote information and communication technologies (ICTs), as ICTs are seen as generic and pervasive with implications for almost all other industrial sectors. Support for the growth of use of ICTs and, consequently, for the growth of the ICT-producing industries may lead to a general promotion of all industries.

Generally, however, industrial policies are seen as sector related policies—that is, policies aiming at promoting specific sectors in the economy. This can be either sunset industries as shipyards in Europe, or sunrise industries as the ICT and biotechnology industries are normally considered to be.

The sector-oriented industrial policies can encompass all kinds of initiatives, which are intended to promote specific industrial sectors. Often, industrial policies have consisted of direct economic aid (subsidies or tax arrangements) or protection (tariffs), but they could also be research and development (R&D) policies or educational policies aiming at promoting specific industries, and they could be policies supporting demand for the products of certain sectors.

Industrial policies, however, do not include all kinds of economic policies. General macroeconomic stabilization policies (e.g., monetary or financial) and general competition policies are not included in the industrial policy category. It is only if sector-specific competition policies are implemented that competition policies are regarded as part of an industrial policy. To be characterized as an industrial policy, there must be something in

*Table 1. Scope of industrial policies*

| | Sector oriented | Horizontal |
|---|---|---|
| Supply support | XXX | X |
| Demand stimulation | XX | |
| Regulatory framework | X | |

addition to the creation of a favorable general economic framework, either directed at specific sectors in a national context or at specific sectors or the whole national industry in an international context.

Table 1 shows the scope of industrial policies. The core of industrial policies includes support for the supply and the demand side of specific sectors, but industrial policies may also encompass support for the supply side horizontally and/or sector-oriented framework regulations.

## FOR AND AGAINST INDUSTRIAL POLICIES

The basic argument in favor of industrial policies is that markets seldom function optimally and that different kinds of state interventions are called for. Conversely, the basic argument against industrial policies is that state interventions will seldom make things better—but probably worse. In the language related to neoclassical economics, market failures are the arguments for state interventions, while government failures are the arguments against. In the more heterodox evolutionary economics, which does not take its point of departure in any perfect market scenario, it is not necessary to make the case that there are market failures to correct. Arguments for industrial policies can be that there are functions in the totality of the politically influenced technoeconomic developments, which public authorities can effectively fulfill (Carlsson & Jacobsson, 2004).

The discussions on the merits of industrial policies are related to two (interconnected) spheres: the national sphere and the international sphere (Navarro, 2003). It is possible to argue for industrial policies in a purely national context. The argument is that there are market failures, which need to be rectified, or functions that need to be fulfilled. The kinds of market failures or functions in question will mostly relate to positive externalities in the economy, which are not sufficiently unfolded. This could apply to all sectors of the economy and, therefore, be initiatives of a horizontal character. But it could also be a more sector-oriented initiative, for instance, in relation to ICTs, the use of which in itself has externalities attached.

Most often the discussions on industrial policies are connected with the international dimensions of the economy. In this regard, the arguments in favor of industrial policies are primarily related to the goal of obtaining or retaining a specific position in the international division of labor, for example, in relation to so-called strategic trade policies, infant industry policies, or fears of deindustrialization.

The most powerful argument against the use of industrial policy to rectify market failures is that it is difficult to see why public authorities would have insights into the functions of the markets, which could do better than unregulated market mechanisms. Furthermore, it has been argued that it is difficult to document significant positive effects of industrial policies (Pack, 2000).

Moreover, there is a risk of capture of public authorities when supporting specific industrial sectors (Laffont, 1996). The specific public authorities in question and the industries being supported may become so dependent on each other that there will be a distortion of the economic decision processes.

The most often used arguments for and against industrial policies revolve around international relations. The heart of the matter is whether it is possible for nations to acquire better positions in the international division of labor and, consequently, a bigger wealth and higher welfare. This applies to the economically poorer nations, where the issue is to get started on building up a position and an industrial basis. But it also applies to the economically richer countries, where the issue is to retain or improve the economic and industrial strength vis-à-vis other countries.

In relation to the economically richer countries, there are defensive as well as offensive reasons for industrial policies. The defensive reasons are connected with the issue of de-industrialization and with supporting industries, which (may be) more profitably could be located in other countries—the so-called sunset industries. The policies flowing from this line of reasoning can be summarized under the heading of protectionism, and one of the arguments against such policies is that it is a kind of "beggar thy neighbor" policy and that it is likely that there will be retaliations from other countries. One of the major implicit arguments for industrial policies is that other countries are taking similar steps and that industrial policy initiatives are, therefore, necessary. The more offensive reasons are connected with the possibilities of conducting strategic trade policies, that is, to promote the industries in the home country, which have a strategic character because of a value-added above the average.

Strategic trade policies were especially discussed academically in the 1980s and early 1990s. An early introduction of the theme was a publication by Brander and

Spencer (1983) focusing on international R&D rivalry. A later example is an anthology assembled by Krugman (1990) with contributions in favor as well as against strategic trade policies. In the introductory chapter to this book, Krugman (1990) discusses two of the main reasons behind strategic trade policies, rent seeking and external economies, where rent seeking is connected with the higher value-added in some sectors and external economies with the especially strong external effects of some sectors in the economy in general. Krugman (1990), in this piece, does not doubt that there are, in fact, strategic sectors in the economy, but he doubts whether it is possible for political authorities to "pick the winners." He, thereby, touches upon one of the major issues in the debates on industrial policies, where the most common point of view in the academic literature is that it is not likely that picking the winners will be a fruitful strategy and that the "choice" of winners is better left to the market.

A variation of the "picking the winners" strategy and a much more widely accepted strategy is to improve not only the general conditions for industrial development but also the more specific conditions for the development of special industrial clusters. Such a strategy is based on the understanding that industries in the different sectors are promoted by specific innovation systems, encompassing not only a concentration of certain industrial competences in certain areas but also a combination of public policies and initiatives, which create a positive framework for industrial growth (Anttiroiko, 2004; Navarro, 2003). Such an argument is also in line with the thinking of Porter (1990) on the "competitive advantage of nations," where the point is not that nations as such are competitive, but that competitive advantages in some sectors can be created and that public policies can play a role in this context.

## FUTURE TRENDS

The understanding of the setting for, for example, the European i2010 initiatives (CEC, 2005)—as for the Lisbon initiatives in general (Lisbon European Council, 2000)—is of a character often leading to industrial policy initiatives. The setup is a competitive situation with the United States and Asian countries, where Europe apparently is losing ground because of a lower economic growth than other countries and regions. This is the reason for the Lisbon agenda, which should result in Europe becoming "the most competitive and dynamic knowledge-based economy in the world" (Lisbon European Council, 2000) with ICTs having a central role in this vision. ICTs not only constitute an important industrial area in their own right but are also important for other business areas as building blocks in the communications infrastructure. The ICT sector is considered as a strategic sector in the economy.

It is in this light that the question of industrial policies is raised. The initiatives relating to the ICT field in general and to the European i2010 policies more specifically can be considered as part of and industrial policy strategy. The same applies to initiatives taken in other parts of the world, including South Korea, Japan, and the United States. Especially in South Korea, it seems as if industrial policy initiatives are playing a role in the amazing growth in broadband penetration and use of broadband communications. But also in Japan and even in the United States, first and foremost at the local and state levels, industrial policy measures are implemented.

With respect to the character of the policy actions deemed as being part of an industrial policy package, the direct economic aids and subsidies for the supply side are only marginal. However, subsidies are accepted in local initiatives, while they are seen as market distorting on a larger national scale. But there are other kinds of initiatives, which help supporting industries supplying ICT goods and services, namely public R&D and education policies. In this connection, it should be mentioned, that education policies also can have an impact of the demand side, in the sense that education of users can promote the use of ICTs.

Stimulation of demand and public procurement policies, on the other hand, have a much larger role. This is seen as being in full accordance with liberal market policies, as long as there is no preference for specific providers in a national context or for nationally based companies in the international arena. In connection with the emphasis on the demand side, there is also an increasing interest in policy initiatives being directed toward the content aspects as opposed to the network aspects.

## CONCLUSION

In summary, six different modes of policy initiatives/tools are listed—with the lightest forms of market intervention first and the strongest at the end. All of them can and are mostly included in national strategies for the development of the industrial base in individual countries. The conclusion is that while industrial policies formerly had more emphasis on financial support, public support is and will in the coming years much more center on technology policy.

- Strengthening and harmonization of the internal uses of ICT infrastructures and services in public institutions.

- Construction of communication systems and structures in relation to the citizens and business enterprises—with influences on the take-up and forms of communications used in the society at large.
- Facilitation of the development of communication systems. This may include creating more transparency in the markets by way of public information on qualities and prices of communication services, and it may include the setting up of forums for discussion of, for example, interconnection and frequency issues among the competing operators and the public authorities.
- Regulation proper, setting the "rules of the game" in the markets and the enforcement of these rules.
- Support for the demand for communications systems and services, which may be based on either the direct demand from public institutions or support for the demand from private citizens and business enterprises.
- Support for the supply of ICT equipment and services, which may involve public funds going into ICT companies, but more often has an indirect character involving public research and development and also public educations of people whose labor power will be used in business enterprises.

The two first-mentioned areas are the ones most clearly related to e-government initiatives. They relate to the use of ICTs internally in public organizations and in communications with citizens and companies. The activities of public administrations in these fields will indirectly lead to the promotion of the use of ICTs on a broader scale in society.

The two following areas are connected with the ICT sector itself—facilitating its modes of functioning and setting the regulatory framework rules. Facilitation as well as regulation can have decisive influences on the industrial development. The whole liberalization process in telecommunications has definitely had a great influence on the growth of this sector.

The last two areas, support for demand and support for supply, are the areas mostly connected with the term "industrial policy." Public support for the demand side can be important for industrial development and is seen as more acceptable than support for the supply side. State initiatives in the field can be of different kinds. State procurement in itself is important, as state organizations often are large customer, and as goods and services based on new technologies can be helped to grow in the market by means of initial fostering. But the state can also help specific sectors by promoting private demand, either by creating a fertile environment for industries, which are large users of specific goods or services, or by helping residential demand.

Support for the supply side includes direct economic support, which has often been seen as the essence of traditional industrial policies. However, this kind of industrial policy measure has lost importance in the European Union (EU) and elsewhere during the past couple of decades. In the EU it is neither favored by the individual member states nor the EU as such. Now and then, member states use direct economic support for specific industries—often mature industries in crisis and/or being challenged by competitors from other countries—but the EU seeks to prevent or, at least, limit this kind of policy, as it is seen as distorting to the competitive environment. Furthermore, it does not necessarily ensure technology development which could strengthen the possible positive external effects of the development in such sectors. Output will be likely to increase, but not necessarily technology development (Bora, Lloyd, & Pangestu, 2001).

There are, however, other kinds of policies supporting the supply side of industries and which are not only generally accepted but also considered as recommendable, as they are more certain to contribute to technology developments. This applies to R&D initiatives as well as educational initiatives, which in both cases can be of a general nature not discriminating between different industrial areas but can also favor specific sectors of the economy, which most often has been the case with publicly funded R&D—for example, the EU ICT programs from RACE and ESPRIT to the present IST programs. It also applies to initiatives promoting industrial development by way of supporting the development of innovative milieus, for instance in the form of science parks, intelligent cities, and so forth (Anttiroiko, 2004).

## KEY TERMS

**Comparative Advantages:** According to the theory on comparative advantages, founded by David Ricardo (1772-1823), all countries have comparative advantages in a number of sectors, as a country will always be doing better comparatively in some sectors than in others. The theory has been developed since its first presentation and is the theoretical basis for free-trade policies.

**Competitive Advantages:** Competitive advantage is a term associated with the American business economist Michael Porter. A competitive advantage can be developed by a company, not a country. However, there may be specific conditions in different national contexts promoting the competitiveness of companies, for example, industrial clusters and/or specific national policies.

**Deindustrialization:** Literally, the term means that industry disappears. However, deindustrialization is a term often used to describe the decreasing importance of manufacturing industries as opposed to service sectors. The pessimist vision is that deindustrialization will mean less economic activity, while the positive vision is that manufacturing industries will be substituted for other activities in service areas with higher value-added.

**Externality:** An externality is an effect of actions of market players, which is not mediated by prices. Externalities can be positive as well as negative. R&D, for instance, can have positive external effects on market players, which are not paying the costs of R&D activities.

**Government Failure:** As a counterpart to market failure, there can be government failures. An example of a government failure could be a decision to support a specific technology development, which turns out to be a dead end in the market. Government failures are reasons for not intervening in the markets, even though problems in the markets can be observed.

**Industrial Policy:** State policies conducted with the aim of strengthening the industrial base of a country or region. General macroeconomic stabilization policies are not considered part of industrial policies. However, industrial policies can encompass a broad range of supply and demand-oriented policy initiatives.

**Market Failure:** There is a market failure when market mechanisms do not function perfectly. There can be different reasons for market failures: information imperfections, natural monopolies, externalities, and public goods. Market failures are reasons for possible government interventions in the markets.

**Sector-Oriented vs. Horizontal Policies:** Industrial policies can be horizontal and/or sector oriented. With horizontal is meant that industrial policies affect all business sectors, while sector-oriented policies only are aimed at specific sectors.

**Strategic Trade Policy:** A nation-state can be said to conduct a strategic trade policy when state support is given to sectors considered as strategic in the economy, for example, sectors with a high value-added, affecting the trade balance between countries.

# Information Systems Integration in E-Government

**Wing Lam**
*Universitas 21 Global, Singapore*

## INTRODUCTION

Through e-government, an increasing number of nations are making major commitments to modernize and reform government in an effort to achieve greater efficiency, broaden access to government services and improve service levels (Schware & Deane, 2003). Technology is seen as a key enabler for e-government (Elmagarmid & McIver, 2001). Ultimately, e-government seeks to centralize and make a cohesive and seamless set of government services available to end-users. Hence, the integration of information systems (IS), both within and between different government departments, will become a critical issue as e-government matures (Golden, Hughes, & Scott, 2003).

As e-government matures, information systems (IS) integration will become critical to the ability to provide centralized and seamless online services. This article examines the different scenarios of IS integration, and discusses the critical success factors for IS integration. The architectures for achieving IS integration as also described. A roadmap for IS integration in e-government is proposed which provides a framework for more detailed project planning and technical decision-making.

## BACKGROUND

The challenge of IS integration is not specific to e-government. IS integration is also a challenge facing many organizations in the commercial sector, particularly those involved in developing enterprise-wide solutions such as e-business, supply chain management (SCM), customer relationship management (CRM) and enterprise resource planning (ERP), which require integration between "islands of applications" (Sawhney, 2001) that have traditionally operated in isolation (Markus, 2000; Themistocleous, Irani, & O'Keefe, 2001). Indeed, a study by research firm IDC (2002), based on 1,350 interviews, indicated that more than 80% of CIOs and CTOs believed integration was either mandatory for addressing mission-critical activities or a key enabler for meeting business-critical needs.

Large-scale IS integration poses at least three major problems. First, the scale of integration and sheer number of IS to be integrated can be overwhelming. Large organizations such as governments tend to have a huge portfolio of IS comprizing hundreds, even thousands of IS (Cummins, 2002). Second, the nature of IS to be integrated is usually quite diverse, including packaged applications, legacy applications, bespoke applications and a myriad of database management systems. Individual IS often have significantly different underlying architectures, with some based on legacy and others based on more modern computing technology, which impedes integration (Lam 2004). Third, older legacy IS may have been inherently designed to be standalone, or integrated with in only very limited ways. However, replacing such legacy IS, which represent huge investments in institutional knowledge, is not always desirable or feasible (Robertson 1997).

Whereas IS integration is extensively dealt with from a technology perspective, there is much less advancement in the strategic planning and management required to achieve IS integration. Such strategic issues are important for establishing an overall framework for more technical decision-making and therefore of interest to chief information officers (CIOs), chief technology officers (CTOs), IS directors and anyone involved in formulating IS strategy in e-government. This article examines strategic planning and management for IS integration in the context of e-government. The article draws from existing research in the field of IS to present and justify a roadmap for IS integration in e-government.

## INFORMATION SYSTEMS INTEGRATION

### Scope of IS Integration

Lam (2004) identifies four main types of IS integration scenarios, namely, enterprise application integration (EAI), B2B integration, B2C integration, and "Webification." The four main types of IS integration can be distinguished in terms of the purpose of integration and the crossing of organizational boundaries, as described in Table 1.

*Table 1. IS integration scenarios*

| Integration Type | Scope of Integration | Purpose |
|---|---|---|
| Enterprise application integration (EAI) | The integration of IS within a single enterprise, either within a business division or with other business divisions within the enterprise | To improve business efficiency and to meet the need for real-time information processing |
| B2B integration | The integration of IS between different organizations | B2B commerce such as integrated supply chain management and B2B trading |
| B2C integration | The integration of back-end transactional systems, often of a legacy nature, with Web-based front-end applications such as storefronts and personalization engines | B2C solutions which provide customers with a Web channel for accessing products, services, or information |
| Webification | The integration of legacy systems with Web-based applications | Ease of access to information held in legacy systems |

In the context of e-government, EAI can be compared to the integration of IS within a single government department or with other departments in a government. B2B integration can be compared to government-to-government (G2G) and government-to-business (G2B) integration. Such scenarios might arise, for example, in relation to joint government initiatives such as the combating of international crime and the need to exchange criminal intelligence. B2C integration and Webification can both be compared to a government-to-citizen (G2C) scenario, or the integration of legacy government IS with Web-based front-end applications such as citizen portals to provide services such as the online submission of tax forms.

## Levels of Integration

IS integration can be viewed at four levels of complexity namely, data, application, method and process (Linthicum, 2001). The four levels of IS integration are described in Table 2.

Various integration technologies and architectures are used to achieve integration at each of the four levels. Federated databases, triggers, and batch processing can be used to achieve data integration. For application integration, application programming interfaces (APIs) and distributed components such as Enterprise Java Beans (EJB) and distributed component object model (DCOM)

*Table 2. Levels of IS integration*

| Level of Integration | Description |
|---|---|
| **Data** | The synchronization of data held in different databases. Synchronization can be achieved either in real-time or in batch mode where some temporary delay in data freshness is permissible to the enterprise. |
| **Application** | Enabling IS to directly access functionality of other IS in a real-time fashion. Popular packaged IS such as SAP and PeopleSoft, for example, provide well-defined application programming interfaces (APIs) that expose the functionality within the IS. |
| **Method** | Providing IS with a common set of reusable business logic from which finer grain application calls are made. For example, reusable business logic for creating a new customer may trigger separate customer creation processes in several different IS. At this level, there is a clean separation of business logic from the technical means by which IS are integrated. |
| **Process** | The abstraction and definition of business process or workflow models from which relevant methods are called. Process integration is particularly relevant in collaborative contexts, such as B2B, where there are significant business information flows between trading partners. |

are needed. Method integration can be achieved using technologies such as message-oriented middleware (MOM) and Web Services. Method integration requires that individual IS are architected in a manner that exposes business services. Process integration requires the use of integration brokers and business process management tools that captures process flow across IS applications (Lee, Siau, & Hong, 2003; McKeen & Smith 2002). Such tools make use of special adapters that connect applications to the integration broker.

Integration at the process level provides the greatest level of integration flexibility. However, an organization does not necessarily need to achieve IS integration at the process level, and in some cases, data integration may be perfectly sufficient.

## Barriers to Information Systems Integration

Several authors have discussed barriers and risks in IS integration. Themistocleous and Irani (2001) identify a "laundry list" of barriers from their analysis of 15 cases in the literature: politics, resistance to change, no single EAI product to solve all problems, lack of training, additional cost of redesigning business infrastructure and processes, lack of EAI skills, cultural issues, high cost of EAI and complexity of understanding processes and systems. Because of the broad spread of barriers, some of the barriers inevitably overlap.

Other authors have focused on specific issues seen as having a critical role in IS integration. In the context of e-business, Yang and Papazoglou (2000) view integration largely as a challenge in interoperability, where compatibility in business processes and support for business transactions are two critical elements. In their work on healthcare and the integration of electronic patient records, Grimson, Grimson, and Hasselbring (2000) and Chari and Seshadri (2004) draw attention to the importance of semantic integration and common data standards. Markus (2000) identifies a number of issues in IS integration, namely (1) the modification of source systems, (2) organizational change to achieve process integration, (3) immature integration technology and (4) proprietary integration technology. Puschmann and Alt (2004) highlight the importance of selecting the right type of integration tools.

# E-GOVERNMENT INTEGRATION

## E-Government Integration Model

Building on the e-government maturity concepts mentioned by Elmagarmid and McIver (2001) and Layne and Lee (2001), the e-government integration model (EIM) produced by the author in Table 3 describes four stages of e-government integration maturity namely informational e-government, transactional e-government, pro-

*Table 3. The E-government Integration Model (EGI)*

| Maturity Level | Informational E-Government | Transactional E-Government | Process Integrated E-Government | Service Integrated E-Government |
|---|---|---|---|---|
| Focus | Information-centric | Transaction-centric. | Process-centric. | Citizen-centric |
| Types of E-Government Services Available | Access to public information (e.g., opening hours, downloading of application forms, "how to" instructions) | Relatively simple services and data collection activities (e.g., online form filling, filing complaints, e-petitions, sending enquiries via e-mail) | Sophisticated services that form part of an overall workflow (e.g., applying for a passport, applying for financial support) | Comprehensive one-stop shop of sophisticated and connected services (e.g., registering as unemployed identifies relevant support schemes available and updates tax position) |
| Scope | Intra-agency | Intra-agency | Inter-agency | Inter-agency |
| Citizen Experience | Citizen finds the relevant information on the Web site and simply reads or downloads the information | Citizen identifies the service they wish to use, registers on the Web site as necessary and submits relevant information via online forms and e-mail | Citizen engages in an online dialogue via the system over a period of time that involves the citizen logging on several times | System intelligently guides citizen to achieve their intended goals, triggering new processes as required and proactively offers direction, advice, and suggestion |

*Table 3. The E-government Integration Model (EGI) (cont.)*

| | | | | |
|---|---|---|---|---|
| **Level of Web Site Customization** | Web site is static; there is no personalization | Limited personalization and minimal interactivity | Significant personalization, where only relevant services are made available | High level of personalization; system makes suggestions |
| **Transactional Model** | No transactional capability | Set of simple and discrete transactions limited to a particular agency | Limited set of both simple and complex transactions | Full set of both simple and complex transactions |
| **Systems Integration and Inter-agency Interaction** | No integration between IT systems | Some integration between Web and back-end IT systems within an agency | High level of integration between IT systems within the state or agency | High level of integration between disparate systems owned by different agencies |
| **E-Government Policy (e.g., security, privacy)** | None, or only ill-defined policies limited to the agency | Partial set of agency-wide e-government policies | Defined policies agreed within individual agencies | Government-wide policies providing consistent rules across all government agencies |
| **Technology Sophistication** | Web site, content management | Portal, Web-integration, back-end processing | Workflow, partial enterprise application integration (EAI) | Workflow, portal, full EAI, citizen relationship management (CRM) |

cess integrated e-government and service integrated e-government. The EIM associates e-government maturity with increasing levels of inter-agency co-operation, collaborative process engineering and tighter IT systems integration.

## Critical Success Factors

What are the critical success factors (CSFs) for e-government integration? In answering this question, a set of CSFs for IS integration was synthesized from a review of the literature (Lam 2004, 2005). Four main groups of CSF are identified, namely, strategy, organization, technology, and project. The set of CSFs was then used to as a basis for identifying the likely CSFs for e-government integration, as shown in Table 4.

## Roadmap Overview

E-government is recognized as a transformational process that progressively advances through several stages of maturity (Layne & Lee, 2001). Similarly, IS integration is not something that governments can achieve overnight, and itself is a transformational process. A roadmap for IS integration is therefore proposed, shown in Figure 1.

The proposed roadmap draws from the CSFs discussed earlier and previous work on IS integration frameworks (Lam & Shankaramanan 2004). The intended users of the roadmap are individuals involved in formulating e-government IS strategy whether at the government department level or at the central government planning level.

The proposed roadmap consists of five main iterative phases, namely (1) establish e-government needs, (2) formulate IS integration strategy, (3) integration program planning, (4) integration project implementation, and (5) organizational transition. Although the phases appear sequential in nature, in practice there will be considerable overlap and iteration.

### Stage 1: Establish E-Government Needs

E-government needs are the drivers for IS integration. E-government needs emerge from e-government strategy and objectives. For example, if there is an objective to provide citizens with online services for passport application and renewals, certain e-government needs can be derived from this objective. In addition, multiple government departments need to work together to achieve collective e-government objectives, hence giving rise to the need to establish terms of reference for inter-department collaboration. Stakeholder expectations also need to be carefully managed at this stage.

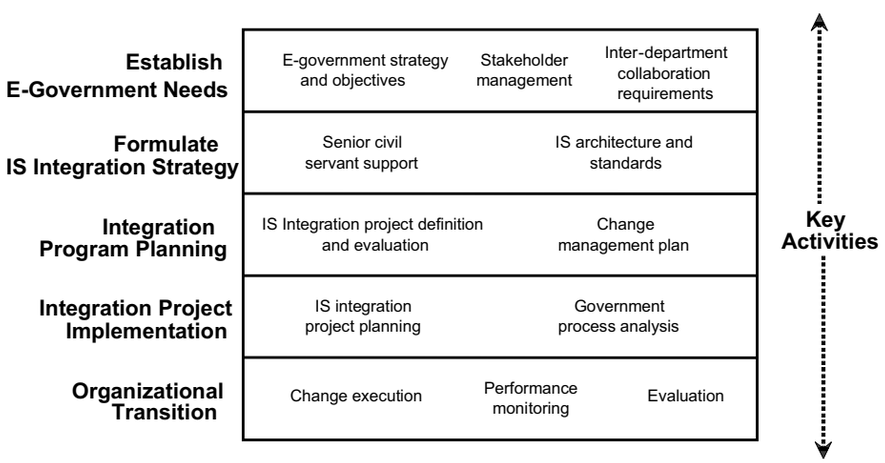
### Stage 2: Formulate IS Integration Strategy

Having understood e-government needs, an appropriate IS integration strategy is formulated. This involves choices of an appropriate IS integration architecture, and estab-

*Table 4. CSFs for e-government Integration*

| | Critical Success Factors (CSFs) in IS Integration | Likely CSFs in E-Government Integration |
|---|---|---|
| **Strategy** | Strong business case for IS integration | IS integration must be driven by the need to provide e-government services that require integration between government IS |
| | Interoperability with business partners | Interoperability between different government departments will be important |
| | Alignment with business strategy | IS integration must be aligned with e-government strategy and objectives |
| **Organization** | Top management support | Support from senior civil servants is critical |
| | Change management | IS integration will require the careful management of change within and across government departments |
| | Good organizational fit | IS integration initiatives must align with the individual goals of government departments |
| **Technology** | Compatible technical standards | Government departments must adopt compatible technical standards |
| | Handling legacy applications | Legacy government IS must be properly handled |
| | Common data standards | Government departments should agree on common data standards to facilitate the exchange of data |
| | Technology planning | Government departments should jointly plan IS integration efforts |
| **Project** | Realistic project plans and schedule | IS integration projects should have a realistic plan given resource availability |
| | Clear understanding of business processes | There should be a clear understanding of the processes used in government |
| | Client involvement, communication and consultation | Individual government departments, citizens, and other stakeholders should be closely involved in IS integration efforts |
| | Required skills and expertise | Government departments should ensure they have the right skills and expertise on board to successfully complete IS integration projects, using outsourcing strategies or external consultancies where necessary. |

*Figure 1. IS integration roadmap*



lishing certain technical standards. In some cases, a central government body may mandate the use of particular interoperability standards to facilitate the exchange of information between government departments. For example, the UK's E-Government Interoperability Framework (e-GIF) (e-Envoy, 2002) defines a set of technical policies and specifications (e.g., use of XML as the primary standard for data integration for all public sector IS) and the creation of an e-government metadata standard. Such standardization efforts require strong support and buy-in from senior civil servants.

### Stage 3: Integration Program Planning

A large number of IS will need to be integrated to meeting varying e-government needs. This falls beyond the scope of a single project, but rather a program of IS integration projects each of which is carried out as a separate project involving different stakeholders. Program planning involves defining and scoping individual IS integration projects, and evaluating them in terms of urgency and complexity. Program planning also ensures that individual IS integration projects fit together into a coherent whole and do not serve conflicting purposes or overlap in scope. Program planning also involves change management planning, and managing the impact of individual projects on existing departmental processes and organizational structures.

### Stage 4: Integration Project Implementation

At this stage, specific IS integration projects are implemented. Relevant project stakeholders will need to be identified for each project, and their expectations managed accordingly. Specific IS integration requirements are gathered from stakeholders, and more detailed project plans created as the specific scope of the project emerges. Government processes are analysed in an effort to identify process improvements that can be achieved via IS integration.

### Stage 5: Organizational Transition

The change management plans formulated earlier are put into action. Government departments migrate from existing IS systems to integrated ones. The migration process may take weeks or months, depending upon the complexity of the integrated solution and organizational mobility. Some organizational restructuring, and the definition of new roles and responsibilities, may arise as a consequence of new ways of working. The transition is supported through awareness and staff training programs. During this stage, an evaluation of new processes and new integrated systems is carried out to determine their effectiveness.

## FUTURE TRENDS

The integration of information systems (IS) becomes increasingly important as e-government matures and governments seek to offer more sophisticated online services to end-users. As such, governments will, in the future, pay greater attention to IT architectures that facilitate the integration of government IS. This includes common standards for data exchange between government IS and departments, and the adoption of interoperability standards such as XML. The use of EAI and business process integration tools is also likely to be introduced in departments where there are serious integration challenges which involve tens, and perhaps hundreds of government IS. Architectural groups spanning several government departments are also likely to emerge as it will be critical to develop integration strategies that cover multiple government departments and groups.

## CONCLUSION

The roadmap for IS integration in e-government provides a starting point for those involved in strategic IS planning, drawing attention to the need to establish an overarching framework for more detailed technical decision-making and project-specific decisions. In using such as roadmap, governments are more likely to break out of the silo mentality that has contributed much to the lack of integration in the commercial sector.

## KEY TERMS

**E-Government:** The use of the Internet and online medium to provide government services.

**Government-to-Citizen Integration:** The integration of back-end systems with front-end applications to make government services available to citizens over the Web.

**Government-to-Government Integration:** The collaboration and coordination of processes and exchange of information between different government groups and units.

**Information Systems Integration:** The tools, methods and activities associated with ensuring that information applications work together seamlessly to meet overall business needs.

**Integration Maturity:** The extent to which processes are collaborative and technology coordinated amongst and between government groups and units.

**Process Level Integration:** The co-ordination of business processes such that they are seamlessly supported by information systems.

## INTRODUCTION

Within the process of globalization and the permeation of all areas of life by technology, electronic government (e-government) is becoming a powerful tool that will effectively integrate and manage the huge amount of existing information, as well as seamlessly integrating citizen interaction with its services (Abie et al., 2004). E-government is the use of ICTs in public administration in combination with organizational changes and the development of new skills, in order to improve public services and democratic processes, and to strengthen support for public policies. The concept of mobile government (m-government) refers to the use of mobile wireless communication technology within government administration and in its delivery of services and information to citizens and firms (Ostberg, 2003). Digital government is a general term which includes e-government and m-government. In this digital world the management and protection of digital information content, and the rights associated with this, from unauthorized access, use, and dissemination has been a matter of concern for many rights holders. Moreover, the protection of privacy has been a matter of great concern for many citizens.

## BACKGROUND

### Access Control In Digital Government Scenarios

When security requirements for digital government applications are considered, authorization often emerges as a central element in the design of the whole security system. Many other security requirements depend on the flexibility, trustworthiness and expressiveness of the authorization scheme. Authorization in conjunction with access control, which is the mechanism that allows resource owners to define, manage and enforce the access conditions that apply to each resource (Reuters, 2001) form the key concepts in the core of digital rights management (DRM).

Among the traditional access control models, rolevased access control (RBAC) is commonly accepted as the most appropriate paradigm for the implementation of access control in complex scenarios. RBAC can be considered a mature and flexible technology. Numerous authors have discussed its properties and have presented different languages and systems that apply this paradigm.

However, very dynamic environments with a high volume of heterogeneous data, like semi-structured data systems, DRM repositories, digital libraries, Web services, digital government systems, and so forth require more flexible constructions for the expression of access control policies. In RBAC, the structure of groups is defined by the security administrator and is usually static. The grouping of users is not flexible enough to cope with the requirements of more dynamic systems where the structure of groups cannot be anticipated by the administrators of the access control system. However, this is exactly the case in digital government applications, and especially with the secure interoperability between different governmental agencies. In such a complex heterogeneous infrastructure, the integration of new resources and the application of fine-grained dynamic policies on them is of key importance. Traditional access control schemes cannot be applied as they are usually designed for use with static infrastructures and do not scale well.

Current access control models are not appropriate for DRM and other open, heterogeneous, and dynamic scenarios because access control is often erroneously considered to apply to locations" instead of objects or resources. Because of this, it is assumed that one or a few access control (enforcement) points are used to restrict access to a set of resources in one location.

In summary, we can conclude that a different approach is required in order to solve the scalability problems of these systems, to facilitate dynamic fine-grained access control management and to provide the means to express access conditions in a natural and flexible way. Furthermore, access control models must take into account the fact that the creation and maintenance of access control policies is a difficult and error-prone activity.

The semantic access control (SAC) model (Yagüe et al., 2003a) provides an appropriate solution to the aforementioned problems, especially for heterogeneous, distributed and large environments such as digital government. As we will show later, the flexibility of the SAC model allows it to easily simulate other models such as mandatory access control (MAC), discretionary access control (DAC) or RBAC.

## Digital Rights Management Technologies

The slogan "information wants to be free" was one of the reasons why in the early days the Internet was seen as a vehicle for the free floating of ideas and information. However, in the last few years this has drastically changed since many companies have realized the Internet's capabilities and its potential as a vehicle for marketing and selling goods and services. The copyright owners of these products therefore promoted the concept of DRM. DRM is an integrated complex context covering not only technologies that limit or prohibit the unauthorized copying or distribution of these products but also includes laws, contracts and licenses that regulate and restrict the use of such material (Becker, Buhse, Günnewig, & Rump, 2003).

Rights management applies to a wide variety of systems and objects, and because of this, it is almost impossible to consider all potential application scenarios. The approach must, therefore, be developed in an open and extensible way. Reuters has proposed the development of a taxonomy of Rights and Obligations for products and services (Reuters, 2001). We think that, even in the case where this taxonomy could be built in a sufficiently complete way, its applicability in the real world might prove challenging, mainly because rights and obligations can have different interpretations in different scenarios, countries, and so forth. Therefore, we propose an open approach, based on the explicit expression of the semantics of these rights and obligations. This approach allows users to better tailor the system to their needs and their particular context.

Usually, the content industries regard DRM as dealing with the problem of unauthorized downloading of copyrighted material, a practice that costs content creators and distributors dearly in lost revenue. However, an important and often overlooked fact is that DRM is closely related to the general field of access control. Therefore, rights enforcement involves an access decision about a resource subject to intellectual property rights.

From the technology point of view DRM technologies can control resource access (number, duration, etc.), altering, sharing, copying, printing, and saving via software or hardware implementations. In the majority of the DRM approaches today not only is anonymity prevented, but the privacy of the user is in danger, since often DRM systems facilitate the profiling of users' preferences which can lead to the identification of the consumer's real identity. DRM technology in the aforementioned context is a relatively new research field that has been rapidly developing since the mid 90s, whose results are controversial (Felten, 2003). DRM solutions have been developed by several companies, but most of them are proprietary in nature. Ongoing work in academia and industry promises exciting developments in the short and midterm. However, as yet, an established, widely accepted, open DRM system for the wired or mobile world does not exist.

The amount of information produced and maintained by governmental organizations is immense and traditional mechanisms can not efficiently cope with it. That, in conjunction with the efforts to come closer to citizens and interact with them on a 24-hour basis via Internet or mobile channels, is leading us to the adoption of new models and technologies in digital government. One such promising technology is DRM, and the need for an integrated DRM framework in digital government is real. DRM is used to control and meter the huge amount of digital information generated and disseminated. In digital government DRM can be used in its classical form as well as the other way round (i.e., providing privacy rights management (PRM) for citizens).

## Classical DRM Usage in Digital Government

In its classical form DRM systems in digital government can protect governmental assets from unauthorized dissemination and enforce fine-grained policy models in connection with those assets.

## Extended DRM Usage in Digital Government

As mentioned DRM can be also used the other way round (i.e., put citizens in control of their personal information kept by the different governmental agencies and allow them to control access to that information). Transparent processing, reporting the processing, finality and purpose limitation, lawful processing, data quality and rights management are some of the components of the privacy facilitation principles in a PRM system (Kenny & Korba, 2002).

As we can see, DRM-enabled approaches can evolve to an even more general framework, protecting digital assets in general and allowing fine-grained policies to be enforced on these assets. Such assets are not confined to simple commercial content but can also be personal information (e.g., medical records), corporate information (e.g., legal documents), and so forth. Therefore DRM fits well into the context of e-government and the efforts that are taking place today in order to provide a more flexible and highly efficient e-government model capable of providing new and better quality services to its citizens, while simultaneously respecting their privacy and allowing them to have some control over it. The three aspects of DRM functionality of interest to PRM are asset creation, asset management and asset usage. Using DRM in the appropriate way (Feigenbaum, Freedman, Sander, & Shostack, 2001) to enhance the control that the citizen has on his or her data is technically possible, and appears to be a good idea. However, we should keep in mind that some problems might arise, such as heterogeneity not only in infrastructures but also in legislation, and we should remember how this is perceived by governments and their citizens.

## AN INTEGRATED FRAMEWORK FOR DRM

We have shown how DRM solutions fit into digital government. This section describes an integrated framework based on the EC-Gate Infrastructure (Maña, Yagüe, Benjumea, 2002) for DRM. The infrastructure is built upon a new access control model: the semantic access control model (SAC) (Yagüe et al., 2002), and the SmartProt system (Maña & Pimentel, 2001), complemented by the development of the rights-carrying and self-enforcing information object (SEO) (Abie, Spilling, & Foyn, 2004).

The SmartProt system is used to protect mobile software elements named *protected content objects* (PCO) (López, Maña, Pimentel, Troya, & Yagüe, 2002), which convey the content and force the user to fulfil the applicable policy before access is granted. One important constraint on the free distribution of protected information in DRM systems is that owners of the information must be able to dynamically change the access control policy. For this requirement to be fulfilled we separate the policy from the PCO. Policies are retrieved from the resource owner during the execution of the PCO and are enforced by it. The separation allows the policy to be changed dynamically in a transparent way and PCOs to be distributed and copied freely, thus enabling superdistribution.

For applications that require objects to contain the policy, there are SEOs which carry with them rights of access to and usage of their own operations, services and content, and are responsible for enforcing these rights, while at the same time preserving their confidentiality and integrity, as well as users' privacy. This solves the problem of how to enforce securely rights of access to, and usage of, ubiquitous information in an environment characterized by equally ubiquitous malicious code. The SEO as a mobile agent is a particularly interesting technological concept because of its many and varied capabilities. SEOs are in fact so versatile that they can be made to combine, filter, index, rearrange, interpret and transform digital information (XIWT, 1997).

The EC-Gate infrastructure provides different tools to control the entire life cycle of the digital content: protection, management, distribution, and commercialisation. When a new piece of content is incorporated into the system it is encapsulated into a PCO, or a SEO that protects the contents and enforces the execution of the corresponding access parameters (access control criteria and, optionally, associated actions such as payment, notification of access, etc). Both access control criteria and actions are specified using the *Semantic Policy Language* (SPL)—which is part of SAC, and are supported by automated tools.

An important complement to the SAC model is the operation of several independent authorization entities providing attribute certification services. The identification of the user is not mandatory, so users' privacy is not threatened. The client possesses a set of attributes, and access control to resources is based on the specification of a set of attributes that the client has to present in order to gain access to them. For interoperability and security reasons, client attributes must be digitally signed (in the form of attribute certificates) by trusted certification authorities. The independence of the certification of attributes is the key to interoperability because it allows attributes to be safely communicated, avoiding the necessity of being locally emitted by the system administrator. For this approach to be secure, a mechanism to establish trust between these access control systems and the authorization entities is necessary. In this context, mechanisms for the integration of an external privilege management infrastructure (PMI) supported by

semantic information about the certification entities have been developed (Yagüe et al., 2003b).

In summary, the EC-Gate infrastructure represents a flexible solution for different distributed scenarios and any kind of content, solves the originator-retained-control problem, can be applied regardless of the attribute certification scheme, implements distributed access control management and enforcement mechanisms, and allows dynamic modification of policies transparently and efficiently. Therefore, we have taken it as the robust core for our integrated framework for DRM.

## FUTURE TRENDS IN THE APPLICATION OF DRM IN DIGITAL GOVERNMENT SCENARIOS

In the process towards successful digital government, the correct handling of privacy, security and trust is an indispensable precondition for reliable legal safeguards, reliable technology, and secure business, and for achieving acceptance by citizens. A DRM system can enable governments and other organizations to protect digital assets and control their distribution and usage, thereby protecting intellectual property rights (IPRs) over digital information. Furthermore they increase security, trust and privacy throughout the entire value chain from producer to distributor to consumer. Therefore the digital government area would benefit from DRM as it can provide digital policy and risk management that can facilitate the automation of digital government activities. It can enable government to make a large amount of information available electronically in a secure and controlled manner, which will open new opportunities and improve services to citizens. It can also enhance the enforcement of IPR, which can encourage the production of digital products and services (Abie et al., 2004).

DRM is important for a number of digital government services, among which are the certification of permissions, the certification of existence and identity, and the administration of welfare services, healthcare, education, telecommunication and broadcasting services. DRM is capable of doing electronically what was once done manually on paper forms. A DRM system requires persistent content protection so that content cannot be used and redistributed illegally. The content is protected during delivery and restrictions of the content usage rights are maintained after the content is delivered to the end user. As a result the required security level in DRM systems goes beyond simply granting digital licenses to authorized users. This means that the protection has to stay with the content, and that end-to-end security has to be maintained (i.e., every link in the delivery chain has to be secured and content must only be accessible to authorized/authenticated persons or compliant devices). That is, rights must be correctly executed and enforced. The focus of the Open Mobile Alliance[1] (OMA) on the development of mobile DRM service enabler specifications, which support the creation of market-driven, interoperable, end-to-end mobile services, is evidence of the importance of mobile DRM applications.

Our DRM solutions, described above, will thus benefit and enhance several digital government services, for example m-healthcare, m-education and m-entertainment.

### M-Healthcare

The healthcare and welfare sector is one of the most crucial application domains. The misuse of medical records can have severe consequences for patients. Their misinterpretation can lead to incorrect medical treatment which may be detrimental to the health of the patient, or even lethal. Therefore it is more important than ever to protect all types of digital medical data—image, audio, video, and so forth. Thus, our DRM solutions can be a great boost to mHealth since they protect both the privacy and the integrity of medical data, while at the same time making them easily and quickly accessible to health service personnel on the basis of fine-grained access control policies.

### M-Education

Our DRM solutions can boost m-education by facilitating the easy and secure management of the creation, retrieval, trading and distribution of online learning objects and by supporting secure collaborative development. However, promoting the exchange and reuse of quality learning objects, and respecting intellectual property and rewarding the various contributors, are the two key issues which have to be dealt with before mEducation can become cost effective.

### M-Entertainment

Using our DRM solutions, digital information, such as music, can be offered to consumers via a virtually limitless range of business models, such as sale of downloads, subscriptions, pay-per-listen, super-distribution, and so forth.

The aforementioned application scenarios are necessarily underpinned by a large number of supportive services, for example securing government documents, protection against loss of data, securing handheld device

access to government networks, the deployment and management of security policies for many mobile devices, roaming services, and so forth.

## Securing Government Documents

The security of every document sent and received within the government network must be guaranteed, for example by digital signature alone or in combination with encryption. Our DRM solution in the form of PCOs and SEOs can provide government departments with the ability to secure documents from device to desktop, or user to user as well as on the server, since PCOs and SEOs are protected and self-enforcing objects respectively.

## Protection against Loss of Data

By virtue of their portability and small size, personal digital assistants (PDAs), Smartphones, and other handheld devices are easily stolen and lost, which means there is a constant risk of the data stored on them falling into the wrong hands. The installation of PCOs and SEOs on every mobile device will ensure that all sensitive information is encrypted and locked, and thus inaccessible to unauthorized, inquisitive individuals.

## Securing Handheld Device Access to Government Networks

To reap the full benefits of a mobile workforce, government agencies must ensure the security of network access to their corporate applications from handheld devices. The installation of PCOs and SEOs on mobile devices also ensures secure connections between wireless devices and the government network, which ensures that the critical information of any agency is protected against unauthorized access and use.

## The Deployment and Management of Security Policies for Many Mobile Devices

When a variety of handheld devices are being used within governmental agencies, an easy and fast way to set up security policies on each device is essential. The use of SEOs and PCOs makes it possible to bind an object to an external policy and/or to insert the policy into it. Policies can be tailored to the exact and specific needs of a specific item, and be associated exclusively with that item rather than cluttering up the whole system. The functional repertoire of an object can easily be extended and the carried policy modified accordingly (i.e., to reflect new or changed behaviours) (Payette & Lagoze, 2000), and access conditions can be set independently of the distribution point (Lopez, Maña, Pimentel, Troya, & Yagüe, 2002). Different policies can be easily created for different users, as well as for the different devices.

## Roaming Services (Technical, Network, and Information Roaming) (Ostberg, 2003)

PCOs and SEOs are mobile and can, by virtue of being comprehensive units, be managed over time by their creators or providers instead of system administrators. Their self-contained and self-protecting nature means they play an important role in the development of mobile ambient intelligent services. There are those who contend that self-protecting container technology can support almost any type of network topology with any number of participants, and that it controls rights flexibly, which means that it is an appropriate tool for super-distribution (Yan, 2001).

# CONCLUSION

It is obvious that the control of the dissemination of information in digital government applications will be of crucial importance in the near future. Access control and authorization will have to be enforced in a dynamic, distributed and flexible way within the context of the huge amount of information generated by digital government. Therefore we propose the use of a flexible and integrated DRM framework that is capable of protecting content and sensitive information in a fine-grained way and, at the same time, respecting citizen's fundamental rights of personal privacy. This will enable digital government to provide more intelligent and flexible services in future scenarios while, at the same time, allowing citizens to control their personal information assets.

DRM is already a fact in the wired world, and will be deployed in e-govenment. However, in wireless communication between e-government and citizens and other external entities, mobile DRM will gain momentum. Mobile phone penetration is generally around 50% (Hobley, 2001), and even above 80% in some countries. This in conjunction with a high-speed third-generation (3G) and beyond mobile infrastructure, which is already in place, will result in the deployment of digital government services to citizens via wireless media. Thus, m-government will materialise and mobile DRM solutions will be of key importance (Beute, 2005) in the near future.

## KEY TERMS

**Access Control:** Prevention of unauthorized use of a resource, including the prevention of the use of a resource in an unauthorized manner. This means that there will be a limitation of the flow of information from the resources of a system to only authorized users.

**Attribute Certificate:** A data structure, digitally signed by an Attribute Authority, which binds some attribute

values to identification information about the holder of the attribute.

**Authorization:** Granting of rights, which includes granting of access based on access rights or privileges. It implies the rights to perform some operation, and that those rights or privileges have been granted to some process, entity, or human agent.

**Certification Authority (CA):** A trusted organization that accepts certificate applications from users, authenticates applications, issues certificates and maintains status information about certificates.

**Digital Rights Management (DRM):** Refers to techniques and tools for managing and controlling the access to and utilization of digital assets. Related to the application of DRM techniques to the privacy-relevant information of users, the concept of privacy rights management (PRM) has recently been proposed.

**Mobile Ambient Intelligence:** This refers to digital mobile environments in which digital services are sensitive to people's needs, tailored to their individual requirements, anticipatory of their behaviors and responsive to their presence.

**Privilege Management Infrastructure (PMI):** The infrastructure that supports the management of privileges in support of a comprehensive authorization service and in the context of a public key infrastructure.

**Public Key Certificate (or Identity Certificate):** A data structure, digitally signed by a Certification Authority, which binds the identity of a user to his/her public key.

**Public Key Infrastructure (PKI):** A process for issuing public key certificates, which includes standards, certification authorities, and communication between authorities and protocols for managing certification processes.

**Source of Authority (SOA):** An attribute authority that a privilege verifier for a particular resource trusts as the ultimate authority in assigning a set of privileges.

# Informational Literacy

## INTRODUCTION

Digital divide is a metaphorical division which separates those citizens who can use new technologies to their own benefit from those who cannot. Digital divide is one of the biggest dangers to consolidation of a harmonic development of the information society.

Historically, projects are mostly centered on helping people that, either for economical or geographical reasons, are not able to have a computer or do not have the possibility to connect that computer to the Internet. Without any doubt, part of the solution resides in creating new telecommunication structures, but that is not the whole solution. There is more in e-inclusion than giving away computers and putting out more fiberoptics. Digital divide is a multidimensional phenomenon which includes lots of different drawbacks. A great many of them are mental in essence, so they can be avoided through education.

The theoretical basis for this approach is to a great degree inspired by the work of the economist Amartya Sen. In Sen (2001) there is a distinction between functionings and capacities. Functionings are elements of technical knowledge towards making something specific, for example, the technical details of sending an e-mail. On the other side, capacities are those pieces of knowledge which include action and social recognition, for example, to arrange a political demonstration using e-mail facilities.

The approach against digital divide which does not stop in the infrastructure, does not go any further than the functionings. That is, learning projects which teach the "four pillars" of computer use: Web browser, e-mail client, word processor, and digital spreadsheet. This is by no means wrong, but it is clearly not enough. Any approach towards diminishing the digital divide must take the theoretical approach described by Sen and work toward capacities, not just functionings.

Digital literacy should not only be about functionings, but about capacities. The final aim of a literacy and ICT campaign should be to give empowerment to the users, not only the technical knowledge of how to send e-mail to buy tickets through a Web site.

By the time this article was written (2005) there were no clear politics going beyond the functioning issues. There are good policies in the US and the EU about "critical thinking", for example, but almost no policies when the application of such curricula is to be used. National politics, in different European countries as well as in the U.S., is mostly centered in teaching the so-called "four pillars": basic communication and ofimatic issues. Most countries develop such courses with no further worries in segmenting the target, so everyone (the elderly, women, migrants, and young people) get the same basic courses with the same professors. An important exception are the pilot projects co-financed by the European Union from programs such as e-learning, Leonardo, or e-content, which do insist on the need of segmenting the targets and find novel ways to approach them. One example is using mobile phones instead of computers to reach teenagers better. Another interesting concept, which may seem to become a major trend in the EU in the following years, is the development of the e-porfolio: a way in which students collect all the relevant information and experience for work and are able to present it using this digital format.

Unfortunately, there are not clear policies yet, and the efforts towards informational literacy are in the hands of either individual researchers or social workers who want to go beyond those four pillars. For example, such a basic element as an informational literacy test has not even been implemented on either a national or European level. Some American universities have created a quite complete one, but it is neither standardized nor nationally distributed. The same can be told about e-portfolios today. Different universities in the EU and the U.S. have their own system and there is not such a thing as a common framework on e-portfolios which everyone can use.

## BACKGROUND

As stated in the introduction, most pedagogical efforts have been directed towards the teaching of functionings. This is the necessary part we need as background to move to a more informational and cognitive type of learning.

Before arranging the contents of the course, a general model specifying the relationships between students and professors is needed. Here we will follow the model developed by the Center for Technological Capacity of Extremadura (Spain) (Equipo Técnico Aupex, 2003), which

is a good example of an advanced digital literacy course based mostly on functionings:

1. **Personal Contact:** Specially directed to avoid the initial fear that the students may have towards ICT.
2. **Seduction:** To show ICT as something attractive in order to stimulate the desire to learn. The mere description of how important ICT is for finding a job and how difficult a world without ICT skills would be usually Is not enough. As a matter of fact, these explanations of ICT use may de-motivate.
3. To teach how to use the different tools, also trying to involve its use in other activities, not directly related to ICT, like making a fanzine.
4. **Compromise:** To turn the student into an active subject in the learning process. The key word here is "collaboration". Advanced courses for digital literacy are based on the paradigm of "collaborative learning" as described, for example, in Bruffee (1999).

This naturally leads to the division of any digital literacy course into three main phases:

1. **Motivation:** Trying to find common interests among students in order to arrange the contents of the course instead of teaching mere functioning without any references to specific tasks.
2. **Capacitation:** The phase when the instrumental knowledge is taught: how to use the hardware, the operating system, and its associated software.
3. **Organization:** To teach how to work in teams on a common project so students can learn from each other, and the learning is associated with the social and cultural reality to which students belong.

That said, there are some issues that should be covered before arranging the informational literacy course. We have to be sure that our students are confident in all of the following areas. As we said before, we are not assuming that functionings are not necessary. Before gaining more proactive abilities that lead to capacities, the following abilities should be taught first.

1. Knowledge of the hardware and the physical structure of networks. This includes, as well, the basic knowledge related to hardware:
   - To turn on and off a computer safely
   - How to properly use the mouse
   - Introducing and removing floppy-disks, CD-ROMs, and DVDs
   - Recognizing the main elements inside a computer, once opened
   - It also includes teaching the basic knowledge about connections: (a) ow to connect and disconnect several computer elements: screen, keyboard, mouse, and so on; (b) how to safely connect peripherals like printers, scanners, and modems; (c) how to connect and synchronize external devices to store information such as pen-drives, mobile phones, and PDAs, and so forth.
2. Knowledge of the logical structure of software. This includes:
   - Basic use of the operating system.
   - Creating folders, moving, copying, and erasing documents.
   - Installing and uninstalling software.
   - Using the Internet browser, understanding what a URL and a hyperlink are, downloading documents and programs, and a very basic introduction to HTML.
   - Concept and main uses of search engines.
   - Using e-mail, basic functions of the e-mail clients, and anti-spam filters.
   - Introduction to other ICT simple applications such as chat programs, P2P networks, online forums, simple tools to publish Web pages, and so on.
3. Familiarity with the ICT vocabulary.
4. Functionality of software.
5. Ergonomics and security.
6. Ethical and social implications of ICT

## INFORMATIONAL LITERACY: THE MAIN STEPS

These are the main elements that have to be considered to arrange an informational literacy program, project, or course that has given capacities (empowerment) as its central aim.

### Acknowledge the Need for Information

This first step implies creating attitudes. Following Bruce (1994), the first characteristic that defines an informationally savvy person is the ability to learn in an independent and autonomous way. Therefore, the first characteristic we need to teach is the right attitude; instead of depending on other people to search, download, and install programs, we need to motivate an autonomy approach instead.

### Identifying the Proper Information Sources

Once the students know they need the information and develop a "I will find it myself" attitude, they need to know

where the information can be found. According to Doyle (1992), the following are needed to create this attitude:

- Recollection of precise and detailed information before making decisions.
- Internalization of the potential sources of information.
- Knowledge of who to ask and which questions they must ask in order to get the information they are looking for.

## Search Strategies

The first step is to show that everybody has an individual style of searching and surfing for information and that there is no magic solution to finding it. Therefore, professors should not just explain their personal styles, presenting them as the best, but must offer a series of different possibilities instead, showing that there is always more than one way of reaching the same end. A good theoretical approach to that subject can be found in Kuhlthau (1993).

As the title indicates, professors must teach strategies, not rigid recipes. Among those strategies, we should indicate the following concepts:

- Describing search engine syntax. A good and practical book to help with this is Calishain and Dornfest (2004).
- Listing specialized portals, based on the motivations and needs of the students, in order to assure capacities development and therefore, empowerment.
- Informing how questions must be delimited find needed information.
- Avoiding "trap expressions" such as "image", "MP3", or "free", which when included in a search will probably lead the user to porn or crack pages, and the user will get some sort of spyware installed.

## Locate and Retrieve Relevant Information

The student needs a strategy to browse through all the information picked up, refine it, and eliminate what is not needed until only the desired info is processed. Again, we need to show that there are several ways of doing that, as a magic recipe for all does not exist.

It is also important to teach the students how to store and label the information found in order to retrieve directly from their computer next time the piece of info needed. It is important to fight the usual fashion of saving anywhere the document we found, leaving it the same name, or the obsession to collect documents, making the students to ask themselves first whether they will need that information later or not before saving anything.

## Critical Evaluation of Information

Critical evaluation of information is one of the key capacities when talking about informational literacy, and it is very seldom taught in digital literacy courses. Critical thinking is a vast subject which cannot be covered here. However, there are some hints of critical thinking related to the Internet which are usually of great help in arranging a digital literacy program. A good description of what critical thinking is, its normative nature, and its importance in the learning curriculum can be checked in Bailin and Coombs (1999).

1. Not everything that shows up on the Internet is true. Newcomers tend to see the Internet as an edited media, like newspapers or TV. "It must be true, I saw it on the Internet", is still a common saying among newcomers.
2. Understand the usual structure of an argument. What are the premises, argument, and conclusion? When is an argument valid? Note typical argumentation structures (Giere, 1997).
3. Be able to detect fallacies, both formal and informal (cf. Weston, 1987).
4. Go beyond one's prejudices and to accept retrieved information that goes against our own beliefs in an objective manner.
5. Do not get just one version of the story, but several.
6. Properly understand the concept of contrasting information and whether it is trustworthy or not. Avoid appeals to authority. Trust more information that comes from a professional organism than casual information found on the Net, from someone without qualifications.

This can be taught practically, arranging information gathering exercises, such as:

- Asking the students to search for information about a subject within Webs from a very different ideological orientation, and ask them to evaluate which info looks more trustworthy and why.
- Asking students to find reports, articles, and papers on a subject about which they have a very specific and strong opinion. These articles and papers should maintain a very different position.
- Using April Fool's jokes, badly written texts, urban legends and so on, which are very easy to find on the Net, teach them the need to verify information.

## Creation, Presentation, and Communication of Information

This is probably the least developed aspect of digital literacy courses. It is as if the main task of educators finishes when students know how to find the information. However, this is not true. It is also needed to analyze the information the students have found, to know how to interpret it to produce an abstract out of it and, especially, to adapt that information to their own uses and needs.

We are talking, therefore, about teaching critical analysis of information and related activities such as text analysis, composition, and other more humanistic instruments. Following Burke (1995), we have compiled the following activities which we consider key:

- **Discourse Analysis:** Being able to get any text, divide it into parts, recognize the main arguments inside, and produce an abstract of the main ideas.
- **Development of Argumentative Structures:** Being able to recognize the type of structure that a specific problem needs and also able to know which prescriptions and recommendations are associated to the stylistic formulation which better suits the material.
- **Relevance in the Sperber and Wilson (1986) Sense:** Being able to transmit the maximum amount of information with a minimum cognitive effort from the reader. That means, from a practical application of Sperber and Wilson theory, to find an equilibrium between texts excessively embellished and linguistically complex and texts that may be too practical and synthetic (i.e., hard to understand).
- **Heuristics to Compile the Needed Arguments:** Know what is relevant and works properly in our final synthesis and what may be curious but goes beyond our main aims.
- **Studying Heuristics:** Information does not become knowledge unless it is finally stored in our minds. We need to give some general instructions on how to arrange the process of studying a certain matter. This is specially true in a digital literacy framework, where pupils will probably not be professional students.
- Use of rhetorical figures in order to make text more interesting: Having a basic grip of the main rhetorical figures (comparison, metaphors, synecdoche, analogies, metonymies, and so on) to produce texts that are more interesting to read. The idea, of course, is not to make a literary workshop. The professor's main aim must be to present how rhetoric is connected to relevance, and how rethoric has interesting cognitive effects which may improve the understanding of the text. Another interesting reference here is Lakoff and Johnson (1980).

Besides these more "classical" abilities there are others more related to ICT. Following Bonsiepe (1995), here is the main list of abilities which must be taken into consideration:

- To localize, select, and divide information visually, in order to create coherent and cognitive presentations of what we want to say in a multimedia format.
- To know how to transduce information to a visual format. This implies both an instrumental presentation (to know which program we need to use, and how to use it) as well as content knowledge (which visual format we want to use and why.)
- To understand the interaction between language, sound, and image within a temporal dimension.
- To learn the basics of computer software to digitalize images, sounds, and text.
- To have a mental model of the main characteristics and uses of the different elements which compose perception (color, textures, size, orientation, contrast, transitions, rhythm, etc.).
- To understand how visual rethoric is used in graphic design and marketing.
- To have general knowledge to test the communicative efficiency of our proposals.
- Ability to coordinate projects in a multidisciplinary manner.

## Ethical and Legal Use of Information

There is a lot of material to teach here, and intuitions can be deceptive sometimes. The important thing is that professors show students different positions in a coherent manner. For example, when discussing questions like peer-to-peer networks, they should not just present the piracy menace, but also talk about other conceptions of copyright, as argued in Lessig (2004). Their concepts describe free software, Linux, and initiatives related to creation and distribution of cultural products, such as Creative Commons. On the other side, one has to fight the tendency to "sell" ICT as a means to obtain copyrighted material for free. This is one of the few subjects about ICT that digital literacy students are probably aware of. We must try to give some legal indications about the importance of respecting copyright, and not only music and movies, but also still pictures (the associated right of the portrayed person to decide whether the picture can be used or not) and other copyrighted material which a great many people do not know have property rights, such as typefaces.

## FUTURE TRENDS

Informational literacy is a new field that has grown recently as both educators and governments realize that literacy based only on functionings is not enough to guarantee a proper entrance into the information society for all.

One of the future trends, as can be seen in Jacobson (2000), for example, is a greater interdisciplinary influence between the field of informational literacy and the design and architecture of information. In its preliminary status, following the classic tendency of "re-mediation", that is, starting the development of analysis of new media using and adapting the structures already existing for older media as described in Bolter and Grusin (2000), the first steps of informational literacy followed very closely by the methodology used for textual media. Again, this approach is necessary, but hardly sufficient, considering all the new and complex possibilities that new media offer. Therefore it should be expected that informational literacy applied to ICT will become more and more visually oriented in the future.

Another emerging trend, clearly growing stronger, is informational literacy for excluded people. Certainly, everybody will find informational literacy useful. However, when we consider excluded people, it is clear that the effect of digital literacy among them will be a lot greater. As a simple example: to us, a Web site like the Gutenberg project, which offers us classical texts for free, is more or less relevant. However, we can also go to a bookstore and buy it. Nevertheless, for a person that is economically handicapped or is at a remote location where bookstores are too far away, having a virtual library at the touch of their fingers is a very relevant alternative. Tendencies show even now how social educators are moving more and more towards ICT teaching for the excluded people when they realize all the empowerment options they offer. This is a tendency which will clearly grow in the future.

## CONCLUSION

Digital literacy goes far beyond the teaching of ICT functionings. They are certainly necessary to assure the proper use of ICT technologies but are not by any means sufficient. If we want to have real citizens in the Society of Information and no mere consumers of digital entertainment, we need also to teach capacities: that is, ways by which citizens can empower their lives, by being able to connect all the formal possibilities that ICT can offer them for their own real needs and desires.

To do so, we need to pay closer attention to informational abilities related to ICT, not just the technical protocols of using them. The main informational abilities needed for such an objective are to acknowledge the need for information identifying the proper information sources, teaching basic search strategies, to locate and retrieve the relevant information, critical evaluation of information, how to create, present and transmit information, and ethical and legal approaches to information.

The two more meaningful future trends one can see right now are the combination of the disciplines of informational literacy and information design, creating a more visually based approach to information in the ICT context, and the development of specific informational courses for excluded people to improve their lives and fight their social exclusion.

## KEY TERMS

**Creative Commons:** A non-profit organization which has as its main aim is to develop a new standard for cultural products, in which the authors have more freedom to decide whether other users can use their own creations in new projects and under which restrictions. More information is available at www.creativecommons.org

**Critical Thinking:** Both a way of thinking and of teaching, in which we try to evaluate information, and decide whether we can trust it or not, forming our own judgments and decisions based on that information. Important parts of informational literacy processes are based on critical thinking issues.

**Digital Divide:** A popular term used to describe the perceived growing gap between those who have access to and the skills to use ICT and those who, for several reasons have limited or no access. Causes vary from socioeconomic status, gender, age, place of living, and so on. One of the main concerns related to this issue is how digital divide can actually amplify socioeconomic or gender discrimination, making barriers even greater, as we move to an information society.

**Digital Literacy:** A blanket expression referring to all the knowledge one must have in order to use computers properly. Therefore, digital literacy should include both instrumental and informational issues. However, it is commonly used only to refer to the first type of issue.

**Information Design:** An interdisciplinary science that searches how to properly design books, interfaces, Web sites, and so on, in order to make them easier to interact with and easier to obtain the information we are looking for.

**Informational Literacy:** A series of competences that a computer user must have in order to be able to obtain, use, and reapply the learned information. Informational literacy presupposes instrumental learning in order to be able to use the computer.

**Instrumental Learning:** A series of competences that a user must have in order to be able to use a computer. We use the term "instrumental" to indicate that we are only considering formal characteristics of how to use a computer, from the ability to turn it on and off, and send an email, with no references on how to process the information we obtain.

**Remediation:** A term invented by Bolter and Grusin in their book with the same title to refer to the fact that when developing projects with new media, authors do not work from scratch, but tend to base their work from older media, using techniques, conventions and topics from older media, transposing them to the new media, that is, remediating them.

**Search Strategy:** To have a certain algorithm to look for a specific piece of info, as opposed to a random surf on the Net or putting some related words in a search engine, but with no precise model in mind as to what we are looking for and why we choose those words.

# Innovative Local E-Government through the PEOPLE Project

**Roberto De Vivo**
*PEOPLE Project, Italy*

**Marco Magnani**
*PEOPLE Project, Italy*

## INTRODUCTION

PEOPLE, one of the most important e-government projects in Italy, was created in 2002, when it was ranked first among almost 400 projects submitted to the Italian government according to its Piano di Azione per l'E-Government, literally, E-Government Action Plan, that is, the program to which the Italian government allocated around •120 million to finance various projects on e-government development. The financial contribution for each project did not exceed 50% of its total expected budget.

The name of the project is the acronym for Progetto Enti Online Portali Locali E-Government, literally, Project Public Bodies Online Portals E-Government.

The purpose of PEOPLE is "to innovate and to simplify the relationships between Local Public Administrations and citizens" through the online delivery of almost all the services provided by local bodies, leading to the fulfilment of 95% of individual and company requests. The project seeks to create a multichannel network system with a Web portal as the main method of access and interaction.

## BACKGROUND

PEOPLE is supported by 55 Italian local authorities from 12 different regions. This group includes both metropolitan areas, like Rome and Florence, as well as small municipalities. The developers of the project therefore had to create a model that was sufficiently abstract to fit all the different contexts, irrespective of local legislation or regulation.

The total population administrated by PEOPLE amounts to 7.5 million, almost 13% of the entire Italian population.

The main reason these administrations were involved in the realization of PEOPLE is the high level of organizational and technological capabilities required. These bodies are the most dynamic in the country and represent best practices as concerns service innovation. This makes PEOPLE a sort of laboratory in which the most innovative Italian local authorities are sharing their experiences and their know-how. To this end, the PEOPLE administrations are organized in a federal model, in which every single municipality has the opportunity to participate in the creation of each single service. The choice is to preserve and enhance cultural diversity by creating a set of solutions based on a common structure and on a shared standardized platform.

The model is equally participated in by every single local authority and is built on the exchange and integration of information; the goal is to promote the sharing of services and solutions that may have been produced locally before the project started or created ad hoc. However, those solutions must be the same for each single participant and for each citizen who wants to use the solution proposed by the project. Consequently, an extremely high level of coordination is needed to make this model work, and this is one of the most critical points that PEOPLE had to face. In order to overcome this problem, the PEOPLE staff created an original management organization based on an efficient, high-tech communication system.

*Figure 1. The areas involved in PEOPLE (Progetto PEOPLE)*

*Table 1. The local government authorities involved in PEOPLE (Source: Progetto PEOPLE)*

| Local Government Administration | Citizens | Region |
|---|---|---|
| Comune di Ancona | 100,409 | Marche |
| Comune di Bari | 347,106 | Puglia |
| Comune di Bologna | 378,356 | Emilia Romagna |
| Comune di Bolzano - Stadtgemeinde Bozen | 97,317 | Trentino Alto Adige |
| Comune di Brescia | 195,442 | Lombardia |
| Comune di Carpi | 62,104 | Emilia Romagna |
| Comune di Cesena | 90,851 | Emilia Romagna |
| Comune di Cremona | 71,321 | Lombardia |
| Comune di Falconara Marittima | 28,307 | Marche |
| Comune di Firenze | 374,000 | Toscana |
| Comune di Genova | 627,599 | Liguria |
| Comune di Jesi | 39,238 | Marche |
| Comune di Mantova | 48,341 | Lombardia |
| Comune di Modena | 176,965 | Emilia Romagna |
| Comune di Paterno Dugnano | 45,661 | Lombardia |
| Comune di Parma | 170,541 | Emilia Romagna |
| Comune di Pesaro | 90,000 | Marche |
| Comune di Piacenza | 95,594 | Emilia Romagna |
| Comune di Ravenna | 140,933 | Emilia Romagna |
| Comune di Reggio Calabria | 179,412 | Reggio Calabria |
| Comune di Reggio Emilia | 148,517 | Emilia Romagna |
| Comune di Roma | 2,665,000 | Lazio |
| Comune di San Benedetto del Tronto | 45,368 | Marche |
| Comune di Sesto San Giovanni | 81,482 | Lombardia |
| Comune di Siena | 54,344 | Toscana |
| Comune di Trapani | 69,700 | Sicilia |
| Comune di Venezia | 274,168 | Veneto |
| Comune di Verona | 258,372 | Veneto |
| Comune di Vigevano | 59,302 | Lombardia |
| Comune di Malo | 12,366 | Veneto |
| Comune di Schio | 37,662 | Veneto |
| Comune di Tiene | 21,107 | Veneto |
| Comune di Santorso | 5,305 | Veneto |
| Comune di Torrebelvicino | 5,516 | Veneto |
| comune di Valdagno | 27,136 | Veneto |
| Comune di Arzignano | 23,454 | Veneto |
| Comune di Chiampo | 12,251 | Veneto |
| Comune di Marostica | 12,823 | Veneto |
| Comune di Pianezze | 1,839 | Veneto |
| Comune di Nove | 4,901 | Veneto |
| Comune di Schiavon | 2,339 | Veneto |
| Comune di Marano Vicentino | 8,902 | Veneto |
| Comune di Villaverla | 5,384 | Veneto |
| Provincia di Bologna | 926,744 | Emilia Romagna |
| Unione di Comuni “Caserta Sud-Ovest” | 139,534 | Campania |

## THE SERVICES PROVIDED

PEOPLE will provide a wide range of services concerning every single life event, as defined by the Italian government. Once the project is completed, there will be around 180 services divided in five groups:

- local tax services,
- grant and authorization services,
- geographic information-system services,
- social and welfare services, and
- register-office services.

Besides these, an efficient online payment service and a reliable registration and authorization system have been created.

Some general services are also planned, such as online ticket reservation and sale for events like exhibitions or concerts, virtual community services, and online document access.

All these services have been developed in the project itself by a well-organized division of labour between the local administrations involved. Each area has been managed by a single administration, which, without regard for the indications from the other authorities, was responsible for the development of all the services in the area.

So far, the project has developed some demonstration services, such as the change-of-address (within the same local area) or the Building Start-Up Certification (Decuncia Inizio Attività, DIA) initiatives to illustrate the technical functionalities of its software.

## THE SOFTWARE

As stated above, PEOPLE is both the project and the aggregation. However, there is yet another interpretation; PEOPLE is the software through which each municipality will provide services to the citizens. The major benefits expected from the use of this software are the following:

- decrease in the development costs for online services;
- means to manage the complexity of e-government-related issues through coordinated and integrated investments; and
- the possibility for small-size local administrations to benefit from low-cost products and solutions provided by other PEOPLE administrations.

Each service comprises several data forms structured in different fields to complete. In order to validate the data provided, the system acts as follows:

- verifies each single word syntactically;
- marks submitted forms, ensuring that all the compulsory fields have been correctly completed; and
- validates and cross-verifies all the data after completion.

Citizens will be free to fill in the forms in any order before signing and sending the request. However, the order of the pages will be defined by the system, which will also take control if a page may not be needed (e.g., as the data has already been provided) or will block the access (e.g., depending on a user's access level as a requester, delegated, or technician). The user will be able at any moment to interrupt the procedure, save the inserted data, and return later to complete the request.

PEOPLE will also allow citizens to sign both the request and any attachment (any kind of document) digitally. In some cases, for example, the DIA, more than one person must sign the documentation, and the process above can be quite complex. PEOPLE will also guide users in this process, identifying the documents that will be needed to be signed and who is supposed to sign them. Citizens will be able to notify the local administration of people authorized to act as their proxies. Each proxy created by a citizen will be valid only within a specific local government area for a specific service and for a specific period of time.

After all documents are completed and signed, the requests will be sent to the local government through a certified e-mail system. The local government officials will receive in a special in-box an e-mail of notification with a link to the citizen's request from the certified e-mail system. This message will contain the text of the main form and all the attachments. Once the message has been read, the e-mail system will request the official to sign a receipt that will be sent to the requesting citizen.

Citizens will also be able to consult their current personal proceedings management page at any point in the application. This page will contain all the forms that have been completed, those that have been temporarily saved, and all the forms awaiting completion from the competent local authority. In the last case, the progress status will also be shown.

PEOPLE has been planned to send the requests to the local administration's back-office system directly. This operation will be started when the legislative and organizational conditions for the automatic reception of requests has been introduced.

## PEOPLE 1.0 FRAMEWORK: THE REFERENCE IMPLEMENTATION

The PEOPLE 1.0 framework is the first version of the project released to allow municipalities to test the results obtained so far and to develop services and systems to link between the online front office and the back office. For this, the virtual service layer of the PEOPLE 1.0 reference implementation is required. This framework has been realized on a vendor-neutral basis in order to guarantee full accessibility and compatibility with the services developed by different ISVs (independent software vendors) in a service-oriented environment.

The framework uses J2EE (Java 2 Platform Enterprise Edition) technologies and components extensively, looking for the latest specifications and standards in Web-service technology provided by the Ministero per l'Innovazione e le Tecnologie, literally, the Ministry of Innovation and Technology, the body responsible for information and communication technology and high-tech development in Italian public administration.

Through this, PEOPLE can achieve the following:

- Allow software vendors to realize online services quickly, using the same patterns and development techniques
- Achieve the same look-and-feel experience for all online services, so standardizing the user experience
- Support the integration and certification of the online services provided by the project and guarantee compliance with architectural standards

The People framework is structured in three layers:

- The front-end layer includes the services based on a multichannel access system, a light work-flow engine used to manage user interactions, and a Web service ensuring interoperability with the other layers of the Web-service-layer and with external calls (i.e., interoperability with other domains).
- The people layer comprises the management components (the so-called PEOPLE console) and the service components (PEOPLE services).
- The back-end layer consists of Web services that answer the front-end requests and interact with the back-end systems.

As a reference implementation, the PEOPLE framework was developed and tested in the Centro di Itegrazione e Collaudo, literally, the Integration and Testing Center, which was created by the project in close collaboration with Enterprise Digital Architect, the private company that works as a technical partner of PEOPLE, in order to certify the correspondence to all PEOPLE requirements and its full usability.

The reference implementation uses vendor-neutral components in a vendor-neutral environment and cannot therefore satisfy all requirements of a given production scenario. These requirements could be trustworthiness, performance, scalability (clustered environments), fault tolerance, or recoverability (what happens to the submitted requests if the system breaks down).

Such requirements are best satisfied by commercial platforms. The project has thus collaborated with the top-five platform vendors: IBM, Microsoft, Oracle, Bea, and Sun. The problem was to implement the PEOPLE framework on those platforms, using their components and features, but without losing any characteristics or benefits in the overall product.

Four of these partners are Java based. The first technical activities concerned the translation of the reference implementation to the specific DBMS (database management system) and application-server environments. Subsequently, various devices were developed to allow the PEOPLE framework to interface with these platform components.

A different approach has been taken for the Microsoft platform because of the difficulties related to the ownership property of programming languages.

The vendor implementations kept the layered structure of the reference implementation. A test and certification process guaranteed full architectural compliance.

This result was achieved by developing a dummy service to verify the following:

- The integration with the reference-implementation PEOPLE node using the service running on the vendor's front-end node
- The integration with the vendor PEOPLE node using the service running on the reference-implementation front-end node

Another cornerstone of the PEOPLE project was the modeling approach. This was tailored to UML (Unified Modeling Language) modeling constructs used in business management.

The modeling group represented online services as business objects and designed the model. A very important distinction was made between shared objects and domain-specific objects.

The main modeling artifacts were the following:

- Business use case diagrams representing and describing online services for each category
- Activity diagrams representing the typical work flow of online services from the first step to data submission (front-end requests)
- Class diagrams referring to online services representing business objects, their associations, and hierarchies in order to distinguish between objects, documents, receipts, requests, responses, forms, and so on

UML diagrams and objects defined the data needed to support the interactions between the front-end applications (online services) and the back-end systems. Data had to implement Web-services standards fully and be generated as XML (Extensible Markup Language) schema definitions (XSDs). XML files exchanged between the front end and the back end had to be compatible with this structure.

The architecture of PEOPLE allows different ISVs with different knowledge of several application domains to be chosen without losing the coherence and the common design of the services.

After a few months, all ISVs could release online services running on a solid architecture compliant with the modeling standards already described.

A crucial part of the service implementation was the testing and certification process to guarantee that the same service would work properly on the information systems of several different municipalities, fulfilling all functional and technical requirements.

The online services certification process was divided into two main activities:

- Functional certification to guarantee the satisfaction of all functional requirements gathered by many users and domain experts belonging to different municipalities, both in the mail-sending scenario and in the Web-services scenario
- Architectural certification to certify correct interaction with the framework, the implementation of a common user experience, and compliance with XSDs generated by UML object models representing data exchanged between the front end and the back end

The functional certification activity was divided into three steps:

- Verification and certification of technical specifications sent by ISVs in order to guarantee coherence between the detailed design and the test plan
- Execution of test cases by user representatives and feedback to ISVs to fix bugs and errors
- Verification and certification of test results

The architectural certification activity involved five steps:

- Test of the services in the reference implementation in order to guarantee correct interfacing with the front-end node and with the PEOPLE node; the services that did not pass this step were returned to the suppliers
- Verification of compliance with look-and-feel standards
- Verification of compliance with accessibility guidelines
- Verification of correct interfacing of infrastructural services
- Test of the vendor implementations' front-end nodes in order to verify interoperability

Once all these activities and steps had been performed, each individual service was declared a certified PEOPLE online service, ready to work in a PEOPLE-compliant environment. In response to the municipalities' priorities, it was decided that two categories of services would be implemented: demographics and tax services. In this way, all municipalities could start the deployment process on the preferred platform, taking account of their back-end systems and integration needs. At the same time, other categories of services were developed by many ISVs for the Java and the .Net environments. To this end, a stabilized framework, a standard model for future development processes, and a tested certification process were used.

Once this first phase of deployment has been completed, all municipalities will be able to easily deploy other family services without difficulty.

## FUTURE TRENDS

As mentioned above, the deployment process has already started, and before the deadline of March 2006, all the services will be available to the PEOPLE administrations' citizens. The PEOPLE network is also expected to be enlarged to at least 300 municipalities. This enlargement will be on a voluntary basis and will depend on a contribution proportional to the administrated population.

## CONCLUSION

PEOPLE offers one of the most important opportunities for the local government in Italy to develop its structure in line with the European e-government legislature and to bridge the digital divide created by the massive introduction of ICTs.

The main benefits expected for all local authorities, irrespective of their size, are the following:

- A strong impulse to develop new integrated systems for companies and citizens
- Scaled costs equally distributed among each local administration taking part in the project
- The creation of online services and high—quality, innovative solutions
- The spread of technical and organizational know-how that is essential for the innovation of local administrations
- The management of the major e-government issues, using integrated, coordinated, and modular investments and architectures
- The optimization of procedural management timetables
- The rationalization of communication systems between different local administrations and within the local administration itself
- The creation of a shared and constantly updated professional level of excellence

## KEY TERMS

**Front End and Back End:** Interface of the PEOPLE program respectively for the front office and the back office.

**J2EE Technologies and .Net Technologies:** The project based on the Java 2 Platform Enterprise Edition (J2EE) language and the Microsoft .Net one, respectively. This choice allows each local authority to choose the preferred language, avoiding further investments to link the new interface to the internal back-office system.

**Multichannel Network System:** The project planned a very complex access system to the PEOPLE network that will allow the connection and the supply of the provided services through different media, such as PCs (personal computers), mobile phones, digital television, and so on.

**Online Front Office:** The main goal of the project is to substitute the physical front office used by public authorities to supply services with a Web portal system, giving citizens the opportunity to access those services from a simple PC.

**PEOPLE Project:** The most important e-government project in Italy, it aims "to innovate and to simplify the relationships between Local Public Administrations and citizens" through the online delivery of almost all the services provided by local bodies.

**Virtual Service Layer:** Layer of the program that acts as a connection between the front end and back end and that contains the structure of each service provided.

# Integrated Online and Offline Advocacy Campaign Strategy

**Alan J. Rosenblatt**
*Internet Advocacy Center, USA*

## INTRODUCTION

Advocacy campaigns are considered by many to be the second cornerstone of a pluralistic, democratic society. While many may focus on the first cornerstone, voting, advocacy campaigns provide the opportunity for citizens to pool their voices to influence public policy in between elections, when the business of governing takes place. Historically, citizens would return their focus to their immediate lives shortly after a presidential election, with a more modest peak during off-year congressional elections. But with the convergence of the Internet and politics, mid-election participation is easier. Online grassroots advocacy tools help interest groups organize in a day, or two, campaigns that can easily generate tens of thousands of e-mails, faxes, telephone calls, and telegrams to policymakers at any level of government, or even at any private or international organization. These campaigns have had a major impact on the legislative process, including drastically reshaping the workload of congressional (Fitch & Goldschmidt, 2005) and agency (Shulman, 2005) staff responsible for processing citizen communication and making legislative and regulatory decisions more responsive to citizen concerns.

Perhaps the most colorful story of the origins of legislative advocacy in the United States focuses on meetings between legislators and favor-seekers in the lobby of the Willard Hotel, near the White House, in the early 1800s. These "lobbyists" would wine and dine lawmakers in order to gain favor on the various issues before congress (American League of Lobbyists, 2003).

While early lobbying was (and to a great degree remains) a process that relies on personal relationships and interactions between a lobbyist and lawmakers, the scope of lobbying has evolved over time to include the integration of more widespread citizen participation through interest groups and grassroots campaigns. According to David Truman in his seminal work on pluralistic politics, interest groups form as a result of a disturbance in the polity that makes people take notice of an issue (Truman, 1958).

Initially, interest groups started locally and grew into national organizations. As they grew larger and more unwieldy across great distances, they faced inevitable stress on an occasional breakdown of their internal lines of communication. The Internet gives the opportunity for immediacy of communication and drastically reduces the effort involved. Interest groups now have a wide range of online tools for developing and nurturing thriving communities of like-minded people without concern for geographic proximity or scheduling/time-zone differences.

From television to the Internet, the public has seen dramatic increases in their access to information about the issues that matter to them. By providing an explosion in the number of channels of communication, television (and radio) broadcasted huge amounts of uniform information. But the communication was only one-way. The Internet added multi-way communication and full-text searchability to a wealth of information on an unimaginable number of topics.

This increased access to issue information, combined with the advent of new, online tools to help citizens communicate with lawmakers, has ushered in a new era of mass movement-based advocacy politics. Educating and mobilizing hundreds of thousands, and potentially millions, of activists to voice their opinions to congress in a short period of time, even in just a day or two, is a reality now. With a good strategy, interest groups can provide sufficient education and guidance to their advocacy communities to make a clear and effective chorus of voices heard in congress.

Early Internet advocacy campaigns tended to focus almost exclusively on the use of Web sites, e-mail, and online advertising as the means for educating and mobilizing citizens to get involved with advocacy campaigns. As citizens and lawmakers have become more comfortable with the Internet, advocacy strategies have become more integrated, combining the new online strategies and tactics with traditional offline strategies and tactics. Where early Internet-era advocacy campaigns were "siloed" into separate online and offline tracks, the turn of the twenty-first century has seen the separate tracks weave into an integrated strategy that uses online and offline tactics to reinforce each other in a manner that dramatically increases the effectiveness of these campaigns, both with respect to mobilizing larger numbers of citizens and giving citizens more influence over public policy formation.

As a result of these new digital tools connecting citizens to policymakers, the line between e-politics and e-government is blurring. Digital technologies bring citizens, either individually or organized by interest groups, deeper into the governmental process—from legislation, to rulemaking, to enforcement, and even into the judicial process. Indeed, the focus among e-government scholars on issues related to transparency speaks directly to this blur. Lack of transparency produces greater citizen calls for more transparency and transparency makes governments more accountable to the citizens at all process levels. Thus, no discussion of e-government is complete without a discussion of e-politics and the heightened involvement of citizens in the governmental process.

## BACKGROUND

To be *integrated*, an advocacy campaign uses *multiple outgoing communication channels* to educate, recruit, and mobilize citizens to take action supporting the campaign. It also sends citizen messages to policymakers through *multiple incoming communication channels*. Where using multiple outgoing channels extends the reach of the message to more citizens, delivering messages through multiple channels into the policymaker's office makes the messages more noticeable and harder to ignore.

Outgoing citizen mobilization and incoming policymaker persuasion messages require distinct strategies to be effective. Outgoing messages to citizen activists must be an eye-catching and a compelling call to action. Incoming messages to policymakers must persuade them to support the campaign's policy position on a bill before congress.

*Campaign channels of communication* include both online and offline modes. Online channels include online advertisements, e-mail, Web sites (both the campaign's and others'), digital video, and digital animation. Offline channels include direct mail, telephone, fax, television, radio, print ads, and billboards.

In addition to employing multiple outgoing and incoming communication channels, what makes an advocacy campaign integrated is the strategy for using these multiple channels in a mutually reinforcing manner, with two goals. The first goal is to mobilize citizens to express their views to policymakers. The second is to persuade the policymaker to support the campaign's position, which, if achieved broadly through members of the decision-making body, yields the desired policy outcome.

While congress and state legislatures are the most common recipients of integrated strategies, they can be targeted to any policymaking body, including regulatory agencies and corporations. Grassroots advocacy software delivers e-mail and faxes to state legislators, governors, even to city council members. Most provide easy-to-use Webforms for sending letters to the editors of local and national news publications and broadcasts. Some allow campaign managers to enter the contact information for anyone (i.e., the president or board of directors of a corporation) into a custom target field to direct a campaign at just about anyone.

Integrated citizen outreach strategies reach more people than online-only strategies because they can reach the third of Americans who do not use the Internet and the other third that use the Internet through a dialup connection. Once they reach people, the campaign can easily identify the best way to contact each person for future communication and mobilization. Once contacted through offline means, it is important to move as many people as possible to an online activist network, but it is also important to identify those who prefer to be contacted by mail or phone and continue to communicate with them in that manner. Since campaigns need to remobilize their activists throughout a campaign, as well as for subsequent campaigns, respecting the wishes of would be activists as to their preferred modes of communication helps to keep them loyal and reliable.

Another key component of an integrated campaign is a centralized database providing a regularly updated, or real-time tracking of activist communication and activity. Using this relational database, a campaign can make strategic decisions regarding budget allocation as a campaign progresses. For example, as the number of messages to specific members of congress reach target goals, online ads and phone calls that were going to be sent to people in those congressional districts and states can be redirected to citizens in other districts and states where performance levels are lagging. This allows a campaign to maximize the efficiency of its ad buys and phone banks, ensuring that all the congressional targets receive sufficient constituent messages to hold some sway.

While the rise of the Internet's popularity has opened new opportunities for engaging the polity in a meaningful way, especially in between elections, the fact remains that a sizable number of citizens remain offline and among those online, many still prefer to do politics the "old fashioned" way. Let's look at the numbers.

According to the Pew Internet and American Life Project, about two-thirds of Americans are online (Pew Internet & American Life Project, 2004a) and 88% of those online say "the Internet plays a role in their daily routines and that the rhythm of their everyday lives would be affected if they could no longer go online (Pew Internet & American Life Project, 2004b)." That said, there are still sizable gaps in access that leave seniors, African Americans, households making under $30,000 a year, and those

with less than a high school education, lagging behind the online rates of younger, wealthier, more educated, and non-African American citizens (Pew Internet & American Life Project, 2004a).

To reach the offline population, it is essential to use offline channels of communication. Telephones, television (including cable TV), newspapers, and direct mail have the ability to reach offline audiences. In some cases, billboards on the sides of trucks and buses, on the side of the road, and on top of buildings can also help campaigns reach out to citizens and drive them to take action to support a campaign.

The substantive advantage of an integrated outreach campaign lies in the rates of citizen mobilization. Industry standards regarding activation rates for traditional direct mail campaigns suggest that a campaign activating 2-4% of those contacted is considered a good response. The expectations for a phone-only or an e-mail-only campaign are the same. This suggests that a campaign reaching out to a mailing, phone, or e-mail list of one million people not already engaged with the campaign, would be delighted if 20,000 to 40,000 of them took action supporting the campaign.

An integrated campaign where, for example, a phone bank program leaves voice messages on a million answering machines with information about the issue, a call to action, and a prompt to look for a direct mail piece already on its way, followed a day or two later with that direct mail piece, which also prompts recipients to look for an e-mail on its way, can dramatically increase the action conversion rates, sometimes as high as 14%. The net result is greater than the sum of the parts because (1) multiple contacts increase the chance that the message is received and remembered; (2) opportunities to take action using the same communication channel as the outgoing message make it easier and quicker for the action to be taken (i.e., phone outreach offers the opportunity to patch-through a call to a congressional office, direct mail includes a tear off postcard to mail to congress, and the e-mail has a link to send an e-mail, fax, or telegram to the congressional office); and (3) the messages in all three communications reinforce each other, drawing attention to the next message in the pipeline and always providing information on a toll-free hotline to learn more and get patched through to congress or the Web address of the campaign's Web site where advocacy opportunities are just a click away.

This brings us to the next concern. With all activists acting online and offline, how does one manage an integrated campaign? In order to effectively manage an integrated advocacy campaign, it is essential to develop a real-time, back-end database to track the outreach to citizens using all communication channels and the resulting actions they take to support the campaign. By tracking this information in a unified database, campaigns are able to adjust tactics mid-stream in order to decrease the cost per activist mobilized. In the case of a campaign targeting congress, budget allocations for citizen outreach can be monitored on a district-by-district basis, as can the messages citizens send to congress. The real-time database helps campaign managers identify districts that have reached targeted levels of action and districts that are lagging. Because phone and online ad campaigns, especially, can be shifted on the fly to increase delivery to lagging districts, the campaign can shift outreach efforts to focus more on those districts, thereby driving more action from them.

## FUTURE TRENDS

Perhaps the most exciting development in integrated advocacy campaigns is the rising popularity of mobile communication devices. Mobile phones and personal digital assistants (PDAs) offer new opportunities to reach out to citizens. These devices can be reached via phone banks and e-mail. They provide opportunities for citizens to send messages to policymakers via phone call, e-mail, fax, or telegram. They can even be used to coordinate large groups of people who are visiting congressional offices in person.

By 1999, five years after the launch of Netscape, the Internet had reached 50% market penetration in five major cities: Salt Lake City, Seattle/Tacoma, Austin, San Francisco, and Washington, DC (Reagan National Advertising, 1999). A year later, national market penetration hit 50% (Pew Internet & American Life Project, 2004c). In 2002, digital data delivery to mobile phones was introduced (Cellular Telecommunications & Internet Association, 2004), gradually enabling more Web content to be delivered to subscribers. By May 2004, 28% of all Americans (41% of Internet users) owned mobile phones capable of receiving text messages, Web content, and e-mail (Pew Internet & American Life Project, 2004d). As market penetration for these devices grows, they will become more and more a part of integrated advocacy campaigns.

Even short of 50% market penetration, digital data delivery to mobile phones can already have an effect on integrated campaigns. For example, by introducing this mobile technology to traditional lobby days, where advocacy organizations bring its members to Washington, DC or to a state capital to make personal visits to senators, representatives, and delegates, the organizers of the visit can better manage the impacts of these visits.

Even if a thousand, or more activists converge on a capital, organizers can hand out leased or inexpensive pay-as-you-go mobile phones to their activists as they

arrive. The phone numbers for these phones can be pre-programmed into an e-mail distribution list, allowing organizers to gather all of their activists for quickly arranged meetings with key legislators.

By pre-programming the phone book of each distributed phone with key phone numbers, including the e-mail address list (the phones can send text messages to e-mail addresses, too, and a single e-mail address can be set up to send a message to every cell phone on the list), individual activists in the halls of the congress or state legislatures can serve as eyes and ears for the campaign. It allows individual activists to report to either the organizers or the whole mailing list comments they are getting from lawmakers and their staff as they visit the offices. With this real-time flow of information, lobby day organizers can quickly and effectively craft strategic responses to arguments being used to deflect efforts by the activists to influence their representatives.

In addition to using mobile phones to coordinate activists on the ground, a simultaneous e-mail, fax, and phone campaign into congressional offices draws additional emphasis to the visits and the goals of the campaign. Thus, with the increased use of mobile technology, integrated advocacy campaigns will continue to shift towards coordinated online and offline strategies.

## CONCLUSION

The advantages of an integrated advocacy campaign draw from the heightened visibility resulting from the use of multiple communication channels. When tightly orchestrated, phones, postal mail, faxes, e-mails, online ads, offline ads, and personal visits make the messages sent to policymakers difficult to ignore. Using online and offline methods to reach out to mobilize citizens increases the chances that they will understand the issue, effectively remember the details of the message when communicating with policymakers, and be more likely to take the requested action. The end result is a campaign with an impact that exceeds the sum of its parts.

## KEY TERMS

**Channels of Communication:** Channels of communication are modes for transmitting information. They include postal mail, e-mail, telephones, television, radio, and so forth.

**Grassroots Advocacy Software:** Grassroots advocacy software are Web-based e-mail tools that allow advocacy campaigns to contact citizens and provide them with a single user interface to send messages to a variety of policymakers and opinion leaders.

**Grassroots Advocacy:** Grassroots advocacy is when ordinary citizens are mobilized to contact their legislators in order to voice their opinions on a policy issue.

**Integrated Advocacy Campaign:** An integrated advocacy campaign is a coordinated program that uses multiple channels of communication to educate, recruit, and mobilize citizen activists to voice their support of opposition to a policy to policymakers using multiple communication channels to deliver those messages.

**Interest Groups:** Interest groups are organizations that have been formed to advocate on behalf of a particu-

lar segment of the polity based upon a common set of concerns.

**Mobile Personal Digital Assistants:** Mobile personal digital assistants are telephones and other electronic organizing devices that connect to the Internet wirelessly.

**Patch-through Phone Program:** A patch-through phone program uses either a live operator or pre-recorded message to inform people about an issue, ask them to talk to their legislator, and immediately provides a toll-free connection to the legislator's office.

# Intelligent Cities

**Nicos Komninos**
*Aristotle University, Greece*

## INTRODUCTION

In the dawn of the 21st century, information and communication technologies have radically altered the construction of our physical environment. Instead of constructing spaces that intermediate between nature and man's physical condition, a new orientation is emerging attempting to create spaces that increase man's intellectual capacity and improve the ways in which we use the environment in order to learn, innovate, and reach new frontiers. Intelligent cities belong to this new orientation; they are part of an ongoing research project for creating environments that improve our cognitive skills, our ability to learn and innovate, to foresee and prevent.

Intelligent cities combine two fundamental dimensions of our era: information technologies and innovation systems.

*...We use the term 'intelligent city' to characterize areas (communities, neighborhoods, districts, cities, regions) which have the ability to support learning, technological development, and innovation procedures on the one hand, with digital spaces and information processing, knowledge transfer and technology tools on the other hand. ....There are three basic components of an intelligent city: (1) the island of innovation formed by a community of people, production, exchange and other activities, (2) the virtual innovation system, which includes knowledge management tools and information technologies for online provision of information and innovation services, and (3) the connection between the physical and virtual innovation systems, in other words, the use of the latter by the island's community.* (Komninos, 2002, p. 198, 201).

To date, many territories have adopted "intelligent city" strategies. Public authorities in Singapore, Taipei (Taiwan), Spokane (U.S.), Seoul and Songdo (Korea), and Cyberjaya and Putrajaya (Malaysia) have implemented plans to make their cities more "intelligent." But, the most elaborated illustration of intelligent cities is to be found in the awards of the Intelligent Community Forum (ICF), which assesses communities, cities, and regions with respect to five criteria of innovation performance and digital government. During the last five years, about 20 territories from all over the world were selected by the ICF as top intelligent cities (http://www.intelligentcommunity.org).

## BACKGROUND

The concept of "intelligent city" is ambiguous. At least four different descriptions of what is an intelligent city (IC) can be found in the literature:

- ICs have been frequently defined as *virtual representations* of cities, as virtual cities; the term has been used interchangeably as an equivalent of the "digital city" and "cyber city." Nonetheless, it is certain that communication capabilities offered by a digital platform or a virtual representation of a city do not suffice for an urban system to be characterized as "intelligent."
- A second approach is derived from various electronic and digital applications involved in the *management of city operations and functions*, which make very frequent use of terms such as "information city," "wired city," "telicity," "knowledge-based city," "virtual city," "electronic communities," "electronic spaces," "flexicity," "teletopia," "cyberville," etc., (Droege, 1997).
- Thirdly, ICs are conceived as environments with *embedded information and communication technologies* (ICTs) creating interactive spaces that bring computation into the physical world. From this point of view, intelligent cities (or intelligent spaces more generally) refer to physical environments in which information and communication technologies and sensor systems disappear as they become embedded into physical objects and into the surroundings in which we live, travel, and work. (Steventon & Wright, 2006). The "Intelligent Room" is a good miniature illustration of such environment; it is laboratory room which supports computer vision, speech recognition, and movement tracking, based on about fifty distinct intercommunication software agents that run on interconnected computers (Cohen 1997).

- Fourth, intelligent cities are conceived as territories that bring *innovation systems and ICTs* within the same locality, combining the creativity of talented individuals that make up the population of the city, institutions that enhance learning and innovation, and virtual innovation spaces facilitating innovation and knowledge management (Komninos 2002, ICF, op.cit).

This diversity in the understanding of intelligent cities is due to the multiple scientific and technology disciples and social movements that take part in their creation, namely the movements towards "cybercities," "smart communities," "intelligent communities," and "intelligent innovation environments."

## CYBERSPACE AND CYBER CITIES

The term "cyberspace" was introduced by Gibson (1984) in his science fiction novel Neuromancer to describe a dystopian future based on virtual reality, artificial intelligence, and high-tech implants. With the explosion of the Internet, the meaning of the term changed radically and actually cyberspace came to describe an emerging universe of virtual spaces existing within the worldwide computer network, the Internet, and the World Wide Web. Cyber cities are virtual entities related to the physical and social environment of cities in two ways: first, by representing this environment with the help of maps, plans, two-and-three dimensional images, and text; and second, by managing this environment through the representation, communication and governance of functions and processes that take place within cities. This second aspect of cyber cities is more compatible with the origin of the term, which comes from "cybernetics," a theory of communication and control which places emphasis on the functional relations between the different parts of a system, and in particular, the transfer of information, feedback mechanisms, and self-organization. Cyberspace and cyber cities have some unique spatial features which make them extremely valuable for managing the physical and social environment of cities: (a) physical distance is not valid and accessibility is just few "clicks" away depending on topological linkages only (Shiode, 1997); (b) cyber spaces can be easily modified; (c) digital representations are not limited by the characteristics of physical space; (d) the production of digital space is extremely low-cost compared to physical space; and (e) digital communication enhances person-to-person communication and contact in local communities. Using these features, city planners may create digital constructs, which complement activities in the daily life of cities and facilitate the solution of urban problems.

## SMART COMMUNITIES

The initiative for smart communities was the first systematic effort to promote the link between cities and information and communication technologies. The World Foundation for Smart Communities launched it in 1997 in close cooperation with the California Institute at San Diego State University, which drafted the *Smart Communities Guide.* "A Smart Community is a community that has made a conscious effort to use information technology to transform life and work within its region in significant and fundamental, rather than incremental, ways" (http://www.smartcommunities.org). Put more plainly, a smart community is a community ranging in size from a neighborhood to a multi-county region in which public administration, enterprises and residents have understood the capabilities offered by IT and attempt to use those technologies to improve their everyday life and work in a significant, efficient manner. Smart communities in the U.S. and Canada are inspired to a large extent by local principles. Local development and prosperity depend less on decisions taken by the central-national government and more on initiatives and guidelines chosen by local leaders. Increased local responsibility is on the rise again in an age when information about markets and growth/development is becoming increasingly globalized. Globalization transfers responsibilities for decision-making at lower level, and smart communities offer some tools to deal with the new challenges (Eger, 1997).

## INTELLIGENT COMMUNITIES

Intelligent communities is a parallel, but more advanced effort. It is an initiative of the Intelligent Community Forum (ICF)/World Teleport Association seeking to promote the use of information and communication technologies for economic development, in large or small communities, in developed or developing countries.

*Intelligent Community is ICF's term for what others have called the wired city, smart community, or e-city. It is the community—whether a town, city, county, or region—that views communications bandwidth as the new essential utility, as vital to economic growth and public welfare as clean water and dependable electricity.* (ICF, 2006).

ICF's major achievement is the annual "Intelligent Community" award. Each year the Forum selects seven communities from around the world, which excel in one or more criteria concerning information and communication technologies, knowledge and innovation. These critertia

are: broadband infrastructure, knowledge workforce, innovation, digital democracy, and marketing and attractiveness of the community.

## INTELLIGENT ENVIRONMENTS OF INNOVATION

Intelligent cities in North America and Canada stand on the convergence of two major trends of contemporary urban development: digital-electronic reconstruction of the city on the one hand, and the city as an environment for creativity and innovation on the other. The European effort to create intelligent cities is based on the same mix of digital technology and innovation capabilities, but it has a different departure from the U.S. approach. In Europe the starting point for intelligent cities and regions was the concern about territorial innovation systems. The central initiatives came from the Innovating Regions Network and the European Regional Development Fund supporting the convergence of innovation, digital technology, and sustainable development of regions. The connection between innovation systems and IT is evident in the actual orientation of EU regional policy towards (1) regional economies based on knowledge and technological innovation, (2) e-EuropeRegio: the information society at the service of regional development, and (3) regional identity and sustainable development (European Commission, 2000).

## FUTURE TRENDS

Intelligence has always been attributed to the individual, characterising outstanding human mental achievements. Human intelligence has a number of specific characteristics, such as perception, learning and memory, planning and feedback action, and communication. Researchers of human intelligence clearly link intelligence to innovation, insisting that intelligence is achieving something that has never been done before by the particular individual. Calvin (1998, p. 14, 18) considers,

*intelligence as the high-end scenery of neurophysiology -the outcome of many aspects of an individual's brain organisation which bears on doing something one has never done before ... intelligence is what you use when you don't know what to do. This captures the element of novelty, the coping and groping ability needed when there is no "right" answer, when business as usual isn't likely to suffice.*

In the field of artificial intelligence, the meaning of intelligence is based on a simulation with human intelligence. Computer intelligence has been mainly defined with respect to the *Turing Test*, according to which intelligence exists when a human cannot distinguish whether a reply to a question has been given by a human or a machine. However, Fogel argues that a good definition of intelligence should apply to humans and machines equally well, and he defined intelligence as the "ability of a system to adapt its behaviour to the meet its goals in a range of environments" (Fogel, 1995, p. 24).

There are also social forms of intelligence: collective intelligence, swarm intelligence, intelligence of a population or a community. These forms of intelligence differ from individual intelligence.

*Collective intelligence ... is that which overcomes "groupthink" and individual cognitive bias in order to allow a relatively large number of people to cooperate in one process—leading to reliable action ... A less anthropomorphic conception is that a large number of cooperating entities can cooperate so closely as to become indistinguishable from a single organism with a single focus of attention and threshold of action.* (Wikipedia, 2006)

Collective intelligence is also important in the field of artificial intelligence. It is considered to be an emerging science, based on a largely distributed collection of interacting computational processes or multi-agent systems where (1) there is little to no centralised communication or control, and (2) there is a world utility function provided that rates possible histories of the full system (Wolpert & Tumer, 2001). Szuba (2001) proposed a formal model for collective intelligence, which assumes an unconscious, random, parallel and distributed computational process run by a social structure.

Intelligent cities will evolve towards a strong integration of all the above three dimensions of human, collective, and artificial intelligence. They will be constructed as multi-dimensional physical, technological, and social spaces of intelligence, learning, and innovation.

Their first dimension relates to people in the city: the intelligence, inventiveness, and creativity of the individuals who live and work in the city. This perspective was described by Florida (2002) as "creative city," gathering the values and desires of the "new creative class" made by knowledge and talented people, scientists, artists, entrepreneurs, venture capitalists, and other creative people, which have an enormous impact on determining how the workplace is organized, whether companies will prosper, whether cities thrive or wither.

The second dimension relates to the collective intelligence of a city's population. In a collection of definitions of collective intelligence by Atlee, the concepts of cooperation and synergy seem to come up constantly:

collective intelligence is defined as "the capacity of human communities to co-operate intellectually in creation, innovation and invention;" "the collective learning and creative process realised through exchanges of knowledge and intellectual creativity;" "the capability for a group to organise itself in order to decide upon its own future and control the means to attain it in complex contexts;" "the sharing of knowledge, know-how and experience in order to generate a higher individual and collective benefit than if they remained alone;" "the cooperation to solve more complex problems than individuals can;" "the capacity of families, groups, organisations, communities and entire societies to act intelligently as whole, living systems." This is the institutional dimension of the city that creates wealth and prosperity through cooperation in knowledge and innovation.

The third dimension relates to artificial intelligence embedded into the physical environment of the city and available to the city's population. This is a public AI, communication infrastructure, digital spaces, and public problem-solving tools available to the city's population. It supports individual choices and assists communication, cooperation, learning, and innovation.

For us the concept of "intelligent city" and the plan to implement it integrates all the three aforementioned dimensions of the physical, institutional, and digital spaces of a city. Consequently, speaking literally and not metaphorically, the term "intelligent city" describes a territory:

- With developed knowledge-intensive activities or clusters of such activities
- With embedded routines of social cooperation allowing knowledge and know-how to be acquired and adapted
- With a developed communication infrastructure, digital spaces, and knowledge/innovation management tools
- With a proven ability to innovate, manage and resolve problems that appear for the first time, since the capacity to innovate and to manage uncertainty are the critical factors for measuring its intelligence

What emerges from these conditions is a combination of individual, collective and artificial intelligence, which arises from people, cooperation, and IT infrastructure. It is the intelligence of the community and the intelligent machines at its disposal.

## CONCLUSION

An intelligent city is a multiplayer territorial innovation system. It combines knowledge-intensive activities, institutions for cooperation and distributed problem solving, and digital communication infrastructure and tools to maximize this problem solving capability.

The basic level of an intelligent city is its population, especially knowledge workers in innovative companies and research and development (R&D) organizations. This level gathers the city's knowledge-intensive activities in manufacturing and services, organised in a series of districts and clusters. Proximity in physical space is an important factor that facilitates the networking of enterprises, production units, service providers, and knowledge workers into innovative clusters, and into the wider urban innovation system.

A second level is made by institutional mechanisms for cooperation in learning and innovation. This level gathers institutions enhancing regional intelligence, benchmarking, venture capital financing, technology transfer, and collaborative new product development. These are intangible mechanisms necessary to mix individual capabilities and skills, and actualize the complex processes of innovation within the innovative clusters of the city.

A third level is made by information technology and communication infrastructures, digital tools and spaces for learning and innovation. These technologies create a virtual innovation environment, based on multimedia tools, network infrastructures, and interactive technologies, which facilitate market and technology intelligence, technology transfer, spin-off creation, collaborative new product development, and process innovation. A collection of such tools and multimedia which enable individuals and organisations to share knowledge and collaborate within virtual spaces, is presented at http://www.urenio.org/virtual-innovation-environment.html. However, the effectiveness of this virtual innovation environment is extremely limited if it is disconnected from creative organizations, communities, and clusters.

The endeavor of creating intelligent cities is still very much in its early days. The first applications are being developed with respect to innovative clusters and technology parks as intelligent clusters and intelligent technology parks. In such islands of innovation, the physical and institutional innovation system is being enriched with digital communication and knowledge management tools, creating an integrated physico-virtual innovation system. There are many indications that such spaces are going to multiply and cover most knowledge districts of cities. The incentive is strong, as the innovation capability of a cluster increases significantly within intelligent environments, offering information, skills, and virtual networks for cooperation.

## KEY TERMS

**Artificial Intelligence (AI):** Systems which tend to simulate knowledge processes of the mind; a paradigm in which people attempt to elicit intelligence from machines.

**Collective Intelligence:** Knowledge capacity of human communities emerging from cooperation in creation, invention, and innovation.

**E-City:** A community or a group of buildings which follow the same IT architecture, infrastructure, and protocols.

**Intelligence:** Advanced mental abilities, including the ability to remember and use what one has learned, to solve problems, adapt to new situations, and understand and manipulate the environment.

**Swarm Intelligence:** Any attempt to design algorithms or distributed problem-solving devices inspired by the collective behavior of insect colonies and other animal societies.

**Territorial Intelligence:** Part of a new family of concepts, such as business intelligence, territorial competitive intelligence, strategic economic intelligence, distributed intelligence, social or collective intelligence, emphasizing the organized and systemic collection, analysis, and dissemination of information for business and development purposes.

**Urban Complexity:** Interaction of many parts of an urban system giving rise to emerging properties that are not found in the constituting elements of the system.

## INTRODUCTION

One of the main reasons for lower levels of participation in the political arena by the common citizen is the apprehended distance from actions such as representative election to perceived change. People feel that they have less and less power to exercise. Impotence leaves to indifference ("it doesn't matter who will I choose ... anyway they won't care/change thinks that I consider important"). More and more technology may put another bureaucratic barrier between people and their legitimate right to exercise power: citizenship.

Politics is the process of formation, distribution, and exercise of power (Bobbio, Matteucci & Pasquino, 1983). In this sense, the term *e-democracy* (Riley & Riley, 2003) has emerged as the goal to be reached by our technology. It is defined by Clift (2004) as the use of information and communication technologies and strategies by democratic actors within political and governance processes of local communities, nations and on the international stage. Such democratic actors/sectors include governments, elected officials, the media, political organizations, and citizen/voters.

The first steps towards e-democracy (i.e., the current e-government frameworks), even though the efforts taken, are mostly centralized (Bicharra Garcia, Pinto, & Ferraz, 2004; Clift, 2004; Macintosh, 2004; Macintosh & McKay-Hubbard, 2004). Furthermore, the information they provide about government decisions and acts and their consequences are presented as (mostly) unproven facts. It is often difficult for the common citizen to check whether the myriad of data and their sources are even legitimate, not to say legal or fare. Certainly, political confidence and faith (even though mediated by technology) have some limits, to say the less. If technology is to be put for a good use it has to be not only accessible to the common citizen, he/she has to feel and exercise power not only through voting on candidates or accessing some services online.

Currently, there are two aspects considered as the main targets of e-government technologies (Riley & Riley, 2003):

- **E-Voting:** Taking part in elections or other ballots
- **E-Participation:** Allowing degrees of access to policy decision making

Thus, for the citizen the actual range of possible actions is rather narrow. Our democratic societies require bridging a gap between current IT based Democracy and well established democratic practices. A suitable option is to be served by democracy enabler social software, allowing a new dimension:

- **E-Enaction-and-Alterity:** Collective planning, monitoring, awareness, and enforcement of already set actions and decisions made by representatives and public institutions

Such an approach tries to incorporate and extend the idea presented by Clift (2003) as "e-democracy + public net-work" and illustrated in Figure 1.

Seeking for direct citizen/stakeholder/leadership involvement, this new dimension, along with the *e-voting* and *e-participation*, can be implemented with decentralized *digital citizenship systems* (DCS), composed by *intelligent citizenship assistants* (CAs). Such systems can create an extended channel to restore the capillarity of power back to the citizens. We will now discuss some

*Figure 1. Networked input and output contrasted to traditional processes. Both, e-democracy and public network are assigned similar IT tools (Clift, 2003)*

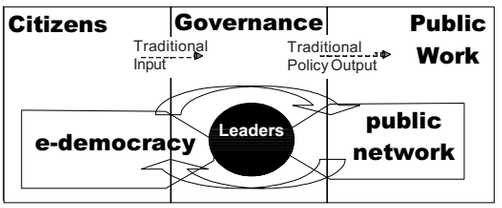

*Figure 2. Networked conception of democracy showing social networks of individuals (connected through CA's forming a DCS) co-existing with traditional (centralized) e-government facilities*

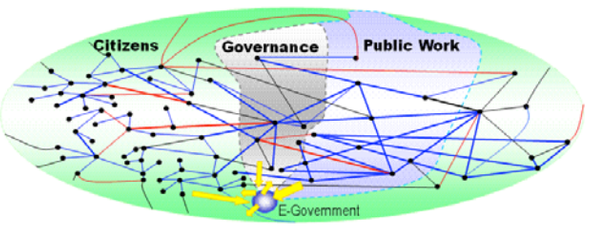


aspects that are to be explored in the quest that may (hopefully) lead to implement DCS in the near future.

## DIGITAL CITIZENSHIP SYSTEMS

Citizenship assistants are conceived as the main components of digital citizenship systems. CAs are *intelligent agents*, that is, programs that run continously, know what to do and when to intervene. Agents communicate with other agents, asking solicitations and executing the requested tasks. An agent has a long list of properties, among which can be highlighted (Jennings & Wooldridge, 1998): autonomy, social hability, reactivity, and proactivity.

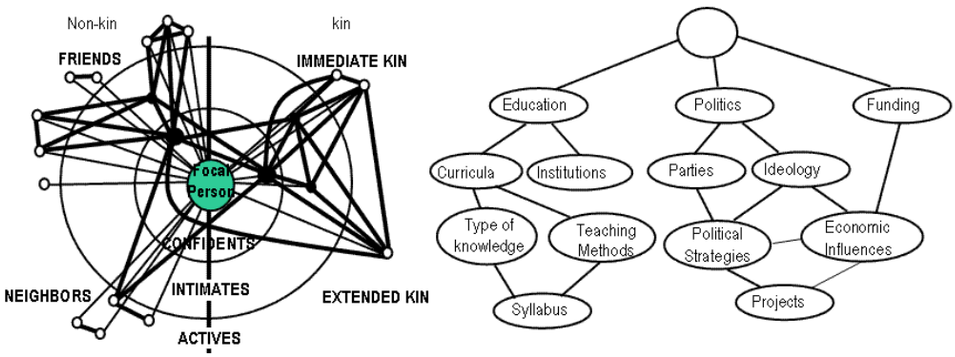
Due to the enormous amount of information accessible through the Internet, and the short time a user generally has to find relevant information, a suitable type of agent for that task is the so called intelligent information agent (Klusch, 2001). Information agents themselves are defined as computational software entities that can access one or multiple information sources that are distributed and heterogeneous and can acquire, mediate and maintain proactively relevant information on behalf of the user or other agents, preferably in a just-in-time fashion (Klusch, 2001). Citizenship assistants agents are a special case of information agents that work in a cooperative, *peer-to-peer* (P2P) manner. As in current peer-to-peer systems like Gnutella and Kazaa, some of them dedicated to share media files, citizenship assistants are conceived to work in a distributed and purely decentralized way (i.e., there is no need of a central authority or control) (Benkler, 2003; Saroiu, Gummadi & Gribble, 2002;).

To better understand such a concept, imagine the following scenario: you, as a citizen, have a dedicated intelligent citizenship assistants (CAs) in the form of a computer program. When elections come, it gathers information about the candidates (bios, affiliation, campaign related funding, etc.) looking not only on Web sites (officials or not) but also on recorded Parliament discussions and sessions, and, what may be most important, asking other people's CAs whether they have more information about obscure points. Still, your CA can analyze, classify, and filter the information according to the social and political positions of the owner of each CA (party, position, known interests, and relations). Furthermore, the CA can repute the information, checking it with the contacts of your social network. The CAs base their analysis on the reputation system formed by the owner's social networks. There is no centralized control in the complex system formed by the CAs, as shown in Figure 2.

As human societies are connected through complex *social networks* (Granovetter, 1973), there are several kinds of ties relating individuals to each other: emotional, authority, reputation, communication, etc. (Wasserman & Faust, 1994). Each contact of an individual is qualified by such ties that are implicitly interweaved referencing past experiences. A CA dedicated to serve an individual, can take advantage of those ties given that a suitable model is provided to explicitly express and qualify them (to some degree). Each individual, immersed in a social network has a subjective view of it, as shown in Figure 3 (left). The same can be said of our knowledge (i.e., given a computationally explicit model of it). A knowledge model can be expressed computationally using an ontology (Fraser et al., 2003; Guarino, 1997) (i.e., a set of interrelated concepts) (as in Figure 3, right).

The importance of CAs is even more evident when considering the effects of political decisions in day-to-day life. Citizens can have a channel to operate directly, starting their engagement focusing on the "visible" effects of politics (children's education, fares, taxes, medical care, public finances). Even more, CAs are not displacing e-government initiatives, their are complementing them, giving a chance for cross-checking data and their sources, taking back the main reasons for politics: social justice, freedom, knowledge sharing and equal opportunities (Heller & Fehér, 1989). CAs of neighbors can en-

*Figure 3. Subjective view of a social network of an individual—left (Müller, Wellman & Marin, 1999); and a very simple ontology—right*



gage (e.g., on monitoring activities of their representatives) communitary planning with public stakeholders, destination, implementation of public budget, and so forth.

Once built, DCS can represent the core common infrastructure for e-democracy and public networks. Working concurrently with e-government infrastructures, DCS can offer a robust alternative for powerful social and political interactions.

## ENABLING TECHNOLOGIES

The technological foundations for digital citizenship systems formed only by CAs are at hand, even though they have to be refined for the political domain. Table 1 summarizes some technologies needed to implement and deploy DCS.

When accessing an Internet site (provided by a server), people do so through a client program (browser). Clearly, control is on the side of the server. Instead, networks of commons are implemented computationally using *peer-to-peer (P2P)* systems. P2P systems are open, distributed, and decentralized, as human communities (Benkler, 2003; Saroiu, Gummadi & Gribble, 2002). Early examples of P2P systems where Napster and Gnutella, dedicated to multimedia file sharing.

Properties like autonomy, social hability, reactivity, and proactivity are implemented in agents through embedded Artificial Intelligence techniques. *Multi-agent systems (MAS)* are computational systems formed by agents (through federations, coalitions, etc.). MAS exhibit social behavior and, depending on the agents, can be auto-organized.

*Digital citizenship systems* can be implemented by *multi-agent systems* connected in a *peer-to-peer* mode. The components of such a P2P MAS (or DCS) would be *intelligent software agents* (or CAs). For the agents to be capable CAs, they should manipulate three basic aspects of human interaction:

- **Social Organization:** Be able to recognize groups and roles that qualify social ties
- **Social Skills:** Be aware of the social contacts that belong to the social network of an individual, be able to repute them and negotiate to proactively engage in activities towards common goals;
- **Knowledge:** Be able to interact with an individual according to a concept map that reflects the individual's profile.

Social organization and skills can be handled given that the CA can manipulate a suitable organizational model. To trace the relations between their contacts and their knowledge representation, agents must be able to represent and reason about groups they presently belong to, and also about groups they made part of in the past. To do so, a MAS organization model is needed. The MOISE+ (Model of Organization for multI-agent SystEms) is an attempt to join roles with plans in a coherent

organizational specification for MAS (Hübner, Sichman, & Boissier, 2002). While the roles build the structure of an organization, the plans build their functioning. The MOISE+ structure is built up in three levels, as can be seen in Figure 4:

1. The behaviors that an agent playing a role is responsible for (individual)
2. The structure and interconnection of the roles with each other (social)
3. The aggregation of roles in large structures (collective)

In the individual level, roles are defined and structured by an inheritance relation. A *role* is a set of constraints that an agent ought to follow when it accepts to enter a group playing that role. Roles are bound in the social level by links (acquaintance, communication, and authority). The links constrain an agent in relation to another agent. For example, an agent is allowed to communicate with another agents only if there is a communication link among them. Roles can only be played in the collective level (i.e., in a group already created from a group specification). In MOISE+, a group specification is defined by: a set of roles; a set of links; a set of role compatibilities; and the number of agents that have to play roles in this group type. For example, in Figure 4 the group *class* must have one agent playing the *professor* role, one agent as *assistant* and, at most, 40 agents as *students*. As in one organization, there can be more than one group, a structural specification is, roughly speaking, a collection of groups and roles.

When an agent has embedded an organization model like MOISE+, it can map the personal network of its human owner and handle the contacts according to social roles and groups, as can be seen in Figure 5.

The third component (i.e., knowledge) can be handled using already existent standards for the Semantic Web: OWL (the Ontology Web Language) is used to convey ontological metadata in the Internet (Kalyanpur, Pastor, Battle, & Padget, 2004). That metadata can be used to make explicit the structure and semantics of the content of Web pages (e.g., in an e-government site) helping the agent that is gathering information to filter specific contents. The metadata can also be exchanged between agents to share information about specific events and content. Programmatic tools for handling and exchanging ontological metadata are already at hand, as Open Source Software (Knublauch, Fergerson, Noy, & Musen, 2004). An example of the interface of a real intelligent agent working in a P2P system for communitary knowledge exchange using ontological metadata is shown in Figure 6.

The consequence of having an agent (CA) with the required skills is that it can integrate three different views of the individual: (i) his or her social contacts; (ii) his or her subjective organizational view of them (assigning groups and roles to them); and (iii) the knowledge (set of related concepts) related to groups, roles and contacts. This can be seen in Figure 7, which depicts the same agent of Figure 6, now filtering the contacts that are more closely associated (i.e. those that were more helpful) with regards to a given concept ("knowledge representation" and "agents"), not forgetting the roles that were assigned subjectively to each contact by the human owner of the agent. For example, the agents not only know "what," but also "who knows who; and who knew what (and when)."

A correlated issue, security, and privacy, long ago raised by Chaum (1985), can also be improved: a CA that knows its owner's profile has the possibility of manifesting a distinctive footprint (something like a "personality trace" that may be reputed by its peers).

*Figure 4. Structural specification using the MOISE+ organizational model*

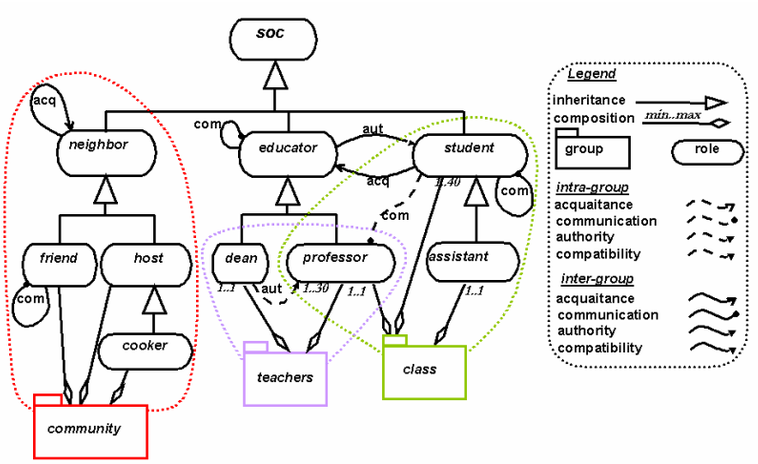

*Figure 5. An agent capable of recognizing contacts in a personal network according to roles and groups (Giménez-Lugo, Sichman, & Hübner, 2004)*

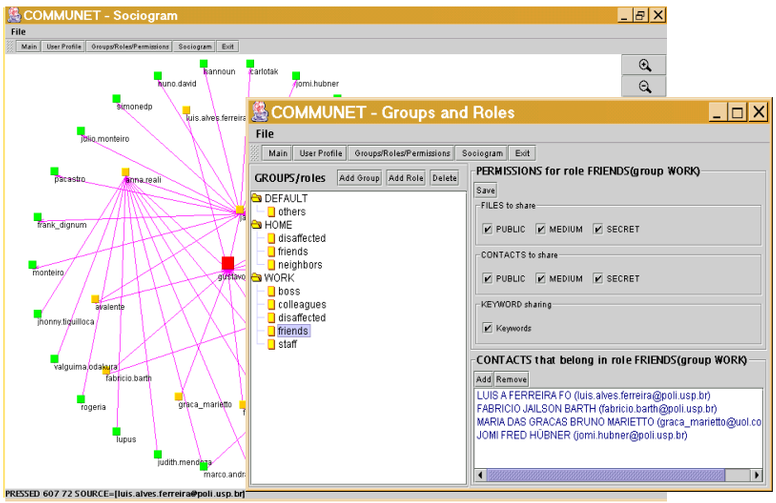

However, additional research work is needed on electronic institutions (i.e., modelling, publication, adoption, and evolution of computationally explicit representations and management of institutions). Such institutions, as well as their internal processes, can be suitably described using ontological metadata, allowing agents to focus on specific roles (e.g., comprising politicians and representatives) and their related actions. Much of the work done has focused on business applications (Esteva, Rodriguez, Sierra, Garcia, & Arcos, 2001). Actually, most of the existing models for electronic institutions simply follow old managerial concepts (matching organizations with enterprises and, at most, with ecologies). There is a need for a sociological and anthropological approach to organizations, incorporating a lato sensu perspective (e.g., communitary and family relationship structures).

To take full advantage of the capabilities of a DCS there is a need for e-government infrastructures that could handle electronic organizations, with capabilities to represent computationally, publicize, and continuously

*Figure 6. An agent capable of using ontological metadata for knowledge sharing in a social network (Giménez-Lugo et al., 2004)*

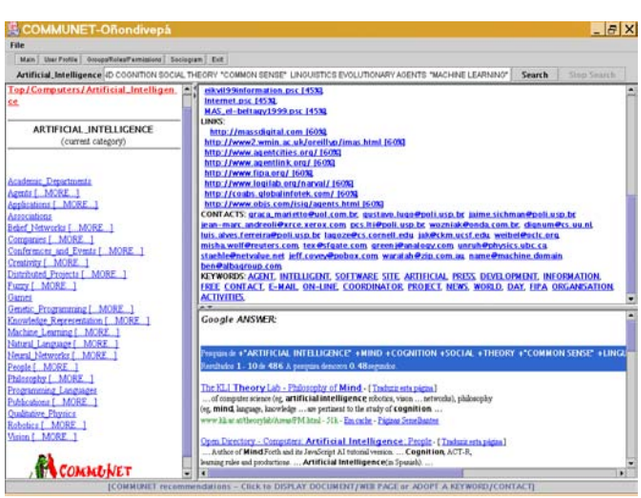

*Figure 7. An intelligent agent can connect the subjective organizational view of an individual with the related knowledge*

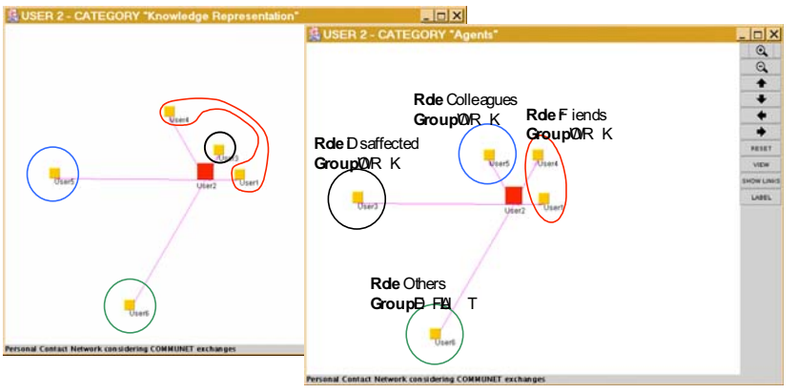

*Figure 8. Diverse communication channels and actions on which a* Citizenship Assistant *can get proactively involved.*

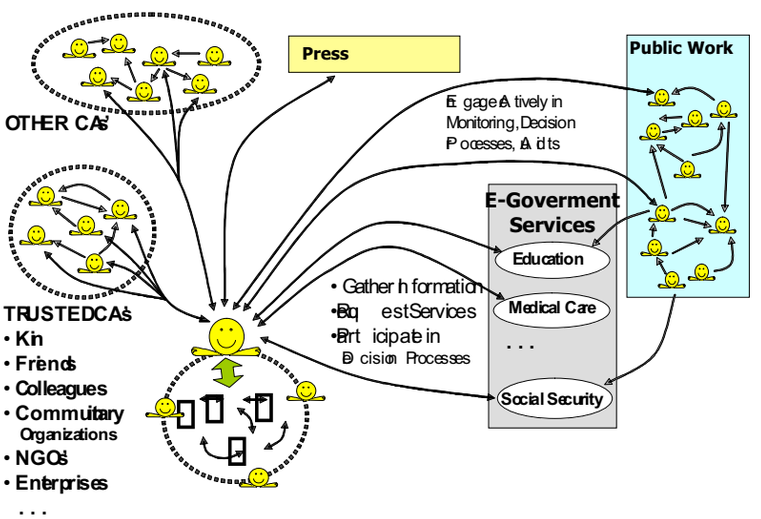

update evolving public institutions. CAs themselves, as auto-organized elements, are considered to be endowed with the appropriate tools to manipulate organizations and their representations. For example, an e-service may use an ontology (Fraser et al., 2003) along with the structural organization of, say the city council's educational committee, to help a CA when it is trying to find the appropriate person to which a group of parents may address a request. On the same way, CAs may be flexible enough to update themselves using new components certified by trusted CAs (as-needed) and sites.

Each CA may have several forms of interaction with the different organizations (private and public) and sources of knowledge and services. Figure 8 shows the envisioned scenario.

Given that e-government services, the press and also private enterprises make available ontological metadata (a process that has already began thanks to continuous business intelligence/business to business efforts), CAs will have a wealth of semantically situated content to harvest. Meanwhile, the main work is focused on improving the capacity to convey semantically sound content between peers (i.e., commons), as this will smoothly lead to refine the very same tools for manipulating ontological metadata from Institutions.

*Table 2. A list of reasons for utilizing physically distributed infrastructures based on intelligent citizenship assistants*

- Citizenship ubiquity
- Citizen-oriented administration of services
- Community–oriented budget management
- Community-driven policy and legislation
- Distributed decision making and control
- Fast and continuous adaptability of governance actions to people decision
- Possibility of online and in-depth audit of public accounts and decisions
- Possibility of *track-check-and-analyze* based audit of representative's actions and decisions
- Higher possibility of detecting locally important communitary issues
- Possibility of building and accessing repositories of communitary knowledge and actions comprising already known problems/solutions
- Opening of direct communication channels for individuals and public organizations alike

Table 2 tries to summarize the arguments that justify the quest for implementing and deploying CA-based digital citizenship systems.

Technology must be people oriented. In this sense, a lot of technical expertise has been bound by market parameters. If there is to be implemented a democratic information infrastucture for political participation, it should encompass decentralized social interaction, far more pervasive than clicking on a Web page of a Web site. Table 2 sketches just some of the services that can be made available through CAs forming a digital citizenship system.

## CONCLUSION

Paraphrasing Benkler (2003), "the reorganization of production (may we say *politics*), and the advances it can bring in democracy, autonomy, and social justice will emerge, if it emerges, only as a result of social and political action". That is the real challenge digital citizenship systems will face.

## KEY TERMS

**Citizenship Assistant (CA):** An intelligent software agent designed for knowledge gathering, filtering and sharing, using ontological metadata. A CA is dedicated to a human user, having the capability to map and handle the personal contacts of its owner as possible sources of knowledge as well as spidering institutional sites for public information.

**Communityware:** A kind of social software dedicated to serve human communities, supporting social networks. Awareness is an important concept for such systems, i.e., given a request from an individual (or a group of them), the system must facilitate a way of retrieving the related (and/or useful) individuals and resources.

**Digital Citizenship System (DCS):** A kind of multi-agent system, formed by citizenship assistants.

**Electronic Institutions:** Institutionalized electronics organizations composed of software agents and individuals playing roles and following specific rules for interaction and functioning.

**Enaction-and-Alterity:** In the sense that experience is an activity of encountering with the world (in which we are embedded). That is being-in-the-world, and when applied to citizenship in particular *being-in-a-democratic-society*. Implying that this *being-in-a-democratic-society* is *thinking-considering-the-others*. The concept was coined referencing two philosophic notions: one based on the work of H. Maturana and F. Varela (*enaction* in the sense of embodied cognition) (Varela, Thompson, & Rosch, 1991) and the other by E. Lévinas (*alterity*, or the relation with the *other-that-is-not-me*)(Lévinas, 1991).

**Groupware:** A kind of software (a subset of communityware, in a sense) that supports collaborative work of teams. However, it is based on explicitly declared processes.

**Intelligent Software Agent:** A computer program that makes use of artificial intelligence techniques to show intelligent (and social) behavior, usually intended to ease common tasks like e-mail filtering and Web searching.

**Multi-Agent Systems:** A kind of systems composed of distributed elements (programs called software agents) that can be modeled and implemented according to a social vision of behavior.

**Ontology:** A set of concept definitions expressed in a way that is suitable to be understood by a computer program.

**Social Software:** A (desirably distributed) computer system, dedicated to serve human societies, that has its functioning built bottom-up (i.e., depending on the actions and decisions of each individual). Such a (possibly very) complex system is composed of a (very) large number of relatively small computer programs (or a set of them) dedicated to individuals that interact with each other in a non-deterministic way.

# Intergovernmental Digital Government through G2G Relationships and Applications

## INTRODUCTION

Increasing governmental complexity is a global phenomenon marked by the need for multiple organizations to interconnect their policies, business processes, information, and systems in the service of shared public goals. These goals encompass some of the most important responsibilities of government including environmental stewardship, education, healthcare, and public safety. For these kinds of responsibilities, working across both vertical and horizontal boundaries is an essential feature and fundamental challenge.

## BACKGROUND

Digital government advocates often point out that citizens should not need to know how government is organized in order to access its information and services. Most digital government initiatives launched in the last decade have therefore taken a citizen-centric focus which encourages alignment of various systems, organizations, and processes toward a single external target—high quality citizen services. These efforts have been dubbed "G2C" or government-to-citizen applications. Similarly, governments have used a "G2B" or government-to-business approach to achieve alignment, rationality, and better performance in the functions which bring businesses into contact with government. Much less attention has been paid to a third approach, "G2G" or government-to-government connections, yet the interdependencies and functions which cross the boundaries of agencies and jurisdictions are crucial to most major public programs. G2G programs may be internal to government such as in financial management, but they also comprise the underlying fabric of most programs that serve citizens and businesses. While the citizen may not need or want to know how government is organized, the structure of government, including its intergovernmental dimension, remains a fundamental factor in the design of programs, systems, and services (Cameron, 2001). This structure is embedded in and supported by legal and constitutional frameworks. However, the emergence of e-government challenges even those frameworks by its need for an architecture that links different parts of government in new ways that restructure not only administration but also budgets, legal authority, and constitutional relationships among units of government and between government and the private sector (Morrison, 2003). The limits of legal authority often rest on the basic assumption that agencies work alone and inside fixed geographic boundaries. Consequently, networked services raise new legislative and regulatory issues of authority, security, privacy, and accountability when information and responsibilities cross-organizational or jurisdictional boundaries (OECD, 2003). In addition, intergovernmental initiatives involve different institutions and agencies with their own organizational cultures and business practices which need to be understood and meshed together into an intelligent whole.

The terms "intergovernmental" and "G2G" are used in several ways. They can denote horizontal arrangements of inter-agency or inter-jurisdictional relations at the same level of government. For example, regional-level transportation, motor vehicle, and police agencies may cooperate to analyze auto accidents, or several municipalities within a region may share a purchasing and procurement system. G2G is also used to describe international systems such as those which support free movement of European citizens across the borders of EU member countries (European Commission, 2003). Vertical G2G systems link multiple *levels* of government in a coherent service delivery or administrative environment. In political science terms, they are systems that mirror federal or federated systems of government, which typically comprise national, regional, and local units and their respective agencies. Regions are typified by states in the U.S. or provinces in Canada. Local governments include cities, towns, and other municipalities. In practice, large intergovernmental systems may have both vertical and

horizontal elements. The principles and strategies presented in this article are relevant in all of these contexts.

## INTERGOVERNMENTAL RELATIONS AND SYSTEMS

Intergovernmental relations among levels of government are characterized by both interdependence and complexity. Interdependence means power is shared requiring mutual accommodation. Complexity derives from the large and differentiated intergovernmental network that prevents any one participant from having "enough information about its components and dynamics to make rational decisions on its own or to operate in isolation from the rest." (O'Toole, 2000, p. 19).

Many models have been developed to conceptualize intergovernmental relations. One useful set contrasts different forms of authority relationships among levels of government (Wright, 1988). In the coordinate-authority model, a national government has defined powers, local authorities are creatures of regional governments, and the regions and localities together exercise powers separate from those given to the national government. The inclusive-authority model conveys a hierarchical, dependent relationship among the levels with the most power at the national level and increasingly less at regional and local levels. In the overlapping-authority model, the three levels of government are seen as interdependent, each having substantial areas of overlapping authority, some areas of autonomous authority, and limited power and influence that necessitate many forms of negotiation and bargaining. This third model, with its many mechanisms for negotiating and managing the interconnections (Agranoff & McGuire, 2004), is most widely accepted as a conceptual representation of modern intergovernmental relations (Opeskin, 2001). It conveys the idea that intergovernmental structures are managed networks of interdependent organizations (O'Toole & Meier, 2004). Three examples of G2G digital government illustrate this model. *Service New Brunswick* offers residents of one Canadian province access to online services of the Canadian national government, the province, and their local municipalities through a single Web portal. Although transparent to citizens, all three levels of government are at work behind the scenes linked by policies, technical infrastructure, and standards. In Italy, Austria, and other European countries, the adoption of electronic citizen identification cards requires an intergovernmental infrastructure of policies, data standards, security protocols, telecommunications networks, and organizational processes that cross national, regional, and municipal boundaries. In the United States, The National Map project provides a variety of geospatial data and information to government, private sector, and individual users. It is the product of a consortium of federal, state, and local partners who voluntarily provide layers of geospatial data for use at global, national, and local scales.

### G2G Issues and Challenges

Research on intergovernmental information systems shows that they operate in an extremely complex environment. This complexity derives from a profusion of authorities, roles, and relationships; great variety in local conditions; diverse agency cultures and missions; ever-changing technologies; and limited ability to adapt to change (Dawes & Pardo, 2002). The basic structural and philosophical differences among levels of government present major challenges. For example, the greatest financial and professional resources for intergovernmental work often lie at the national level, but the best knowledge of clients and service delivery considerations is regional or local. Local officials tend to be generalists and to work closely with the communities they serve; by contrast, regional and national officials tend to be specialists, to focus on broader policy concerns, and to be removed from the day-to-day demands of program operations. In addition, local officials are focused on the specific needs of their own communities, while regional and national officials are more concerned with broad consistency and equity across larger geographic, demographic, and cultural divisions. In jurisdictions with many local units, the wide variation in local conditions—economic, demographic, geographic, cultural, and historical all add to the complexity (Dawes, Pardo, Connelly, Green, & McInerney, 1997).

When digital government systems are built to support intergovernmental functions, they often oversimplify diversity and complexity, leading to inappropriate or uncoordinated policies and actions and causing poor performance and unclear accountability. Oversimplification is especially problematic in two respects: when it masks the often low level of technical expertise and infrastructure at the local level and when it ignores the business practices already in place. Moreover, the tendency of governments to create a proliferation of programs (each with its own legal authority, funding stream, reporting requirements, and administrative structure) has led to a similar proliferation of independent information systems that each support only one business function or satisfy one particular program need. As a result, a large and growing number of individual systems for G2G business relationships are employed across levels of government. This multiplicity of systems require their own hardware, software, security, and business rules. In order to perform business functions on each system, users require numerous log-ins and

authentications. Usually data entered into one system cannot be used in another. Duplicate requests for information are made and fulfilled as individual organizations respond to uncoordinated requirements. Systems are seldom interoperable across levels or agencies or designed with the full range of information needs or business practices in mind. This situation poses a significant burden and entails higher than necessary costs for everyone. (Cook et al., 2004).

To be successful in this environment, G2G systems must recognize and account for enormous diversity of community settings, technical expertise and infrastructure, organizational structures and cultures, and staff skills. They must also deal with overlapping legal authorities; different fiscal years; and independently elected officials at each level. Finally, they need to be meshed into the fabric of ongoing business processes and working relationships and often must relate to other information systems at the national, regional, and local levels.

## Principles for Guiding G2G Digital Government Initiatives

Several critical success factors pertain to any effective information system. They include top management support, a clear and measurable purpose, focus on business needs as the driver and technology as a vehicle for achieving them, consistent and frequent communication, and incremental and modular approaches to system design and implementation.

While the factors listed above are important for all digital government initiatives, G2G projects have additional needs. Because the interconnections reflect overlapping authorities, these systems require coordination, negotiation, and consensus-building across multiple legal structures as well as policy, management, and technical perspectives. Accordingly, three principles are strongly associated with more effective G2G initiatives:

- **Peer Relationships:** The differences in operations, mission, size, specialization, and infrastructure across government units are of significant consequence. In order to work toward the same or complementary goals, all participants need to understand and appreciate one another's abilities, strengths, and limitations. This kind of understanding is most likely to occur when the participants regard one another as peers in an interconnected network, rather than as superior and inferior players in a hierarchy. Peer-level relationships include open dialog, mutual adjustment, and shared resources, benefits, and risks. These in turn imply basic trust and extensive information sharing and interaction (Cook et al, 2004).
- **An Enterprise Approach:** Enterprise thinking emphasizes the interdependencies among different domains, organizations, and levels of government. In terms of public services, "enterprise" may also include the private businesses and nonprofit or civil society organizations that play important roles in the administrative or service delivery processes. (Goldsmith & Eggers, 2004). Enterprise approaches seek to capitalize on the relative strengths of different players and to tie them together through the use of models, standards, partnerships, and shared resources. This "joined up" strategy can transform policy making, program evaluation, public management, and service delivery (UK Cabinet Office, 2004). Enterprise management emphasizes complete business processes and coordinated design, development, implementation, and operation of functions regardless of where any particular activity or task takes place. (Cook et al., 2004).
- **Information Treated as a Cross-Boundary Asset:** Much of the benefit that can be derived from G2G initiatives rests on the creation and use of shared data repositories that all the participating organizations accept, use, and support. Standards and policies allow the participating organizations to replace multiple, uncoordinated databases with comprehensive and authentic data resources that are defined and managed for the benefit of all users. When they meet stringent tests for quality, security, and usability, these shared data resources can drive down costs, increase accountability, and support integrated services and programs (Dawes, 1996).

## Strategies for G2G Digital Government

While principles provide high-level guidance and direction in G2G digital government, practical strategies support the everyday actions that help move initiatives closer to success. The following strategies have demonstrated value.

- **Establish a Joint Governance Body:** Governance comprises the structures and processes by which policies are adopted, disputes are resolved, and decisions made. For information systems and strategies to work well in a G2G environment, governance must include formal representation and active participation of officials from every level. One critical aspect of successful shared governance is an acknowledgment that all the participants have a legitimate role to play. This is not to say that all are equal in every respect. Their resources and respon-

sibilities will vary, but the decision-making process must give full consideration to needs and capabilities of each level of government and kind of organization. A shared governance mechanism provides a forum to voice needs and concerns throughout the life cycle of an initiative. (Allen, et al., 2004). An example is the e-Core Advisory Committee for EMaryland Marketplace, the State of Maryland's e-procurement portal This cross-agency and intergovernmental governance committee meets regularly to provide cross-boundary communication and guidance, devise alternatives for resolving policy questions, and keep a focus on long-term goals. Members represent primary procurement agencies, other major state agencies, and local governments. (Krysiak, Tucker, Spitzer, & Holland, 2004)

- **Perform End-to-End Process Analysis:** Intergovernmental information systems are electronic applications that support processes shared across multiple levels or agencies of government. Development of effective systems depends in large part on understanding complete processes and their multifaceted environments. Those who perform the tasks should participate directly in process mapping, analysis, and improvement. This is particularly important when processes cross the boundaries of organizations, programs, and levels of government, as participants will better understand their specific roles in the context of the entire process. This kind of process analysis is also essential when a new process will operate along side or in tandem with existing ones. As part of this effort, field visits are invaluable in gaining an understanding of local conditions as well as learning about operations and customers from those on the front-line. (Cook et al., 2004). In Catalonia, for example, the Open Administration Project including its inter-administrative portal (CAT365), is tackling the difficult challenges of both vertical and horizontal process re-engineering in order to design new electronic service channels and to harmonize them with traditional service delivery arrangements. (Aibar & Urgel, 2004).
- **Assess the Complete Cost Structure:** Traditionally cost estimates for information technology initiatives include well known categories such as hardware, software, design, development and implementation. But with G2G initiatives other equally important components, especially project management and relationship management, are often left out because they are difficult to estimate or simply overlooked. Moreover, cost structures should be comprehensive and reflect the financial implications for each level of government. For example, the New York State-Local Gateway project, the majority of the state-level costs were estimated to be attributed to design and development whereas the local-level costs centered on implementation and changes in existing business processes (Cook et al., 2004).
- **Apply Specialized Project Management Techniques:** G2G projects do not have a unified authority structure culminating with a single leader. They therefore require managers with specialized skills and a set of analytical, collaboration, and problem-solving tools well-suited to hold the intergovernmental network together. The OECD emphasizes the importance of both traditional management skills and additional competencies in performance management, accountability frameworks, and collaboration (OECD, 2003). More than anything else, intergovernmental managers must understand and manage complexity. They must coordinate interdependent streams of work, and communicate and broker relationships among all the key stakeholders throughout the life of the project. They need to employ an array of communication practices to ensure that all stakeholders (including elected officials, senior executives, and the public, as well as the project participants) are continually and adequately informed (Dawes & Pardo, 2002).
- **Demonstrate and Refine Ideas by Prototyping:** Prototyping presents the opportunity to gather realistic information about a process or system and provides a forum for identifying improvements in architecture and design. Prototypes test certain aspects or characteristics of a desired system without incurring the cost or time of actually building a full system. They include just enough functionality, data, and presentation features to build mutual understanding between designers and users and to test key elements of the design. The most valuable aspect of a prototype is that it makes implicit understandings explicit so they can be tested by others. In Europe the INSPIRE project (Infrastructure for Spatial Information in Europe) incorporates prototypes and pilots to develop representative use-case scenarios, demonstrate feasibility, and determine costs and benefits of interoperability for supporting Pan-European environmental policies and impact assessments (Dufourmont, Annoni, & DeGroof, 2004). Prototyping can be invaluable in G2G systems because it forces the multiple assumptions of different participants to be examined in a practical, tangible, and inexpensive way. Because they demonstrate essential functionality, prototypes can solidify mutual understanding and reveal differences in expectation long before formal system development makes change difficult or impossible to attempt. (Cook et al., 2004).

- **Measure Separate and Collective Aspects of Performances:** G2G digital government initiatives have a dual character. They support a coherent business process or service, but to do so they rely on performance in different organizations at several levels of government. The involvement of multiple actors makes it especially important to devise performance measures and measurement approaches that address all three traditional categories of performance: inputs, outputs, and outcomes, all suited to the kind of service or function being supported (Stowers, 2004). It is equally important to differentiate where in the relevant business processes the different measures are being applied in order to understand which activities in which organizations contribute to different results. For this reason, performance measures must focus both on the ultimate results and on the major components of work that produce it. Separate and collective determinations of what data is needed to measure effectiveness will be needed. Ideally, the system itself would be designed so that relevant performance data is captured and analyzed in the course of normal operations.

## CONCLUSION

G2G applications are critical in providing effective digital government. They support the many internal operations of the public sector and provide the underlying foundation for a large proportion of public services. This important work has evolved rapidly with the introduction of advanced information technology which provides more flexible tools for coordination and information sharing. However, successful G2G initiatives also address the legal, political, organizational, and operational dimensions of working across the levels of government. They employ principles and strategies that are suited to the complex and interdependent nature of intergovernmental relations. These principles and strategies deal simultaneously with both the whole enterprise and its component parts. Despite substantial challenges, intergovernmental collaboration has to the potential to link the layers of government in the pursuit of important public goals—negotiating issues, capitalizing on relative strengths, and accommodating diverse needs and conditions.

## KEY TERMS

**Enterprise:** An approach that emphasizes the interdependencies among different domains, organizations, and levels of government and focuses on understanding and addressing broad purposes.

**Federalism:** A system of governance in which a national, overarching government shares power with subnational or state governments. A federal system has (1) a written constitution that divides government powers between central government and the constituent governments, giving substantial power powers and sovereignty to each, (2) levels of government, through their own instrumentalities, exercising power directly over citizens, (3) a constitutional distribution of powers that cannot be changed unilaterally by any level of government or by ordinary process of legislation (Shafritz, 2004, p. 116).

**Government to Business (G2B):** A digital government initiative that delivers a service from government directly to businesses. A G2B initiative usually try to achieve alignment, rationality, and better performance in functions that bring businesses in contact with government.

**Government to Citizen (G2C):** A digital government initiative that delivers a service from government directly to citizens. A G2C initiative usually encourages alignment with systems, organizations, and processes toward high quality citizen services.

**Government to Government (G2G):** A digital government initiative that is internal to government but may cross agency and jurisdictional boundaries. A G2G initiative usually links multiple levels of government in a coherent service delivery or administrative environment.

**Intergovernmental Information System:** A technology application that links multiple levels of government agencies together in a coherent service delivery or administrative environment.

**Intergovernmental Relations:** The complex network of interrelationships among governments political, fiscal, programmatic, and administrative processes by which higher units of governments share revenues and other resources with lower units of government, generally accompanied by special conditions that the lower units must satisfy as prerequisites to receiving the assistance (Shafritz, 2004, p. 159).

# Inter-Governmental Relations in the Provision of Local E-Services

**Robert Kelso**

## INTRODUCTION

Australia is a nation of 20 million citizens occupying approximately the same land mass as the continental U.S. More than 80% of the population lives in the state capitals where the majority of state and federal government offices and employees are based. The heavily populated areas on the Eastern seaboard, including all of the six state capitals have advanced ICT capability and infrastructure and Australians readily adopt new technologies. However, there is recognition of a digital divide which corresponds with the "great dividing" mountain range separating the sparsely populated arid interior from the populated coastal regions (Trebeck, 2000). A common theme in political commentary is that Australians are "over-governed" with three levels of government, federal, state, and local. Many of the citizens living in isolated regions would say "over-governed" and "underserviced." Most of the state and local governments, "… have experienced difficulties in managing the relative dis-economies of scale associated with their small and often scattered populations." Rural and isolated regions are the first to suffer cutbacks in government services in periods of economic stringency. (O'Faircheallaigh, Wanna, & Weller, 1999, p. 98). Australia has, in addition to the Commonwealth government in Canberra, two territory governments, six state governments, and about 700 local governments. All three levels of government, federal, state, and local, have employed ICTs to address the "tyranny of distance" (Blainey, 1967), a term modified and used for nearly 40 years to describe the isolation and disadvantage experienced by residents in remote and regional Australia. While the three levels of Australian governments have been working co-operatively since federation in 1901 with the federal government progressively increasing its power over that time, their agencies and departments generally maintain high levels of separation; the Queensland Government Agent Program is the exception.

## BACKGROUND

Competition between the levels of government and between departments, driven largely by economic rationalism and corporatisation of government, has increasingly focussed on the efficient delivery of services and this is where the influence of ICTs has been most noticeable. In the words of the current federal auditor-general:

*[T]he necessary closer links brought about by technology, and the immediacy demanded by the public for delivery of services irrespective of which government is responsible, bring into sharper focus the need for better project governance and accountability. Particular emphases are being placed on responsiveness of service delivery and overall performance of government.* (Barrett, 2003)

While providing the means of reducing costs and equalising the service delivery opportunities across the nation, the use of ICTs are challenging the established structures of government institutions, agencies, and their bureaucratic procedures by opening them up to interdepartmental and private sector competition. The improvements in communications have led to changing community expectations of government, described by Botsman and Latham (2000) as "the enabling state, people before bureaucracy."

The state of Queensland covers an area of 1.7 million square kilometres accounting for almost 25% of the total land area of the Australian continent; it is seven times the area of the United Kingdom, more than twice the size of Texas and five times larger than Japan. With 3.8 million residents, and more than 35% of the population living outside the State's southeast corner, Queensland is the fastest growing and most decentralised state in Australia (Pop. 20 million). The distance between the state capital Brisbane and the northern boundary in the Torres Strait is more than 2000km. Providing government services in the sparsely populated remote regions is expensive, many have only been retained due to adaptation and technological innovation. Examples starting from 1929 include the pedal-powered short-wave radio and the Flying Doctor service, the high-frequency radio School of the Air, 1951, and the introduction of an integrated whole of government Intranet using 16 bit processor and satellite technology in the early 1980s.

## QUEENSLAND GOVERNMENT AGENT PROGRAM

Current ICT innovations can be found in two Queensland government initiatives. The Queensland Government Agent Program (QGAP), uses a "one-stop-shop" approach to provide a wide range of services for client populations dispersed over vast rural and remote areas (Kelso & Shepherd, 2002), and the Smartservices Queensland project provides "…anywhere, anytime access to government services" (Queensland Government, 2004). At its inception there were similarities between the QGAP model in Queensland and a similar scheme in Nebraska. In a time of rural downturn, government partnered with primary industry support networks to retain services in rural communities (Arber, 2005). QGAP combines a variety of service delivery models, the most recent of which is called Smart Services. The Smart Services program uses ICTs to, "… provide Queenslanders with a "front door" to government transactions, information, and referrals through the internet, phone, and face-to-face customer service." (ibid). Smart Services caters for the whole of Queensland, metropolitan, regional, and remote. The Smart Services program was developed out of an earlier initiative called Access Queensland. A strategy statement for that earlier program (Access Queensland, 2000) describes a range of applications including:

- A farmer west of Longreach accessing information relating to salinity of property and booking an inspection from local inspectors in one interaction
- An Aboriginal artist in Cape York through one point of contact and one interaction being able to register her business access her business "start-up" kit and enroll for an upcoming business training course
- A householder paying ambulance subscription; car registration; and housing repayments in one interaction at one location
- A New York resident booking a permit for a Fraser Island camping holiday
- A retiree registering for a seniors card and associated government concessions

The examples previously used focus upon bridging significant distances; Longreach is more than 700km from the coast while Cape York is more than 2000 kilometres from the capital city. The facility provides the ability to make multiple transactions across a single counter. However, it is probable that the New York resident would have faster access to the Web site than a remote Queenslander, as the level of service can be diminished in remote areas because of the lower download speeds of the existing copper wire telephone network (the current legislated minimum is 26.4 kpbs). Metropolitan and high-density population centres enjoy higher service levels through broadband, wireless, ISDN, and cable services. In many remote areas, one of the few high speed public access points to the Smart Services Web sites are available through the QGAP office with its dedicated data connection.

QGAP agencies are one-stop shops managed under a state government program where people can conduct all government business or obtain information. The largest QGAP outlets offer in excess of 400 specific services covering all three tiers of government. ICTs are central to this availability of services in providing internet and intranet access across the normally restricted internal and external boundaries dividing Federal, State and Local Governments and their departments. QGAP officers can facilitate a range of services including vehicle registrations, wills, estate matters, rent collection, birth, death, and marriage certificates, wildlife and environmental permits, liquor permits, insurance and ambulance subscriptions, and workplace health and safety issues. In many ways, this single shop-front approach offers the same level of service access afforded to city people. In some ways it is a superior service because it can be delivered across a single counter rather than having to visit each separate department or agency. QGAP staff are selected for and supported in delivering customer focussed service and will generally provide assistance or advice on virtually any government problem or query, even in cases where it is not a paid service function. The Queensland Transport Department has been the greatest user of the service accounting for about 70% of all work but all departments have benefited by being able to provide greater access to their services in remote communities. An example of the benefit is provided by Police and other emergency Services which are often single officer stations in remote locations. The obvious problem is that time spent in the field is time away from the front counter. The introduction of a QGAP allows the officer a release from clerical duties to spend more time on operational matters.

General QGAP enquiries account for 30% of activities, transactional services such as licences and permits 60% and other services the remaining 10%. Common requests for federal government information include immigration, taxation, and Medicare and both state and local government provide information on counselling services, tourist information, commercial advice, and wildlife management. As the federal government does not maintain service centres outside of the state capitals or provincial cities the QGAP is often the only official presence representing the federal government in many isolated regions of the state. QGAP has achieved high community support through its convenience in transacting government business and the

high level of service offered by its staff. Locals travel shorter distances to transact government business although in many cases this is still significant with journeys of 200 kilometres each way not being unusual.

The majority of information services result in some form of referral to another agency or department and for many clients accuracy of such information or personal service had been difficult to obtain in the past. ICT interconnection across departments and agencies is unique to QGAP and enables QGAP officers to obtain information for a client as well as assist with the referral where needed. This is a major public relations benefit for government as a whole. QGAP is supported by QDIAL. This is a free call telephone service which receives in excess of 1500 calls per month. The federal government's equivalent, CountryLink, receives over 3500 calls within Queensland per month.

Queensland government departments and agencies participate in QGAP as either a lead department or a user department. Lead departments manage the individual QGAP centres, control the assets such as buildings and ICT infrastructure and employ the staff. The largest QGAP agencies have access to nearly all government intranet sites at varying levels and can conduct business across the whole of government. User departments pay the lead agency for each transaction service. A common example would be where Queensland Transport provides staff and dedicates an office with QGAP signage and computer terminals. QGAP will then train the operator to cover a range of up to 420 separate transactions for a variety of other state, federal or local government departments. In some centres the QGAP facility is staffed by arrangement with local government or a private provider. In the cases of a private provider access to services is extended past the normal government operating times. One example is where a private provider opens from 6 a.m. to 9 p.m. seven days a week 363 days per year.

The QGAP access to multiple departmental intranets is unusual for the public sector in Australia. As a result of the separation between federal, state, and local Governments it is unusual to find a one-stop-shop approach enabling three levels of government service delivery. Due to political and bureaucratic reasons, for the majority of the 20th century there were clear divisions between the three levels of government in Australia. There were also clear divisions between departments within governments. By combining the duties and services of three levels of government, QGAP is providing a model for governance which is based on community need rather than departmental politics; it is increasing flexibility, expanding access, and reducing costs.

QGAP and smart service have exploited opportunities created by cheap powerful ICT equipment. Access to the government intranet systems enables an agent in a regional community to enjoy the same levels of access to head office as their metropolitan cousins. This has had some interesting outcomes. In the case of some QGAP personnel who, in delivering services for a number of governments, have come to see themselves as service "brokers" for their immediate community rather than as servants of the government which employs them.

Modifying existing services for delivery via ICTs has resulted in some services being available in a more economic and flexible format. Although these initiatives have been accompanied by the closure of a number of individual departmental offices and their replacement by a single "shop front" outlet, the combination of well trained counter staff with high speed ICT access to the whole of government has actually raised the level of service in those communities. A further unintended outcome has been the recognition by governments of the need to adapt to the new service requirements and aspirations of non-metropolitan citizens. There are similarities between QGAP and Liverpool City Council in the UK which have one-stop shops and an electronic "Pod Squad" http://www.egovmonitor.com/node/1189 . However, the UK initiative is driven largely by technology whereas the QGAP model is initiated by social need, underpinned by a fee-for-service structure which is made possible by the application of efficient ICT.

## ICTS CONNECTING THREE LEVELS OF GOVERNMENT

Federal and State governments have committed to ensuring that all communities, including those in rural and remote areas, have fair and relatively easy access to the same range of services available to people in the larger urban centres (Sorenson, 2000). Many of the administrative arrangements for QGAP and Smartsite arose out of the changes associated with reforms which were adopted in the 1980s in the Australian public sector, under a number of headings including, new public management, managerialism, market-based public administration, and entrepreneurial government. The managerial agenda across all of these is remarkably similar on the direction of reform and focuses on ways to improve the efficiency and effectiveness of the public sector. All are heavily reliant upon the efficiency gains delivered by the widespread adoption of ICTs. However, those changes have resulted in some fundamental challenges to the traditional public service structures.

Through the innovative application of ICTs, QGAP and Smartservice have demonstrated a whole of government approach which has resulted in:

- Commercialisation of government business and service-provision
- Increased liberalisation or competition within and between departments and agencies
- Contracting-out of government services to private sector providers
- Contracting-in, from the private sector to provide services
- Competitive tendering for the provision of services between departments, and
- Purchase of supplies or services which government agencies used to provide themselves.

More services are delivered in a networked fashion and levels of accountability and efficiency have improved (Kelso, 2001, p. 79-81). A new kind of public servant is emerging, one which can work across local, State and Federal government and deliver services in the most efficient manner. QGAP was originally a response to an economic rationalist overreaction which closed government services in remote areas because they were perceived as loss-makers. The QGAP model now runs 68 sites at a cost of approximately $3 million to return $27 million in profit (2004 financial year).

## FUTURE TRENDS

Efficient ICT internet and intranet interconnection of QGAP has enabled geographically isolated government agents to interact with a much wider cross-section of departments and agencies than their head-office or metropolitan counterparts (Kelso, 2003, p. 210). In many cases, these interconnections span across three levels of government; this is unique in the Australian political system. As Barrett (2003) points out, "Citizens should not necessarily have to deal with any number of government departments, perhaps at federal, state and local levels, in order to progress a particular course of action. One important aim of joined-up government is to integrate government services with the primary focus being on the needs of the citizen." Added to this is the capability provided by ICTs for governments to audit and account for expenditure and income in more cost-efficient and timely ways than was possible using the traditional public service reporting models. As the uptake of ICTs improves, the traditional communication model of distributing information out from the administrative centre has evolved to now include an interactive element where citizens and consumers have 24 hour electronic access to decision makers and service providers. Communities can now influence governments through e-democracy initiatives such as online petitions to the parliament (Qld. Government, 2002) and Community Forums. There is, however, a fundamental benefit driving the changes to the systems, the timely online payment of bills and licences is an attractive reason for governments to ensure that all citizens are connected and transacting in the most efficient way possible.

## CONCLUSION

The QGAP initiative takes the existing technological systems used by different government departments and combines them into a more efficient and effective system. The success of the QGAP initiative can be traced to a number of factors. The first is that for many isolated residents, any level of service by government is better than no service at all. The second factor is that "joined-up" government facilitates higher levels of accountability. Finally, a one-stop shop approach using an interconnected Internet and intranet system has, for the first time, provided the opportunity for nearly all government departments to provide services to isolated residents, that is, services across all three levels of government. Most importantly, the effective and efficient use of ICT has demonstrated how services which were once considered uneconomic can be delivered in a manner in which they return a profit to government.

## KEY TERMS

**Digital Divide:** The divide between the technologically well-serviced urbanised coastal strip and the lower service inland and "outback" regions. In a large part of Australia, this also follows the "great dividing range" of mountains which run just inland from the populated east coast and is the division between the "city" and "the bush."

**Enabling State:** A term used by Botsman and Latham (2000) to describe a model of empowerment by connecting individuals to governments and reducing the influence of bureaucratic gate keeping.

**Isolated:** In Australian terms a person living more than 100 kilometers or more from their nearest town or neighbour would be considered isolated.

**One-Stop Shops:** A shopfront outlet delivering services for three levels of government.

**QGAP:** The Queensland Government Agent Program.

**Smart Services:** The Queensland Government initiative designed to deliver services through a variety of electronic systems.

**Tyranny of Distance:** A term coined by historian Geoffrey Blainey which explains the influence of distance upon the development of Australia.

# Internet Voting

## LEGAL REQUIREMENTS AND TECHNICAL SOLUTIONS

Internet voting denotes electronic voting (e-voting) systems that allow votes to be cast using the Internet. There are, however, other types of e-voting, like those based on optical ballots, those using computers without remote connection or those sent by phone (Kersting, 2004; Tula, 2005). All these systems can be used in political elections or private ones (binding examples of Internet voting: the 2000 Democratic primary in Arizona or an election in a chapter of the Institute of Electrical and Electronics Engineers in 1997).

Since Internet voting will be applied to a democratic framework, it should offer the same conditions required in traditional elections (Cranor, 1997; Gritzalis, 2003; Prosser, 2004; Trechsel, 2005). Therefore, the suffrage must be at least universal, free, equal, and anonymous (Mitrou, 2002).

*Universal* voting means that any person entitled to take part in an election should be able to cast a vote, and this in an authenticated manner to avoid impersonation by malicious third parties. An identification procedure is required to *authenticate* the voter, which entails more difficulties than the traditional exhibition of a paper identification (ID). There are at least three approaches to identifying the user of an Internet voting system: through something the user *knows*, the user *is* or the user *has* (Schneier, 1996).

Knowledge of a username and the corresponding password is the most widely used identification procedure ("something the user knows"). It has the advantage of simplicity and usability by a vast majority of users. Nevertheless, it has two major problems. This system makes vote selling very easy, since the voter only needs to send his or her username and password to the buyer. The second problem is the trade-off between security and usability. Reasonable security requires long passwords, which increases the risk of typing errors by voters.

The second approach is to use a public key infrastructure (PKI) (Adams, 1999). In this case, every voter has a key pair of a public-key cryptosystem ("something the user has") and that public key is certified, for instance, by the electoral authority. Since the voter is authenticated with his or her digital signature, this system requires a high protection of the voter's private key to avoid its unauthorized use by another citizen. A user-held cryptographic token or smart card is a good solution to store and operate the user's private key, because such hardware devices can be regarded as being tamperproof in most practical situations.

Biometric identification is the third approach to identification ("something the voter is"). It is the oldest form, because physical recognition is a biometric procedure used not only by humans but also by animals. The voter uses a device that obtains a biometric measurement; for instance, a fingerprint. This measurement or pattern is sent to the authentication service that verifies whether it matches the data previously stored about the voter. Important issues when using biometrics to authenticate a voter are: (1) to ensure that the biometric pattern came from the right person at the time of the verification; and (2) to ensure that the collected pattern matches the one stored for the voter (both patterns are likely to be slightly different due to measurement errors or variable biological conditions, so exact matching is unlikely even if both patterns correspond to the same person).

A combination of several of these three identification approaches is a sensible solution.

*Freedom* is another important requirement that may be jeopardized if the voter receives inaccurate information

during the voting procedure. It should be realized that information technologies greatly facilitate these kinds of inputs (i.e., political pop-ups). The voter should also receive complete, accurate and understandable information about the operation of the Internet voting system. Therefore, training campaigns and on-site assistance are required.

Internet voting, although it can also be used in controlled polling stations, is particularly attractive in a distributed scenario where the vote is allowed from any computer (i.e., from home). However, a distributed scenario entails additional dangers because it becomes possible to create a voting market, even a massive one, or to practice extortion upon some citizens (i.e., the employer upon employees). An Internet voting system not used in official polling stations can hardly eliminate these problems, and the solutions—criminal protection or a reduced application to some specific groups of voters (i.e., citizens living abroad)—may not be enough from a democratic point of view. This is, therefore, one of the key problems of Internet voting (Jefferson, 2004). However, some countries currently admit postal voting, which is subject to similar dangers; thus, Internet voting could also be acceptable to those countries. It is actually a social and cultural problem.

Additionally, freedom in voting requires adapting to the electoral tradition of each country. An electronic vote should not reduce or eliminate the idiosyncrasy of an electoral system. For instance, blank votes and especially null votes cannot always be analyzed as voter's errors. They are part of political behavior and, if they are allowed in traditional systems, they must also be included in any Internet voting procedure (Barrat, 2004).

An *equal* vote requires that voters and the candidates receive a correct treatment. Therefore, the voting system screen should be designed to avoid any discrimination. The order of the political parties and their logos must be carefully established. It is also compulsory to have a simultaneous exhibition of all candidates, since using multiple screens would benefit the first ones. On the other hand, the system must avoid multiple votes by the same voter and should not exclude a citizen legally entitled to vote. Finally, equality requires a system that can guarantee the accuracy of the results; in particular, it should be impossible to change or delete a vote already cast. While perfect accuracy will avoid these situations or, at least, will detect and solve them, a system is said to provide partial accuracy if it is able to detect manipulation, but unable to solve it.

The digital signature is a good tool to provide these accuracy and integrity properties (Fujioka, 1992). The digital signature yields proof that the vote has been cast by a valid voter and has not been modified afterwards. Specific storage devices that do not allow information to be erased once it has been written can also be used. Nonetheless, security properties of an Internet voting system are ultimately dependent on the software implementation; therefore, the security properties of a system must be auditable (*vid. infra*).

The *anonymity* of the vote means that nobody, not even the electoral board, can link the content of one vote with the person who cast it. The system should also avoid the disclosure of partial results. The traditional procedure achieves these goals in a very simple way: a ballot (with or without envelope) is inserted into a transparent urn that can be controlled by any voter until the final tally. An Internet voting system cannot offer a similar procedure, since anonymity depends on the software source code and a citizen without technical knowledge cannot check it.

The anonymity of the vote and the secrecy of the intermediate results are usually assured by the encryption of the vote with the public key of the electoral authority (Benaloh, 1986; Chaum, 1988). However, the private key used to decrypt the votes protected with the public key is a very sensitive piece of information. It is not desirable that this key be possessed by just one person because that person can be an easy target for coercion. A usual strategy is to split the knowledge of the key between the members of the electoral board using a cryptographic threshold scheme that requires a pre-set number of board members to recover the private key (Shamir, 1979). If the number of co-operating board members is less than the threshold previously fixed, they do not obtain any useful information about the private key.

On the other hand, there are two basic methods to guarantee privacy and anonymity in an electoral procedure: mixing (Chaum, 1981) and homomorphic encryption (Benaloh, 1986).

In the first one, the voter obtains an authorization token issued by an electoral authority. There are several methods for obtaining the token anonymously, so that the election authority cannot later link the token with a particular voter (Sako, 1995; Nurmi, 1991; Fujioka, 1992). In the second step, the voter sends his or her vote and the authorization token using an anonymous channel implemented with a set of servers—"mixing servers": each server receives the votes, permutes their order and reencrypts and sends them to the next one. Once the last mixing server has sent the votes the tally process begins. Every vote is decrypted and the server verifies that the authorization token is valid. These mixing server operations are complex and current research focuses on obtaining a mixing method that can be efficiently and universally verified.

In the homomorphic protocol, the voter encrypts his or her vote and computes a proof that demonstrates the correct construction of the vote. The proof does not

reveal any information about the vote. The voter sends the encrypted vote and the proof to the election authority. All the encrypted votes are multiplied together, and decryption of the final result yields the sum that would have been obtained by adding votes in the clear. The key used to decrypt the vote is divided among several authorities that must co-operate in the decryption process to obtain the final result. There are methods to check the accuracy and correctness of the process so that, in this case, universal auditability is guaranteed. However, the computation of the proof to demonstrate the correct construction of the vote is complex, which can be a problem when the voter's computing device has restricted computational power (as is the case if the voter computes his or her vote using a smart card). A second drawback is that the ballot format is limited, so that it does not allow complex voting procedures (i.e., write-in candidates).

Technology is a key factor, but it is not the only matter of concern. We have already seen some legal aspects that must be addressed with the technological ones. Essential elements of any voting procedure, like the correct identification of the voter, the anonymity of the vote and the correctness of the tally, are not easy to verify in Internet voting, whereas they are straightforward in traditional systems. An effort to improve *auditability* in Internet voting is needed (Riera, 2002; Muralt, 2003). Nowadays, the only really accurate option is a complete software audit. Some systems give a receipt that could increase the voter's confidence. When the system is used in a polling station, there can be a paper receipt with several options: a receipt with only participation data, a receipt with the content of the vote that could be given to the voter so the voter can insert it in a traditional urn or, finally, a receipt with the content of the vote shown only to the voter. In the latter option, the voter sees the receipt, checks that its content is correct, confirms the vote and finally the machine itself puts this receipt in an internal urn. If the system is not used in a polling station, no receipt with the content of the vote can be issued because this solution could facilitate voter coercion. Some technical solutions give the voter a code for his or her vote, and afterwards the electoral board publishes them together with the tally.

However, the solutions based on receipts do not guarantee individual nor universal auditability. Paper receipts certainly allow a manual tally to be computed to confirm the electronic one; in practice, this option is seldom used, because it severely diminishes the speed attractiveness of electronic voting. In the case of a receipt with a vote code, the citizen must make confidence to electronic data that he cannot check. As said above, performing a complete audit of the voting software is the most rigorous approach. Therefore, at least from a legal point of view, the implementation of the voting system should be totally transparent to allow any citizen, and not only the electoral boards, to check the code.

The system should be audited before, during and after the election. Before the election, the devices and the software used must be audited and sealed so that it will be detected if they are tampered with. The use of open source code should be viewed as a good practice, because security experts and the entire community could help to detect and correct errors. During the election, all actions must be logged, because this information will help to find and repair any errors. Finally, the seals and the information recorded must be verified after the election to make sure that no abnormal circumstance happened.

## SOCIO-POLITICAL FRAMEWORK

From a socio-political perspective, the use of Internet voting raises several issues for debate. We can differentiate those arguments against the use of Internet voting from those in favor of it.

Among the former, three main arguments are discussed: first, criticisms about the security and reliability of the Internet; second, problems that arise connected to the digital and social divide; and third, arguments related to the changes in the process for casting the vote itself.

The digital and social divide stands out as the most important issue (Norris, 2001). It focuses on the differences of technology use among citizens. So it is not just about how many citizens could have Internet access or which is the percentage of citizens that use computers (Demunter, 2005). The digital and social divide goes further: Internet voting assumes that citizens are not only able to use the Internet for voting, but also to become instructed and informed on the options/candidates they can choose from. Comparative data from various surveys shows a well-known picture where men have greater access to the Internet that women; younger people than older; richer than poorer; highly educated than those with lower levels of education and so forth. Thus, the concept might be widened, involving not only technological issues but socio-economic, cultural, educational and legal aspects.

Beyond the digital divide, there exist other arguments against Internet voting related to social perception. From that point of view, it is said that people are afraid of using new technologies. Some scholars argue that *off-line* people—those excluded or self-excluded from information and communications technologies (ICT)—do not feel confident enough to use Internet not just for voting, but also for anything else (e.g., using credit cards or shopping online). Such a *technophobia* may seem a bit

irrational, but is the consequence of most people being unable to understand how ICT work. In other words, people know *the existence* of those technologies, but do not know *how* they really work. For instance, while in traditional voting systems citizens can *see* both the ballot and the urn and can in principle attend the counting process, using Internet voting prevents them from doing so (Reniu, 2005; Barrat, 2004a).

For a significant number of citizens, the moment when votes are cast is still a strongly symbolic moment. Such citizens are reluctant to surrender the possibility of social interaction with other people in exchange for a number of alleged advantages inherent to casting the vote from home. Indeed, the moment of casting the vote is understood as a way of reinforcing socio-political identification with the community and implicitly renew the *res publica* social contract. In this respect, Internet voting is blamed for promoting strictly private behaviors, whereas the ultimate goal of elections is to elicit the general will.

On the other hand, arguments in favor of Internet voting are not limited to comfort for voters. The main positive reasons refer to increased participation enabled by information technologies both in terms of quantity and quality (Braun, 2005). On one side it is said that Internet voting provides more possibilities for citizens to take part in elections, especially for those living abroad, in isolated areas or experiencing difficulty to reach a polling station due to illness. Moreover, Internet voting stimulates people to participate because its update effect on the electoral process will result in a more informed citizenship. On the other side, the quality of participation will increase thanks to the vast amount of information available on the Internet that will help voters attain a well-informed opinion.

Last but not least, we have to take into account the economic and political benefits. Using Internet voting will not only reduce the cost of traditional elections—which require a substantial human and logistic deployment—but also will help environmental sustainability by reducing the use of paper. In addition, Internet voting allows quicker tallies that result in a reduction of uncertainty in electoral processes and thus reinforce the democratic legitimacy of the system. In conclusion, as several public opinion surveys point out, Internet voting will provide citizens with a fast, comfortable and easy-to-use way to take part in the governing process (Trechsel, 2005a).

## KEY TERMS

**Blank Vote:** A valid vote that does not choose any candidate or, in case of a referendum, any of the offered options.

**Client Voting Platform:** Electronic device used by the voter to cast a vote. It can consist of hardware only or both hardware and software.

**Digital Divide:** Sociological concept that underlines the different approaches of the population to the ICT. Both the access to these technologies and the know-how for using them emerge as key elements of a new social gap that depends on several factors such as country, economic status, age or gender.

**Individual Auditability:** The property whereby every voter can check that his or her own vote has been correctly cast and managed.

**Manager Voting Platform:** Electronic devices that manage the election and offer three basic functionalities: the reception of the votes, their tally and, finally, their publication.

**Null Vote:** A vote cast in an incorrect way (i.e., by introducing two different ballots in the envelope, introducing a non-official ballot, etc.). This vote can be cast inadvertently, but sometimes there are citizens who wish to cast an invalid vote to protest against something.

**Universal Auditability:** The property whereby anyone can check the whole electoral procedure and confirm the correctness of the final tally.

# IT Management Issues in Digital Government

## INTRODUCTION

A common thread among municipal governments is that they harbor a variety of enterprises under one roof. For example, police, fire, public works, social services, assessor, recorder, health services, human resources, and so forth. may all be constituent parts. They all provide services to the public, and many of these services are rapidly acquiring an online orientation (i.e., they are becoming e-services). Since they are all part of a single governmental entity, there is a need to review these online offerings to assure that the level of service provided is satisfactory and that there is a common look reflective of the parent political entity. This is discussed in the section titled "E-Government Services Review". The common look or adherence to standards on Web sites can be facilitated by having appropriate IT governance for the disparate departments in the form of a chief information officer (CIO) who represents the interests of the parent political entity on an overall basis. One mechanism the CIO can use to invoke an IT vision for the County is to develop a strategic IT plan that the operating departments can then use as a guideline to plan their IT actions. This is discussed in the section of the article titled IT Governance and Strategic Planning. In the development of e-government services, as well as other systems projects, care needs to be taken regarding a number of important factors in order to assure that development work is done within time, cost, and quality constraints. This is discussed in the section of the article titled "System Development Guidelines".

Los Angeles County has an annual budget of close to $17 billion, encompasses about 30 major operating departments, and expends more than $700 million each year on information technology operations. Providing review and counsel to this effort is a 10-member Information Systems Commission, of which the author has been Chairman for the past 10 years. The Commission has concerned itself with such topics as e-government services, IT governance and strategic planning, and systems development. This article presents managerial insights drawn from this experience that should be applicable to large public agencies across the country.

## BACKGROUND

The growth of government e-services is accelerating. Not only are more of the traditional government services becoming available online, but the level of sophistication and maturity of these services is also increasing. The opportunity exists for government services to make a paradigm leap in availability and usefulness. Services should become more oriented toward user needs and life events. However, such efforts require guidance and review in order to assure that they are going in the right direction.

This article lists various services and then indicates certain aspects that a review might cover. In addition, it discusses the potential evolvement of such offerings to become more process and problem oriented. Coordination between services, the need for a single point of entry, and a common look are other necessary attributes for the growth of e-services. Toward these ends, there is a vital role for the CIO function and for a Strategic IT Plan. Furthermore, the development work that will need to be done in the e-services arena can benefit from the application of best practices of systems development.

## E-GOVERNMENT SERVICES REVIEW

Most public agencies offer a considerable number of services to the public via the Internet. Periodic review of these services will ensure that the public is deriving maximum benefits from e-government. Such review would focus on the e-services offered by various operating departments. Specific transactions could fall into such categories as "non-interactive," "partially interactive" (i.e., downloading materials and then later completing the transaction in a non-electronic mode), and "interactive" (i.e., completing the transaction online). The nature of the transactions offered indicates the maturity level of e-government. Lam (2004) offers a categorization of maturity based on whether the transactions are informational, transactional, process integrated, or service integrated. Siew and Leng (2003) propose an alternate scheme based

on whether services describe, explain, consult, or connect. Los Angeles County seems to be entering stage three of both of these classification schemes.

Some examples of Los Angeles County e-services follow, divided into two groupings:

1. Non-interactive information available to the public, including:
   - Job opportunities
   - Financial aid programs (qualification and how to apply), including food stamps, medical services, and welfare
   - Locations of correctional facilities and inmates
   - Fees for service, building permits, bid results, and invoice status
   - Road closures, flood control, and rainfall
   - Waste management and recycling
   - Rosters of public officials
   - Election results
   - Procedures for document recording
   - Voting information, application for absentee ballots, polling place locations, sample ballots, and so forth.
   - Study guides for position examinations
   - Property assessment data and home sales
2. Partially interactive and interactive applications, including:
   - Fictitious name searches
   - Sample tests for positions
   - A wide variety of forms in PDF format that can be filled out online or downloaded and then printed and mailed in (search for forms can be done by keywords, category, or form number)
   - Web user inquiries answered by displaying responses from a database, if available, or otherwise routing the inquiry to appropriate parties for response
   - Application for, payment, and receipt (via printing) of transportation permits
   - Personalized traffic reports (which allow the public to define a travel route and be paged if an incident has occurred on that route or if there is congestion)
   - Crime tip input
   - Probation reporting
   - Complaints and commendations
   - Filing of business property statements
   - Emergency requests for birth and death certificates
   - Ordering of authenticated maps

Although these services cover a wide spectrum of activity, they are not as yet fully integrated with each other, and there is also need for further development based on user needs rather than organizational structure. Borins (2004) reports similar findings in other organizations. Pan and Lee (2003) advocate the use of customer relations management techniques to achieve a holistic view of the organization's customers in order to better serve their needs, deliver greater value, and ultimately increase customer retention. According to Boyle and Nicholson (2003), there should be a single point of contact for any member of the public to access any government service.

The economic benefit of such e-services to a governmental agency can be reflected in a decrease in the number of telephone calls that the agency's employees need to handle (thereby achieving labor cost savings), a decrease in the number of people showing up at the agency's offices for over-the-counter transactions (more labor cost savings), cost decreases realized from the consolidation of certain agency operations because of a decrease in the volume of transactions at each of them, savings in postage and handling, greater accuracy, etc. From the public point of view, time is saved through not having to physically go to agency offices, lower fees for some services, accessibility of services that were previously not available in a non-electronic form, 24/7 availability of services, etc.

From an expense standpoint, the cost of building, implementing, operating, and maintaining such e-services applications have to be considered. In some cases, certain of the benefits and all of the costs are quantifiable. Research results indicate that often just the quantifiable aspects of the benefits easily pay for the costs of the applications in two to three years, thereby justifying the investment on that basis alone. A payback period of two years is generally deemed excellent for project investment. Borins (2004) indicates that there are strong financial incentives for government entities to switch users over to the Internet. Based on several economic analyses that are available in Los Angeles County, this would appear to be borne out. For example, a Simple Permits System for Los Angeles County that cost $175,000 to develop (with annual maintenance costs of $5,000) has engendered annual labor cost savings worth more than $150,000.

Specifically, with regard to the e-services listed previously, the E-Government Services Review conducted by Los Angeles County addressed the following questions and areas of concern:

1. What services and transactions are being offered or are planned to be offered
2. What forms can be downloaded
3. What databases can be directly or indirectly (i.e., by use of an intermediary) accessed by the public

4. Are services organized around topics and functions or around organizations
5. What is the level of security and privacy of transactions, including the use of electronic signatures and follow-up on fraudulent transactions
6. What suggestions have been put forth for services not offered or expected to be offered
7. What is the fee structure for services, and what is the rationale for the structure
8. Have the following issues been evaluated with regard to Web sites?
    a. Information content and orientation: Does the architecture provide quick and user-friendly access to information and services? How easy is it to discover what services are offered and how to access them
    b. Accessibility, navigability, and reliability: Do the links work
    c. Feedback mechanisms and the handling of e-mail sent to the site by users: How efficient are these processes
    d. How up-to-date is the material on the Web site
    e. Has the Web site identified its audience and built the site to serve their needs
    f. Are there clear "how-to-use" instructions, help facilities, and site maps
    g. Are there consistent formats, good page design, and meaningful titles
    h. Is the speed of response adequate, and do pages download efficiently
    i. Is the URL of the site and its pages clearly visible and memorable
    j. Can the site be readily found using search engines

Recent other assessments of public Web sites include Cullen and Houghton (2000), Curtin, McConnachie, Sommer, and Vis-Sommer (2002), and Ho (2002).

## IT GOVERNANCE AND STRATEGIC PLANNING

The Los Angeles County Review suggested that there was a need for greater standardization among constituent Web sites. A similar finding in other venues has been reported by McGinnis (2003). He indicates that individual government agencies have tended to create their own Web sites independent from one another rather than with a strategic plan for future integration from the outset. This applies to Los Angeles County as well, and it has been independently reported for other entities by Atkinson and Leigh (2003).

The common look or adherence to standards on Web sites can be facilitated by having appropriate IT governance for the disparate departmental entities in the form of a CIO who represents the County on an overall basis. It is has been fairly well established by now that most large-scale public organizations need the services of a CIO. Pervasive use of the CIO designation is reported by Ingraham, Joyce, and Donohue (2003) and Borins (2004). Issues inherent in the establishment of an Office of the CIO in a public entity are described by Freeman (2004). The question of standards in relation to Web sites is discussed by Tambouris and Spanos (2002).

Once general support has been established for the CIO concept within a city or county, a question may arise over the reporting responsibilities of the CIO in the chain of command. The arguments that may be used in favor of the CIO reporting directly to the CEO (usually a mayor, a county executive, or, as in the case of Los Angeles County, a Board of Supervisors) include:

1. The position of CIO reports to the CEO or its equivalent in practically all major corporations and governmental entities
2. The CIO should not be burdened with another layer of management (e.g., a department head) between the CIO and the CEO. The CIO inevitably has to interact with other department heads on IT matters, and it would be awkward to have the CIO report to one department head while having to negotiate with other department heads
3. The CIO must not have any conflict of interest, real or perceived, with regard to IT. If the entire mission of the CIO's Office is to perform the functions of County CIO, then there can be no conflict of interest. However, if the CIO reports to an existing department, there can and will be conflicts of interest
4. The government agency will not be able to attract a truly qualified person to the CIO position unless that person has sufficient freedom to operate. This includes the freedom to confer with the CEO

The IT vision of the CIO can be documented in a strategic IT plan, which indicates the direction to be followed at various phases and in all elements of the IT endeavor. The document for Los Angeles County is called the Integrated Business Automation Plan, and it covers areas such as software development process (e.g., all application development should be WEB-enabled); local area networks (e.g., there should be a standard LAN enterprise environment with Windows NT as the preferred operating system); common collaborative software (e.g., the preferred software would be the

Microsoft suite of products); enterprise networking (e.g., there should be a ubiquitous communications capability among all locations via a new modernized network); PC workstations (e.g., each employee should have access to email, internet/intranet, collaborative software, etc., connected to a LAN); database technology (e.g., to be SQL compliant); and standards for Web development (e.g., required linkage to the County portal).

In Los Angeles County, the Integrated Business Automation Plan is updated annually. It indicates the expenditure for IT efforts, including positions, services and supplies, telecommunication, contract services, hardware and software, leases, fixed assets, and other miscellaneous expenditures. Year-to-year comparisons have shown a continued increase in the number of networked computers and a reduction in the number of stand-alone units. Increased activity in Internet/intranet application development, data warehousing, document management, video conferencing, and LAN expansion are other highlights. The plan is a high-level operating document for the use, management, and development of information technology resources, and it focuses on how IT resources will be allocated and used.

## SYSTEMS DEVELOPMENT GUIDELINES

As reported by Globerman and Vining (1996), the literature on the management of IT projects has noted a high rate of cancelled projects, delays, cost overruns, and inadequate system performance. In the development of e-government services, as well as other systems projects, care needs to be taken regarding a number of important factors in order to assure that the development work is done within time and cost constraints. Among these factors are acceptance testing standards, contract specifications, contractual binding arbitration and cost reimbursement clauses, management dispute settlement mechanisms, requirements specifications, project management, resources for systems implementation, software examination, a development lifecycle that is as short as possible, and independent quality assurance. A complete description of this may be found by Freeman (1996). It has been seen in Los Angeles County that neglect of these factors can lead to disastrous consequences. However, public sector practitioners, such as those in Los Angeles County, have attempted to learn from their experiences and to develop best practices accordingly. Some examples follow:

1. Parallel acceptance tests (with appropriate documentation) for systems that replace existing applications
2. Independent review of specifications before issuance of a request for proposals (RFP)
3. If at all possible, a contractual requirement for binding arbitration to handle disputes, with an agreed-upon penalty structure
4. A graduated system of dispute settlement in both the contractor and user managerial chains
5. An adequate mechanism for change control
6. A standard for project management, including well-defined project review cycles
7. Assignment of a project manager by the public agency who has had experience with systems of the same dollar magnitude and complexity
8. Budgeting of sufficient resources needed to accommodate the implementation phase of the system. This includes user training, dual operation, conversion, physical facility changes, and documentation
9. Making training funds available not only for the trainers but also for the trainees. This would include overtime or replacement help in order for employees to do their regular jobs while they are being trained

## FUTURE TRENDS

Borins (2004) indicates that many public CIOs believe that government and democracy will become largely electronic within ten years' time. The discussion of the economics of e-services in this article provides a rational underpinning for this conjecture. Thus, it seems likely that e-government will become pervasive. This will require reorientation of existing services so as to provide one-stop shopping for all citizens for accessing all government services. These services will no longer be presented along "stovepipe" organizational lines but rather would deal with functional service dedicated to solving problems based on life events and needs. Given the massive scope of e-services in the future, the establishment of the CIO function will be necessary in order to provide standards and integration. A strategic plan can be used to provide guidance to the development efforts of individual departments.

## CONCLUSION

This article has listed a sampling of e-government services in place in Los Angeles County and has discussed these from the perspective of e-government maturity. The economic benefits of such services was described, and it was indicated that many show a relatively short pay-off period. A method of review for such services was delineated. The necessity for a common appearance for ser-

vices from a given governmental entity was shown, and the role of the CIO in achieving such a look as well as adherence to standards was described. The organizational alignment of the CIO within the governmental entity and the use of a strategic IT plan to delineate the IT vision was discussed. In order to develop systems and Web sites, certain factors must be heeded. These were described as best practices derived from the Los Angeles County experience. The information technology issues treated in this article likely have applicability to large public agencies across the country.

## KEY TERMS

**Chief Information Officer (CIO):** Someone charged with guiding the IT effort of an entity from the viewpoint of the enterprise as a whole.

**Customer Relationship Management (CRM):** A set of IT techniques that allow for the creation of an integrated view of customers and the use of this information to coordinate services to these customers.

**E-Maturity:** The level of sophistication and complexity of government e-services.

**E-Services:** Use of information and communications technology to deliver public information and services.

**IT Strategic Plan:** A document charting the course and scope of the IT effort in an entity.

**Portal:** A single Web-based point of access for information and services.

**Universal Access:** Providing capability for online participation by all segments of the population.

## INTRODUCTION

Today, information security is one of the highest priorities on the IT agenda. In 2003, Luftman and McLean (2004) conducted a survey of Society for Information Management members to identify the top 20 information technology (IT) issues for executives. Security and privacy issues were ranked third, after IT/ business alignment and IT strategic planning. Concept of information security applies to all the data stored in information systems or being communicated in information networks and encompasses measures applied on all layers of open system interconnect (OSI) model of international standards such as application, networking, and physical.

Sophisticated technologies and methods have been developed to:

- Control access to computer networks
- Secure information systems with advanced cryptography and security models
- Establish standards for operating systems with focus on confidentiality
- Communication integrity and availability for securing different types of networks
- Manage trustworthy networks and support business continuity planning, disaster recovery, and auditing

The most widely recognized standards are:

- **In the United States:** Trusted Computer System Evaluation Criteria (TCSEC).
- **In Canada:** Canadian Trusted Computer Product Evaluation Criteria (CTCPEC).
- **In Europe:** Information Technology Security Evaluation Criteria (ITSEC).

All of theses standards have recently been aggregated into Common Criteria standards. And yet, the information systems continue to be penetrated internally and externally at a high rate by malicious code, attacks leading to loss of processing capability (like distributed denial-of-service attack), impersonation and session hijacking (like man-in-the-middle attack), sniffing, illegal data mining, spying, and others. The problem points to three areas: technology, law, and IT administration.

Even prior to the drama of 9/11, several computer laws were enacted in the USA and yet more may come in the future. Still the fundamental threats to information security, whether they originated outside the network or by the company's insiders, are based on fundamental vulnerabilities inherent to the most common communication protocols, operating systems, hardware, application systems, and operational procedures. Among all technologies, the Internet, which originally was created for communication where trust was not a characteristic, presents the greatest source of vulnerabilities for public information systems infrastructures. Here, a *threat* is a probable activity, which, if realized, can cause damage to a system or create a loss of confidentiality, integrity, or availability of data. Consequently, *vulnerability* is a weakness in a system that can be exploited by a threat.

Although, some of these attacks may ultimately lead to an organization's financial disaster, an all-out defense against these threats may not be economically feasible. The defense actions must be focused and measured to correspond to risk assessment analysis provided by the business and IT management. That puts IT management at the helm of the information security strategy in public organizations.

## INFORMATION SECURITY THREATS

Security threats to a computer system fall into a number of classes. Some well-known *threats* focus on disclosure of sensitive information; destruction of resources, interruption of processing, damage of data confidentiality, integrity, and availability, corruption, modification, theft, removal, and accidental loss, operator input error, and transaction processing errors.

Some threats influence the availability and reliability of the site, which is usually called a denial of service (DoS) attack. The Code Red virus is an example of a DoS attack.

Code Red was programmed to overflow Web servers with data, which it did so effectively that it resulted in making a huge portion of the Internet unavailable, as sites became clogged with more data than they could process. Other attacks target the content and data of a site, as individuals seek to damage, spy, steal, change, delete, or place something on the Web site. In addition, we have to be ready to deal with natural disasters such as earthquake, flood, and fire.

The common *purposes of the intended threats* include embezzlement and financial gains, curiosity, economic espionage, economic damage, personal financial injury, illegal search for evidence, and others.

The intruders employ a wide range of tools and techniques (some of them available on the Internet). A somewhat extensive but still incomplete list of hacker's tools and techniques include (Anderson, 2001; Preetham, 2002):

- **Backdoors:** Programs that are written to infect the victim's computer and open a secret door for the hacker.
- **Denial of Service (DoS):** Programs that designed to disrupt communications, sessions, transactions, or any other kind of business activities over the network.
- **Dumping Diving:** It is a process in which a social engineer searches an organization's garbage to find valuable information.
- Reading data erroneously left on the disk.
- **Impersonation:** In this approach, a social engineer gains detail information about an employee in an organization. Then the social engineer impersonates that employee by calling the help desk or another employee to gain access to sensitive information.
- **Loss of Processing Capability**
- **Man-in-the-Middle Attacks:** An attack in which a hacker can read, insert, and modify messages between two persons/systems without either one knowing that the communication line between them has been compromised.
- **Password Cracking:** Programs written to recover passwords from data that has been stored in or transmitted by a computer system, usually, by repeatedly verifying guesses for the password.
- **Replay Attack:** A form of nework attack in which a valid communiation is maliciously repeated or delayed. This is done by an attacker who intercepts the data and retransmits it as part of a masquerade attack.
- **Sniffers:** Programs that can see the traffic going throuhg a network or part of a network.
- **Social Engineering:** The greatest single danger identified by Information Security specialists (can be particularly damaging in public organizations)
- **Spoofing:** A technique hackers employ to alter the sender's identity within a packet.
- **Trojans:** Programs that provide a perceived benefit for the victim while conduction malicious activities in the background.
- **Viruses:** Programs that are written to crash a system, consume system's resources, or transmit vital information back to the hacker.
- **Worms:** Programs that are developed to replicate themselves on a desired medium. They are an effective tool for denial of service (DoS) attacks.

There are some preventive, detective, or response defense mechanisms, but each of them is effective only to some extent. None of them is full proof, and not all of them are economically or organizationally feasible for implementation at a public organization.

The list of hacker's tools and techniques is growing as new software (operating systems, applications, common-use utilities, and file types) continue to be introduced in the organizational and personal information networks. Information Security professionals agree that these trends will continue for foreseeable future.

## COMPUTER LAWS

IT Security in public organizations must be guided by several computer laws which were enacted in the USA and which directly address specific issues of computer information privacy and protection:

- **Privacy Act of 1974:** To regulate federal government's use of private data.
- **Medical Computer Crime Act of 1984:** Sets federal criminal penalties for mi-use of medical records over telecommunications lines.
- **Comprehensive Crime Control Act of 1984:** Covered a range of computer crimes.
- **Computer Fraud & Abuse Act of 1986:** Defined computer fraud against federal interest computers.
- **Electronic Communications Privacy Act of 1986:** Covered illegality of capturing, altering or misuse of digital information.
- **Computer Security Act of 1987:** Defined security classification of electronic data.
- **Federal Sentencing Guidelines 1991:** Requires corporations to report computer crimes.
- **Economic Espionage Act of 1996:** Defined espionage against private companies.
- **U.S. National Information Infrastructure Protection Act of 1996:** Directly addresses the security of information systems and the need to protect the confidentiality, integrity and availability of information.

- **Health Insurance and Portability Accountability Act of 1996 (HIPAA):** Focused on privacy and security of healthcare information.
- **Financial Modernization Act of 1999 (Gramm-Leach-Billey Act):** Defined "safeguard" rule for protection of individuals financial information
- **Patriot Act of 2001:** Has broad implications to individual privacy. (information privacy).

All of the previous laws apply to public organizations to some degree, however, some of them are distinctly focused on specific types of organizations. Thus, healthcare organizations (such as hospitals, pharmacies, clinics, healthcare insurances) are regulated by HIPAA with two principle parts:

- Privacy Rule proving protection of patients' identifiable personal health information
- Security Rule designed to secure electronic transmission of such information

Financial institutions (such as credit unions, educational institutions, publicly held financial organizations) are regulated by Financial Modernization Act of 1999 (also known as the Gramm-Leach-Bliley Act) to protect consumers' personal financial information held by financial institutions with three principal parts:

- Financial Privacy Rule regulating collection and disclosure of customers' personal financial information by financial institutions;
- Safeguards Rule (that applies to institutions that collect information and to organizations that receive customer information; and
- Pretexting provisions designed to protect consumers from individuals and companies that obtain their personal financial information under false pretenses.

Federal government organizations (such as civil and military institutions) are specifically subjects of the Computer Fraud & Abuse Act of 1986 and the subsequent U.S. National Information Infrastructure Protection Act of 1996.

Patriot Act 2001 (short title: Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act of 2001) is a wide range security provisions applicable to all spheres of public organizations.

New laws placed a new light on the responsibilities of corporate officers for information security, proper use, and protecting privacy of information. A recent article in CIO Magazine (Scalet, November, 2001) indicates that "...To hear some people tell it, corporate liability for failed information security is the coming apocalypse. Several experts predict a flurry of personal injury lawsuits filed by customers whose personal information has been disclosed, corporate lawsuits based on damage caused by security breaches at business partners and class-action lawsuits filed on behalf of irate stockholders." Defense attorneys are exploring whether corporate officers could be held personally liable for information security breaches (Dodson-Edgars, 2002).

Due to the nature of its information holdings, a public organization could be subjected to more stringent law requirements and exposed to more public scrutiny of its information security than a private corporation. Building fault-tolerant systems (i.e., a system capable to detect and attempt recovery from failure is at the core of information security planning for large organizations).

## POLICIES AND PROCEDURES

It is commonly accepted in the Information Security community that above all other efforts, a well-designed policy and procedures (both based on commonly accepted and a good Information Security administration assures the most successful defense against hackers and disasters.

- A policy, however, is driven by business rules, often targets information technology, and is addressed to people. Policies and procedures are bounded by business rules and new business requirements, which make it more difficult to secure the enterprise's assets
- Policies and procedures also target information technology. But over period of time, new software packages and operating systems are becoming more complex and feature rich. As security issues are addressed, they require keeping up with patches, a daunting task at large enterprises as well as for home users
- Finally, policies and procedures are addressed to people. Building security awareness and emergency readiness among employees is a critical (and often skipped) task of Security Administration. IT teams tend to do more with less; in the absence of adequate management tools, mundane security chores such as managing device ports to control confidentiality of incoming and outgoing data traffic may quickly be considered a low priority

### Information Security Assurance at Public Organizations

The *security* features of public sector *information* systems are quite important as these are regularly part of

critical infrastructures or handle personal or sensitive data. Public sector organizations usually include all local, city, state, and federal governments along with non-profit institutions and agencies.

E-government is a relatively new form of a virtual public organization. Relying on information technologies such as the Internet (possibly in the future intranets and extranets) and wireless networks, it has the capacity to alter relations of citizens and businesses with various units of government. These technologies can provide assistance in: collecting, processing, and analyzing data; improved delivery of public sector services to citizens; enhanced interactions of government units with business and industry; citizen empowerment through access to information; and more efficient government management (Bekkers & Zouridis, 1999; Loukis & Michalopoulos, 1995). The ensuing benefits include fewer corruptions, more transparency, increased convenience, additional revenue, and less cost.

Ordinarily, the interactions between a citizen or business and a public agency take place in a government office. E-governance can help place service centers closer to the clients. Examples of such centers include an unattended service kiosk in a government agency or in another public location closer to the client, or access to the services through the use of a personal computer from home or office.

Government information systems differ in a number of ways from their counterparts in the private sector. The strategic nature of many government agencies means that failures of their information system can lead to large-scale disruptions to many economic and social activities and even endanger human lives. For example, disruptions in emergency service systems could be catastrophic. Thus, the availability of information is a crucial feature of their operation. Also, confidentiality and integrity of data are of the highest concern for public related agencies such as IRS, Medicare, and Social Security services, which deal with personal, confidential, or sensitive data. Breaches of information security, which lead to unauthorized leakage of information or modifications of stored or transient information, and loss of trust in public sector organizations.

It should also be noted that public sector organizations operate in a specific way and in uniquely challenging environment. Frequently, they must function with inflexible institutional procedures limiting their procurement, hiring and rewarding activities. They are usually not subjected to the forces of the market economy, while they are often constrained by political considerations. The above factors contribute towards a set of specific issues regarding public sector information systems security (Loukis & Spinellis, 2001).

The estimates of effort and cost of implementation of information security assurance (or, in short, IA) are typically based on the following:

- Results of analysis using models or historical data for converting characteristics of the work products and tasks into labor hours and cost; such historical data include the cost, effort, and schedule data from previously executed IA projects
- Methodology (models, data, and algorithms) used to determine needed material, skills, labor hours, and cost; it includes identifying the critical computer resources for the IA project and having cost and effort estimates for them

The accuracy of these estimates depends on the availability of relevant models and historical samples for IA data. Multiple models and/or methods may be used to ensure a high level of confidence in the estimate. However, it is also likely, that for a specific public organization building an IA infrastructure may be unprecedented or include the type of tasks that do not fit the available models. In such cases, judgmental estimates provided by a group of experts may suffice. Overall, the IA-building efforts that do not follow an analogous work done somewhere else are riskier; require more preliminary cost-analysis research and more time to develop reasonable models and assumptions for estimate.

## BASIC DEFENSE MECHANISMS

Confidentiality, integrity, and availability (also known as the C.I.A. concept) are at the core of information security concept. Information protection is focused on prevention, detection, and response (or correction) to disclosure, alteration, and denial of service activities. The access control mechanisms are implemented through administrative (polices and procedures), technical (e.g., restricting access) and physical (e.g., infrastructure, badges) means.

Access control is one of the most technically elaborate areas of supervision. The technology employed here varies from passwords (what you know), to tokens (what you have), to biometrics (what you are).

Remote access authentication systems and procedures place additional significant requirements and load on the system infrastructure, often involving additional servers (for password authentication) and procedures. Access rights are managed based on privileges of a user, security sensitivity of information, and the "need-to-know" requirement.

The system configuration is focused on protecting the information resources depending on their security

sensitivity, with the most secure information guarded within "trusted network" (a part of the entire organization's system or network). The most common tools employed here are proxy servers, routers, and firewalls. Proliferation of wireless networks poses an increased risk. Virtual private networks (VPN), which are very popular for wired networks, are also very effective for wireless networks.

Cryptography is a vital mechanism for ensuring data confidentiality and integrity. New standards, encryption algorithms can make data communication via public networks very well protected. However, it needs to be reminded, that there is no absolutely unbreakable encryption algorithm. Protection is always a factor of time.

Computer components and the way they function in collaboration is another area that needs to be securely protected. Administrator needs to understand and define trusted computing base (TCB) that would encompass hardware, software, and firmware. The TCB serves as a benchmark for indications of possible security intrusions.

Development and implementation of applications must follow an acceptable model to reduce risk of security violations. Thus, the Capability Maturity Model® Integration (SEI, 2004) of Carnegie Mellon University is a frequently recommended for well-controlled applications with repeatable functions.

Business continuity and disaster recovery planning ensures that the business can continue in an emergency and will maintain availability of the critical systems. It includes, among others, business impact analysis (BIA), which provides assessment of all business functions measured in terms of accumulated financial loss by period of time. Disaster recovery planning (DRP) is of utmost importance and is discussed below.

## DISASTER RECOVERY PLAN

*An organization should also make sure it has developed a disaster recovery plan, along with the security measures, that incorporate redundancy of systems and offsite backups in case the worst scenario happen.* (Jost & Cobb, 2002)

This planning model is based on values. Crises thrust an organization's values into the realm of public scrutiny. This must be recognized early in the crisis planning process. Here are the nine steps we recommend in crisis planning (Kamer, September 2004).

1. **Step 1. Establishing the Crisis Team:** This has to be done by the CEO. It should have representatives from finance, operations, communications and marketing, human resources, and information technology departments. The crisis team tasks are to manage the process of drafting the crisis plan, establishing a schedule of training and testing, and securing the resources.
2. **Step 2. Articulating Workable Values in Crisis:** One of the objectives of crisis planning is to demonstrate that the organization during crisis can act promptly and show its true colors. This process will helps managers to pay attention to the right set of objectives in a crisis situation—not just giving the impression that the crisis has been dealt with.
   The defining moments of organization forces managers to disclose, examine, and select the ethics of their organization. Defining moments reveals the basic characteristics of an organization. They show what the company really does instead of what it hopes to do (Badaracco, 1997). This is especially true in crisis, as any manager who has been there can attest. Decisions to contact the press, release a warning, or buying an advertisement explaining the organization's position are hardly ever-easy options.
3. **Step 3. Crisis Risk Assessment:** It is impractical to assume that any disaster recovery plan can anticipate all of the potential crises. Organizations involved in crisis planning usually have some understanding of potential crisis situations such as virus attacks, fires, floods, and earthquakes.
   Under what circumstances an ordinary everyday event may become a crisis? What conditions already exist within the organization that may all of a sudden become public embarrassment? Are there crises that have happened to others and may happen to your organization? These are the risks. The assessment should evaluate the damage that these risks may inflict on the organization. Those with the highest cost should be the primary focus of the crisis planning
4. **Step 4. Define Roles:** When facing crisis, managers will accept different or expanded responsibilities. This is especially true in cases involving natural disasters, large-scale industrial mishaps, or crisis involving various agencies. People may find themselves dealing with individuals that they do not regularly make contact with–or, at times, individuals they don't know
   The disaster recovery team must recognize the possibility of new faces, define the main roles, and name who will assume those roles. Much of this approach originates from the incident command system (ICS), a military-like management system first utilized in California in the beginning of 1970s to combine resources to handle wild fires (Auf der Heide, 1989).

5. **Step 5. Develop Interim Responses:** Disaster recovery planning helps to identify problem areas that call for immediate action. On these occasions, the management should not delay the required actions needed to fix the problem until a written plan is prepared.
6. **Step 6. Write the Plan:** A comprehensive disaster recovery plan sometimes may give the organization a false sense of protection. The plan is needed to document the organization's view of crisis management from values through execution. That has to be in writing, because it should last executives and employees' turnover. It functions as the organization's policy manuscript, a training handbook, and a playbook. The most valuable part of the plan will be the lists–telephone numbers, materials records, and media lists.
7. **Step 7. Train on the Plan:** Upon the completion of the crisis plan, attention must be paid to the training of the employee. It's important to discuss with the employees the reasons behind developing the plan. Also, employees should be aware of how to use the plan, what motivated the decision to put it together, and how it is designed to shield organization values, activities, and standing in the community. In many occasions, disaster recovery planning allows organizations to become aware of their deficiencies in the area of media training. In addition, top officials may recognize that the news media preparation they may have had in the past may be insufficient for the handling of crisis communications.
8. **Step 8. Test the Plan:** Crises times bring deep emotion and extreme pressure to the organization. Operations, good will with the public and in many cases lives are at risk. The crisis plan will not be effective if it is not accompanied with trainings, simulations, and drills. Only through testing the participants are able to feel the real deal and the plan's deficiencies can be revealed (Kamer, January 1998).
9. **Step 9. Modify the Plan:** The plan needs to be viewed as a living document. It's imperative that one member of the crisis team be explicitly responsible for refining and updating the plans. It's also good practice that the plan includes an expiration date. This causes the crisis team to modify the plan at least on annual basis. Comments and responses from trainings should be included into the plan.

Additional guidelines, standards, and regulations can be found in the following sources:

1. **National Institute of Standards and Technology (NIST):** NIST offers technical publications along with training assistance to accelerate the development of innovative technologies.
2. **National Computer Security Division:** The mission of National Computer Security Division is to enhance the information systems security by researching, analyzing, and advising agencies of IT vulnerabilities and devising techniques for the cost-effective security and privacy of sensitive federal systems.
3. **Office of Personnel Management (OPM):** OPM provides training requirements and guidance relating to personnel management within the federal government.
4. **Government Accountability Office (GAO):** GAO evaluates federal programs and issues legal opinions on IT deficiencies.
5. **General Services Administration (GSA):** GSA secures technology and provides training services for federal agencies.

## FUTURE TRENDS AND CONCLUSION

Threats of information warfare and threats to public security highlighted by the events of September 11 as well economical threats posed by ever-growing population of hackers and availability of hacking tools will likely result in new industry regulations concerning information security, intrusion detection, crisis planning, and recovery. Forward-thinking companies are already seeking to avoid increased regulation by implementing best practices in the crisis management arena. Understanding of basic threats and defenses including this nine-step methodology provides an important starting point for public organizations to begin information security and disaster recovery planning in this new era of risk.

## KEY TERMS

**Computer Networks:** It is a system utilized for estabishing communication among among two or more computers.

**Disaster Recovery Plan:** A document that lists all activities required to bring back a system to the conditions that existed before the disaster occurred.

**E-Government:** It refers to the use by public organizations of information technologies that have the capability to alter the relations with citizens, businesses, and other government entities.

**Information Warfare:** It is the offensive and defensive use of information and information systems conducted during times of crisis or conflict to achieve or promote specific objectives over an adversary's information and information systems.

**Security:** In the IT area, security refers to techniques for making sure that data stored in a computer system cannot be accessed or modified by any individual without permission.

**Threat:** An activity that, if realized, can cause damage to a system or create a loss of confidentiality, integrity, or availability of data.

**Virus:** A program that is loaded onto a computer system without owner's knowledge and it is capable of reproducing itself and causing damage to files or other programs on that computer.

**Vulnerability:** A weakness in a system that can be exploited by a threat.

## INTRODUCTION: THE LACK OF EDUCATIONAL DESIGN

### Fact

Today, most e-government Web sites are limited to providing and disseminating legal or legally relevant information (hereafter legal information; see "Key Terms" section). Generally speaking, the online provision of legal information is not made in line with sound educational principles. Most likely, this could be said about the provision of all kinds of information on e-government Web sites. As I am a lawyer, I only feel entitled to assess legal information. Hence, I would like to limit my reflections in this article to legal information. As a number of examples suggest, e-government Web sites are not conceived as legal e-learning environments (e.g., http://www.ch.ch, http://www.admin.ch, http://www.bund.de, http://bundesregierung.de, http://www.help.gv.at, http://europa.eu.int, http://www.firstgov.gov. All visited January 4, 2005).

### Problems

(Mis)conceiving the state's online presence is detrimental since the lack of educational design fails to ensure that users can assimilate and process the legal information which e-government Web sites provide in an effective and sustainable manner. Within the communicative framework applied here, mere provision means that so-called *e-government addressees* (see "Key Terms" section) are not assisted in their efforts to assimilate and process the legal information they find on e-government Web sites. Their chances of building up legal or legally relevant knowledge (hereafter legal knowledge) are compromised as a result. There is good reason to doubt that the prevalent uneducational design of legal information can arouse the interest of the envisaged target audience(s), let alone evoke positive emotions. Furthermore, it is to be doubted whether current design can do proper justice to the cognitive and emotional needs which e-government addressees undoubtedly have. Moreover, the lack of appropriate educational design would appear to call into question the mid- to long-term success of managing legal information on e-government Web sites in an uneducational fashion.

### Questions

These problems raise several questions: How can e-government addressees assimilate and process legal information in a sustainable manner? How can e-government Web sites be designed such that their addressees can build up their legal knowledge more effectively? How should legal information on e-government Web sites be designed to arouse (and sustain) their target audience's interest, offer it pleasure, and meet its cognitive and emotional needs? How should legal information management on such Web sites be practiced to assure mid- to long-term success? How might the e-government actors responsible for creating such sites reconceive what is now mere legal information dissemination as legal information communication? Would legal information on e-government Web sites need to be scripted in line with educational principles? Should such sites be designed as legal e-learning environments? Given the broad range of electronic learning environments, how would legal e-learning scenarios need to be designed in the context of e-government Web sites? Which specific requirements of what I have called *legal (information) design* (Brunschwig, 2001; see "Key Terms" section) would apply to legal e-learning environments on e-government Web sites?

### Relevance of Questions

Resolving the previous problems would have a number of significant benefits: E-government addressees would be able to assimilate and process legal information in a sustainable manner. They would be able to build up their legal knowledge with fewer constraints. They would absorb legal information with greater interest, pleasure, and gratification, thereby inducing a learning curve. Their cognitive and emotional needs would be met more adequately. Moreover, the image of those responsible for managing online legal information would improve in the mid- to long term because they could no longer be (dis)qualified as merely disseminating legal information but would be acknowledged for their efforts to communicate it. In creating e-government Web sites along stringent educational principles, these sites would be conceived as legal e-learning environments much more effectively, aligning them with the specific context of e-government Web sites and their addressees' needs.

## Hypothesis

Designing e-government Web sites as legal e-learning environments would benefit all those concerned in the ways sketched previously above.

## Current State of Research

There is very little published research on whether e-government Web sites can be designed as (legal) e-learning environments and, if so, how (e.g., Bose, 2004; Vatter, 2004). Bose (2004) aims at identifying the technologies available for establishing online education and training. Vatter (2004) notes that it is a matter of enabling both "learning *for* e-government applications" and "learning *with* e-government applications" in terms of "a complementary educational conception of the application" (p. 10). Whereas the majority of publications I have seen focuses on e-government and knowledge management (e.g., Liebowitz, 2004; Wimmer, 2003, 2004), this article seeks to contribute to the scant research on designing legal information on e-government Web sites in line with stringent educational principles.

## Procedure

In developing at least rudimentary answers to the previous questions, I will first venture briefly into legal history to discuss the reflections on education of a prominent representative of the French Enlightenment who made a persuasive case for the state as a teacher, particularly as its citizens' legal instructor. I will then outline key aspects of e-learning and key aspects of legal e-learning in the context of e-government Web sites. I will close with findings, future trends, and a conclusion.

# BACKGROUND

## A Brief Excursion into Legal History

That the state should act as a teacher, particularly as a legal instructor, is not a new postulate. The eighteenth century witnessed a heated and controversial debate on the relationship of the state and education. Marie-Jean-Antoine-Nicolas de Condorcet (1746-1825), an authoritative representative of the Enlightenment movement in France, advocated state education in a number of his writings, most strongly in *Sur l'instruction publique* (1791/1792) and *Rapport et projet de décret sur l'organisation générale de l'instruction publique* (1792). As Condorcet's reflections contribute to substantiating and validating my key postulate that e-government Web sites should be designed as legal e-learning environments from a historical vantage point, I will outline the gist of his reflections regarding the learning contents and objectives (to use the terms of modern educational studies) the state should focus on, how he accounted for these contents and objectives, and which groups of learners he envisaged.

Condorcet maintained that public instruction (*l'instruction publique*) should cover all knowledge areas, including the law (Condorcet, 1791/1792, p. 154.; Hager, 1993, p. 78). The purpose of state instruction is to develop all the learner's talents and skills, to impart legal knowledge (chiefly as regards the individual citizen's rights and obligations towards the state), and to equip learners (citizens) with the knowledge they require in their professional lives in order to best serve the commonwealth. On the one hand, instruction aims at benefiting the learners' interest to attain happiness and satisfaction; on the other, it urges learners to act in the interests of the general public (Hager, 1993, p. 78). Condorcet's core argument for public instruction is that in a just state the equality and freedom of citizens cannot exist without the provision of a universal basic education ensuring that citizens are edified as regards their rights and obligations (Hager, 1993, p. 80; Lüchinger, 2002, p. 312). Providing *all* citizens, indeed *all* human individuals, with the opportunity to learn was paramount in Condorcet's thinking. He appealed not only for the instruction and education of children and adolescents, but also for the state to make provision for adult education (Hager, 1993, p. 79; Lüchinger, 2002, p. 31). Lifelong learning was more than justified, he argued, because knowledge once acquired was subject to date since science and (professional) practice never ceased to produce new insights. Many people, Condorcet argued further, had been deprived of an education in their childhood or youth, which validated lifelong education even more (Lüchinger, 2002, p. 315).

# E-LEARNING IN GENERAL

## E-Learning Defined

The relevant literature defines *e-learning* in various ways (see Back, Bendel, & Stoller-Schai, 2001, p. 28; Colvin Clark & Mayer, 2003, p. 13; Dichanz & Ernst, 2002, p. 43; Rosenberg, 2001, p. 28). It is beyond the scope of this article to discuss what are partly controversial notions of e-learning. The semantics of this compound can be construed "from the meaning of its parts and the manner in which the complex expression is formed from these" (Linke, Nussbaumer, & Portmann, 2004, p. 157). Accordingly, we can interpret the *e* (for *electronic*) and *learning*, and how they are related. Proceeding in this way helps

develop a working definition which substantiates my postulate—that e-government Web sites should be designed as legal e-learning environments. On the one hand, this working definition will bring into focus the technology (i.e., digital media) which learning requires; on the other hand, it will cast light on learning as a process. Inasmuch as it is feasible, this working definition will take into account a host of relevant—and related—aspects (such as learning contents, learning objectives, learning methodology, the rationale for learning for what is learnt, the temporal, spatial, and social contexts in which learning occurs, and instructor and learner profiles). Most definitions of e-learning consider these aspects, either separately or in conjunction with one another. As for *learning*, I will frame this key term in terms of learning psychology and cognitive psychology; as for *electronic*, I will draw on approaches in information management and educational studies.

The term *electronic* refers to the features of learning, that is, where and how "learning" occurs (in an electronic-digital environment). In the relevant literature, "electronic" has a broad range of meanings. It is common to use the term when there is mention of the digital media used in so-called *New Learning*. These media are information- and communication technologies (intranet and internet) and comprise learning programs which are available on various storage media, such as disks (still), CD-ROMS, and DVDs. As several authors have noted, these media also include PCs, digital TVs, mobile phones, and other digital apparatuses (Back et al., 2001, p. 28; Colvin Clark et al., 2003, p. 11 and 13; Dichanz et al., 2002, p. 46 and 48; Rosenberg, 2001, p. 28).

Before considering two particular approaches to learning (direct instruction and constructivism), I would like to look at general notions of learning. The psychology of learning views learning as a process (Edelmann, 2000, p. 278). Together with our memory, it is part of the human information processing apparatus (Edelmann, 2000, p. 276). As Edelmann (2000) states, "learning is dispositional" (p. 278). He describes it as analogous to acquiring or modifying particular psychological dispositions (i.e., attitudes), that is, the willingness to adopt a certain behavior or take specific action (Edelmann, 2000, p. 278). Cognitive psychology also views learning as a process which takes place 'inside' learners, involving them in acquiring knowledge, skills, and attitudes (Leutner, 2002, p. 116). Whereas "skills" refer to the ability to apply the knowledge acquired, "attitudes" denote the positive or negative "orientation towards objects or issues" (Leutner, 2002, p. 117). Expanding the cognitive-psychological view to encompass that of behavioral psychology means that "the situation in which the learning process is set plays a central role" (Mandl, Gruber, & Renkl, 2002, p. 140). In these terms, learning is "a process in which factors within a person interact with situative components external to the individual. Although there is no single or unified definition of *situation*, there is a consensus that the term refers not to material aspects alone, but equally to the learner's social environment and hence to other individuals" (Mandl et al., 2002, p. 140).

Direct instruction assumes that learning proceeds passively, that is, chiefly in a receptive and instructor-dependent manner (Edelmann, 2000, p. 287). In line with this approach, learners acquire factual and fact-based knowledge (declarative knowledge, i.e., "knowing that"), whereas procedural knowledge (i.e., "knowing how") takes second priority (Dörr & Strittmatter, 2002, p. 39; Edelmann, 2000, p. 287). Direct instruction is instructor-dominant (Edelmann, 2000, p. 287), that is, the instructor assumes the role of a moderator (Dörr & Strittmatter, 2002, p. 39).

If learning is conceived in constructivist terms, by contrast, learning is an active process (Dörr & Strittmatter, 2002, p. 32; Edelmann, 2000, p. 287; Mandl et al., 2002, p. 140) where application—respectively transfer-oriented declarative and procedural knowledge is built up (Dörr & Strittmatter, 2002, p. 32; Edelmann, 2000, p. 287; Mandl et al., 2002, p. 140). In this view, learners are more or less self-directed (Edelmann, 2000, p. 287). Further, learning is problem-based and authentic in that the tasks (or problems) which learners are meant to solve resemble those they will have to deal with at some point in their real world experience (Edelmann, 2000, p. 287). Learning is cooperative, moreover, in that it involves working with others in teams (Dörr & Strittmatter, 2002, p. 32; Edelmann, 2000, p. 287). Learners are therefore largely instructor-independent and occupy a central position (Edelmann, 2000, p. 287), whereas the teacher or instructor acts as their guide or adviser (Dörr & Strittmatter, 2002, p. 39). The constructivist approach is virtually completely aligned with current learning reform concepts. The only additional aspect is that learning is considered a *lifelong* process (Edelmann, 2000, p. 288). As we will see, the constructivist and direct-instruction notions of learning complement one other excellently in e-learning.

On the basis of the previous, I would like to use the working definition of *e-learning* provided at the end of this article (see "Key Terms" section).

## Features of E-Learning Environments (E-Learning Platforms)

(1) How can e-learning environments be described? (2) What does or should designing e-learning environments along educational lines look like? Which elements do or should e-learning environments comprise? (3) How do these requisite elements relate to the approaches dis-

cussed above? In dealing with these questions, and with a view to legal e-learning on e-government Web sites, I will focus on intra-and internet-based learning environments (i.e., online learning).

Dörr and Strittmatter (2002) argue that "learning comprises various factors of 'internal' and 'external' learning circumstances. The notion of the learning environment aims in the first instance at external conditions, particularly learning materials, tasks, and their design…" (p. 30). Müller and Dürr (2002) advance another general description: "Learning platforms comprise a bundling of Web and data processing technologies. Together they provide instructors, learners, tutors, administrators, and authors (where appropriate) with an infrastructure which ensures a uniform working environment. As such, they provide a framework for the distribution of WBTs (Web-based Trainings) and enable learning success monitoring and comprehensive communication among all participants" (p. 166).

E-learning platforms should include the following key educational features (the list is not exhaustive): learning materials, tasks, communication features, cooperation possibilities, tutor features, and learner-tracking. E-learning platforms differ from non-e-learning platforms in that the contents of the latter include no educational features, nor do these platforms aim at educational purposes. To be more specific, non-e-learning platforms do not feature learning materials and learning tasks. They offer no communication features and cooperation possibilities which serve learning and teaching purposes exclusively. They do not possess tutor possibilities and they lack learner tracking.

*Learning materials* refer to those media (i.e., technologies or formats) in which information is provided, such as downloadable Adobe PDF templates (Döring, 2002, p. 249), hypertexts and hypermedia (linked GIF or JPEG files), audio and video streaming that can be used with standard programs (Windows Media Player or RealPlayer). These media are frequently updated and can be accessed by learners. As regards the coding of learning materials, static images (photographs, graphics) or animated images (videos and animations) can be found as well as written or spoken texts or mindmaps (through their combination of text and image, mindmaps are very useful multicodal entities). Learning materials are structured in three ways: either in line with the needs of learners or with the methodological-systematic requirements of a given subject or discipline, or both.

*Tasks* are indispensable on e-learning platforms. The relevant literature sets out demanding specifications for e-learning tasks: First and foremost, they should enable learners to be self-directed (Dörr & Strittmatter, 2002, p. 31; Müller & Dürr, 2002, p. 170). Mandl et al. (2002) state that tasks should be complex and consist of very different component problems (p. 143). They argue furthermore that "the learning environment should provide the learner with multiple contexts to ensure that knowledge is not restricted to a single context, but can be transferred onto other problems. Further, learners should be given the opportunity to view problems from multiple perspectives, thereby instructing them to view and engage with contents under different aspects and from changing vantage points. This is intended to promote the flexible application of knowledge" (p. 143). Dörr and Strittmatter (2002) argue strongly for authentic tasks, that is, ones which are based on (life and practical) experience and are linked with (the learners') professional or private lives (p. 31). The demand for authenticity means that tasks must be situated, that is, associated closely with the professional or private situations, or both, which (adult) learners encounter (Dörr & Strittmatter, 2002, p. 31; Mandl et al., 2002, p. 146). Finally, tasks should be self-reflexive in that they make reference to the meta-level of learning, thereby inviting learners to reflect on their learning. As Mandl et al. (2002) note, tasks should grant learnes time and space to consider what it is they are doing when they are acquiring specific knowledge and skills during a task (p. 145). Particular attention should be paid to describing and analyzing the processes in which learners are involved in resolving a task (Mandl et al., 2002, p. 145; Müller & Dürr, 2002, p. 169). Further requirements include bringing the knowledge store into clear view, assessing its quality, and disclosing the subject-specific language used (Mandl et al., 2002, p. 145).

These reflections lead straight to the third necessary element of e-learning environments: *communication features*. Müller and Dürr (2002) state that "one of the decisive advantages of online learning over offline variants (e.g., CD-ROM-based learning programs) is that by being connected to an online network, such as a company-intranet or the internet, learners have access to a number of communication options […] Learning platforms provide […] different asynchronic and synchronic communication tools. The most widespread synchronic technologies are chats, whiteboard (see "Key Terms" section), video- and audio conferencing, and application sharing (see "Key Terms" section). The most widespread asynchronic communication technology is e-mail. Other widespread asynchronic tools are Web-based discussion fora and 'newsgroups'" (p. 167). These communication features allow learners to engage with each other, enabling them to tackle tasks in pairs or groups (p. 169).

The above leads to another prerequisite for successful e-learning environments: *cooperation possibilities*. E-learning platforms should permit social learning, that is, paired or small-group learning (Döring, 2002, p. 249; Dörr & Strittmatter, 2002, p. 31; Mandl et al., 2002, p. 144). Müller and Dürr (2002) emphasize the importance of "group discussions that take place with the help of asynchronic

technologies—particularly discussion fora—in working groups and teams. These can enrich the learning process significantly, for instance when other net-based learning modules fall back on these fora, or when experts acting as moderators promote learners in various different ways. In this setting, synchronic technologies permit rapid communication within chats, and so forth; moreover, they are able to promote team-learning highly effectively through Web-based video and audio conferencing or […] application sharing or whiteboard technology"(p. 171) Cooperative learning contributes both to exchanging knowledge and experience, and to promoting the acquisition of interpersonal decision-making skills (Müller & Dürr, 2002, p. 172).

*Tutoring features* are another prerequisite for e-learning environments: E-learners need experts to guide and support them (Mandl et al., 2002, p. 144). Müller and Dürr (2002) note that "many learning platforms offer mechanisms enabling tutors to intervene in an individual or group learning process. These tools are seldom used to run an instructor-centered session; the instructor rather assumes the role of a coach" (p. 171). Inasmuch as learners misunderstand or misconstrue learning contents or have not digested these properly, experts can step in, make adjustments, make suggestions for improvement, or both (Müller & Dürr, 2002, p. 171). As for methodology, tutoring features allow experts to outline and explain a procedure in detail, that is, to reveal the underlying methodological rationale of a task (Mandl et al., 2002, p. 147). Should learners lack motivation or should their motivation decrease, tutors can respond appropriately and turn this negative development around (Müller & Dürr, 2002, p. 171). In order to connect with learners, tutors should be able to use asynchronic technologies (e.g., e-mail and discussion fora) and synchronic ones (e.g., chat, audio- and video conferencing, whiteboards, application sharing) (p. 171). On balance, tutoring features have significant motivational value (p. 171).

Learning environments would be incomplete if they lacked *learner tracking*: This feature provides learners with personalized feedback regarding their progress (Dörr & Strittmatter, 2002, p. 31; Müller & Dürr, 2002, p. 165). Döring (2002) notes that this can occur in the shape of "self-tests, efficiency checks, scoring, and grading" (p. 249). Whereas such monitoring is aimed at identifying the individual learner's strengths and weaknesses, it also serves to reveal the opportunities and limitations of any given learning program (Müller & Dürr, 2002, p. 170). Specifically, learners should be informed whether they have made mistakes and, if so, which (p. 170). The positive effects of such learner tracking are that learners are provided with the opportunity to assess themselves in a factual and clear-headed manner. Tracking, moreover, should potentially result in program quality enhancement (p. 170). Learner tracking requires "data-base-supported user administration that records actions and results so that learning levels can be assessed on a continuous basis" (p. 165). User, that is, learner administration must safeguard the individual's private sphere and ensure data protection and data security (Burscheidt, 2002, p. 196; Müller & Dürr, 2002, p. 165).

How are the above educational elements of e-learning platforms related to the direct instruction and constructivist approaches to learning? Inasmuch as they have been scripted along educational lines, learning materials correspond to the direct instruction approach because they solely permit receptive and instructor-dependent learning. As a rule, learners do not have the possibility to deal actively with learning materials because these are designed only and exclusively by instructors. Learners must therefore absorb learning materials passively. These materials do not offer cooperation possibilities. In this respect, learners depend on those designing the materials provided. Whereas certain features of e-learning environments can be attributed to constructivist approaches, learning materials, which are basically instructor-dependent, are an exception. Examples of instructor-dependent learning materials include downloadable Adobe PDF templates, instructor presentations in audio and video streaming formats, and hypertexts and hypermedia. Hypertexts and hypermedia are associated with the constructivist approach in that they comprise hyperlinks which provide learners with scope to navigate a program in line with their personal learning needs, ensuring self-directed learning. Tasks can be attributed to the constructivist approach in that they provide an impetus for problem-based learning, just like communication features, by allowing for and encouraging cooperative learning. The same applies to cooperation opportunities and tutoring features: cooperative learning would be inconceivable without commensurate cooperation opportunities and tutoring features are imperative to confer the role of adviser on the instructor.

## Reasons for E-Learning

There are several reasons in favor of e-learning. In line with the fundamental educational triangle, they pertain to learners, instructors, and learning contents alike.

Because knowledge is subject to ongoing change and expansion, we are called upon to update ours as best as possible and to become lifelong learners (Lang, 2002, p. 25). "People can access e-learning anywhere and any time. It's the 'just in time—any time' approach that makes an organization's learning operations truly global" (Rosenberg, 2001, p. 30). Depending on their knowledge and their "situation-contingent and interest-directed" (Lang, 2002, p. 32) needs for information, learners can self-direct their learning. They take their own route through

the hypertextual and hypermedial learning material provided by deciding which and how much information they wish to search for, assimilate, and process. Learners also determine their learning speed themselves (Lang, 2002, p. 32). They can choose between different social (i.e., interpersonal) formats by opting for synchronic, asynchronic relations, or both with other learners, tutors, or both, deciding whether they wish to communicate about contents, their relationship, or both. Learners construct knowledge on the basis of exchange and dialog (Colvin Clark & Mayer, 2002, p. 22; Lang, 2002, p. 33). Such learning partnerships, learning teams, or both, can be long-lasting and reach beyond the duration of an e-learning program, as Rosenberg notes (2001, p. 31). E-learning implies that learning contents are mostly multicoded, that is, presented simultaneously in the shape of texts, images, and sounds. Multicoded learning contents have positive effects on learners because they involve thought *and* feeling (Lang, 2002, p. 31 and 34); similar to problem-based learning, multicoded learning contents deliver high and rapid results (Colvin Clark & Mayer, 2002, p. 22).

Another reason in favor of e-learning is that it provides instructors with opportunities to assume their educational role beyond the usual constraints of time and place (Lang, 2002, p. 36). E-learning modifies the instructor's role positively, enabling him or her to advise and coach individual learners (and to moderate online discussions among several learners), rather than merely delivering or presenting material (and at times overengaging in self-presentation) (p. 39).

E-learning benefits learning contents, too, by structuring these either hypertexually or hypermedially (Lang, 2002, p. 32). Multicoding is less cost-intensive than print media; it also has greater potential than traditional (e.g., paper-bound) media. Hypertext and hypermedia allow for the coding of learning contents as animated images (animations, video) and sounds; these features are particularly well-suited to simulating realistic cases (Colvin Clark & Mayer, 2002, p. 21). Lang (2002) points out that multicoded information "has higher information density compared with single (i.e., monocoded) media, complex impression quality, and therefore added information value. Complex statements can be presented in a more authentic and closer-to-life manner, on different levels of abstraction, and from different perspectives" (p. 34). Compared with traditional teaching settings and their spatial and personal limitations, online learning contents are able to connect with any scalable number of learners (Rosenberg, 2001, p. 31). While contents are the same for all learners, they can be customized to suit individual needs (p. 30). And as Colvin Clark and Mayer (2002) note, "what is special about the computer's role in learning is that the learner's actions taken in the simulation are evaluated by a program that responds with hints or feedback supporting immediate correction of errors" (p. 22). On balance, learning contents are thus characterized by feedback features; they can be updated at any time (Rosenberg, 2001, p. 30); they are platform-independent (Rosenberg, 2001, p. 31); and they are quickly accessible regardless of time and location (Lang, 2002, p. 36).

In view of all these reasons in support of e-learning, I would like to point out that e-learning, however, is only beneficial if its quality exceeds e-learning of average or even insufficient quality, or that of poor traditional learning for that matter. Monitoring quality is therefore essential.

## LEGAL E-LEARNING

### Features of Legal E-Learning Environments (Legal E-Learning Platforms) on E-Government Web Sites

Our lives are full of events which are highly relevant to e-government. I would like to illustrate this claim with a case study. It features a Swiss citizen (i.e., a potential e-government addressee) who wishes to resolve a specific legal problem. The case focuses on inheritance and property law and serves to illustrate the previous more general reflections on e-learning environments and e-government Web sites. As I did my legal training in Switzerland, the case views the issues from the perspective of Swiss law, particularly as regards the legal questions involved and how they might be answered. While an international readership might feel that this approach compromises the broad perspective adopted so far unnecessarily, I would argue that the legal issues arising from the event of death constitute a universal *life event* (see further http://www.ch.ch/urn:ch:de:ch:ch.01.02.15:01 and http://www.help.gv.at/Content.Node/79/Seite.790000.html. Both visited February 2, 2005). But as different (national) legal systems regulate the legal consequences of death differently, focusing on a *single* case would appear to be inevitable.

The facts of the case are: A woman (hereafter client) and her siblings have been joint heirs for four years. The undivided estate consists of a detached house (and furniture). The client's youngest sister has been living in the house since their mother's death. The sister has left her own furniture in her apartment (which she now sublets to a student). Now, after four years, the client would finally like to settle the partition of the estate with her siblings. She raises the following issues (and questions): (1) She would prefer her brother's wife, with whom she has a strained relationship, not to be present at the partition negotiations. What are her rights here? (2) She is seeking

a settlement which would enable her siblings and her to apportion the furniture prior to negotiating how to apportion the real estate. Would this be feasible in legal terms? (3) She is looking for a settlement which will entitle her sister to indefinite right of residence in the property, with her own furniture and at no extra cost. What might such a settlement look like?

## Learning Materials

In the context of legal e-learning, the client in the previous case (and other e-government addressees in the same or a similar situation) should be provided with appropriate learning materials. These should comprise details on partition, communities before partition, mode of partition, completion and effect of partition (Swiss Code of Civil Law, Art. 602 ff.), right of residence (Art. 776 ff.), and usufruct (Art. 745 ff.). Possible formats include downloadable Adobe PDF templates, hypertexts, and hypermedia, or audio- and video streaming. The relevant legal norms and other pertinent details on inheritance and property law (such as orthodox and precedent-case interpretations of these norms) should be presented both as spoken and written texts *and* as inanimate or animated pictures, or as mind maps (on visualizing legal norms, see Brunschwig, 2001). Learning materials should be structured such that they meet the e-government client's legal information requirements.

## Task

The case provides an exemplary learning task since it meets several key requirements of such tasks. It consists of several inheritance and property law issues (besides other legal issues which I will leave aside here) and therefore lends itself to multiple approaches, thereby promoting problem-solving skills. And it meets two other essential requirements: it is authentic (i.e., based on the client's life experience and closely connected with her everyday life) and it is situated (i.e., associated with the client's personal circumstances). The task could therefore be integrated effectively in a legal e-learning environment, although it would need to be designed along educational lines to ensure self-directed learning (i.e., allowing for individual learning speed and enabling the present client and other learners to take decisions about which and how much information they wish to search for, assimilate, and process). Should learning tasks on e-government Web sites designed along educational lines be self-reflexive? There would be no harm if e-government addressees developed an awareness of the thought processes which resolving legal problems bring into play. Acquiring certain legal terminology would be merely one benefit. In our case, this would include several notions, such as community of heirs, objective partial partition (only one part of the estate is apportioned, such as household effects, whereas the property and house remain in the deceased's estate), right of residence, and usufruct.

## Communication Features

Asynchronic or synchronic communication tools would serve our client well as they would enable her to communicate with others sharing her predicament. These tools would allow her to tackle the legal problems she faces in an online self-help group, for instance. To this end, the state should consider establishing virtual cafés for e-government addressees to host chats and video and audio conferencing. Such relaxed settings would provide those seeking to resolve legal problems with discussion partners sympathetic to their case; suggested lines of approach (and answers) could be sketched on whiteboards to everyone's benefit. Obviously, e-mail, discussion fora, and news groups would be just as feasible to preclude the individual e-government addressee's isolation.

## Cooperation Possibilities

If the client in our case tackled her legal problems together with others online, this would qualify as social learning. If e-government actors with legal training (in inheritance and property law in our present case) were to moderate the group's syn- and asynchronic discussions, thereby enriching its (legal) knowledge and experience, this would not detract from their expert knowledge and it would certainly benefit the group's decision-making skills.

## Tutoring Features

Our client (and others similarly affected) would require the guidance and support of e-government actors trained in inheritance and property law. As tutors, these experts would monitor—and intervene in—our client's approach to her legal problems, particularly should misunderstandings arise, respectively if the knowledge required to solve the case is not absorbed effectively enough. Tutors should provide information on methodology (i.e., meta-information) if requested. In our case, this might involve outlining or even presenting a model answer. Tutors would coach and guide learners should their motivation decrease. Tutors would have standard asynchronic and synchronic technologies at their disposal to connect with our client and her fellow learners. The state could charge fees for such tutorial services (or what New

Public Management refers to as *products*). Whereas these fees would need to cover the costs such a service would incur, they should not exceed the individual's financial resources and should certainly undercut the exorbitant fees charged by lawyers. On balance, fees should be as low as possible.

### Learner Tracking

Subject to the agreement of e-government clients, e-government Web sites designed in line with educational principles should feature learner tracking. Our client (and her online associates) should be given individual feedback. It is imperative, however, that tracking safeguards the individual's private sphere and complies with existing data protection acts.

## Rationale and Objectives of Legal E-Learning on E-Government Web Sites

Regarding e-government addressess, we can cite the following reasons for implementing legal e-learning on e-government Web sites: It is a fact that many people are at least partially unable to safeguard their rights or assume their obligations satisfactorily under difficult circumstances—simply because they lack adequate legal knowledge. Unable to liaise with others—because they are often unaware that others share their experience and predicament—many are left alone with their legal problems. Whereas the previous tutorial service would still be affordable, seeking legal counsel in the form of a lawyer (or law firm) would most probably overstretch many people's financial resources. Not that lawyers would lose their share of the legal (counselling) services market. Equipped with greater legal knowledge and therefore with a more profound awareness, e-government addressees would seek professional advice sooner and in better time; although they are still laypersons, they would be able to express their situation, case, and concern in clearer and more precise terms. Besides, those empowered in this way would consider taking out legal protection insurance a matter of course (and would be more likely to make appropriate financial provision for such cases). Taking out legal protection insurance would be as self-evident as a health insurance policy (at least in Switzerland).

Given increasing media literacy, particularly among young people, Poledna (2004), for instance, expects the state to tap the potential of new information and communication technologies (ICT) more effectively (p. 85). It could do so by implementing characteristic features of legal e-learning environments on government Web sites, for instance. Legal e-learning on such sites would aim at enhancing e-government addressees' legal knowledge of their rights and obligations, thereby ensuring that they could manage these more effectively. This would transform e-government Web sites into empowerment zones. Another objective would be to enhance solidarity among e-government addressees, particularly among those who share legal problems on account of their personal circumstances. Last but not least, government-supported (and -funded) legal e-learning would serve to meet increasing expectations as regards the state's provision of legal information, specifically by tapping the potential of ICTs.

As for e-government actors (such as prospective tutors), there are many good reasons that substantiate legal e-learning: Client relationship management is a crucial aspect of e-government. E-government actors, however, often lack the specific teaching skills and methods required to impart legal information more effectively. Their chances of establishing, respectively sustaining their relations with e-government addressees successfully are often impeded as a result. Government actors will therefore presumably welcome the opportunity to work with the above features of legal e-learning environments in order to do better justice to the cognitive and emotional needs of e-government addressees to process legal information to the full. It might irritate prospective tutors that they cannot exploit ICTs fully in their exchanges with clients. Which purposes might e-government actors acting as tutors pursue? They could, for instance, aspire to raising their e-government clients' legal information status to match their own, thereby empowering their clients to play a more active and more proficient role in (legal) life. This would enable e-government addressees to make better-informed decisions in ballots and elections, for instance, and it would provide them with a clearer understanding of official procedures and decisions, helping them trust and accept these on the basis of more qualified legal information (Poledna, 2004, p. 88).

The widespread and lamentable lack of an educational design of legal information on e-government Web sites substantiates the case for legal e-learning. The purpose of legal e-learning on government Web sites would be to support and encourage e-government addressees to build up and apply their legal knowledge as required, chiefly by empowering them to resolve and deal more effectively with the legal problems which their lives confront them with.

## FINDINGS

We can now answer the questions raised at the outset: (1) (Re)designing e-government Web sites as legal e-learning environments would enable e-government addressees to assimilate and process legal information in a sustainable manner. (2) E-government Web sites should be (re)designed as legal e-learning environments to arouse

the target audience's interest, give it pleasure, and meet its cognitive and emotional needs. (3) Designing legal information and its management in line with stringent educational principles would prove successful in the mid to long term. (4) E-government actors could transform what is currently mere legal information distribution into communicating legal information by integrating it into legal e-learning environments (i.e., designing it in line with appropriate educational principles). (5) E-government Web sites should be (re)designed as legal e-learning environments. (6) Legal e-learning environments on e-government Web sites should comprise learning materials, tasks, communication features, cooperation possibilities, tutor features, and learner tracking.

These findings are beneficial in that they have established a sustainable foundation for (re)designing legal information on e-government Web sites in line with stringent educational principles, respectively applying these principles to creating future e-government Web sites along the lines of state of the art teaching and learning. These findings, moreover, verify the initial hypothesis and will hopefully encourage forward-looking steps to be taken in (re)designing e-government Web sites.

## FUTURE TRENDS

As e-learning environments become more common in e-government, e-government Web sites providing legal information will be designed along increasingly stringent educational lines. Educational studies, learning and cognitive psychology, counselling studies, visual communication, legal iconography, and what I have referred to as *legal (information) design* elsewhere (see "Key Terms" section) will fertilize e-government and therefore assume increasing significance in its development. For now, I would like to take consolation from Condorcet: "Je me consolerai sans peine d'avoir passé toute ma vie pour un rêveur, si je puis espérer qu'un siècle après moi, l'execution d'une de mes idées puisse faire un peu de bien. (It would be a consolation to have spent my entire life as a dreamer if I could live in the hope that a century after I have passed away the execution of one of my ideas would cause some good.)" (as cited in Lüchinger, 2002, p. 6).

## CONCLUSION

### Discussion of the Overall Coverage of the Topic

One of the guiding assumptions of this article is that e-government addressees are willing and adaptive, that is, they are individuals capable of acquiring the media literacy, interpersonal skills, learning and working strategies required for successful (and gratifying) legal e-learning. Such a positive concept constitutes both a strength and a weakness. A weakness in that this article looks past the actual learning abilities and willingness to learn of e-government addressees: Some are neither eager nor willing to learn, for whatever reasons. Conversely, however, more and more people are recognizing the advantages of ICT (and, by implication, of e-learning). They either have the skills and strategies which (legal) e-learning requires or they would be willing to acquire them, particularly if it is a matter of safeguarding their legal rights. Not all e-government addressees, however, have up-to-date hard- and software (Döring, 2002, p. 250). This article fails to take into account those who lack the technical prerequisites for (legal) e-learning. The fact that hard- and software have become more affordable balances this oversight somewhat. It is to be hoped that costs will decrease further. The state, moreover, should consider providing e-government addressees with the necessary technical infrastructure (including a citizen's card) free of charge, such as in public buildings or in public places.

This article calls upon e-government actors to modify their perceived role in that they would be prepared to act as tutors and coaches on legal e-learning Web sites (and to invest time and effort in acquiring the new necessary e-tutoring skills through vocational training). It could well be that this appeal falls on deaf ears—which might be another weakness of this article. However, I am convinced that there are innovative and eager spirits among e-government actors who would welcome the expanded role that legal e-learning environments offer. I have not provided any critical assessment of the time which (re)designing legal information on e-government Web sites along educational lines would require (Döring, 2002, p. 252). Instead, I have focused on what are more pressing questions. Because e-learning environments are cost-intensive (Döring, 2002, p. 250 and 252), I suppose this article could be criticized for ignoring the deplorable reality of debt-burdenend state budgets. This is indeed a considerable reservation. Nonetheless, I would maintain that the state has adequate tax revenue at its disposal and that ultimately it is for parliament and the electorate (in Switzerland at least) to decide how resources are allocated. Funding legal e-learning on e-government Web sites from the state budget is therefore not entirely inconceivable.

Given the much-lamented flood of legal information, tackling it by means of implementing legal e-learning environments on e-government Web sites seems completely utopian. I would therefore recommend integrating chiefly that particular legal information which is indis-

pensable to e-government addressees to solve, respectively deal more effectively with those legal problems resulting from common *life events*. The fact that the learning and application situation (i.e., the situation in which what has been learned to resolve a legal problem is applied) converge in e-government-specific legal e-learning, which seldom occurs in most learning contexts, is arguably one of the key strengths of this article (on the need to close the gap between learning and application situations, see Mandl et al., 2002, p. 148).

## Concluding Remarks

Notwithstanding the weaknesses of this article, I would maintain that e-government Web sites providing legal information can, and should, be (re)designed as legal e-learning environments. Should this article encourage politicians, e-government addressees, and e-government actors to seriously consider whether and, if so, how the state could assume its role as its citizens' online tutor, it will have reached its key objective, which has been sitting between the lines so far.

## ACKNOWLEDGMENT

I wish to express my sincere gratitude to Dr. Mark Kyburz for our most inspiring discussions and for translating and editing this article.

## KEY TERMS

**Application Sharing:** "Application Sharing enables two or more users to make synchronic use of any application" (http://www.computerlexikon.com. Visited January 28, 2005). "Through application sharing users can create, view, and edit files by accessing a software application simultaneously at different locations" (Back et al., 2001, p. 285).

**E-Government Addressees:** The term refers to a country's citizens, foreign nationals with permanent or temporary residence, and enterprises based there. It implies that legal information on e-government Web sites is centered on persons. The term is inspired by Text Linguistics where the term *addressee* refers to the person a text focuses on. *E-government addressees* are therefore those brought into focus by e-government Web sites. Given the communicative approach adopted in this article, the term *e-government addressees* is used rather than the less specific *public*.

**E-Learning:** E-learning is an active process where learners build up application-, respectively transfer-oriented declarative and procedural knowledge. In doing so, learners are more or less self-directed. In a lifelong process, they engage in cooperative learning, based on authentic problems. Their learning occurs in various media, such as information and communication technologies (intranet and internet), in learning programs which are available on various storage media (such as disks, CD-ROMs, and DVDs), or both, and employs digital apparatuses (PCs, digital TVs, mobile phones, and other digital apparatuses).

**Legal E-Learning:** Analogously to e-learning, legal e-learning is an active process where learners build up application-, respectively transfer-oriented declarative and procedural knowledge of legal information (see below). In doing so, legal learners are more or less self-directed. In a lifelong process, they engage in cooperative learning, based on authentic legal problems. Their legal learning occurs in various media, such as information and communication technologies (intranet and internet), in legal learning programs which are available on various

storage media (such as disks, CD-ROMs, and DVDs), or both, and employs digital apparatuses (PCs, digital TVs, mobile phones, and other digital apparatuses).

**Legal (Information) Design:** Legal (information) design is an emerging, application-oriented discipline in jurisprudence. Fully committed to a holistic approach, it designs legal information by giving it new, tactile, and multi-dimensional shape. This involves visualizing legal information, for instance, shaping it to meet educational and counselling needs. It draws on a range of disciplines, including (legal) iconography, visual communication, educational studies, learning and cognitive psychology, and counselling studies (on legal information design, cf. http://www.inderscience.com/ijlid).

**Legal Information:** The term refers either to the process of providing or gathering information in relation to legal or legally relevant knowledge or to the contents themselves, that is, the legal or legally relevant knowledge conveyed (on the relationship between *information* and *knowledge*, e.g., Lang, 2002, p. 26; on the notion of legal information, cf. Poledna, 2004, p. 69f; http://www.inderscience.com/ijlid).

**Whiteboard:** "A whiteboard is a virtual blackboard, an electronic workspace which two or more users can share to work in a synchronic fashion; whiteboard software applications are operated in application-sharing modes" (Back et al., 2001, p. 302)**.** "A shared window used in video conferencing, similar to a board, where sketches, images, drawings, and so forth can be posted. This window appears on all joint users' screens and can be altered at any time" (http://www.computerlexikon.com. Retrieved January 28, 2005).

# Legal Issues for E-Government in Developing Countries

**Subhajit Basu**
*Queen's University Belfast, UK*

## INTRODUCTION

The development of government online should be seen as an evolutionary process (Morison, 2003). The rate of evolution depends on complex factors (Morison, 2003), including perceived incompatibilities between cultures and technologies, an idealistic preference for self-reliance, and a simple lack of economic or human resources to acquire and utilise the technology. Notwithstanding these causes, effective use of ICTs is biased by race, gender, and location. However, the technologies have been developed to a large extent in and for the cultural and social norms of a small number of developed countries. Although there are global flows of knowledge, skills, and artefacts from the epicenters of e-government in the industrialised world to transitional and developing economies, these flows are more unidirectional transfers than bidirectional exchanges (Minogue, 2001). This article attempts to provide a cognitive map of two of the major issues. First, it provides an overview of the legal issues related to e-government from the perspective of developing countries, and second, it critically examines how far technology leapfrogging could serve as an alternative pathway toward development of e-government in developing countries.

## DIFFUSION OF E-GOVERNMENT IN DEVELOPING COUNTRIES

"The information revolution should be geared towards enhancing global citizenship and global economic prosperity; a diversity of paths towards the achievements of national information societies should be respected; the evolution of policy for the development of an equitable global information society should be co-ordinated internationally to ensure the sharing of information and resources" (Mandela, 1995). There are many definitions of e-government, and the term itself is not universally used. Definitions of e-government range from "the use of information technology to free movement of information to overcome the physical bounds of traditional paper- and physical-based systems to the use of technology to enhance the access to and delivery of government services to benefit citizens, business partners and employees" (Basu, 2004, p. 110). Similarly, e-governance is more than just a government Web site on the Internet. The strategic objective of e-governance is to support and to simplify governance for all parties: government, citizens, and businesses. Therefore, the objectives of e-governance are similar to the objectives of good governance. Good governance can be seen as an exercise of economic,

*Table 1. Factors impeding an enabling e-government environment in developing economies*

| | |
|---|---|
| Intuitional Weakness | • Insufficient planning<br>• Lack of clear objectives<br>• Inadequate systems |
| Human Resources | • Shortage of qualified personnel<br>• Lack of professional training |
| Funding arrangements | • Project costs underestimated—cost overruns<br>• Insufficient project funding<br>• Unfinished/incomplete projects<br>• Unsustainable projects |
| Partnerships | • Lack of vendor representation and support |
| Technology and Information Changes | • Inappropriate hardware/software<br>• System incompatibility<br>• Inability to interface to legacy systems |

political, and administrative authority in order to better manage affairs of a country at all levels (Backus, 2001).

Most developing countries understand the enormous potential of ICT, not only as a tool for improving governance and creating more jobs, but also more significantly as a means to enhance the standard of living of the people. Although the policy statements differ from country to country, there are some fundamental similarities in the objectives, which can be summarised as follows:

- Establishment of an information infrastructure that comprises a high-speed broadband communication backbone, nodes, access network, distributed data warehouses, and service locations in order to cater to the needs of trade, commerce, industry, and tourism, and also to enhance the delivery of government services to the people.
- Facilitation of the flow of direct investments.
- Development of human resources for ICT through increased use of ICT in educational institutions and through academic and training programmers that improve the employability of educated youths in the ICT sector.
- Facilitation of decentralised administration and empowerment of people through the application of ICT (Basu, 2004).

Behind the hi-tech glamour of these promises, however, lies a dirty reality that the majority of projects are failures (Heeks, 2003). In order to explore this further, we can divide e-government initiatives into three camps:

- **Total Failure:** The initiative was never implemented or was implemented but immediately abandoned.
- **Partial Failure:** Major goals for the initiative were not attained and/or there were significant undesirable outcomes.
- **Success:** Most stakeholder groups attained their major goals and did not experience significant undesirable outcomes (Heeks, 2004).

There is very little data about rates of success and failure of e-government in developing countries. Failure is certainly the dominant motif of multiple-case studies of e-government in such countries, but these studies have produced no statistical data. Hence, I have relied on the research done by Richard Heeks (2004), which produced the following working estimates for e-government projects in developing/transitional countries:

- 35% are total failures.
- 50% are partial failures.
- 15% are successes.

Is the occurrence of failure a problem? It is in a very direct sense because of the economic opportunity costs of resource investment in e-government failure as opposed to success.

## E-GOVERNMENT AND LEGAL ISSUES

The success of e-government initiatives and processes are highly dependent on government's role in ensuring a proper legal framework for their operation. A requirement for e-government processes to be introduced and adopted is their formal legal equivalence and standing with the paper process. OECD governments are aware of the need for a framework in which to provide enforceable electronic transactions, both in the e-government sphere and for e-commerce, and have taken action. For example, the legal recognition of digital signatures is necessary, if they are to be used in e-government for the submission of electronic forms containing sensitive personal or financial information. The key concern for developing countries is to identify the legal issues. As explained before in this article, it would not be difficult to provide definitive guidelines for developing countries regarding what type of legal safeguards would be necessary to protect the interests of the government and to create binding and enforceable obligations on the government; however, each of the developing countries is in a different stage or phase of e-government and differs in its political aspirations and structure of government. Hence, the requirements would differ and so would the courses of action.

Developing countries would face few key questions in converting to or adopting electronic processes. Initially, the first question that would arise is the question of legitimacy. Legitimacy may express itself through expressions of authority to act, which is related to but not the same as saying that an action is not illegal. In some settings, the legitimacy of government action would affect the enforceability of the action, either on the part of government against a person subject to that government's rule or on the part of a private citizen against the government. Hence, to provide legitimacy to act electronically can only be conferred by legislative measures and supported by an effective legal framework. This framework should be capable of identifying and addressing legal obstacles to e-government. Legal obstacles may include the differences that exist between traditional data collection requirements (i.e., sharing information collected by and provided to various government agencies) and the ease of collecting and sharing data electronically.

Legitimacy also turns on the standards of appropriateness. What kind of qualities should e-government action

have, or what standards should it meet in order to achieve the desired level of legitimacy? In certain situations, an electronic process would prove to be good enough to meet its legal needs without regard to whether it is comparable to or as good as its prior process. At the other extreme is the situation in which electronic conversion would require a complete reengineering of a course of action in order to address the legal risks and issues that a particular system presents or that are not being addressed as effectively in the existing system. Since due to lack of resources, most developing countries would still depend largely on their existing paper-based systems as a reference point in their analysis, the legal framework would require them to have a point of compatibility, which would be quite unique for developing countries. As the situation stands, at least in the near future, most of these developing countries would require having both systems of transaction. In order to achieve the legislative revisions, enactment would be required, as current laws, rules, and regulations might not recognise the legality of electronic documents and processes. For example, legislation should ensure that electronic authorisations, contracts, and signatures would have the same legal effect as those on paper. (However, due to the nature of technology, giving them the same legal effect may change or even eliminate the traditional ways in which these items are completed, such as notarizing a document). Additionally, governments may consider the required quorum at meetings to be met through the electronic participation of officials rather than by the officials' physical presence.

It can be said that much of what a government or those who deal with a government would look for in an electronic communication is a latent degree of assurance regarding the security of communications and their sources, or who sent them. Any user would be concerned primarily about the integrity of the information communicated in the sense that it is trustworthy and that it has not been altered since it was sent. Similarly, the concern also would be about jurisdiction; however the issues relating to jurisdiction would be similar for both developed and developing countries. The only point of concern is how it would be addressed. E-government for developing countries also would put the judicial system of these countries to test. Generally, the judiciary in these countries is not always in tune with the use and advancement of technology.

Electronic communications appear particularly susceptible to attacks on privacy. In most of the developing countries, privacy is a softer issue, and hence, even with proper legal framework, it can be argued how far privacy of personal information would be maintained. Likewise, fair access to public services is one element that would bring back the issue of digital divide within the developing countries—providing facility to the more able citizens. At some point, this would cause the law to impose constitutional limitations on government's ability to move wholly online in order to maintain equality (Krebs, 2001). The legal status of government documents is always of high importance simply because of the weight of authority. People see this in the priority they frequently are given in evidence statutes. This could be considered as a higher form of authenticity accorded to these records, but it has an impact on the demands made of electronic communications, so that they would deserve the same respect that paper documents receive. Pushing this theme further, it can be argued that the integrity that the public expects of government communications is not just that they are unaltered but that their content is true. That is not a question of the medium used.

Finally, government use of electronic communications has to be politically acceptable to the opinion makers of a society. No amount of technical excellence can guarantee that any manifestation of e-government would meet this standard. One does hear from politicians and sometimes from business people that government should lead the way to making people confident about electronic communications being safe and effective. This is a technical aspect of the legitimacy argument that proper government use can encourage general use of paperless records, but how far the governments in developing countries and, particularly, the politicians themselves are comfortable with the technology is a matter of debate. Not all of these concerns are related specifically to developing countries, and neither do all these concerns rise to legal consequences. Any discussion about e-government for developing countries could not be made without discussing these issues; however, the difference is in the level of priorities. Some factors would play more important roles in some governments than in others. Ideally, a legal framework that allows for the implementation of e-government processes and services will do the following:

- Preserve basic public policy goals such as privacy and security, retention, and public access to information.
- Provide the statutory basis of, authority for, and regulations related to the government processes and services that may be supplied electronically.
- Assign responsibility for and ownership rights to the data provided and accumulated electronically.
- Address the sharing of data collected by one government agency with other government agencies that require the same information.
- Clearly define jurisdictional responsibilities related to intergovernmental transactions and business-to-government transactions.

- Provide a mechanism by which legal requirements are recognised and enforced.
- Provide a basis for the establishment of fees related to electronic processes and services.
- Identify the records that should be maintained, the period of retention, and the required storage media.
- Not be technology-specific or favour one form of service delivery (traditional or electronic).
- Minimise costs and the potential for litigation.

## FUTURE TRENDS

### Technology Leapfrogging for a Connected Future

There has been much discussion on the issue of convergence of less developed economies since the classical work of Solow (1957). Solow's (1957) studies highlighted that poor and developing countries will converge faster than the developed countries, when the capital stock and output are lower than their steady state levels. One of the key assumptions in these studies is that developing countries have access to technology and markets that is equal to developed countries. However, several empirical evidences showed that these assumptions may not hold.

The feasibility of having a successful e-government is directly dependent on the government's overall ability and readiness to spend money on the necessary information technology and related costs (Basu, 2004). There is a substantial spending difference between developed and developing economies, which is quite apparent if we look into conventional budgetary structures. An e-government infrastructure in general comprises network infrastructure, security infrastructure, application server environment, data and content management tools, application development tools, hardware and operating systems, and systems management platform. However, many developing countries do not have the technology to develop the infrastructure necessary to deploy e-government services throughout their territories. A constructive way to overcome this problem is what is known as *technology leapfrogging*.

The specific use of IT to accelerate development and to promote economic growth often is referred to as technology leapfrogging—the implementation of a new and up-to-date technology in an application area in which at least the previous version of that technology has not been deployed (Antonelli, 1991). In developed economies, newer versions of technology often are used to upgrade older versions, but in developing economies, where older versions of technology often are prevalent, leapfrogging over the successive generations of technology to the most recent version creates more possibilities and often provides access to newer, more efficient, and often cheaper alternatives to traditional capital-intensive technologies (Working Group of the Pacific Council on International Policy, 2002)..

In the conventional view (i.e., as seen by technology developers and donors), developing countries passively adopt technology as standard products that have been developed in industrialised countries and that can be employed usefully and immediately. However, successful use of IT requires much more than mere installation and application of systematised knowledge. It also requires the application of implied knowledge regarding the organisation and management of the technology and its application to the contextual environment in which it is to be used. This implied IT knowledge often represents experience with the deployment of previous technology accumulated over time, such experiences contributing toward the shaping of new technology. If these earlier experiences are lacking, this may inhibit the accumulation of knowledge, which is required in order to make the new generations successful. Furthermore, new techniques frequently require modifications, if they are to be applied successfully to a new environment, and such modifications generally require a high level of skill.

The learning processes of organisations and societies often are constrained by their past practices, their existing knowledge base, and their propensity for innovation. Consequently, while leapfrogging may appear as an attractive option for late adopters, it may not provide the intended results in all circumstances. The greatest danger is that a new cargo cult may arise, where developing economies observe the benefits that later and succeeding generations of IT bring to industrialised nations. Hurrying to acquire the same technology, developing countries rely on the blind belief that similar benefits will quickly accrue to them. Such opportunities may exist, but a reality check is appropriate in order to protect the investment of the scarce resources available for IT in most developing nations and to distinguish between the circumstances where leapfrogging may or may not be successful.

As the situation stands today, it is in the interest of developed countries to play an important role in promoting technology adoption in developing countries with international organisations such as the United Nations or the World Bank providing the necessary funds. However, pushing e-government initiatives in order to achieve a significant impact on establishing a digital society and a connected economy could prove to be an elusive goal without proper investments in basic services such as healthcare and education. E-government solutions and approaches used in developed countries also may prove inadequate without a clear understanding of local constraints and conditions.

## CONCLUSION

E-government is an unlikely key for bridging the digital divide. The notion that technologies can prescribe their own courses of action is mythical; the responsibility for technological outcomes lies in the social order of individuals, groups, and institutions through which lives are organised (Shimmon, 2000). However, there is synergy to be created between technology and social context. This is not deterministic synergy; it will vary by context and, therefore, will entail adaptation of the technology and social context. If there is no prior experience in using computers, then there is probably no relevant social context. In some aspects, this may make it easier to introduce new technology, as there will be no old values or contexts to change; however, a context has to be created. If the existing context for information is informal or non-paper-driven, automation may be difficult. In both situations, new rules will have to be learned and accepted. When leapfrogging, one must be careful to identify both technical and social considerations, ensuring that technology is not embedded to the detriment of the social. Further, one should not assume that there is only one way to leapfrog; all social contexts will have one or more different leapfrogging solutions. As such, truly interactive e-governance remains a goal for developed and developing nations alike. Table 2 summarises some of the key challenges with which developing economies are faced in the development of e-government in developing countries.

*Table 2. Worksheet for developing economies*

| Key Challenges | Recommendations |
|---|---|
| Infrastructure Development | • Develop projects that are compatible with the economy's telecom infrastructure<br>• Consider public access kiosks and mobile centres if teledensity is low<br>• Introduce telecom competition and remove regulations on wireless and other digital technologies in order to accelerate deployment<br>• Bring connectivity to underserved areas and ensure sustainability<br>• Assess government's historic and current use of technology in order to learn from past successes and failures<br>• Establish a realistic development timeframe |
| Legal Framework | • Legislature must ensure that laws and policies support rather than impede e-government<br>• Policymakers implementing e-government must consider the impact of current laws and policies<br>• Consult with all stakeholders in order to assess how existing frameworks may impede the development of e-government<br>• Give legal status to online publication of government information<br>• Clarify laws and regulations in order to allow electronic filings with government agencies<br>• Reform processes by simplifying regulations and procedures |
| E-Literacy | • Be careful not to marginalise groups of people solely on the basis of e-literacy<br>• All e-government projects should include an educational component<br>• Provide aides at public access points to help train citizens in basic computer skills<br>• Ensure that content is in the local language<br>• Make sure that all user interfaces are easy to use and that Web site navigation is solid |
| Accessibility | • All governments must serve all members of society, irrespective of their physical capabilities<br>• All online services must be designed with global accessibility standards in mind |

*Table 2. Worksheet for developing economies (cont.)*

| | |
|---|---|
| Privacy | • This is one of the most important issues facing governments today<br>• Governments collect vast amounts of data on their citizens, and extra precaution must be taken to ensure the privacy of citizens' personal information<br>• Privacy issues must be addressed in the planning and design stages of all e-government systems<br>• Educate and train government officials in the importance of privacy<br>• Design applications that integrate privacy protections<br>• Minimise the collection and retention of personal information<br>• Limit access to the databases of citizen information by government employees |
| Security | • Security must be addressed early in the design phase<br>• Security breaches can shatter public trust in e-government, and getting it back is nearly impossible<br>• Trust is a critical component of e-government; without it, citizens will not use the systems<br>• A senior government official needs to be responsible for managing security issues; this individual must be knowledgeable in all aspects<br>• All government employees must be trained on the importance of maintaining the highest level of security<br>• All systems should keep information collection to an absolute minimum, and proper controls must be in place to ensure that databases cannot be compromised |
| Transparency | • Government transparency should be embedded in the design of all systems<br>• E-government can play an essential role in helping governments demonstrate transparency to citizens<br>• All Web sites should post rules, regulations, and requirements for all government services<br>• Citizens should be able to track the status of their online applications<br>• Many high-ranking government officials use the online environment to demonstrate principles of open government and transparency |

It is possible, however, that as developing countries continue implementing e-governance strategies, those with advanced foundations will address citizen needs in ways not yet seen in developed countries. The aim should be to provide citizens with convincing content and services that meet their essential needs. Perhaps the future is connected to the have-nots, but keeping them connected will be the real challenge.

## KEY TERMS

**Digital Divide:** The stratification of people according to access to interactive computer-based technologies; on one side, groups and individuals possessing the ability to participate within the network society and on the other, those who are absent or excluded from it.

**Digital Signature:** An authentication technology providing confirmation of origin, assurance of integrity of the content, and non-repudiation.

**E-Governance:** The strategic objective of e-governance is to support and to simplify governance for all parties (government, citizens, and businesses).

**E-Government:** Focuses on the use of new information and communication technologies (ICTs) by governments as applied to the full range of government functions. In particular, the networking potential offered by the Internet and related technologies has the potential to transform the structures and operations of government.

**Electronic Authentication:** A process that attests to the attributes of participants in an electronic communication or to the integrity of the communication.

**Information Communication Technology (ICT):** Includes any communication device or application encompassing radio, television, cellular phones, computer and network hardware and software, satellite systems, and so forth, as well as the various services and applications associated with them, such as videoconferencing and distance learning. It also can mean technologies used for accessing, gathering, manipulating, presenting, or communicating information.

**Legislation:** The act of making or enacting laws.

**Technology Leapfrogging:** The term for shortcutting technology development. This concept highlights the possibilities for developing countries to introduce state of-the-art technology and to become the first to adopt modern technologies.

# Legal Knowledge Systems

**Thomas F. Gordon**
*Fraunhofer Institute for Open Communications Systems (FOKUS), Germany*

## INTRODUCTION

There are many conceptions of e-governance (Malkia, Anttiroiko, & Savolainen, 2004; Reinermann & Lucke, 2002). Our view is that e-governance is about the use of information and communications technology to improve the quality and efficiency of all phases of the life cycle of legislation. In this conception, computer models of legislation play a central role. We use the term "model" in a broad way, to cover every kind of data model of legislation or metadata about legislation, at various levels of abstraction or detail, including full text, hypertext, diagrams and other visualization methods, and legal knowledge-bases using Artificial Intelligence knowledge representation techniques. The appropriate kind of model depends on the particular task to be supported.

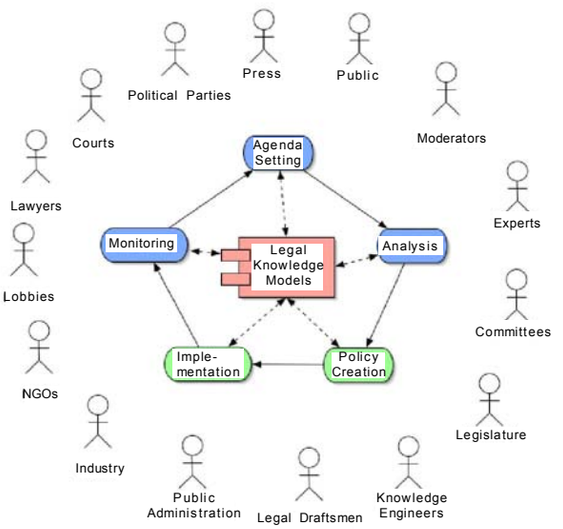
In this article, the focus will be on the use of legal knowledge systems (LKS) to support the implementation phase of the life cycle of legislation. Legal Knowledge Systems are also known as legal knowledge-based systems (LKBS). LKS can greatly improve the correctness, consistency, transparency and, last but not least, the efficiency of the administration of complex legislation.

The rest of this article is organized as follows. The next section explains the relevance of legal knowledge systems for governance. This is followed by a section motivating the use of LKS to support tasks in the implementation phase of the life cycle of legislation and providing a brief introduction to LKS technology. Next, various application scenarios for implementing public policy and legislation using LKS are discussed. Although research on technology for legal knowledge systems continues, it is a mature technology with many impressive applications in regular use by public administration. The article concludes by reiterating its main points and identifying open research issues.

## BACKGROUND

As shown in Figure 1, based on a diagram in Macintosh (2004), governance can be viewed cybernetically as a class of control systems. Many of the kinds of actors involved in governance are illustrated in Figure 1, including the press, political parties and lobbies, non-governmental organizations (NGOs), the general public and various governmental actors.

*Figure 1. The life cycle of legislation*



All phases of the life cycle of legislation create, use, maintain, or evaluate computer models of legislation and other sources of norms (e.g., regulations, court cases, and best practices). These are called legal knowledge models in the figure. One could distinguish between the full text of the legal sources and metadata, abstractions, or models of these sources, but for the sake of simplicity, a full text database of some legal source is viewed as a kind of computer model.

This model of governance leads to the following definition of e-governance: the use of information and communications technology to improve the quality and efficiency of all phases of the life cycle of legislation. In this conception of e-governance, computer models of legislation and other sources of norms play a central role. The appropriate kind of model depends on the particular task to be supported. In the rest of this article, the focus will be on ways to use a particular class of models, legal knowledge systems (LKS), to support the implementation phase of the life cycle of legislation. There are also important applications of LKS for other phases of the life cycle, in particular to support policy creation and legislative drafting. Conversely, other ICT technologies have a

role to play in the implementation phase, such as business process reengineering and workflow management systems. But these subjects require separate explication.

## INTRODUCTION TO LEGAL KNOWLEDGE SYSTEMS

Computer models of legal rules and regulations for helping public agencies to administer complex legislation are nothing new. A large part of IBM's growth in the 1950s was due to the successful adoption and proliferation of large data processing applications for administering taxes and social benefits in the public sector. From the beginning, computer models of legislation have usually been implemented procedurally: applying knowledge of the law and administrative procedures, a step-by-step procedure is designed and then implemented in computer code for guiding clerks through the process of applying the legislation. The overwhelming majority of software applications for administering legislation are still implemented this way, although modern programming languages, such as Java, are replacing COBOL and new software engineering methods for modeling procedures, such as activity diagrams of the Unified Modeling Language (UML), have largely replaced flow charts.

Procedural models of the law are expensive to build and maintain as the law changes. Since knowledge about the law is tightly intertwined in the procedural approach with knowledge about how to solve a particular legal or administrative task, it is very difficult to reuse models in different applications of the same law to reduce development and maintenance costs. In the 1970s, interdisciplinary research between lawyers and computer scientists began on ways to model the law and support legal reasoning, based on a deeper understanding of the law and legal processes (Buchanon & Headrick, 1970). An active international research community, going by the name of Artificial Intelligence and Law[1], was founded and grew in the 1980s. This community, as part of the larger field of artificial intelligence (AI), developed methods and technologies for modeling legislation, regulations, and case law and supporting a variety of legal reasoning tasks, using rule-based systems, case-based reasoning systems and other AI methods. See (Rissland, Ashley & Loui, 2003) for a recent overview of the Artificial Intelligence and Law field.

In the mid 1980s, the first prototype legal applications of rule-based systems for public administration began to appear (Sergot et al., 1986). Initially these were often called legal expert systems, because the focus was on modeling the expertise of legal experts. Today the broader term legal knowledge systems (LKS) is usually used. It is broader in two ways: (1) it includes the use of all possible sources of legal knowledge, especially original, authoritative legal texts, such as legislation and case law, in addition to the commentary or opinion of legal experts; and (2) it includes all ways of modeling legal knowledge using computers, such as case-based reasoning methods or so-called neural networks, in addition to rule-based technology.[2]

The first production applications of legal knowledge systems for public administration began to appear in the late 1980s and early 90s. The Australian company SoftLaw[3], for example, was founded in 1989. SoftLaw's entire business is based on "the provision of its legislative rule-based technology and related methodologies and services to test, capture, execute, and maintain the complex legislative and policy rules that are used by government and regulatory agencies to administer government programs."

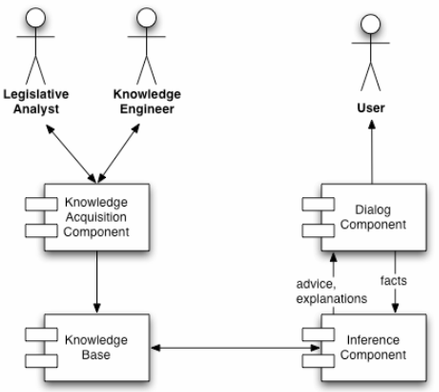
One of SoftLaw's first production applications was a rule-based system for the Australian Department of Veteran's Affairs, to help administer the entitlements of veterans to pensions and other benefits. An independent audit of the agency's performance had shown that decisions were often highly inconsistent, lacked adequate grounds or justification or incorrectly calculated entitlements. These quality issues were the primary motivation to reform the process using legal knowledge systems. In addition to resolving these quality problems, SoftLaw claims the use of LKS led to an 80% productivity increase.[4]

Some more recent projects and applications include a legal knowledge system developed for the Dutch Tax Authority in the context of the European POWER project (van Engers, Gerrits, Boekenoogen, Glassée, & Kordelaar, 2001) and a feasibility study for the German county of Herford on the use of an LKS to support clerks with the assessment of support obligations of family members for their elderly parents (Glassey & Gordon, 2005). SoftLaw collaborated with Northgate Information Solutions to build a Web-based legal knowledge system for the British government, called Assert, which helps citizens to assess their entitlements to a wide-range of housing-related welfare subsidies.In the United States, the Department of Labor has published over 20 legal knowledge systems on their Web site, to help employers and employees to understand their labor law rights and obligations.[5]

Although there are different approaches to building legal knowledge systems, at a certain level of abstraction they all have the same basic architecture and share the same set of features compared to the conventional, procedural approach to building legal decision-support systems (Fiedler, 1985). The basic LKS architecture is shown in Figure 2.

As shown in this figure, an LKS consists of four main components:

*Figure 2. Architecture of legal knowledge systems*



- The *knowledge acquisition component* is a specialized kind of computer-assisted software engineering (CASE) tool and integrated development environment (IDE) for legal knowledge systems. Notice that CASE and IDE tools are integrated in the LKS methodology. As in model-driven architectures (MDA), the executable application is generated automatically from its design; rather than programmed manually. Ideally, models of the law and regulations are cleanly separated from procedural knowledge about how to apply the law to solve a particular legal task. A knowledge acquisition component will include tools for separately modeling the relevant laws, task-specific procedural knowledge and related supporting documentation and a way to link these elements to define complete applications. Developing a legal knowledge base is a collaborative effort requiring software engineers specialized in knowledge systems, called knowledge engineers, and experts in the legal domain, such as legislative analysts. A knowledge acquisition component may provide particular support for the collaborative aspects of the knowledge acquisition process.
- The *knowledge base* component is a product of the knowledge-acquisition process. It is a declarative computer model of the selected legal sources.
- The *inference component*, also known as an *inference engine*, is the part of the runtime environment that applies the knowledge base and facts and other information provided by the user to generate questions, answers and explanations.
- The *dialog component* is the part of the runtime environment responsible for managing the interaction between the system and the user. It is responsible for keeping track of the state of the dialog, applying discourse and rhetorical knowledge so as to interact with the user in a supportive and collaborative way and translating between any formal representation languages used by the knowledge base and some natural language understood by the user. It is closely connected to the user interface of the system but not necessarily a part of it. Several different user interfaces, each with a different look and feel (e.g., for the Web, various operating systems, personal digital assistants or cell phones), may be able to use the same dialog component.

The advantages of LKS for implementing support systems for the public administration of complex legislation and regulations are manifold. Cleanly separating the model of the legal domain from task-specific, problem-solving code makes it much easier to maintain and verify the system as the legislation or regulation is amended. This reduces development costs and improves the "time to market" (i.e., the time required to get the revised system up and running), making the updated service available to citizens and other "customers" of the public agency. The ability of an LKS to generate clear explanations, with supporting references to the primary legal sources (statutes, cases, etc.), improves the transparency, acceptability, and traceability of administrative decisions.

The dialog component of an LKS provides a much more flexible form of interaction with users than conventional data processing applications. The conventional way is data driven: all possibly relevant information is collected from the user, by filling out a form, the data is then "processed" procedurally to produce an output and, finally, this output is formatted in a report. The interaction with the user in an LKS is goal driven: the user asks a question and the system asks for only as much input from the user as required for answering the question. The user retains control of the dialog at all times. The goal can be changed. Previous answers can be modified. The user can ask why a question is being asked.

In summary, legal knowledge systems provides substantial opportunities to improve the correctness, consistency, transparency, and efficiency of the assessment of claims, compared to conventional data processing methods.

## APPLICATION SCENARIOS

E-government applications are often categorized using a layered model, starting with the provision and dissemination of information, continuing with support for communication and collaboration between governmental

agencies (G2G), businesses (G2B) and citizens (G2C), and ending with providing support for transactions. The kinds of transactions that have been put online are typically quite limited. The usual examples include applications for dog licenses, change of address notifications or the registration of business names. These are all simple or "shallow" transactions requiring little or no legal reasoning. LKS provide the opportunity to broaden the scope of the kinds of transactions that can be brought online to include *deep transactions* (i.e., the determinative processes requiring detailed knowledge of complex legislation and regulations) (Johnson, 2000), such as social security or tax administration.

Johnson identified four application scenarios of LKS for supporting determinative processes: intelligent data collection, one-stop shops, outsourced services and, finally, self-service (Johnson, 2000).

Moving existing paper forms onto the Web, using for example the Portable Document Format (PDF), is reminiscent of early automobiles designed as horseless carriages. It fails to appreciate the full potential of the new technology. The *intelligent data collection* scenario makes use of the flexible dialog component of an LKS to provide a much more powerful, user-friendly and interactive way to collect information from a user. Since the dialog is goal-directed and problem-focused, only relevant data is collected. This enables the agency to reduce the time required of the user to provide the information or to collect more detailed, but still relevant, data without increasing the burden on the user.

The idea of a *one-stop shop* for delivering public services is to reorganize public administration by joining the front offices of various departments into a single front office. Although this is primarily an organizational change, it is made more feasible by the use by advanced information and communications technology. For example, e-mail and other forms of computer-supported communication can be used to help overcome the increased distance between front and back offices, which used to be located together in the same building. LKS also have a role to play here. If a one-stop shop is to be more than a pamphlet counter, it must be capable of actually delivering services and not just information about services. That is, front-office personnel must be capable of making administrative decisions requiring the application of detailed knowledge of law and regulations. Since a one-stop shop provides a wide variety of services, this is only feasible if the lack of specialist knowledge by front-office staff is compensated by the use of LKS and other decision-support systems. LKS empowers front-office personnel to reliably make correct decisions, without specialist knowledge of legal details. This scenario changes the role of the back office. Instead of processing forms to decide cases, the back office can take responsibility for developing and maintaining the knowledge bases needed by the LKS applications. Moreover, the shift of responsibility for processing applications and claims to the front office frees up capacity of the back office to perform more extensive and thorough audits, assuring information provided by users is correct and backed by sufficient evidence.

There is a trend towards *outsourcing* public services to private companies, for example by forming *public-private partnerships*. But responsibility for determining entitlements and making other administrative decisions requiring a deep understanding of complex legislation and regulations cannot be outsourced unless there is some way to assure the personnel of the private company will correctly apply the law. Legal knowledge systems provide a way to achieve this. The public agency retains control over the development of administrative policy, by creating regulations interpreting legislation and modeling these regulations in the knowledge base of an LKS. The explanations produced by an LKS provide an auditing trail enabling the agency to review decisions made by the private partner. Performance can be precisely monitored. New distribution channels for public services become feasible. For example, automobile dealers could perhaps process applications for car licenses, similar to the way they now serve as agents for insurance companies, and provide a one-stop shop for the "buying a car life event," including the whole package of a car, car insurance, and car license. If being able to provide this service helps to sell more cars, public administration may be able to outsource this service at low cost, or perhaps no cost. This scenario would be a win-win-win opportunity for consumers, car dealers and public administration.

The final application scenario for LKS we consider here is *self-service*, where a citizen or other user interacts directly with the LKS, for example via a Web interface, optionally with the assistance of a lawyer, tax consultant, or other personal advisor. This scenario is not as novel or ambitious as it may seem at first glance. After all, citizens and business are expected to know and abide by complex legislation when managing their daily affairs. And in some cases, public administration already expects citizens to process their own claims and applications, for example when completing their yearly tax returns. But LKS makes this way of delivering services viable for a much broader ranger of determinative processes. The benefits to public agencies include a reduction in the amount of personnel resources required for processing claims, freeing up staff for other tasks, such as policy development, auditing and monitoring. Citizens too would experience benefits. They would be able to process their applications from their home, at their own convenience. They would quickly obtain a decision, or at least a preliminary decision, together with a

thorough and comprehensible explanation. Finally, citizens would be able to analyze the legal consequences of hypothetical situations, to help them to plan for the future. This example shows how LKS not only can help to improve the quality and efficiency of an existing public service, but enable completely new services.

## FUTURE TRENDS

The cybernetic view of governance places legal knowledge at the center of the cyclic process of policy-making, legislative drafting, policy implementation and administration, monitoring and evaluation. Managing the life cycle of legislation is of central importance for governance. Since much work on governance focuses on organizational or communication issues related to the trend away from hierarchical towards networked forms of management and collaboration, the central role of public policy, legislation and regulations as the primary instruments for guiding and directing society may need emphasizing.

The important role of legislation for governance leads to an increased awareness and appreciation of the potential of legal knowledge systems for eGovernance. It can be anticipated this will lead to a renewed interest in legal knowledge systems by public administration.

Most efforts of public administration to bring transactions online have been restricted to shallow transactions, such as change of address notifications. Only when deep transactions are supported (i.e., those transactions requiring the application of complex legislation and regulations), will the full potential of information and communications technology for improving the correctness, consistency, transparency, and efficiency of determinative processes of public administration be realized. Legal knowledge systems provide an advanced and effective technology for realizing this potential.

Possible topics for future research include applying business process re-engineering methods to analyze the organizational implications of legal knowledge systems. How is the distribution of roles and required skill profiles affected? Can the efficiency and productivity increases reported in the literature be explained and confirmed? Another topic concerns possible dependencies between the complexity of legislation and legal knowledge systems. Is there a danger that the use of legal knowledge systems might exacerbate the trend towards ever more complex legislation? Or can the quality of legislative drafting be improved using LKS methods, resulting in simpler, clearer laws and regulations?

## CONCLUSION

Now that legal knowledge systems have been successfully deployed in a number of important production applications by public administrations in Australia, the Netherlands, the United Kingdom and the United States, and a small but growing LKS industry has emerged, there is every reason to believe that the time for a rapid adoption and expansion of legal knowledge systems in public administration has come.

## KEY TERMS

**Artificial Intelligence:** The branch of computer science which develops computer models of reasoning and problem solving methods and decision support systems applying such models.

**Cybernetics:** The science of control systems.

**Deep Transactions:** The processes of public administration which determine rights (e.g., for social benefits) and obligations (e.g., income taxes) by applying complex legislation.

**Dialog Component:** The part of a knowledge system responsible for managing the interaction between the system and the user.

**E-Governance:** The use of information and communications technology to improve the quality and efficiency of all phases of the life cycle of legislation.

**Inference Engine:** The part of a knowledge system which applies the model of the domain to the facts provided by the user to draw inferences, ask questions and generate explanations.

**Knowledge Acquistion Component:** The part of a knowledge system which provides modeling and other development tools for building and testing knowledge bases.

**Knowledge Base:** A computer model of the concepts, rules, cases, and other kinds of knowledge of some application domain.

**Knowledge System:** A computer program, or suite of computer programs, for developing and using knowledge bases to solve problems.

**Legal Knowledge Model:** Any kind of data model for legal knowledge, including full text databases, hypertext, diagrams and other visualization methods and legal knowledge bases developed using Artificial Intelligence technology.

**Legal Knowledge Systems:** A broad term used to cover all applications of information and communications technology for supporting the acquisition, use, structuring, dissemination and maintenance of legal knowledge.

## ENDNOTE

1 The leading international organization in the field is the International Association for Artificial Intelligence and Law (IAAIL), which organizes the International Conference on Artificial Intelligence and Law (ICAIL).

2 Legal knowledge systems are also known as "legal knowledge-based systems." But the trend is to use the term "legal knowledge systems." For example, the yearly conference of the JURIX Foundation changed its name from Legal Knowledge-Based Systems to Legal Knowledge and Information Systems in 2000. The name "legal knowledge systems" broadens the field to also include legal applications of knowledge management methods and technology and helps to emphasize that these systems are not only based on legal knowledge, but comprehensively support the acquisition, use, structuring, dissemination, and maintenance of legal knowledge.

3 The company SoftLaw changed its name to RuleBurst in 2005.

4 Of course, such claims should be taken with a grain of salt until they have been empirically replicated and verified by independent research.

## INTRODUCTION

As the Web is growing exponentially, the way of provision governmental information and services has been changed by the newly supplied technological capacities and digital channels. More and more governments all over the world are trying to acquire an electronic profile, in order to offer advanced services to their users (citizens and businesses). Two basic factors have significant contribution to this direction. The first considers the continuous increase of the users' daily needs (e.g., information searching, certificate requesting). Traditionally, the completion of these tasks implies a lot of valuable time to be lost in the tracking of responsible actor and in the waiting in queues. The second one refers to the ongoing access of the users with the Internet. This new way of communication facilitates the transactions and helps in providing better public services.

It is clear that e-government's successful development and operation demands proper design, which will comprise the basis for its application. Information and communication technologies (ICT) may contribute essentially to this direction, as long as government and users adopt them under the framework of a broader reorganization of the public sector. This adaptation can be implemented gradually in levels, which will enable the unobstructed data flow from/to government and will give the opportunity to citizens and businesses to obtain the highest access to the provided governmental services. Only under these circumstances, this transition will lead to a series of strategic, administrative and operational benefits (NOIE, 2003; OGC, 2003), for example, best coverage of users' needs, cost and time savings, and so forth.

This article is intended to present a level-based approach for the development of e-government services, starting from the lowest one to the highest and more complicated. Following gradually this sequence of technological levels and incorporating with strategy, coordination, and know-how, an organization can realize the vision of e-government, provide reliable online information and services to their users and improve their efficiency and effectiveness.

## BACKGROUND

Although the literature relating to this area proliferates, the definition and the various models of e-government are still unclear among researchers and practitioners of public administration. According to the E-Governance Institute (2004),

*E-governance involves new channels for accessing government, new styles of leadership, new methods of transacting business, and new systems for organizing and delivering information and services. Its potential for enhancing the governing process is immeasurable.*

Another quite broad definition, which incorporates its four key dimensions that reflects the functions of government (i.e., e-services, e-democracy, e-commerce and e-management) is the following:

*E-government is the use of information technology to support government operations, engage citizens, and provide government services.* (Dawes, 2002)

E-government can be distinguished into three basic categories: (a) *government to citizen (G2C)* that relates to the relationships between governments and citizens; (b) *government to business (G2B)* that relates to the relationships between governments and businesses; and (c) *government to government (G2G)* that relates to the

*Table 1. Pioneer countries in e-government*

| Country | Description |
|---|---|
| CANADA | Canada's e-government portal offers information and services organized by the target-group in which are attended (e.g. Canadians, non-Canadians, businesses, etc.). Departments and agencies, structure of the government of Canada, provinces and territories, municipalities, new initiatives for Canadians, government contacts, justice and law, public safety, and so forth are only some of the supported services. http://www.canada.gc.ca |
| SINGAPORE | Singapore's government Web site supports three portals for (a) citizens and residents (b) businesses and (c) non-residents. eCitizen is positioned as the first-stop for government services on the Web and enables users to search for and access a diversity of information, as well as to conduct a wide range of online transactions with government agencies (including culture, recreation and sports, defense and security, education, learning and employment, family and community development, health and environment, housing, transport and travel). eBusiness is a gateway to a host of government services ranging from accessing information that is pertinent to businesses, exploring governmental assistance, to filling in important forms needed to start or grow a business. Finally, the portal for non-residents provides information about visiting, relocating, working, studying or doing business in Singapore. http://www.gov.sg, http://www.ecitizen.gov.sg, http://www.ecitizen.gov.sg/nonresidents, http://www.business.gov.sg |
| UK | UK's portal constitutes a trial of British government to provide services via Internet. Today, the portal offers: guidance to government, judicial system, submission of applications for VAT, taxes return, registration to vote, finding local childcare, application to universities, agricultural subsidies from Commission, and so forth. http://www.ukonline.gov.uk |
| USA | USA also has early demonstrated a steady advance in e-government, which is close, related to the fact that they are one of the main providers of software and hardware solutions. The high penetration factor of American citizens in Internet has significantly contributed to reach this fact. Their first portal created for this purpose is an effort to gather all governmental web sites in one place (one-stop shop). http://www.firstgov.gov |

activities that improve and upgrade governments' services (Egov, 2003).

Table 1 presents some of the best practices in e-government worldwide.

## E-GOVERNMENT LEVELS

The application of e-government is not a trivial or straightforward procedure. It demands strategy, management as well as the use of technological tools for planning, design, implementation, and evaluation. So, the transfer from traditional government to an electronic one can be realized gradually in levels (Markellou, Panayiotaki, & Tsakalidis, 2003). These levels, beginning from lowest and advancing in most complicated, are depicted in Figure 1. Specifically, two paths can be identified: (a) the *obligatory upgrade* indicates that when the starting level of an arrow is implemented, then the ending level of the arrow must be implemented as well; and (b) the *optional upgrade* indicates that when the starting level of an arrow is implemented, then the ending level of the arrow may be implemented as well. Moreover, the presented levels are grouped into three sets: (a) the *obligatory levels* are the levels met during the obligatory upgrade path; (b) the *optional levels* are the end levels of an optional upgrade path; and (c) the *obligatory levels if certain path followed"* are the levels that must be implemented when certain optional upgrade paths are followed. In the following paragraphs the description of each level of the proposed approach is given. Levels 1, 3, 4, 5 are proposed for G2G purposes, while Levels 6-13 are proposed for G2B and G2C purposes.

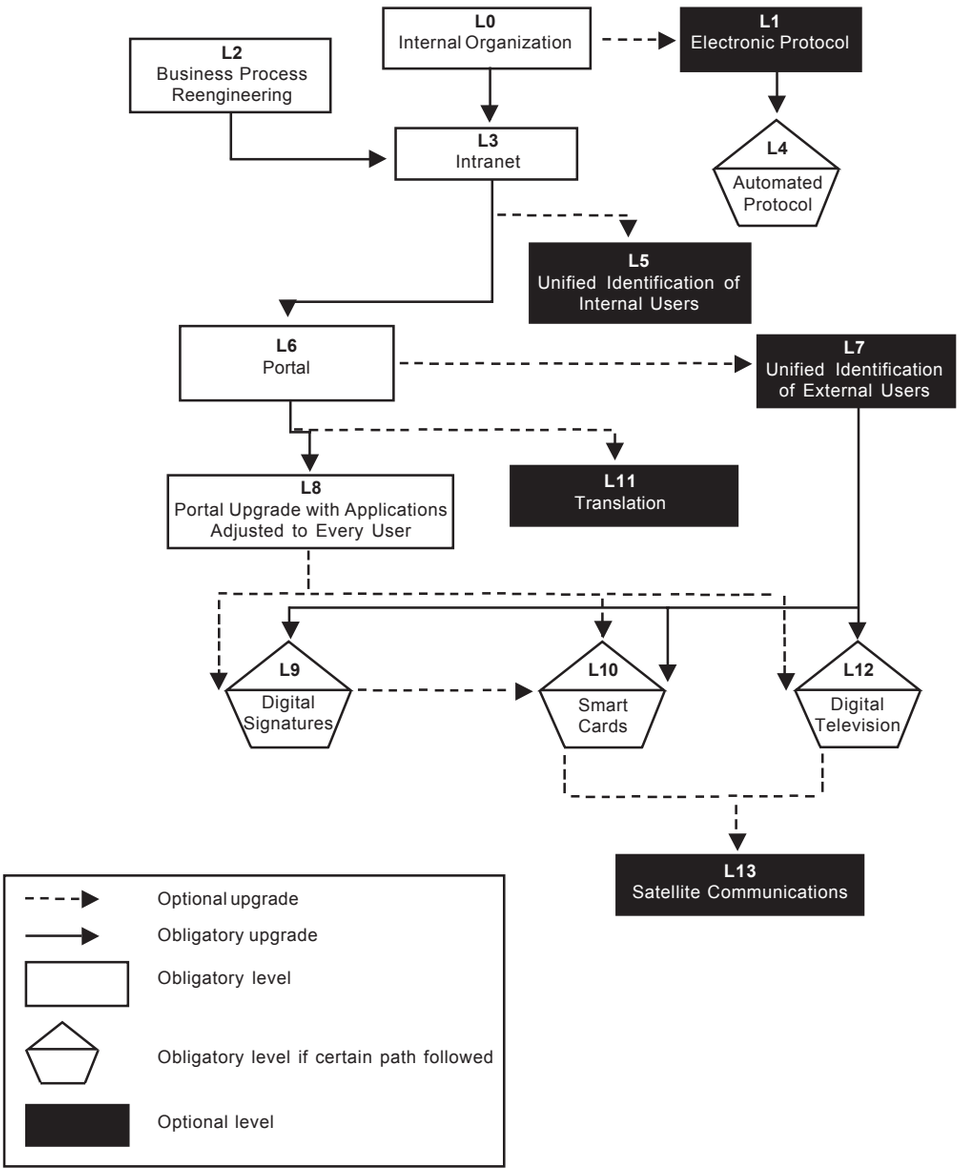
### Level 0: Internal Organization

The lowest level considers the authority's internal organization. This includes the supply of hardware/software infrastructure for office applications, as well as the necessary network interconnection. This level constitutes prerequisite for the implementation of the remainder levels in order to fully support e-government services.

### Level 1: Electronic Protocol

This level refers to the computerization of authority's documents with the passage from the conventional protocol (manuscript) to the electronic one (file). Specifically, the book of incoming/outgoing documents is suppressed and document distribution henceforth is kept electronically for timesaving and facilitation in document searching and recovering. Each service has its own protocol

*Figure 1. Application levels of e-government*



numbering, which is usually granted by the secretary of the specific authority manually.

## Level 2: Business Process Reengineering

This level includes (a) a feasibility study of documents' flow replanning, internal processes interrelation, and authority's flow chart processes preparation for the next level; and (b) specifications, planning and implementation of the applications that need modifications and improvements (legacy systems). The differentiation of each public authority, depending on the type and the breadth of their applications, is considered. For each authority, new levels of applications should be created after a feasibility study. For the passage to the following levels, all processes from the organizational side should be registered in order to achieve their unification and communication in the whole public authority. At the same time, it should be defined how the applications that are already used by authority's services are suitable to remain operational with small interventions and modifications.

## Level 3: Intranet

The authority's employees via a Web-based environment are able to use their departmental Intranet applications or other departmental applications without having installed them into their personal workstation. Except for the single logon facility (developed in forthcoming level) other functionalities may concern document management, workflow management, employees' calendar and to-do list, online library, telephone list, and so forth.

## Level 4: Automated Protocol

Level 1 automatically provides a protocol number to the applications it is required, without the need of manual use of electronic protocol. This application constitutes the input and output gate of documents and files that the organization manages in total. Its layout will provide the system ability of recording, monitoring, checking and informing the total of internal and external activities that are realized by the persons in charge of receipt and service of citizens, consequently the improvement of working conditions and the upgrade of provided services.

Segregation of the incoming and outgoing documents should be provided. Moreover, a separation of internal and external registrations from the authority's point of view is required for the distribution of documents. The communication among the software functional units should be safely realized with the use of encryption. The possibility of security gradation at the processing performed by the protocol is required and where it is needed, the document in question must be coded respectively.

## Level 5: Unified Identification of Internal Users

This level deals with the study, design and implementation of single sign-on (a common login/password for all applications that require one), which will correspond to one single internal user. Nowadays, at the several applications installed and used at governmental services, each employee/user has a different login/password to be identified as unique by the applications and to be able to access and use them. Within this level, a unique pair of login/password will be assigned to each user, enabling him or her to access all applications used internally in his or her service.

## Level 6: Portal

Level 6 deals with the implementation of a portal addressed to citizens presenting information on the public sector without the need of user authentication. Indicatively, it can contain information, such as announcements, online libraries, links to other e-governmental portals/sites, information searching, help desk, and so forth. Through this level, the government's image to the public seems integrated and not as a collection of different partial pieces. The citizen can be served by visiting a one-stop shop.

## Level 7: Unified Identification of External Users

E-government applications often need unique identification per citizen, and if possible single sign-on for all applications. Level 7 deals with the study, the design and the implementation of single sign-on, which will correspond to one single external user/citizen. This level applies to e-applications, accessed only by the citizen's personal attendance at the specific public department. The applications described at the following section, under the framework of Level 8 are not included at the applications mentioned here.

## Level 8: Portal Upgrade with Applications Adjusted to Every User

The main scope of this level is the portal update and enrichment with applications that demand external users' authentication, which varies from weak to very strong. The scope is the portal to permit several users' categories to access information and services according to the privileges granted to them. The portal's target groups/categories are citizens, businesses, ministries' and other public authorities' employees, organizations' employees, and administrators.

The portal should provide a central point of data accumulation and interconnection with several different applications and systems used by various participants, located in different sites. Therefore, the issue of security and the issue of personal data manipulation are of high priority and importance. For the portal's reliable and efficient operation, the definition of security policy is required. According to this policy, the citizen will use single sign-on to enter the specific location and will be recognized by the system until he logs out. The services provided by the portal relate to all the aforementioned users' categories and indicatively are: information interconnection of Internet sites, information search, retrieval and data submission for further processing, e-mails sending/receiving from public authority, discussion forums, and so forth.

Additionally, the upgraded portal may contain further functional characteristics, such as search engine with sorting capabilities, unified and automated users' support

through multiple communication channels (Web, e-mail), personalization for each user, 24/7 secure and layered functionality, with at least 99,99% availability, and so forth.

## Level 9: Digital Signatures

Digital documents are more vulnerable to alterations or forgeries, opposed to hard-copy documents. To avoid therefore the danger of unwanted modifications, digital signature processes have been developed, supported by cryptographic methods. However, the legalization must be firm, concrete and well established, in order for applications, documents and transactions demanding citizen's signature to be equivalent to their electronic versions digitally signed and sent from the citizen's workstation. A digital signature is not the electronic printing of the handwritten signature, as the term misleadingly implies. It is a "locked" abbreviation of an electronic document. This abbreviation could be characterized as the electronic document's fingerprint. The root of the process to create a digital signature are the cryptographic algorithms, which use different keys for "locking" and "unlocking" an electronic message. It fulfils mainly two functionalities (a) affirmation, as the receiver may be certain that the delivered message belongs to the sender, without any intermediate modifications and (b) confidentiality, as the receiver is assured that he is the only one who will read the message and not any unauthorized people as well. Supplementary cryptographic methods must be implemented to support confidentiality.

## Level 10: Smart Cards

Smart cards compose the most well-known authentication method of the people participating in transactions (Auerbach, 2003). These cards are capable of respecifying the data stored at their memory and can be used in advanced applications. Level 10 constitutes an advanced and secured authentication pattern, taking advantage of the characteristics of smart cards, in order for the citizen to use the portal and includes personal data encryption. At these cards, unique data on their owner are stored, used for their authentication, such as personal ID, as well as data relevant to the advanced applications, facilitating the smart cards' holders' transactions with the government, automating procedures, which in the conventional way are time consuming and demand bureaucracy and long queues at citizens' help desks, and so forth. Depending on each authority's peculiarities, a large number of applications using smart cards came up and can be classified to several layers according to their operational dimension.

## Level 11: Translation

Economic emigration, as well as free movement of persons within countries (e.g., E.U.) is a phenomenon that has abnormally increased recently. Additionally certain countries use more than one official language (Switzerland, Cyprus, Canada, etc.) All the services provided by e-government must fulfill the needs of multilingual citizens and nonnative emigrants, as they are enrolled in other countries' system. Level 11 copes with the adaptation of e-applications to multicultural environments. All the aforementioned functionalities must satisfy multicultural and multilinguistic requirements in order to satisfy all citizens, while searching for a job and transacting with e-governmental services.

## Level 12: Digital Television

Digital television (DTV) has been in development for more than a decade. Level 12's target is the citizen to access the portal via DTV, leading to the ultimate stage of e-government where each citizen (native and nonnative) accesses e-services through his television, in a way similar to zapping through television channels according to his preferences, as television is a communication mean more accessible and familiar to the average citizen.

## Level 13: Satellite Communication

Governmental executives take advantage of satellite signals (GPS) while traveling aboard in order to exchange information and opinions. This advanced stage composes the way of informing the governmental executives on the evolution of national affairs, during their traveling abroad due to their obligations, through satellite signal. Moreover, it provides the capability of sending information to the portal, in order to promptly inform the citizens, as well as of discussing with other executives and the citizens on vital governmental issues.

# FUTURE TRENDS

The transition from the traditional model of governance to the digital one, involves not only technological but also organizational, economic, social, legal and democratic dimensions. In this framework, a number of future challenges and risks have been identified and should be solved from both sides: government (e.g., complexity, poor IT infrastructure, human resources and financial constraints, legal issues) and users (e.g., lack of familiarity and trust, digital gap).

One of the most crucial barriers that e-government should overcome concerns interoperability. This requirement relates to local and regional public administrations, enterprise sector and it also goes beyond the national borders and involves other countries administrations. The interoperability of ICT systems and applications, the sharing and re-use of information and services, the interlinking of various administrative processes, within and between sectors are essential factors for the delivery of high quality, innovative, seamless and customer-centric e-government information and services.

Another point of consideration relates to the e-government requirement that information/services sharing both within and across organizational and administrative boundaries, should comply with personal data protection principles, laws and regulations. Generally involves the following tasks: digital data collection, data storage, data processing, data transfer, and data share. This, in its turn, affects the way e-government architectures will be designed and implemented.

Moreover, several issues related to privacy should be addressed. The future challenges and research in the direction of delivering e-services without jeopardizing– but in fact protecting- privacy relate to: standards support, intelligible disclosure of data, disclosure of methods, provision of organizational and technical means for users to modify their user model entries, user model servers that support a number of anonymization methods, and adapting user modeling methods to privacy preferences and legislation.

Finally, secure interconnection and intercommunication comprises key aspect and does not address only the advances in cryptography and protocols for secure Internet communication (e.g., SSL, S-HTTP). It also encompasses a whole range of policies, legal processes and operational guidelines.

## CONCLUSION

Governments, facilitated by IT and the Internet, promote and support e-government, aiming to more rapid and more efficient citizens' servicing. This attempt is not an easy one, since it demands correct and prompt design, infrastructures' availability at wide-scale and modification of citizens' mentality. Nevertheless, following gradually a series of levels, the transition from the traditional government to e-government may succeed. Existing conventional e-government implementations have subconsciously applied only Levels 4-6.

ICT may contribute essentially to this direction, as long as the state and the citizens adopt them under the framework of a broader reorganization of the public sector. The outcome will be the allowance of the unobstructed information flow from/to the public sector and the offering of the possibility to the citizens, as well as the businesses, to acquire better access to the governmental services.

It is also important to mention that the evaluation of e-government initiatives plays crucial role in their successful application and operation. The provided governmental information and services should be examined using various measures and criteria (e.g., security, privacy, usability, content, services, communication, citizens participations, disability access, multilingualism, and so forth (Bongers, Holland, & Vandeberg, 2003; Holzer & Melitski, 2003).

Finally, some arguments focus on the democratic processes, since it is difficult to ensure that all citizens have access to the necessary IT infrastructure in order to benefit from the available services (Spencer, 2003). Moreover, the use of e-government emerges the need of protection users' privacy and elimination of their personal information misuse (Earp & Baumer 2003; Kobsa & Schreck, 2003). The new technologies and products for protecting user's privacy on computers and networks are becoming increasingly popular. However, none can guarantee secure communications. So, electronic privacy issues in the foreseeable future will become highly crucial and intense.

## KEY TERMS

**Digital Signature:** A digital code that can be attached to an electronically transmitted message that uniquely identifies the sender. Like a written signature, the purpose of a digital signature is to guarantee that the individual sending the message really is who he or she claims to be. Digital signatures are especially important for e-commerce and e-government and are a key component of most authentication schemes. To be effective, digital signatures must be unforgeable. There are a number of different encryption techniques to guarantee this level of security.

**Digital Television (DTV):** It is a new type of broadcasting technology that will transform current form of television. DTV technology will allow broadcasters to offer television with movie-quality picture and CD-quality sound, along with a variety of other enhancements. DTV technology can also be used to transmit large amounts of other data into the home, which may be accessible by using one's computer or television set.

**E-Government:** This term refers to any government functions or processes that are carried out in digital form over the Internet. Local, state and federal governments essentially set up central Web sites from which the public (both citizens and businesses) can find public information, download government forms and contact government representatives.

**Government to Business (G2B):** The objective of G2B is to reduce burdens on business, provide one-stop access to information and enable digital communication using the language of e-business (XML). Moreover, the government should reuse the data reported appropriately and take advantage of commercial electronic transaction protocols.

**Government to Citizen (G2C):** The goal of G2C is to provide one-stop, online access to information and services to individuals. Citizens should be able to find and access what they need quickly and easily.

**Government to Government (G2G):** The aim of G2G is to enable governments and organizations related to them to more easily work together and to better serve citizens within key lines of business.

**Portal:** A Web site or service that offers a broad array of resources and services, such as e-mail, forums, search engines, and on-line shopping malls. The first Web portals were online services, such as AOL, that provided access to the Web, but by now most of the traditional search engines have transformed themselves into Web portals to attract and keep a larger audience.

**Smart Card:** A small electronic device about the size of a credit card that contains electronic memory and possibly an embedded integrated circuit (IC). Smart cards containing an IC are sometimes called integrated circuit cards (ICCs). To use a smart card, either to pull information from it or add data to it, one needs a smart card reader, a small device into which one inserts the smart card.

# The Lifecycle of Transactional Services

**Costas Vassilakis**
*University of Peloponnese, Greece*

**George Lepouras**
*University of Peloponnese, Greece*

## INTRODUCTION

Electronic government can be defined as the use of information and communication technologies in government for at least three purposes: providing public services, improving managerial effectiveness, and promoting democracy (Gil-Garcia, 2004). This definition recognizes transactional services (i.e., services that involve filling-in, submission, and processing of electronic forms) as a vital component of e-government, since public service provision and interaction between citizens and government is mainly modeled through such services (eEurope, 2000). It is worth noting that among the 20 public services included in (eEurope, 2000) as "first steps towards 'Electronic Government,'" 18 of them (90%) are transactional services, with the remaining two being informational services (information search and retrieval). Similar ratios hold for electronic services worldwide: for instance, the government of Dubai analyzed *all* services it offers and has concluded that 1,200 of these services are transactional, out of a total of 1,500 services (AmeInfo, 2004) (80%; again, the remaining services are informational). Historically, governments have first implemented informational services (provision of information related to the procedures and regulations related to governmental services), then proceeded with downloadable forms which can be filled-in and submitted manually (one-way interaction), subsequently moved to providing the ability to online submit forms whose data were processed later with human intervention (two-way interaction) and finally reached full electronic case handling (Cap Gemini, 2004).

*Figure 1. Expected benefits for electronic service users*

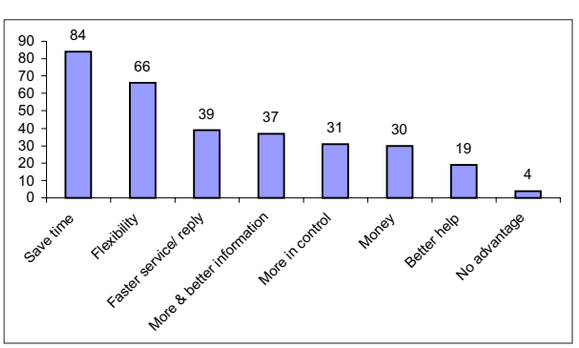

*Table 1. Development of e-Government in the EU*

| | Oct 2001 | Oct 2002 | Oct 2003 |
|---|---|---|---|
| Services fully available online | 20% | 35% | 45% |
| Services available online | 45% | 60% | 67% |

In the past few years, governments are systematically working on realizing e-government policies and frameworks, which include the delivery of transactional services for enterprises and citizens. Citizens and enterprises expect that provision of rich spectrum of transactional services will to result to a number of benefits, as reported in (Top of the Web, 2003) and illustrated in Figure 1.

The progress of these works have been quantified and evaluated in reports; notably, the reports (Cap Gemini, 2003; Cap Gemini, 2004) have targeted the e-government development status in the European Union and have produced results showing the developments and trends in the EU countries. Some interesting findings from these reports are shown in Table 1.

Note that services available online includes services a portion of which has been made available online, and some other portion is still carried out manually; services fully available online are fully processed in an online fashion and have no manual portion. A similar quantification approach is taken by the UN Global E-government Survey (UN, 2003), which identifies five stages of service delivery, namely, emerging presence, enhanced presence, interactive presence, transactional presence and networked presence, with interactive presence and transactional presence being the counterparts of online availability and full online availability (networked presence refers to a government-to-citizen framework based on an integrated network of public agencies for the provision of information, knowledge, and services). In this report, the average service online availability indicator for the top 15 countries is computed to be 63.8%, whereas the average service full online availability indicator is 20.2%[1].

The results of the studies presented above clearly indicate that despite the users' high expectations from transactional services and the governments' will and support for their development, the progress achieved insofar lags behind the desired levels. First, in the time frame of approximately one decade (governmental services have appeared on the Web in the mid-nineties), even the basic online services are not fully covered; moreover, the *growth speed* towards the full coverage is dropping (15% for the period 10/2001 to 10/2002 against a mere 7% for the period 10/2002 to 10/2003). Second, for services that do have a point of presence on the Web, full electronic case handling is provided only for the two thirds of them, while the remaining one third includes (at least one) stage that is performed manually. From the users' point of view, some pessimism can be identified in the issue of *better help*.

## BACKGROUND

The roots of the shortcomings identified in the previous section can be traced back to a number of challenges and particularities that pertain to the management of transactional services:

1. The domain knowledge needed for development of electronic service is highly complex (e.g., administrative legislation, tax regulations) and in many cases it is possessed by domain experts employed in the pertinent organizations in the form of *tacit knowledge* (Lam, 2000), which cannot be easily communicated to systems analysts that traditionally extract and catalogue the requirements for software systems.
2. The legislation and regulations governing the electronic services are volatile and subject to frequent changes. Such changes impact portions of the electronic services, which must be rapidly identified and adapted to meet the new regulations. Once components are adapted, the service should be redeployed.
3. The front-end accessed by citizens should be connected to the organization's back-office system, in order to provide fully automated services (Jupp, 2001).
4. The task force that is involved in service development is quite large and with diverse skills. This task force will consist (at a minimal basis) of domain experts, systems analysts and developers, user interface experts (necessary because the electronic service is targeted to people with little computer experience), HTML coders and security specialists (citizens and enterprises will be reluctant to use a service if they are not sure that their data will be safe (Vassilakis, Lepouras, Fraser, Haston, & Georgiadis, 2005). Cooperation and coordination in such a group is inherently difficult, not only because of the large number of the members, but also because of the different "languages" spoken by its members.
5. The users of the transactional services do not generally possess a high level of domain knowledge regarding the legislation and requirements of the business process that the services model. It is thus imperative that extensive help (explanatory texts, examples, and FAQs) is provided, especially for complex transactional services (e.g., tax return forms). It is worth noting that such "help items" are generally produced in the phases of user requirement analysis (while domain experts explain to system analysts the tasks that the software has to carry out), but they remain recorded as internal project documentation, rather that being made available to users for reference.

Note, that some of these challenges (especially 3-5) may apply in other contexts of transactional services (e.g., business-to-citizen services [including e-commerce]) or business-to-business services. In these contexts, however, the situation may be less complicated due to a number of reasons: for example, in e-commerce the required domain knowledge is much simpler, while in business-to-business services the users are usually trained personnel. In this work, we will limit our discussion to e-government transactional services, which appear to be the most demanding case.

Currently, transactional services are handled as "typical" software artifacts and are developed and managed using traditional software engineering paradigms, including the spiral model (Boehm, 1988), the waterfall model (Schach, 1999) and the rational unified process (Kruchten, 2000). All these paradigms include a user requirements analysis phase followed by software design, development and testing/evaluation before the final deployment. Different methodologies allow for iterative execution of various phases, for the purposes of modifications or refinement due to feedback from subsequent phases.

For the phases of development and deployment, in particular, a number of products have emerged in the past few years, showing that the software industry recognizes both the potential of the transactional services and the challenges related to their lifecycle. Commercial products include Adobe Acrobat e-forms (Adobe, 2004), PureXML E-Form (PureEdge, 2004) and Oracle E-Business Suite 11i™ (Oracle Corporation, 2004). These tools are however mainly addressed to personnel with IT expertise, and their main task is to relieve IT personnel from the burden of writing "routine" code that handles the interaction be-

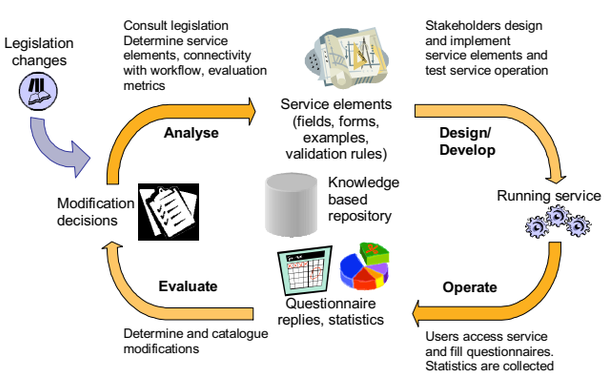
tween the user's browser and the Web server delivering the service. Although this is a significant aid to IT personnel, these tools cannot be used to tackle the issues identified above.

In the standards realm, the W3 consortium has published the XForms specification (W3 Consortium, 2002), which standardizes the specification of Web forms. A major contribution of the XForms standard is the separation of content, structure and user, which are modeled as form purpose, form presentation, and form data, respectively; however, browsers have not insofar incorporated support for XForm documents. Thus their usage remains limited.

## TRANSACTIONAL SERVICE LIFECYCLE

In order to alleviate the challenges identified in the previous section, a *transactional services development environment* has been designed and implemented, which supports all the phases of transactional services lifecycle, which are depicted in Figure 2[2]. Using this development environment, domain experts can directly input their knowledge regarding the transaction service (stemming directly from the analysis phase or pre-existing as individual tacit knowledge). This knowledge is codified into concepts of high levels of abstraction, such as fields, forms, or services, which are familiar to all stakeholders. Domain experts also attach to these concepts examples and documentation (usually expressing tacit knowledge) that will directly be used as help for end-users, and define *validation rules* (i.e., restrictions on the field values in the submitted documents) usually stemming from the related legislation. When documents are submitted through the transactional service, the field values should be checked to determine whether all validation rules are satisfied; if some of them are not met, the service user should be prompted to alter the values entered. Finally, domain experts attach *legal information* to the concepts, usually consisting of laws, directives, and regulations, which govern the operation of the service.

*Figure 2. Supporting the lifecycle of the transactional service*



Managers are a second stakeholder group that uses the development environment to define metrics and procedures for facilitating service evaluation. In particular, managers may define online questionnaires for service assessment by its users as well as statistics regarding the service usage (number of submitted documents, number of validation rule violations, time taken to fill in documents or document pages, etc.). Statistics may also be collected at a more fine-grain level (e.g., error rates of specific validation checks) percent of document submissions using specific fields and so forth.

IT staff is the final stakeholder group using the platform in the design and development phase. IT staff complements the information provided by domain experts with elements that are necessary for the operation of the electronic service. For example, users of transactional services should generally authenticate themselves by providing a user name and a password, which should be checked against some repository. Additionally, documents submitted by the users of the transactional service should be entered in the workflow of the service provider, in order to be processed and formulate the replies that will be returned to the service users. These are typical tasks that require IT expertise in the context of a transactional service. IT expertise may also be required in the design and implementation of the user interaction (HTML forms, active behavior [informational messages and alerts, automatic calculation of sums], etc.). IT staff finally may define statistics for technical aspects of service operations (e.g., form download speeds, CPU time needed for various tasks), which can help them fine-tune the service content and/or the platform delivering the service.

The information entered by all stakeholders is stored in an organization-wide knowledge repository (Figure 2). Such a repository is a valuable asset for organizations, since it promotes information sharing and reusability. For example, legislation regarding the authentication requirements for electronic services needs to be entered only once in the platform and will be readily available for all electronic services to use, while examples created by a domain expert for a service after a thorough study of the related legislation will be accessible by other domain experts that only need the "digested" information, without the need to go through the legal documents anew.

Once all elements for a transactional service have been defined, service deployment may commence. Service deployment is realized through a generative programming (Czarnecki & Eisenecker, 2000) engine included

in the SmartGov platform, the *Integrator*. The Integrator extracts from the knowledge-based repository the elements of the transactional service and translates them into a collection of files containing the visual (HTML forms) and the business logic (validation checks, data storage/retrieval, etc.) portions of the service; these files may be directly used for delivering the service to the public. For example, for each form of a service, the Integrator creates an HTML page containing an appropriate input widget for every form field. Moreover, validation checks that have been entered by domain experts in a high level of abstraction (e.g., "field *Gross Income* should be greater than field *Net Income*") are translated to code that implements these validation checks (e.g., *if (documentField["GrossIncome"].value<=documentField["NetIncome"].value) errorMessage("Gross Income should be greater than Net Income")*).

After its deployment, the service is put in its operational phase, with users accessing the service and submitting documents. Throughout the operational phase, the statistics defined in the design/development phase are collected and stored into the knowledge-based repository. Each statistical value is correlated with the concept it applies to, for example, the time needed to download a form is associated with the specific form, while the number of violations of a validation rule is linked with the particular validation rule (which is in turn linked with the fields it involves). This correlation facilitates the evaluation phase, since it is eases the task of locating service components for which specific statistics exceed a specific threshold or drop below it, giving thus indications that amendments are needed. For example, if the number of violations of a specific validation check is excessively high, more thorough documentation and examples may be provided; if users complain about the form readability (a metric that can be collected through online questionnaires), HTML forms can employ bigger font sizes; if portions of the service take long to execute, IT specialists may perform some optimization. The output from the evaluation phase is directed to the analysis phase, although in certain situations the design/implementation phase can commence immediately, skipping the analysis phase (e.g., a change in the font size only affects the implementation).

Another source of requirements for modification stems from changes in the legislation and regulations governing the electronic services. In such events, the linkage between legal information, entered by domain experts in the design/development phase, and service elements is exploited to locate elements that are affected by the legislation changes. Once the elements have been identified, the necessary maintenance activities can be undertaken; these activities may span across the analysis and the design/development phase, if revisions are major, or be limited to the design/development phase only. Naturally, the legal information should be updated as well, to reflect the current status.

The use of the platform has been evaluated by stakeholders that have participated both in the development and the usage of transactional services and the results are documented (SmartGov consortium, 2004b). The quantitative measurements have demonstrated that various aspects of transactional service lifecycle management improve through the use of the platform, including, for example, reduction of development and deployment time, improved services to the citizens, reduction of development/maintenance costs, etc. Moreover, the transactional service stakeholders have shown a very positive attitude against the platform, not only as regards to the platform usability and efficiency, but stating that the introduction of the platform constitutes an improvement to their working conditions as well, since they are promoted from mere information providers to active developers. This promotion additionally eliminates the shift of power barrier identified in (Vassilakis et al., 2005), according to which domain experts refrain from giving away their tacit knowledge for fear of losing the power and status associated with it; stakeholders are now accredited for the knowledge they offer, thus their status improved.

## FUTURE TRENDS

Most of the work, in the context of e-government services, has focused on the development of individual informational and transactional services, with various levels of sophistication. A natural next step in this area will be the promotion of service integration and interoperation, for providing added value to consumers of services, such as the handling of *life events* (Wimmer & Tambouris, 2002). Since the services involved in life events usually span across multiple governmental agencies, technical, methodological, and organizational barriers for such interoperations should be addressed. Holistic frameworks for electronic government, encompassing not only the provision of transactional services, but also the aspects of democracy promotion and managerial effectiveness (Gil-Garcia, 2004) will be also of essence.

## CONCLUSION

Transactional services are an indispensable component of electronic governance, since they are the primary means for delivering online public services. Administrations have made considerable progress insofar, but the inherent complexity and the special requirements in the

management of the transactional services' lifecycle are not satisfactorily addressed by current practices, leading in sub-optimal results in these efforts. This article has identified the critical issues in the lifecycle of the transactional services and has proposed a development environment and associated tools that can support organizations in the management of transactional services. With such tools, organizations can more effectively manage existing services and speed up the development and deployment of new services, bringing the vision of e-government closer.

## KEY TERMS

**Form Field:** In the context of transactional services, the electronic counterpart of areas that users fill in data (e.g., name, address, birth date, total income, etc.). A form field typically has a *label*, describing the data that the user is called to fill in and a *data type*, dictating the set of values that are allowed to be entered (numbers, dates, strings, etc.). Some fields may be "closed," (i.e., allow the user to choose a value from a list), whereas other fields may be *read-only* and not allow their value to be changed.

**Form Field Group:** A collection of individual form fields that model a compound concept. For instance, the fields "street name," "number," "zip code," and "country" can be combined to the form field group "address." The counterpart in a paper-based environment is specific areas on document forms.

**Informational Services:** Electronic services that provide information related to the procedures and regulations for transactions with the government. The services *per se* are not necessarily provided electronically.

**One-Way Interaction Services:** Electronic services that allow the downloading of electronic forms for the purpose of printing and manual submission.

**Transactional Services:** Electronic services that implement a complete transaction between the service user (citizen or enterprise) and the service provider (government). Typically, such services include submission of data by the service user, processing by the service provider and return of a reply (results of processing) to the user.

**Transactional Service Stakeholder:** A person playing a role in the development, deployment and operation of a transactional service. Typical stakeholders are managers (deciding which transactional services should be implemented and evaluating the operating transactional services), domain experts (who possess the domain knowledge for the modeling of transactional services), IT experts (who provide the technical know-how for the implementation) and end-users of the service.

**Two-Way Interaction Services:** Electronic services that allow the downloading of electronic forms, online filling, and submission of data. Processing of data and return of replies is performed in an off-line fashion by the organizational back-end.

**Validation Rule:** A business rule applying to the values entered in the form fields of a transactional service, and must be satisfied by all submitted documents. Typical examples of validation rules are "entering a value in field A is mandatory," "the value of field A should be in some specific range," "field A should be greater than field B," and "if field A is filled in, field B must/must not be filled in." More complex validation checks may also appear.

## ENDNOTES

1 The indicators in the UN survey appear smaller because (a) they consider a wider range of services and (b) they pertain to the period April-May 2003, giving a 6-month handicap to the Cap Gemini measurements.

2 This work has been performed in the context of the SmartGov project (Georgiadis et al., 2002; SmartGov Consortium, 2004a), co-funded by the IST framework.

# Maintaining Information Security in E-Government through Steganology

**Huayin Si**
*University of Warwick, UK*

**Chang-Tsun Li**
*University of Warwick, UK*

## INTRODUCTION

Traditional government structures are sometimes regarded as overly bulky. However, with the rapid expansion of interconnected computer networks and the progressive development of information technology (IT), it is now possible to exchange massive amounts of data at light speed over great distances. These infrastructures and technologies provide the opportunity for governments to transform themselves from huge monsters to compact and efficient organizations. Realizing the potential benefits of IT, as of summer 2004, 198 governments had started their e-government plans to construct digital government based on the Internet (West, 2004).

One of the essential features of e-government is the transmission of confidential information via computer networks. Depending on the sensitivity of the information, the security of some information should be treated at the same level as national security. Although each e-government has its own networks, no government can say no to the Internet, because it would be a waste of resource. However, the Internet is an open environment; therefore, protecting data flowing on the Internet from attacks is a pressing e-government issue.

All governments with such strategies have sought help from cryptographers and devoted huge amounts of both money and time to the development of specially designed information systems and advanced cryptosystems to strengthen information security. Unfortunately, cryptography is not adequate in some applications. As computing power keeps increasing and the techniques of cryptanalysis keep advancing, contemporary cryptosystems cannot and will not work forever. At the 24th Annual International Cryptology Conference (CRYPTO'04), MD5 and a series of related cryptosystems, which are currently in widespread use, were proved unreliable (Wang, Feng, Lai, & Yu, 2004).

From the last decade, *steganology*—the technique for digitally hiding and detecting information – is attracting more attention. It is already regarded as a powerful complement to cryptology and a promising technique for ensuring e-national security. Unlike cryptology, which renders the encrypted information completely meaningless, steganology keeps the host media perceptually unchanged after hiding the secret information. This article will provide an in-depth explanation of the two components of steganology, namely *steganography* and *steganalysis*, and discuss their potential applications in the realm of e-national security.

## STEGANOGRAPHY

Markus Kahn (1995) defined steganography as "the art and science of communicating in a way which hides the existence of the communication. In contrast to cryptography, where the enemy is allowed to detect, intercept and modify messages without being able to violate certain security premises guaranteed by a cryptosystem, the goal of steganography is to hide messages inside other innocent messages in a way that does not allow any enemy to even detect that there is a second message present." This definition has been widely accepted within the information security community.

The application of steganography can be traced back to ancient times. In 499 B.C., Histiaus shaved the head of his most trusted slave and tattooed an important message on his scalp. When the slave's hair grew back, the information was concealed and the slave was sent to Aristagoras, who then shaved the slave's head again to reveal the message, which instructed him to revolt against the Persians (Herodotus, 1992). That probably is the oldest instance of steganography. As the technique improved, invisible ink and microfilm emerged in modern applications. The watermark on bank notes is the most common contemporary instance of steganography.

In the modern world, steganography is a covert communication technology that allows secret information to be hidden in *cover message*/media. The resulting message with the hidden information is called the *stego message*.

Steganographic techniques can be divided into two broad categories: *digital watermarking* and *digital fingerprinting*. Digital watermarking focuses on the embedding algorithms and is used for purposes of copyright protection, authentication and integrity verification. The hidden information, namely, the *watermark*, in digital watermarking is relatively simple, normally the digital signature of the owner or a random pattern generated with a secret key. Digital fingerprinting concentrates on the method (sometimes referred to as protocol) of generating the hidden information, namely, the *fingerprint*, so as to meet requirements such as uniqueness and counterfeit-proofness. Fingerprinting techniques always utilize watermarking techniques to embed the generated fingerprint. In other words, the essential difference between these two categories is that the fingerprint embedded by fingerprinting techniques is unique for every single copy of the cover message, while the watermark used by watermarking techniques is always the same for all copies of the cover message and is related to the cover message and its owner. Different schemes of these two categories also have other special features to meet the specific needs of their applications.

Some other common properties of steganography techniques are as follows:

- **Transparency:** The distortion introduced by the embedding process should be imperceptible to humans so that the impact on the perceptual quality is minimized.
- **Robustness:** For most applications, such as copyright protection, survivability against all kinds of malicious attacks and incidental manipulations, such as lossy compression and format trans-coding, should be maintained unless the manipulations have rendered the content useless in some sense.
- **Payload:** Payload (i.e., the embedding capacity) is important for digital fingerprinting. Since the function of the fingerprint is to identify the individual recipient/buyer, the fingerprint should be long enough to provide space to keep the uniqueness when a huge number of copies of the cover message are to be distributed. In this case, embedding capacity is the deterministic factor of an effective fingerprinting scheme (Su, Eggers & Girod, 2000).

## Digital Watermarking

The idea of digital watermarking is to embed a small amount of secret information—the watermark—into the host media to achieve goals like copyright assertion, authentication and content integrity verification, and so forth. The superiority of digital watermarking over cryptography is that the latter provides no protection after the content is decrypted, while the former provides "intimate" protection at all times, because the watermark has become an inseparable constituent part of the host media. All the capabilities of a watermarking scheme, including the balance between the transparency and robustness to avoid any perceptible artefacts and the other properties to meet its special application, are dependent on the design of the embedding algorithm. To optimize performance, the embedding algorithm is always specially designed for a certain type of media, such as image, video, audio and so forth, to avoid any possible security gap. Digital watermarking schemes can be classified into three categories: *robust watermarking*, *semi-fragile watermarking* and *fragile watermarking*.

Robust watermarking is intended for the applications of copyright protection and digital rights management (DRM), wherein the watermark containing copyright information should be detectable after attacks that aim at erasing the watermark but maintaining the value of the host media. Cox, Kilian, Leighton, and Shamoon (1997) proposed the concept of spread-spectrum (SS) watermarking, which has inspired a great number of recent works in this field. Adopted from communication theory, the idea of SS watermarking is to treat the low-energy watermark as a narrow-band signal and spread it into multiple components in the spectrum of the host media, which is treated as a wide-band signal. By spreading the watermark in the spectrum, the energy of the watermark in a signal frequency is limited, and thus the robustness is guaranteed even when some frequency components are missing. However, the high robustness of SS watermarking is gained at the expense of low payload, so it is not quite suitable to the purpose of digital fingerprinting. To further improve the robustness without causing more artefacts, human perceptual models (HPM), including human visual system (HVS) and human auditory system (HAS), have been proposed and incorporated in the watermark embedding process (Barni, Bartolini & Piva, 2001). Feasible perceptual models facilitate adaptive watermark embedding in components where HPM is less sensitive.

Semi-fragile and fragile watermarking have been developed for the purposes of authentication and content integrity verification, in which the embedded watermark is expected to be destroyed when the attacks are mounted, so that the alarm will be raised by the detector when it fails to extract the watermark. The difference between these two sub-categories is that semi-fragile watermarking regards some designer-specified operations as non-malicious actions while fragile watermarking treats all kinds of manipulations as malicious. Counterfeit-proofness is a key objective (semi-) fragile watermarking schemes are expected to achieve. Counterfeiting attacks, such as cut-

and-paste, vector quantization attack and transplantation attack, are about replacing regions/segments in the watermarked media with fake patches/segments. This problem can be solved through correlating adjacent regions/segments of the media during the embedding process so that neighbors of the replaced regions/segments will raise the alarm in the verification process when the original regions are missing. Methods of establishing neighborhood dependency/correlation can be found in Li and Yang (2003) and Si and Li (2004).

While there are many watermarking schemes for images, audio and video, schemes for text are relatively scarce. Unfortunately, text is the dominating type of data in e-governments. Some published schemes, such as those developed by Huang and Yan (2001), focus on modifying the formations of the digital documents, such as font size, line spacing and layout. These modifications are imperceptible to human eyes but can still be detected by the decoder even after being printed and photocopied several times. However, this type of scheme depends on the formations of the documents so much that re-typing the text is always an effective, albeit awkward, attack. Attackers with an optical character recognition (OCR) system, which scans and digitizes printed documents, will find that defeating the security of watermarked textual documents is a trivial task. Much more effort needs to be expended, therefore, to increase levels of security in this area.

## Digital Fingerprinting

A digital fingerprint is a unique pattern/message to be embedded in the host media for identifying the recipient. Digital fingerprinting cannot resist illegal copying, but it enables the copyright owners or media distributors to trace the recipients who leak or redistribute the fingerprinted media.

This section begins with a discussion of some of the terms used in the description of fingerprinting (Boneh & Shaw, 1998). A *mark* is a position in the host media, which can take one of $k$ values, and a *fingerprint* is a collection of $l$ marks. Therefore, a total of $k \cdot l$ fingerprinted copies of the host media can be produced. A *distributor* provides legal copies with different fingerprints to the *users*, and a *traitor* is a user who illegally redistributes his or her fingerprinted copy to potential *attacker*($s$). The main vulnerability of digital fingerprinting schemes is the possibility of a *collusion* attack, in which a sufficiently large number of the fingerprinted copies are collected to detect some marks that differ in more than one of the collected copies. Based on those detected marks, the strength of fingerprints can be attenuated by averaging the values of the marks so as to create a new copy that carries no trace of the colluders' identities. Therefore, an additional requirement for digital fingerprinting is anti-collusion, which means that even after the attackers have gathered a sufficient number of legal copies, they still cannot detect and attenuate the fingerprints. More technical details about this process can be found in Trappe (2003) and Celik, Sharma, and Tekalp (2004).

Digital fingerprinting is applicable in the areas of *traitor tracing* and *anonymity protection*. The idea of traitor tracing is quite straightforward (Chor, Fiat, Naor, & Pinkas, 2000). Confidential data are secured with access control and anyone who has the right to access the data must have his or her identity or password known to the central system. The central system could generate the fingerprint according to this identity and embed the fingerprint into the copy before encrypting the data and allowing the fingerprinted data to be retrieved or sent via the networks. Should the fingerprinted data be leaked, the traitor could be traced by checking the fingerprint. Another extended application of this idea is document distribution tracing. As we know, sending a sensitive document through a channel to the destination/recipient should follow a process of recording and monitoring. To prevent forged documents being distributed through the channel, every unit/node in the channel should embed its fingerprint on the passing document, and the next unit verifies all the fingerprints that the document should carry. If all are present, this document is deemed authenticated; if not, it is forged and the source can be traced back based on the present fingerprints. Given the fact that embedding capacity is limited, the problem of the above idea is that when too many fingerprints are embedded into one media, the response of every fingerprint at the detector may be reduced below the threshold so that they cannot be recognized. Another problem is in distinguishing the embedding sequence of the fingerprints. Ongoing research is expected to perfect this application, however.

Voting is an important vehicle for ascertaining public opinion. Concerns surrounding the efficiency, accuracy and justice of traditional elections based on paper ballots have always existed. To overcome those problems, electronic voting systems have been undergoing development for some years. However, the potential impact of security breaches of electronic voting systems is far greater than with traditional voting systems. The use of fingerprinting could be of considerable significance in mitigating these concerns, however. A case similar to electronic voting is anonymous reporting, which helps governments fight against corruption and crime. The shared property of these two cases is that people do not want to reveal their identities and the government has to ensure that the anonymous action is trustable and non-malicious. Pfitzmann and Waidner (1997) introduced the idea of *anonymous fingerprinting*. A third party, namely, a *registration center*, informs the government of its

signature, and the anonym has to register with this center in a *registration protocol* in which he or she must prove his or her identity and get a certificate from the center. This certificate is registered in the center but contains no publicly derivable information about the holder. During the voting or reporting, the anonym and the government interact in a multiparty protocol: The anonym has to present his or her certificate signed by the center and gets a fingerprinted receipt; the government generates the fingerprint from the anonym's certificate and keeps the fingerprint as proof, but in fact knows nothing about the real identity of the anonym. If further verification is needed, however, the government could extract the certificate from the fingerprint and show it to the registration center as proof of the corresponding identity. More advanced anonymous techniques can be found in Pfitzmann and Sadeghi (2000) and Choi, Sakurai, and Park (2003).

## STEGANALYSIS

Functioning like the traditional government, an e-government also has the responsibility of monitoring public data flow. Currently, most governments believe that limiting the strength of public cryptosystems or banning them completely is adequate to ensure national security. For instance, the United States (U.S.) government restricted Microsoft Co. to selling their Internet Explorer software with the highest encryption levels (128-bit) before relaxing export controls in 2000. Another example is that PGP, a successful cryptosystem, was also banned by the US government at one time. From the point of view of a government, this may be a reasonable step to take as far as national security is concerned. However, it leaves the majority of Internet users exposed to privacy breaches. This situation drives the public to resort to steganography for their privacy protection. Because steganography works in such an imperceptible way, governments will have to face many difficulties in detecting covert communications. The consequence of failing to detect covert communications among international terrorists, for example, could be disastrous. So *steganalysis*, the opposite of steganography, may be even more important than steganography from the perspective of e-national security.

Steganalysis is the art and science of detecting or interfering with covert communications, which exploit steganographic techniques. Steganalysis includes three stages: seeking suspicious features, extracting the hidden message and destroying the message. While developing steganalysis algorithms for a specific steganographic scheme is possible, there is no systematic theory or general steganalysis technique available yet. See Chandramouli (2003) and Chandramouli and Subbalakshmi (2004) for the latest information about steganalysis.

## CONCLUSION

We have discussed the properties, roles and applications of steganology in e-national security in this article. Currently, the lack of attention being paid to steganology, especially steganalysis, by governments is a serious problem. This has dangerous implications in terms of both traditional national security and e-national security. While the benefits of steganography should be fully exploited, malicious uses of steganography should also be tackled through steganalysis. Compared to the rapid development of steganography, the slow progress of steganalysis is unsatisfactory, and therefore, more government support is necessary. Cryptology and steganology together function to protect different facets of a nation's security. Integrating the two disciplines is certainly a significant step toward better security against unwanted operations and higher privacy protection in our complex and ever-changing world.

## KEY TERMS

**Collusion Attack:** A coalitional act of removing digital fingerprints. It is based on the idea that both the position and content of the fingerprint embedded in every fingerprinted legal copy are different. If attackers obtain a large enough number of legal copies, they can garner sufficient knowledge about the positions of the fingerprints by comparing all the copies such that they could then arbitrarily modify the information on the positions so as to fool a fingerprint detector.

**Digital Fingerprinting:** The techniques of generating a unique fingerprint for each copy of a host media and embedding the fingerprint into a copy using the robust watermarking techniques. Because of the uniqueness of the fingerprint, digital fingerprinting can be used for tracing and identifying copyright pirates.

**Digital Watermarking:** A method of embedding secret information (watermark) into host media for the purposes of copyright protection, authentication, content integrity verification and so forth.

**Fragile Watermarking:** A category of digital watermarking that requires the embedded watermark to be un-extractable after any manipulation on the watermarked media. It is widely used in the applications of authentication and content integrity verification.

**Robust Watermarking:** A category of digital watermarking that requires the embedded watermark to be robust enough to survive any manipulations, malicious or not. Because of its robustness, digital watermarking schemes are widely used in the applications of DRM and Intellectual Property Protection (IPP).

**Steganalysis:** The art and science of detecting or interfering with covert communications, which exploit steganographic techniques.

**Steganography:** The techniques and theories of hiding secret information in host media without introducing perceptible distortion.

**Steganology:** The theories and techniques for information hiding. Steganology encompasses two opposite components—steganography and steganalysis.

# Managing Information Exchange in E–Government Initiatives

**Vincent Homburg**
*Erasmus University Rotterdam, The Netherlands*

## INTRODUCTION

In the literature on e-government, the focus is predominantly on the organization of the front office and on the interaction among governmental agencies and citizens (Chadwick & May, 2003; Edmiston, 2003; Tat-Kei Ho, 2002). However, in order for e-government initiatives to be successful, back-office streamlining also has to be taken care of (Bekkers & Homburg, 2005; Homburg, 2005a). In a sense, back-office operations are the backbone of any form of e-government, and they may require information exchange and knowledge sharing among various units, departments, or organizations.

The e-government phenomenon occasionally has paved the way for stirring rhetoric of technological and institutional change. For example, Wimmer, Traunmüller, and Lenk (2001) predict that "organizational boundaries will fade and give way to innovative organizational design. In this way, cooperation between administrative agencies will span wide: over distances, across organizational boundaries and even across hierarchical echelons" (p. 1).

Actual e-government applications, however, show that the practice of e-government may not be as attractive as some of its benevolent proponents might claim. Back offices can be regarded as networks of organizations in which goals necessarily do not overlap and in which interests may collide. In practice, in these networks, information is the primary medium of value and exchange (Davenport, Eccles, & Prusak, 1992), and relatively uncontrolled sharing of such a powerful resource threatens information monopolies and may provide those organizations who receive information with significant power gains (Bekkers, 1998; Homburg, 1999, 2001; Homburg & Bekkers, 2002; Markus, 1983). Consequently, existing dependencies in organizational networks might be affected, and it can be expected that the exchange of information in back offices invokes a complex mixture of cooperation and conflict (Cunningham & Tynan, 1993; Homburg, 1999, 2001; Homburg & Bekkers, 2002; Knights & Murray, 1992; Kumar & van Dissel, 1996).

In this article, I address the following research question: What does the nature and dynamics of interorganizational relations mean for the development and implementation of e-government information systems, and what methods and strategies are used to design and implement these systems? The focus in the analysis is on the interorganizational relations that are mobilized through the integration of various back-office systems (Bekkers & Homburg, 2005; Homburg & Bekkers, 2002). In the remainder of this article, I analyze existing e-government initiatives and, more specifically, information relations among various back offices, using a political economy view on information exchange (Homburg, 1999), and I explore methods and strategies of ICT process management in policy networks (de Bruijn, ten Heuvelhof, & In 't Veld, 2002).

## BACKGROUND

Many policy processes are fragmented over several administrative organizations. In practice, e-government requires information exchange and organizational redesign in the back office. From a strictly instrumental point of view, the information relations among various organizations can be modeled in terms of secure XML document containers (Greunz, Haes, Schopp, & Stanoevska, 2001) or, in terms of conversation rules, conversation classes and continuation rules using speech act theory (Heesen, Homburg, & Offereins, 1997).

At an institutional level, however, other sets of questions arise. These questions are related to the complex mixture of cooperation and conflict that emerges when organizations start exchanging information across traditional organizational borders (Bekkers & Homburg, 2005; Homburg, 1999, 2001; Knights & Murray, 1992; Kubicek, 1995; Kumar & van Dissel, 1996). In order to illustrate some of these questions, I present some anecdotal evidence of difficulties that arise when organizations exchange information across organizational boundaries. Since these difficulties are not typical for the public sector, I present anecdotal evidence from governmental organizations as well as from private sector organizations.

A private sector illustration is the TransLease information system, a system used by 1,000 British repair agents working for vehicle leasing and contract hire companies (Allen, Colligan, Finnie, & Kern, 2000).

TransLease uses standardized data formats throughout the network (which also enshrine the rules of trade) as the backbone of the system. In practice, actual use of the system proved to be far below expectations. An evaluation showed that the TransLease system did not provide the envisaged mutual benefits to its participants. "A dominant theme for repair agent complaints was their perception of an 'unfair' balance of power, which meant they felt that lease companies would tie them into a system that would reinforce and amplify existing power structures" (Allen et al., 2000, p. 10).

A public sector illustration is the Criminal Justice System in the United Kingdom (Bellamy, 1998). The UK has heavily decentralized and compartmentalized criminal justice agencies, including, for instance, the police, the probation service, and the courts. Early work on automated support centered on an elaborate dataflow model that showed the benefits of a new information system. It was soon clear, however, that the costs and benefits were divided unevenly among the parties involved and that the specific cultures and professional norms of the various agencies were not reflected in operational methods and information management priorities. Therefore, a more piecemeal, incremental approach was chosen, in which various professional groups (lawyers, police officers, probation officers, and prison officers) were allowed idiosyncratic discourses embedded in distinctive data definitions and standards, yet these distinctive domains were very selectively connected using EDI interfaces and e-mail links[1].

The TransLease and CJS cases are, to a certain degree, modest examples of problematic initiatives concerning information exchange among organizations. Obviously, in these kinds of situations, more than mere exchange of information is at stake. Beyond a rather neutral, technocratic account of the development of the information systems in the previously mentioned cases, information exchange takes place in political economies (Homburg, 2005b); with the exchange of information, dependencies among organizations are affected, positions are challenged by ICTs, and partly unintended and very fundamental questions about accountability are raised within the network of cooperating organizations. In this context, it is not uncommon for politicking, hoarding of information, or sometimes even downright sabotage to occur (Homburg, 2005b). Therefore, managing information exchange in political economies requires specific management strategies and tactics, which are analyzed in the subsequent section.

## INFORMATION MANAGEMENT IN POLITICAL ECONOMIES

### Analysis: Case Studies of Interorganizational Information Systems

In this section, the following two case studies of the development of interorganizational, back-office information systems are presented: the development of the Dutch Municipal Register of Citizens' Residential Data and the development of the Dutch Vehicle Registration. The analyses presented here are based on secondary analyses of evaluation reports of the two systems and on interviews and observations.

#### Case 1: Dutch Municipal Register of Citizens' Residential Data (GBA)

The Dutch Municipal Register of Citizens' Residential Data (GBA: *Gemeentelijke Basis Administrati*e) is an authentic registration in which name, address, date of birth, sex, nationality, and so forth of residents in The Netherlands are recorded. Since the 1970s, there has been a lot of discussion on the question of what an authentic registration of residential data should look like. Initially, the discussions revolved around the idea of a centralized register. However, a centralized architecture of such an information system raised fundamental issues concerning the protection of privacy and, moreover, concerning the institutionalized relationships among various levels of government (i.e., the central level and the local, municipal level). In 1984, a decentralized initiative—GBA—a was launched. The discussion on GBA involved the municipalities, which, at that time, owned paper-based registers: the Netherlands Association of Municipalities (the municipalities' interest association), the Ministry of the Interior, and a Project Bureau (established in 1989). The Project Bureau's original task was to develop, among other things, standardized applications on behalf of the ministry. Gradually, the idea of a decentralized register took shape. The register was to be used and partly administered by more than 500 municipalities, while the data were to be used by more than 300 public and private organizations. In the decision-making processes, with respect to the development of GBA, it became clear that various conflicts of interests existed with respect to the envisaged control over (or ownership of) the system. These conflicts existed with respect to the following domains:

- the control over and ownership of the GBA computer systems;

- the control over and ownership of the network connecting the separate systems;
- the control over and ownership of the data embodied in the system;
- the legal framework in which the aforementioned ownership and control issues were formalized;
- the division of costs and benefits over the parties involved.

In fact, it is possible to discern various arenas in the decision making with respect to GBA. An example of such an arena is the decision making with respect to the ownership and control over applications (system level). Originally, it was the task of the Project Bureau to develop applications. The municipalities, however, thought that this would jeopardize their autonomy, and they at least wanted to be able to select a system supplier by themselves.

Various elements of a political economy are present in the decision making with respect to GBA; over time, there had been disputes with respect to the question of whether there should be a centralized system or a decentralized system, and after the decision had been made to implement a decentralized system, there were more or less constant quarrels over control and ownership issues with respect to several aspects of the system. As a result, the composition of project teams changed as individual members left these groups and others joined them.

Eventually, in the process of waxing and waning, a solution was found by granting municipalities control and ownership over the data (municipalities were responsible for the acquisition, maintenance, and dispersion of data), whereas central government was responsible for the system level (i.e., development of a data model, on the basis of which eventually 15 system suppliers developed applications). Furthermore, the development of the legal framework took place in parallel with the development of the system itself.

## Case 2: Dutch Vehicle Registration (NKR)

The second case concerns the development of the vehicle registration (NKR: *Nieuwe Kenteken Registratie*). The registration was initiated in 1981 and eventually put to use in 1995. The goal of the registration was to identify owners of licensed vehicles and vessels. Uses are to be found in the fields of taxation, liability, criminal prosecution, traffic safety projects, and environmental policy. Because of this wide variety of uses, many of the following parties were involved in the development of the register: the Ministries of the Interior, Economic Affairs, Finance, Justice and Transport, Public Works, and Water Management. Furthermore, the Dutch Center for Vehicle Technology and Information and the Central Traffic Police Commission also were involved. Apart from these institutions, representatives from the automotive industry (i.e., auto repair agents) and post office branches were consulted.

The development of the register was carried out by a project organization and not only involved the development of the system in a technical sense but also required several changes in legislation. The intended system owner was the Center for Vehicle Technology and Information. As a consequence, this organization transformed from a relatively technically oriented expertise center to an information service provider for many governmental organizations, which, in this specific case, also involved the transfer of various tasks to this organization.

Many discussions took place in the project organization; as a result, the project organization's composition changed repeatedly. At the same time, a new piece of legislation (WVW: *Wegenverkeerswet*, Act on Roads and Traffic) took place, which affected the functional requirements of the register. In reconstructing the decision-making process, it is striking that, as happened in the GBA case, three arenas could be discerned: one in which the system was designed, one in which data ownership issues were discussed, and a legal arena in which changes in legislation were prepared. These arenas did not match exactly with the (sub)project that had been identified beforehand; moreover, issues concerning the system, data ownership, and legal issues evolved more than one moment in time and in various (sub)projects, and sometimes, at specific moments in time, issues were more or less explicitly related to each other (e.g., the data ownership and legal issues).

Eventually, it was decided to attribute data management issues related to general data (in terms of procedures for gathering, registration, manipulation, and dispersion of data) to the Center for Vehicle Technology and Information and issues related to specific data to various ministries; it was also decided to attribute system management responsibilities (system development, maintenance, educating personnel, etc.) to the Center for Vehicle Technology and Information. In this way, a division of tasks emerged that was intrinsically complex but more or less compatible with the (institutional) diversity of interests.

## Reflection and Lessons Learned

In the cases of GBA and NKR, political-economic logic resulted in very sensitive decision-making processes regarding the development of interorganizational information systems. It is striking that, in both cases, discussions and struggles over control and data ownership took place in arenas that did not overlap with the subprojects that had been defined beforehand. Moreover, arenas and (sub)projects were intertwined. Crucial to the

advancement of these initiatives was that solutions to the complex problems were achieved by coupling issues from various arenas at strategic moments in time (e.g., the coupling of legal issues with issues regarding system and data management can be characterized as making use of windows of opportunity rather than of deliberate prespecified choices). In the literature on complex decision making, there seems to be an increased appreciation for specific techniques that are expected to be able to better fit the dynamics and nature of networks and interorganizational relationships than do project management techniques; namely, process management techniques (de Bruijn et al., 2002; Homburg & Bekkers, 2002). By using process management, the fact is accepted that decision making takes place in various arenas that are not defined beforehand; the element of risk in terms of policy windows or windows of opportunities, as perceived by the parties involved, is a solution to problems rather than a phenomenon to be ignored. It is the explicit role of the process manager to have a sharp eye for policy windows as random events, as these events provide the opportunity to couple decision-making processes in various arenas. In doing so, it is very likely that solutions can be reached that are impossible to accomplish using regular project management techniques.

The development process of GBA and NKR probably is understood better from the point of view of process management than from the point of view of project management. Therefore, I claim that process management techniques provide a more fruitful alternative to project management techniques, as the former seem to be better able to deal with the dynamics and nature of interorganizational relationships than the latter can. Therefore, the use of process management techniques in the development of interorganizational information systems (and in the integration of back offices) provides a promising perspective on the problem of integrating the back office of e-government initiatives. Central to the idea of process management of (interorganizational) ICT is that managing interorganizational ICT requires attention to processes of consensus building and cooperative behavior rather than that of a step-by-step development of an ICT architecture. Since the process of consensus building and establishing cooperative behavior is very hard to achieve beforehand, process management's goal-seeking behavior (within general constraints) is more appealing than project management's goal formalization.

## CONCLUSION

In this article, I have analyzed information exchange that has taken place under the heading of two e-government initiatives. By using a political economy point of view on exchanging information in networks of organizations, it is concluded that information exchange is a very sensitive subject. This premise has been illustrated by presenting anecdotal evidence of the TransLease and NHS cases. In the interorganizational relations in which information exchange takes place, more than operational standardization takes place; moreover, with standardization of automated information exchanges, existing dependencies, positions, and interests possibly are affected. In practice, even data wars have been observed that were associated with the specific nature and dynamics of interorganizational relations. In the GBA and NKR cases, crucial to the advancement of e-government initiatives was the notion that actual development of information systems took place in various arenas (e.g., a system design arena, a data ownership arena, and a legislation arena) that had not been identified beforehand but that rather emerged. By coupling issues and decisions in various arenas, gradually, a goal-seeking management approach proved to be fruitful in overcoming painstaking conflicts of interests. This kind of management strategy and tactics is known as *process management* in the literature, and the cases in this chapter show that process management approaches are well suited to deal with the nature and dynamics of the habitat of e-government initiatives—networks and interorganizational relations. Process management techniques provide interesting and fruitful strategies to deal with the challenges and, therefore, are an attractive alternative to traditional management techniques in ensuring viable e-government initiatives.

## KEY TERMS

**Arena:** Set of actors that negotiate and seek consensus with respect to specific issues, guided by institutions and/or (often self-selected) rules.

**E-Government:** Redesign of information relations with stakeholders in the environment of the focal organization.

**Integration:** Standardization of data definitions and data models in or between organizations.

**Policy Window:** Opportunity for linking decision making in various arenas.

**Political Economy:** Mechanisms of exchange of information, (interorganizational) dependencies, interests, and power in or between organizations.

**Process Management:** Management approach (toward information systems development) focused on coupling decision making in various arenas, such as legal, organizational, and technological arenas.

**Project Management:** Management approach (toward information systems development), in which risks are being minimized by breaking down large efforts in small, controllable subactivities.

## ENDNOTE

[1] A similar case description exists for the Dutch value chain of penal law enforcement (Grijpink, 1997).

# Managing IT Outsourcing for Digital Government

**Yu-Che Chen**
*Iowa State University, USA*

## INTRODUCTION

IT outsourcing has become an increasingly important strategy in meeting the demand for digital government services in many developed countries. In the United States, government IT outsourcing is expected to become the fastest-growing segment of the overall federal IT market.[1] In 2002, the federal government spent US$55 billion on IT service contracts (Harris, 2003). The European Union also witnessed mega government IT outsourcing deals. One of the most visible deals is the British government's National Health Service modernization plan, which features a host of multi-year IT outsourcing contracts whose total exceeds £5 billion (Collins, 2004). Government interest in IT outsourcing will likely be sustained by growing interest in creating value for citizens (Accenture, 2002).

The confluence of many factors has made IT outsourcing an appealing option for governments around the world. Governments around the world are facing the challenge of delivering more services with fewer resources to meet the demands of their citizens and businesses. Information technology is able to increase efficiency in service production and delivery. However, alone, governments find it difficult to provide the financial resources and competitive wages which attract needed IT talent to deploy e-government services (National Academy of Public Administration, 2001). Against this background, outsourcing becomes a value proposition for government. With outsourcing, government can gain access to IT expertise while gaining efficiency derived from private-sector economies of scale. Nevertheless, good management is needed to realize IT outsourcing's potential for creating value.

This article focuses on IT outsourcing in the public sector, analyzing management issues, and offering practical solutions. The background section defines IT outsourcing as well as its associated benefits and risks. The next section offers a process-oriented practical methodology as a tool for public managers to navigate the entire life cycle of IT outsourcing projects. More importantly, this process provides a structured way to maximize benefits and minimize costs associated with IT outsourcing. Then, a discussion of future trends examines IT outsourcing issues on the horizon. This article concludes with a general set of recommendations.

## BACKGROUND

IT outsourcing by government is the utilization of external organizations for the production and/or provision of information technology services. This external organization is usually a company that provides IT services. The types of services include networks, applications, data centers, Web-hosting, and so forth. Britain's outsourcing of desktop operating systems and applications for the National Health Service, using Sun Microsystems, is an example (Sun Microsystems, 2004). Another example is the U.S. Navy-Marine Corp's multi-billion intranet outsourcing contract with Electronic Data Systems (EDS) (Wait, 2002).

Maximizing the benefits of IT outsourcing begins with a background analysis of its associated benefits and risks. The ultimate value of IT outsourcing lies in using information technology to transform business processes to meet the objectives of the organization (Accenture, 2003). It goes beyond merely having access to networks or more computing power. The real value comes from using information technology to reengineer business processes. This transformation entails better, faster, and more affordable services.

More specifically, the benefits associated with IT outsourcing include access to IT expertise, cost-savings, quick deployment, improvement in cash flow management, and flexibility in employment (Antonucci et al., 1998; Chen & Perry, 2003b). When a new major IT project is developed, governments often find themselves lacking the necessary IT expertise. This is due mostly to the fast-changing nature of information technology and government's competitive disadvantages in hiring and training skilled IT personnel. Cost savings are possible via leveraging economies of scale at the vendor side. For example, rather than building network capacity one government agency at a time, governments can outsource network services to network companies that can provide

identical services at much lower unit costs. Quick deployment is a natural consequence of the increased technical and financial capacities obtained through a service provider.

The benefit of cash flow management can be realized by arranging with private companies to pay only for ongoing services (Gant, Gant, & Johnson, 2002). The service provider provides the initial capital investments and recovers costs through service fees over time. Flexibility in employment is another benefit of IT outsourcing. Service providers are more flexible than governments when responding to changes in demands for specific IT skill sets.

However, IT outsourcing can also expose government to a number of risks. One is the loss of control over service level and service quality. Control is particularly difficult to exert when there is a large gap between what the government knows about service level and quality and what the service provider knows. With incomplete access to critical information, government may find it difficult to validate the claims of its IT service providers. Security is another risk factor, particularly when critical data is stored in facilities outside government perimeters. Government network-connected information systems supported by service providers may subsequently be subject to security threats. Moreover, training and background screening of IT personnel are important in addressing security threats.

Complex procurement processes and employment issues pose two types of risks for IT outsourcing by a government (as opposed to outsourcing by a private company). Cumbersome procurement rules and procedures in the public sector tend to prolong the negotiation and implementation of IT outsourcing contracts. Employment issues are particularly salient in government. How personnel are treated in an IT outsourcing deal may significantly impact the overall success of the project. The importance of this issue has been reflected in several recent IT outsourcing projects. For example, in one outsourcing project, the state of Pennsylvania guaranteed no lay-offs to ensure the support of the existing IT staff for the project (Tungate & Michael, 2002).

## MANAGING IT OUTSOURCING: A PROCESS-BASED APPROACH

Public managers play a central role in realizing the full potential of IT outsourcing while minimizing its risks. The proposed process model is generic for governments of diverse needs and types. The discussions below focus on individual phases in the process also address the public sector. The model presents a "process" that governments must undertake as they plan and execute IT outsourcing projects. Following this process and attending to issues as they emerge at each phase, significantly increases the chance of capturing the benefits of IT outsourcing while minimizing entailed risks.

This process-oriented approach requires that digital government managers adopt a different mindset. An IT outsourcing arrangement should be treated as an ongoing relationship that requires constant adjustments. This approach is best suited for complex public sector environments with changing political leadership and competing objectives. Moreover, an IT outsourcing arrangement, by its nature, progresses through a lifecycle (a process). The proposed process model consists of six phases and has been adopted and modified from Chen and Perry (2003a).

### Determination of a Sourcing Strategy

In the first phase, public managers need to define the sourcing strategy. This involves defining the government's strategic business goals and ensuring that IT aligns with them (McIvor, 2000). At this phase, the focus is on the government's strategic IT goals (i.e., affordable citizen-centric quality online services). The determination of sourcing scope and strategy requires an adequate level of internal IT management capacity. An experienced IT management team is more capable of assessing the associated benefits and risks. The proper level of IT management capability is critical for making informed selection of service providers, managing relationships, and making performance adjustments.

The sourcing strategy for government has three general objectives: continuous service improvement, business continuity, and compliance with relevant laws and regulations. In formulating a sourcing strategy, the organization must consider how to continuously improve service. Business continuity is another issue in determining the sourcing strategy. The strategy must provide sufficient safeguards against IT service disruptions caused by major disasters. The safeguards should be placed in a risk-management framework to help prioritize service items for business continuity. Compliance with relevant laws and regulations is another objective of the sourcing strategy. Thus, privacy, security, and employment regulations are likely to comprise the main issues.

### Analysis of Sourcing Needs and Operational Relationship

Translating the strategic objectives into specific sourcing needs and operational relationships is the main task of the second phase. Prior to considering a specific vendor, government first must specify the information system's functional requirements that enable the delivery

of strategic IT services. For example, business continuity may be defined by performance measures such as time required for bringing service back online after a major disaster.

When outlining possible operational relationships with service providers, government should take a partnership approach. This would involve identifying the strengths of a service vendor and specifying how those strengths may complement government operations. For example, Northern Ireland's health service was looking for a centralized data center solution to address its fragmented and increasingly costly databases (McCue, 2003). It sought a service provider experienced in data migration, system integration, and centralized data centers.

In determining the role that the service provider will play, government must examine each phase of the system development lifecycle as a systematic way of developing the functional requirements. These requirements will in turn give a clear indication of needed operational relationships. Armed with specifications for the functional requirements and operational relationships, public managers are ready to proceed to the next phase.

## Selection of Service Providers and Contract Negotiation

The first step of this phase involves continuing to build an in-house IT management team for the purpose of engaging service providers and reviewing contracts. This team should possess technical knowledge capable of evaluating the merits of competing contract bids. It should also be equipped with contract negotiation and management skills. Though outsourcing arrangements vary significantly, government must find service providers that can provide complementary operational competency as well as adaptive and integrative services. System integrators are preferred because they can manage system integration as well as adapt to change. Integrators are relatively more adaptive because they are not locked into a particular platform or application. They can deal with rapid changes in technology and service needs by introducing new products and services.

The IT outsourcing contract should be a service-level agreement that incorporates performance matrices, data stewardship, and penalty clauses. Performance matrices capture the measures used to monitor performance levels in critical areas such as uptime for business continuity, user satisfaction with overall performance, and ability to handle complex requests. Data stewardship addresses privacy and security concerns. The agreement must delineate the responsibility boundaries for securing data stored in an information system. Penalty and termination clauses—such as those featuring dispute resolution mechanisms, for example—should be established to address the possibility of unsatisfactory services or interruption of services (Lee, 1996). The signing of service contracts concludes this phase.

## Transition to the Service Provider

For government IT outsourcing, the transition encompasses both the employment and information system dimensions. Government must formulate and execute a comprehensive plan to smooth the transitioning of in-house personnel affected by the project. This may involve training programs or employment opportunities with the service providers. Employment issues must be carefully addressed, as they may prove to be one of the most controversial items, particularly in light of political and regulatory situations surrounding any government agency.

The information system dimension includes data/system migration and system integration. The magnitude of this task depends on the complexity of the existing system, the quality of data, and the extent of change involved. During the migration, a protocol for protecting privacy and securing systems is necessary for accountability. This protocol must map steps involved in migrating data and systems.

Government should budget ample resources to manage the transition in both dimensions. This phase, compared to other phases, is probably the most resource-intensive. Much resource is required for cleaning the data, establishing common standards, and migrating to the service provider. Additional resources should be budgeted to cover unforeseen costs.

## Service Performance Management

This phase involves managing the service performance of the ongoing outsourcing relationship. One important objective of this phase for government is to align performance measures to the strategic objectives outlined in the first phase. During this period, service needs are likely to change due to changing circumstances in market conditions or regulatory requirements. In response, government should review its sourcing strategy to determine the changes needed for performance requirements or service enhancements.

Maintaining frequent and quality communication with service providers and key stakeholders allows government to better manage service performance. Communication has the purpose of addressing service problems and identifying tasks for continuous improvement. This effort can be enhanced with a performance management information system that can capture performance information (Rubin, 1997). Moreover, a dedicated IT manager

or management team is critical for success in managing service performance. This team needs adequate resources if it is to stay focused on the strategic goals, conduct continuous improvement, and facilitate timely exchange of service information and expectations.

## Contract Termination, Renewal, and Transition Management

This last phase involves managing the expiration of an existing IT outsourcing contract. This phase is least understood and discussed but of prominent importance in maintaining business continuity and improving future IT services. If not properly managed, governments are likely to see their services disrupted. Another possible challenge is contract transition from one service provider to another. Due to long-term dependence on the service provider and high costs of transition, government may find itself locked in by its existing vendor. Lack of experience and planning on the part of government may further impair its ability to navigate the transition (Peled, 2001).

During the selection of service providers and contract negotiation phase public managers have the opportunity to specify terms for contract termination, renewal, and transition. The clauses for termination and transition provide a structure and process for both the government and the service provider. These clauses should address both personnel and information technology assets. For example, San Diego County developed a specified depreciation schedule for each of its technology assets (Peterson, 2004). To avoid possible contract lock-ins, public IT managers should choose standard infrastructure and application solutions rather than developing customized ones.

To further ensure success in contract transition, public IT managers can develop a process specifically focused on human resources and physical assets. This process would incorporate issuing a request for proposal at least one year before contract expiration. Moving IT services back into government should also be considered as an alternative. The request for proposal should be supported by information gathered in the service performance management phase and it should involve a re-evaluation of sourcing needs and operational arrangement. This proposal should feature data and solutions that directly address the transition of staff members and information technology assets.

# FUTURE TRENDS

Public managers need to understand future trends in IT outsourcing to manage outsourcing effectively. The first important trend is the maturing of the IT outsourcing market, a maturity indicated by its expanding global scope. Global sourcing by European countries—as part of a worldwide sourcing phenomenon—will witness strong growth (Gartner, 2003, 2004). Outsourcing an entire array of IT services, such as outsourcing an entire business process, has also gained momentum.

Also, security and privacy will become critical elements in government IT outsourcing. In the U.S.'s 2003 federal budget, over a quarter of IT spending was security-related (Porteus, 2002). Since government is the last line of defense in disaster situations, government requires that contractors ensure business continuity by implementing needed security measures. Any government IT outsourcing project also needs to safeguard citizen privacy. For example, the European Union's 1995 Directive on the protection of personal data deals with confidentiality in the use and movement of data. It prescribes a privacy policy for EU governments to implement in IT outsourcing.

Another development is the growing popularity of partnerships between government and the technology industry. In the partnership model, financial risks associated with digital government projects can be shared. For example, the partnership model makes possible a wide range of financial solutions for the Interagency Public Key Infrastructure in the United States (Cahan, 2002). Of further benefit, the partnership model can help governments cope with rapid changes in technology and service needs, a critical capacity which may otherwise be unavailable in traditional purchasing models.

# CONCLUSION

IT outsourcing has become an increasingly popular way of deploying digital government services. With the maturing of the IT outsourcing market and increases in government management capacity, there is significant potential for transforming government's current use of information technology. IT outsourcing has the benefit of leveraging private-sector financial resources and technical expertise. Public managers can use IT outsourcing to deliver value to citizens while controlling risks. This article has offered a process-based methodology as a tool for public managers to realize the full potential of IT outsourcing. This process begins with identifying a sourcing strategy, culminates with on-going performance management of the outsourcing relationship, and ends with contract termination and transition.

The process methodology calls for a relationship-based approach focused on the entire lifecycle of an IT outsourcing project. The relationship-based approach

moves beyond one-time procurement thinking and seeks to map out a long-term relationship. An on-going relationship requires frequent adjustments, depending on market conditions and changing service needs. Thus, a performance management team is needed to maintain quality and frequent communication.

Several key recommendations can be drawn from the process model. First, public managers must constantly align every phase of the process to the strategic goals of IT outsourcing, focusing on quality and affordable service, security, and business continuity. Second, government must anticipate political and legal considerations surrounding an IT outsourcing project. Employment and privacy issues have legal implications for such projects. Finding a good strategic fit between government and its IT service provider may help sustain momentum in the event of changes in political leadership.

Frequent and quality communication among key stakeholders is also critical; such communication helps early on in the selection of service providers. Also, it is a critical ingredient for success in service transitioning and performance managing. Lastly, the commitment of top management and assurance of ample resources are essential for realizing the potential of IT outsourcing. When an organization invests in each stage of the process—from defining sourcing needs, finding strategic partners, to managing transitioning and performance—it determines whether the IT outsourcing project will fail or succeed at delivering high-level digital government services.

## KEY TERMS

**Business Process Outsourcing (BPO):** When organizations delegate back-office functions such as human resources to outside vendors.

**Digital Government:** The use of information and communication technology to deliver information and services to stakeholders including citizens, businesses, nonprofit organizations, government employees, and other units of government.

**Global Sourcing:** Sourcing practices that involve buying services from other countries and around the world. It is an emerging practice, particularly in the area of information technology.

**Interagency Public Key Infrastructure:** The U.S. federal government's goal of providing hardware, systems, standards, and policies necessary to secure electronic transactions across federal agencies.

**IT Outsourcing:** Utilization of external organizations for the production and/or provision of information technology services.

**Process-Based Approach:** An approach to IT outsourcing based on six phases as articulated in the article.

**Service Level Agreements:** Agreements that specify the performance metrics for specific services such as bandwidth availability and response times for queries.

# Managing Security Clearances within Government Institutions

**Lech Janczewski**
*The University of Auckland, New Zealand*

**Victor Portougal**
*The University of Auckland, New Zealand*

## INTRODUCTION

An Internet search (Google) on government + security clearances + policy indicates that at present, establishment of individual security clearances within the government departments (and within U.S. State Departments in particular) are based on two factors:

- Evaluation of the candidate past
- Need to know policy

Evaluation of the candidates past (done very often with the polygraph use) is aimed at establishing past activities of that person. Special emphasis is placed on finding possible contacts with organizations/countries hostile to the evaluating agency. For instance, all CIA agents must periodically undergo such tests (Mahle, 2005). The results would determine possible range of security clearances of an individual.

The *Need only policy* (discussed later in the article) is further used to adjust security clearances of individuals. We (the authors) we unable to find practical realization of the *Need to know* policy and the presented research is an attempt to cover this gap.

Managing information security depends on business environment, people, information technology, management styles—to list the most important. Within this domain, the following seem to be recognised as routine procedures:

- **Development of a Strategic Plan to Protect Information Resources of the Business Organisation:** Despite the existence of enough evidence indicating constantly increasing number of security violations and resulting losses, the majority of business organisations failed to develop their security managing strategic plans. Fifty percent of them do not have even a disaster recovery plan (Jordan, 1999). Without such a plan, any effort to tighten up security of information within the organisation is a non-effective procedure
- **Development of Information Security Policy (ISP):** ISP is a document that outlines the main checkpoints that are directed specifically at an individual organisation's operations (Forcht, 1994). ISP could be a page or many pages depending on the level of details of the checkpoint procedures (Leung, 1998).
- **Classification of Security Levels, Security Clearances, and Security Labels:** This is the domain of the security models, starting from classic Bell-La Padula, Biba and USA Department of Defence Orange Book models. Security levels deal with the classification of information in terms of its accessibility. Security clearances determine the rights of persons/program to access the data. Security label is a mechanism to match security levels and security clearances
- **Development of Reference Monitor:** Virtually every security policy can be modelled in terms of subjects (people and programs) accessing objects (information either in electronic form or hard documents). This view of security policy implies that some decision procedure should exist to decide which requested accesses should be allowed and which should not. It acts as a filter through which all access requests made by subjects must pass. The term "access" means rights to read a document only, or to change it, or even destroy. This type of filter has come to be known as a Reference Monitor. (Amoroso, 1994). There are numerous publications presenting research in the field (e.g., Janczewski & Low, 1998). The research concentrates mainly on the issue of how to build and run a reference monitor
- **Technical Issues Related to the Development of a Security Kernel:** The reference monitor manages the controlled access to particular information but there are numerous technical issues related to the development, implementation and running of a sys-

*Figure 1. Taxonomy of assigning security clearances methods*

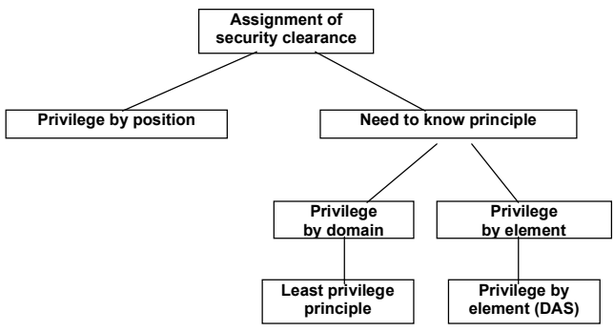

*Figure 2. Organisational structure of the department*

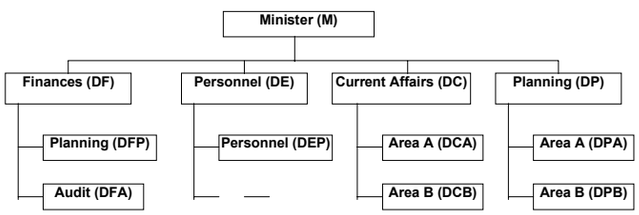


*Note: Abbreviations (in brackets) will be used later in the text to denote the positions*

tem in a secure way. "Secure way" means that information is protected against unauthorised access or change, and is available on request.

An analysis of the previous chain of security arrangements shows a significant weak point. It is the procedure of assigning security clearances to an individual. In a typical business environment, this procedure is based on the position of a given person within the hierarchy of an organisation. The general principle is that "the higher a person is within the company hierarchy the higher security clearance he or she must have." This approach clearly incurs significant problems. In the one extreme a person might have a security clearance that is too high for his or her job, which increases the total cost of the security system. Higher security clearance incur higher cost (for instance of security training). On the opposite side a person with a security clearance too low for his or her job must obtain temporary authority for accessing specific documents. This could be costly as well, time consuming and it could decrease the efficiency of operations. Portougal and Janczewski (1998) demonstrated in detail the consequences of the described approach in complex hierarchical structures.

A competing and more logical idea is to apply the "need to know" principle. Under this principle, everybody has access only to the information needed to perform direct duties. Unfortunately, this principle does not give adequate guidance to the management as to how to set-up security clearances for each member of the staff. Amoroso (1994, p. 298-299) describes the "principle of least privilege." The recommended application is based on subdividing the information system into certain data domains containing secret or confidential information of similar types. Users have privileges (or rights to access) to perform operations for which they have a legitimate need. "Legitimate need" for a privilege is generally based on a job function (or a role). If a privilege includes access to a domain with confidential data, then the user is assigned a corresponding security clearance. The main flaw of this approach is that a user has access to the whole domain even if he/she might not need a major part of it. Thus the assigned security clearance may be excessive. A similar problem arises regarding the security category of an object. A particular document (domain) could be labelled "confidential" or "top secret" even if it contains a single element of confidential (top secret) information.

*Table 1. Database elements listing*

| | Database elements | CP |
|---|---|---|
| 1 | Budget | 1 |
| 2 | Staff | 1 |
| 3 | Salary | 1 |
| 4 | Issues | 1 |
| 5 | Issues (by cost) | 1 |
| 6 | Issues (by department) | 1 |
| 7 | Budget (by department) | 1 |
| 8 | Salaries (by department) | 1 |
| 9 | Staff (by department) | 1 |

Another realisation of the "need to know" principle is based on data access statements (DAS), defined for every employee as part of their job description. DAS lists all data elements needed by an employee to perform his or her duties effectively. Thus the assignment of security clearance is shifted from the domain level to the element level. This approach allows not only defining individual security clearances, it also connects this problem to more general problems of the security of the organisation as a whole, including the problem of security cost and cost optimisation.

Figure 1 summarises existing methodologies of assigning security clearance to members of organisations.

## A GOVERNMENT FACILITY EXAMPLE

To illustrate the problem of data security in a government environment we consider the case of a government department. Within this department there are four divisions, each of them in charge of one or two groups of subjects. The "Current Affairs" division deals with issues directly related to the main thrust of the department activities.

It should be noted that:

- Each division deals with different subjects
- Each organisational unit employs at least one manager
- If a person has access to specific data but uses only part of it, it is assumed that he or she is using all of it. Therefore all data collected is used

The department has an information system. Table 1 lists all the data elements used within this organisation. Every data element has an assigned confidentiality parameter (CP), which characterises its importance from the point of view of security. For more about assigning CP's refer to Portougal and Janczewski (1998).

In this example, we assume that each data element is independent, so knowledge of a particular element does not allow one to find the value of the other. In order not to overcomplicate the example we assume all CP equal to 1.

Schuler (1992) defined the following components of a job description:

- Job or payroll title
- Job number and job group to which the job belongs
- Department and/or division where the job is located
- Name of incumbent and name of job analyst
- Primary function or summary of the job
- Description of the major duties and responsibilities of the job
- Description of the skills, knowledge, and abilities
- Relationship to other jobs

The job description is the best place to define the security clearance of employee through DAS. It could be, for instance, an additional "bullet point' in the previous list.

Formally DAS (Portougal & Janczewski, 1998) was defined as follows:

1. *Data access statements* (DAS) of a staff member is a vector, containing *data access statements elements* (DASE) as its components
2. Each DASE defines what type of access to information/data is allowed (read, write, delete, etc)
3. Each DASE is defined as a result of the analysis of the job description document related to the given position
4. Each DASE has a confidentiality parameter CP assigned (being an element of the organisation's database it should have the same value CP, e.g., from Table 1)

DAS statements for the organization presented in Figure 2 are shown in Table 2. The row numbers indicate corresponding DASE, like "1" denotes the Budget. The columns corresponds to each manager (the headers were taken from Figure 2. At the bottom row the total value of information accessible is shown (T). This is the SCV–*Security Clearance Value*, thus tying the assignment of a security clearance to the volume of accessible information.

## MODELLING SECURITY CLEARANCES

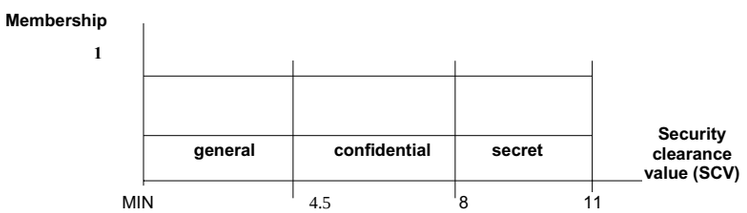
It is obvious that there is a correlation between security of the system, numbers of security measures, and their costs, for example:

***more security measures ⇒ more secure system ⇒ more costs***

*Table 2. DAS for all employees of the Ministry*

| | M | DF | DE | DC | DP | DFP | DFA | DEA | DEP | DCA | DCB | DPA | DPB |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | √ | √ | √ | √ | √ | √ | √ | | | | | | |
| 2 | √ | √ | √ | √ | √ | | | √ | √ | | | | |
| 3 | √ | √ | √ | √ | √ | | | √ | | | | | |
| 4 | √ | √ | | √ | √ | √ | √ | | | √ | √ | √ | √ |
| 5 | √ | √ | | √ | √ | √ | √ | | | √ | √ | √ | √ |
| 6 | √ | √ | √ | √ | √ | | | | | √ | √ | √ | √ |
| 7 | √ | √ | √ | √ | √ | √ | √ | | | √ | √ | √ | √ |
| 8 | √ | √ | √ | √ | √ | | | √ | | | | | |
| 9 | √ | √ | √ | √ | √ | √ | √ | √ | √ | | | | |
| T | 9 | 9 | 6 | 9 | 9 | 5 | 5 | 4 | 2 | 4 | 4 | 4 | 4 |

*Figure 3. Security levels (crisp representations)*



Many sources (only one source is listed) (Frank, 1992, Figure 1) indicate the previous correlation is not linear but rather has a tendency to grow exponentially. Similar situations exist in the case of assigning security clearances. The higher security clearance of an employee means a higher expenditure to the employer. The structure of costs would be somehow different from the security measures previously listed. The costs like those listed next would be of significance:

- Examination of candidate credentials
- Security training
- Security equipment (especially for accessing protected zones, either physical or system)
- Management of the system controlling the security clearances

Again one might expect that there is a correlation of security clearances with costs:

***higher security clearance granted ⇒ higher costs for the organisation***

The security clearances are designed to subdivide the employees of the organisation into classes according to data access privileges (e.g., secret, confidential, and general). Following the usual approach, borderlines should be drawn, defining the minimum amounts and importance of data in use for each category. Sometimes this subdivision is performed either by employees' position or by assigning security levels to data domains, and then using these levels for defining clearances. With the CP and SCV defined the problem becomes more logical to solve.

In our example (Figure 3), let us have three security levels: *general*, *confidential,* and *secret*. We shall define the borderline SCV between *general* and *confidential* as 4.5, and the borderline SCV between *confidential* and *secret* as eight. If the total SCV of information in use by an employee is less or equal to 4.5, then this person is not required to follow special security procedures at all, and he/she would be assigned a general clearance. If the total SCV is between 4.5 and eight, then the *confidential* clearance should be applied, meaning that this employee is under an obligation to use and follow all the security procedures defined for this clearance. Similarly, if the SCV of data in use is more than eight, then this employee should be assigned the *secret* clearance.

Though this procedure is simple and easy to understand, nevertheless it has two weak points:

1. This procedure implies that the security experts will be able to define the borderlines. In reality, it is not so easy, and sometimes the decision about the borderlines is provided by reasons well outside the model, for example by position

2. Under this procedure, it is hard to explain why employees with SCV close to the borderline from different sides have different clearances. What is the crucial reason for an employee with SCV equal to 7.95 has a clearance *confidential*, but his colleague with SCV =8.03 has *secret* clearance

Both points indicate an inadequacy in this security clearance model. Basically, the inadequacy comes from using a classical *crisp set* for modelling, like those used by Pfleeger (1997). The crisp set is defined in such a way as to dichotomise the individuals into two groups: members (those that certainly belong to the set) and not members (those that certainly do not). A sharp distinction should exist between members and non-members of the class. This is definitely not so in our case. The classes of security clearances do not exhibit this characteristic. Instead, the transition from a member to a non-member of one class appears gradually rather than abruptly. This is the basic concept of fuzzy sets.

In the first fuzzy model example it is assumed only two security clearance classes: *general* (set G) with no security cost and *secret* (set S) with a security cost *A* for each member of the class. The membership functions of class S are given in Figure 4. The vertical lines on Figure 4 represent the employees of the Department and the value of their membership function in the set S. The Minister and most of his or her deputies have the value equal to 9/9, Head of the Personnel Division has it equal to 2/9, Head of the Area B Planning Division has it equal to 4/9, and so on (as 9 is the total value of information within the Ministry).

If we assign to every manager the security clearance *secret*, then the cost of the security system will be equal to 13*A* (As there are 13 managerial positions in the company). If this is not affordable, then some of the managers will be put into G class. This involves a risk of information leak.

*Figure 4. Membership function for the fuzzy set "secret"*

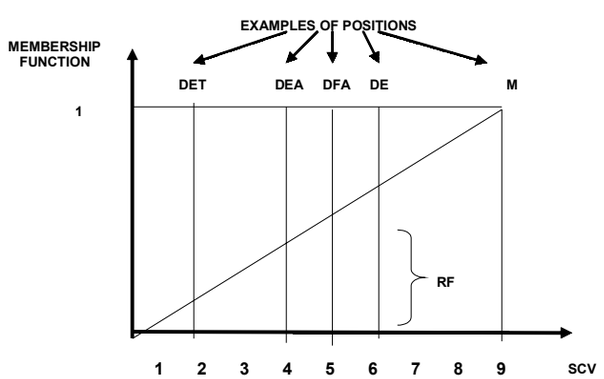


*Figure 5. Risk function and its cover by 3 classes G, C, and S*

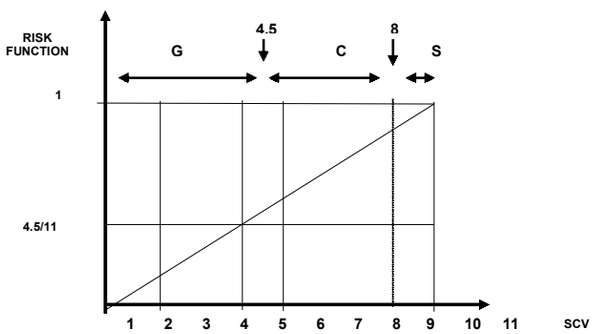

Let us assume that this risk is proportional to SCV (the more a person knows the higher is the risk). We shall introduce the *risk factor* (RF) for an employee *i* as:

$$RF_i = SCV_i / SCV_{max}$$

A good estimate for the *company risk factor* (CRF) would be either:

$$CRF_{max} = \max_i RF_i,$$

or

$$CRF_{av} = S_i RF_i / N,$$

where N is the total number of employees. $CRF_{max}$ characterises the risk of information leak from the most informed employee. It is better for evaluation than $CRF_{av}$, when the $SCV_i$ of the employees are diverse. Sometimes both are useful.

The risk factor can not be used directly for the evaluation of real security threats. It is only a coefficient in a more complex equation with unknown chances of a breach of security and losses from it. But the assumption of its proportional value to the security risk gives it a good comparative meaning (Figure 5).

Let in our example the department has a security budget of 4*A*, or that it can afford to assign the secret clearance only to four top three employees: M, DF, DC, and DP. The security risk factors will be:

$$CRF_{av} = (0+0+6+0+0+5+5+4+2+4+4+4+4)/9/13 = 4.2/13.$$

$$CRF_{max} = 6/13$$

If we increase the security spend to 5*A* (7.7% increase, one more person classified as S), then the $CRF_{av}$ will drop

to 3.5/13 (5.3% decrease), and $CRF_{max}$ would not drop by 7.6%. However there could be cases when there is no change of the $CRF_{max}$ . Then it cold be worth to think whether to increase the security spend or not. Thus, the main benefit of the CRF is the possibility to use it for comparing different assignments of security clearances.

Though the two presented models are too simplistic, nevertheless it shows the main problem of a security system design. The problem is that practically no organisation can afford a security system with a zero risk factor, and it is forced to look for a suitable trade-off between the cost and the risk factor.

We shall show that introduction of intermediate classes helps in security improvement without cost increases.

Let we introduce an intermediate clearance *confidential* (set C). We shall assume that the security procedures designed for this clearance eliminate the risk of data leakage for all employees with $SCV_i$ no more than 4.5. Let the cost of these procedures be $B = A/3$, and the security is $3A$. The possible variant of assigning clearances to employees is shown in Fig. 5. In this variant we sacrifice the clearance S for the DE, changing it to C, which incurs a security risk factor of (6-4.5)/13. The security risk factors will be:

$$CRF_{av} = (0+0+5+0+0+5+5+4+2+4+4+4+4)/9/13 = 3.2/13.$$

$$CRF_{max} = 5/11.$$

This shows a significant improvement in security estimates.

Generally, an analysis of both company risk factor functions $CRF_{av}$ and $CRF_{max}$ show the best way for their optimisation, but this analysis is outside the scope of this article.

## SECURITY MODELLING FOR DATA ELEMENTS WITH DIFFERENT CONFIDENTIALITY PARAMETERS

One of the assumptions of the described model is that CP is equal for all the data elements. This assumption restricts the area of this model implementation to the organisations that consider all data elements equally important. In most cases, the data elements are conceptually not homogeneous from the confidentiality point of view. It is not very difficult to accommodate this. Portougal and Janczewski (1998) suggested an expert evaluation procedure that helps to establish real values of CP from the point of view of security experts.

The method of calculating $CRF_{av}$ and $CRF_{max}$ stays the same but DASE would have different values thus shifting the position of an individual along the horizontal axis (Figure 3).

## CONCLUSION

The suggested method will improve the data accessibility and at the same time the security of information systems, which is very important for the digital government.

1. By introducing data access statements (DAS) as part of employee's work description, access to information is granted to every employee on the data element level as opposed to the existing practice of granting access on a domain level
2. We suggest changing the existing practice of assigning security categories to data base domains, and to assign instead a confidentiality parameter (CP) to every element of the database. The data base will be characterised from the confidentiality point of view in more detail
3. We showed that current crisp models of assigning security clearances do not include cost and efficiency optimisation. Instead we developed optimisation models, based on fuzzy sets theory
4. As a measure of efficiency of the security system we introduced the company risk factor (CRF), which makes possible to compare different ways of security organisation under a limited budget

Further research in this direction include the development of optimisation models, based on analysis of both company risk factor functions $CRF_{av}$ and $CRF_{max}$ and the structure of the set of feasible solutions. Another direction of research includes the development of models optimising costs of the security system under risk constraints.

## KEY TERMS

**Confidentiality Parameter:** Numerical expression of Security level.

**Data Access Statement (DAS):** A list of all data elements needed by an employee to perform her/his duties effectively.

**Data Access Statement Elements (DASE):** Elements of DAS. Each DASE defines what type of access to information/data is allowed (read, write, delete, etc).

**Information Security:** A discipline which deals with three important information parameters:

- **Confidentiality:** the prevention of unauthorised disclosure of information.
- **Integrity:** the prevention of unauthorised modification of information.
- **Availability:** the prevention of unauthorised withholding of information or resources.

**Information Security Policy:** The document reflecting all the decisions and activities for company employees in terms of protecting the information assets.

**Security Clearance Value (SCV):** A sum of all confidentiality parameters (CPs) associated with a given position of an employee.

**Security Clearances:** A security clearance is defined as a hierarchical attribute that can be associated with the users of an information system to help denote their access rights to the information. For instance in a business organization all the users having the secret security clearance may access all the information while holders of the confidential security clearance could only access the information labelled general or confidential.

**Security Levels:** A security level is defined as a hierarchical attribute than can be associated with entities within information system to help denote their degree of sensitivity. For instance, in a business organization, all the information could have one of the following security levels: general, confidential, and secret.

**Security Model:** A set of arbitrary and detailed rules defining access rights of information users within a given environment.

# Mechanism of E-Government Undertaking in Japan

M

**Yuko Kaneko**
*University of Yamagata, Japan*

## INTRODUCTION

According to the report submitted by the Evaluation Committee of Experts, Government ICT Strategy Headquarters in December 2005 (ECE, 2005), Japan has already established the globally advanced e-government infrastructures for such services as online application and filing. The report also acknowledged that the quantity and quality of information, guidance and search engine at the government portal, "e-Gov", and individual government Web sites have reached almost the same level as those of the government Web sites of the other world-famous ICT nations.

These achievements have resulted from the continuous undertaking of introducing information and communication technologies (ICTs) in the government operations from 1960s (ECHMCA, 2001).

In this article, the successful accomplishments of e-government initiative are described followed by the analysis of institutional arrangements and mechanisms concerning e-government initiatives. Lastly, the future challenges will be suggested.

## BACKGROUND

The Japanese government started its government-wide efforts for the management reform of administrative affairs in the late 1950s. Coincidently, the first computer in the national government was introduced by the Meteorological Agency in 1958. Since then, the government has been aggressively introducing computer and communication equipments and systems for improving efficiency and efficacy of public administration. This undertaking was not carried out independently by individual ministries. In 1968, the Cabinet decided on the future measures for the use of computers and at the same time an interministerial committee of computer use was established to promote the use of computers in more coordinated way. The committee was organized by a central management office, the former Administrative Management Agency of the Prime Minister's Office, consisted of the representatives from all the ministries and agencies who were the heads of the data processing divisions. The committee decided the computer utilization plan every fiscal year and all the ministries and agencies carried out necessary measures for promoting computer use in their organizations based on the plan (ECHMCA, 2001).

From 1960s to 1980s, the number of mainframe computers in the government kept on growing rapidly (Kaneko, 2004a). Batch processing of mass data by huge mainframes was the way of the day. Computers were utilized initially in the areas of research and statistics and then, by late 1970s, in such areas needing process of massive data as drivers' licenses, social insurances, and so forth (Kaneko, 2001). Databases for supporting policy formulation emerged later in the 1980s.

In the late 1980s, such remarkable development as downsizing, open-system, networking and user-friendly software was achieved in the ICT field. The government's undertakings to introduce personal computers (PCs) into policy planning/development and implementation lagged behind those of the private sector. With a view to promoting aggressive introduction and exploitation of ICT, a government-wide action program was needed. In 1994, the Cabinet decided upon a Master Plan for Promoting Government-Wide Use of ICT for realizing efficient and effective public administration by aggressively making use of ICT in all the government affairs.

Based on the master plan, the introduction of PCs and construction of LANs (local area networks) in the government offices progressed reasonably. Moreover, a WAN (wide area network) system (so-called Kasumigaseki WAN), connecting all ministries to facilitate the safe exchange of information between them, was constructed and it was put into operation in 1997 (Kaneko, 2004a).

Thus, it can be said that these continuous undertakings from 1960s have paved the way to the e-government initiatives.

## ANALYTICAL VIEWPOINTS

All OECD countries have some sort of e-government program such as PAGSI in France, BundOnline in Germany and UK Online(OECD, 2003a, 2003b). Some are based on laws and top-level political commitment on the other hand other countries have a less ambitious e-

government program, in which e-government is more a method to improve government outcomes within existing structures. As all countries have an e-government program, all countries have some sort of organizations with overarching responsibility for carrying out the program. The authority of these organizations differs widely from imposing mandatory obligation to offering solutions (OECD, 2005).

In this article, mechanism of e-government undertaking includes a national e-government program and institutional arrangements for implementing the e-government program. In describing the Japanese case, two viewpoints are adopted. One is the degree of political commitment concerning an e-government program and the other is the degree of the authority of the organization that is responsible for implementing an e-government program.

## MAJOR ACHIEVEMENTS TOWARD E-GOVERNMENT

The Japanese e-government program envisages two main goals, one is to provide "user-oriented administrative services" and the other is to realize "streamlined public administration with high budget efficiency" (GOJ, 2003b). And the various initiatives have been executed based on these two goals. The major achievements of the government's actions toward e-government as of December 2005 (Kaneko, 2005)are described according to the goals of the e-government program.

### To Provide "User-oriented Administrative Services"

#### Online Processing

There has been real progress enabling citizens and businesses conduct online application and filing for almost all the national administrative procedures (GOJ, 2005). As of March, 2005, 96% of the targeted national administrative procedures are available online such as filing tax and applying for the social insurance system. As basic underpinning of online application, various initiatives have been completed such as GPKI enabling to confirm authenticity mutually, LGCA , enabling to confirm identification and the online payment systems allowing citizens to pay charges online. According to the survey conducted by the Ministry of Internal Affairs and Communications in 2004 (MIC, 2004), more than 80% of applications and filings were conducted online.

*Figure 1. Achievements in online processing*

| Achievements | Date |
|---|---|
| 96% of all administrative procedures of the national government by on-line | Mar-05 |
| GPKI (Government Public Key Infrastructure) | Apr-01 |
| LGCA (Local Government Certification Authorities) services | Jan-04 |
| E-payment system for fees and other revenues | Jan-04 |
| E-bidding for procurement and purchasing | Mar-04 |

#### Improvement of the Government Portal "e-Gov"

A government portal site, "e-Gov" (http://www.e-gov.go.jp) has been in operation since April 2001 to make the people access the government information more easily and comprehensively (GOJ, 2005). Not only guidance for administrative procedures but also a powerful search engine to look for all the government Web sites, a law data retrieval system and extensive links to databases provided by the ministries are on "e-Gov." From January 2004, the public comment information has been integrated and the policy proposals from the citizens can be accepted at "e-Gov."

#### One-Stop Service

A single window service was started for the export/import procedures and the port control procedures in July 2003 (GOJ, 2005). Likewise, a new one-stop service for registration and other procedures related to owning automobiles was started in December 2005.

### To Realize "Streamlined Public Administration with High Budget Efficiency"

#### ICT Infrastructure

Each official is provided with one PC and all ministries have completed deploying the ministry LAN environment, which is connected to the government-wide network, Kasumigaseki WAN enabling mutual access among ministry LANs (MIC, 2002). The network infrastructure in the government sector has been extended to involve LGWAN (local government-wide area network) linking the entire local governments and the judicial network (court network) linking the court branches (MIC, 2004).

### Renovating Administrative Systems and Operations by the Use of ICT

While setting up various information systems including the network infrastructure, the budget allocation for building such systems and its cost efficiency are coming to be under public scrutiny. With a view to renovating administrative systems and operations by the use of ICT, the existing information systems together with the entire government business operations were sorted out and the operations needing renovation were specified for which optimization plans were to be decided (GOJ, 2004). In each optimization plan, concrete measures including integration or shared usage of systems, outsourcing as well as the estimated savings in time and costs are to be described. It was decided in January 2004 that the optimization plans for 79 operations were to be formulated by the end of March 2006. As of December 2005, 9 optimization plans targeting the common operation of the ministries and 12 targeting the specific operations of the individual ministries have been adopted.

## NATIONAL E-GOVERNMENT PROGRAM

### Introduction

Japan has a well-coordinated e-government program as "Program for Building E-Government" (GOJ, 2003b). This program is an action plan to implement the policies for realization of e-government included in "E-Japan Strategy," a national strategy for promoting the use of ICT in the whole society (GOJ, 2001, 2003a). The E-Japan Strategy was adopted based on the ICT Basic Law. In the following, the brief outline of the legal arrangement, the national ICT strategy and the e-government program (Kaneko, 2005) are described.

*Figure 2. Achievements in optimization*

| Achievements | Date |
|---|---|
| Adoption of Optimization Plans for 9 commonly applicable operations: Payroll, Procurement, Inventory Management, Benefits & Allowances, Travel Expenses, etc. | Dec-05 |
| Adoption of Optimization Plans for 12 specific operations: Patent, Radio Wave Control, State Pension, National Forestry, Food Administration, Meteorological Services, etc. | Dec-05 |

### ICT Basic Law

In January 2001, the Basic Law on the Formation of an Advanced Information and Telecommunications Network Society (The ICT Basic Law) came into force. The objective of this law is to promote measures for the formation of an advanced ICT network society expeditiously and intensively. For this purpose, the law stipulates the basic ideas, principles and policies as well as organization for promoting measures strategically.

The law establishes the Strategy Headquarters for the Promotion of an Advanced Information and Telecommunications Network Society (ICT Strategy Headquarters).

Under the law, the Headquarters are to develop a priority policy program for the formation of an advanced IT network society, in light of the urgency to adapt the Japanese society to the world's rapid and drastic changes in the socioeconomic structure caused by the utilization of ICT.

### E-Japan Strategy and Priority Policy Program

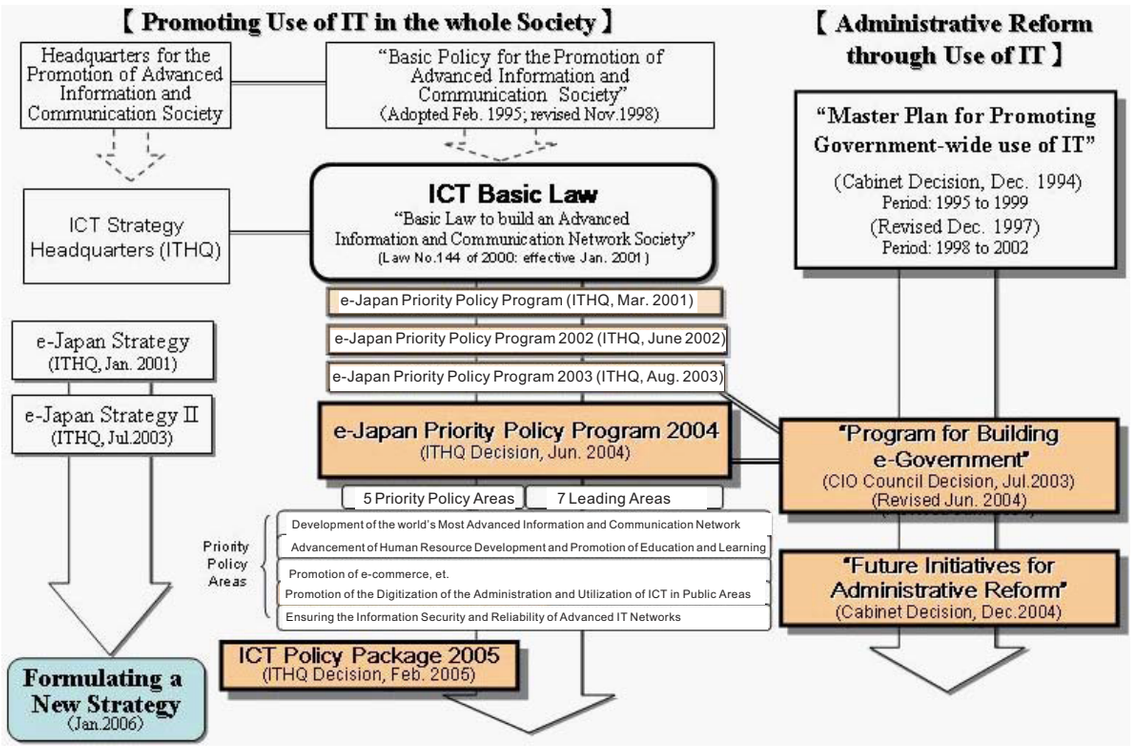
In January 2001, "E-Japan Strategy" was adopted by the ICT Strategy Headquarters (GOJ, 2001). It is a medium term national strategy aiming at making Japan the world's most advanced ICT nation within 5 years by such means as building the world's most sophisticated information and telecommunication network, which would make the citizens possible to access the Internet easily at low rates. The strategy shows the leading principles for preparing a priority policy program, a concrete work plan. The realization of e-government is identified as one of the high-priority policy areas in the Strategy.

In March 2001, the ICT Strategy Headquarters decided an E-Japan Priority Policy Program that included specific and detailed measures of the individual ministries. In the Priority Policy Program, government actions needed for the realization of e-government were described under the item of "Promotion of Digitization of the Administration and Utilization of ICT in the Public Sectors." The Priority Policy Program is an action plan for each fiscal year and it has been reviewed and amended once every fiscal year since then. The latest version, the ICT Policy Package 2005, was decided by the ICT Strategy Headquarters in February 2005.

### Program for Building E-Government

As mentioned above, the Japanese government has been undertaking the management reform of administrative affairs by the use of ICT from the1960s. With the devel-

*Figure 3. Basic framework of policies for e-government in Japan*



opment of ICT, the government came to face the challenges to reinvent and reconstruct not only its computer systems but also its business processes *per se*.

In December 1994, the Cabinet decided upon "Master Plan for Promoting Government-Wide Use of ICT" covering from 1994 to 1998. This was virtually the first cabinet decision that stated the overall policy and enumerated concrete measures of utilizing ICT inside the government. With rapid installation of PCs and network infrastructures in the government offices as well as the explosive diffusion of PCs and use of the Internet in the society, the master plan was revised in 1997 to become a new 5-year plan covering from 1998 to 2002 (GOJ, 1997).

While the E-Japan Strategy and Priority Policy Programs consolidate all the ICT policies and programs, the revised master plan stood as it was as a blueprint for creating e-government and at the same time its main policies and measures were included in the E-Japan Strategy and Priority Policy Programs.

After the completion of the target period of the master plan, July 2003, a program for building e-government was decided as the successive plan to the master plan under the ICT Strategy Headquarters (GOJ, 2003b). The program is a 3-year plan from fiscal 2003 to fiscal 2005. Over the past 2 1/2 years, various policy initiatives have been undertaken based on the program

## APPARATUS FOR PROMOTING E-GOVERNMENT

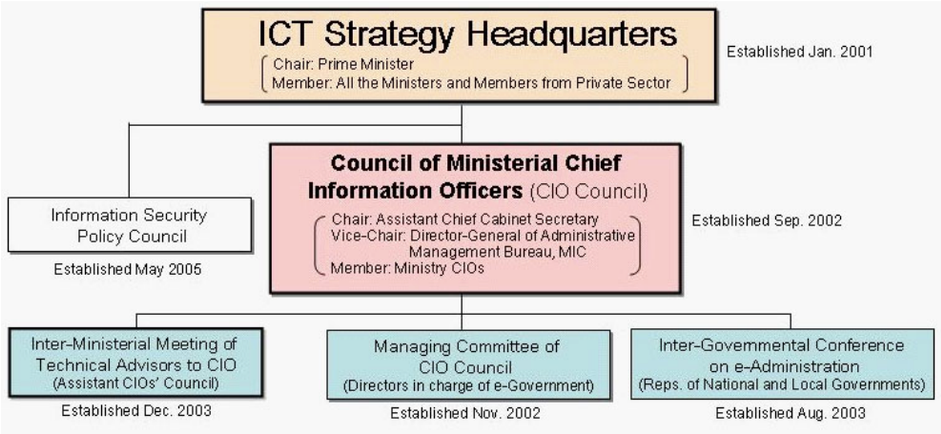
### Introduction

In any OECD country, when a country has an e-government program, it has some sort of organizations with overarching responsibility for carrying out the program. Japan has such organizations, namely the ICT Strategy Headquarters, CIO Council, Inter-Ministerial Committee of Assistant CIOs as counsel bodies and the Administrative Management Bureau of the Ministry of Internal Affairs and Communications as a substantial driving body.

### ICT Strategy Headquarters

The ICT Strategy Headquarters was established in January 2001 based on the ICT Basic Law. Headed by the Prime Minister, the Headquarters is composed of all ministers of state and ten acknowledged experts from the private sector. The main mission of the Headquarters is to hammer out ICT strategies including e-government policies. The Headquarters meets when fundamental policies or programs are to be decided. Since its establishment, the Headquarters met 34 times by December 2005. It is the

*Figure 4. Apparatus for promoting e-government*



place where the political leaders can take strong leadership to promote ICT policies for both the private sector and public sector. Based on the decisions by the Headquarters, ministries execute their own ICT policies such as constructing the advanced ICT networks and establishing necessary legal institutions enabling e-commerce rather independently.

## CIO Council

As mentioned above, an interministerial body (Inter-Ministerial Committee of Computer Use) was established in the late 1960s with a central management office, the Administrative Management Bureau, playing an overarching role. The status of this committee was upgraded into "Inter-Ministerial Committee of Directors General on Computer Systems" in 1983 with a view to strengthening its coordination functions for accelerating the use of ICT for administrative reform. Under the Committee, some inter-ministerial meetings and taskforces were organized to improve ICT knowledge and skills, to exchange experiences and professional know-how among the officials and to foster common grounds for government-wide concerted undertaking of ICT use.

After the establishment of the ICT Strategy Headquarters, the Inter-Ministerial Committee of Directors General on Computer Systems was transformed into a Ministerial Chief Information Officers Council (CIO Council) under the ICT Strategy Headquarters in September 2002.

The Council, headed by the Assistant Chief Cabinet Secretary, is comprised of all ministry CIOs, who are usually the Directors General of the Minister's Secretariat or their equivalents. Ministry CIOs are in charge of overall systematic coordination and management of budgets, personnel, organizational structure, policies concerning the use of ICTs inside the respective ministries so that the CIO Council can effectively coordinate ICT matters across the whole government including budgets, personnel, and organizational structures and so on.

The Council is also a decision making body. All the important policies of e-government initiatives in principle have to go through the Council. Thus, the CIO Council is pushing forward various measures concerning e-government in an integrated and collective manner among ministries.

Under the CIO Council, like before, the Management Committee of CIO Council and some taskforces are organized to promote the coordinated works among ministries toward e-government.

## Interministerial Committee of Assistant CIOs

Technical advisors to CIOs (Assistant CIOs) were appointed from among outside experts by December 2003 in respective ministries. Their mission is to support their ministry CIOs in business analysis and formulating optimization plans. At the same time, an interministerial committee of Assistant CIOs was organized under the CIO Council with a view to sharing experiences of respective ministries and exchanging views on technical matters; 21 meetings were held by December 2005.

## Administrative Management Bureau, Ministry of Internal Affairs and Communications

In the centre of "e-government" initiatives is located the Administrative Management Bureau, Ministry of Internal Affairs and Communications. Together with the Cabinet

Secretariat, the Bureau plays a secretariat role for the CIO Council and Inter-Ministerial Committee of Assistant CIOs and acts as a substantive promoter for e-government initiatives in Japan.

The bureau can be called a central management office. The establishment of the bureau dates back to the early 1950s when Japan regained its independence after its defeat in the World War II. The bureau has been in charge of promoting administrative reform, controlling the staff number of civil service, examining the establishment of public organizations and coordinating government information systems. In addition, the bureau has an authority to examine the annual budget requests for computer and communication systems and equipments from the individual ministries and to submit its comments to the Budget Bureau of Ministry of Finance. The comments of the bureau are seriously taken account of by the Budget Bureau during the budget preparation process. With its authorities for staff number control, organizational examination and ICT-related budget request, the bureau can effectively coordinate the government-wide undertakings for realization of e-government. Its coordination power is strong because the power is based on the laws. On the other hand, the bureau often convenes informal working sessions to exchange information, views and opinions between individual ministries. Fostering cooperative working relationship among ministries is one of the crucial conditions to smoothly and effectively implement government-wide reform measures including ICT exploitation (ECHMCA, 2001).

After the establishment of the ICT Strategy headquarters, the bureau came to carry out more innovative e-government initiatives with strong political support. It is often the case that every ministry resists to reform the current organizations and operations when the problems of current practices have not be identified. Without political commitment, the bureau can only implement reform measures after negotiation and compromise with the other ministries. The initiatives of the Headquarters are strong because the Prime Minister, Chairman, takes a strong leadership. The bureau can work out advanced reform measures with the support from the Headquarters.

## Organizational Changes in the Government

As the use of ICT for management reform has been a government-wide undertaking from 1960s, each ministry has its own unit in charge of comprehensive control of own computer and communication systems and equipments inside the ministry. The unit, often called "Data Processing Division" or "Information Management Division" plays a role of a focal point of the ministry when ICT related interministerial cooperation and coordination are to be required. The head of such division became a member of the Inter-Ministerial Committee of Computer Use. And later a supervising official of the head of the division became the member of the Inter-Ministerial Committee of Directors General on Computer Systems and currently the CIO Council.

While an interministerial coordination institution was being established, each ministry created its own ICT promotion committee to promote the use of ICT in its operation of government affairs.

After the E-Japan Strategy was adopted, an executive office was newly established in the Cabinet Secretariat and additional officials were allocated to the Administrative Management Bureau of Ministry of Internal Affairs and Communications. In the respective ministries, to deal with new jobs such as making optimization plans and strict management of ICT procurement, ICT experts from the private sector were newly appointed as officials with limited term. In addition, various business affairs such as examining the current systems and making proposals for optimization are often contracted out to a third party firm, not to the vendors of the current systems.

On the other hand, the government has been cutting down the number of civil service based on a series of staff number reduction plan. The use of ICT in government operation improves the efficiency and is regarded as one of the effective means for a smaller government. From January 2001 to March 2005, 2.2 % of the national civil service was cut down due to the efficiency gain (GOJ, 2005).

# FUTURE TRENDS

The current e-government program, "Program for Building e-Government" includes concrete measures that will have been carried out by the end of March 2006. Over the past 2 1/2 years since the program was formulated, various policy measures have been undertaken based on the program. Now, the government is in the process of evaluating the current progress and planning a new national ICT strategy to be decided in January 2006. A draft of the new strategy was released to the public on 8 December 2005. In the draft, the goal of e-government is set to realize citizen-oriented e-government in which citizen can find more convenient and high-quality services as well as to create more efficient e-government with program management offices (PMO) both for the individual ministries and for the government as a whole.

By now, some policy initiatives in the current e-government program have been accomplished, on the other hand some of them are in the process of implemen-

tation. The latter may be included in the new strategy. Major challenges to be included in the new strategy are mentioned in the following.

## To Accelerate the Use of Online Applications

While progress has been seen that 96% of the national administrative procedures are now available online, its utilization rate as a whole is rather high (more than 80%) but that of general purpose online application systems remains low so far (MIC, 2004). The current challenge is to encourage and enhance the use of general purpose online application systems by citizens and businesses. To address this issue, the following initiatives are being executed.

- An action plan for encouraging online usage is expected to be prepared for those procedures with 100,000 or more applications a year or those frequently applied for by businesses by the end of March 2006.
- "E-Government Facilitators" have been appointed from among attorneys acting as a proxy for citizens and ICT expert since April 2005 so as to improve the public awareness toward online procedures.

## To Develop and Enhance Government Portal "e-Gov"

Further works are conducted to ensure consistency in items common to "e-Gov" and ministry Web sites, including display positions on homepages. In addition, the government is working to improve "e-Gov" by extending links to the local governments, integrating reception systems developed by respective ministries.

## To Promote "One-Stop Services" through "e-Gov"

Works are under way to integrate functions of accepting on-line applications to "e-Gov" as much as possible so that One-Stop Services will be realized to accept multiple applications all at once at "e-Gov." Moreover, it is expected that an e-government customer support center will open by the end of March 2006, where citizens can get necessary instruction how to operate e-government related procedures.

## To Implement Optimization Plans

The government is now working hard on formulating all the optimization plans no later than the end of March 2006. The estimated savings in time and costs will be included in the optimization plans. From April 2006, the implementation phase of the optimization plans will be started. It is expected that this undertaking will realize streamlined public administration as well as better and more efficient public services.

# CONCLUSION

In the Japanese undertaking toward e-government, political commitment for the e-government program is not so strong but the e-government program rather serves the administrative reform to streamline the government organization and operation. After the national ICT strategy was established, the central management office could promote more aggressive reform measures by the use of ICT due to the political commitment to the strategy. The overarching organization of the e-government program is formally the ICT Strategy Headquarters but the real promoter and facilitator of e-government program is the Administrative Management Bureau. Its coordinating power is relatively strong because its has authorities of controlling staff number, examining government organizations and budget requests for computer and communication systems and equipments stipulated by the laws.

The target date of the E-Japan Strategy has passed and now a new national ICT strategy is being prepared. From 2001 to 2005, various undertakings have been carried out in the public sector as well as the private sector to better exploit ICT in the Japanese society. Inside the government, based on the e-government program, the introduction of ICT into every day operation of government affairs is aggressively carried out. Still, the civil servants tend to behave themselves unconsciously assuming that paper-based communication, coordination and management of affairs are still right. Such paper-based organizational culture may hinder the progress of e-government (Kaneko, 2001, 2004b).

To transform such organizational culture into a new culture appropriate for e-governance, fostering of ICT-based thinking and improvement of ICT literacy among the civil servants should be promoted further by making use of the expertise and knowledge of the private sector. The strong leadership of the top management is indispensable. The top management should reflect on their assumption of the existing organizational culture and take the initiative in changing the culture in the government.

Successful transfer from the present government to e-government depends primarily on human factors. E-government will be managed and administered by real flesh and blood officials. An acceptance of the changes brought about by the use of ICT in procedures and techniques

concerning government works and a positive attitude on the part of officials to the routine use of ICT will be necessary if e-government is to be successfully realized.

## KEY TERMS

**Basic Law on the Formation of an Advanced Information and Telecommunications Network Society (ICT Basic Law):** The law for promoting measures for the formation of an advanced ICT network society expeditiously and intensively, stipulating the basic ideas, principles and policies as well as organization for promoting measures strategically.

**E-Japan Strategy:** A medium term national strategy adopted by the ICT Strategy Headquarters in January 2001 aiming at making Japan the world's most advanced ICT nation within 5 years. The strategy shows the leading principles for preparing a priority policy program, a concrete work plan.

**E-Japan Priority Policy Program:** An action plan materializing E-Japan Strategy for each fiscal year. It includes specific and detailed measures of the individual ministries. The first program was decided by the ICT Strategy Headquarters in March 2001. It was reviewed and amended once every fiscal year since then. The latest version, the ICT Policy Package 2005, was decided in February 2005.

**Kasumigaseki WAN:** A Wide Area Network system connecting all the ministries to facilitate the safe exchange of information between them. Kasumigaseki is the name of the area in Tokyo where most of the central government offices are located. It has been operational since January 1997.

**Master Plan for Promoting Government-Wide Use of ICT:** A cabinet decision of 1994. The first 5-year plan stipulating the overall policies and enumerated concrete measures of utilizing information technologies within the Government. Revised in 1997.

**Ministerial Chief Information Officers Council (CIO Council):** An interministerial organization established in September 2002 under the ICT Strategy Headquarters. Headed by the Assistant Chief Cabinet Secretary, and comprised of all ministry CIOs (usually the Directors General of the Minister's Secretariat), it is in charge of coordinating ICT matters across the whole government as well as deciding all the important policies of e-government initiatives.

**Program for Building E-Government:** A 3-year plan decided by the CIO Council in 2003 and incorporated into the Priority Policy Program 2003. It aims at realizing user-oriented public services and streamlined public administration with high budget efficiency.

**Strategic Headquarters for the Promotion of an Advanced Information and Telecommunications Network Society (ICT Strategy Headquarters):** The Headquarters established in January 2001 based on the ICT Basic Law, headed by the Prime Minister, and composed of all the ministers of state and ten acknowledged experts from the private sector. Its main mission is to hammer out IT strategies and polices of E-Japan initiatives.

# Modern Drought Monitoring Tool for Decision Support System

## INTRODUCTION

Drought is a natural disaster that influences many aspects of society. Since the demand for water is increasing along with the population in many parts of the world, water supply interruptions caused by drought can be expected to produce greater impacts. This is because the impacts of drought are determined not only by the frequency and intensity of meteorological drought but also by the number of people at risk and their degree of risk (Wilhite, 2000). For example, the increase in population in Africa and Asia increases drought vulnerability significantly. Thus, policies that promote the development and implementation of appropriate drought mitigation measures today will help to reduce the economic, social, and environmental impacts associated with future droughts and the need for government intervention.

To monitor drought, different types of indicators (e.g., drought indices) have been used in many parts of the world. Because there is no single definition for drought, determining which indicators to use poses more difficulties for planners. Decision makers use different policies and strategies based on the historical records of their countries. For example, in Australia, when meteorological drought (annual rainfalls in the lowest 10% of recorded values) occurred over at least 10% of the continent, it coincided with damaging agricultural droughts resulting significant losses of crops and livestock (Heathcote, 2000).

Because of the varied and potentially catastrophic losses resulting from drought in many parts of the world, both governmental and non-governmental decision makers need better predictive and monitoring tools to assist them in dealing more effectively with drought. Better early warning and prediction is the foundation of a new drought management paradigm based on risk management. In South Africa, the Weather Bureau issues extended outlooks for short and long periods using numerical modeling and statistical methods (Vogel, Lang, & Monnik, 2000). In United States, recent advances in science and technology are enhancing drought monitoring capabilities and the availability of such information, which allows decision makers to make more knowledge-based decisions to lessen the impacts of drought.

In this article, we highlight the role of government in drought planning and mitigation, the potential of data mining techniques and their outputs (e.g., maps and tables) for improving informed decision making, and also present a newly developed drought monitoring tool, the Vegetation Drought Response Index (VegDRI) as an example over the central United States.

## BACKGROUND

Recurrent droughts and their significant impacts on societies are increasingly forcing governments to play a more significant role in drought management in many parts of

the world. Given the complexity of drought, where the impacts can accumulate gradually over time and vary widely across many sectors, a well-designed decision support system is critical to effectively manage drought mitigation and response efforts (Goddard, Harms, Reichenbach, Tadesse, & Waltman, 2003). The traditional mindset of government in the United States and elsewhere has been to react to drought (i.e., crisis management approach) through the provision of relief or emergency assistance to the affected areas or sectors. With this approach, drought only receives the attention of decision makers when it is at peak levels of intensity and spatial extent and when water management options are quite limited. This approach has been characterized as ineffective, poorly coordinated, and untimely (Riebsame, Changnon, & Karl, 1991; Wilhite, 2000; Wilhite & Wood, 1994). Not only is this approach extremely costly, relief provided through this process is often politically driven, programmatically misdirected, and poorly targeted. Relief often serves as a disincentive for the sustainable management of natural resources because it reinforces existing management practices, practices that may not be sustainable in the long term. This reactive approach is not good policy and must be replaced by an anticipatory, preventive approach that reduces risk through the adoption of appropriate mitigation programs and policies (e.g., risk management approach). Today, nations are increasingly pursuing a more proactive approach that emphasizes the principle of risk management and sustainable development (Wilhite, 2000).

Technological advances and better use of available drought monitoring tools improves our ability to more effectively manage water and other shared natural resources during periods of drought. These changes can facilitate the shift to risk management because they allow governments on the national, state, and local level to address some of the more serious deficiencies of the crisis management approach. For example, our ability to monitor and disseminate critical drought-related information has been enhanced by new technologies such as automated weather stations, satellites, computers, and improved communication techniques (e.g., the Internet).

Previous drought planning efforts have been hampered by a lack of adequate early warning systems and insufficient information flow within and between levels of government. However, an improved understanding of complex atmospheric-oceanic systems and the development of new computer models have improved drought forecast skills for some regions. If they become part of a comprehensive early warning system, these advancements and others can provide decision makers with better and timely information. One of the recently developed techniques relevant for such drought monitoring and prediction is data mining.

## THE USE OF DATA MINING TECHNOLOGIES IN IDENTIFYING DROUGHT

Data mining is a technique that uses a variety of data analysis tools to discover meaningful patterns and relationships of physical variables in different data sets (Berry & Linoff, 2000; Han & Kamber, 2001; Two Crows, 1999). This technique is used in multidisciplinary fields, bringing together techniques from machine learning, pattern recognition, statistics, databases, and visualization to address the issue of information extraction from large databases (Cabena, Stadler, Verhees, & Zanasi, 1998). The method has been used for commercial applications to increase profits (Cabena et al., 1998; Groth, 1998). These techniques are being utilized more frequently to extract hidden relationships and information from large databases to allow managers to make knowledge-based decisions (Berry & Linoff, 2000).

Data mining can also provide mechanisms for resourceful and efficient data handling and extraction of information in drought research. This is extremely important because monitoring and prediction of drought relies heavily on the use of climatic, oceanic, satellite, and biophysical data. At present, extracting useful information from these data and producing drought monitoring tools hold many challenges. Data mining techniques such as association rules, decision trees, and neural networks can help in finding a relationship among meteorological, satellite, oceanic, and biophysical variables.

Recent studies have applied data mining techniques to understanding drought characteristics in the central United States (Harms, Deogun, & Tadesse, 2002; Tadesse, Wilhite, Harms, Hayes, & Goddard, 2004). Harms et al. (2002) developed data mining algorithms that identify the drought episodes separate from normal and wet conditions. The algorithms generate association rules defined as "if X then Y," where X is the rule antecedent and Y is its consequent. Tadesse et al. (2004) used this rule-based association technique with the global oceanic indices as antecedent episodes and drought as consequent episode to find the relationships between climatic and oceanic parameters within the state of Nebraska. This study indicates that there is a strong relationship between the global oceanic condition and drought occurrence in Nebraska. This information is important in helping to predict future drought occurrences. Studies in ecological research have also introduced data mining techniques and found that they are powerful tools to address complex ecological problems involving both numeric and categorical data (De'ath & Fabricius, 2000).

In another drought monitoring research study, Brown, Tadesse, Hayes, and Reed (2005) focused on simple

predictive modeling of drought using a combination of seasonal satellite vegetation metrics and climate and geophysical variables. In order to extract patterns from these variables, they used a data mining technique known as regression tree modeling to develop models to monitor drought during the growing season. These rule-based models are collections of rules, each of which is associated with a linear expression for computing a value called the Vegetation Drought Response Index (VegDRI), which is used to identify drought conditions. The VegDRI provides a unique and detailed source for monitoring drought conditions over natural and anthropogenic landscapes. Tadesse et al. (2005) expanded the study to predict future drought conditions (based on vegetation stress) by integrating data mining and satellite image processing techniques to assess vegetation conditions. The study indicated that drought information for vegetation stress can be delivered up to six weeks in advance and in a finer spatial detail (1 $km^2$) than other widely used drought monitoring maps such as the U.S. Drought Monitor map (http://www.drought.unl.edu/dm/), which uses climate division data with roughly a 100 $km^2$ spatial resolution.

In general, the results of studies on the application of data mining in drought research show that:

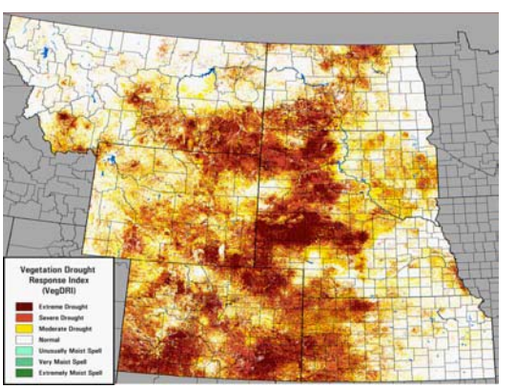
1. Because of synergy between data mining techniques, faster computing capability, open access to data, and integration of data provided in large databases, we can answer questions that traditionally were too complex and time-consuming to resolve
2. Data mining tools search databases for hidden patterns and find predictive information that drought experts may miss because it lies outside their expectations
3. Data mining techniques are fruitful for business activities such as marketing, fraud detection, and credit scoring. In drought research, these techniques have only recently been utilized and have tremendous potential
4. Data mining helps in exploring and discovering the relationships between ground-based climatic observations and oceanic observations to enable better understanding of causes and effects as they pertain to drought. Using time-series of these variables allows for identification of the temporal relationships of the climatic and oceanic variables and how they tie into the current and future presence of drought. This is useful for improving drought monitoring capabilities and for developing proactive drought risk management practices
5. Current developments and trends in drought research using data mining techniques can help people and institutions develop and implement methods to reduce societal vulnerability to drought. This supports the effort that is necessary in governments toward preparedness, early warning, and risk management, rather than crisis management. It will also assist in the design and development of an integrated and automated system for drought monitoring and prediction that can be adapted for use by a variety of decision makers and users

To illustrate the potential of data mining and its application in drought research, the following section describes prototype drought monitoring tools that are produced using data mining techniques in the central United States.

## INTEGRATING SATELLITE AND CLIMATE DATA TO IDENTIFY DROUGHT: AN EXAMPLE IN THE CENTRAL UNITED STATES

A collaborative effort between the National Drought Mitigation Center (NDMC), the High Plains Regional Climate Center (HPRCC), and the U.S. Geological Survey's EROS Data Center (EDC) is underway to develop and deliver geospatial information about drought in the central United States. In this project, a prototype drought monitoring system that integrates information from climate and satellite databases using data mining techniques is developed (Brown & Tadesse, 2003). Data mining based on a classification and regression tree (CART) technique was used to model drought using climatic data, biophysical data, and a satellite-derived vegetation index. Since 2002, this research has investigated the relationships between climate data and satellite-derived greenness information for monitoring the effects of drought on vegetation. Figure 1 shows an

*Figure 1. Vegetation Drought Response Index (VegDRI) map of central U.S. for July 25, 2002*



example of a product from this collaborative research that is used as an indicator of drought-affected vegetation for seven states in the north central United States.

This product has a resolution of 1 $km^2$, which provides a detailed map of the vegetation stress due to drought. This means that the VegDRI contains sub-county detail that cannot be found in existing climate-based drought maps. The information can also be organized with other information such as land cover in a layer using geographic information system (GIS) software. The combination of the land cover and VegDRI map allows for an areal assessment of drought impacts on different landscapes. Such GIS layers (maps) can be disseminated to the public using a Web-delivery system for any state or region.

A prototype drought monitoring Web delivery system is available at http://gisdata.usgs.net/website/Drought_Monitoring/. This interactive Web mapping application was developed by USGS to support visualization of drought information (e.g., VegDRI maps). The map viewer includes other layers such as satellite-derived vegetation greenness data, climate data, biophysical data (e.g., land cover), and digital elevation data that may provide relevant geospatial information for decision makers. Such Web delivery provides large amounts of information efficiently and rapidly to interested users.

Feedback from potential users of the new drought monitoring tools, such as VegDRI, is an important mechanism to improve the product and the delivery system. To this end, two workshops were held with potential users of VegDRI in South Dakota and Nebraska. These discussions identified a wide range of potential applications for the product. State and federal agricultural agencies cited the potential use of VegDRI in helping to verify drought disaster claims on range and croplands and in making other rangeland and forestry management decisions. For example, federal managers responsible for determining appropriate livestock grazing numbers on federal lease lands could use VegDRI maps to help decision making. Forestry personnel recognized the potential value of VegDRI in fire planning efforts such as scheduling prescribed burns and identifying high-risk fire areas. Similarly, individual producers also identified the potential use of VegDRI maps for filing disaster insurance claims and making farm marketing decisions. Finally, environmental management agencies noted the benefits of VegDRI for monitoring wildlife habitat quality. The availability of this and other new drought monitoring tools with relevant geospatial data enables a wide range of decision makers to act timely and efficiently to reduce the impacts of drought. National and international disaster assistance and relief organizations and government institutions can benefit from fast and user-friendly delivery of information for effective planning and management of available resources.

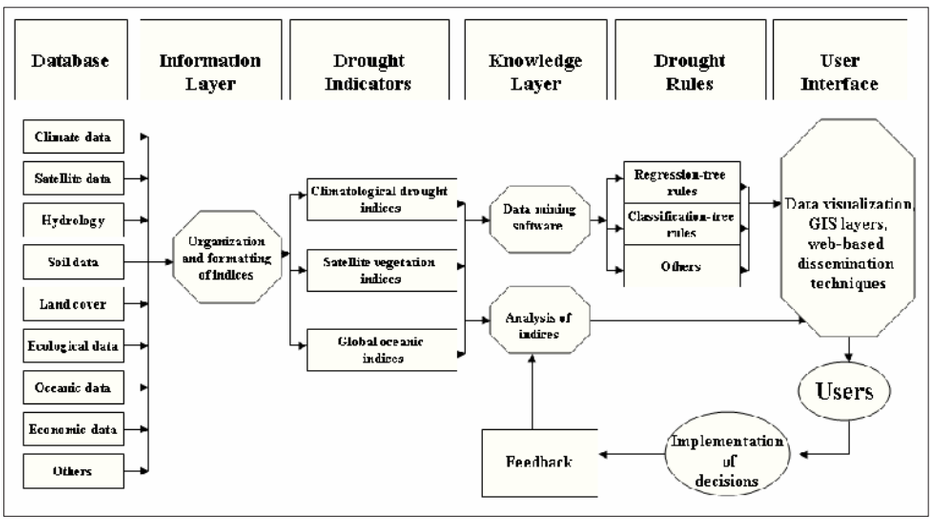
## FUTURE TRENDS: INTEGRATED INFORMATION FOR DROUGHT MONITORING IN DECISION MAKING

The use of data mining technology is increasing in drought monitoring research. Many drought studies have focused on the frequency, intensity, and spatial extent of drought in a state or region. However, the complex characteristics of drought and its infrequent nature as compared to both normal and wet conditions in climatic time-series data requires the development of specifically designed data mining algorithms. For example, a hydrological drought that depends not only on seasonal precipitation but also surface and ground water levels may need a different approach and tailored models than an agricultural drought. Such specific drought models may need to be developed to assist specific societal sectors in managing drought in the future.

The VegDRI model is designed to monitor vegetation response to drought. The successful implementation of the VegDRI monitoring technique in the central United States, along with increasing technological improvements, may provide an opportunity to extend the application of these methods and tools across the United States and abroad. Despite such innovations, the development of new techniques and drought monitoring tools is not the only part of a decision support system. An integrated and systematic approach in using modern tools is of paramount importance in decision making. Thus, a comprehensive decision support system for drought monitoring is an important factor that should be developed and implemented if governments plan to meet the challenge of mitigating the impacts of drought.

Figure 2 shows a hypothetical approach for an efficient, proactive drought decision support system. In this flow chart, the database is built in a data warehouse containing many relevant variables. The next step is the information layer that computes the drought indices. From an operational point of view, it is important to identify each type of drought using its triggering mechanisms. Thus, drought indices for each type of drought (for example, agricultural drought) should be calculated. It may be important to compare and contrast the values of each index and make verifications with ancillary data. Data mining techniques are applied to find the relationships between parameters that are useful in making improved analyses of drought based on the patterns derived from the data. After the analysis of the outputs and trends, the results need to be organized and expressed in an easily understandable format using data visualization and GIS techniques. The information can be disseminated using a Web-delivery system that may be easily accessed by decision makers, government and non-governmental in-

*Figure 2. Hypothetical flow chart for a proactive drought decision support system*



stitutions, and individual users such as farmers and ranchers. Finally, the outputs can be used to make logical decisions. In the figure, the loop that indicates the feedbacks in comparing and verifying the outputs is essential for improving drought monitoring tools and decisions. The rules generated using data mining techniques are part of the decision support system that is described in the hypothetical flow chart to improve drought monitoring. Moreover, governments should have a systematic approach for assessing the vulnerability of key sectors, regions, and population groups in the country and in their potential actions to mitigate those impacts.

Rapid development in the information and communication technologies has progressively moved toward fast and efficient access to data and information. The use of these technologies is invaluable in helping to mitigate droughts and their impacts on the economic development of a society. Thus, it can contribute in the e-government world by expanding the use of the Internet and computer resources to provide government services in effective management, reducing impacts, and efficient planning of early warning systems for natural disasters such as drought.

## CONCLUSION

To reduce the impacts of drought, governments need to have or develop a sustainable drought mitigation and response plan that includes timely and reliable monitoring of drought and water supply conditions. An integrated approach to drought monitoring that incorporates information on the vulnerability of key sectors, regions, and population groups in the country enhances the effectiveness of actions that may be taken to mitigate the impacts of drought in the future. The government should also assist the stakeholders in preparing for and responding to drought impacts, including the development of a water conservation strategy and public awareness programs.

Modern drought monitoring tools have the potential to reduce drought impacts significantly because of their flexibility (adaptability) and relatively higher spatial resolution (e.g., VegDRI has 1 $km^2$ resolution). Drought maps and prediction products using data mining tools could be made available to decision makers in any state or region through Web delivery. The use of data mining techniques is expected to enhance the efficiency and accuracy of drought monitoring, especially in agricultural and water resources management.

## KEY TERMS

**Biophysical Parameters:** Measure of the biophysical conditions that may influence the vegetation response to climate variability, such as land cover, ecological land type, percent of land in farms in irrigation, and available water capacity of soil data.

**Climatic Drought Indices:** Indices based on climatic observations such as precipitation and temperature. These include the Palmer Drought Severity Index (PDSI) and Standardized Precipitation Index (SPI). The SPI was designed to quantify the precipitation deficit for any location (for example, a weather station) based on the long-term precipitation records for a desired time interval. The SPI calculates the precipitation deficit for specified time periods (e.g., in the past one month, three months, six months, nine months, and twelve months.) The PDSI is an index that represents the soil moisture departure for a region by implementing a simple supply-and-demand model for a water balance equation. Thus, the PDSI value is an indicator of how the soil moisture compares with normal conditions. The PDSI is calculated based on parameters including precipitation, temperature, and soil moisture conditions.

**Data Mining:** A technique that uses a variety of automatic or semi-automatic data analysis tools to discover meaningful patterns and relationships of physical variables in different data sets that can also be used for prediction.

**Drought Decision Support System:** A system that provides support to the group or individual decision making process with tools that facilitate organization, prioritization, and consensus development to perform a variety of tasks associated with assessing risk and efficient action to reduce and mitigate the impacts of drought.

**Drought Monitoring Tools:** Tools in the form of maps or tables that include various kinds of climatic, satellite,

and oceanic indices to indicate or predict drought condition. These tools can be disseminated via the Internet to monitor drought.

**Oceanic Indices:** Indices that show the global oceanic condition, such as Sea Surface Temperature (SST) variability of the Pacific Ocean. The indices include the North Atlantic Oscillation (NAO) Index, which is defined as the normalized pressure difference between a station on the Azores and one on Iceland; the Pacific Decadal Oscillation (PDO) Index, defined as the leading principal component of North Pacific monthly sea surface temperature variability; and the Southern Oscillation Index (SOI), computed using monthly mean sea level pressure anomalies at Tahiti, French Polynesia; and Darwin, Australia.

**Satellite Indices:** Indices that show the water stress or vegetation condition based on the satellite data. The indices include the Normalized Difference Vegetation Index (NDVI), which is based on the response of vegetation in visible and infrared channels of the satellite.

**Vegetation Drought Response Index (VegDRI):** This index is built on the model integrating the satellite and climate data that indicates the impact of drought on vegetation. The VegDRI is calculated using data mining techniques that integrate complex information from satellite measurements, climate-based drought indices, land cover types, soil characteristics, and additional environmental factors such as ecological type and percent of irrigated lands in farms. These VegDRI maps deliver continuous spatial coverage, and are inherently finer in spatial detail (1 $km^2$ resolution) than other commonly available drought indicators such as the U.S. Drought Monitor.

# Monitoring Technologies and Digital Governance

**Peter Danielson**
*University of British Columbia, Canada*

## INTRODUCTION

Digital government is a technological adventure. It applies new technologies—in particular, computer-mediated communication—to the ongoing development of democratic forms of government. While the primary focus in digital government literature is on computer-mediated politics and formal governance, these technologies have wider effects. Generally, new information technologies enable new forms of control (see Beniger, 1986, for an excellent history and the general connections between information, control, and governance). The technological changes that make digital government an option alter the possibilities of governance at all levels. Driven by the declining price of computer hardware (so-called Moore's law) sensors (e.g., cameras, RFID tags), computers and networking make it possible to find out about and to control many hithertofore uncontrolled aspects of our lives. This article considers the effect of new monitoring technologies in the broad sense introduced by McDonald (2001) as inclusive of the range of control mechanisms—personal, informal, social, market, legal, and political—that we deploy.

In general, we expect technological innovation to create ethical problems. Innovations move communities from technological and social situations for which their norms are well adapted to new situations in which the fit tends to be worse (Binmore, 2004). Even seemingly small changes in technology, especially communications and monitoring technology, produce significant stress on norms. (Consider how cell phones and then cell phone cameras challenge norms governing privacy in public spaces.) Therefore, we should expect moves toward digital government to face ethical problems. This article considers problems due to a suite of monitoring and surveillance technologies that promises significant benefits but raises issues in terms of the values of control, privacy, and accountability.

## BACKGROUND

We need to remember how new the ensemble of monitoring technologies is. Gelernter's (1991) seminal proposal to build a mirrorworld allowing citizens to examine many aspects of their local government and healthcare system in real time seemed wildly utopian when published in the early 1990s. Now, the Internet has become so integrated into everyday life in rich countries that schoolchildren are surprised that some books are not available online.

This article suggests that we should consider a wide range of examples in order to form our evaluation of monitoring technologies. Our approach contrasts with what is favored in the sociological and popular literature critical of technology, much of which focuses on two metaphors: Orwell's (1949) Big Brother and Foucault's (1977) account of Bentham's (1969) panopticon prison design (Lyon, 1994; Mann, Nolan, & Wellman, 2003; Rheingold, 2003). Both metaphors suggest that more monitoring technology means stronger governance in the sense of tighter control. However, as we shall see, it is not clear that introducing surveillance in some contexts (we will consider the case of the clinical consulting room) has these unidirectional effects. Rather than trying to coin less misleading metaphors, it seems better to engage in an informal technological survey, forecast, and risk assessment. We will consider selected cases of new monitoring technology, sketching how each changes the players, options, strategies, social norms, and outcomes in social situations and using what we call an informal strategic approach (Danielson, 2005). Indeed, merely surveying some of the myriad new monitoring technologies currently available should be educational, as most of them have a low public profile.

To draw on a particularly significant example, the number of video cameras used for surveillance has increased enormously. Much of the public space in London is under government video surveillance, and the estimated 200,000 cameras in Shanghai are planned to double by 2010 (Epstein, 2004). The Chinese example makes two additional points. First, as the world's leading non-democratic state, China raises the question of the role of democracy in digital government. We face a terminological choice. On the one hand, digital government could be given a neutral interpretation related only to efficient governance of whatever kind. On this reading, effective (but non-democratic) digital government would include China's use of video or network surveillance to monitor

and suppress political dissent (Walton, 2004). This article will follow the alternative convention, under which digital government assumes democratic goals. (The clearer term for this value-driven approach is *digital democracy*.) Similarly, we shall use the term *governance* with a normative bias, looking for ways to improve self-control and legitimate governance, for example, and not manipulation or tyranny.

Second, Epstein (2004) reminds us that by turning to surveillance cameras, China deploys modern technology to perform a job that, under Mao Zedong, was largely society's responsibility. This brings us to a recurring theme: technology may not simply introduce or increase governance, but it may shift the balance between various controlling mechanisms and parties.

While surveillance is timely, relevant, and obviously controversial, we will not begin our account with surveillance for several reasons. First, surveillance technologies are unique in their strategic functions. Often, they gain much of their power by revealing themselves to their subjects; think of all those signs announcing hidden cameras. (This is the shared truth in the Big Brother and panopticon metaphors.) Truly invisible surveillance cannot deter people as readily as more obvious surveillance. Therefore, surveillance understates one of the main problems with new monitoring technologies in a democracy—their generally unnoticed role. This leads to the second, more general reason to put off discussing surveillance: it is very complex. In this article, we use *monitoring* to include surveillance (see Danielson and McQuade [2005] for a more nuanced account).

We select our examples with three goals: (1) to cover a wide range of emerging technologies; (2) to use technologies embedded in varied social relationships, institutions, and cultures; and (3) to start with the simpler case of physical things, move to non-human animals, and end with persons. In effect, we will try to apply a simple Kantian model that ranks ethical significance as least for things and as most for persons. As we shall see, technological change will not respect this ethical scheme.

## NEW MONITORING TECHNOLOGIES

### Things

The technologies under consideration change ordinary objects like books, commodities in stores, cell phones, and cars in a characteristic way: they become easier to monitor. They cease to be isolated and become linked to a communications system, where they can be stored in a private database (at minimum) and perhaps even addressed and interrogated. These are forms of dataveillance, whereby things become linked to records in large databases. For example, UPC scanning allows shops to use customers to help to maintain inventory. Loyalty cards go further, linking products via their purchasers into purchasing histories that retailers use for planning or for selling to third parties.

This technology changes individuals' strategic situations; we should be asking who is scanning our purchases and transit tickets, which is a question most of us previously needed to ask only about our credit cards, identity papers, or driver's licenses. Unless people understand which personal information is being read or exchanged, their participation in transactions is unlikely to be fair. Perhaps introducing some new terms that are common in writing in this field will alert us to think of more things that are now part of an infosphere with an infocloud surrounding them. Or, in time, we may generalize from our experience with card and UPC scanners in shops and other venues. The Internet, which began as a research platform, continues to play that role. Several ongoing experiments help us to envision what we might expect from a developed infosphere that includes many of the objects we use every day. An example is the Microsoft Research Advanced User Resource Annotation (AURA) system, whose motto is "Annotate the Planet!" and which allows people to link products to arbitrary Web pages via their product identifiers.

### Books and Barcodes

Books are a good place to start. They are familiar, full of information, and traditionally quite local and inert. That is to say, one can walk past the shelves in a library knowing that there is a great deal of information in the books but needing to take each one down and actually read it in order to find out it. Even then, one won't readily find out if one has already read it (and when), who else has read it, where it was reviewed, and how the reviewers rated it. Second, each book is created with a unique identity (the ISBN) that it wears on its barcode. This is the link between the traditional book and books enhanced with an infosphere. Readily available open-source software allows one to surf the infosphere of books by scanning their barcodes.

Barcoding can support various follow-up technologies. Some stores currently supply terminals that allow customers to check prices via barcodes. Local wireless networking would allow an allergy meter to alert a consumer with Internet-based information to avoid any of an open-ended list of allergens or any other features that they (or their agents) programmed into it. Projecting into the near future, one can imagine a multi-factor value analysis output: no serious allergy alert, mediocre nutrition, good environment, excellent price, personal use history, and so forth.

### Boxes and RFID

Radio frequency identification (RFID) is a technology that uses radio waves to read information from a tag. Compared to barcodes, RFID allows sensing at a greater distance and the ability to tag non-manufactured items. The first feature allows RFID tagging to enable sophisticated inventory tracking systems, and as the price of RFID tags drops, these tags, required by logistically advanced organizations like Wal-Mart for large packing cases, will be found in packages of decreasing size and in consumer products. RFID tags in clothing are the most controversial, since they would expose the wearer to personal monitoring.

## Food and Animals

The use of RFID and other tags in food and animals raises additional issues. First, some of this tagged information needs to be authoritative. Allergic and dietary contents already are required fields on limited printed physical labels; prices need to be fixed locally by the store (owner). But even these fields likely will be augmented by other non-authorative and critical contributors. Consider the debates about the allergenic risks of transgenics (Expert Panel on the Future of Food Biotechnology, 2001) and the relative risk/value of (anti)nutrients like transfats and bovine growth hormone, respectively. Enhanced labels become sites for ethical and political disagreement.

Notice that expanding labels using the Internet as discussed previously with AURA resolves two related objections to expanding consent via labeling controversial foods. First, limited space on mandatory product labels is no longer a problem, once barcodes are linked to whole Web sites. Second, competing non-scientific claims about health and safety no longer need be adjudicated by the labeling authority. Like book and movie reviews, there is space on the Internet for diverse views to be heard.

RFID tags have been implanted in living animals, beginning with valued pets and moving to livestock, which can be tracked to control BSE and tuberculosis. Human tagging was approved by the U.S. Food and Drug Administration in October 2004 for medical records but has been used already by Mexican government officials for security purposes (Sullivan, 2004).

## Persons

### Surveillance

In spite of the growth of video surveillance and its prominence in the literature, the focus on government surveillance cameras may miss rapid change in the surveillance environment. Lyon (1994) makes several important distinctions between modern surveillance and the Big Brother model fostered by the prominence of Orwell's (1949) novel, *1984*. First, modern technology supports dataveillance vs. video surveillance. As the old saying reminds us, pictures are much more complex than words or, more yet, numbers. Accordingly, it is much easier to survey, sort, and classify high-level data such as bank records or e-mails than it is to view photos or videos. Digital video techniques such as face recognition blur this distinction.

Second, as costs decline, the technology becomes decentralized. Much modern surveillance is conducted by small businesses or private individuals. The highly influential videos of the Rodney King beating and photos from the Abu Ghraib prison illustrate the power of digital technology dispersed among individuals, which Mann et al. (2003) label *sousveillance*. Cell phone cameras are an extreme example of this trend. While many have noted that in 2004 digital cameras (69m units) outsold film cameras (47m units), perhaps more significantly, both together were surpassed by a relatively new invention—the cell phone camera (186m units) (Move Over, Big Brother, 2004). Although digital and cell phone cameras both gain from easier networking, cell phone cameras are automatically wirelessly networked.

Third, modern surveillance is often non-governmental. Indeed, as the two previous examples show, it is often a countervailing influence to government attempts to monopolize information.

### A Micro-Case: The Virtual Chaperon

Monitoring technology adds more information and facilitates forms of access and control. The political case is quite complex. The sources (public, corporate, and private) of surveillance data are quite varied as are the parties—the publics—who might gain access or control over access to these sources. In order to understand the problems and opportunities offered by newly feasible surveillance technologies, we propose to examine a small micro-case. The Virtual Chaperone, developed at the Imperial College School of Medicine in London, videotapes a clinical encounter and encrypts the record immediately to DVD, providing the patient and the provider with an authoritative record (Clark, Bann, Edwards & Darzi, 2003).

The Virtual Chaperone has been developed in nearly ideal circumstances from an ethical perspective. The Virtual Chaperone was designed to meet and to raise the standards of clinical bioethics, the most highly developed form of professional ethics. The Virtual Chaperone suggests the complex relationship between surveillance and ethics. On the one hand, fully trustworthy agents do

not need chaperones; they do not grope patients or fabricate claims of abuse. Real agents are not perfect, so they need supervision. But ethics is not simply supplanted by technology. The need for and the right to privacy that led originally to private medical examinations speak even more strongly for protecting videos of intimate examinations. So, additional technologies—encryption and access, in this case—are needed in order to support a thorough solution. The Virtual Chaperone also shows that surveillance need not simply extend power relations, as Foucault's (1977) many students insist. The device's developers claim that both parties feel mutually protected. This needs to be tested and critically examined, of course. But elementary strategic considerations suggest that a reduction in uncertainty and lower litigation costs are beneficial to both parties (Big Sister Is Watching You, 2004).

Inexpensive miniature video sensors, processors, and memory let the Virtual Chaperone be generalized to a personal black box for everyone, but especially seniors with failing memory. "The type of scenarios which originally motivated SenseCam center on personal memory recall. For example, where did I leave my spectacles or keys? ... All the exciting events (and falls measured by accelerometer and so images of which were captured) can be replayed by mother after she gets home. What happened to me? If one is cycling and falls injured by the side of the road, the emergency medics can review the data in the SenseCam … and give appropriate medical treatment" (Gemmell, Williams, Wood, Lueder, & Bell, 2004, p. 2). However, moving this technology out of the ethically constrained clinic raises many issues. For example, who gets access to the cyclist's data after an accident? These issues have been played out in another venue.

## Cars and Black Boxes

Most cars manufactured by General Motors and those increasingly manufactured by Ford contain event data recorders (EDR), the automotive equivalent of the black boxes (actually, orange boxes) long used in airplanes and ships. This technology focuses attention on who owns or otherwise controls the information collected in a contentious context in which the players, drivers, manufacturers, and government have different interests. We suggest that *black box* really is the appropriate term, as presently it is very difficult for the driver/owner to get at the information stored inside, and thus, control is very difficult. "General Motors has not released the information necessary to directly confirm or translate the raw data" from its event data recorders (Poplin, 2003).

Again, the personal case is at the simple end of the spectrum. While black boxes have been used for years in shipping and aviation, their introduction into private automobiles has been much more controversial. This may be due to the strategic environment. In cars, the recorders were introduced at the initiative of the manufacturers in order to protect them from legal claims that safety equipment failed by showing that the airbags functioned or that speed was excessive. Moreover, the recorders put owners/drivers at additional legal risks. In contrast, the owner of a truck fleet may use recorders strategically to solve a principle agent problem with drivers, but the owner's interest in the technology is straightforward.

## Patient, Genomic, and Other Information

Like surveillance, clinical medical records and genomic information present extremes of information that is easy to divulge (a single hair follicle suffices for the latter) but very risky, since individuals can lose control; individuals risk loss of jobs, health insurance, and social stigma (Kitcher, 1996). Information technology plays a large role in the genomic revolution (Moor, 1999), in particular, enabling the field of bioinformatics with its need for large databases matching clinical, genomic, and environmental data.

Remarkably, this has led to results of genomics appearing on the Web for public use. For example, about half of the visits to the Toronto Children's Hospital Chromosome 7 site (http://www.chr7.org) are from ordinary people (Sherer, 2004). Notice that this bypasses official gatekeepers of genetic information; namely, genetic counselors, so that it not only raises issues of biomedical ethics but changes the politics of genomic medicine. Also, such sites help disorder advocacy groups to form, changing the large-scale politics of health care. The previously mentioned site has a For Families page listing research and support groups (see Stockdale and Terry [2002] and the interesting site of the U.S. National Organization for Rare Disorders [http://www.rarediseases.org] discussed there).

Notice, as well, that network technology raises questions about what it means for something to be public. The information on the Chromosome 7 Annotation Project is from published scientific sources. Therefore, the collators can say that they only are easing access to already public data. However, this overlooks the practical obscurity of physical access to inaccessible scientific papers.

## Calendars and the Information Commons

Again, we may learn by looking at less charged examples. Take the example of group calendaring, which is easy to implement in an environment of networked computers but, as it turns out, very difficult to achieve. That is, while

many of us use personal computers, personal digital assistants, or cell phones to plan our personal calendars, and although most of these devices intercommunicate, most of us do not share our calendars in our workgroups. This has been plausibly explained by users' strategic motivations. "The group calendaring value of electronic calendaring is lost unless everyone cooperates. People do not have an incentive to maintain their calendars in such a way that they support group use" (Bullen & Bennett, 1991, p. 271). Here is a basic problem overlooked by schemes like Gelernter's (1991) that envision wide-scale sharing of personal information. Any information sharing imposes some cost; in addition, medical, financial, religious, and political information poses serious risks. The benefits come mainly from others sharing their information. This makes sharing information a version of the tragedy of the commons (Hardin, 1968). Privacy rights do not speak directly to this problem, which shows that we will need to work on new questions of motivation as we move to implement large-scale social information sharing like that which is required by genomic health care.

## FUTURE TRENDS

What general lessons can we learn, given the likelihood that technological change will present challenges entirely unforeseen in this article? Three features make the ensemble of monitoring technologies problematic for the future:

1. Moore's law applies to sensors and communication technology as well as to computers, so we can predict confidently that new problems will be presented by monitoring technologies. Sensors will become smaller, cheaper, and easier to network and to hide.
2. These technological changes will not respect existing moral or regulatory categories. The economics of integrated circuit-chip-based technology means that technologies like RFID or GPS become cheap across the board, so they are likely to generate all sorts of new, unexpected uses. In addition, the drivers of technological change are uneven. It is surprising that RFID chips already are placed in people before we have had a chance to get used to them (i.e., adjust our norms on less vital applications) in books, cartons, or food. GPS was introduced in automobiles to track rental units. Then, parents began using it to track young drivers.
3. Most monitoring technologies have not developed in ethically rich environments. As noted, bioethics has shown itself capable of developing and putting into practice sophisticated evaluations of emerging health care technologies, including monitoring technologies. In contrast, many monitoring technologies (the extreme are covert technologies such as Nanny Cams) have developed outside of critical oversight and institutional governance.

## CONCLUSION

We collect our suggestions as a set of recommendations:

1. **Awareness:** It is useful to know that a monitoring or surveillance device is in use at a particular location on in a particular device. This recommendation ranges from cell phone cameras that make a mandatory noise (as required in Korea) or flash to surveillance cameras that emit an infrared beacon. This leads to greater accountability.
2. **Transparency:** It is useful to be able to read the data (e.g., with a credit report). Many technologies conflict with this principle: transit tickets with tracking magnetic stripes, surveillance cameras in commercial and pubic locations, and supermarket loyalty cards. We recommend that all users of these technologies provide simple ways for their subjects to read or see the data involved.
3. **Control:** It is useful to be able to control one's data in order to enable negotiations over use. As new users adopt technologies, a particular problem is bad default settings, which leave monitoring devices open to unsuspected access. The unanticipated growth of sophisticated search engines intensifies this loss of control. For example, searching with Google on the string inurl:"ViewerFrame?Mode=" finds unprotected security cameras a year after the problem was uncovered (Poulsen, 2005).
4. **Openendedness:** We can overemphasize the risks to privacy posed by these technologies. Open data can be useful in ways in which it is difficult to anticipate. We have mentioned possibilities of labeling and reviewing items by linking alternative sources of data to tags, as has been done for UPC barcodes by the AURA system discussed previously. GoogleMaps and the publication of genomics data are serious current examples.

## KEY TERMS

**Big Brother:** Orwell's (1949) fictional depiction of a totalitarian state employing two-way television for constant surveillance gave rise to this metaphor for the surveillance state.

**Black Box:** Event data recorders (EDRs), which are found in aircraft, in ships, and increasingly in automobiles, store a record of inputs on speed, orientation, engine settings, and impact in a form recoverable after a serious accident.

**Dataveillance:** The systematic use of personal data systems in the investigation or monitoring of the actions or communications of one or more persons (Clark, 1988).

**Global Positioning System (GPS):** Devices that establish location within meters by means of satellite-based radio triangulation.

**International Standard Book Number (ISBN):** A unique identifier for books designed for commerce. Periodicals are marked with the similar ISSN (International Standard Serial Number).

**Monitoring:** The systematic observation of things, places, processes, or persons.

**Moore's Law:** The empirical observation attributed to a co-founder of Intel that the complexity of integrated circuits doubles every 18 months.

**Panopticon:** A technologically advanced prison in 1787 introduced by Bentham (1969) and developed by Foucault (1977) as a metaphor for surveillance.

**Radio Frequency Identification (RFID):** A technology that uses radio waves to read information from a tag.

**Surveillance:** The targeted monitoring of persons for evidence of crime or other sanctioned behavior.

**Universal Product Code (UPC):** The original numerical barcode used on commercial products, typically read by a laser scanner on point-of-sale terminals.

# Natural Resource Information Management at State Government Level

## INTRODUCTION

Spatial information management (SIM), which includes utilization of geographical information systems (GIS), is used in a wide variety of information resource applications.

GIS applications have been able to make use of the extraordinary expansion in available data from remote sensing operations such as satellite imagery. SIM has been able to build upon these systems using software support for spatial databases and interactive mapping applications. Private sector applications tend to be specific to sectors of interest, whereas public sector systems have wide application across sectors.

The information management that is applied has a technical dimension facilitated by GIS. It also has analytical and strategic dimensions that require detailed investigation and planning for the corporate context in which the SIM is undertaken.

This contribution provides a brief overview of some of the contextual influences on SIM, and then details a case study of a particular application to natural resource information management in a government department.

## NATURAL RESOURCES APPLICATIONS: BACKGROUND

### Standards and Coordination

Governments have been concerned to coordinate information within national frameworks that can be applied at local levels. For example, in Australia and New Zealand, there is the Australia New Zealand Land Information Council (ANZLIC) that manages a national strategy for land and geographic information. In Australia's case this is directed towards an Australian Spatial Data Infrastructure (ASDI) operating at federal and state level (ANZLIC, 2004).

ASDI aspires to foster a distributed data network incorporating validated core data sets with associated products and services to support economic, ecological, and social development. Its agenda is also to ensure archiving of data for future use, avoid duplication of datasets, and provide best practice quality assurance.

Included among the guidance provided by ANZLIC is an information management toolkit (National Land and Water Resources Audit & ANZLIC, 2003). This toolkit, among other things outlines data management principles; compliance; approaches to interpretation and visualization of data; data discovery and access; guidelines for software selection; map production; global positioning systems (GPS) practice and guidelines; and project management.

The national frameworks in turn may be responsive to international efforts in the same direction. For example, the large number of datasets of different types that are employed in SIM has led to attempts to standardize and coordinate the description of data within these datasets. This so-called metadata is now standardized as an international standard ISO 19115 (International Standards Organization, 2003).

The standard defines hundreds of data elements all within a broadly based thematic classification involving 19 categories. Eight of these: atmosphere, biodiversity, environment, farming, geoscience, inland waters, oceans, and planning (for future use of land) are of particular concern in the natural resources area. However, other categories such as boundaries and location (positional information) are also of interest.

### Infrastructure

Although ASDI provides a national framework in Australia, there are normally State-based mechanisms for ensur-

ing development and delivery. At this level in Australia, examples include:

- Queensland Spatial Information Infrastructure Strategy (QSIIS). A key delivery initiative is Information Queensland (IQ)
- Western Australian Land Information System (WALIS). A key delivery initiative is the Shared Land Information Platform (SLIP)
- New South Wales Natural Resources Information Management Strategy (NRIMS). A key delivery initiative is the Community Access to Natural Resource Information (CANRI, 2004)
- Northern Territory Land Information Management Coordination Group (LIMCG). A key delivery initiative is the Northern Territory Land Information System (NTLIS).

Each of these initiatives requires cooperation and participation between three tiers of government, the private sector, and the community, each of which has roles and responsibilities in the development of the spatial information industry at the state level. These initiatives assist easy access to relevant and reliable integrated spatial information in each State and provide a supporting infrastructure which enables jurisdictions to improve productivity and efficiency, make lifestyle and community choices and manage each state's resources.

Research in spatial information system design and data infrastructure at a national level is being undertaken through mechanisms such as the Cooperative Research Center for Spatial Information. The research outcomes of this project will provide a foundation for identifying best practice and key performance indicators to aid in implementing a virtual Australia.

## NATURAL RESOURCE INFORMATION INTEGRATION: CASE STUDY

### A State Level Government Department

The Queensland Department of Natural Resources and Mines (NR&M) has lead-agency responsibility for the management of land, water, native vegetation, and mines in that State. Through planning and management responsibilities for these natural resources, it has a vision for "enhanced community benefit through sustainable natural resource management" (Queensland Department of Natural Resources & Mines, 2004). NR&M holds an array of data and information about these resources, gathered by various means over many years, with a replacement value estimated to be around A$5 billion. Ready availability and access to data and information is critical to delivering business outcomes and responding to emerging natural resource management issues.

Machinery-of-government changes over the last decade brought together several agencies into NR&M. With these came a legacy of disparate information systems with an equally disparate approach to the management of the data and information contained in them. It was apparent that issues such as salinity and water quality, water resource planning, vegetation management, greenhouse gas emissions, and erosion relied on an integrated response from more than just one business area—they required a "whole of landscape" approach to solving these topical issues. Another consideration was that much of the data had previously been captured for specific and somewhat isolated projects with differing requirements. This contributed to ad hoc information management (IM) processes throughout the organization resulting in such anomalies as pockets of data with differing scales, and attributes captured to various standards.

In 2000, senior management commissioned a business case to analyze the existing practices and provide a blueprint to create an environment where any required natural resource information could be easily integrated for rapid answers to issues arising. This Environment for Natural Resource Information Integration (ENRII) initiative stated that:

*The main focus is the data and information management processes needed to support the delivery of the department's integrated resource management outputs. The aim is to ensure data are accessible, well structured, of suitable quality and consistency, available for use efficiently and in a timely manner, and protect the value of the department's corporate natural resource data holdings, for now and the future.* (Queensland Department of Natural Resources and Mines, 2001, p. 9)

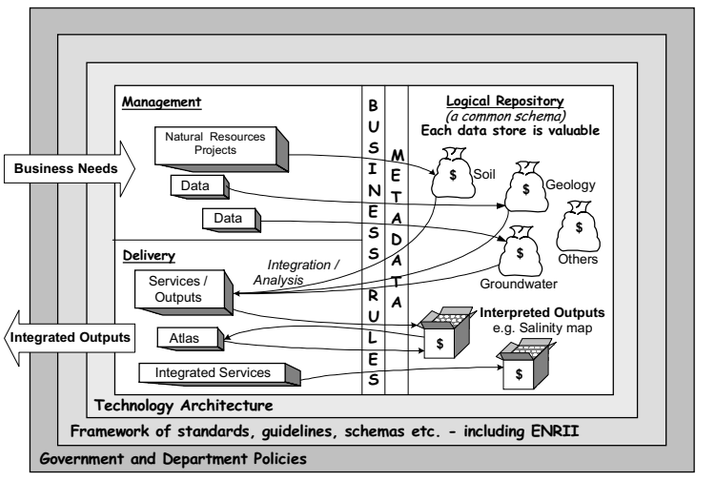
This case stimulated senior management to embark on a journey of cultural change from the former "silo mentality" of managing individual business-specific data stores, to a corporate approach with much broader benefit.

### ENRII Concept

The ENRII concept is to bring about a change in the organization to improve the management of data and information needed for natural resource management activities through:

- A framework of standards, specifications, and operational level guidelines

*Figure 1. ENRII–a conceptual view*



- Having efficient critical database management systems in place that provide "point of truth" storage for data and information; where data and information are acquired, used and re-used for many purposes by many business areas and other stakeholders
- Effective methods to access, use and distribute data and information
- Optimal network performance and data transfer methods
- Integration of data and information for natural resource management activities across all business areas

The concept highlights that data and information management must be seen and resourced as part of normal business practice, and not as an optional extra. A complementary suite of policies, standards, and architectures must be in place to support the storage, management, and delivery of corporate data and information, as shown in Figure 1.

The rectangles in Figure 1 can be likened to "onion rings" where each aspect of management is contained within, or builds on, a wider aspect, yet all work together to provide an integrated infrastructure for managing corporate data and information. Data move into and out of logical repositories past two "gate-keepers," namely the business rules which govern things such as how the data will be stored and who can access the data, and the metadata that describes fitness for purpose.

## Methodology

Examination of how IM practices were carried out focused on business functions as opposed to the structural units of the organization. It was thought that "what we do," had a greater chance of longevity than "where we sit" considering the machinery of government changes that had occurred in the past. This was vindicated towards the end of the business case project, when the Forest output was moved away from the department, and the Mines output was added. The methodology was able to cater for the changes without any reengineering.

Research was undertaken across the whole of the department via a comprehensive questionnaire for each of the identified business outputs. A reference group assisted the ENRII team in providing guidance to 44 experienced staff that regularly used and processed departmental data and information. A companion to the questionnaire provided standardized answers to assist in gaining a comparative result. Senior managers and executives were also interviewed.

The major steps in the methodology were to:

- Define functional business activities, model these in context
- Investigate current IM processes using the questionnaire and analyze the results
- Link IM processes to the business functions and assess synergies, deficiencies
- Assess the benefits of having a coordinated and consistent department-wide IM framework
- Assess possible solutions to solving the identified problems
- Assess broad costs and economic benefits for improving corporate IM processes
- Propose an action plan with recommendations on how to proceed

*Figure 2. High demand data sources*

| Data Source | Business Functions Supported |
|---|---|
| Digital Cadastral Database (DCDB) | 52 |
| Climate | > 20 |
| Geology | > 30 |
| Imagery (satellite) | 39 |
| Soil and Land Resources | 39 |
| Vegetation (regional ecosystems) | 27 |

## Findings

### Interaction and Process Flow

Considerable interaction between business areas in supplying and sourcing available data was revealed. It was found that 240 unique data sources were identified in the questionnaires and that these supported over 80 business activities. Of the 240 data sources, 59 each support more than 10 business functions. The six highest demand data sources are listed in Figure 2.

Once the flow of information, products, and services were mapped between business functions including transactions with external agencies, a picture of integration emerged. More clarity become apparent about the diverse and complex nature of information needs.

Information process flow (IPF) diagrams were prepared to articulate the priority data sets and how these may be used to deliver outcomes for the department. An example is shown in Figure 3, where data sets are analyzed within processes to produce outcomes.

Such diagrams provide the basis for understanding data and information needs and flows, and how the data might best be managed and made available. Mapping these IPFs forms the basis of a knowledge system that puts rigor behind information processes and promotes understanding on how data and information flows are an essential contributor to delivering whole systems science for natural resource sustainability.

Assessment and analysis from developing the business case also provided much information about current practices, as explained in more detail following.

### Data Storage

A significant proportion of important data sets are stored only on the local server. Figure 4 illustrates this with the

*Figure 3. IPF diagram for groundwater flow systems*

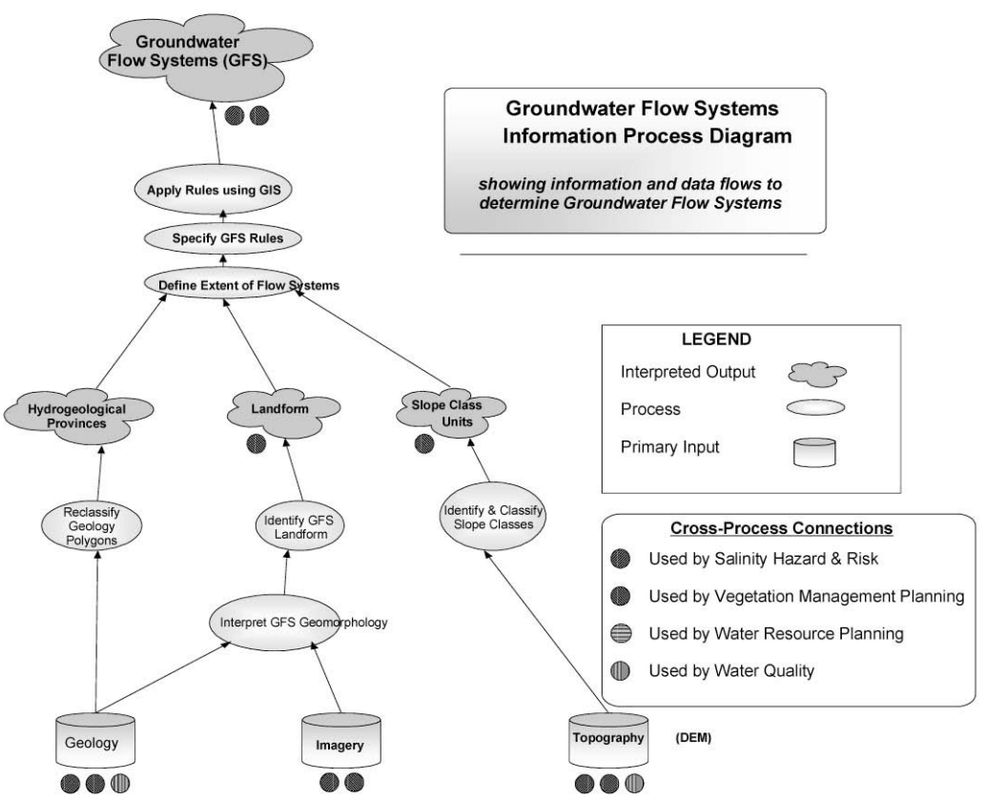


*Figure 4. Data storage and flows*

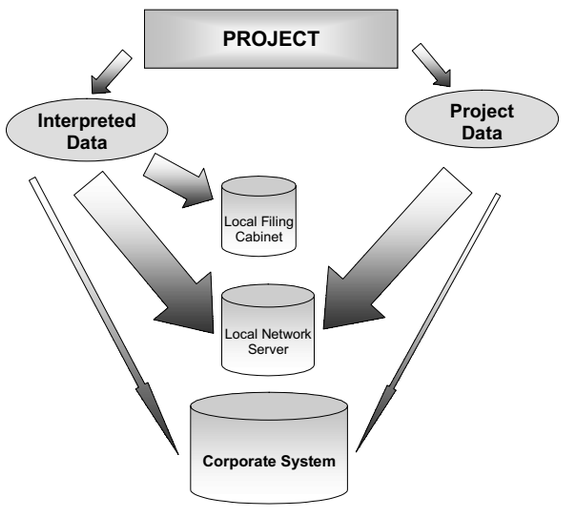


size of the arrow being an indication of the amount of data stored in the respective storage point.

This presents significant problems in the management of data including:

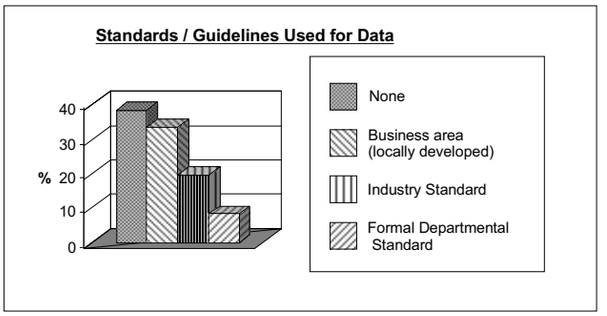
- Duplication of effort in storing data
- Inefficiencies in the storage space used by duplicated data sets
- Inconsistencies in updating the data across different regions
- Inconsistent decisions based on out of date "duplicated" data across regions

## Standards

A framework for standards, guidelines, and procedures make sure there is an alignment to business drivers, particularly in respect to data management systems, data access, and data sharing. Figure 1 shows how a standards framework fits within the conceptual view of ENRII. A framework looks at:

- Establishing agreed standards for data collection, management, documentation and processing
- Reducing duplication of effort in establishing standard (not developed in isolation)
- Establishing naming conventions for data sets and data storage methods
- Ensuring standards exist and are easy to find and are accessible
- Ensuring standards can be interpreted, understood, and adhered to

*Figure 5. Standards/guidelines used for data*



Standards, guidelines, and procedures are required to ensure data is captured or stored in a form that can readily be integrated with other data held by the department. This data can then be collated to build regional and statewide layers on the network. Standards also help steer any development or re-development of data sets and protect the value of the department's corporate natural resource data holdings. Figure 5 shows that some datasets have either no standards, or it is unknown if any standards are used.

The result is an inability to build regional and statewide layers to consistent standards. There are a significant proportion of standards, guidelines, and procedures that are locally developed within business areas. These are developed by individual business areas and may not be accepted throughout the department. The fact that a necessity exists for locally developed standards may indicate that formal standards are not available or not regarded as being suitable for the data. Nevertheless, a corporate approach to promulgating these standards is desirable to minimize inconsistencies across the department.

## Data Suppliers

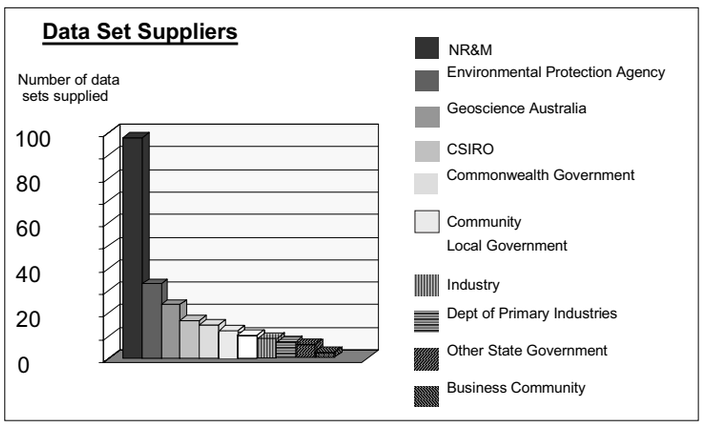
The department receives data from many organizations in order to do its core business, as illustrated in Figure 6.

Often, different business areas will obtain the same data for individual business needs leading to unnecessary duplicate storage of copies and versions across the organization. This reinforces the need for a corporate store of natural resources data to enable efficient access in real time from a recognized single point of truth.

## Action Program

ENRII consists of five main initiatives focusing on the data and information needs that support the core business of NR&M. Three of these are underway and are

*Figure 6. Data set suppliers*



discussed in this section. Two future initiatives are discussed under Future Developments.

## IM Standards and Custodianship

NR&M follows a custodianship model that provides a select group of senior policy managers with delegated responsibility for managing data and information relevant to the department's business. Data is categorized under themes based on the ISO 19115 metadata broad topic categories, which provide a comprehensive approach to high-level groupings of data.

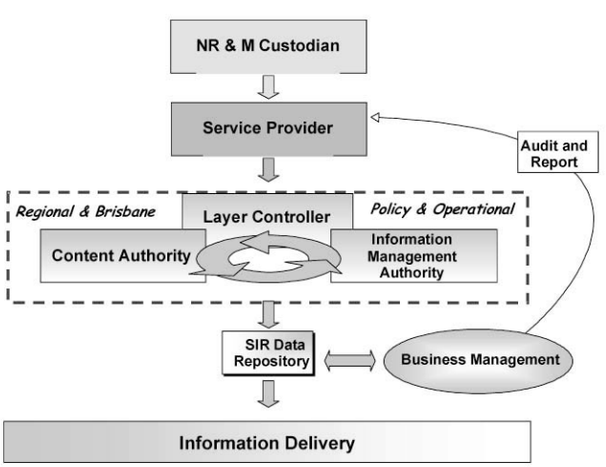
IPF diagrams such as Figure 3 allowed custodians to understand the totality of their responsibilities for not only the underlying data sources, but also the business processes and higher level information outputs that contribute to a high-level business outcome. Endorsement by NR&M custodians for each of the information flows mapped under this process was a major milestone in bringing about a cultural change to understanding the value and significance of the whole process. These diagrams formed the basis of adopting standards and developing protocols for managing the whole process and ensuring that all contributing data and information stored along the way was to a known and agreed level of quality assurance. This included such things as adopting standards for metadata (ISO 19115), data dictionary (NR&M Data Naming Convention) and agreement on standard presentation descriptions. Protocols for viewing, using, and updating the data within the organization and access constraints for external distribution were developed.

To ensure that these standards and protocols were implemented, a training and accreditation program was introduced throughout NR&M to train over 50 staff throughout the State in three distinct roles of layer controller, data management authority and content authority. This is illustrated in Figure 7. The roles are complementary to ensure that the data are verified and described as "fit for purpose" from a scientific, technical, and information management perspective. The process strives for a level of confidence in the data by both the end-user and the custodian and has been a significant step forward in bringing a cultural change to take IM into normal business practice.

## Spatial Information Resource (SIR)

The ENRII initiative developed the SIR as a corporate resource to managing natural resource spatial data and information that was previously captured for independent projects or did not have a logical corporate "home"

*Figure 7. Custodianship model*



(Queensland Department of Natural Resources and Mines, 2002b). Initially, the facility is storing data and information used in the NAP process, and will be the "single point of truth" repository for this information for the whole of the department. This approach advances the management of spatial information according to custodial requirements and helps to set standards and protocols over the previous ad-hoc and inefficient local arrangements. The information in this facility is managed within the framework of roles and responsibilities that operationalize the departmental custodianship standard.

At the data management level, the facility allows storage of base and interpreted data for individual projects as well as providing a statewide layer view. Only authorized users undertake data layer updates that are stored on the central server. Data volumes are scalable according to current and emerging needs. The facility provides efficient spatial data serving including the use of smart images of data as opposed to streaming only of required data for local use via Internet technology. The data served to all users is thus consistent from a "single point of truth."

The SIR facility provides a multi-user access & management environment for:

- GIS applications
- Web mapping applications (Open Geospatial Consortium (OGC) Web Map Services)
- Data discovery and access services

### Corporate Registry Service (CRS)

A current activity is the development of a registry (or catalog) service built on a services-oriented architecture using emerging open standards and specifications. It will become a gateway for NR&M staff to find and initiate Web-based data and information services from the department's many authoritative source data repositories. This will allow sharing and reuse of these Web services across the organization.

The initial implementation demonstrates seamless integration of a number of Web services from five candidate systems within NR&M. Each individual business system publishes its catalogue (or list) of Web services, which describes what those services contain (metadata), and what those services do (capabilities). The process provides a common mechanism to describe, classify, register, search, find and access data and information services from the point-of-truth data stores. This is achieved by adopting appropriate standards to enable interoperability between the data stores.

For example, many business outputs need to use property boundaries as a reference for location. By publishing a "data service" in the CRS, property boundaries are delivered to business users' applications from their "single point-of-truth."

Numerous other Web services may be created, accessed and shared in a similar manner. As well, the combining of more than one service may be achieved to form more detailed or complex outputs.

A service-oriented architecture provides seamless integration through the loose-coupling of business functions (applications/corporate databases, etc.) by offering a suite of Web services that are available for re-use by many applications across an agency. These Web services are described with metadata and perform a prescribed function set by the service provider to meet the needs of service clients. Web services are essentially re-usable business objects, in that they can be developed once and used many times. The corporate registry service is a key component of a service-oriented architecture. Such architecture will enable business systems in NR&M to share data and information to meet the department's need for more holistic approaches to natural resource management.

## FUTURE DEVELOPMENTS

### Knowledge Management Processes

In a large organization, data and information may be used in many contexts beyond the initial purpose for which it was captured. The data stores may be managed well in "silos," but possibly in ignorance of how the information flows through various processes to reach high-level organizational objectives. These objectives in themselves are recognized as "must-haves," in order to achieve business goals, but achieving the information transfer is often misunderstood, undocumented and hence inadequately resourced. Furthermore, the way that the information flows and the effects that processes have on the data, form the basis of the organization's knowledge management.

Work completed for IPFs to date provides a platform for documentation of a corporate knowledge management system that will show how work practices, modeling procedures and operational processes are undertaken. It will provide a rich source of understanding of how business outputs are arrived at from a policy, planning, and scientific aspect.

### Influence of Cultural Change

Each of the previous initiatives is reliant upon a significant cultural acceptance to change the way that data and

information at all levels is managed, resourced, and preserved. The ENRII philosophy is to promote a corporate culture where major projects are undertaken with "eyes wide open" with respect to the information needs. Organizations need to plan for the whole lifecycle management of data and information generated and assembled not only for a specific need but also for the future after a project is completed.

## CONCLUSION

ENRII is an investment by the department in support of its corporate objectives (Queensland Department of Natural Resources and Mines, 2002a). The approach provides a model for similar SIM initiatives at government level, in particular by:

- Taking a leadership role in the stewardship of natural resources
- Building organizational capability to improve business performance

Each of the initiatives outlined fosters a cultural change within NR&M relating to its understanding, use, and management of information in order to unlock the wealth of this information for the benefit of the community and future generations. These are not achieved without addressing challenges such as:

- Allowing time and providing resources to plan for future
- Fostering culture to look beyond short-term project needs
- Actively collaborating across business boundaries
- Determining how to fund and maintain through a full lifecycle
- Providing leadership and management

These should lead to impacts that include:

- Enabling effective response to the government
- Providing better informed support for decision making
- Achieving improved services delivery
- Significantly improving access to data and information

## KEY TERMS

**Authoritative Source:** A place where data and information from the point of truth are made accessible for others to use. The access constraints and quality of data and information delivered from the authoritative source is the responsibility of the custodian of that data and information.

**Catalog Service:** See Registry Service.

**Custodianship:** Responsibility for data stores and information flows.

**Geographic Information System (GIS):** A specialized form of an information system capable of assembling, storing, manipulating, retrieving and portraying location-referenced information from a database.

**Information Process Flow:** Schematic illustration of relationship between data, its interpretation, and outcomes of its use.

**Knowledge Management:** Application of information management with human resources procedures to make effective use of unstructured personal knowledge and

structured corporate information to address corporate objectives.

**Metadata:** Information that describes other information—in spatial terms this may range from the creator of a document to map coordinates.

**Point of Truth:** The single place where data and information are maintained and updated to meet the requirements of their custodian. The point of truth may or may not be an authoritative source for use by others depending on the level of risk to the primary maintenance function.

**Registry Service:** A tool providing client applications the ability to discover data and information services from online catalogs through searching metadata about these services. OGC conformant registry (or catalog) services will enable a Web browser to report Web sites that contain certain data themes for certain geographic areas for certain time frames.

**Spatial Information Management:** The management procedures required for dealing with location-referenced information, including management of GIS and the procedures associated with GIS use.

**Web Services:** Self-contained, self-describing, modular applications that can be published, located, and invoked across the Web. Web services perform functions that can be anything from simple requests to complicated business processes or geoprocessing resources. Once a Web service is deployed, other applications (and other Web services) can discover and invoke the deployed service according to its described capabilities.

# Negotiation Strategies Based on Decision Conferencing

**José A. Rubio Blanco**
*Rey Juan Carlos University, Spain*

## INTRODUCTION

Our current democratic institutions stem from times in which transportation and communications were difficult and time consuming. With the time, politics have evolved little and politicians have developed a style in which, except at political campaigns, they have little feedback from citizens. Most ideas so far relating Internet and politics are directed toward facilitating traditional political methods through new technologies. Our feeling is that there are ways to transform, rather than facilitate. This transformation is possible because when the way in which the citizens interact with their representatives is modified, and this transformation makes possible that citizens play an active role, they could make decisions of major quality and more agreed by consensus, which is not possible with the mere automatic use of the new technologies, since it is not the same thing to allow that a citizen could vote from his or her house, facilitating the use of the traditional political methods, that in addition to be able to guide to this one in the different phases of the decision making, doing that his or her judgments and preferences are taken in account by the system. We propose migrating to Internet methodology of decision conferencing to support group-decision conferences through our architecture, QUIXOTE, born of Toward Electronic Democracy (TED) project of the European Science Foundation (ESF).

Thanks to our architecture we distribute rationality to better resolve political decision making, helping groups through the Web facilitating them the use of decision and negotiation analysis methods.

## BACKGROUND

There have been several attempts to give a new approach to the democratic processes, and to the way in which the citizens are related to their governors. All this to revitalize the democracy and to make that the opinion of the citizens will be really considered, being this is something very necessary as pointed out by authors such as Pateman (1970) or Putnam (2001). Until now, attempts to transform democracy through the Internet have chased just to facilitate through the new technologies the standard political methods, which we think leaves much to be desired. For this reason, our intention is of transforming these processes making that the citizens interact in all the phases of the decision making. With this we could make it possible to reach solutions more agreed by consensus and of major quality, being this necessity is something already pointed out by the United Nations (2004) in its reports on the degree of preparation of the different countries for electronic democracy and government.

Therefore, to change our representative democracy to a deliberative one we use several tools, as decision analysis, thanks to which we can identify and construct all the elements of interest of a decision problem determined, being able to advise citizens on the consequences of their actions and choices since we give a treatment adapted to the uncertainty inherent to the problems of decision making. With this we could make better and more informed decisions since we explored all the implications and subjective suppositions of the different citizens. In the same way, thanks to the structuration of the decision problem, the clarification of the different aims and the qualitative and quantitative study of the possible choices, we can do that the citizen has a major knowledge of the decision problem which he or she faces, showing him or her, therefore, the best strategy to follow according to his or her interests. Moreover, inside the tools of the decision science, we also use the negotiation analysis, with which we will be able to treat those cases in which there are different parts implied that can reach joint agreements.

To this set of tools we have to add the cryptography, thanks to which we can assure that all the processes and the interchange of messages between the system and the citizens, is realized in a safe way, being this is an indispensable requirement in this type of system.

## QUIXOTE ARCHITECTURE

We build an asynchronous Internet-based implementation of decision conferences to support group decision processes, migrating with this way to the Internet the methodology of decision conferencing (McCartt & Rohrbough, 1989). With this methodology we can focus on a particular task or problem combining participants'

judgments with data. The main tasks to develop in this phase are:

- Represent the diversity of perspectives on the issues
- Generate shared understanding of the issues
- Develop a sense of common purpose
- Create the structure of a model that of the decision problem
- Develop a better appreciation of uncertainty

In QUIXOTE, this decision analysis would be carried out by a decision analyst on a master system for the decision-making problem owner, where the system would provide support for the entire decision-making cycle (Clemen, 1996) using several modeling techniques to construct the preferences in certainty and uncertainty, identify and structure the problem, and add the judgments and behaviors of the citizens. At various stages of the process, some or all of the models would be fed into a server, which could be accessed by different stakeholders and the general public. When an issue is being addressed the server provides pages inviting comments and submissions, for later develops pages actively which allows users to interact with the model to explore the implications of their individual perspectives and judgments, with what the citizens could construct their preference models. All is supported by the Internet with confidence built in through a cryptographically secure open truthful exchange (CSOTE) approach (Rubio, 2004; Rubio, Rios Insua, Rios, & Fernandez, 2005).

The difficulty lies in the different values and beliefs of the stakeholders, which would opt for different alternatives. For that reason is necessary to enter into a negotiation round in which a more consensual solution might be sought. Also we have to consider the contexts in which no consensus is reached, where we appeal to a voting scheme.

## DECISION CONFERENCING

Once users have built their preference models, they will assess their utility functions (French & Rios Insua, 2000) privately and communicate it to the system. The system allows for the specification of basic properties of multiple objectives as number of objectives, their scale and range, whether the objective is to be minimized or maximized and the assessment of each component utility function with the probability equivalent method (Rios & Rios Insua, 2004; Rubio, Rios Insua, Rios, & Fernandez, 2004). Later, with the preferences of each participant, we may proceed to compute his or her optimal alternative. For that purpose, the system includes a module that allows users to evaluate the influence diagram, with which we structure the decision-making problem, based on his or her utility function, to obtain his or her preferred maximum expected utility course of action. Frequently, the various parties involved will reach different optimal solutions and for that reason a round of negotiations may be undertaken to try to reach a consensus. This negotiation is done by the CSOTE method and a modification of the balanced increment method (Rubio et al., 2004), where at each iteration the system offers a solution to participants and if this is accepted, it stops, that being a consensus. To help the negotiators to reach a consensus the balanced increment method show the ideal expected utilities achievable within the nondominated set of solutions, which guarantees that there is no other alternative unanimously preferred by the citizens.

## THE CSOTE METHOD

One of the most important issues related with e-democracy is the confidence and trust among system users. For this reason, we have built on what we call the CSOTE framework, in contrast with the FOTE and POTE frameworks described by Raiffa (2002). By CSOTE we understand cryptographically secure open truthful exchange of information among participants and the system, enhancing reliability of all processes, achieved through confidentiality of system data which will be accessible to only authorised parts, communications security protecting bidirectional channels user system, data integrity so that they are only modifiable by data owners and accessibility mitigating system attacks. All these issues may be achieved through cryptographical methods, and specifically with public key cryptographical methods (Goldreich, 1999; Lee, 2001; Schneider, 1996), with which we develop a more open, flexible, and reliable framework for negotiations in which the involved parts may reveal their real objectives and achieve satisfactory agreements. This also aids us in automating negotiation processes as we may support all the issues we are interested in.

Specifically, we can use these methods in the following phases of the negotiation: interaction with the system, negotiation phase, and voting phase if there is no consensus. In the interaction with the system a participant must send his information to the system and, possibly, may wish to obtain a summary of the opinions of other users. For this purpose, we use, among others, the following methods:

- **Partial Secret Revealing Techniques:** They are based on the global knowledge of a function, with

each party knowing and revealing only a part of the information of the function and ignoring the rest. Some applications are facilitate comparison of the utility functions of participants, should they wish to, with minimal revealing of information. With it, they could find out which of them is more risk averse or compare their weightings of various objectives, without revealing their exact values, to find out which participant gives bigger importance to a criterion.

- **Zero Knowledge Techniques:** We use ElGamal's cryptosystem as a basis to determine the equality or inequality of two discrete logarithms and build knowledge proofs to verify users' information. Thanks to which the users may obtain any kind of partial information about other users' preferences, with them no revealing no more than the necessary information, and therefore protecting the rest of it.

In the negotiation phase, the CSOTE methodology is specially relevant. Once the users' preferences have been stored, we may proceed to look for alternatives satisfying the involved parts. For that purpose, we use, among others, the following methods:

- **(k,n)-Threshold Schemes:** An interesting piece of information (a secret) is divided in parts, in such a way that we only need to know $k < n$ of them to recover the secret. We apply this method to ensure that the choice of a certain action is made only if k users out of the existing n go for it.
- **Selling of Secrets Techniques:** With them, a buyer chooses what (secrets) to buy, with the seller not knowing what he or she has sold. We use the RSA cryptosystem, generating k cryptosystems, with special features, together with Jacobi symbols to enhance transparency in negotiations. To wit, with them, users may undertake exchanges and, moreover, negotiate over any set of elements or objectives in a transparent manner. Moreover, each user has the possibility of weighting their choices, as well the importance of the elements to negotiate.

Finally, if there is no consensus, we enter into the voting phase. To undertake this process, we must take into account the transparency, the capacity of the user to verify his or her vote and, last but not least, the capacity to avoid a voter as not being able to give proof of his or her vote to another entity, so as to avoid vote dealing. At the moment, most known schemes are based on critical assumptions which make them vulnerable, including the existence of truthful communications and a truthful third part. Alternatively, we opt for using schemes which include a tamper-proof randomizer (TPR), which allows us to randomize votes, leaving aside the need to use reliable third parts.

## FUTURE TRENDS

One of the main aspects in which we have to center all the efforts is the treatment of the so-called mental tunnels, which lead to systematic mistakes in the decision making (Kahneman, Slovic, & Tversky, 1982), reason by which any group decision support system have to be robust against this type of threat to the rationality since until now in the majority of existing systems this type of problems has received a not completely exhaustive treatment (Hämäläinen, 2003; Mustajoki, Hämäläinen, & Marttunen, 2004), and given the importance of this topic the implementation in the group decision support systems of these cognitive aspects have to be studied with major depth. In the same way, we have to be capable of making intuitive systems, which can be easily used by citizens, because below this type of systems are mathematical concepts, in many cases foreign to the average citizen, reason by which these concepts have to be explained in such a way that any citizen feels comfortable in their use.

Therefore, the adequacy of this type of systems to the average citizen is undoubtedly the major labor to develop, and although there are already different studies realized in this field (Gregory, Fischhoff, & McDaniels, 2005; Mumpower, 2001; Rowe & Frewer, 2000, 2005), still the aspects to study are considerable.

## CONCLUSION

Rather than using new technologies to facilitate standard political decision making mechanisms, our scheme would radically modify them by allowing more participation from stakeholders and a more consensual approach, not remaining therefore in a mere automation of the traditional political systems, going beyond since the citizens could participate in a more active way. We have outlined issues concerting trust and confidence, key in e-democracy.

In the same way, we have pointed out the new technologies that can help us to rationalize the political decision making, being able to make decisions of major quality and to help ourselves stop the political discontent extended in the society in the last years, since the citizens could see the political decision making as an opportunity in which to express their opinions, taking active part in these processes. Moreover, it has been demonstrated that under suitable circumstances the groups demonstrate a notable intelligence (Surowiecki, 2004). So, in the decision making the collective decision is in the habit of being an indication of excellence, being the key of the success in satisfying the conditions that

the group needs to demonstrate its intelligence, which can be reached by all the tools showed for the group decision making.

This type of framework of decision making will be of great importance in the future, since a considerable number of countries and organizations are studying ways in which to develop electronic participation systems, looking for a suitable way with which to cover all the chased needs. We believe that our system, and the concepts treated in it, can perform well in the future.

## KEY TERMS

**Balanced Increment Method:** Multilateral negotiation method where the system does equitable offers to the parts, and according to the given answers the system continues giving solutions up to coming to consensus.

**Cryptographically Secure Open Truthful (CSOTE):** CSOTE is a negotiation paradigm that overcomes other paradigms such as FOTE and POTE by means of a great set of cryptographic methods, not making suppositions about the style of stakeholders, so as they forget the strategy taken to limit.

**Full Open Truthful Exchange (FOTE):** FOTE is a negotiation paradigm developed by Raiffa in which it is

supposed that all the parts involved in the negotiation use a collaborative style saying all the truth.

**Influence Diagram:** Graphical method that allows the problem owner to structure the decision-making problem in terms of uncertainty, decision, and value nodes.

**Partial Open Truthful Exchange (POTE):** POTE is a negotiation paradigm developed by Raiffa in which it is supposed that all the parts involved in the negotiation use a collaborative style saying the truth but not all the truth.

**Probability Equivalent Method:** Method in which the system raise to the user the comparison of several bets. The idea consists of proposing a concrete initial value of probability for the bets, and to be fitting the probabilities until the user feels indifference among these, which was indicating the looked value.

**Public Key Cryptography:** Based on the use of a pair of keys, where with one we encode and with the other we decode a message. One is in the possession of the owner, private key, and the other key is publicized, public key.

**Server:** A computer in charge of providing decision models to different stakeholders.

**Utility Function:** Associate with a stakeholder, reflect his or her weighting of attributes and the inclination or aversion to risk.

# Net Diplomacy

**Prodromos Yannas**
*Technological Educational Institution of Western Macedonia, Greece*

Looking back to the not-so-distant past, one is struck to learn how much the world has changed in the last 30 to 35 years. New developments in major spheres of activity and new ways of knowing have altered, redefined or even transformed, in some cases, the ways we think, act and do things in the world. Changes are evident in all walks of life. In global politics, the end of the Cold War and the fall of communism have brought to the fore new actors and new issues. Nation-states are the principal but not the sole actors on the world stage. International organizations (IOs), non-governmental organizations (NGOs), transnational corporations, social movements and other non-state entities like media organizations and terrorist groups play an important role in setting the agenda and exerting influence on a global scale. Traditional concerns of sovereignty and security are still important, but policy-makers and academics are asked to re-conceptualize these concepts in lieu of the challenges posed by globalization and new threats to human security, like economic and ecological degradation, terrorism, massive immigration flows, the spread of infectious diseases and contamination of the food chain, to name a few.

To deal and adjust in a very competitive world economy, the corporate sector has espoused flexible accumulation, a regime based upon vertical production disintegration (sub-contracting, outsourcing, etc.) and encompasses innovation and differentiation in the production and marketing of products and services (Harvey, 1990).

Breakthroughs of a similar magnitude have also occurred in the areas of strategic thinking and military organization. Military operations incorporate new information and communication technologies (ICTs) and technological surveillance systems with the aim to bring the enemy to its knees through precision, surgical targeting. For military units to perform optimally, the command system must be decentralized and important decisions must be left to the operating units. Military analysts in the United States (U.S.) have gone so far as to label the new logic in the thinking and conduct of warfare a revolution in military affairs.

Underlying new developments in all realms of human activity has been an information revolution (Keohane & Nye, 1998). The innovations and breakthroughs in the ICTs of the past 30 years have no parallel in history. Developments in telephony have been superceded by fax and TV, satellites, cable TV networks and, last but not least, the expanding potential of computers connected in networks in the private (intranets) and public (Internet) spheres of life. The Internet and World Wide Web have grown exponentially, with 812,931,592 million people at present capable of accessing the Internet (Internet World Stats, 2004). All major powers that comprise the G-8, with the exception of Russia, figure in the list of top 10 countries with highest percentage of Internet users per capita. The U.S. leads the way, with a 68.8% Internet penetration rate, followed in descending rank order by Canada (64.2%), United Kingdom (58.5%) Germany (57.1%), Japan (52.2%), Italy (49.3%) and France (40.6%). (Internet World Stats, 2004). Other countries on the list include South Korea (62.4%), Brazil (10.8%) and China (6.8%) (Internet World Stats, 2004).

Speed, the vast quantity of information available and easy, low-cost access to information are main features of the information revolution transforming identities and recasting professional practices like diplomacy in a new light. According to Keohane and Nye (1998), information comes in three forms: strategic, commercial and free. Strategic information is ingrained in intelligence and reconnaissance systems and vital for early warning, preventive measures as well as for carrying, if needed, military operations. Companies provide commercial information in exchange for a payment. Products are traded and sold and services are offered over the Internet. The burgeoning activity surrounding e-commerce falls in this category. Free information is the most widespread form in the public sphere. Nation-states and non-state actors alike post information on the Internet to communicate, persuade and motivate their audiences to action. Information's pivotal role in global affairs is acknowledged in the concepts of soft power and information edge. The persuasiveness of free information enables an actor to exercise soft power; that is, to accomplish desired outcomes because other actors acknowledge and follow the lead of the initial actor in setting the agenda and/or establishing norms and institutions that bring about the desired outcome (Keohane & Nye, 1998). Information as a component of soft power can offer a comparative advantage or an information edge to those states and non-state actors that know how to use and exploit the new ICT (Nye & Owens, 1996). For example, some nation-states develop information edge in the area of strategic communication,

whereas non-state actors develop networks, disseminating information over the Internet and mobilizing supporters on global issues.

The sweeping winds of the information revolution could not leave unearthed even areas of activity known for their conservatism and skepticism to adjust to rapid change like the practice of diplomacy. Up to the present, diplomats as a profession have privileged courtesy, patience and compromise as modes of operation. Diplomatic time is slow and change is accomplished by an incremental step-by-step approach. Diplomats, as members of the diplomatic corps, observe formal as well as tacit rules of behavior and share a communal sense of belonging reinforced by their socialization practices and ritualized interactions. In terms of skills, diplomats rely upon face-to-face interpersonal relationships and have been lagging behind the military officers in upgrading their technical skills. In mediating conflicts and negotiating settlements, diplomats are inclined to favor secret meetings among state elites over open communications and deliberations engaging broader segments of societies. In terms of training, their educational backgrounds originate from a number of academic disciplines (i.e., history, literature, political science, economics, international relations, etc.) and the glue that seems to bind professional diplomats together is their common realist orientation to the understanding of world affairs (Onuf, 1989, p. 249). One can easily surmise that the profile of diplomats is not conducive to the fast pace, transparent and publicly debated mode of communication engendered by the information revolution. Perhaps diplomacy and information and communication technologies may not be a good match but the former can afford to ignore the later at the risk of its own peril.

There is widely held agreement that the key diplomatic functions involve representation, communication and negotiation. To these functions one may add promotion of economic-commercial and legal interests, promotion of cultural relations and policy advice to decision-makers (Jönsson, 2002, p. 215). What remains, though, still in dispute is who represents what entities. Narrow conceptions of diplomacy, advanced by the realist school in international relations, acknowledge professional diplomats as agents of states in an international system of nation-states. Broad conceptions of diplomacy, more attuned to critical and interpretive perspectives in International Relations extend representation to include non-state actors and define diplomacy as "a regulated process of communication between at least two subjects, conducted by their representative agents over a particular object" (Constantinou, 1996, pp. 25-26). Diplomacy involves the sustained exchange of information and the practice of persuasion among state and non-state actors for reaching agreement and solving problems on national and global issues. The communication function remains central to both conceptions of diplomacy and inquiring into the effects of the information revolution on diplomatic practice is pertinent as ever.

The key question to ask is how the information and communication technologies, along with the force of globalization and the emergence of a vocal global civil society, are impacting the conduct of diplomacy. To address this question, we will examine changes that are occurring at the substance and the practices of diplomacy. We will then proceed to demonstrate, by reference to a number of examples, how governments have adjusted to the information revolution and how non-state transnational actors have been empowered by information and communication technologies.

Information and communication technologies (ICTs) and the force of globalization have undermined territorially-based state sovereignty. Territory as a dimension of world affairs is downgraded and the conception that the world resembles more a network of nodes representing organizations, individuals or portals in cyberspace warrants serious consideration. Nation-states are still the principal actors and retain the power to grand or withhold recognition in a system of states. However, interdependence among nation-states, the effacing of the domestic-foreign divide in addressing global issues and problems and the new opportunities afforded by the use of information and communication technologies, have brought about both a re-conceptualization in the substance and practices of diplomacy and a diffusion of diplomacy to transnational non-state actors that comprise global civil society. Presently, diplomacy is "shared by all who speak and act on a global level to arbitrate, negotiate, mediate, or any way represent the multiple perspectives that make up these publics" (Brown & Studemeister, 2002). As a consequence, diplomatic activities are carried out not only by professional diplomats but also by others like nongovernmental organizations, social movements, activists and representatives of transnational businesses. All these entities address global issues either collaborating through the formation of global policy networks or coalescing against policies of states and international organizations. It is becoming increasingly apparent that the actors of the new networked global society appeal and attempt to persuade a global public opinion of a multilayered and ever-shifting composition of interests.

As already mentioned, speed, easy access to vast amounts of information and transparency characterize the information revolution. Each of these characteristics is impacting diplomacy in a number of ways. Speed allows high-level officials in foreign ministries to process and analyze information. In this respect, officials charged with decision-making benefit in the sense of receiving information in a matter of seconds from a variety of sources, not

just relying on the reports of the field officers. The process of decision-making is also widened, allowing individuals to engage in policy formation as team players and not necessarily according to their positions in the hierarchy of the foreign policy bureaucracy. At first glance, speed may be rendering redundant the work of field officers. Taking a closer look, one realizes that field officers perform the indispensable service of experiencing first hand local conditions, interpreting and analyzing information and taking into consideration cultural and historical sensibilities in reporting back to their foreign ministries at home. As former U.S. Secretary of State George Shultz has remarked, "information technology cannot replace solid diplomatic reporting" (Shultz, 1997). Speed also enables field diplomatic officers to coordinate better with headquarters and other branches of government in crisis situations. The other two characteristics—access to information and transparency—break down the idea that effective diplomacy is conducted behind closed doors and push diplomats to engage in public deliberations with other entities and be held accountable for their actions to global public opinion.

Information and communication technologies (ICTs) have also impacted the content, the organizational structures and the human resources of foreign policy bureaucracies. In terms of content, government organizations utilize the Internet to disseminate and receive information on various initiatives such as developing a foreign policy agenda, presenting data and other useful information to traders and investors as well as promoting a desired image of the country. In sum, governments engage in the business of designing web portals that appeal to targeted audiences of the global networked society like experts and activists in the foreign policy area, investors, exporters, and potential tourists to name a few. The ICTs have given rise to a new organizational form, the virtual embassy, a diplomatic post that can even operate from a hotel room with a professional diplomat whose computer connections enable him/her to carry out basic functions and communicate with headquarters back home. Additionally, ICTs encourage team-work among individuals working in hierarchical organizations including foreign bureaucracies. Video conferencing is widely used for the exchange of information and governments, like the Canadian, have on occasion created virtual task forces, connecting electronically their members to address and deal with a foreign policy problem (Smith, 1999). In terms of knowledge competencies, professional diplomats were up until recently classified as generalists or specialists and, depending on their area expertise, mastered two or more foreign languages. To adjust to the challenges posed by the information revolution, professional diplomats are asked today to supplement their knowledge base with management training and acquisition of computer skills.

Specific types of diplomacy seem to be exploiting and benefiting from the use of the web: traditional, economic and public diplomacy. Traditional diplomacy, whether in the bilateral or multilateral form, has used the web to advance foreign policy priorities, to facilitate the processing of documents and to even receive citizen feedback on important foreign policy initiatives. For example, Canada's Department of Foreign Affairs and International Trade (DFAIT) features on its website extensive coverage of the country's position on environmental issues and its strategy for sustainable development (Smith and Sutherland, 2002; Potter, 2002). In consular affairs, a number of countries like Denmark and Finland process through the Internet visa applications of foreign nationals. The interactive features of the Internet are more fully exploited in cases where governments or supranational entities like the European Union solicit the views of the public, either through chat rooms, discussion forums or web polls. A case in point is the websites that the Commission of the European Union and the foreign ministries of some member-states like Finland and Greece launched offering material and an online forum of discussion on the future of Europe. The Internet can also be used as a tool in the area of negotiations provided parties share common language and culture. Online meetings can be a cost-cutting and secure way to complete work on the preliminary stage of the negotiations but cannot be a substitute of face-to-face diplomatic negotiations (Kurbalija, 2002). Crisis situations involving humanitarian operations have attracted the research interest of the U.S. Institute of Peace (USIP), a federal organization funded by the U.S. Congress. Since 1995, USIP has been investigating under the Virtual Diplomacy Initiative how governments use information and communication technologies to respond and manage international crises (Brown & Studemeister, 2002). At the core of the initiative is the creation of a common culture of information-sharing and communication between civilian and military branches of government and between non-governmental organizations in carrying out humanitarian and peace operations. The technical term used for the task of information sharing is called interoperability: an electronic "handshake" that enables separate communication systems to share information among themselves towards a common end (Solomon & Brown, 2004).

Economic diplomacy is the second area that has benefited from the use of the Internet. Foreign ministries in collaboration with other government agencies and organizations representing the corporate sector, have created national websites that are replete with valuable information provided by economic counselors and attaches scattered throughout the globe for the benefit of

the countries' exporters and investors. Websites include a whole array of data like company profiles, business leads, trade fairs and events, investment opportunities, laws and regulations pertaining to foreign investment and trade finance arrangements. ICTs and the Internet can really make the difference in the conduct of public diplomacy, the practice of trying to appeal and influence another nation's public opinion or global public opinion. In an information-saturated world, projecting a favorable image of one's country to outside audiences (foreign media, politicians, business entrepreneurs, etc.) is considered a valuable intangible asset. States can draw upon their history, culture, political tradition and commitments to norms and values to craft, project and market a brand for themselves. Following the shift from geopolitics to postmodern image politics, the time is ripe for the emergence of a brand state, a state's concern of its image and reputation to the outside world (Ham, 2001). At the disposal of a brand state, the Internet can become a potent marketing tool and its interactive potential allows surveying segments of global public for image-monitoring purposes. Moreover, Internet facilitates dialogue, an indisputable aspect of communication for any state that engages in public diplomacy efforts (Riordan, 2004).

The information revolution has increased the power of more than 37,000 NGOs and countless social movements in confronting issues of global interest. The Net has enabled these global civil society actors to (a) interconnect on a global scale, (b) exchange and disseminate information, and (c) mobilize supporters into action. In the new communications environment, global activists have managed, by harnessing ICTs, to address and reframe issues, reverse government policies and even promote and help implement new diplomatic initiatives. Examples abound but the list of the most noteworthy cases includes the global anti-corporate protests regarding the Multilateral Agreement on Investment (MAI), the creation of transnational networks whose support for the Zapatista movement reversed the Mexican government's policy in the Chiapas region from a military to a political solution (Cleaver, 1995), support human rights activists granted to Burmese dissidents for human rights and political reforms in Burma and the Nobel Prize-winning international campaign to ban landmines that culminated in the signing of the Ottawa Treaty in 1997. NGOs expressed in February 1997 public opposition to the MAI on the internet and, along with other actions like letter-writing campaigns, petition signings and public protests, managed to bring in April 1998 negotiations to a halt (Kobrin, 1998). Internet became in 1994-1995 the alternative medium used by NGOs to make available to global public opinion material (letters, communiqués, electronic book, multimedia compact disk, etc.) that were not reported by media organizations. "By the end of 1994", as policy analysts contend, "a remarkable number of Web pages, e-mail listserves, and gopher archives had been created on the Internet" (Ronfeldt & Arquilla, 2001, p.183). Moreover, the Net was instrumental in forging connections among peace and humanitarian activists, feminists, and advocates for the human rights of indigenous people and impelled them to action (Cleaver, 1995). The Internet played a similar role in the early 1990s in disseminating information and mobilizing human rights activists and Burmese expatriates. The pro-democracy global campaign bore fruit as witnessed by the passing in 1996 of legislation in the U.S. State of Massachusetts barring companies doing business in Burma from signing contracts with the State of Massachusetts and the subsequent decision of major U.S.-based multinationals to withdraw from Burma (Danitz & Strobel, 2001). The International Campaign to Ban Landmines (ICBL) involved more than 1000 NGOs which collaborated with states to exchange information, mobilize public pressure, lobby governments and legislatures and draft a treaty prohibiting antipersonnel land mines. The ICBL, in existence since 1992, was a successful grassroots campaign that utilized the full potential of Internet tools, e-mail for internal networking and coordination as well as contacting government officials, web pages for diffusing information to activists, the press and policy-makers and fund-raising purposes. The ICBL is an apt demonstration of how global civil society actors, making ample and strategic use of the Internet, could seize the diplomatic initiative from governments, set and control the agenda and persuade states to join in a global policy coalition (Price, 1998).

In case the interests of NGOs clash with those represented by dominant actors such as states and transnational corporations, the internet provides to NGOs an electronic forum to express opposition to established views and an effective mechanism to mobilize people to take action on issues of global concern. NGOs have used the internet to diffuse information and forge global networks on issues ranging from the broad concerns of anti-globalization protests to the more specific issue of genetically modified foods. Melissa Wall (2002) has documented the use of the internet by NGOs around the world to challenge dominant discourses of the World Trade Organization (WTO) and to induce thousands of people to participate in the Seattle anti-corporate protest movement in December 1999. It is reported that an estimated 1500 NGOs signed the protest's declaration that was created online by Public Citizen (Tkalac and Pavicic, 2003, p. 498). Similarly, Jayne Rodgers (2003) demonstrates how international NGOs like Greenpeace and Friends of the Earth have utilized the interactive potential of the internet to raise awareness and prompt people to action against genetically modified foods.

The information and communication technologies have empowered NGOs and other actors of global civil society. The new communications environment, a byproduct of the information revolution, has had a profound impact on all areas of human activity including the practice of diplomacy. With the advent of ICTs, the content, organization and practice of diplomacy have been transformed and there is no way of grasping the changes yet to come as major technological breakthroughs unfold in record time before our eyes. At the dawn of the twenty-first century, a trend towards the de-coupling of diplomacy from its modern sovereign base is beginning to emerge with the aid of ICTs. Professional diplomats will have to share the diplomatic field with global civil society actors. Increasingly, the issues of diplomatic concern are global in scope and gain a global audience. The diplomatic game is becoming more complex, participatory and exciting.

## KEY TERMS

**Brand State:** A state's concern with its image and reputation to the outside world.

**Diplomacy:** A regulated process of communication between at least two subjects, conducted by their representative agents over a particular object.

**Global Civil Society:** An arrangement of political interaction parallel to interstate relations that focuses on the self-conscious constructions of networks of knowledge and action by decentered non-state or sovereignty-free actors across national boundaries.

**Interoperability:** Technical and political compatibility and the sharing of a common culture of communication among separate communication systems.

**Net:** The global system of internetted computers, communications infrastructures, online conferencing entities, databases, and information utilities. The Net is comprised of a public (the Internet) and a private (private digital networks) digital space.

**Net Diplomacy:** Diplomacy associated with the emergence of a networked global society.

**Public Diplomacy:** The practice of trying to appeal and influence another country's public opinion and global public opinion.

**Soft Power:** The ability to achieve desired outcomes through attraction and persuasion rather than coercion. It works by convincing others to follow or getting them to agree to norms and institutions that produce the desired outcome.

# New Governance Strategies for a Government IT Policy

**Abraham Sotelo Nava**
*Federal Government of Mexico, Mexico*

## INTRODUCTION

How can a country's government be sure that e-government will, in turn, generate value for its citizens? Presently, nearly all governments understand the potential impact information technology has in reducing the costs of governmental operations as well as in delivering information and public services with greater opportunity, flexibility, and reach. Nevertheless, in fundamental aspects, such as confidence in public institutions, citizen participation, or quality-of-life standards, there is little evidence showing that IT has been able to create visible improvements.

The aforementioned observations force us to revisit the previous promises of e-government (OECD, 2003) and to rethink the current system of governance in order to turn these promises into reality. Indeed, this necessary reconsideration raises two important questions: First, how can we take advantage of the nature of governmental work and its consequent relationship with a country's citizens, and second, how should local and national governments, the private sector, a country's overall society, as well as its individual citizens cooperate and interact in an effort to ensure that e-government delivers the most important information and services to a country's citizens? Table 1 summarizes the main issues, questions, and ideas that will be addressed.

The answers to these questions may perhaps appear in new governance strategies that facilitate the development of IT public policies that comply with the promises of e-government. Table 2 summarizes the previous and current concerns of e-government.

*Table 1. E-government under scrutiny*

- The glitter of e-government is fading.
- The mere truth is that everybody needs e-government, but nobody demands it.
- There are unfulfilled promises of cuts in costs.
- We have e-government in spite of government.
- Everybody does e-government, so now what do we do as government?
- Taking the *e* out of e-government

*Table 2. What do we want?*

| **Yesterday** |
|---|
| Informatization of government information and services |
| E-service anywhere and anytime |
| Money |
| Self-leadership |
| **Today** |
| Things people need, Web based or not |
| Simpler and integrated services |
| No cuts to IT budgets |
| Leaders |

## FRAMEWORK OF GOVERNANCE FOR E-GOVERNMENT AND IT POLICY

To achieve the desired design, implementation, and evaluation of IT public policies required by e-government, certain criteria that enable the analysis and selection of such policies or initiatives need to be considered. First, policy strategies and objectives should be specified; initiative should be analyzed and aligned with the e-government program strategies and objectives. Second, regarding policy and public administration objectives, the initiative needs to be analyzed and aligned with the country's development, science, and technology strategies and objectives. Third, the initiative should be analyzed in the context of the instruments and tools of public policy (political, institutional, economic, and legal instruments). Finally, the initiative should be analyzed under the components of a governance framework (Norris, 2001). (The model follows this order: Generate and transfer knowledge for use in the decision-making process; put knowledge and decisions into action; facilitate change for the incorporation, acceptance, and application of concepts, models, initiatives, and projects; align the initiative to the higher order objectives and achieve political sup-

*Table 3. A summary of the components of an e-governance framework*

| |
|---|
| **1. Knowledge;** The generation and transfer of knowledge for use in the decision-making process |
| • Definition of issues |
| • Needs and solutions identification |
| • Knowledge management and information management (projects, good practices, technology; Canada Site, 2005) |
| • Continuous learning |
| |
| **2. Authority:** Put knowledge and decisions into action |
| • Mandate |
| • Organizational structures |
| • Regulations and legal framework |
| • Policy and guidelines |
| . |
| **3. Ownership:** Facilitate change for the incorporation, acceptance, and application of concepts, models, initiatives, and projects |
| • Decision-making processes |
| • Cost and benefit allocation |
| • Management of synergies, and win-win and zero-sum situations |
| • Identification of needs and interests |
| • Active engagement of participants |
| |
| **4. Internal Accountability** |
| • Strategic alignment and clear contribution to higher order objectives |
| • Performance evaluation |
| • Garnering of financial, institutional, and political support |
| |
| **5. External Accountability** |
| • External performance evaluation |
| • Inclusion of users' feedback |
| • Evaluation of take-up (Accenture, 2004) |
| • Transparency |
| • Citizen participation and engagement |
| |
| **6. Operations** |
| • Project-management techniques and tools |
| • Interinstitutional management of resources |
| • Cooperation mechanisms |
| • Technical and operational evaluation |
| |
| **7. Policy Instruments** |
| • Budget |
| • Nonfinancial incentives |
| • Legislation (laws, regulations, and norms) |
| • Mandates, decrees, orders |
| • Organizational structure |

port; open spaces for citizen participation and transparency; and facilitate the operation and implementation of the initiative.)

The new IT governance and regulatory framework strategy will help institutionalize e-government in part by formalizing existing structures. For example, in Mexico, the head of the E-Government and IT Policy Unit will become the more formal ICT coordinator general for the federal government, the E-Government Network will become the Executive Council, and informal groups of people interested in specific themes on e-government will be formalized as specialized technical committees (OECD, 2005).

Additionally, the IT governance and regulatory framework strategy will create new structures that will help broaden responsibility and ownership of e-government. Table 3 summarizes the governance framework components.

## TRENDS AND SOME GOOD PRACTICES TO FOLLOW

The current trend for e-government in the most advanced countries is to adapt strategies and models of governance, as illustrated by some comparative studies (INFOTEC, 2003, 2004; Nath, 2003).

The objective of these new governance strategies is to render the natural mechanics that exist between the work of the government and citizens more efficient, always trying to fulfill the potential of e-government. Additionally, these governance strategies are looking for help to clearly outline the coordination, collaboration, and cooperation mechanisms between the three levels of government—the private sector, civil society, and citizens—in order to ensure that e-government delivers information and services that are the most popular with citizens. In other words, these strategies will always include the necessary space for the gathering and understanding of citizens' worries, opinions, and needs, as well as the channels that will deliver answers most rapidly.

The experiences of these countries also serve to demonstrate which practices are best in terms of an organizational structure that successfully encourages the functional development of IT policies in government (E-Government Office of Brazil, 2005; E-Government Office of Canada, 2005; E-Government Office of Chile, 2005; E-Government Office of Colombia, 2005; E-Government Office of France, 2005; E-Government Office of Portugal, 2005; E-Government Office of Singapore, 2005; E-Government Office of the United Kingdom, 2005; E-Government Office of the United States, 2005). Table 4 shows some good practices to follow in order to have a better organizational structure for e-government.

There is strong demand from citizens and businesses for the government to improve transparency and anticorruption efforts, and many leaders believe that e-government provides a means of doing so. The Federal Law on Transparency and Access to Information, in combination with the use of ICT, in the case of Mexico has greatly

*Table 4. Organizational structure: Some good practices to follow*

**Establish a government CIO (chief information officer) department that will accomplish the following:**

- Direct and monitor the work of a high-level council of ministries as well as the work of other councils (executive and advisory council)
- Advise the members of the high-level (minister) council
- Manage and monitor the work plans and goals defined by the minister council, as well as provide input and reports of the programs defined by the council
- Develop, monitor, and control the application of IT policies in the federal government
- Coordinate the strategic ICT programs of the specialized committees and monitor the progress of transversal projects
- Mentor federal government CIOs on ICT policies and e-government program matters
- Make proposals on the establishment of specialized committees

**Establish as principal organ a high-level council (ministers) with the following mandates:**

- Define and periodically update the agenda of relevant ICT issues
- Establish priorities and strategic ICT and e-government programs
- Make mandatory ICT policies that are proposed by the executive secretary (office of the government CIO) and developed by the specialized technical committees

**Use the expertise of government agency IT leaders as well as experts from other sectors in a CIO council that will do the following:**

- Assess IT in the agencies of the federal government
- Provide input (best practices, experience, and solutions) for the specialized technical committees
- Monitor the specialized technical committees' work
- Promote intersectoral cooperation
- Approve projects and policies generated by the specialized technical committees
- Issue consensual recommendations on IT and e-government issues
- Discuss e-government agenda items with a pluralistic and interdisciplinary perspective
- Promote research on priority issues

**Establish specialized technical committees for priority issues of the ICT and e-government agenda with the following mandates:**

- Conduct specialized research on selected issues; results will be used as input for policies
- Trend analysis and definition of best practices
- Develop public policies in terms of ICT and e-government
- Coordinate and develop projects

extended the opportunities for individuals to interact directly with government. Yet, making information available online is only the first step toward transparent government, and there is now a need to make the information more accessible and easy to use.

E-government has helped improve the quality of government services in Mexico. For example, the citizens' portal puts all Mexican government information and services in a single place and tailors the information provided to different groups (e.g., for students, the elderly, children, businesses, etc.). Nevertheless, there are many constraints on demand, and little has been done to reorganize service delivery to put the citizen and the user at the centre (OECD, 2005).

Mexican government organizations are implementing e-government both in response to a top-down push for e-government (through the Good Government Agenda) and through an internal understanding of how e-government can improve transparency, efficiency, and citizen engagement. The top-down approach is driven largely by the priorities of the current administration, in particular, the goal of government reform. The individual drive from within organizations is based largely on a desire to improve trust in government (through increased transparency and citizen engagement) and the recognition of financial limitations that require increased efficiency (OECD, 2005).

## CONCLUSION

How can one be certain that e-government is able to generate value for a country's citizens? Undoubtedly, the promises of e-government will be accomplished if the IT public policies are better designed and implemented. Moreover, this will only occur if the policies are created and applied under a rigorous model of governance and supported by a world-class organizational system.

## KEY TERMS

**Chief Information Officer (CIO):** The senior executive responsible for information management and information technology at the corporate level (Canada Site, 2005).

**E-Government:** The use of information and communication technologies, and particularly the Internet, as a tool to achieve better government (OECD, 2003).

**Governance:** The concepts, philosophy, and strategies that define the broad function of the government (Norris, 2001).

**Information Management (IM):** Integrating information standards, processes, systems, and technology to enable the exchange of information among providers and users in order to support the management objectives of an organization (Canada Site, 2005).

**IT Public Policy:** Governmental policies that make possible the operation of an e-government strategy (mandates, guides, and rules for IT management, use, procurement, and evaluation).

**Knowledge Management (KM):** Typically, the systematic management and use of the knowledge in an organization, or "the leveraging of collective wisdom to increase responsiveness and innovation" (Delphi Consulting Group, n.d.).

**Take-Up:** The full benefits of e-government will be realized only if citizens and businesses use it, but most governments still find themselves confronted with the challenge of low usage and the need for innovative methods to drive take-up (Accenture, 2004).

# New Media and Democratic Citizenship

**Bruce W. Hardy**
*University of Pennsylvania, USA*

**Dietram A. Scheufele**
*University of Wisconsin-Madison, USA*

## INTRODUCTION

### Citizenship and New Media

The issue of the civic potential of the Internet has been at the forefront of much scholarly discussion over the last 10 to 15 years. Before providing a comprehensive overview of the different schools of thought currently dominating this debate, it is necessary to briefly describe how researchers have defined the terms *citizenship* and *new media*. Across different literatures, two ways of examining citizenship emerge. The first approach examines citizenship broadly as citizen involvement in the political process. Scheufele and Nisbet (2002), for example, identified three dimensions of citizenship: feelings of efficacy, levels of information, and participation in the political process. The second approach taps citizenship much more narrowly as social capital (i.e., the more emotional and informal ties among citizens in a community) (Shah, Kwak, & Holbert, 2001).

Depending on which definition of citizenship they followed, researchers also have been interested in different types of new media use with a primary focus on the Internet. Some have examined the Internet as a medium that functions in a top-down fashion similar to traditional mass media. These scholars mostly are concerned with how online information gathering differs from traditional media use, such as newspaper readership or TV viewing. More recently, scholars have begun to examine different dimensions of Internet use, including chatting online about politics, e-mail exchanges with candidates and other citizens, and online donations to campaigns.

### Cyber Optimism vs. Cyber Realism

In part as a result of these diverse sets of definitions, researchers of political communication have yet to come to a consensus about the practical uses of the Internet in promoting active citizenship. Some researchers, often labeled cyber optimists, suggest that this new medium can reverse waning levels of political participation, based on the assumption that users will access information and will coordinate political activism via the Internet (Bimber, 1998; Davis, 1999; Kaid, 2002; Rhiengold, 1993). Many of these scholars view the Internet as a vehicle for increasing political participation by means of educating individuals, measuring public opinion, facilitating communication with political actors, providing public forums, and making both registering for and participating in elections easier (Davis, 1999).

Conversely, other researchers suggest that the Internet's potential for civic renewal is limited, and that the Internet, at best, complements traditional media channels (Althaus & Tewksbury, 2000; Hardy & Scheufele, 2005; Johnson & Kaye, 1998; Margolis & Resnick, 2000, Margolis, Resnick, & Tu, 1997; Scheufele & Nisbet, 2002). Furthermore, some researchers have suggested that the Internet may negatively affect community involvement and may replace social interactions with solitary activities (Nie, 2001; Nie & Erbring, 2000).

## BACKGROUND

### The Effect of the Internet on Democratic Citizenship

This lack of consensus among political communication scholars is due, in part, to the nature of this new medium. As Jennings and Zeiter (2003) noted, "Trying to assess the political impact of the Internet … involves shooting at a moving target" (p. 311). That is, the rapid expansion of adoption of this new medium combined with the continual introduction of newer technologies that make the Internet more efficient result in a constantly morphing entity. Moreover, the civic consequences of the variety of different uses of the Internet have yet to be examined systematically and empirically.

Unfortunately, many of the existing empirical examinations of the role of the Internet in promoting citizenship are plagued by significant methodological problems. One problem is the attempts of many researchers to reinvent the wheel when it comes to operational definitions of Internet use. Rather than developing measures of Internet

use based on well-developed measures of traditional media use, for example, researchers have relied simplistically on time-spent measures instead of content- or channel-specific measures (Shah et al., 2001). Shah and his colleagues stated, "Studies on the psychological and sociological consequences of Internet use have tended to view the Internet as an amorphous whole, neglecting the fact that individuals make very different uses of this emerging medium" (Shah et al., 2001, p. 142). In other words, there has been a misguided focus on the online/off-line distinction in research that has examined the linkage between technology and citizenship. A study by Moy, Manosevitch, Stamn, and Dunsmore (2003) found that the online/off-line distinction has little explanatory power in examining the civic consequences of the Internet when controlling for specific dimensions of Internet use. Moy and her colleagues demonstrated that a time-spent measure did not have any significant effects on levels of civic engagement, when more specific uses of the Internet are included in an explanatory statistical model.

A second problem is the conceptualization of the Internet as a single dimension. Given the integration of technologies found within the medium (Bimber, 2000), users can access civic information, exchange electronic mail, chat about politics, and/or donate money to political campaigns by logging on to the Internet. These different communication acts and information exchanges could have very different civic consequences. For example, time spent searching information on governmental Web sites is different from time spent in political chat rooms arguing over normative political opinions. Bimber (2000) correctly stated that searching for "'the effects of the Internet' may become a conceptually muddled pursuit" (p. 330). Furthermore, seeking civic information online should not be considered a single act but should be differentiated between different types of Web site use (Hardy, 2004).

A third reason why empirical research has not yet come to a consensus about the practical uses of the Internet in promoting active citizenship is what Bimber (2000) calls "mutualism, the interdependence of new and old modes of communication in civic life" (p. 330). Most political intuitions now are using the Internet as a complimentary tool to traditional media instead of a separate entity. Simply put, political campaigns use Web sites as well as television commercials. Therefore, the Internet is becoming an integrated part of an overall media infrastructure instead of becoming an independent communication system. Researchers such as Scheufele and Nisbet (2002) have suggested that citizens who seek political information online are likely to be the same individuals that seek information from traditional media sources. In other words, the Internet is an additional source of political information that fits well into an overall media system; it is not an independent entity.

## CYBER CITIZENSHIP

### The Current State of Cyber Citizenship

Although much empirical research on the civic consequences of the Internet has been plagued with problems of conceptualization, there is a growing body of literature that has looked more closely at patterns of use instead of overall connectivity to the Web. Research suggests that political informational uses of the Internet encourage community involvement and political participation (Norris, 1998). A study by Hardy (2004) demonstrated significant pro-civic consequences of different types of information available on different types of Web sites. In this study, Hardy differentiated between primary-source Web site use and secondary-source Web site use. Primary-source Web sites were conceptualized as Web sites that are connected to governmental institutions, special interest groups, and political actors, while secondary-source Web sites were conceptualized as commercial news Web sources such as CNN.com or MSNBC.com. This study showed that primary-source Web site use was related positively and directly to levels of political participation but was not related to political knowledge. Secondary-source Web site use was related directly and positively to levels of political knowledge but was related indirectly to levels of political participation. The effect of secondary-source Web site use on political participation was mediated by political knowledge.

What these findings suggest is that citizens are using primary-source Web sites to retrieve mobilizing information only. Mobilizing information is information that "helps people act on attitudes they already have" (Lemert, 1981, p. 118). In advertising, mobilizing information is the address of the business, hours of operation, and other information that allow individuals to act. For example, if an individual is shopping for a new computer, an advertisement on television that gives the location of an electronics store allows the individual to act on his or her intention of buying a computer. In the realm of politics, mobilizing information would be information such as the time and place of a local meeting, location of polls on election day, contact information of political actors, and so forth. This information enables individuals to participate politically.

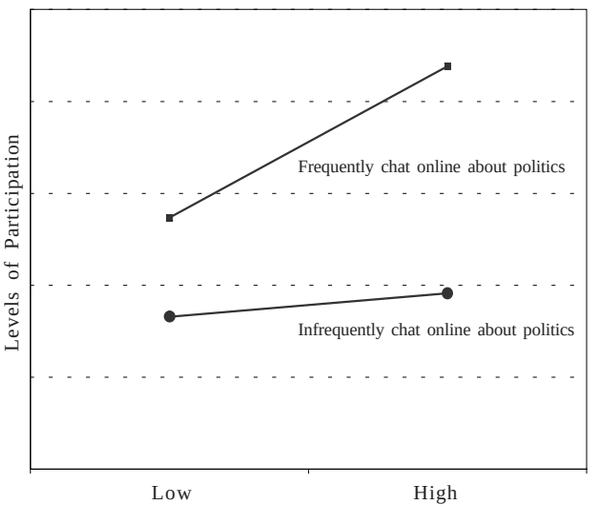
Therefore, individuals are visiting governmental sites to find mobilizing information, such as time and place of local meetings, which allows them to act on their intention of being an active citizenship. On the other hand, individuals are not using these governmental Web sites to find information about public issues and public policy; individuals use commercial news Web sites for that information.

Unlike traditional mass media, such as television, radio, and newspapers, the Internet provides not only a

resource of political information but also a forum for political expression (Dahlgren, 2000). The online forums of political expression can take the form of interpersonal discussion among citizens or direct contact with political actors and public officers. For example, Bimber (1999) examined citizen communication with government officials via electronic mail. His findings suggest that the lowered cost of communication associated with e-mail induced citizens with lower political connectedness or lower stakes in politics to assess this political activity as worthwhile. This suggests that the ease of contacting public officials via e-mail is encouraging political action by citizens that normally would not put forth such effort involved in using traditional forms of communication. Unfortunately, Bimber's (1999) study does not provide insight into the effectiveness of contacting public officials via e-mail. He hints that public officials are not as responsive to e-mails as they are to contact via phone and letters.

Unfortunately, very little empirical research has been conducted concerning chatting online about politics. In an analysis of America Online's chat rooms, Hill and Hughes (1998) found that "few actual issues or governmental policies are debated, with the norm being discussions of events and personalities" (p. 118). They also conclude that debates in chat rooms consisted mostly of normative statements that require little evidential backing, and thus political discussion in chat rooms provided or used little information. Therefore, the shared understanding of collective problems and highlights of opportunities for political involvement assumed to be brought on by political discussion may not happen in these open chat room environments. On the other hand, a few studies have found that chatting about politics online does promote active citizenship. For example, looking at the Internet as both a resource of information and a forum for political expression, Hardy and Scheufele (2005) examined the impact of political information seeking online and chatting about politics on levels of political engagement. This study found that both information seeking and chatting on politics were related positively and directly to higher levels of political participation. Along the same lines, a study by Shah, Cho, Eveland, and Kwak (2005) found interactive civic messaging and online information seeking to strongly influence civic engagement. However, more interesting are the findings of the Hardy and Scheufele (2005) study that suggested that chatting about politics helps individuals extract relevant information from online sources and promotes meaningful participation in the political process. That is, the effect of information seeking online on political participation is stronger for those who chatted more frequently online about political issues than those who infrequently or never chatted online about politics (Figure 1). This reasoning parallels findings about the interplay of traditional news use and interpersonal

*Figure 1. Political information seeking online, conversations about politics and political participation*



communication that showed similar patterns (Scheufele, 2001, 2002). In other words, the important role of interpersonal communication as a necessary condition for meaningful citizenship is relatively stable across media.

The common thread among studies demonstrating positive links between Internet use and active citizenship is that most of the behaviors that individuals do online are also the same behaviors that promote active citizenship off-line. For example, political interpersonal communication, be it chatting or face-to-face, has been shown consistently to impact the relationship between mediated information and political engagement. Chaffee (1972) wrote, "The more people talk with one another about information from mass media, the greater is the total impact of the media on social action" (p. 99). As previously outlined, research has shown that this relationship is relatively stable in the online/off-line domains.

## FUTURE TRENDS

### Will There Ever be a Cyber Citizen?

What all of this suggests is that the practical uses of the Internet in promoting active citizenship are the same practical uses of mass media and social environments found in the off-line world. Therefore, promoting active citizenship is a social, not a technological, activity. It is not inherent of the Internet to promote democracy. The Internet is a technological tool that motivated citizens

can utilize in order to find information and to be political expressive. However, the motivated individual can find information and be politically expressive without the Internet, as well.

The real question thus remains: Is it easier to be an active citizen online than it is off-line? Unfortunately, this brings us back to the somewhat fruitless online/off-line distinction that has plagued much of the previous research in this area. Future research now should look at individual political acts and if and how the costs of these acts are affected by the Internet. For example, donating money to a certain political candidate has become much easier with online donations. Success stories of the United States presidential campaign of 2000, such as John McCain's raising $415,000 through his Web site in 24 hours of his New Hampshire primary victory (Melillo, 2002) and Bill Bradley's reputedly raising $3 million on his site (Political Campaigns Discover Online Advertising, 2000) were just precursors to Howard Dean's success in the 2004 presidential primaries. All of these cases suggest that active citizens, indeed, are finding the activity of donating money to political campaigns easier via the Internet. As more technological advances are incorporated into the Internet, other civic activities such as participating in public meetings, mobilizing rallies, and voting may become easier. Researchers then should examine the impact of the Internet on these specific activities.

## CONCLUSION

Unfortunately, there is no reason to be overly optimistic. The Internet is merely a tool that can allow us to improve communication among different groups in society, such as communication among citizens and between citizens and policymakers. The Internet also can streamline processes, such as fundraising, campaigning, or systematic deliberation. As seemingly obvious as these statements may be, it is important to keep in mind that the Internet does not have magical powers that will turn apathetic citizens into active citizens. There is much research that suggests that active citizens off-line are the same active citizens online (Althaus & Tewksbury, 2000; Bimber, 2001; Scheufele & Nisbet, 2002). Or, as Bimber (2001) put it, "Having access to the wealth of political information and communication available through the Internet is not by itself connected with participation" (p. 61).

However, the Internet is not in a static state. It is a medium and a communication environment that is constantly changing. The civic consequences of the Internet are likely to change continually as more individuals go online and as more technological advances are incorporated. It is also reasonable to assume that cohort changes over the next decades also will bring about changes in the role that the Internet plays in democracies. Jennings and Zeitner's (2003) findings, for instance, suggest that a key determinant of the civic consequences of the Internet is the "intersection between the stage of individual political development and incorporation of the Internet into one's media repertory" (p. 331). Thus, as newer generations in the population mature, projections and findings of the civic role of the Internet in a democratic society will need to be reexamined continually.

## KEY TERMS

**Cyber Citizenship:** Active participation in democratic life in which an individual accepts and exercises his or her rights and responsibilities in society using the Internet as the main means for political participation.

**Cyber Optimist:** An individual who believes that the Internet can reverse waning levels of political participation.

**Cyber Realist:** An individual who believes that the Internet will not reverse waning levels of political participation and that the Internet is just another piece of the overall media infrastructure.

**Democratic Citizenship:** Active participation in democratic life in which an individual accepts and exercises his or her rights and responsibilities in society.

**Mobilizing Information:** Information that enables citizens to be politically active.

**Mutualism:** The interdependence of new and old modes of communication in civic life (Bimber, 2000).

**Online/Off-line Distinction:** A distinction between individuals who access the Internet and those who do not. Often found in research when examining the political impact of the Internet.

**Primary-Source Web Sites:** Web sites that are connected to governmental institutions, special interest groups, and political actors.

**Secondary-Source Web Sites:** Commercial news Web sites.

# Non-Technical Risks of Remote Electronic Voting

**Anne-Marie Oostveen**
*Rathenau Institute, The Netherlands*

**Peter van den Besselaar**
*Rathenau Institute, The Netherlands and Universiteit van Amsterdam, The Netherlands*

## INTRODUCTION

A few years ago, remote electronic voting seemed like a good idea for the near future. Globally, voting turnout figures are dropping dramatically (Electoral Commission, 2002) and politicians are therefore trying to find ways to increase civic participation. One solution is to make the voting process more convenient by giving voters the opportunity to submit their governmental election ballots over the Internet from home or work, or through their mobile phones using SMS. In this way, people will not have to leave the comfort of their homes or their work routines to have their voices heard. What a great boost this would be for our Western democracy! Citizens who live overseas, housebound people, or business travellers, everybody could use a computer to cast a ballot online. However, we will argue in this article that for several reasons remote electronic voting does pose a real challenge for e-government and might not necessarily be the best way forward.

## BACKGROUND

Many politicians and legislators are in favour of this new voting technology. They expect it will bring convenience to the voters, may increase turnout among the young, may result in cheap, efficient vote counting, and may reduce the incidence of human error (Dictson & Ray, 2000; Mohen & Glidden, 2001). Technological development of electronic voting is stimulated by national governments, and also in the context of the European Union (EU) Framework Programs.[1] On the other hand, opponents of Internet voting claim that besides large security risks, and the lack of equal access to the Internet for all citizens, it is not the voting *method* that matters. Low turnout is perceived as a symptom of a deepening crisis of democracy. Widespread indifference to, and ignorance of politics, is causing an evaporation of the concepts of citizenship and participation (Eliasoph, 1998). Previous reforms to make voting more convenient have had little effect on turnout levels and virtually none on the composition of the electorate (Internet Policy Institute, 2001). In our own research in which we examined a series of experiments with e-voting and e-polling, we did not see any positive influence on voting turnout. In four different sites a series of three e-polls took place, and in each case, we saw a declining turnout, suggesting that the effect of new technology on turnout is at best only temporary (Van den Besselaar, Oostveen, De Cindio, & Ferrazzi, 2003).

Nevertheless, even without affecting voting turnout, e-voting and e-polling technologies are of great importance. In order to clarify the opportunities and risks for democratic processes, we studied some 15 experiments with an e-voting system. The conclusion is that "voting in your underwear" (Arent, 1999) does not seem a valid option—at least not at this moment. Various technical, organisational, and behavioural issues are at stake. We discuss the main issues here.[2] We focus mainly on remote e-voting, but several of the risks discussed are also relevant for e-voting in a polling station using a voting computer, and for other (nonelectronic) forms of remote voting, such as postal voting.

## SECURITY AND VERIFIABILITY

Many people are concerned about the *security of remote voting* (Harris, 2003; McGaley & Gibson, 2003; Rubin, 2000). When people use computers from home or work, the machines are never as secure as the voting machines used in supervised kiosks or polling stations. Personal computers might be more vulnerable to hackers, denial of service attacks, viruses, or phantom Web sites which are used to divert voters (Kohno, Stubbefield, Rubin, & Wallach, 2003). Another problem with the use of personal computers at home or work is that the *requirement of verifiability* becomes very difficult to realize (Mercuri, 1993). Internet voting systems pose a problem in that the tallying process is not transparent. Voters should be able

to see that their votes are tabulated correctly. The best way to do this is to provide a voter-verifiable physical audit trail (Mercuri, 2001). If citizens do not trust that the elections they participate in are fair and that the votes are counted correctly, then they may not accept that the final votes represent their opinion. At polling stations the voting system could provide such a voter verifiable audit by printing a permanent paper record of each vote. In case of any doubts about the results of the election, there is then the possibility of a manual recount of these paper ballots (McGaley & Gibson, 2003). However, voting computers often do not have this facility, which makes recounting impossible—also in the polling station. If we switch from e-voting in the polling station to Internet voting from home, this becomes an even more serious problem: the paper trail is then impossible.

Yet, technical vulnerabilities are not the only threats to the security, integrity, and secrecy of Internet ballots. Social issues also play a very important role. Voting systems should guarantee a democratic election which is free, equal, transparent, and secret. However, *remote* e-voting cannot guarantee any of these criteria. This article will give an overview of five nontechnical reasons why we think (remote) e-voting poses a real challenge for e-governments around the world (Oostveen, 2006).

## FREE AND SECRET VOTING

In a recommendation report written by the Council of Europe (2004), five basic principles of democratic elections and referenda are specified. Elections need to be universal, equal, free, secret, and there should be direct suffrage. These principles apply to traditional voting as well as to new voting methods. With e-voting the voters must be identified by the system; the tallier must be able to distinguish the votes cast by valid voters from those cast by voters who are noneligible. At the same time the votes must remain anonymous and secret. No one should be able to determine how any individual voted, and voters should not be able to prove how they voted because this would facilitate vote selling or coercion. Remote e-voting increases the risk of coercion of the voter by, for instance, a dominant spouse, the teacher at school, or the boss in the office.

Our research shows that the possibility of coercion is a real concern among voters (Oostveen & Van den Besselaar, 2004). We organised 12 focus groups and one online forum in four different countries with voters and organisers of ballots (pollsters). We ensured that there were vast differences in the socio-demographic makeup across the respondents in each of the focus groups, including age, gender, income, and ethnicity (further details in Oostveen & Van den Besselaar, 2004; Oostveen, 2006). The greatest risk of e-voting, according to the majority of the panellists, is the possibility that a voter can be forced by someone else to vote for a certain alternative. An Italian voter pointed out: "At first I thought it was a good idea, but now I fear the influence and pressure that family members could exert on voters." With remote voting there will never be the same privacy that a voting booth provides.

This phenomenon of "family voting" is also possible with other voting technologies. Husbands could accompany wives into the polling booth, and this indeed is also a real problem in many cases. However, appropriate regulation may prevent this from occurring, because voting in a polling station is in the public domain and therefore controllable. Postal voting makes coercive family voting also a possibility. As is often argued, the education of voters and a stable political situation may heavily reduce the risks of family voting. In our view, however, the voting system should be robust also in periods of political tension. Therefore, postal voting does not seem to be a good idea either.

Remote electronic radicalizes this problem. Our research shows that many voters do not trust that their privacy is guaranteed in e-voting systems. And these voters feel that surveillance may alter their voting behaviour, as our research indicates (Oostveen & Van den Besselaar, 2005). Here, there is a need for additional research and experimentation before deciding about the deployment of the new voting technology.

## DIGITAL DIVIDE

E-voting has to deal with an existing digital divide, in which there is an upper-class bias (Alvarez & Nagler, 2000; Phillips & von Spakovsky, 2001). This digital divide can be expected to influence the participation in, and the outcome of, ballots. According to many observers the digital divide is declining, yet this is generally measured in terms of *access* to the Internet. However, divides may be much more subtle and related to skills required to install the software and hardware, learning, social networks that provide help, ownership of advanced versus older types of computers, insights into the security and risks, and so on. From the literature we learn that despite the narrowing of the "digital divide," Internet connections are still not distributed evenly across racial, gender, age, regional, and socioeconomic lines. This applies even more so for the skills needed to use the technology (Wellman & Haythornthwaite, 2002). Demographic groups with less access and less familiarity in using computers might find some types of e-voting difficult or intimidating. There-

fore, government may be making it easier for some people to vote, but not for others. In the end, e-elections may be even less representative than traditional ones (Alvarez & Nagler, 2000). In our own study we saw considerable differences in the frequency of use of ICT (Oostveen, 2006). This frequency of using ICT is related to the amount of difficulties with installing and using the system. We, therefore, cannot assume that every citizen has equal access to e-voting possibilities.

Although most of the voters involved in our research would be willing to use e-voting systems themselves, they are of the opinion that remote e-voting should only be used as one alternative voting method. According to the respondents, such a system cannot be used exclusively. One respondent remarked: "The middle class will be more likely to have a computer, but the working class will not. So it will enhance the vote of those middle-class people." The voters also fear that e-voting will discriminate against older voters because of their limited experience and knowledge of computers. It was said: "Yeah … the older you are, the less willing you are to change and it will discourage elderly people from voting" and "Older people panic about computers and will be put off from voting."

The organisers of the ballots emphasised that e-voting should not replace the traditional voting systems in the near future, as it may exclude from participating, groups who are able to use the traditional ways of voting. This is a legitimate claim, and politicians in favour of e-voting do generally agree with it. However, the prospect of saving money is often dominant in the introduction of e-voting, and the inclination to keep expensive parallel systems alive may therefore in practice be low. Experiences in other sectors support this. Whereas, for instance, the credit card was introduced as an additional means for paying bills, transactions have increasingly become exclusively related to credit cards, such as reserving a hotel room or renting a car. And e-voting in the polling booth has replaced paper voting completely in the Netherlands: so there is a clear tendency of new voting technologies replacing older technologies. This may also be the case in the future with remote voting.

## CULTURAL EFFECTS

A third issue that comes into play when people do not vote from a polling station is the erosion of the "civic ritual" of physically casting a vote in a location where members of the community gather (Dictson & Ray, 2000). The loss of the civic ritual is commented upon in many academic articles about e-voting. Critics argue that it would make elections less of a community event, which might create a greater gap between citizens and government, thereby decreasing participation. What some people believe is that voting is more than the simple act of indicating one's political preference; it is a vital public ritual that increases social solidarity and binds citizens together (Mohen & Glidden, 2001). Of course, as is often argued, modern society shows a tendency toward individualization, and remote electronic voting fits into this tendency. However, it is a normative issue whether one wants to reinforce or counteract this fragmentation of society by selecting appropriate technologies.

Our interviews indicated that the loss of the actual ritual of voting is indeed something to consider (Oostveen & Van den Besselaar, 2004). The pollsters are very concerned about the loss of the "civic ritual" of casting a ballot and consequently the loss of the importance and the value of voting. Their fear is that the system could be considered "too cold" by the voters. The pollsters voiced their concern that the loss of the civic ritual could decrease the significance related to voting and hence overall turnout. They go even further by pointing out that making the current voting procedures easier might produce an increase of "spread ignorance," that is, an increase of "superficial behaviour" and/or a growing oversimplification of voting behaviour. As e-voting may destroy the civic rituals it can have a negative influence on the political culture and therefore is best avoided. The voters' focus groups also identified traditional voting procedures as a ritual that should be preserved. A respondent remarked: "For elderly people traditional voting is often a kind of important tradition." The representatives of a trade union that piloted the system also articulated that the use of remote e-voting would negatively influence the internal communication and formation of opinions within the organisation.

## ORGANISATIONAL ISSUES

A fourth important issue is the logistics of organising a remote e-ballot. The process of registering, distributing hardware and software, organizing help desks and other forms of support for voters, is a complex and difficult task. It requires planning of activities of various institutions and actors (for instance, the organiser of the ballot, the certification authorities, and the "supplier" of the e-voting service).

Our research showed that limited resources and budget have an impact on the success of organising a ballot and increasing turnout (Oostveen, 2006; Van den Besselaar et al., 2003). Public relation materials, translation of documents, and support all require a substantial amount of money. Changes, especially those involving new technologies, are intensive users of resources which

are often scarce in many organisations. Because we think that e-voting systems have particularly great potential in local organisations, trade unions, community networks, and other contexts where it is more difficult to devote resources to voting and polling than in traditional elections, special attention to the issue of resources is required. Many potential users of e-voting technology will have to use it with relatively low resources. Other organisational problems encountered had to do with the large number of actors involved in the project. As various actors play a role such as the organiser of the ballot, the certification authority, and the e-voting service provider, the complexity of organising e-voting is a serious issue that needs further attention.

Furthermore, a change or a lack of personnel, and difficulties in distributing the materials were other organisational issues that came up during the field experiments. We would like to highlight the problem of distributing the materials (hardware, software, documentation). It would be tempting to assume that distributing materials to the voters can only be a problem in a small-scale pilot study. A lot of time, effort and planning need to be invested to ensure that a pilot, or indeed a real e-ballot, runs smoothly. This did not only prove to be the case in our project but also in other larger pilots. One example from the United Kingdom illustrates this. On June 10, 2004, the UK government embarked on the largest experiment in postal voting. During the European and local elections in England, about 14 million voters in the East Midlands, North East, North West, and Yorkshire and the Humber had to vote by post. There were no normal polling stations in those areas. Thousands of ballot papers were not delivered on time. In some cases printers missed the deadline to get the papers to the Royal Mail. Other problems included misprinted ballot forms. Technical issues were blamed for delays by one of the 12 printing contractors, while the illness of a managing director has been blamed for delays at another company. This example illustrates that even at high-stake, well-financed elections, the distribution of materials and problems with personnel can have disastrous results with people being denied the opportunity to vote.

We do not want to suggest that it is impossible to organise a large-scale e-election; however, the examples of successful experiments can easily be matched by counterexamples.

## BEHAVIOURAL EFFECTS

Finally, we pay attention to the social psychological issue of social identity (Ellemers, Spears, & Doosje, 1999; Tajfel, 1978) in relation to remote e-voting. The main difference between remote e-voting and traditional voting is that remote e-voting can be done in the privacy and security of one's own home rather than at a polling station in the community. The social psychological implications of this have been paid little attention hitherto. One important implication of e-voting is that when one votes at home, isolated behind the computer terminal, a more individual level of identity (and more individual self-interests) is likely to become salient compared to when one votes in the community hall, surrounded by other people from different groups and backgrounds or at work surrounded by colleagues. In the latter two cases, collectivist and even multicultural concerns may be more salient. Research shows that people's social identities have a very powerful impact on their perceptions, emotions, and behaviour (Ellemers, Spears, & Doosje, 2002). As Andrew Brader (2001, p. 4) points out, "people act in ways specific to their situation."

Different voting contexts not only influence which identities and interests are made salient, they can influence behaviour relating to these identities and interests for *strategic* reasons. For example, being confronted with different groups of people at the polling station (or on the way to it) may make one feel more accountable to these audiences (e.g., ethnic minorities, the poor) than when at home on one's own, or surrounded by one's family. When group members define themselves in terms of their collective identity they focus on the similarities between themselves and fellow in-group members with reference to experiences, needs, interests, or goals. As a result "my" and "your" experiences, needs, and so forth are transformed into "our" experiences and needs (Stürmer & Kampmeier, 2000, p. 107). This is particularly likely to affect voting behaviour when this is identifiable (and thus accountable) to an audience that might disapprove. For example, many preelection polls underestimate self-interested or right-wing preferences, because they fail to take into account that people might not want to admit to such preferences in public. Contexts in which people perceive there is scrutiny of their choice may, therefore, affect voting for strategic or self-presentational reasons. Examples of a high-accountability context are votes that are conducted in public (e.g., in mass meetings with a show of hands), rather than by private ballot. Although e-voting may seem private, one of the concerns associated with this technology is whether it is indeed secure, or open to "surveillance" by those administering the system. The perception of surveillance may moderate voting preferences perceived to be critical of such authorities.

Another factor that may well cause features of e-voting to influence voting preference is the degree of social interaction and discussion around political topics prior to voting. Voting from the home increases the likelihood that choices will be discussed within a limited and

homogeneous group context, whereas voting in the community may open the voter up to disparate social influence from others, especially those relating to more prosocial or collectivist concerns. This process of validating views through discussion has been called group consensualisation (Haslam, 1997). Because discussion is likely to polarise in line with group norms and identities (Spears, Lea, & Lee, 1990) the parties to discussion can be highly influential.

Our own field experiments support the expectation that voters' social identity varies in different situations (voting in polling booth, voting from home, etc.) and that the voting media may have an effect on the voting outcome (Oostveen & Van den Besselaar, 2005).[3] Of course, we are not claiming that political preferences will be entirely determined by the voting context. However, these contextual effects may be especially important in the case of "floating" voters who often decide elections.

## CONCLUSION

We saw in this article that introducing new technology is always a complex undertaking which has many different aspects. These aspects are technical, as well as social, political, organisational, and behavioural. Historically, social aspects and democratic values have only been partially considered in the systems design process; the main focus has been on technical and economic factors. The five nontechnical issues we have addressed here may affect the final outcome of the elections and the political representation of the votes cast and should therefore not be neglected by politicians, legislators or researchers.

E-voting is a relatively new innovation and *remote* e-voting systems are in the first stages of development. Therefore, we are only beginning to clarify many of the important issues. However, it seems clear that many experiments are necessary, in both small- and large-scale environments, in order to develop the technology in a responsible way.

## KEY TERMS

**Civic Ritual:** A ritual is a formalised, predetermined set of symbolic actions generally performed in a particular environment at a regular, recurring interval. The general purpose of civic rituals is to engage a group of people in unified action to strengthen their communal bonds.

**Digital Divide:** The digital divide is the disparity in access to technology that exists across certain demographic groups. The digital divide exists between those in cities and those in rural areas. The digital divide also exists between the educated and the uneducated, between economic classes, and globally, between the more and less industrially developed nations.

**Electronic Voting:** E-voting is an election system that allows a voter to record his or her secure and secret ballot electronically. Electronic voting includes voting using a punch card, optical scan, or computer in a kiosk, or by using the Internet or (mobile) telephone.

**Privacy:** A system is private if neither election authorities nor anyone else can link any ballot to the voter who cast it, and no voter can prove that he or she voted in a particular way.

**Remote Electronic Voting:** Remote e-voting is an election system that allows a voter to record his or her ballot electronically from home, work, or school, instead of using a supervised polling station or kiosk.

**Social Identity:** Having a particular social identity means being at one with a certain group, being like others in the group, and seeing things from the group's perspective. In other words, people behave by acting in concert within a group with which they identify.

**Verifiability:** A system is verifiable if anyone can independently verify that all votes have been counted correctly.

## ENDNOTES

1 However, this is also part of a general techno-economic policy to stimulate the deployment of the information highway, in order to get the e-society going.

2 More details about the methodology and results of our research can be found elsewhere: Van den Besselaar et al., 2003; Oostveen and Van den Besselaar, 2004, 2005; Oostveen, 2006.

3 Not much research has been conducted on this topic. One other study by Christin and Trechsel (2005) suggest that e-voting is neutral. These contrasting results show that more research is needed.

# Online Citizen Consultation and Engagement in Canada

**Graham Longford**
*University of Toronto, Canada*

**Christie Hurrell**
*University of British Columbia, Canada*

## INTRODUCTION

Like other western liberal democracies, Canada has witnessed the erosion of political participation and civic engagement on the part of its citizens. Recent studies of Canadian democracy have revealed numerous symptoms of malaise, including declines in voter turnout, participation in traditional political institutions, civic literacy, and trust in government (Gidengil, Blais, Nevitte, & Nadeau, 2004; Nevitte, 1996). Governments at the federal, provincial, and municipal levels have launched numerous democratic reform initiatives in response. Along with proposals for electoral and parliamentary system reform, governments in Canada have responded with new *citizen consultation* initiatives designed to increase public participation in the policymaking process. Incorporating the use of new information and communication technologies (ICTs) into these initiatives, such as online citizen consultation tools, has become a common method used to engage Canadians in the policymaking process. A gradual shift in the language and practice of citizen involvement in the policymaking process has also been taking place, one in which citizen consultation is being complemented by richer and more sustained forms of *citizen engagement*. This chapter examines the political context and conceptual underpinnings of online citizen consultation and engagement in federal policymaking in Canada, reviews a number of recent examples, and assesses their outcomes in light of their potential to overcome the democratic malaise currently ailing Canada's political system.

## BACKGROUND

Citizen consultation has been an increasingly common feature of the policymaking scene in Canada since the 1960s. In the early 1990s, however, following popular repudiation of two major constitutional agreements negotiated by political elites, it became clear that Canadian citizens' demands for more meaningful opportunities to participate in policymaking were increasing, even as they were becoming alienated from traditional avenues and institutions of participation such as political parties and elections. Nevitte (1996) suggests that these demands stem, in part, from the democratization of higher education in the post-WWII period, as a result of which Canadian citizens have become less deferential and more "cognitively mobile," thus narrowing the knowledge-skill gap between citizens and political elites. New ICTs, including the Internet, have also facilitated citizens' access to policy-relevant information and news. Canadians increasingly believe that they are knowledgeable about national issues, and they are becoming less willing to leave policymaking and governing up to public officials whom they may not trust. The federal government responded in the late 1990s by introducing new mechanisms for citizen input into a number of areas, including social policy, health care, and rural issues (Patten, 2001; Phillips & Orsini, 2002).

Phillips and Orsini (2002) have described a gradual shift in the federal government's approach to involving citizens in the policymaking process. In the 1960s, governments began to hold *citizen consultations*—hearings, town halls, and so forth—as a way to involve citizens in the policy process outside of elections. Such consultations tended, however, to be state-centered, with government framing the issues and dictating agendas. The purpose of such consultations was typically to obtain information from citizens and to notify them of pending government action. Unable to influence agendas and uncertain about the influence gained through such exercises, citizens became suspicious of and impatient with such forms of consultation over time.

The concept of *citizen engagement* has emerged in the last half decade in Canada as governments have pondered newer, more meaningful models of citizen involvement. Phillips and Orsini (2002) define citizen engagement as involving "interactive and iterative processes of deliberation among citizens (and sometimes organizations) and between citizens and government of-

ficials with the purpose of contributing meaningfully to specific public policy decisions in a transparent and accountable way" (p. 3). Citizen engagement is intended to be less state-centered than traditional consultation by embodying both government- and citizen-convened involvement processes. More importantly, Phillips and Orsini (2002) stress,

*it emphasizes the importance of genuine two-way dialogue among citizens, and between citizens and governments [...]* Citizen engagement would thus exclude many instances of public consultation *because the latter does not produce a genuine dialogue, nor does it give citizens much real influence over policy outcomes.* (p. 3-4, emphasis added)

Citizen engagement is closely related to the theory of *deliberative democracy*, as elaborated by political theorists like Jurgen Habermas and James Fishkin, and as implemented in *deliberative dialogue* exercises by governments and third-party organizations (Fishkin, 1991). Deliberative dialogues bring together diverse groups of citizens to engage with experts, policymakers, and each other on major public policy issues of the day. In face-to-face deliberative dialogues, citizens "consider relevant facts and values from different points of view, work together to think critically about options and expand their perspectives, views, and understandings." (MacKinnon, 2004, p. 4). Deliberative dialogues show more potential than traditional consultation to stimulate citizen engagement (Saxena, 2003).

The Government of Canada's interest in increasing citizen consultation has also been driven by developments in public sector uses of new ICTs, especially as the concept and practice of *e-government* has achieved acceptance. In the late 1990s, new ICTs were embraced by Canadian parliamentarians and public servants as means to improve service delivery and to communicate and consult with the public and organized interest groups (Centre for Collaborative Government, 2002; Malloy, 2004; Richard, 1999). In addition to the anticipated administrative and service delivery benefits, the government portrayed its *Government Online* (GOL) initiative as offering an antidote to the civic malaise gripping the country. In terms of providing information to citizens and offering them more access to policymakers and the policymaking process, the federal government has achieved some impressive results thus far. A vast quantity of online information has been put at the disposal of Canadian citizens, who have in turn embraced the effort. The Canada Site (http://www.canada.gc.ca), the government of Canada's main Internet portal, provides access to over 450 federal Web sites and millions of pages of documents and information on government programs and services, and was visited by roughly 16 million unique users in 2003 (Public Works and Government Services Canada, 2004a). The Parliament of Canada maintains a legislative Web site (http://www.parl.gc.ca) that allows citizens to monitor the status of bills and the work of the various legislative committees of the House of Commons and the Senate. Individual parliamentarians have begun to establish a significant Internet presence as well, with 58% operating Web sites, many of which offer interactive tools for constituents to communicate with Members of Parliament via online feedback forms and surveys (Centre for Collaborative Government, 2002).

## ONLINE CONSULTATION AND ENGAGEMENT IN CANADA: POLICY AND PRACTICE

As in many other jurisdictions, the Canadian government's use of the Internet and related technologies to engage and consult with citizens is at the developmental stage, with most projects being undertaken on a pilot or experimental basis. Nevertheless, in addition to using the Internet to provide citizens with information, the federal government has begun to use a variety of online tools to solicit policy feedback from citizens and, in some cases, to provide opportunities for citizens to engage interactively with officials, politicians and each other (Public Works and Government Services Canada, 2004b). The Privy Council Office (PCO) is the government agency responsible for online consultations. The PCO has prepared guidelines for online consultation and engagement. Some of the advantages of online consultations identified by the PCO include the ability to reach traditionally inactive portions of the population such as rural communities and youth, and the more flexible mechanisms of participation that the Internet offers busy Canadians. While government-wide policy and practice on using the Internet for public consultations remains elusive, various departments and agencies have used a number of online tools to solicit and gauge public opinion and reaction to policy initiatives. Online consultation tools currently in use by federal departments include e-mail, online surveys, interactive workbooks, discussion forums, and content management systems. In 2003, the Department of Canadian Heritage, along with the PCO, launched a Web site entitled "Consulting Canadians" (http://www.consultingcanadians.gc.ca). The site is a consultation portal where citizens can find structured lists of consultation exercises taking place (on and off-line) across the country.

Online consultations in Canada can be classified according to the distinction between *online feedback* and *online discussion* (Public Works and Government Ser-

vices Canada, 2004b). The former provides opportunities for citizens to offer feedback and input on a particular issue via e-mail or online surveys and workbooks, usually in response to a policy discussion paper or series of proposals released by the government. In the latter case, the online consultation includes opportunities for citizens to interact and engage not only with government but with *one another* in online discussion and debate. In the words of a recent government report: "online discussion based consultations provide opportunities for the public, or selected representatives from particular interests or communities, to join a conversation, share ideas, collaborate on projects and build relationships through electronic communication" (Public Works and Government Services Canada, 2004b). Online feedback, according to Phillips and Orsini's conceptual distinction, falls under the category of consultation, whereas online discussion corresponds more closely to engagement.

The following highlights some of the more noteworthy and ambitious examples of online consultation and engagement recently initiated by the Government of Canada. They vary widely in scope, inclusiveness, technologies used, degree of feedback versus discussion enabled, and the number and representativeness of participants. Some have been highly successful, while others have achieved only modest or even disappointing results.

- **Agriculture and Agri-Food Canada:** Launched The Rural Dialogue in 1998, a series of country-wide face-to-face and electronic consultations designed to canvass public opinion and engage rural publics on issues of concern. The major online component of the Dialogue was the Rural Dialogue Online Discussion Group, enabled by a listserv dedicated to citizens from rural and remote regions for the discussion of issues relating to rural Canada. (http://www.rural.gc.ca/listserv_e.phtml)
- **Status of Women Canada (SWC):** Launched an electronic roundtable discussion via an e-mail list in May 2000, as part of its consultation process seeking input from women's groups on a UN "Beijing +5" document. The electronic roundtable attracted 60 participating individuals and organizations. Roughly 130 postings to the list were made over an eight week period.
- **The (Romanow) Commission on the Future of Health Care in Canada:** Conducted an extensive series of public hearings and consultations on the future of health care in 2001-2002. In September 2001 the Commission launched a Web site (http://www.healthcarecommission.ca/) containing a variety of resource materials related to the Commission's work and public hearings. The site received over 36 million visits by the time the Commission's final report was released. Site visitors also completed over 16,000 online consultation workbooks examining various issues and options in health care (Commission on the Future of Health Care in Canada, 2002a).
- **Industry Canada (IC):** Initiated a nation-wide "engagement process" on a federal Innovation Strategy announced in 2002. After releasing two major discussion papers, the government convened thirty-four regional consultation meetings to gather public input and responses. In addition, over 30,000 e-mails were sent out inviting interested individuals and key stakeholders to participate, and directing them to fill out and submit an online consultation workbook. The electronic component of the consultation was a major failure, however, as only 600 responses and a mere 130 workbooks were received.
- **Department of Foreign Affairs and International Trade (DFAIT):** Initiated a Foreign Policy Dialogue (FPD) with Canadian citizens from January to May, 2003, which included a significant online component, in addition to town halls, expert roundtables, a youth forum, and other off-line venues. The FPD Web site (www.foreign-policy-dialogue.ca) consisted of two main sections: in one, citizens were invited to respond to a set of questions raised in a discussion paper; in the other, a discussion section, citizens could participate in a less-structured set of forums where they debated foreign policy issues with one another. The FPD site received almost 1.5 million hits and was visited by more than 62,000 unique users. Over 2,000 messages were posted to the discussion forums, and the discussion paper was downloaded over 28,000 times (Site statistics: Jeffrey, 2003).
- **House of Commons Sub-Committee on the Status of Persons with Disabilities:** Conducted an online consultation on the Canada Pension Plan Disability program between December 2002 and March 2003. The consultation Web site received over 15,000 visits, and roughly 1,400 individuals responded to a series of issue polls and/or to the site's invitation to share stories or present solutions.
- **Department of National Defense:** Conducted an online public consultation in the summer of 2002 as part of its Defense Program Update, a review of national defense priorities and capabilities. Over 17,000 submissions were received, overwhelmingly from members of the military and their families.

## CASE STUDIES

While a number of the examples of online consultation and engagement described above were considered highly successful, there are grounds for adopting a more cautious view. The majority of experiments described above fall under the more modest category of online citizen involvement mechanisms (i.e., *online consultation* or *feedback*). As such, they risk reproducing the shortcomings of traditional citizen consultation. In addition, even those initiatives that succeeded in generating significant public awareness and participation, such as the Romanow Commission, had significant shortcomings. Space does not permit a detailed assessment of all the initiatives described above. Instead, the remainder of this chapter is devoted to an assessment of two—the Romanow Commission's online consultation and the online component of DFAIT's Foreign Policy Dialogue. Both were successful in many respects. And, yet, when examined more closely in light of the theory and practice of engagement, it becomes clear that the development of online citizen engagement is still in the initial stages.

### Romanow Commission on the Future of Health Care in Canada

The recent online consultation by the Romanow Commission on the Future of Health Care in Canada was a success in many ways, with over 36 million hits to the Commission's Web site and 16,000 online consultation workbooks submitted. The site also contained a variety of high quality resources, including Commission research reports, summaries of the Commission's fact-finding work, and links to third party resources and analysis. However, a number of aspects of the consultation also underscore the potential limitations of such exercises. First, after working through a series of readings, citizens who filled out the online workbook were invited to indicate their preference for one of four pre-selected "options" for future health care policy, raising the problem of issue-framing and agenda-setting. In addition, while the Commission Web site contained background information and statements regarding the pros and cons of the various options presented, there was no way to ensure that workbook responses were based on careful political judgment. Moreover, as the Commission's own demographic analysis later revealed, respondents were highly unrepresentative of the Canadian population as a whole. The typical respondent was an older, well-educated female employed in the health professions (Jackson, Zagon, Jenkins, & Peters, p.vii). While canvassing the views of stakeholders like these is worthwhile, neither the process nor the outcome should be mistaken for broad citizen engagement.

The qualitative disadvantages of online citizen consultation, in terms of promoting civic literacy and social cohesion, were evident as well. The online consultation workbook offered the Commission little more than a snapshot of responses to reading material and policy options digested by respondents over approximately a twenty-minute period (the average time taken by respondents to complete the Workbook). This was in contrast to the series of daylong, face-to-face deliberative dialogues also held by the Commission, which involved randomly selected participants from across the country. Participants in the day-long deliberative dialogues reported not only increased understanding of the issues, but a greater commitment to the process of negotiation and compromise, and increased levels of respect for and solidarity with their fellow dialogue participants (Maxwell et al, 2003).

### Foreign Policy Dialogue

The Foreign Policy Dialogue (FPD) was a policy consultation and discussion process initiated by DFAIT to gather public policy advice on Canada's role in the world. The Dialogue was groundbreaking in a number of respects, not least because few national governments invite citizens to take part in the shaping of foreign policy on or off-line (Graham, 2002). The FPD Website was organized around an official consultation paper produced by DFAIT. Unlike the Romanow Commission's, the Foreign Policy Dialogue's Web site included a space for citizens to engage with one another via an online discussion forum. One of the other innovative aspects of the FPD was that it operated as a partnership between DFAIT and byDesign eLab, a civil society organization. The civil society partner was responsible for the design and maintenance of the site, as well as for screening all posts to the site to make sure they adhered to a set of *civil speech* rules.

As noted above, the FPD site received 1.5 million hits and over 62,000 unique visitors. Like the Romanow Commission site, however, the FPD site, and especially the discussion forums, came to be dominated by a small group of heavy users who logged into the site many times a day, thus compromising the representativeness of the results. In addition, while the Dialogue Web site enjoyed strong ministerial support, government participation in the online discussions was slight. Because government officials did not actively engage with citizens during the course of the online consultation, participants were basically left with an advanced *consultation* model, where they provided government (and each other) with feedback, but in which they were not truly *engaged* by government. Post-dialogue analysis revealed other limitations, one of which is the difficulty of adequately reporting the results of a large

volume of citizen advice. After the Web site closed, the civil society partner analyzed the data and produced a report for DFAIT that included not only detailed site statistics but also a qualitative analysis of citizens' input. The lasting impact of the Dialogue process on Canadian foreign policy development remains unclear, however. The consultation focused on broad policy issues not conducive to specific policy responses, and this is reflected in the report.

On balance, the results of the Romanow Commission and DFAIT online consultations can be summed up as mixed. Both represented groundbreaking and innovative responses to citizens' demands for greater input into the policymaking process in Canada. Both offered Web sites that were relatively rich in content and offered interactive features like online workbooks and/or online discussion forums. Compared to most other online consultations conducted thus far, they received fairly heavy traffic as well. However, they shared a number of important limitations, including a lack of representativeness, a lack of opportunities for genuine online engagement between citizens and government representatives, and a lack of clarity on how results would influence policy. Failure to address these limitations in future online consultation and engagement exercises risks reproducing the shortcomings of previous models of consultation.

## FUTURE TRENDS

With the relative success of the online components of the Romanow and DFAIT consultations, the use of online consultation is becoming increasingly common at the federal level. Over half of all federal government staff have now used some form of online consultation in their work (Online Consultation Technologies Centre of Expertise, 2005). At the time of writing, the federal Consulting Canadians Web site listed 27 active public consultations in progress, many of which had a substantial online component. In addition, experiments and pilot projects are being conducted with more recent technologies such as wireless devices, Weblogs, podcasts, and RSS (Real Simple Syndication) news feeds in order to deliver government news and information in new, increasingly customizable formats. The recently announced Government of Canada Wireless Portal (http://canada.gc.ca/mobile/wireless_e.html), for example, allows citizens to use Web-enabled mobile devices such as cell phones and personal digital assistants (PDAs) to access government information and services, including news releases and backgrounders and Members' of Parliament contact information. Most of these experiments, however, fall under the rubric of online information provision and consultation, as opposed to the richer modalities of citizen engagement both on and offline that harbour greater potential to impact on civic participation broadly speaking.

The use of online consultation has also begun to spread to the provincial and municipal levels of government across Canada. The province of Ontario, for example, used online consultations in 2003 and 2004, along with more traditional face-to-face consultations, to solicit public opinion on the province's budget priorities in the face of consecutive deficits (http://www.townhallontario.gov.on.ca/), engaging over 14,000 Ontarians in the process (Borins, 2004). The City of Toronto has also incorporated online technologies into a number of recent public consultations, including its Listening to Toronto (2003-2004), City of Toronto Act (2005) and Governing Toronto (2005) consultations. As at the federal level, however, the long-term impact of such consultations on public policymaking and, ultimately, civic engagement, remains to be seen. In addition, in the event that such consultations do prove influential, governments will have to take greater care to ensure that the results of such exercises are truly representative of the full spectrum of citizen experiences, interests and opinions, including making efforts to enable all Canadians to participate in the emerging online public sphere.

## CONCLUSION

In response to the decline of civic engagement in Canada, enthusiasts of online consultation have argued that the adoption of new mechanisms of public involvement will reinvigorate citizen-government relations and revitalize the practice of democracy. Such hopes are understandable given the circumstances, but evidence that political participation and engagement can be restored using online technologies remains thin, and they run contrary to substantial academic research on the Internet and political participation, which is inconclusive at best. Out of this research comes a variety of concerns, including the impact of the digital divide in further marginalizing disadvantaged groups in the political process, and the balkanized nature of the online public sphere (Gidengil et al., 2004; Hague & Loader, 1999; Putnam, 2000; Sunstein, 2001; Wilhelm, 2004). Future research and practice will need to face these issues squarely to ensure that online consultation and engagement make truly useful contributions. Online consultation should continue to have a place in government tool-kits for involving and engaging citizens, but not at the expense of other innovative channels of communication, such as face-to-face deliberative dialogues, or efforts to reform democratic institutions such as electoral or parliamentary systems. A reform

strategy mixing and integrating the two will likely produce the best results.

## KEY TERMS

**Citizen Consultation:** A process of involving citizens in policymaking by inviting them to respond or give feedback to government on a particular policy issue or proposal. Traditional consultation exercises such as public hearings and opinion surveys fit into this category, as do some electronic consultations that provide a feedback form or an e-mail address for citizens to send in their comments.

**Citizen Engagement:** A partnership between citizens and government in which citizens enjoy opportunities to dialogue both with government and one another on policy issues, and in which citizens actively engage in the policymaking process by proposing policy options and shaping the policy dialogue.

**Civil Speech:** A requirement for successful dialogue in the public sphere. Civil speech helps to ensure a productive and tolerant space for dialogue that is aimed at finding common interests and goals. Civil speech goes beyond good manners or etiquette to encompass an orientation towards understanding, and an attitude of respect for the opinions and experiences of all participants in a discussion.

**Deliberative Dialogue:** A policy decision-making technique in which citizens interact with both policy experts and one another to consider multiple perspectives on a given policy issue. The approach involves extended dialogue, critical thinking, and learning from both experts and fellow citizens.

**Online Feedback:** A process by which the government creates opportunities for citizens to provide feedback and input on a particular issue, using the Internet. Examples of online feedback include using Web-based forms, responding to questions in an online poll, or submitting qualitative responses to a policy document via e-mail.

**Online Discussion:** A process by which the government provides opportunities for citizens to interact with government and one another in a discussion, debate or meeting online. Unlike online feedback processes, online discussion-based consultations provide opportunities for the public to join a conversation, share ideas, collaborate on projects and build relationships through electronic communication.

# Online Dispute Resolution

**Melissa H. Conley Tyler**
*University of Melbourne, Australia*

## INTRODUCTION

Every community—whether physical or virtual—will inevitably experience conflict. New ways of interacting through information and communication technology has led to new conflicts, such as domain name or e-commerce disputes. At the same time, governments need to deal with the entire range of disputes in society, whether crimes, neighborhood disputes, ethnic conflict, or disputes with its own employees. A key role for government and for e-governance is providing mechanisms to help resolve these disputes.

The emerging area of online dispute resolution (ODR) potentially offers a useful set of tools and techniques for resolving disputes. Capable of being used for both online and off-line disputes, ODR has already proved that it can provide effective resolution for at least some disputes: more than 1.5 million cases had been successfully resolved online to July 2004 (Conley Tyler, 2005).

Governments and e-governance institutions around the world are adopting or considering the applicability of ODR as a tool for digital government.

## BACKGROUND

ODR refers to dispute resolution processes conducted with the assistance of information technology, particularly the Internet.

ODR has been available since 1996 and has rapidly passed through three broad stages of development:

- A "hobbyist" phase where individual enthusiasts started work on ODR, often without formal backing
- An "experimental" phase where foundations and international bodies funded academics and nonprofit organizations to run pilot programs
- An "entrepreneurial" phase where a number of forprofit organizations launched private ODR sites (Katsh & Rifkin, 2001, pp. 47-72).

ODR is now entering a fourth "institutional" phase where it is piloted and adopted by a range of official bodies including courts and government dispute resolution agencies (Conley Tyler, 2003).

Two main forces have been driving the development of ODR to date (Conley Tyler & Bretherton, 2003). First, the difficulty of utilizing traditional dispute resolution methods in low-value cross-border disputes has led to interest in low-cost, cross-jurisdictional dispute resolution methods. This has been a particular concern for governments and intergovernmental organizations interested in fostering e-commerce (Federal Trade Commission, 2000; OECD, 1999; Trans Atlantic Consumer Dialogue, 2000). Without effective remedies in the "borderless marketplace," where traditional court-based remedies are not a realistic option, consumers and business may decide not to transact (Consumers International, 2001). Consumer confidence is seen as a key issue in increasing the level of online commerce.

At the same time, the forces that promoted alternative dispute resolution (ADR) as an alternative to court adjudication in recent decades are also driving the development of ODR. Some ADR enthusiasts have been motivated to investigate the potential of the online medium to provide more effective techniques for dispute resolution—in some cases, from simple curiosity (Raines, 2006). The search for more convenient, cost-effective, efficient, and durable ways of resolving disputes will continue for as long as disputes exist (Brannigan, 2004).

## CURRENT STATE OF ODR

### Types of ODR

ODR has adapted traditional dispute resolution processes for use online, including facilitated negotiation, mediation, arbitration, and case appraisal. Courts now provide some of their functions online in some jurisdictions. *Facilitated negotiation* is the simplest form of ODR in which an online space is provided where parties can negotiate directly. This can include *collaborative peacebuilding tools* that facilitate multiparty discussions (Balvin, 2005; Hattotuwa, 2005). *Online mediation* involves a trained neutral who facilitates the negotiation process either via a secure Web site or e-mail (Raines, 2006). In *online arbitration* or *adjudication,* a skilled neutral (either a private arbitrator or a judge) will adjudicate on one or more issues, receiving evidence either via

electronic documents or videoconferencing. *Case appraisal* is where a neutral party considers a dispute and provides nonbinding advice. This can include, as for iCourthouse (www.i-courthouse.com), through a virtual "jury" mock trial.

In addition, a number of new ODR techniques have been developed to take advantage of new information and communications technology. These do not have precise analogs in the "real world." *Automated negotiation* allows communication between disputants without a human intermediary. It includes processes such as "blind bidding" where parties submit confidential settlement offers during a number of rounds. A computer program automatically notifies them of a settlement at the arithmetic mean once the offer amounts are sufficiently close (see Cybersettle, www.cybersettle.com, for an example). *Negotiation support systems* have also been designed to take advantage of the online medium (Belluci & Zeleznikow, 2005; Kersten, 2005; Lodder & Thiessen, 2003). They are expert systems that allow manipulation of negotiation variables by one or both parties to help them plan and conduct negotiations.

## Communication Methods

The communication tools used in ODR have changed as online technology has developed (Kaufmann-Kohler & Schultz, 2004). Early ODR sites tended to rely mainly on e-mail meaning that communication was delayed, text based, and insecure. By contrast, most services launched since 2001 use a secure Web site encrypted by Secure Socket Layers (SSL) technology where parties are given a password to access a Web site area dedicated to their dispute.

Sites can either allow asynchronous communication through threaded discussion (bulletin boards) or real-time chat facilities. Instant messaging is being used by some sites, as is "secure e-mail" via an encryption program. Caucusing (the ability for one party to meet among themselves or with the neutral without the other party) is a basic feature in newer systems. Some sites offer facilities such as case tracking and document editing.

A number of providers integrate ODR methods with traditional tools such as phone, fax, teleconference, and face-to-face meetings. Videoconferencing is offered by a number of sites (Conley Tyler, 2005). The majority of sites provide a single-language service; however, there is an increasing number of bilingual and multilingual services.

## Types of Disputes

The range of disputes resolved by ODR has been broad: from family law to Internet domain name disputes; from small claims to insurance disputes. Online and off-line consumer disputes have been a major focus of ODR sites.

It is not surprising that many ODR sites were established mainly to resolve online disputes; however, a number of sites have focused mainly or exclusively on off-line disputes (Conley Tyler, 2005).

The areas of dispute handled fall into five broad categories:

1. **Consumer Disputes:** For example, ECODIR (www.ecodir.org), the European Union's prototype online consumer dispute resolution site or Square Trade (www.squaretrade.com), a U.S. service that offers facilitated negotiation and mediation of mainly online disputes, including eBay auction disputes.
2. **Internet Disputes** (especially domain names)**:** For example, the Asian Domain Name Dispute Resolution Centre (www.adndrc.org), based in Hong Kong, which arbitrates Internet domain name disputes.
3. **Commercial, Family, Workplace, and Neighborhood Disputes:** This includes providers such as The Claim Room (www.theclaimroom.com), a UK company that provides mediation for mainly commercial litigation disputes and SmartSettle (www.smartsettle.com), a Canadian company that helps people prepare for negotiation by analyzing their preferences and the options on the negotiation table. Others deal with quintessentially "real world" disputes within workplaces and families: the Federal Mediation and Conciliation Service (www.fmcs.gov) is a U.S. government service that brings laptops to the workplace to conciliate labor/management disputes while Family Mediation Canada (www.fmc.ca) provides Web-broadcast teleconferencing and joint document collaboration for parties in family disputes.
4. **Complex Litigation:** A number of courts now provide online facilities including the Federal Court of Australia's eCourt (www.fedcourt.gov.au) which enables electronic filing and document management and offers a "virtual courtroom," particularly for Native Title hearings in remote areas. Singapore's e@dr (www.e-adr.gov.sg) is another example.
5. **Peace and Conflict:** Info-Share (www.info-share.org) provides tools for bringing the parties in the Sri Lankan peace process together electronically while the Cultures of Peace News Network (www.cpnn.org) is a global network of sites created by United Nations Educational, Scientific, and Cultural Organization (UNESCO) to enable people to share information on promoting peace.

What is striking is the number and variety of situations where people are choosing to resolve their disputes online.

## Uptake of ODR

As of July 2004, at least 115 ODR sites and services had been launched with examples in each continent including South Africa, Peru, and the Philippines (Conley Tyler, 2005). Most ODR sites were located in North America or Europe; however, there has been notable growth in the Asia Pacific (Hattotuwa & Conley Tyler, 2006). While most ODR systems rely on fixed technologies such as personal computers, some ODR systems have started to use mobile technologies such as short messaging service (Hattotuwa & Conley Tyler, 2006). This may help to overcome the "digital divide" (Parlade, 2003; Wahab, 2005) and make ODR more attractive in the developing world (Hattotuwa, 2006).

The number of cases dealt with by ODR sites varies widely: from only one case to more than one million disputes (Conley Tyler, 2005). Lack of information for all sites makes it difficult to make comprehensive judgments (Consumers International, 2001). While some sites that do not caseload information may have attracted fewer cases (Schultz, Kaufmann-Kohler, Langer, & Bonnet, 2001), other factors such as client confidentiality may prevent some providers from reporting on their results.

Settlement rates fall between 50% and 95% and are broadly comparable with settlement rates for ADR generally (Conley Tyler & Bretherton, 2003). There is no evidence that online settlements are less durable than other ADR outcomes. Enforcement of ODR outcomes may be problematic in some circumstances (Kaufman-Kohler & Schultz, 2004, pp. 209–233).

Most ODR sites have formal policies and procedures, including dispute management protocols, standards of conduct, codes of practice, and privacy policies (Conley Tyler & Bornstein, 2005; Wiener, 2001).

## Advantages and Disadvantages of ODR

ODR has a number of advantages over traditional dispute resolution methods:

- Bridging distance, saving travel and venue costs
- Enabling parties to access expertise outside their local area
- Improved transfer, retrieval, and storage of data
- Enabling delayed communication 24 hours per day
- Improving access to justice for some groups (e.g., those who are isolated, disabled, under threat of physical violence, or shy in face-to-face settings)

However, ODR also has potential disadvantages:

- Text-based methods reduce communication cues which can lead to misinterpretations, negative interpersonal behavior, and frustration due to delays in response
- Online communication advantages those who are familiar and comfortable with the relevant technology and tools. (By contrast, face-to-face dispute resolution advantages people who are physically attractive, articulate, well-educated, or members of a dominant ethnic or racial group.)

The list of advantages of ODR helps explain why ODR tools are being used by an increasing number of people to resolve their disputes. ODR can be a convenient, quick, and low-cost option. For some disputes, such as low-value, cross-border Internet transactions, ODR may be the only financially feasible settlement option. In other cases, the choice can be because of costs, time, or inclination. Sometimes people in dispute simply prefer not to meet. Technology can be particularly useful where parties would be in physical danger if they were to meet (Hattotuwa, 2005).

Because it disadvantages some disputants, ODR is not a substitute for other methods: it should be seen as an additional tool for dispute resolution (Conley Tyler, Bretherton, & Bastian, 2003).

As ODR practice develops, guidance will be required on the appropriate situations for its use. Some disputes are not suitable for any type of ADR. Other disputes are eminently suitable for ODR, such as online disputes and single transaction disputes. At this stage there are no agreed guidelines about the type of disputes that can be resolved through ODR: the key limitations are the needs of the parties and the ADR practitioner. More guidance on these issues will become available as ODR practitioners begin to reflect on their skills and techniques (Raines, 2006).

# LESSONS FOR GOVERNMENT

The current state of ODR thus shows an impressive and growing body of experience and best practice, including through government-provided ODR. The future is likely to bring increased adoption of ODR by governments and other formal institutions.

A case study of the Department of Justice Victoria illustrates the government rationale for ODR and demonstrates a high level of interest in ODR among the general public and government dispute resolution agencies. This is likely to have parallels in government contexts in other jurisdictions.

## Government Rationale for ODR

The Government of Victoria, Australia's second most populous state, is committed to bringing the benefits of

information technology to all its citizens. Investigation of ODR was a logical consequence of its previous information technology policies.

In 1999, the Victorian Government issued *Connecting Victoria*, a blueprint for growing the State's information and communications technology to ensure that all citizens would benefit from technology. One of the key commitments in this policy was to have all suitable government services available online by 2001: a goal which was achieved. Victorians now have access to over 450 government services through www.vic.gov.au and the evidence suggests that online government services have been well received: a survey of online users found that 82% of respondents said electronic service delivery made government services more accessible and 62% thought it improved service quality (summarized in Conley Tyler, Bretherton, & Bastian, 2003).

As well as improving its service delivery, the Victorian Government believes its adoption of "leading-edge" technology will have two other effects:

- It will help make government itself more open, efficient, and accessible.
- It will encourage business and citizens to adopt e-commerce and the Internet.

In line with these aims and its *Growing Victoria Together Strategy*, the Victorian Government committed funds to the Department of Justice to investigate ODR. It was seen that ODR could contribute to the priority action area of promoting rights and respecting diversity, including:

- improved access to courts, legal aid, victim support, and ADR.
- improved awareness of rights and the promotion of equal opportunity.
- improved access to services for culturally and linguistically diverse Victorians.

## Assessing Government and Citizen Demand for ODR

In 2002, the Department of Justice Victoria commissioned the International Conflict Resolution Centre at the University of Melbourne to undertake research evaluating current ODR practice, assessing likely demand for ODR, and recommending whether the government should proceed with ODR. The needs assessment was conducted through online and hard-copy surveys, focus groups, and public and stakeholder consultation (Conley Tyler, Bretherton, & Bastian, 2003) and may be the first time a government has conducted a detailed study of public demand for ODR.

Survey and focus group participants represented a broad cross-section of the community, including people who had never used computers, rural and regional participants, people from a non-English speaking background, people from a range of age groups, and a person with hearing impairment. Government agencies consulted included a court, an administrative tribunal, a consumer complaints agency, an industry regulator, and a neighborhood mediation service. These provided a range of dispute resolution services including complaint handling, mediation, investigation, and adjudication. The main communication methods currently used by these agencies were telephone, mail, and face-to-face contact, with only one agency conducting a large part of its communication online.

## Results

Surveys, focus groups, and expert consultation revealed overwhelming public interest in ODR services (Conley Tyler, Bretherton, & Bastian, 2003).

More than 70% of respondents reported that they would be willing to consider ODR both for general disputes and for disputes with an online company. Daily and weekly computer users and people who use banking and auction sites were more likely to consider ODR. The major factors influencing choice of process were cost, speed, and convenience. Dissatisfaction with existing methods of dispute resolution was a factor in motivating participants to consider online options. A number of participants were fairly fatalistic about disputes and might currently end up seeking no redress because of dissatisfaction with existing methods. This suggests that ODR may have a role in promoting access to justice.

However both focus groups and surveys revealed a smaller but significant group of people who are uncomfortable with online communication and are unlikely to use ODR in any circumstance. Given this, ODR should be considered as an addition rather than as a substitute for any current dispute resolution service.

Consultation also revealed considerable interest in ODR from government institutions. Five of the agencies consulted saw a fit between their current strategies and some form of ODR. Agencies consulted identified a number of important advantages to ODR, including the ability to bridge distance, to improve transfer and storage of data, to improve access to justice for some groups, and offer a number of efficiency benefits. Some concerns were also identified, including reduced communication cues, user impatience, privacy, security, accessibility, and equity.

The majority of agencies consulted saw the benefits of ODR and were interested in introducing some ODR techniques as an additional service. ODR was not viewed

as a substitute for existing services or as suitable for every case. One of the major drivers was the belief that ODR was inevitable given changing community expectations of service delivery.

The process undertaken by the Department of Justice can serve as a model for other governments and institutions in considering whether to introduce ODR.

## FUTURE TRENDS

The demonstrated high level of interest in ODR among both government agencies and the general public suggests that the future is likely to bring increased adoption of ODR by governments and other governance institutions in order to deal with the inevitable conflicts that occur in any community.

An important lesson from the experience of ODR to date is not to underestimate the speed at which online technology develops (Rule, 2003). Sites created as recently as 2000 can now appear out of date while the technology of 1997 is obsolete. The future may see the imaginative use of images, graphics, shapes, and symbols and greater use of video and audio streams and video conferencing. This will have implications for dispute resolution practitioners' skills (Conley Tyler & Bornstein, 2006; Conley Tyler & Raines, 2006; Syme, 2006) and the adoption of technology by government and e-governance institutions.

## CONCLUSION

ODR has developed rapidly and is now offered by more than 115 dispute resolution agencies around the world, including government providers. ODR encompasses a diverse range of dispute resolution processes using a range of communication tools and is potentially applicable to most disputes. It should now be considered as a standard tool for government and governance online.

## NOTE

A full bibliography of research in ODR is available at Conley Tyler, M., & Allen, E. (2005). *Online dispute resolution library index*, launched 4 April 2005. Retrieved December 9, 2005, from www.odr.info. Thanks to Rose Balian for her assistance in preparing this entry.

## KEY TERMS

**ADR:** Refers to processes other than judicial determination in which an impartial person assists those in a dispute to resolve the issues between them (NADRAC, 1997). Processes can be divided into determinative, advisory and facilitative types.

**Arbitration:** The main determinative process in which the parties to a dispute present arguments and evidence to a neutral third party who makes a determination that is binding on parties.

**Case Appraisal** and **Mock Trial:** These are advisory ADR processes. In each process, an ADR practitioner considers and appraises the dispute and provides non-binding advice as to the facts, law, and possible outcomes.

**Conciliation, Mediation,** and **Facilitated Negotiation:** These are facilitative processes. In each case the parties to a dispute, with the assistance of a neutral third party, identify the issues in dispute, develop options, consider alternatives, and endeavor to reach an agreement.

**ODR:** Term used in this paper for ADR processes conducted with the assistance of information technology, particularly the Internet. Other terms used are "Online ADR," "eADR," "iADR," "virtual ADR," and "cyber mediation/arbitration." Simply providing information about ADR on a Web site is not online ADR.

**Online:** A colloquial term that refers to communication through an electronic medium, especially the Internet. Online communication includes:

- **E-Mail:** A virtually instantaneous transfer of text messages.
- **Instant Messaging:** A variant of e-mail that can be used asynchronously and also allows synchronous online chat.
- **Online Chat:** A synchronous, text-based exchange of information.
- **Threaded Discussion** (also known as bulletin boards)**:** An asynchronous, textual exchange of information organized into specific topics.
- **Videoconferencing:** Aynchronous transfer of video information

**Off-Line Disputes:** Any disputes that arise in the "real world" outside of cyberspace. These include family, neighborhood, and employment disputes.

**Online Disputes:** Any disputes that arise through or because of online communication methods, including disputes within online communities.

# Online Learning for Public Institutions

**Keith Sullivan**
*Dalhousie University, Canada*

## INTRODUCTION

Three factors have accelerated the need for continuous learning for public administration employees: (1) improvements in information technologies that provide greater opportunities to gather, store, and transmit knowledge; (2) the increase in jobs required to produce and to manipulate knowledge; for example, the Canadian federal government estimates that 75% of its employees are knowledge workers; and (3) employee mobility is increasing, as shown by a yearly turnover of 40% of the U.S. workforce, or approximately 50 million employees.

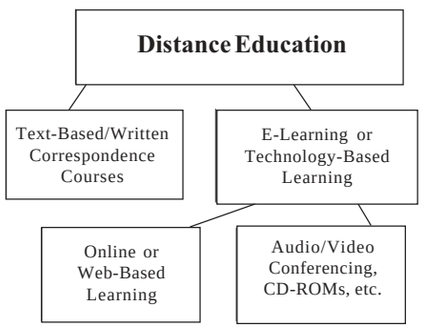
Therefore, continuous learning is becoming an important issue for employers and employees. In a survey of the 50 U.S. state governors on higher education issues, the most important issue was encouraging lifelong learning (Klor de Alva, 2000), leading to a need for learning management, where an organization controls internal and external knowledge as an important performance factor for both individuals and the organization.

In the past, continuous organization learning in the public sector was associated with dedicated central learning centers. For example, the Canadian federal government's education center for middle- and senior-level public servants, the Canada School for Public Service, had two large centers with classrooms and libraries, one with residential capacity.

Most of the new knowledge obtained by public servants required large expenditures of capital and time in order to move employees and instructors away from their places of work to learn together in classrooms. Not only is this model expensive, but it also places a significant gap between learning a concept and being able to apply that concept to daily work. Online gives the learning manager a new tool that might be more cost effective (Langford & Seaborne, 2003).

With the development of new information technologies, many leaders are questioning the place-bound synchronous classroom model as the best model for developing educational experiences. For example, U.S. governors' next three important higher education issues after lifelong learning were (1) providing opportunities to obtain education anytime and anyplace via technology, (2) requiring postsecondary institutions to collaborate with business and industry in curriculum and program development, and (3) integrating on-the-job experience into academic programs (Klor de Alva, 2000). The new instructional model that is emerging delivers smaller units directly to the employee and very close to their work site or home; it is often called online education.

*Figure 1. (Wild, 2003)*



## WHAT IS ONLINE EDUCATION?

As shown in the following diagram, e-learning is a subset of the more comprehensive term *distance education*. Text-based written educational experiences that have been delivered for many decades (often called correspondence schools) are the other part of distance education. E-learning can be divided further into the delivery of education via electronic media such as CDROMs, audiotapes, and so forth, and online learning with instruction based on the Web. The military uses the interesting descriptive term *advanced distributed learning* for online education, which paints a wonderful image of how information technologies work (i.e., streaming the learning experience throughout the world).

## BACKGROUND

In 2001, Pearson, the large British media group that owned 50% of *The Economist*, believed that there was "a potentially vast market for electronically delivered teaching

material." The U.S. alone spent $800 billion on education in 2000, and in that same year, 40% of all U.S. college classes were using Internet resources (Scardino, 2001). In February 2004, Global Network Academy reported 35,766 online courses in 8,052 programs.

IBM and Microsoft have workplace online programs in order for their employees to obtain advanced degrees and credits. The companies cover the cost of the courses, and the workers take the courses at home on weekends. IBM employees obtain their degrees from the University of Texas at Austin, while Microsoft employees enroll at the Oregon Health and Science University's School of Science and Engineering (*Information Week*, 2002).

Warwick University in Britain and Acadia University in Nova Scotia require all students to use laptops for their studies, and students at public colleges in Massachusetts must own a laptop computer in order to enhance their online learning. Spearheaded by the University of Dundee in Scotland, more than 50 schools in 16 countries are working together to develop an online medical school called the International Virtual Medical School. One of the objectives is to counter the pattern of medical students going abroad for their education and not returning to their country. The degrees are to be granted by individual universities, all of which are accredited. The plan is to have students in a clinical setting about 30% during the first two years of the program and 70% in the following years (Mangan, 2002).

The University of Phoenix Online and the University of Athabasca have been two of the most successful online universities. The former has grown over the last few years from 19,000 to more than 65,000 students. This university does not have a physical campus and is not developed for the employees to meet any faculty or students on campus (A. Siegrist, personal communication, 2003). The admissions criteria for an undergraduate degree are a high school diploma and access to a work environment that allows application of the learning concepts. University of Phoenix Online trades on the New York Stock exchange as the Apollo Group. In September 2000, the initial offering was $14 and traded for more than $77 in February 2005.

The University of Athabasca has more than 30,000 students, doubling its enrollment from 1999 to 2005. The programs are based on an open university model that does not require any level of prior academic achievement. They have gained the respect of Canadian traditional universities by allowing students to transfer Athabasca credits into traditional universities. However, it is not hard to final examples of failures. Many online programs founded during the Internet boom did little but hemorrhage money. Pensare, an online MBA company using Duke courses, and Quisic, an online program developed with the Tuck School of Business at Dartmouth, were scrapped. SUNY Buffalo had an online MBA program that lasted only 18 months.

In mid-September1997, the California Virtual University (CVU) enthusiastically opened its doors, promising a Web site that would feature the online and distance education offerings of all California accredited colleges and universities. By April 1999, all that remained was a listing of online courses and programs offered by other California institutions. CVU's plans for a virtual library and online guidance counseling service were abandoned.

The University system of Georgia started a pilot program in 1997 with 8,000 laptops, requiring students at Clayton College & State University and Floyd College to lease laptops for $300 per semester. Students and faculty praised the program. But the state university system went $1.5 million in debt from the three-year experiment, and Georgia decided to end mandatory student laptop leasing programs. Students now are required to purchase laptops (Chronicle of Higher Education Online, 2001).

Many people believe that online learning cannot be as effective as traditional classroom learning with certain subject matters. The argument, even from technology knowledgeable people, is that the humanities are ideal for operating via electronic text, but areas that require any degree of physical dexterity and direct observation, such as general medicine and specialities like brain surgery, do not seem compatible for online teaching (Levinson, 1997). However, there is no empirical evidence to support this view, and it ignores the growing trend of medical personnel remotely interacting with patients through scopes and sophisticated testing.

There is a gender difference for online learners. According to a study of the American Association of University Women, women find greater levels of difficulty taking online classes than men do. Interviews were conducted with 500 students, predominately female, of which almost 33% were pursuing degrees, not just a few courses for enrichment or career advancement. The study concluded that women essentially were adding a third shift, of coursework to their regular jobs and homemaking/childcare duties. In addition, the cost of online classes was adding stress, because the funds required for tuition, online subscriptions, and equipment were equivalent to traditional classes (Chronicle of Higher Education Online, 2001).

## FORMAL INSTITUTIONAL ONLINE LEARNING

The remainder of this article analyzes formal institutional online learning. Like many aspects of the virtual world, writers spend a lot of time looking at the *e* (electronic) part of an e-concept and less time on the other aspects of the concept; in this case, the *l* (learning) part. Both parts are

important to analyze, but with online learning, the *learning* part should take precedence. If you have a firm grasp on how to help students to learn, the software and hardware to best complete the job should be easy to determine. For example, the two major heavyweights on the software side are WebCT and Blackboard. The ease with which they work on computer platforms is important, but even more important is the learning principles on which they are based. This article presents criteria with which to analyze online learning programs.

What is known about the quality of online classes delivered by institutions? So far, very little, first, because these programs are only a few years old; and second, because technology is improving so rapidly that each month brings new possibilities for exchanging information.

There are understandable reasons why the perfect methodology has not been developed for learning. The first is that learners and instructors come into the classroom as very complicated and changing organisms. How they connect with the material being examined is related to countless variables, the most important of which are their intelligence, prior knowledge, and life experiences, each so complicated that it cannot be analyzed in full and related to the material being taught. The learning experience is related even to daily life experiences, such as the commute to class, what happened at home before class, and the amount of sleep obtained the night before. Therefore, the teacher always is faced with learners with different needs and motivations, and a one-size-fits-all concept will never apply. Although these variables make it impossible to design a perfect program for everyone, online learning may be a very significant breakthrough for instruction and learning, because it allows for much more individualization than has been possible before.

## Online Learning Studies

There have been some helpful studies about online learning and a body of knowledge is being developed; for example, a comparative study of interaction of more than 100 students from the MBA programs at Athabasca University and the University of Western Ontario's Richard Ivey School of Business (classroom-based). Athabasca's course methodology is very basic, including printed materials mailed to students and online and asynchronous text discussions. Western Ontario's courses use a typical classroom-based synchronous methodology. Of the four types of interactions examined—social, procedural, explanatory, and cognitive—the Athabasca students reported that they had better explanatory and cognitive interactions. The Ivey students reported higher social and procedural interactions (University Affairs, 2001). Neither methodology was clearly superior over the other.

Another study undertaken as part of a college of business preparation for its reaccreditation review compared programs by learning outcomes (Kretovics & McCambridge, 2002). The MBA program, available in three forms of delivery, had similar course syllabi and instructors in two of the three-learning contexts. The three delivery types were a traditional on-campus classroom synchronous program, a similar executive program, and a distance education program offered online through a learning software program supplemented by videorecordings of each on-campus class session.

All the students were measured, first on their self-reported performance on learning outcomes assessment instrument from the beginning of their MBA program to the end and, second, on learning outcomes assessment. The results indicated that face-to-face interaction between the student and the instructor may not be essential to the instructional process. A well-developed virtual community can meet student needs as well as in-class time. The findings lead to the conclusion that distance students actually may learn more than traditional classroom-based students (Kretovics & McCambridge, 2002).

In a study on effectiveness of an online introductory psychology course at the University of Massachusetts, the majority of students gave high course evaluation ratings, but the online students reported being more satisfied with the instructor and the amount of interaction and feedback (Poirier & Feldman, 2004).

It is increasingly clear that the learning applications that will dominate the Web will take full advantage of nonlinearity and its potential for instantaneous feedback and learner interaction. The richness of the medium at high bandwidth presents a learning environment in which the learner becomes immersed. It is possible to have mass customization, which draws the learner into a process that will motivate him or her to be totally involved. Students can work their way through learning materials in a way that best fits their individual learning styles. The route and the pace can be adapted for each learner. This new learning environment will bear no resemblance to today's faculty lecture notes or textbooks (Heterick & Twigg, 2001).

Many college administrators say that the quality of their institution's online courses soon may eclipse their brick-and-mortar offerings, according to a report by Babson College and the Sloan Consortium. The study concluded that about one-third of college administrators believes that within three years, the quality of their institution's online programs will be better than the on-campus offerings. Almost 60% said that their present online courses were at least equivalent to the quality of their on-campus classes. The same survey found that 11% of postsecondary students took at least one course

online in the fall of 2002, with more than one-third of those students taking all their courses online. Students taking online classes are on the increase, because public colleges are producing more online offerings. On the other hand, one-third of college officials, mostly from private baccalaureate institutions, predicted that online courses will not play a major role in their programs (Chronicle of Higher Education, 2003).

## Ingredients for Quality Online Education

The most important point of any course is the extent to which it provides a good learning experience for the student. Good learning experiences never can be guaranteed, but following are five ingredients that will increase the likelihood of an outstanding experience.

### Instructor and Course Developer

In an online course, a student will have less direct contact with an instructor than in a traditional class and will rely more heavily on a learning path described in the course materials. Therefore, the content and the design of the class methodology are very important. The institution delivering the program should clarify the qualifications of both the course developer and the instructor. If a student cannot find this information, he or she should be concerned.

At least one of the most popular online universities, the University of Phoenix, has a policy that online faculty members must work full time in an area related to their courses. I am suspicious of this policy and question how these people have the experience and depth of knowledge to design and deliver a quality course and program. It reminds me of the surgeon at a cocktail party who said to a renown author that when he retires, he wants to write. The writer, sensing a lack of respect for her expertise, quickly replied that she wants to become a surgeon when she retires.

The instructor should know the most relevant content to include in the course and how to apply it. This is not an easy task, because it requires both a depth of knowledge in relevant academic research and experience teaching students in the field.

### Content and Course Requirements

A student should expect the same quality of work required in a traditional campus-based class and more assignments than the traditional course. Why more assignments? Traditional classroom seminars require students to read material before the class in preparation for intelligent weekly three-hour classroom interactions. An online course should require something to replace this lost learning opportunity. One way to do this is to require additional writing, online chats, and/or testing.

### Reputation of the Institution

Every institution must build a reputation for quality work. It is possible for a new institution to deliver excellent programs and still to be an unknown quantity. However, all things being equal, when choosing a program, a student should pick a prestigious university. This will enhance a student's degree and possibilities for advancement.

### Cost

Cost is related only indirectly to quality, but it is an important factor, nonetheless. Online classes tend to be expensive in relation to campus-based classes. Dalhousie's MPA on-campus course fee is $595, while the MPAM online course fee is $1,700. Without the normal expenses for classrooms and libraries, it does not seem logical that online course tuition is substantially more expensive.

The cost is high now, because most programs are in the development stage with few students. The economics of scale apply to university courses in the same way that they apply to producing DVD players. At the same time, don't forget the cost and effort expended in traveling to a traditional class setting. Most graduate courses will have at least 13 classes that require 13 trips to the campus with 36 hours in the classrooms.

### Instructional Methods

How is online learning suited to different instructional methods? The U.S. National Training Institute of Applied Behavioral Science completed research on the average retention rate of material learned through seven different modes of instruction. The results reflect the percentage of students retaining material six weeks after a teaching experience (NTL Client Relations Center, 2003). From these results, the study ranked modes of instruction from least to most effective as follows: lecturing, audiovisual aids, demonstrations, discussion groups, practice-by-doing, teaching others, and immediate use. The origin and validity of this research is rather vague, but it appeals to me because it meshes with a general intuitive feeling about effective learning and is constantly reinforced by student evaluations of my courses. These modes of instruction are discussed next and related to online education.

## Lecturing

Lecturing has been the main mode of instruction in professional development and traditional university classroom settings. However, it may have the shortest retention rate among the different modes of instruction. In the past, slow Internet transfer made the delivery of lectures via streaming video impractical and actually may have made online instruction better than traditional classroom instruction. Instructors simply could not place their lectures online. Online instruction had to rely on other, more effective modes of instruction.

Increasing bandwidths and faster computers can deliver streaming audio and video online. But don't be impressed if an online site claims to emphasize lectures via streamed video, because their use must be evaluated in light of a potentially poor retention rate. Online education could take a step backward, if lectures become a major portion of online instruction.

## Reading

Reading text on the screen was the first use of the Internet for learning. Two of the most financially successful online programs—Athabasca University and University of Phoenix Online—have relied heavily on text-only instruction. Even with their success, a low retention rate for only text reading should introduce caution about programs that are based too heavily on text. On the positive side, online education through text has two major advantages over the print material used in traditional classrooms. The first is the opportunity to include hypertext markup language (HTML) for linking to different sources around the world and to learners worldwide. The second is the opportunity to have the material available for students anywhere in the world.

The major disadvantage is that most students still find reading online difficult, particularly if the software does not provide for making notes and for highlighting.

## Audiovisual Aids

The use of audiovisual aids improves the retention of material. PowerPoint presentations, pictures, video, and audio should be used to enhance key points of the lessons. These modes are more feasible online now than just a few years ago. The same audiovisual materials available in a classroom can be provided online with the advantage of access when the student is ready, as often as required, and anywhere there is an Internet connection.

## Demonstrations

Demonstrations push retention rates of learners even higher. Online learning allows the instructor through video to choose the exact environment needed to obtain optimum results. In addition, the learner can replay the demonstration as many times as required in order to understand the concepts. This is a distinct advantage over the classroom setting, where repeating a demonstration is usually not feasible and almost never in control of the student.

## Discussion Groups

Does an online program have discussion groups? The opportunity to discuss material in groups provides an additional increase in retention rates. Online text-only discussion groups lose some of the sensory characteristics of communication but actually have some advantages over in-class discussion groups by changing the playing field. Visual and auditory cues often give certain people advantages or disadvantages based on prejudices and irrelevant characteristics (e.g., size, accent) that distort communication. The text-only chat takes these irrelevant cues away and makes a student concentrate on the substance of the message. In traditional classroom discussions, the gregarious person usually dominates the shy introvert, often giving an advantage to males. With online chats, the student with good keyboard skills (often a female) has the advantage. In addition, online discussions can be placed on a Web site as a record for both students and professors and available for students that could not participate in the original discussion. This is never possible in typical classroom environments.

## Practice by Doing

Instruction should reinforce content with practice by doing through questions and exercises that increase retention rate. Requiring students to complete questions directly related to the material accomplishes practice, the simplest being short multiple-choice or precise short-answer questions. A more difficult form requires students to complete essay questions based on the material taught, and the most challenging mode uses essay questions based on material taught in case studies.

## Teaching Others

The instructional methods of teaching others and immediately putting knowledge into use are the most potent

learning techniques. Their commonality is moving the bulk of the process over to the learner.

If you have been required to teach a classroom of students, you understand the significant amount of work required for preparation. Therefore, it should be no surprise that it is one of the most effective learning experiences. The instructor (in this case, the student) must understand completely the material to be taught in order to answer questions and to provide additional explanations. Online students can teach by developing PowerPoint presentations with voice overlays in order to provide content and questions to other students. The material then is placed on the class Web site.

### Immediate Use

Immediate use involves acquiring knowledge and quickly applying that knowledge to a problem, which provides a very effective learning technique. This learning technique is well suited to online education. Since online learning can occur at a computer terminal at or near the workplace, the instructor can design questions and exercises that the student can apply immediately to the workplace.

## FUTURE TRENDS

What are the future trends of online education, especially in public organizations? As learners cross the often difficult barrier between what they know (classrooms) to the new and unknown online learning, they will understand that the online learning experience overall can be better. Therefore, there will be a swing, slowly but steadily, to online education. Public recognition cannot be gained overnight, and it will require many years of public servants receiving online quality learning as assessed by the learner and employer.

A second trend will be a differentiation between course developer and teacher. Online classes are based on meticulous and carefully prepared written and audiovisual materials and less on a theatrical performance from the professor, so it is easier for an instructor other than the course author to teach the class, potentially to thousands of students. Course developers will be compensated more than course teachers.

These online courses will generate hundreds of thousands of dollars in tuition fees, so who should benefit from these revenues? These issues, debated before over the use of textbooks, produced the well-accepted practice of royalties to the author from each copy sold. This could be the model used with online classes.

Software and hardware will continue to provide different and better opportunities for learning, so the possibilities for instruction already discussed in this article will continue to change and improve. For example, how will handhelds and wireless change the options for instruction?

Information technology has changed expectations for all aspects of learning, including the administration of the courses and programs. In the future, students will expect online access to course descriptions, program descriptions, applications, acceptance and rejection letters, tuition payments, and library facilities.

## CONCLUSION

This article emphasizes that learning still must be the driving force of any online instruction. Public institutions around the world still must provide learning environments for their employees and must see online learning as an effective alternative to the traditional classroom setting. Online learning is developing so rapidly that it is difficult to predict the future, except to say that there is a good chance that it will eventually dominate the delivery of courses.

Using the Pyramid of Learning, an analysis of the types of instruction possible for online settings indicates that well-designed and well-implemented online learning can be a learning experience at least as effective as classroom instruction.

## INTRODUCTION

The right of a citizen to petition Parliament is arguably one of the fundamental ways individuals can engage in democratic processes, by providing their views on what governments should do and requesting action on a particular issue.

In 2000, the Scottish Parliament agreed to a trial of an e-petitioner system whereby members of the Scottish public are able to lodge, sign and view petitions to the Scottish Parliament's Petitions Committee using the internet. Originally developed and hosted by the International Teledemocracy Centre, constituents can now place petitions on the Scottish Parliament Web site in a format that offers a discussion forum for each petition.

In 2002, the Queensland government (Australia) launched an e-democracy policy framework that introduced three digital democracy initiatives, including e-petitions. This particular initiative is presented in the case study below. A second Australian state (Tasmania) commenced a 12-month trial based on the Queensland model in July 2004. These three parliaments are the only parliaments to allow e-petitions as at October 2004, although the Canadian, Basque, European parliaments and the German Bundestag have apparently shown an interest in Scotland's e-petitioner system (MacIntosh, 2004).

Although these are only three parliaments that accept electronic petitions, online petitioning is also being used for engaging with governments and elected members. For example, in the United Kingdom, the prime minister's office accepts electronic petitions and lists those with more than 300 genuine signatures on the number 10 Downing street Web page, together with a link to the government's response to the petition. However, petitions are not hosted on that site and a separate Web site must be established to explain the purpose of the petition and to collect signatures. Fourteen petitions on a range of diverse issues were listed on the site for the period between April 2001 and July 2003, ranging from 306 to 83,440 signatures per petitioned issue.

There are also non-government Web sites providing information about, and tools for, creating online petitions. For example, www.petitiononline.com (Artifice, Inc, 2004) provides a privately sponsored free online hosting service for public petitions that includes an automatic formatting system for the Web petition; collects, displays and maintains petition signatures; automatically rejects duplicate signatures and confirms receipt to signatories; and allows for electronic delivery through e-mailing the petition URL to the target recipient. In mid 2004, the site claims over 20 million signatures have been collected on a range of topics.

## BACKGROUND: E-PETITIONING IN QUEENSLAND

The e-petitions service commenced in Queensland in August 2002 as a trial initiative. It was evaluated after 12 months of operation and became a permanent feature of the Queensland Parliament in late 2003 through the adoption of standing orders. It was designed for the purpose of making the petitioning process more transparent and responsive, to make it easier for the public to have their say on issues that are important to them, and to provide greater potential to reach a wider audience than is the case for paper petitions.

The e-petitions facility is located on a dedicated page of the Queensland Parliament Web site at www.parliament.qld.gov.au/petitions. It was developed in-house and is maintained by the Queensland Parliamentary Service. The Web site allows individuals to locate and join a current e-petition, find out information about the status of an e-petition, and view the ministerial response to the petition when it has been tabled in Parliament. A member of the public can also become a principal petitioner and initiate an e-petition, but for Parliament to host the e-petition on the site, it must be sponsored by a

member of Parliament (MP) and checked for conformity with sessional orders by the clerk of the Parliament. Once an e-petition is closed, it is presented to Parliament by the clerk of the Parliament in hard-copy format. An e-petition is posted on the site for a minimum of one week and a maximum period of six months.

The Web site also provides a central reference point for information about the petitioning process generally. It displays all electronic petitions and all paper petitions tabled in Parliament since the commencement of the trial of e-petitions and the ministerial responses tabled in Parliament.

Key features of the petitions Web site are:

- A list of all current e-petitions showing title, subject matter, exact wording of the petition, eligibility, the principal petitioner's name and contact details, a count of signatures to date, and a closing date
- A list of closed e-petitions with the same details and also showing the name of the sponsoring MP, the date tabled and referred to the minister or the date of the minister's response together with a link to that response
- A list of tabled paper petitions with the same details as for e-petitions including a link to the ministerial response where available
- General supporting material such as information about the petitioning process, rules, conditions of use, privacy statement, and forms
- A user survey and feedback mechanism
- Links to MP contact details and information directly from the petitions page
- A "send a link" function allowing users to post the link to other individuals
- An option for signatories to select to receive an automatic e-mail notification when the ministerial response is posted

An analysis of statistics for the first 15 months of operation of e-petitions in Queensland (Henderson, 2003) showed 26 e-petitions had been tabled (compared to 157 paper petitions over the same 15-month period), a further two had closed but not yet been tabled and there were another five current e-petitions. Table 1 provides a comparison of e-petitions and paper petitions over this period. By mid-September 2004, 36 e-petitions had been tabled, two had closed but not yet been tabled and there were seven current petitions, compared with 363 tabled paper petitions.

Not surprisingly, given the relatively short period of time that e-petitions have been operating, the overall number of tabled petitions and signatures per petition over the 15-months of operation are higher for the traditional paper-based process.

It should be noted that differences between the paper-based and electronic petitioning processes will account for some of the difference between the numbers tabled over this period. The sessional orders establishing the e-petitioning system allowed only one petition "dealing

with substantially the same grievance and requesting substantially the same action by the House" to be published on the Parliament's Web site at the one time. In contrast, several copies of the one paper petition could be tabled in Parliament at different times and by different MPs. For example, the issue of horse racing cutbacks in regional and remote Queensland was addressed by one e-petition during this period, whereas three paper petitions, with the same appeal to Parliament, were tabled for the same issue.

Additionally, the difference in the number of signatures for e-petitions and paper petitions is in part due to the length of time that an e-petition can remain open for signature (i.e., six months) as compared to a paper petition, which has no time restrictions.

The e-petitioning system is not intended to replace paper petitions but rather provides an additional way via online technologies to make the parliamentary process more efficient and transparent and to improve engagement between the community and its elected representatives. An internal evaluation, which included interviews with principal petitioners, sponsoring members of Parliament, and officers of both the department and Parliamentary services, found a high level of support for the system in the community and among members of Parliament. In particular, the evaluation highlighted an increase in transparency as ministerial responses to paper petitions were also made available online.

## PRACTICE LESSONS

Major issues identified during the development and implementation of e-petitioning in Queensland were reported by Laurie (2004), for example, signature authentication, security safeguards, and technical and resource requirements. The Audit and Evaluation Services of the Department of Premier and Cabinet also identified various implementation issues in an internal evaluation of the Queensland system in 2003. Seaton (2004) describes a range of 'obstacles to success' for the development of the Scottish Parliament e-democracy initiatives (which include e-petitioning) including voter disinterest, infrastructure and home PC use, and lack of promotion of initiatives. Malina, Macintosh, and Davenport (2001) have reported an evaluation of the Scottish e-petitioner system, identifying issues such as the need to find new ways of promotion petitions and generating participation by sponsors and addressing security and confidentiality concerns by users. These analyses provide a base for developing the key practice learnings presented in the following paragraphs.

### Information Security and Privacy

Protecting the security of information and personal privacy, and establishing confidence of users that online systems are secure and that their privacy is respected, are critical issues in the take-up of online interaction with government (Lowe, 2003, Riley, 2002, United Nations Department for Economic and Social Affairs, 2003).

In Queensland, names and addresses of signatories are not published in any form on the Web site, although printed copies of tabled e-petitions are available on request from the Parliament's Table Office (which is the same process as applies for paper petitions). Queensland has an explicit e-petition data retention policy under which the personal details collected from signatories (name, address, e-mail address) are deleted after the ministerial response to the petition is tabled in Parliament or after six months of tabling of the e-petition if there has been no ministerial response in that time. The Web site makes this policy explicit in information posted on the site. There is also a detailed privacy statement on the Web site setting out how personal information will be protected. The "Conditions of Use" statement posted on the site makes explicit that breach of these conditions, such as the use of false names, amounts to a contempt of Parliament and that there are penalties for doing so.

### Authentication

Ensuring that signatures on a petition, whether in electronic or paper format, are genuine persons, meeting relevant eligibility requirements, is an important issue to prevent forged or falsified documents being submitted. Authentication is not an easy matter, given issues about personal privacy in collecting valid and verifiable personal details, and community concerns about collecting personal information online. Laurie (2004) notes that several authentication options were considered when scoping Queensland's e-petitioning process, but that no universally available or equitable means (that is, one that does not exclude eligible petitioners) for authenticating petitioner personal details in an online environment were identified.

Queensland has adopted the option of making it mandatory that petitioners supply an e-mail address. Although not providing a strong authentication standard, it needs to be considered in the context of paper petition signature authentication, where personal details provided have always been accepted at face value. In order to prevent people mass-joining e-petitions with an automatic submission program, the e-petition system has been designed to generate a unique identifier to be used in each electronic submission which is displayed

before the "sign-on" petition submission screen, must be included in the submission form, and is monitored by the program to ensure each identifier is only used once.

## Promotion

One of the most consistent challenges for online public engagement is awareness of the existence of the initiative (Coleman & Gøtze, 2001). The Queensland internal evaluation identified the need for improved marketing and education of the service, both across government and within the community. Seaton (2004) also notes more effort needs to be made to make people aware of the Scottish e-democracy initiatives and their ability to participate.

E-petitions, along with Queensland's other e-democracy initiatives, have been publicised through a range of methods, including media launches, e-mail bulletins, stalls and promotional items (such as mousepads giving the URLs for the initiatives) at major community events such as Brisbane's annual 10-day Royal Queensland Show, and presentations at community and professional forums. A new multimedia display in Parliament House also provides e-petitions and e-democracy information to 60,000 visitors, including 26,000 school children, who tour the House each year. Other avenues being explored include building e-democracy into civic education curricula to further promote awareness among children and young adults.

## Access

As with all e-democracy initiatives, universal access remains an issue, given that not everyone has ready PC access or the requisite skills and knowledge to take advantage of the opportunities offered through online engagement.

In Queensland, almost two-thirds of people have Internet access at home (Department of Innovation and Information Economy 2003), making online engagement an easily accessible avenue for the majority of Queenslanders. In Scotland, where levels of home-PC are lower, a system of free online access to the Parliament's Web site through a network of partner public libraries has been established and work is also going on to engage community groups that have online access centres (Seaton, 2004).

## Up-Take and the Importance of Demonstrating Government Responsiveness

E-petitions provide an alternative avenue to paper-based system for those people wanting to engage with governments through parliamentary processes. It also provides an opportunity to encourage participation by others who may not already engage with government through traditional methods because of barriers such as time, convenience, disability, geographic distance, or other circumstances that may be mitigated by offering online processes for engagement. An important aspect of encouraging online engagement is responsiveness, so that citizens perceive there is a genuine commitment by governments to listen and respond to matters raised through these processes. The design of the Web site can both demonstrate and be used to monitor level of commitment to doing so.

In Queensland, a core element of the e-petition process is posting of information about the Ministerial response. The Web page listing of closed petitions provides a simple-to-read table comprising title of each petition, its closing date, tabling date, date referred to the relevant minister, and date the response was tabled in Parliament, together with a direct link to the ministerial response. Petitioners also have the option of choosing to be notified by e-mail when the ministerial response is posted. Laurie (2004) notes that a major outcome of the e-petitioning process has been the increased responsiveness to petitions generally, at a rate that is much higher than in previous years. Over the first 15 months of operation, 85 per cent of e-petitions had been responded to in Parliament, taking an average of 48 days between tabling and ministerial response (Henderson, 2003).

# FUTURE TRENDS

Providing the opportunity to establish, sign, and lodge petitions online using a Web site hosted by Parliament itself is currently available in only a very small number of places. However, the experience of Queensland and Scotland demonstrates that it is a practical and useful avenue and it is likely that we will see far more examples of electronic petitioning systems in the future.

# CONCLUSION

A case study of e-petitioning in Queensland (one of the only three parliamentary e-petitioning systems operating at mid 2004) showed that online petitioning processes provide a practical and effective avenue for engagement. Key practice lessons derived from implementation of the Queensland and Scottish systems relate to information security and privacy, signature authentication, promotion and awareness, universality of access, and demonstrating government responsiveness.

## KEY TERMS

**Community Engagement:** Involving citizens in government planning and decision-making.

**E-Petition:** A petition published on the Web before being formally lodged.

**E-Democracy:** The use of information and communication technologies in democratic processes.

**ICTs (Information and Communication Technologies):** The class of technologies that allows the processing, storage and communication of digital information, including networked and portable computer systems, advanced mobile telephone systems and services, interactive digital television, and similar applications.

**Petition:** A signed statement from a person or group of people making a formal request to Parliament about a particular issue or law.

**Queensland Electronic Petitioning System:** An ICT-enabled process for initiating, signing, and lodging of public petitions with the Queensland Parliament.

# Open Source in Government

O

**David Berry**
*University of Sussex, UK*

## OPEN SOURCE

Open source software (OSS) is computer software that has its underlying source code made available under a licence. This can allow developers and users to adapt and improve it (Raymond, 2001). Computer software can be broadly split into two development models:

- Proprietary, or closed software, owned by a company or individual. Copies of the binary are made public; the source code is not usually made public.
- Open-source software (OSS), where the source code is released with the binary. Users and developers can be licenced to use and modify the code, and to distribute any improvements they make.

Both OSS and proprietary approaches allow companies to make a profit. Companies developing proprietary software make money by developing software and then selling licences to use the software. For example, Microsoft receives a payment for every copy of Windows sold with a personal computer. OSS companies make their money by providing services, such as advising clients on the GPL licence. The licencee can either charge a fee for this service or work free of charge.

In practice, software companies often develop both types of software. OSS is developed by an ongoing, iterative process where people share the ideas expressed in the source code. The aim is that a large community of developers and users can contribute to the development of the code, check it for errors and bugs, and make the improved version available to others. Project management software is used to allow developers to keep track of the various versions.

There are two main types of open-source licences (although there are many variants and subtypes developed by other companies):

- **Berkeley Software Distribution (BSD) Licence:** This permits a licencee to "close" a version (by withholding the most recent modifications to the source code) and sell it as a proprietary product;
- **GNU General Public Licence (GNU, GPL, or GPL):** Under this licence, licencees may not "close" versions. The licencee may modify, copy, and redistribute any derivative version, under the same GPL licence. The licencee can either charge a fee for this service or work free of charge.

Free software first evolved during the 1970s but in the 1990s forked into two movements, namely free software and open source (Berry, 2004). Richard Stallman, an American software developer who believes that sharing source code and ideas is fundamental to freedom of speech, developed a free version of the widely used Unix operating system. The resulting GNU program was released under a specially created General Public Licence (GNU, GPL). This was designed to ensure that the source code would remain openly available to all. It was not intended to prevent commercial usage or distribution (Stallman, 2002). This approach was christened free software. In this context, free meant that anyone could modify the software. However, the term "free" was often misunderstood to mean no cost. Hence, during the 1990s, Eric Raymond and others proposed that open-source software was coined as a less contentious and more business-friendly term. This has become widely accepted within the software and business communities; however there are still arguments about the most appropriate term to use (Moody, 2002).

The OSMs are usually organised into a network of individuals who work collaboratively on the Internet, developing major software projects that sometimes rival commercial software but are always committed to the production of quality alternatives to those produced by commercial companies (Raymond, 2001; Williams, 2002). Groups and individuals develop software to meet their own and others' needs in a highly decentralised way, likened to a Bazaar (Raymond, 2001). These groups often

*Table 1. A summary of open-source applications and technologies*

| |
|---|
| • Web sites (e.g., Apache) |
| • Network infrastructure (e.g., BIND, Sendmail) |
| • Operating systems (e.g., GNU/Linux, FreeBSD) |
| • Applications software (e.g., GIMP) |
| • Group network ssoftware (e.g., Drupal) |
| • Business systems (e.g., Amazon.com's Web site) |
| • Distribution/peer-to-peer filesharing |

*Table 2. A list of reasons for utilizing open source in government*

- To enable transparency
- To save money
- To maximize alternative providers interoperability
- To improve software standards
- To provide timely public interest data
- To facilitate a competitive software market
- To avoid vendor lock-in
- To ensure open standards are implemented
- To allow security and coding checks to be made visually
- To optimize equipment
- To connect to other government to government (G2G) systems

make substantive value claims to support their projects and foster an ethic of community, collaboration, deliberation, and intellectual freedom. In addition, it is argued by Lessig (1999) that the FLOSS community can offer an inspiration in their commitment to transparency in their products and their ability to open up governmental regulation and control through free/libre and open source code.

## CRITICAL ISSUES OF OPEN-SOURCE SOFTWARE

Advocates of OSS argue that, because it harnesses a large team of developers, bugs and errors can be rapidly spotted and fixed, thus increasing reliability and security. They also say that having a large team means that OSS is by necessity "modular" (made up of discrete units, each with a specific function). Modularity simplifies software design and can increase the reliability as well as flexibility of software (Statskontoret, 2003). Advocates also argue that, by making the source code available with the software, there is no danger of "lock-in" because document formats are transparent. However, critics point out that proprietary software can also have a high degree of reliability, flexibility, and security and can also conform to open standards.

Many commentators argue that OSS projects can suffer from weak project management (because of their products' complex development structure) and that OSS can be difficult to use. The OSS community point out that new project management tools are being introduced and that efforts are being made to increase the user-friendliness of OSS desktop applications. There are often concerns that OSS is unsupported and contains unauthorized intellectual property (IP) belonging to third parties. However, the OSS community say this can also be the case with proprietary software. Moreover, large firms such as IBM and Hewlett Packard now manage open-source projects and indemnify users to give them added insurance (e-Government Unit, 2004).

There is broad acceptance that OSS and proprietary software are comparable in terms of software quality. It is acknowledged that switching costs can be high, whichever software model is used. There are conflicting reports on how total cost of ownership (TCO) varies for the two models. It is widely agreed that TCO should be evaluated only on a case-by-case basis. Many analysts believe that there is increasing symbiosis between the two models. For example, modularity is now seen as an important factor in the development of both proprietary and OSS. New project management tools are being used to manage both types of software projects.

Worldwide, the uptake of open source has been variable, with some countries taking a more proactive approach encouraging such use (e.g., Brazil) and others a more neutral position (e.g., the United Kingdom) (CSIS, 2004; OGC, 2004). With government budgets increasingly stretched and with increasing needs for interoperability both internally as joined-up government and externally as government-to-government (G2G) data systems, open

*Table 3. A summary of critical issues in open source*

**Total Cost of Ownership**
Debates are still ongoing about the best method of comparing the costs of proprietary vs. open source.

**User Ignorance and Perceptions**
Lack of adequate understanding of the open source and it usefulness. User reluctance to retrain on the new software.

**Support**
There is some reluctance to trust anarchic groups on the Internet for the future support of a software product, although this is belied by the amount of corporate support (e.g., IBM, HP) that now exists.

**Software Patents**
Software patents are widely seen to be detrimental to the open-source development method. Currently software is not patentable, although the EU has been discussing a new directive to clarify its position.

**Government Support**
It is difficult to persuade departments to move away from "known" products to lesser known open-source ones.

**Project Management**
Dispersed development means that care has to be taken with the management of open-source projects in the public sector.

**Maintaining and Integrity of Data**
Maintaining up-to-date and accurate information on the site for viewers to use. Open standards and open source are seen as contributory to this effort.

**Security**
Maintaining secure and safe systems and keeping unauthorized user access out.

**System Incompatibilities**
Cross-platform incompatibility that prevent particularly between proprietary and open-source components.

source is thought to take an increasingly larger role in government ICT systems, particularly contributing as part of large infrastructural projects where common users would not need to experience the less developed user-interfaces of open-source software (Hahn, 2002; Weber, 2003, 2004).

## CONCLUSION

Open source is now a mature and useable technology that is being explored by many businesses and governments around the world (DiBona, Ockman, & Stone, 1999; Rushkoff, 2003). Its methods have begun to revolutionise software production and enabled many of the dot-com corporations to take off with impressive results (e.g., Amazon.com) (Lessig, 1999). Its use in government is still under consideration and much opposition from existing market suppliers, although now a more pragmatic attitude seems to be prevailing. Its most interesting possibility is the transparency it offers in allowing citizens to read and check the basic data processing functions of government (Chadwick, 2003; Lenk, 1999; Nissenbaum, 2001; Van de Donk, Snellen, & Tops,1995). Use of open source in government is expected to increase over the next decade as the growing data processing needs push more efficient and cost-effective use of existing hardware together with greater needs for interdepartmental interoperability (Economist, 2003; Lerner & Tirole, 2002). Increasingly, open source is also becoming an international relations issue (e.g., China, Brazil) as it allows countries to develop expertise in computer processing and development and avoid expensive (usually American) licensing costs (Moody, 2002; Weber, 2004).

## KEY TERMS

**Binary:** The compiled source code that is machine-readable and executable. Can be executed on the computer without the need for the underlying source code. Usually distributed alone as proprietary software and with the source code as free software or open source.

**Code:** The programming source code, sometimes referred to as the crown jewels due to the fact that the source code contains all the intellectual property and programming logic needed to implement the software.

**Copyleft:** A clause in the GNU GPL that limits the use of free software unless modifications and distributions are released with the source code included. Prevents the closure of the software into a proprietary software product.

**Copyright:** The key legal instrument that protects the underlying intellectual property in both open-source and free software.

**Distro:** Distribution companies that specialize in distributing free or open-source software.

**Free Software**: Software distributed with source code that adheres to the terms of the GNU General Public License (GPL).

**GPL:** The General Public License. Issued by the Free Software Federation (FSF) to release free software under a copyright license.

**Open Source:** Software distributed with source code that adheres to the terms of an open-source license (such as the GPL or the BSD license). The differences between open-source and free software generally refer to the "copyleft" clause of the GNU GPL.

**Open Standards:** Clear documented interoperability guidelines that allow different software products to work together. Supported by open-source, free software, and proprietary software vendors.

**Proprietary:** Software that does not include the source code as part of the software product (i.e., as binary) or distribution (e.g., Microsoft Word).

**Source Code:** Human readable textual documents that contain the basic functional algorithms of the software and designate the flow of operation and functional capacities. Compiled into binary files to be run on computers.

## INTRODUCTION

Free open/source software (FOSS) is a new software development paradigm that emerged in the last decade and relies directly on the volunteer efforts of geographically dispersed developers of varying professional affiliations and proficiencies, that are coordinated in ad-hoc schemes, based on recognition of the work carried out by relevant "core groups" of volunteers, and follow pragmatic directions, emerging from community feedback.

In direct contrast with previously established business practices (Raymond, 2000), this software development paradigm is fuelled by full disclosure of the source code, volunteer effort, and a number of "freedoms" granted to the software user regarding his ability to interact with the software and propagate its use.

By promoting code reuse and the adaptation of freely available best practices, FOSS development practices minimize redundancy and concentrate "investment" on innovation (Von Hippel & Von Krogh, 2003). The support FOSS projects receive, from the user-developer community, serves to provide guidance, reduce maintenance costs, and enhance software sustainability, while the service-oriented model of FOSS allows for a broad range of contractors to provide support, and helps in minimizing the total cost of ownership.

It is these characteristics FOSS, as we will demonstrate in this article, that render it flexible, economical and reusable, and thus appropriate for use in building publicly funded information and communication technology (ICT) projects (Infonomics, 2002), especially those aiming at the dissemination of information to citizens, such as online environmental portals.

## BACKGROUND

### Free/Open Source Software: Definition and History

FOSS represents a software development paradigm, and as such, it is fairly new, compared to its precursors whose roots go back to the 50s and 70s. Historically, although the software model itself could be said to derive from the UNIX operating system, the FOSS development community, and underlying ideological movement is a little more than a decade old. Table 1 recaps some of the salient moments in FOSS history.

The FOSS development community consists of individuals, or groups of individuals, who contribute to a particular FOSS product or technology: as a consequence of the previous statement, this also includes the users of the software. Although referencing various forms of voluntary affiliation around FOSS projects, the community is the driving force of FOSS software development. It constitutes a community of practice (CoP) (Kimble, Hildreth, & Wright, 2001), and its motivations and processes have been recorded elsewhere in detail (Ghosh, 2003; Lerner & Tirole, 2001; Shah, 2003). CoP's are described as "intrinsic conditions for the existence of knowledge," (Lave & Wenger, 1991) attested to by the fact that the FOSS community provides fertile ground for user-consumer involvement in online joint innovation (Hemetsberger, 2003). The FOSS process refers to the approach for developing and maintaining FOSS products and technologies, including software, computers, devices, technical formats, and computer languages.

The terms open-source and free software refer to software developed and distributed on largely common principles. The definition of free software recognizes some fundamental freedoms as imparted by the author

(Stallman, 1999) to the user, inside a license agreement; namely the freedom to run, redistribute, study and improve, or adapt the program according to specific needs. The open source definition (Perens, 1998) further extended these principles and focused on the development process rather than the political ideology underlying the free software movement.

Unrestricted access to the software source code is a precondition for most of the aforementioned freedoms, and the usefulness and reuse potential of FOSS is dependent on the continual revision and adaptation of its source code. In proprietary and closed development environments, the frequency of revisions is dominated by the sales cycle but can also be stilled by managerial decree. In FOSS, the "life expectancy" of software, is a direct outcome of its popularity with developers, who will choose to devote time to improve functionality, and users, who will provide constant feedback to developers on needed improvements and fixes.

## International and European Public Sector Information Policy Initiatives

The public sector information (PSI) sector represents a considerable part of the information production "market" and has been using non-negligible funds to support this production, in order to serve the public, while supporting authorities and various decision-making bodies in their administrative tasks: PSI is an important component of the content market and a key economic resource for commercial exploitation. The size of the European content industry is some 433 billion euro, about 5% of European GDP. It is estimated that 12% to 25% of the data used in e-Commerce is sourced from PSI. PSI is therefore a prime content resource (Davies, 2005), while Environmental Information accounts for a considerable percentage of PSI produced (> 50%). This information corpus, produced on the basis of various legislative mandates, is usually disposed to a physical or electronic archive, which is rarely revisited and re-used, although it represents a considerable public investment. By the introduction of online services (e-government, e-health, e-learning, etc.), governments promote the public interest for enhanced efficiency and effectiveness (European Commission, 2004) and become themselves important suppliers and users of ICT's, thereby influencing their take up.

Within the EU, a variety of important policy initiatives have been undertaken towards the development of a framework for the definition, access and usage of PSI, Environmental Information being the most prominent and massive part of the PSI corpus. The most important of these initiatives are listed in Table 2, while some of them are presented in detail hereafter.

### World Summit on the Information Society 2003 Action Plan

The objectives of the World Summit on the Information Society Plan of Action (World Summit on the Information Society, 2003) are "to build an inclusive Information Society; to put the potential of knowledge and ICTs at the service of development; to promote the use of information and knowledge for the achievement of internationally agreed development goals, including those contained in the Millennium Declaration; and to address new challenges of the Information Society, at the national, regional and international levels." To this end, the Action Plan calls on governments to take action, in the framework of national development policies, in order to support an enabling and competitive environment for the necessary investment in ICT infrastructure and for the development of new services. Measures to that direction include establishing legislation on access to information and the preservation of public data; instituting policy guidelines for the development and promotion of public domain information as an important international instrument promoting public access to information; creation of digital public libraries and community public access points; facilitating access to journals and books, with special care taken to promote accessibility for all, including disadvantaged, marginalized and vulnerable groups, and using affordable technologies and non-text based computer interfaces.

Although the WSIS action plan does not explicitly mention FOSS as a key element in developing an "information society for all," its potential in reinforcing the policies proposed in the Action Plan is underscored in a variety of its articles, as well as stated directly in peripheral texts, such as the Tokyo Declaration (UNESCAP, 2003), which declared that "development and deployment of open-source software should be encouraged, as appropriate, as should open standards for ICT networking."

### eEurope 2002 and 2005 Action Plans

The central message of the eEurope 2002 Action Plan (European Parliament, 2002) was that the digital, knowl-

edge-based economy is a powerful engine for growth, competitiveness and the generation of employment, while at the same time improving citizens' quality of life (European Commission, 2002). The Action Plan outlined eleven key areas where effort should be concentrated in order for all three pillars of the Lisbon Strategy to be fully implemented in ICT policy. Following on its heels, the objective of the eEurope 2005 Action Plan (European Commission, 2002a) was to provide a favourable environment for private investment and for the creation of new jobs, to boost productivity, to modernise public services (e-government, e-learning, e-health), and to provide equal opportunities for participation in the global information society. eEurope 2005 therefore aimed to stimulate secure services, applications, and content based on a widely available secure broadband infrastructure. It should be noted that a key target of the Action Plan was the development of interactive public services, accessible for all, and offered on multiple platforms.

## Directive 2003/98/EC on the Reuse of Public Sector Information

The Directive (European Parliament, 2003b) identifies public sector documents as an important primary material for digital content products and services, in the evolution towards an information and knowledge society, one that will become an even more important content resource with the development of wireless content services.

The Directive states that:

*Making public all generally available documents held by the public sector—concerning not only the political process but also the legal and administrative process—is a fundamental instrument for extending the right to knowledge, which is a basic principle of democracy. This objective is applicable to institutions at every level, be it local, national or international.*

To this end, it outlines the conditions for reuse of public sector documents, while emphasizing the need for broader cross-border geographical coverage of PSI underpinning community-wide services and the opportunities for European companies to exploit its potential and contribute to economic growth and job creation.

The explanatory memorandum for the proposal on the Directive outlines the reasoning behind the need for reuse of PSI:

*Citizens and businesses alike can greatly benefit from a good provision of (public sector) information on the Internet. It will facilitate their communication with the public administrations and can increase their participation in the democratic process. Public sector information is very important for democratic and civic life. Equally, public sector information is a key resource for economic activity and proper functioning of the internal market. By increasing the use of public sector information, it is expected that better quality information will be used by a larger group of citizens and companies and that it will allow them to better take advantage of their rights in the internal market.*

The Directive recognizes that the considerable differences in the rules and practices of Member States relating to the exploitation of PSI resources constitute barriers to bringing out the full economic potential of this key document resource and proposes that minimum harmonisation and adoption of a general framework for the conditions governing reuse should be undertaken at the community level. It should be noted that the Directive does not mandate reuse in any way, and does not refer to computer programs.

## European Legislation Focus: Public Access to Environmental Information

Based on the production and distribution of various products and services, the emerging global knowledge economy depends critically on networks, information flows, and technological diffusion. In this economic environment, information mastery and the introduction of knowledge-intensive services and means of production have become keys to a city authority's, a company's and even a country's competitiveness and effective performance. In this context, public sector information, and more specifically environmental information (EI), is continuously being produced (via measurements, mathematical models, human experience, telemetry, etc.), but only parts of are used, sometimes only once. Moreover, EI provides a tangible incarnation of PSI and the sensibilities attached to the state of the environment in recent years have led to a practical need for the timely and authoritative dissemination of environmental information to citizens and decision makers. By the adoption of Council Directive 90/313/EEC on freedom of access to information on the environment, on 7 June 1990, the EU pioneered the global movement to promote citizen awareness and increased participation in decision-making processes by advocating public access to PSI.

The "Aarhus Convention" on Access to Information, Public Participation in Decision-making and Access to Justice in Environmental Matters (UN Economic Commission for Europe, 1998), drafted by the UN Economic Commission for Europe (UNECE) and adopted by the EU on 25 June 1998, placed obligations on public authorities to ensure greater public participation in environmental issues and easy access to justice if these rights are

denied. It called for effective dissemination of environmental information as well as greater transparency in decision-making procedures. In accordance with the convention and in line with the new technological developments and needs for updating the environment related legal framework, two "pillar" Directives concerning access to environmental information (Directive 2003/4/EC) and public participation in environmental decision-making (Directive 2003/35/EC), were adopted by EU Member States earlier in 2003, and provide for a Europe-wide harmonised framework fully in line with its ambitious standards. From an implementation standpoint, The "Aarhus Convention", along with its "pillar" Directives can be seen as a successful application, on all levels (e.g., global, European, local) of the principle of fostering increased public participation to the decision making process through promoting access to PSI, as it was first expressed in Directive 90/313/EEC.

The frameworks presented above, taken in conjunction with EU legislation that underlines the extended need for efficient environmental management with the support of appropriate tools (as in the so called Air Quality Framework Directive 96/62/EC), as well as the initiatives outlined in the previous section, point to the conclusion that electronic services provide the means for making best use of the abundance of EI produced by supplying tools to retrieve, structure, display and process related data, and by providing added value services on the basis of EI. It is interesting to note that these "targets" are within the vicinity of the goals of FOSS development and application, as discussed in the following chapter.

## FOSS AND ENVIRONMENT RELATED QUALITY OF LIFE SERVICES

### Benefits of FOSS Use

The use of FOSS software towards building environment related quality of life services hinges on three points (Schmitz & Castiaux, 2002) providing benefits to users, developers, and operators of the software: economy, quality, and philosophy.

- **Economy:** Reusing and adapting freely available best practice software, instead of resorting to monolithic proprietary solutions or developing everything from scratch leads to minimizing redundancy in development efforts and by extension, in concentrating investment on innovation. Relying on the community to spark developer interest in the software and provide user feedback reduces maintenance costs and prolongs its' useful life cycle. A corollary of this is that the functionality and maintainability of the software is not impaired by artificial limitations (i.e., not intrinsic to the software itself), such as expiring licenses and financial plights affecting a single developing entity. The total cost of ownership (TCO) of solutions based on FOSS from a contractor point of view is alleviated (European Working Group on Libre Software, 2001; Kenwood, 2001), since consulting fees are fully useful expenditures, in contrast with licensing fees which mostly serve as instruments of amortization for developing companies. Since public sector information services development is largely supported by public funding, such amortization should not burden beneficiaries of their services. For the service-oriented model of FOSS, it should be noted that costs of support and maintenance can be contracted out to a range of suppliers, as per the competitive nature of the market ensured by source code disclosure (Lerner & Tirole, 2001):
- **Quality:** The main objective in software engineering is not necessarily to spend less but rather to obtain a higher quality for the same amount of money, and aim to enforce the best possible safeguards for quality and safety in the product. Avoiding to "reinvent the wheel" by using funds to develop new applications rather than re-inventing already developed parts, speeds up technological innovation -as is also the case with the increased cooperation and full source code disclosure and availability required by FOSS tenets. Moreover, the model used for software development, while operating outside a "traditional" organization. Finally, as has been repeatedly demonstrated in recent years (Perens, 2001; Schneier, 2001), software security concerns are better addressed through a continuous process of issue disclosure and user-developer cooperation in order to overcome them
- **Philosophy:** Global public goods are non-excludable, non-rival, trans-boundary advantages to society from the provision of certain utilities and from satisfying particular wants and needs such as the elimination of pollution that can be broadly classified into five main types: environment, health, knowledge, peace and security, and governance (European Commission, 2002b; Gardiner & Le Goulven, 2002). The FOSS process can be said to present the potential for a "Social Return of Investment" on public funding, by virtue of its' ability to produce non-monetizable benefits for society, in the form a body of code that can be utilized in building sustainable informatics infrastructures for the public. We argue therefore that FOSS constitutes in itself a

global public good of knowledge, while at the same time presenting the potential to further the production of global public goods of all types. Reliance on proprietary software for science results in vendor "lock-in" as regards to data formats, making it difficult to pursue common protocols for data interchange and storage, for instance, as it is required by modern systems dealing with the problems of environmental data heterogeneity (Visser, Stuckenschmidt, Wache, & Vögele, 2001). In contrast, FOSS developers and proponents promote the use of open scientific standards, through their use in applications, as a means of consolidating researcher efforts, minimizing the cost and dependencies of technical innovation. In addition, the FOSS software movement serves the further collaboration between public bodies, professional communities and the private sector in the interests of creating a flexible and lasting service environment for the public. The free dissemination of technological advances (both in terms of cost and material availability) relating to informatics services, although not a panacea, can be seen to eventually help eclipse the digital divide (Schauer, 2003), by allowing poorer countries to "catch up."

## FOSS in Government: Timeline

Due to the benefits outlined in the previous paragraph, FOSS has seen increased rates of adoption by governments and supranational organizations in recent years. Hahn (2003) catalogues the main actions in support of FOSS by governments around the world, ca. 2003. A more comprehensive chart, providing information on the number and type of FOSS software policies and legislation considered by national, regional, or local governments around the world is being published by the Center for Strategic and International Studies (Lewis & Keiber, 2004) and updated regularly. It looks at whether the policy or legislation mandated the use of, expressed a preference for, encouraged the use or commissioned research into FOSS.

The European Commission has supported a number of initiatives (http://europa.eu.int/information_society/activities/opensource/) in the FOSS domain since 1998, with initial steps conducted through the creation of the Working group on Libre Software. The 6th Framework Programme of Information Society Technologies work programme for 2003-2004 stated that "The development of open standards and open source software will be encouraged when appropriate to ensure interoperability of solutions and to further innovation."

Table 3 provides an abbreviated timeline of the use of FOSS in conjunction with European PSI, as relevant to the context of this article, and in relation to FOSS associated legal and regulatory actions.

## Case Studies: FOSS and Public Sector Environmental Information Services

In the following section, we present a couple of informatics projects (funded under EC initiatives) that strove to produce environmental-ecological information services for public use. Proceeding from the early recognized need for open architectures, platform independence and common data protocols, these systems gradually came to fulfill and embrace the philosophy and principles of the FOSS model.

### The APNEE/APNEE-TU Projects

The APNEE project (http://www.apnee.org) (Bøhler, Karatzas, Peinel, Rose, & San Jose, 2002; Karatzas, 2004) contributed to the European research on public information systems and services, by developing citizen-centered dynamic information services aimed at providing intelligence about the ambient environment. These services advise the citizen about the air quality in terms of an air quality index and offer guidelines for behavioural change. Awareness services are based upon an array of information channels to reach the citizen. APNEE further utilises various intuitive presentation formats to convey information. The configuration of such ambient technologies and the selection specific information channels has been evaluated in field trials in different European regions.

It was apparent from the beginning of the APNEE project that a flexible, modular and cost-effective architecture was needed, to support the environmental information needs of urban agglomerations through easy-to-use and easy-to-access interfaces that would allow a measure of personalization/customization in order to prove attractive to citizens. For this reason, development of the APNEE regional server was based on FOSS technologies.

APNEE/APNEE-TU is composed of a set of reference core modules, including the database, the service triggers, the regional server application and basic functionality modules (licensed as FOSS), as well as proprietary extension modules developed by telecommunication partners to provide services based on local ICT infrastructure conditions. The environmental database forms the backend of all APNEE-TU services and consists of a schema for environmental data series, as well as warnings, medical advice, pollutant information; spatial data for the WebGIS component, and personalization data for subscribers. APNEE-TU provides an object-relational persistence layer to allow cooperation with a variety of FOSS and commer-

*Table 3. UN/EU FOSS related actions, ca. 2005*

| | |
|---|---|
| **2001** | European Working Group on Libre Software report "Free Software / Open Source: Information Society Opportunities for Europe" is published; UNESCO introduces Free Software Portal |
| **2002** | EU-sponsored Infonomics Institute study introduces FLOSS aggregate term; "Pooling Open Source Software" feasibility study by IDA is published; Danish Board of Technology report highlights potential for major public savings in open source software |
| **2003** | IDA establishes the Open Source Observatory |
| **2004** | EC announces Open Standards Definition; UNDP/APDIP International Open Source Network established |
| **2005** | IST/FP6 FLOSSWorld project allocated 660.000€, involving 17 partners in 12 countries worldwide, aimed at promoting global collaboration on FOSS |

cial RDBMS systems. The regional server is the centrepiece of the APNEE platform, providing a Web-based anchoring point for APNEE services, configured and localized as per the needs of each installation site, as well as administrative interfaces for a variety of functionalities, such as subscription to the newsletter, and email services. Push services consist of modules that are triggered by changes in the database, sending SMS and email alerts and warnings to the citizen periodically, or upon user specified conditions. Pull services respond to applications requesting information from the database, including requests made from users via WWW, PDA, or WAP, and requests from automatic processes using Web Services interfaces.

In recognition of the value of the FOSS software paradigm towards building informatics systems for the public, and in order to preserve and disseminate development efforts, the APNEE-TU project produced a "reference implementation," composed of the environmental database, regional server and core modules, which is licensed as FOSS.

## The EIONET Open-Source Software

Another interesting activity in the area of FOSS usage for environmental information exchange and related information services, comes from the European Environment Agency (http://www.eea.eu.int). In the frame of its activities, EEA decided to release a major portion of the software developed as part of, or in relation to the European Environmental Information and Observation Network (EIONET, http://www.eionet.eu.int/), as open-source software. The first release came on March 2004, and took into account the series of standards on Information Technology and Metadata Registries (ISO/IEC 11179, http://metadata-standards.org/11179/). It is worthwhile to note that the decision by EEA to support open source was mainly aimed at promotion of code reuse, supporting freedom of software development, protecting the investment already made by EEA for the creation of the software, and introducing open-source peer-review procedures to the software modules published.

# FUTURE TRENDS

On 1 June 2005, the i2010 initiative was launched by the European Commission, with the stated aims to create an open and competitive single market for information society and media services within the EU, to increase EU investment in research on information and communication technologies (ICTs) by 80%, and to promote an inclusive European information society. During the 5th European Information Society Conference that followed June 2-4, local government representatives from across Europe adopted the Krakow Declaration on Local Agenda i2010 and the promotion of digital solidarity among the cities of the world (CCRE, 2005). The declaration participants stressed the importance of ensuring broadband access, with an eye on promoting PSI use, and of strengthening the enabling role of local and regional administrations in guaranteeing adequate and secure technological infra-structure and in promoting ICT-based inclusive services and applications. To these ends, participants suggested a set of goals as part of the i2010 Local Agenda, to be implemented in all European countries. Goal 1 focuses on the need to support and implement policies in regions and local areas ensuring broadband access to online services for all citizens in Europe by 2010, while Goal 8 specifically mentions the need to expand the use of open source software and open standards in the public sector to increase e-government interoperability nationally and within Europe.

In addition, developments in the semantic Web and ontology sectors that are related to the environmental sector, have been recorded via the number of IST FP6 projects that include these issues in their objectives (http://www.cordis.lu/fp6), while a service-oriented need is emerging, concerning electronic information providence for quality of life, as suggested by the growing number of related services (weather, traffic etc.) which are provided via Web portals and mobile phone operators. Thus, it is expected that the environment-related public sector will serve as core content provider for human-centered electronic information services in the future, that will address individual needs on the basis of semantics defined on an individual level. These needs, when combined with cost limitations and flexibility-adaptability requirements, provide sufficient justifications for the usage of FOSS to support the creation and operation of PSI oriented, environment related, personalised, electronic information services for the support of quality of life and the advance of decision making towards achieving sustainability goals and enhance business perspectives for the ICT market.

## CONCLUSION

European policy on public sector information, and more specifically information related to the environment, has been strongly suggesting its exploitation for the creation of citizen oriented services, in the frame of empowering democracy and participation, and towards enhancing efficiency and effectiveness of the public sector. In addition, the recent developments attesting to the popularity and usage of FOSS by governmental bodies and agencies, and organisations related to the environment, provides proof of concept concerning the creation of quality of life information services on the basis of free/open-Source software. The need of the citizen to be informed and aware about environmental issues is supported by the legislative framework concerning the relevant right of access, and leads to the conclusion that citizens should also have the right of having access to freely available information and informatics infrastructures and resources, that allow for the creation of personalised services, having direct impact to the living conditions and supporting e-participation and e-governance. This may allow for the "transformation" of citizens from "passive" consumers of information services to active participants in a society based on e-democracy.

## KEY TERMS

**Community of Practice (CoP):** Organizational development concept referring to the process of social learning that occurs when people who have a common interest in some subject or problem, collaborate to share ideas, find solutions, and build innovations.

**Free/Open Source Software (FOSS):** Hybrid term that refers to both Free Software and Open Source Software, which is useful due to an unresolved dispute for the naming of the aggregate movement.

**Information and Communication Technology (ICT):** refers to both computer and communication technology. IT (or information technology) is defined as any equipment or interconnected system (subsystem) of equipment that includes all forms of technology used to create, store, manipulate, manage, move, display, switch, interchange, transmit or receive information in its various forms. Information can be in the form of: business data; voice conversations; still images; motion pictures; multimedia presentations and other forms including those not yet conceived. The meaning of communication refers to a system of shared symbols and meanings that binds people together into a group, a community, or a culture.

**Personal Digital Assistant (PDA):** A small, portable computing device, generally handheld, with a small screen that allows various input modes.

**Public Sector Information (PSI):** The public sector collects, produces, reproduces and disseminates a wide range of information in many areas of activity, such as social, economic, geographical, weather, tourist, business, patent and educational information.

**SOAP:** A standard XML-encoded remote procedure call protocol over HTTP; SOAP forms the foundation layer of the Web services stack, providing a basic messaging framework that more abstract layers can build on.

**Total Cost of Ownership (TCO):** The effective, combined cost of acquisition and deployment of an information technology throughout all its perceived useful life (EWGLS 2001).

**Wireless Application Protocol (WAP):** Open industry standard for mobile Internet access.

**World Summit on the Information Society (WSIS):** A UN-sponsored global conference about information and communication, organized by ITU.

**XML-RPC:** A very simple remote procedure call protocol encoded in XML.

# Open-Source Solution to Secure E-Government Services

## INTRODUCTION

Nowadays, a global information infrastructure connects remote parties through the use of large scale networks, and many companies focus on developing e-services based on remote resources and on interactions between remote parties. In such a context, e-government (e-gov) systems became of paramount importance for the public administration, and many ongoing development projects are targeted on their implementation, security, and release (Bettini, Jajodia, Sean Wang, & Wijesekera, 2002). For open-source software to play an important role in this scenario, three main technological requirements must be fulfilled: (1) the identification and optimization of de facto standards for building e-gov open-source software components, (2) the adoption of open-source techniques to secure e-gov services and (3) the standard integration of these components into an open-source middleware layer, capable of conveying a completely open-source e-gov solution. This article highlights that e-gov systems should be constructed on an open-source middleware layer, providing full public responsibility in its development. The role of open-source middleware for secure e-gov services deployment is discussed, focusing on implementing a security environment without custom programming. An alternative solution is given and consists of the adoption of a stand-alone architecture that fulfils all security requirements.

## BACKGROUND

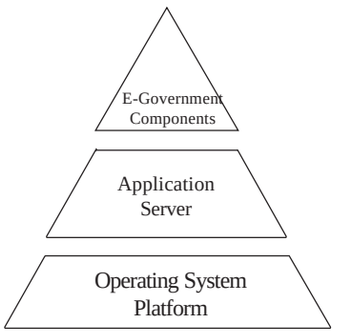
Accessing information on the global Net has become a fundamental requirement of the modern economy. Recently, focus has shifted from access to traditional information stored in WWW sites to e-services such as e-gov services, remote banking, or airline reservation systems (Corallo et al., 2005; Feldman, 2000).

In particular, the perceived importance of e-gov services is growing (Ardagna, Cremonini, Damiani, De Capitani di Vimercati, & Samarati, 2005). Today, e-gov services provide various kinds of functionalities to individual citizens and companies alike (e.g., paying fines, answering registry office requests, releasing authorizations, and so forth). It is widely acknowledged that e-gov services should follow a layered software structure that is outlined in Figure 1 (Ardagna, Damiani, Frati, and Montel, 2005; Damiani, Grosky, & Khosla, 2003). The structure depicted as follows is composed of three layers, where the first comprises a community of software components, managed by an application server (second layer) in turn running on an operating system platform (third layer). Specifically, the three levels are:

- **E-Government Components Layer:** All software components that implement e-gov services.
- **Application Server Layer:** Middleware over which the application will be deployed. It provides some additional functionalities such as management of security, clustering and persistence. In this manner, the developer can focus on the implementation of application components.
- **Operating System Platform Layer:** The operating system platform over which the application will be distributed.

Many proprietary e-gov projects are affected by budget, transparency, vendor lock-in, integration, and interoperability limitations that represent main crucial problems affecting e-gov applications; also, the European public

*Figure 1. E-Government's three-layered structure*



administration sector is increasingly reluctant to depend on proprietary solutions for e-gov services and highly support the introduction of open source in public administration.

The introduction of open-source approach can supply above limitations. First, although open-source software is not necessarily free, in most cases is considerably cheaper than proprietary software, giving economic advantages for the public sector.

Second, open-source software, often, adheres to open standards, which means that software development could influence standard and it is conducted in public forums, in contrast to proprietary approach.

Third, in e-gov scenarios, data are exchanged between involved entities and then it is necessary to rely on secure systems to protect the parties against external checking, and/or undesirable release of information to unauthorized users. Security and quality of open-source code, hence, become the major requirements in e-gov environment. Open-source code enables users and other interested parties to check whether the program is written in a secure way and to identify dangerous elements for stability and security of the applications.

Then, open-source paradigm also guarantees supplier independence. A lock-in situation, in fact, arises when software is purchased and depends on when and how the supplier modifies the product. This lock-in problem does not affect open-source software. Data is not stored in a proprietary format, and it is possible for users to change between several different systems and therefore also between several different suppliers.

Finally, customization and re-use are simply addressable because source code is freely available and modifiable; hence, public authorities can adapt open-source software to their particular needs, resulting in lower customization costs.

At this point, we can argue that an important non-functional requirement for e-gov projects could be to implement the entire application following the open-source approach.

However, many ongoing projects do not completely satisfy the above requirement because only the first and third layer, of the structure depicted in Figure 1, are developed following open-source paradigm, while the middleware is, often, a commercial application server, subject to a license and all the limitations that this license implies. For example, the Italian project PEOPLE (http://www.progettopeople.it) is aimed at providing local authorities with a complete set of open-source software components that run on the Linux operating system.

This approach is claimed to provide an open-source e-gov environment; still, experience has shown that in a deployed system a substantial amount of the executable code, including the one implementing important functionalities such as access control, authentication, and so on, usually belongs to a proprietary application server.

In the following is showed how a complete open-source e-gov application can be secured without custom programming. It is firstly presented a solution that relies on open-source middleware functionalities and then a solution to develop a stand alone framework that could be applied to implement authentication services for users that require e-gov services.

## OPEN-SOURCE APPLICATION SERVERS IN E-GOV APPLICATIONS

With the rising of popularity of e-services, there is an increasing need for dynamic, maintainable, secure, and scalable programming platform. The J2EE specification has been introduced to satisfy this requirement. Therefore, an application server based on this standard is able to provide all the needed services to build a modern application. Most e-gov applications heavily rely on middleware that provides several "horizontal" functionalities, that can be used in an e-gov environment to simplify and improve developed applications, such as security, persistence, clustering, transaction, and cache management.

JBoss (JBoss, 2005; Scott, 2003), an open-source fully J2EE compatible application server, is one of the most widely accepted implementation available on the net and represents an interesting solution for e-gov services. One of the most important characteristics of JBoss is its highly modular design.

The adoption of JBoss functionalities to implement a security environment provides clear separation between business components and security modules and does not require any kind of code customization.

In particular, using JBoss features, it is possible to implement a complete and secure access control environment by the configuration of JBoss XML descriptor files and modules only.

Access control is a fundamental part of any e-gov application and must support the definition of restrictions

that establish who is allowed to access applications, control what operations users may perform and protect messages during transit from sending to receiving applications. Current J2EE specifications define a simple role-based security model for Enterprise Java Beans (EJBs) and Web components. The JBoss component framework that handles security is the JBossSX extension framework that provides support for both the role-based declarative J2EE security model as well as integration of custom security through a security proxy layer.

The default implementation of the security model is based on Java Authentication and Authorization Service (JAAS) login modules and subjects. The security model advocated by the J2EE specification is a declarative model. It is declarative in that security roles and permissions are described using a standard XML descriptor rather than embedding security into business components. By configuring the JAAS login modules bundled with JBoss the integration without custom programming can be completed. JAAS includes a set of standard modules for the use of file, database, and lightweight directory access protocol (LDAP)-based security information. Every user is able to write own security modules that fulfill more specific requirements. In the following sections is outlined how security features can be implemented in e-gov applications. In particular, to implement a complete security environment, an access control management could be configured in three main steps:

a. **Configuring a Database Security Domain:** In the common case, our e-gov application takes all needed information for authentication and authorization from a dedicated database, hence tables about username and password, user roles and association between user and role are built and relative components to manage tables are implemented. The introduction of security within an application is done through the definition of its security domain and the customization of JBoss-specific deployment descriptors. Including the following element in *jboss-web.xml* and *jboss.xml*, access control is applied to, respectively, Web application and EJB layer, binding a security manager instance for the application under the security domain named, for instance, by the JNDI name *java:/jaas/MySecurity*. In order to add the chosen database-based login configuration to the application, the *login-config.xml* file must be configured defining the following modules:
   - **dsJndiName:** JNDI name of database containing user and role tables.
   - **principalsQuery:** SQL statement to retrieve the password for a specific user.
   - **rolesQuery:** SQL statement to retrieve the role of the user.
   - **hashAlgorithm:** Selects an hashing algorithm to crypt password (in our case MD5).
   - **hashEncoding:** Selects the encoding algorithm to convert the binary hash value to a string (in our case base64).

b. **Configuring Authentication Process:** After the definition of the Security Domain, the authentication process must be configured. Authentication verifies that a user is who he claims to be. A standard method of configuring the login process for Web application is defined through the specification in Tomcat's *web.xml* file of the URL of login page and login error page. Now, the user can insert login and password that are sent to the login module specified in the ACTION tag.

c. **Configuring Authorization Process:** After a successful authentication process, the user must have the permissions to perform all the operations associated with her role. There are two ways to perform authorization: *programmatic authorization*, the user has to hard-code security checks into bean code, and *declarative authorization*, the container performs all authorization checks, depending on authorization security policies defined in the deployment descriptor.

Traditional e-gov applications use the declarative method through access restriction to EJB or individual EJB methods through *ejb-jar.xml* file or to specific URLs through *web.xml* file, defining which roles are allowed to access them, as shown in Figure 2. In this XML descriptor fragment, we define two roles, *Standard* and *Admin*, with different permissions: role Admin could access all methods of Operator method, but role Standard can only access *getOperator* method. This way, security is entirely managed through JBoss configuration files.

A drawback of declarative approach is how users information and associated roles are built, as they have to be hard coded in a XML file and deployed to a database to create and populate the needed *DatabaseServerLoginModule* tables.

## SINGLE SIGN-ON: A SOLUTION FOR E-GOVERNMENT SECURITY

In the e-gov environment, as previously said, high-sensitive data is exchanged between the involved parties. Hence, an infrastructure that guarantees security, integrity, and confidentiality is needed to avoid external checking and undesirable release of private information. Security of stored data becomes a major requirement of e-gov scenario. In this section, in particular, we analyze and discuss an emergent and widely accepted solution, named single sign-on (SSO), for securing and optimizing user authentication, focused on open-source frameworks.

*Figure 2. Deployment descriptor for users and roles declaration*

      </method-permission>
         ...
   </assembly-descriptor>
</ejb-jar>
```

From the account management point of view, traditional approaches required an independent management of accounts in each service domain and the use of different authentication mechanisms. Several usability and security concerns have been raised, leading to a rethinking of the log-on process aimed at coordinating and, where possible, integrating user log-on mechanisms and user account management tools for different service domains.

A service/architecture that provides such coordination and integration is called single sign-on (Galbraith et al., 2002; Single Sign-On, The Open Group, 2005) (see Figure 3).

The advantages given by the introduction of SSO architecture in a pre-existing multi-services intra-domain scenario could be summarized as follows:

- Reduction of (1) time spent by the users during log-on operations to individual domains, (2) failed log-on transactions, (3) time used to log-on to secondary domains, (4) costs and time used for users profiles administrations.
- Improvement to users security. Users have to manage only a couple of username/password.
- Secure and simplified administration. With a centralized administration point, system administrators reduce the time spent to add and remove users to the system or modify their access rights (authorization).
- Improvement of security through the enhanced ability of system administrators to maintain the integrity of users accounts configuration, including the ability to change users access permissions in a coordinated and consistent manner.
- Improvement of services usability. Users have to interact with only one login interface.

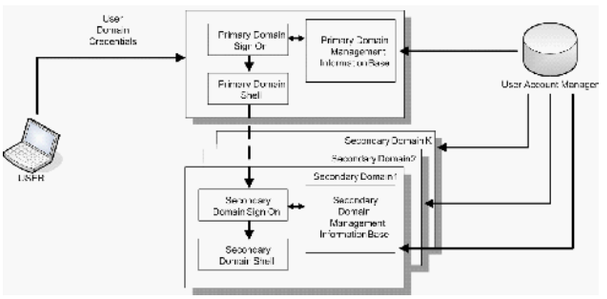
In the SSO approach the primary domain is responsible for collecting and managing all user credentials and information used during the authentication process, both to the primary domain and to each of the secondary domains that the user may potentially require to interact with. This information is then used by SSO services within the primary domain to support the transparent authentication to each of the secondary domains whereby the user actually requests to interact. The information provided by the user to the primary domain can be used in several ways to log-on to a secondary domain:

1. **Directly:** The user information is forwarded to a secondary domain as part of a secondary log-on.
2. **Indirectly:** The user information is used to retrieve other user identification and credentials information, stored within the SSO management information base. The retrieved information is then used for a secondary domain log-on operation.
3. **Immediately:** A session is established with a secondary domain as part of the primary domain session initialization. Client applications are automatically invoked and communications performed at the time of the primary log-on operation.
4. **Temporarily:** Information is stored or cached and used when the secondary domain services are requested.

SSO provides a uniform interface to users accounts management, allowing a coordinated and synchronized management of domains.

The aim of any SSO solution should be to make the login process to multiple sites as secure as giving a username and password to each site. To achieve this goal, different security issues need to be taken into consideration. First, SSO solutions should be based on strong authentication mechanisms; with the traditional password-based mechanism, the theft of a user password could compromise the whole system and also if passwords are not stolen, storing them on a single server makes this server a single point of attack. Therefore,

*Figure 3. User single sign-on to multi-service domain*



for high security environments, a password-based mechanism cannot be sufficient and a certificate-based authentication (e.g., based on X.509 certificates) is preferable.

Another important aspect is related to the security of the server where authentication information (e.g., passwords or certificates) is stored. A robust SSO implementation should ensure the security of that server and the prevention from malicious access to confidential data. Encryption is a viable solution for securing the storage of the users credentials.

A SSO solution should then be designed to guarantee that the key information cannot be determined. For instance, keys could be stored on a smart card or derived each time the user logs on using her password.

Many implementations have been presented to the Internet community as for instance *Central Authentication Service* developed by Yale University, (Aubry, Mathieu, & Marchal, 2004; Central Authentication Service, 2004), *Liberty Alliance project* (Liberty Alliance Project, 2005; Galbraith et al., 2002), a business and technology consortium of more than 130 global organizations that was constituted in 2001, and its SSO implementation *SourceID* (SourceID, 2005), founded in 2001 by Ping Identity Corporation Company, Shibboleth (Shibboleth Project, 2005), an open-source implementation, of Internet2/MACE, *Java Open Single Sign-On* (JOSSO) (Java Open Single Sign-On, 2005), an open-source J2EE-based SSO infrastructure hosted by SourceForge.net and finally *Microsoft Passport* (Microsoft .NET Passport, 2005), one of the most known proprietary Single Sign-On implementation.

## FUTURE TRENDS

For what concerns security issues future enhancements consider techniques that will improve security in case of high sensitive e-gov services. The first solution is the introduction of strong authentication, as said before, because, for high security environments, the traditional username/password authentication mechanism is not enough. Malicious users can steal a password and act in place of the user. New approaches are therefore required to better protect services against unauthorized accesses. A good solution to this problem could integrate username/password with strong authentication mechanisms based on biometric properties of the users (fingerprints, retina scan, and so on).

The second solution concerns mostly the concept of trust and is named Federation. A user should be able to select the services that she wants to federate or de-federate to protect her privacy and to select the services to which she will disclose her own authorization assertions.

For instance, an e-gov portal could offer a set of pre-federated services and list a set of available services that can be dynamically federated or de-federated. Dynamic federation can be useful when different implementations of the same service are available. Again with reference to the portal example, different public organizations can supply a particular service and the user can select the organization she prefers or de-federate the one that she dislikes.

## CONCLUSION

This article presented how to develop and secure open-source e-gov services, arguing that beside the operating system platform and the application code base, also the middleware must be open-source. In particular, JBoss Application Server represents one of the best solutions and provides a complete range of middleware services, including security and clustering management. In particular, this article is focused on providing two principal open-source solutions that allow securing e-gov services: a security implementation that relies on open-source middleware functionalities and one that relies on stand alone framework that provides SSO functionalities. Both of these solutions do not require the insertion of custom code inside business components.

## KEY TERMS

**Access Control:** A mechanism composed of policies that restrict access to computer resources. It is any mechanism by which a system grants or revokes the right to access some data, or perform some action. Normally, it occurs after user authentication.

**Application Server:** A program (framework) that handles all application operations between users and an organization's backend business applications or databases. Application servers are typically used for complex transaction-based applications. To support high-end needs, an application server must have built-in redundancy, monitors for high-availability, high-performance distributed application services and support for complex database access.

**Authentication:** A process whereby users, computers, or applications present valid information (credentials) to demonstrate their identity that can be verified by the authentication layer.

**Authorization:** A mechanism that determines the requestor access rights that are maintained throughout the session; in particular, rights define who can or cannot execute which action on which resource.

**Federation:** An approach, also for Web applications, which uses standards-based protocols to enable one application to assert the identity of a user to another, thereby, avoiding the need for redundant authentication.

**Service Domain:** The environment within a particular service acts. It includes profile repository, security mechanisms, context and session manager and the service itself.

**Single Sign-On (SSO):** An authentication process in a client/server relationship where the user, or client, can enter her authentication information and have access to more than one application or access to a number of resources within an enterprise. Single sign-on avoids the need for the user to start further authentication processes when switching from one application to another within a multi-service environment.

**Strong Authentication:** A method to improve security against unauthorized accesses, in high sensitive environment, with respect to the traditional username/password authentication mechanism. A good solution could integrate username/password with strong authentication mechanisms based on biometric properties of the user (fingerprints, retina scan, and so on).

**Trust:** An aspect of a relationship between two parties, whereby a given situation is mutually understood and commitments are made toward actions in favour of a desired outcome.

# An Opportunity for E–Democracy in Rebuilding Lower Manhattan

**Claudia G. Green**
*Pace University, USA*

**Suzanne K. Murrmann**
*Virginia Tech, USA*

## INTRODUCTION

Following the events of September 11, 2001 (9-11), the Civic Alliance to Rebuild Downtown New York established a forum for the purposes of gathering citizen opinions on the nature of the rebuilding of New York City's Lower Manhattan area. Citizens gave their opinions on the development of space for a memorial, performing arts spaces, museums, restaurants, hotels, residences and businesses. This effort was named "Listening to the City." Civic Alliance organized two types of citizen opinion-gathering strategies: face-to-face focus groups and online dialog focus groups (www.listeningtothecity.org). The purpose of this article is to assess citizen satisfaction with veness of the online format of citizen involvement in making decisions regarding the rebuilding of Lower Manhattan following the attacks of 9-11. The results contribute to our understanding of the use of Internet technology in gathering citizen opinions in urban development and planning.

## BACKGROUND

In the United States (U.S.), research into digital government and citizen participation conducted in the late 1990s and early 2000s has highlighted the need to re-think the paradigm of citizenship. The three primary changes of traditional paradigm have been: (1) considering the citizen as a customer; (2) understanding the citizen's capacity in participation in public affairs and policy making; and (3) addressing the underlying weaknesses and problems in this form of representation democracy (Holzer, Hu, & Song, 2005). The ultimate goal of digital citizenship has been to develop and maintain new human relationships between the individual (citizen), people (community) and organization (government). The goals of these projects have been to operationalize the process of direct citizen involvement and influence in policy priorities; to enhance government accountability; and to encourage digital citizenship.

The primary case study research in digital democracy has been centered on Minnesota State Government Department; City of Santa Monica; California Governor's Office; City of Virginia Beach; Winston-Salem, North Carolina; and Prince William County, Virginia. In these cases, citizens have been asked to present their perceptions and concerns through surveys and other feedback mechanisms to gain their participation and to empower citizens to set priorities. Each of these government entities has demonstrated its desire to have enhanced government accountability by publishing Accountability Reports on the Internet and the California Scorecard. These entities also realized the need to address the underlying weaknesses and problems of representative democracy by providing convenient platforms for the public to access and respond to public issues.

Urban planning incorporates regulation as well as social/political and economic inclusion, which has costs as well as benefits (Hoffmann, 2003). Civic involvement in planning is critical and involves an exchange between government and the community, giving the community control while disciplining and stabilizing the planning process. The outcome of participative planning is community pride and collaboration, important civic values (Johnson & Ward, 1972). Planning, particularly in urban areas, has become market driven, since many of these areas are under-serviced and under-retailed (Porter, 1995).

Organizations have effectively harnessed Internet technology to streamline their communications inside and outside the organization. The concept of "community" has been redefined by the Internet through chat rooms and discussion group technology, where citizens can take active roles in real time (synchronous) or respond at their convenience 24 hours per day, 7 days per week (24/7) in an asynchronous format.

By 2000, more than 54 million US households had one or more computers (US Census Bureau, 2001). In households where income was $75,000 or higher, 88% had one or more computers, and Internet usage in households of more than $75,000 was 79%. Single persons were the least likely to have a computer and Internet access. In metropolitan areas, such as New York City, 46% of households had computers and 38% had Internet access (U.S Census Bureau, 2001).

However, online information gathering often tends to result in collecting data from the wealthier, more educated "information rich" as opposed to the entire population (Kakabadse, Kadabadse, & Kouzmin, 2003). Therefore, before accepting online information gathering as a panacea for citizen involve-

ment, one must be aware of the risk that not all voices may be heard. Random sampling may also be problematic, since such a sample will be limited to those citizens who have a home computer, high-speed Internet access and are computer savvy; (Palmquist & Stueve, 1996) and often, are female users (Barry, 2000).

In addition to the advantages of ease, speed and efficiency, online gathering of citizen opinions features the ability to easily provide searchable background material and references on the topics being discussed. This feature allows a citizen who may not be an "expert" on the topic at hand to become knowledgeable. The use of online resources in the form of newsletters and references can easily facilitate becoming knowledgeable on a topic in a short period of time (Bouras, Katris, & Triantafillou, 2003).

The methods by which communities can be involved in urban planning and development have been influenced by the rapid expansion of the Internet. Participation in an online forum is a function of motivation, ease of communication and the social economic status of the individual (Wang & Fesenmaier, 2003). Individuals are motivated to participate when they perceive that they can contribute actively and freely, and provide unique information. They may also have their needs for affiliation and power satisfied. The feeling that one can contribute to and have an impact on the group motivates participation in the group.

A mediating factor in an individual's motivation and ability to participate in an online community exchange is its ease of use, as well as the level of that person's computer efficacy. Computer efficacy can be described as an individual's perception of his or her ability to use the computer.

A particular personality— for example, active, efficacious or generous— will contribute to participation in the online community. According to Wang and Fesenmaier (2003), people who participate in such activities are more likely to be expressive, sensing-judging, high in self esteem, high in competence, high in internal locus of control, low in need for approval and high in moral development. In addition, participation is also a function of a person's involvement in his or her community.

In 1995, there were only 5 Web sites; by the number of Web sites increased. This dramatic development of the

The purpose of this research was to examine citizens' opinions on the use of online technology to facilitate their input on the rebuilding of New York City's Lower Manhattan area following the terrorist attacks of 9/11.

## METHODOLOGY

During the summer of 2002, AmericaSpeaks convened a series of large-scale public participation forums entitled "The 21st Century Town Meeting" following the 9/11 attacks. Working with leaders, citizens and media organizations, AmericaSpeaks coordinated two face-to-face citizen groups at the Javits Center July 20 and 22. AmericaSpeaks also recruited Web Lab, a non-profit group dedicated to developing the use of the Internet, to explore public issues by convening 26 online dialog groups between July 29 and August 12. Over that 2-week period, citizens participated in online discussion groups. In these dialogs, 818 people working simultaneously in 26 small discussion groups (30 people per group) participated in the exchange of ideas and reviewed proposals and debated policy issues. Thirteen groups were assigned a facilitator; the remaining groups were unfacilitated. The groups responded to six concept plans presented for the rebuilding of the World Trade Center site and the surrounding area. Each plan consisted of memorial space, open spaces, areas for housing cultural institutions, a hotel, 11 million square feet of office space and a new transportation center. Not only did the citizens exchange more than 10,000 messages, but they also participated in 32 opinion polls on various topics that emerged during that period of online discussion.

Using small group discussion (SGD) software, citizens were assigned by computer to groups based on their demographic characteristics to assure diversity within each group. Unlike traditional online discussion boards, SGD software (1) assigns participants to multiple small groups, rather than creating a crowded, anonymous mass; (2) uses group member "bios" and introductions to promote intimacy and dramatically reduce "flaming"; and (3) sets a limited lifespan for each group, promoting commitment and providing closure. SGD software was developed by Web Lab to use the power of the Internet as a positive, transformative force in society at large (www.weblab.org/home.html).

Following the online dialog sessions, all 550 people who participated received an electronically distributed online survey to gather their opinions on the effectiveness and efficiency of the online dialog process. The survey was comprised of 50 objective questions, 13 demographic questions and 6 open-ended questions in the following categories: (1) computer usage and political action activities; (2) dialog sessions content and group facilitation; (3) number and content of messages posted by other participants; and (4) ability to post messages.

## RESULTS

Two hundred and forty-four individuals responded to the follow-up survey (Table 1). The majority of the respondents (54.7%) indicated that they were between the ages of 35 and 54. The gender of the respondents was evenly divided between females (51.7%) and males (48.3%). Although minority groups were represented, an overwhelming 81.9% of respondents were Caucasian. Seventy-seven percent of the respondents possessed college or postgraduate degrees. Income levels appeared to be equally distributed between the range of $25,000 to $100,000. However, 32.3% indicated an income of more than $100,000 and 9.1% indicated incomes of less than $25,000.

The respondent group was comprised of very active computer users, with 63.5% indicating that they typically spend more than 4 hours on the computer each day. Seventy-seven percent stated that they went online several times per day, primarily to respond to e-mail. Interestingly, 38.8% indicated that they were not frequent users of online chats and discussion rooms. However, 65.9% indicated that they used the Internet for research at least once per day or more. A majority (78.6%) indicated that they used the Internet to obtain news, and 72.0% purchased goods and services online at least once every few weeks.

A large majority (91.1%) of respondents indicated that they had voted in elections in the past 2 years. Approximately 59% had made financial contributions online; however, only 30.8% had contributed money to a political campaign and 56.1% had attended a public meeting or demonstration. Approximately 74% of the respondents said they had contacted an elected official by phone or e-mail. Only 18.1% said they had volunteered or worked on a political campaign in the last 2 years.

There was general agreement that having a facilitator was helpful to the online dialog process. Facilitators provided guidance and a helping hand to the online dialog process. Individuals in the non-facilitated groups indicated that they enjoyed and benefited from self-facilitation; however, a large percentage (41.0%) stated that though their group was able to self-facilitate, they would have preferred to have had a facilitator. An overwhelming majority (69.2%) of participants from both types of groups stated a preference for inclusion in a facilitated group in the future, but not surprisingly, more respondents from facilitated groups (82.0%) indicated this preference when compared to those from non-facilitated groups (50.0%).

Fifty percent (50%) of respondents agreed with the length of the dialog. Approximately 67% of respondents said that their views and feelings were affected by participating in the online dialog. A majority (53.5%) indicated that their respect for individuals within their group had increased somewhat or a lot, and that they cared about the group dynamics in their dialog group.

When respondents from facilitated groups were asked how effectively facilitators dealt with group members who acted inappropriately, only 34.3% indicated that they were very effective. A majority of respondents (81.4%) said that all or most participants listened to other participants. This was more pronounced in the non-facilitated groups (46% = almost all) than in the facilitated groups (33% = almost all). Ironically, 57.3% of respondents reported that people tried to dominate in facilitated groups, whereas 48.3% stated that people tried to dominate discussions in non-facilitated groups. In both the facilitated and non-facilitated group, 17.1% of the respondents stated that individuals dropped out of online dialog groups due to insults. This was more likely to occur in facilitated groups (23.1%) than in non-facilitated groups (14.2%).

During the online dialog, participants had the opportunity to respond to online polls on a variety of topics related to the rebuilding of the World Trade Center site and use of online technology. Regarding the rebuilding process, participants voted on the importance of the following topics: hopes and concerns about the rebuilding process; adding a major element to the New York City skyline; whether a new tower should be built and how high the tower should be; how the open spaces should be used; having a unique, mixed-use space; developing a transportation hub (Grand Central of Lower Manhattan); having housing on or adjacent to the World Trade Center site; the importance of multiple income levels and diversity in housing provided; deciding who should participate in the decision-making process; and dedicating the memorial to certain groups. Participants also responded to online polls on how confident they felt that their opinions would be heard; how satisfied they were with the online dialog; where they accessed the online dialogs; and other related topics.

As part of the online dialog, participants had the opportunity to read messages posted electronically at their convenience. Approximately 67% of the respondents reported that they read more than three-quarters of the group messages. Major reasons stated for not reading messages included being too busy (63.0% = some to a lot of impact) and having too many messages (58.7% = some to a lot of impact). Group members reportedly pushed their views more excessively in facilitated groups (51.3%) as opposed to the non-facilitated groups (37.8%). However, the impact of insensitive or abusive members appeared to be less pronounced in the facilitated groups

*Table 1. Demographic characteristics of survey respondents*

| **Characteristics (n = 244)** | **Respondents (number)** | **Respondents (percentage)** |
|---|---|---|
| **Gender** (n = 232) | | |
| Male | 112 | 48.3 |
| Female | 120 | 51.7 |
| **Age** (n = 232) | | |
| 14-19 | 3 | 1.3 |
| 20-34 | 70 | 30.2 |
| 35-54 | 127 | 54.7 |
| 55-64 | 27 | 11.6 |
| 65 and over | 5 | 2.2 |
| **Race** (n = 232) | | |
| Caucasian | 190 | 81.9 |
| Hispanic | 12 | 5.2 |
| African-American | 11 | 4.7 |
| Asian-Pacific Islander | 9 | 3.9 |
| Other | 10 | 4.3 |
| **Income** (n = 232) | | |
| Less than $25,000 | 21 | 9.1 |
| $25,000 - $49,999 | 44 | 19.0 |
| $50,000 - $74,999 | 47 | 20.3 |
| $75,000 - $100,000 | 45 | 19.4 |
| More than $100,00 | 75 | 32.3 |
| **Education** (n = 212) | | |
| Advanced Graduate Degree | 85 | 40.1 |
| Bachelor Degree | 79 | 37.3 |
| Associate Degree | 9 | 4.2 |
| Some College | 26 | 12.2 |
| High School Degree | 5 | 2.4 |
| Some High School | 3 | 1.4 |
| Grade School | 5 | 2.4 |

(51.3% = no impact) when compared with the non-facilitated groups (44.3% = no impact). It appeared that difficulties with using the online process were not a major factor limiting the reading activities of members, with 55.1% reporting no problems with the use of the site.

Participants in the online process were asked about their experiences with posting messages. Respondents reported that the time they spent posting messages ranged from less than15 minutes to more than 2 hours, with no significant difference between facilitated and non-facilitated group members.

## FUTURE TRENDS

A review of the demographic characteristics of the participants in the use of online dialog technology reveals that they are a very select group of citizens. A comparison with data from the 2000 US Census survey on computer usage in US households suggests that these participants represent a small segment of metropolitan households that have a computer with an Internet connection. Citizens who participated in this project tended to be highly educated, with one or more college degrees; and wealthy, with a majority reporting an annual income of $75,000 or more per year. Additionally, they tended to be frequent and regular users of Internet, and politically active. They do not represent the population at large. Therefore, if this method where used again, without modification, the results would be skewed, resulting in hearing the voices of the wealthy citizenry to the exclusion of the average citizen.

In general, the respondents enjoyed participating in the process and preferred being in a facilitated group as opposed to a non-facilitated group. It became clear that facilitators helped the groups stay focused on the topic at hand and controlled respondents who may have tried to dominate a group or who insulted others with their comments. Even though respondents in some of the non-facilitated groups indicated that they had a very positive group experience, they were not in the majority. Therefore, the need for a facilitator would probably result in less conflict and more active participation in all online groups. The facilitator should have more extensive training, which would include group dynamics and conflict resolution. The facilitator should set guidelines at the beginning of the process. Many respondents felt the guidelines were not clear and, therefore, were not easily enforceable by the facilitator. One alternative would be to allow the group to set guidelines, rules and consequences for participation in the online group process. The facilitator should have clear guidelines and prior training before coordinating online groups.

Based on the nature of the responses, citizens seemed to feel that the purpose of the process was to give their opinions and to have their voices heard (the citizen model) as opposed to just trying to get their trust, confidence and acceptance of pre-existing plans (the administrative model). To reinforce the importance of hearing the voices of citizens, in the initial orientation to the online group process, it is important to let the respondents know the outcome of their participation in this process. This would be communicated by answering the questions: *What happens with the results of the online dialog? Who will use it? How will it be used?* Answering these questions early in the process may increase the dedication and commitment of respondents to the process. For this project, however, these questions were not answered for the citizen respondents.

Many respondents thought the background materials, including newsletters, documents and maps, were helpful. This approach to transparency of information was also supported by Bouras, Katris, and Triantafillou (2003) in their study of electronic polling to support public awareness. This process allows those people who are not experts on the topic to become better informed. Respondents' views and feelings were affected by participating in the online dialog in that they were able to communicate with other people in a convenient format and with people from other socioeconomic backgrounds. This process became an educational one in addition to providing an avenue for the voices of citizens to be heard. In the process of posting, respondents were able to think out their response, reflect and process it more clearly than in a face-to-face discussion. They also had the opportunity to "hear" each and every person's ideas, since the dialog was available for reading online 24/7. There appeared to be a consensus that it was not possible to read all of the postings due to the volume, the length of postings and the time frame for the online dialog. There were a few technical problems responding to polls, and one person mentioned that the 56K modem was not ideal for this process. Based on this comment, a clear outline of guidelines for appropriate computer hardware and software might prevent or resolve the few technical problems in future projects.

## RECOMMENDATIONS

Online computer technology has many positive attributes that facilitate gathering the opinions of citizens on urban development in that it is inexpensive, quick and easy. However, because of the cost and availability of this technology, it does not effectively get opinions of all segments of the population. It is not just the use of technology in question here, but the ability to have the free time to spend contributing to the community, as opposed to working to support families, especially those with young children. Based on this research, the following are recommendations for the use of online technology to gather citizen opinions regarding community issues regarding urban development:

- Involve citizens early in the urban planning and development process to be able to incorporate their opinions and gain acceptance

- Provide educational material to inform citizens about the nature of the planning and development
- Promote involvement of new actors and development of public private partnerships to contribute in urban planning
- Obtain a more representative sample with regard to ethnicity, education, income level and geography
- Provide training for facilitators and back-up support during the online process
- Fully inform respondents as to how the results of the online dialog will be used to contribute to the process/ problem being considered
- Include a question about respondents' experience with previous online dialogs to determine the skill and expertise of the group.

## KEY TERMS

**Administrative Model of Citizen Involvement:** Citizens are involved in the planning process of a public project for the purposes of gaining their trust and confidence in the project and, in addition, gaining their acceptance of decisions that are made (Seifert, 2003).

**Citizen Model of Citizen Involvement:** Provides citizens a voice in planning and decision making for the purposes of improving the plans and decisions made (Seifert, 2003).

**Digital Government:** A transformative force affecting all levels and functions of government wherein the relationship between the citizens, community and government is being digitized.

**Flaming:** Personal attacks and insults that may occur in group interactions to members or moderators of groups.

**"Listening to the City":** A focus group opportunity following the attacks of 9-11 in Manhattan, N.Y., giving people a chance to contribute their opinions and ideas regarding redevelopment of Lower Manhattan and the creation of a permanent memorial to the victims of 9/11.

**Small Group Discussion (SDG) Software:** (1) Assigns participants to multiple small groups; (2) uses group member "bios" and introductions to promote intimacy and dramatically reduce "flaming"; and 3) sets a limited lifespan for each group, promoting commitment and providing closure. (developed by Web Lab, *www.weblab.org/home.html*).

**The Civic Alliance:** A New York City organization composed of 85 businesses, environmental, community, university and labor groups committed to fostering the involvement of citizens in the rebuilding process.

**Urban Planning:** The area of architecture that relates to design and organization of urban spaces.

# Parliament and E-Governance in Finland

**Paula Tiihonen**
*Parliament of Finland, Finland*

## INTRODUCTION

The Standing Committee for the Future in the Finnish Parliament has a motto: *It is the duty of parliament to observe the changing world, analyse it, and take a view in good time on how Finnish society and its political actors should respond to the challenges of the future. Democracy cannot be realised simply by accepting changes that have already taken place.* Indeed, parliaments have a role in e-governance all over the world, and this role will be discussed briefly in this article with a reference to the case of the Parliament of Finland.

## BACKGROUND

Why are parliaments important? The information society and e-governance are on agendas all over the world. Every nation tries to jump into the knowledge-based society as quickly and as deeply as possible.

In November 2004, the World Bank organised a seminar on "e-Governance: From Successful Pilot to Sustainable Implementation" in India (Bangalore). One hot topic, especially in the debate in the press, was the effectiveness of this new and promising development aid called e-governance. Evaluation of development aid is not easy, but it seems that e-government initiatives in developing and transitional countries have not been particularly successful. It has even been calculated that 35% are total failures, 50% are partial failures, and only 15% are successes. There is no actual evidence that e-government failure rates in developing countries should be any lower than those in industrialised countries. But there are plenty of practical reasons to support the idea that e-government failure rates in those countries might be much higher.

One basic mistake has been that politicians, as decision makers and opinion leaders, have not been really committed to e-governance. For them, it has been just one issue of technology among others in line, not really their business at all. Still, e-governance, as with any other part of governance (Tiihonen, 2004), is not a task for experts—it is a matter of common interest, together building a better future for people.

What kinds of models concerning building e-government or e-governance, are in the world for the active use of politicians? Not many, but Finland—and, in this case especially, the Committee for the Future in the Finnish Parliament—offers one of these. The role of parliaments is the same all over the world: to reactively handle proposals for legislation and annual budgets given by governments. But, can a parliament be a forerunner and an active player for a new society? Yes. This can happen in Finland, where, in 1906, women were the first in the world to get full voting and candidature rights, which can be an explanation for why, after 100 years of this kind of great social innovation, the same Finnish Parliament was the first country in the world to decide that our common future is so important that politicians also have to take real responsibility for it.

The Committee for the Future was established at the beginning of the 1990s and functioned on a temporary basis from 1993 until 2000. Then, on December 17, 1999, in conjunction with adoption of the new constitution, Parliament decided to grant the Committee for the Future permanent status (http://www.parliament.fi/FutureCommittee).

The Committee for the Future in the Finnish Parliament has the same status as the other standing committees. Each of the standing committees has its corresponding ministry, and in the case of the Committee for the Future this is the Prime Minister's Office. From the very beginning, all 17 members of the Committee have been parliamentarians. Its current tasks are defined to be I) to prepare material to be submitted to the Finnish parliament, such as government reports on the future, II) to make submissions on future-related long-term issues to other standing committees, III) to debate issues relating to future development factors and development models, IV) to undertake analyses pertaining to future-related research and IT methodology, and V) to function as a parliamentary body for assessing technological development and its consequences for society (Arter, 2000).

## POLITICS: FOR OR AGAINST NEW TECHNOLOGY, NEW THINGS?

Politics in this context is about values, attitudes, atmosphere and opinion building, and, not forgetting the most important, opinion leading. Normally, politics is against new technology and generally against change. It is said

that voters do not always want all these new things. But in the Finnish case, the case is just the opposite, which is why politics is needed—to support new ideas, and, among them, new innovations and new technology (Tiitinen, 2004).

For the past fifteen years, we experts have told that in the New World—at least in the New Economy based on Information and ICT, on Knowledge and Wisdom—the role of the state and parliament no longer holds importance. Governmental tasks will be minimised, if not diminished all together. But again, the Finnish case has proven something else. On the contrary, the role of the governments in the new e-world or u-world is changing, but it is certainly not getting smaller. Without active participation by governments and parliaments, really useful, effective and economically valuable e-services—public and private—will never succeed. The state's role is to provide an enabling environment for the new development and support new initiatives for efficient economy and competitiveness. The state—in practice parliaments—have to take care of "fare play" among different players in the information society. In Finland, Parliament has to make sure that citizens have equal possibilities also in the e-governance.

In Finland, Parliament has taken an active role. Some examples: the state has for 50 years been responsible for equal school and education possibilities for all citizens which means free of charge education system from bottom up. The level of education, the strong input in polytechnics and engineering, have later supported the telecommunications R&D development. In the period of the last depression (at the beginning of the 1990s) the public policy incentive was to strongly increase R&D funding from public resources, which was just the opposite policy than in most countries. Today, the private sector is the major financier of R&D. The technology policy and the national strategy to build Finland as one of the leading information societies have enhanced the use of ICT, both in public administration, private business and every walk of life in society (Klus & Kalscheuer, 1997).

In general, and also in the knowledge economy, good governance without corruption plays an invaluable role. Institutions, both administrative and political, really do matter, even if we think that we are moving from governing to governance (Tiihonen, 2004). It is a fundamental task of parliaments to make sure that there are reliable, well-functioning and innovative governments, ministries, and other basic public institutions.

Here is one more example from Parliament. In 1997 the Committee for the Future was given a second official principal task, that of assessing the effects of technology on society. The following reasons were named as evidence that a need for assessment work existed:

*The argument that there is a need for technology assessment in the Parliament can be justified in two ways. The accelerating development of science and technology is having substantial effects on society, economic development and the life of the individual. Technology assessment helps parliamentarians understand these influences better and take them into account in political decision making. The other justifying factor relates to Parliament's tasks and democracy. When legislative and budgetary proposals of significant importance for society are submitted for its consideration, Parliament must, if it is to be able to exercise oversight of the Government's actions, already have a good enough foundation of knowledge on which to assess these proposals.*

Technology assessment linked in one way or another to parliamentary work has proved itself to be a successful solution in several European countries. What is meant by technology assessment in a parliamentary context is appraisal of the effects on society of using the results of scientific research and technology. The questions and needs stipulated by the parliament provide the point of departure. Technology assessment generally encompasses broader sectors of science and technology, such as biotechnology, mass communications, transport, energy, and so forth. From the very beginning, the Committee for the Future has examined technology and such phenomena of change in the structure of our society as globalisation, innovation, and governance as a development feature permeating the whole of Finnish society.

However, in Finland, one centrally important deviation from other parliaments was made right at the beginning. No unit independent of Parliament has assumed responsibility for technology assessment, as has been done in Germany, for instance; instead, the task is performed by the committee itself so the 17 Members of the Parliament sitting twice a week 2-3 hours in meetings. To support its work, the committee can commission studies from various research institutes or think tanks.

Some examples. It was 5 years ago that Parliament of Finland, while analysing Finland's future prospects, highlighted innovation, with special emphasis on its human aspects. With this respect to these challenges and opportunities the Committee decided to write a report on knowledge management at the level of politics and policy making (Suurla, Markkula, & Mustajärvi, 2002).

The subject of one of the most recent technology assessments was the Finnish knowledge society model—more specifically, its sustainability in its second phase (Himanen, 2004) The person invited to do the background research was Dr. Pekka Himanen of the University of California at Berkeley where Manuel Castells is a profes-

sor. Castells visited Finland and took part in discussions of the Committee. The Committee as a whole acted as the steering group for the work and deliberated the researcher's results in its meetings, and visited a common seminar in Berkeley, California, and so forth. The committee also used the results as an aid to prepare the presentation it gave as the basis for discussion at a plenary session. This report and its deliberation in Parliament attracted an exceptional amount of public attention. Altogether, the system of working together for the better information society—the dialogue between Parliament and the Government—was successful.

## FUTURE TRENDS

The Finnish case is an example how important it is that power centres of politics are involved and really committed to build the information society. There are a lot of signs and weak signals that e-governance, in order to make a difference, needs more and more support from decision makers. The review of the Committee for the Future called Challenges of the Global Information Society (Himanen, 2004) came to the conclusion that the most critical aspect in the development of the information society is the development of the deep-set structure of society. These elements must explain why so many countries try to copy the Finnish model.

## CONCLUSION

The Finnish model is unique. Perhaps it is too early to say anything about real success. One thing, however, is certain: the committee has taken its place in the Finnish parliamentary system as an innovative political body. First, it is an adage of political life at any level that the first step to power is to take the initiative and put yourself in a position where you can set the agenda. In the Finnish Parliament, the Committee for the Future has taken this adage seriously. It has created a new forum that works at the inner circles of the parliamentary system and—even more important—it has demonstrated that parliamentary measures can still be used to take the initiative within democracy.

Second, it is an excellent vantage point when the main task is dialogue with the Prime Minister's Office and government on future-related issues. The Committee for the Future is a good forum where parliamentarians can broaden their views beyond everyday politics and their own country's problems. The committee's work has become quite international in character. Quite a large proportion of the ministers in the present cabinet are former members of the Committee. They include the prime minister and the ministers of finance, labour, and the environment. Two important party leaders are members of the Committee. The present chairman of the committee, MP Jyrki Katainen, was chosen as the leader of the biggest opposition party (The National Coalition Party) in the summer of 2004, one year after the elections. He appreciates and enjoys his work on the Committee for the Future so much that he has continued to chair it.

## KEY TERMS

**Commitment:** Interaction dominated by obligations.

**Democracy:** Rule by the people.

**E-Governance:** A broader and more future oriented governing system of information society than e-government, which is the use of information technology in the internal processes of government and the delivery of government products and services to citizens and industry.

**Parliament:** A legislature.

**Policy Making:** A course of action adopted and pursued by a government, party, ruler or statesman.

**Power:** Possession of control or command over others.

**State:** An organized political community occupying a definite territory, having an organized government, and possessing internal and external sovereignty.

## INTRODUCTION

A majority of governmental problems are geographical in character and are becoming more complex as citizens/residents expect more for less. Governance, among many things, involves allocating human, natural, monetary, and infrastructure resources within and across jurisdictional boundaries in an efficient, effective, and equitable manner. Such allocations are becoming increasingly more challenging under budget constraints. Many public policy problems are called "wicked" and "ill-structured" (Rittel & Webber, 1973) because they contain intangibles not easily quantified and modelled. The scoping of such problems includes structures only partially known or burdened by uncertainties, and potential solutions mired by competing interests. Examples of such problems in a geographic domain include locally unwanted land uses (LULUs) such as landfill and hazardous waste facility siting, and more recently, polluted urban land use (so-called brownfield) redevelopment projects called into question due to the potential for increasing neighbourhood contamination. Dealing with locational conflict in an open manner is becoming more important as citizen-stakeholder participation increases in public policy/problem circumstances (Crowfoot & Wondolleck 1990).

## BACKGROUND

The primary rationale for enhanced stakeholder participation in public land and resource planning is based on the democratic maxim that those affected by a decision should participate directly in the decision-making process (Smith, 1982). Poole (1985) provides motivation for research on group decision making by saying "we [should] focus on groups because they are basic (many social theorists have called the small-group the building block of society), because they are important (many consequential decisions in government and business are made by groups), and because they are interesting (group behaviour is considerably more complex than the dyadic case). ... [Although] decision-making represents only a small portion of group behaviour, it is perhaps the most important behaviour groups undertake. As well as being significant in its own right, decision making sets the course for other group activities" (p. 206).

To add to that, Zey (1992) states "that decisions [in society] are most frequently made by groups within the context of larger social collectives" (p. 22). Following up in the same book on decision making, Simon, Dantzig, Hogarth, Piott, Raiffa, Schelling, et al. (1992) conclude that "the resolution of conflicts of values (individual and group) and of inconsistencies in belief will continue to be highly productive directions of inquiry, addressed to issues of great importance to society" (p. 53). Events across the world show that the motivation is stronger now that ever before.

Over the past 3 decades, geographic (geospatial) information systems (GIS) have been developed and used to address geospatial problems of all kinds, including some of those described above. GIS has for a long time been touted as a type of *decision support system* (Cowen, 1988). In the late 1980s researchers started to recognize that a conceptual foundation was needed for continuing the maturation of GIS, which emerged as a field called geographic information science (GIScience; Longley, Goodchild, Maguire, & Rhind, 2001). For the most part, GIS grew as a single-user technology; that is, a technology that considered a single-user (group and/or organization) perspective only, even when dealing with many complex decision problems described earlier. Based on research about groups (McGrath, 1984) and group decision support (DeSanctis & Gallupe, 1987), in the early 1990s, GIS researchers began to recognize the shortcomings of a single-user perspective in the GIS technology and started to explore the use of GIS for addressing group-based, wicked, ill-structured, public issues (Armstrong, 1993). That technology is now referred to as participatory GIS (Harris, Weiner, Warner, & Levin, 1995) or public participation GIS (Nyerges, Barndt, & Brooks, 1997). Many researchers realized that the single-user GIS technology was inadequate to the task—although the technology is still used in many places. Consequently, Participatory GIScience, as a subfield of GIScience, is emerging as an area of study that provides systematic, *conceptual foundations* for development and use of Participatory GIS (PGISystem) technology including data, software, hardware and group process (Jankowski & Nyerges, 2001). A recent review of PGISystems appears elsewhere (Rinner, 2003).

## A FOUNDATION FOR PGISystem-BASED DECISION SUPPORT

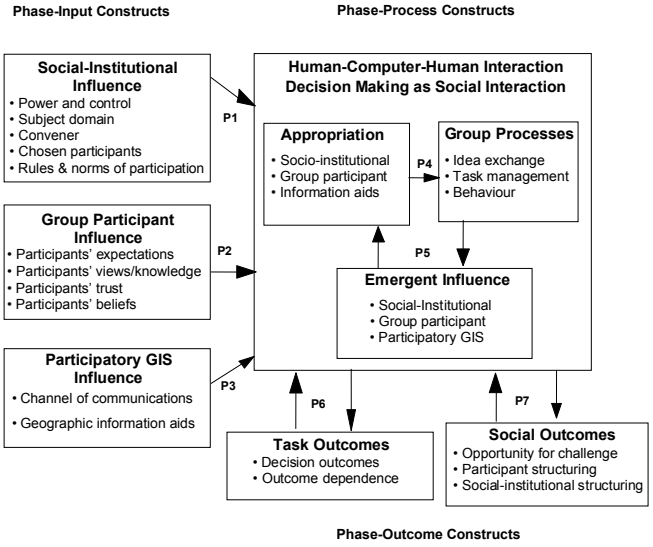
A major concern within PGIScience is bridging a gap between theory and application of PGISystems, as sound frameworks can lead to more robust as well as flexible technologies that can address some of the complex geospatial decision support problems described earlier. Information needs and the associated decision support tool requirements can be addressed by a good understanding of the decision situation at the time and place (context) within which it occurs. As an example, we can offer the six-phase landscape modeling process elucidated by Steinitz (1990), used as a framework agenda in several large landscape planning projects across the world. That six-phase process involves: (1) database representation modeling, (2) land development process modeling, (3) scenario evaluation modeling, (4) change of landscape modeling, (5) impact on landscape modeling, and (6) decision evaluation modelling. Each model description feeds to the next phase, but the entire process is iterative to "catch" aspects overlooked. The flow of information in participatory decision processes can be addressed by a two-level description of process, what we call a macro–micro strategy (Jankowski & Nyerges, 2001). To use a macro-micro strategy for characterizing participatory decision situations imagine a matrix comprised of six columns representing the macrophases defined by the Steinitz's six-phase process, and four rows representing microactivities: (1) gather, (2) organize, (3) select, (4) review. Those microactivities derive from Simon's (1979) work on management decision making. For any given decision task, Simon found that people perform some amount of intelligence gathering, design a problem structure, select a choice of options among the design, and review their work before proceeding. Consequently, the six macrophases together with four microactivities constitute 24 "phase-activity" steps of the particular version of the macro-macro framework, at least in terms of a systematic articulation of what Steinitz (1990) outlined.

The significance of "phase-activity" labeling is that a *phase* speaks to the issue of what is expected as an outcome in the overall strategy, while an *activity* is an action (i.e., use of a GIS tool) that fosters creation of the outcome. Thus, the attractiveness of the macro-micro approach is that a group could use any GIS-supported project agenda (plan) to articulate macrophases, while asking themselves what information tools are needed to support the microactivity processing. The macro-micro strategy for analysing decision situations is a normative description of an expected decision process. Of course, decision processes are not likely to proceed in a rational way, mostly because people's judgments often depart from normative rationality (Kahneman, 1974). However, if a group (or multiple groups) was (were) dealing with rather complicated geographic decision situations like transportation improvement or hazardous waste cleanup, such a process could be used as an agenda to outline an analytic-deliberative decision process as a recommended way to proceed (National Research Council, 1996). Whether groups follow their own project/meeting agendas is up to them. Balanced agenda plans are more often useful than not, as a balanced discourse agenda fosters communicative rationality in building a shared understanding about discourse within an analytic-deliberative process (Habermas, 1984).

Keeping the "actual" versus "normative" view in mind, it is important to understand how people undertake decision making while making use of geographic information technologies. That understanding, particularly if developed in a systematic way through social science research, provides an important contribution to PGIScience. In order to provide a more in-depth articulation of what can transpire during a participatory decision-making process involving the use of PGISystems and other decision support technologies, Nyerges and Jankowski (1997) developed Enhanced Adaptive Structuration Theory (EAST), which is now in a second version as EAST2 (Jankowski & Nyerges, 2001). EAST2 is a network of constructs and their relationships providing a theoretical framework to organise and subsequently help explain *each macrophase* of a participatory decision process. That means that EAST2 as a framework is re-applied to each of the six modeling phases in the Steinitz (1990) landscape planning process. Applying the framework is a way of easily unpacking complexity by articulating each macrophase in terms of the most salient aspects of the phase. Thus, when more aspects change as a process moves forward from phase to phase, we can say that a decision situation becomes more complex. As such, EAST2 has both a research and a practical value. From the research perspective, EAST2 helps to explain the expected and observed realizations of participatory decision processes involving inter- and intraorganizational groups and human-computer-human interaction. From the practical/application perspective EAST2 helps set up group decision support systems for specific decision situations. But how can a theoretical framework comprised of constructs and their relationships effectively contribute to building PGISystems?

EAST2 provides the basis for developing PGISystems and selecting tools appropriate for a given task due to its comprehensive character. In Figure 1, the EAST2 framework consists of a set of eight constructs, with 25 *aspects* as the basic elements (bulleted items) of the theory that outline significant issues for characterising group decision making, and a set of seven premises (the P's) that describe the *relations* between the eight constructs (hence the aspects contained within those constructs). The 25 aspects in different combinations for each premise can "map" different relationships, which may occur during a group decision-making process that involves human-computer-human interactions. The aspects in conjunction with the premises, allow us not only to formulate research hypotheses about the use of PGISystems and its likely outcomes but also help us assess which methods and decision support tools will likely address decision support needs.

*Figure 1. Enhanced adaptive structuration theory 2 (EAST2) framework for unpacking complex decision situations in the context of PGISystems use*



## APPYLING THE EAST2 FRAMEWORK IN A DECISION SITUATION ASSESSMENT

Over the past several years, EAST2 has evolved into a mechanism through which decision analysts can perform complex decision situation assessments. Performing a decision situation assessment is a way to grapple with the how information technology can support complex decision problems. Using EAST2, decision situation assessments have been performed in a variety of application contexts (e.g., public health services, transportation, habitat redevelopment, hazardous waste cleanup, water resource planning, and earthquake-induced landslide decision support). Through such applications we have found that four levels of decision situation assessment are possible. From a general approach to a detailed approach they are: (1) situation overview, (2) situation phases, (3) situation phase-constructs, and (4) situation phase-construct-aspects. Each of those approaches described below starts out with a question that focuses the nature of the assessment.

### Situation Overview

Has PGISystem been useful / is PGISystem useful / or can PGISystem be useful at all, as articulated within a general description of the situation in terms of convening (input), process, and outcome concerns associated with geospatial information use? An overview assessment provides us with the "laugh test". That is, if a PGISystem has been used or is being considered for use, there are certain core issues, that once addressed, should help avoid the circumstance of someone "laughing out loud and saying—you used a PGISystem to do what?" In many respects we can actually differentiate among planning, capital improvement programming, and project implementation-level decision situations. There are three main concerns within a decision situation overview about PGISystem use. First, what are the concerns about convening a decision situation? Second, what are the concerns about the process involved in a decision situation? Third, what are the concerns about the outcomes of a decision situation?

### Situation Phases

Has PGISystem been useful / is PGISystem useful / or can it be useful, as articulated within a phase-to-phase description of convening (input), process, and outcome concerns associated with geospatial information use? The decision situation assessment framework draws together numerous results from theoretical and applied research about the development and evaluation of participatory decision processes, many of which made use of geographic information systems due to their complexity. A general form of an analytic-deliberative (A-D) decision process is described in a National Research Council (1996) report entitled *Understanding Risk: Informing Decisions in a Democratic Society*. That process, was investigated in more detail as three phases by Renn, Webler, Rakel, Dienel, and Johnson (1993) and Renn, Blattel-Mink, and Kastenholz (1997), and has been shown to work rather well in complex environmental decision situations.

- Phase 1. Scoping a decision problem in terms of stakeholder values and criteria
  Examine convening, process, and outcome concerns.
- Phase 2. Generating alternatives and their impacts to address the problem scope
  Examine convening, process, and outcome concerns.
- Phase 3. Evaluating alternatives and recommending a solution
  Examine convening, process, and outcome concerns.

### Situation Phase-Constructs

Has GIS been useful / is GIS useful / or can it be useful, as articulated within a description of all (or a selected set of) constructs within each (or selected set of) phases associated with geospatial information use? The EAST2 framework uses the same eight constructs to model "complexity" in each of the phases (see Figure 1), whether it be the three A-D phases mentioned above (Jankowski & Nyerges, 2001), or any number of phases as motivated by a particular organizational decision situation. Remember, as mentioned earlier, the grouping of constructs into three categories (convening-input, process, and outcome concerns) in Figure 1, *is not* the same idea as the three phases, but is a way of generalizing and clarifying the character of the constructs. Using the constructs grouped by

concerns provides a way of turning a *decision situation overview* assessment into a Phase-based decision situation assessment. The compatibility is clear. Thus, the eight constructs in essence become the building blocks for our understanding of how people engage within EACH phase. The constructs establish a foundation for learning about a particular phase, and guide a GIS analyst to conclude what is important for a particular decision situation assessment. We now note that differences in constructs emerge when articulated from one A-D phase to the next.

## Situation Phase-Construct-Aspects

Has PGISystem been useful / is PGISystem useful / or can it be useful, as articulated within a description of all (or a selected set of) aspects, within all (or selected set of constructs) constructs, within each (or selected set of) phases associated with geospatial information use? Each of the constructs can be described in terms of "aspects" of the decision situation (see bulleted items in Figure 1). Aspects in a sense are like "metavariables", that is when enumerated and articulated they can be understood to influence each other within a phase or even across phases of the decision process. These metavariables form a basis for "social science based evaluation" of decision processes (Jankowski & Nyerges, 2001), which is why the decision situation assessment framework can lead to a deep and broad understanding of a decision situation. When we take the framework to this level, and consider the relationships among constructs and aspects then, we are using the framework at a theoretical level as presented by Jankowski and Nyerges (2001).

## FUTURE TRENDS

Decision making is likely to become more complex rather than less complex, as societies discover more externalities to include within decision situations. The framework presented herein is not a software tool per se, but a thinking tool that can help sort through the complexity of problems that are to be addressed with PGISystem software tools. This framework can be implemented within a word processor, as we have done for land use, transportation and water resource studies. We encourage others to do the same. The PGISystem-based software tools that are growing in popularity worldwide, and discussed in other sections of this book, might some day incorporate some of the framework. We are working on such research as related to Web-based decision support tools, but these are not ready as yet (see www.pgist.org)

## CONCLUSION

When elected officials, agency specialists, and interested and affected parties together allocate resources within and across jurisdictional boundaries in an efficient, effective, and equitable manner, they are performing democratic governance at its best. A major goal of PGIScience, as a subfield of GIScience, is to provide a systematic, conceptual foundation for the development and use of PGISystem technology to support efficient, effective, and equitable allocation of resources—within whatever definition of those three concepts a community decides. A major concern within PGIScience is bridging a gap between theory and application of PGIS, as sound frameworks can lead to more robust as well as flexible technologies that can address complex geospatial decision support problems. EAST2 provides such a bridging of the gap, as it helps decision analysts assess complex circumstances both broadly and deeply. Finding an appropriate mix of that breadth and depth is up to an analyst. With four different levels of decision situation assessment possible as described herein, we have found success in a variety of applications. We encourage others to consider use of the framework, scientists and practitioners alike, and look forward to hearing about their efforts.

## KEY TERMS

**Analytic-Deliberative Decision Process:** The analytic component of a decision process provides technical information that ensures broad-based, competent perspectives are treated. The deliberative component of a decision process provides an opportunity to interactively give voice to choices about values, alternatives, and recommendations.

**Decision Situation:** The collection of content, structure, process, and contextual elements associated with people addressing a decision problem.

**Decision Situation Aspect:** A basic element of enhanced adaptive structuration theory, organized in terms of decision situation constructs.

**Decision Situation Assessment:** An investigation of complex decision problems that makes use of the theoretical framework in enhanced adaptive structuration theory.

**Decision Situation Construct:** Eight categories of a decision situation phase, each construct organizing a collection of decision situation aspects.

**Decision Situation Phase:** Any major event in a decision situation composing the process of a decision situation.

**Enhanced Adaptive Structuration Theory:** A theory of complex decision making supported by advanced information technology, particularly participatory geographic information systems.

**Macro-Micro Decision Strategy:** A two-level characterization of decision process in terms of major phases (outcomes of major steps) and micro activity (actions of the minor steps).

**Participatory Geographic Information System:** A geographic information system, an information technology composed of computer mapping software integrated with database management software and spatial analysis software, specifically developed to address complex geospatial problems within a group setting.

**Participatory Geographic Information Science:** A subfield of geographic information science that combines in a systematic manner theoretical, methodological, and substantive concepts within a group context.

## INTRODUCTION

The societal task of e-government services is to support the achievement of the aims of citizenship (i.e., participation in society and personal independence), that is, autonomy (cf. Barbalet, 1988, p. 68-69; Roche, 1992, p. 93-94). These aims require many different resources of citizens, including for instance societal information serving practical needs and the ability to obtain this information. Knowledge about one's own social rights, such as pensions, is the type of information that citizens usually need at some point in their lives and also obtain through various means, using for instance their own "network competence" (see Jääskeläinen & Savolainen, 2003). Network competency stands for the knowledge of networked information sources and services plus their skilled utilization (Savolainen, 2002, p. 218).

E-government, where the starting point is the verified needs of the citizens and which applies information technology to everyday life, promotes the realisation of citizenship. In order for public Internet services to fulfil this obligation, different sets of criteria have been created and competitions have been held. One such contest is the eEurope Awards. The Finnish Internet Portal for Pensions "Tyoelake.fi" was ranked among the first five in the category "Better Life for European People." (www.e-europeawards.org/html/body_results) This article describes the features which explain why the Tyoelake.fi service is an example of an eGovernment service built through cooperation between many active parties and where the user viewpoint is crucial.

## BACKGROUND

The aim of the eEurope Awards is to develop modern public services. The eEurope Awards are organised by the European Institute of Public Administration with the support of the Information Society Technologies Programme of the European Commission for the years 2003-2005. The overall goal of the eEurope Awards is to promote best practices in order to make Europe the most competitive knowledge-based economy by 2010. The applications submitted for the eEurope Awards are evaluated and ranked by an independent jury composed of eminent experts from all over Europe in the relevant fields. (www.e-europeawards.org.)

Considerations affecting the evaluation include access, user-friendliness, and usability, user-centred organisation of the information, cheapness of usage, and application of commonly used technology. Other positive features are taking into account of special groups as well as the increasing of democracy, of openness, of approachability, and of participation, cooperation between the private and the public sector as well as the experiences gained; how the service saves the citizens' money, improves quality of life, and the time and effort needed. In the competition, innovativeness is also important—the service should contain something new. Usability of the experiences gained and of the new ideas in other e-government services was also valued.

The Tyoelake.fi service is built and maintained by the Finnish Centre for Pensions, the central body of the private-sector earnings-related pension scheme. In Finland for private-sector employers, employees, and self-employed persons earnings-related pensions are handled by private sector pension providers that partly compete with each other. Earnings-related pensions from public-sector employment, such as employment by central and local government, are administered through their own pension providers. The employment registers of the Finnish Centre for Pensions contain, among other things, data on all the employment contracts in Finland over a period of 40 years needed for the calculation of pension accrual.

The motives for developing the Web service Tyoelake.fi can be found in the development of the population in Finland. The large age groups born after the Second World War are approaching an age when personal interest in pension matters increases. There is a desire to direct part of the increasing demand towards electronic self-service. At the same time, there was a desire also to give others than those approaching retirement age a chance to receive information about their pension accruing from work and to monitor matters relating to their own pension benefits. This can be seen as promoting the mobility of labour both inside and outside Finland.

## USER-CENTRED CONTENT AND BROAD ACCESS OF THE SERVICE

Planning and building the Tyoelake.fi service was an administrative challenge, which required the cooperation of more than 50 authorized pension providers. The Finnish Centre for Pensions was responsible for creating the service. Also, the Tyoelake.fi service is currently managed by a committee of parties responsible for private sector, central, and local government pensions. Most parties participating in this cooperation already had their own Web pages, but the general view was that creating a joint authentication solution would save costs. In addition, a common comprehensive site was the aim, with access to the pension providers' own Web pages. From the users' viewpoint, the

pension scheme is a comprehensive whole and the underlying administrative model is of little significance to them.

The Web site is intended for ordinary citizens actively participating in working life whose pensions accrue from salaried employment or self-employed activities. However, the majority of users are people who will retire within the next few years. The contents of the Web pages are based on these people's information needs as identified through experience and surveys. They include general information about pensions, personal services, and also forms. Information can be searched for through the content structure, through the section with questions, through the search functions or through the pages targeted at different age groups.

In the left-hand column, the structure of the data contents show the main sections, which are pension accrual, amount of the pension, questions, pension benefits, insurance, the statutory earnings-related pension scheme, reforms, application forms, and links. The structure of the sections follows the principle of going from general information to more specific information. The language used is indented to be simple standard language. Special terminology and references to the legislation are avoided. When a special term appears in the text, it is explained in a special pension glossary, and the text has a link to the glossary. User focus also includes a section with questions, where the multiple examples provide an opportunity to identify with the situation of the person in the example.

The services of the Web site are contained behind the key "personal data." Personal data refers to the personal services which require authentication, of which there are currently five: employment record, estimate of the pension amount, pension calculator, contact data to one's own pension provider, and further questions.

The keys for young adults, the middle-aged, and the aging lead to a page with topics or certain selected issues from the information content relevant for each age group. For instance, young adults are provided with information about the possibility of receiving a disability pension. The issues selected are changed from time to time.

The Web site has been built to be trilingual, thus the contents are available in the official national languages, Finnish and Swedish, and also in English. Since the Web site is in three languages, it is made available to all the potential users. The text version made for the visually handicapped further extends the number of users.

The user has also been in focus in the technical build-up of the Web pages as it does not require the latest hardware or software. Instead, the Web site can also be used with old PCs intended for use by individuals at home.

Notices are published in the middle column of the front page and topics of special interest to users are found in the right-hand column. The feedback and the questions that the users have asked about pension benefits are transmitted by electronic mail. For the administration of the feedback and the questions, a course of action utilising the current decentralised service network has been created. The service is thereby directed to the party who is able to clarify the matter in the best possible way.

## SEVERAL MEANS OF AUTHENTICATION

In the Tyoelake.fi service there are several means of authentication. The insured user may use a card with PKI technology. The card contains the Population Register Centre's certificate. The other option is to use the authentication technology of one's own Internet bank, in which case the bank verifies the identity of the client. Online banking is used extensively throughout Finland, and consequently the service already reaches approximately 80% of the working population. In Finland, the use of information networks and the utilisation rates of the Web services provided by banks are very high in international comparison. The banks are not entitled to store the service users' data. For the service, the earnings-related pension scheme pays the banks an agreed price. The insured individual does not incur any costs from the service, but on the contrary saves time and trouble, which is beneficial to well-being. The implementation has also been carried out in good cooperation with the Data Protection Ombudsman and other authorities.

The exchange of personal data has been protected by SSL encryption. The e-mail messages between the organisations offering the service are sent through the VPN network. The replies to the questions asked by the users are sent through open e-mail, but the e-mail messages only include general information as personal data is sent by letter to the address stored in the population information system. In the data transfer between the portal Tyoelake.fi and the authorised pension providers, the parties are identified by means of certification.

The introduction of the authentication service of monetary institutions in a public service www.tyoelake.fi was a unique solution in Finland and internationally and unprecedented in an open service using huge national registers. The authentication solution of the portal Tyoelake.fi is cost saving. The service improves insured individuals' opportunities to verify the correctness of their own data included in the registers and to receive individual information on their pensions. This strengthens the confidence in the statutory pension provision and the social rights, and gives insured individuals a more secure basis for future planning.

## THE NEEDS OF CITIZENS IN ELECTRONIC PENSION SERVICES

During the planning of the service, the target group was defined as citizens in need of pension information. The authorities, personnel within the industry, researchers, and politicians were excluded from the target group. Their need for special information is answered by the Web pages of the Finnish Centre for Pensions, www.etk.fi. In this way, it was possible to concentrate in the

Tyoelake.fi service on information relevant for the lay people.

In the pension scheme, practical information has accumulated in different ways about what kind of information users request on pension matters. The view of the citizens gathered through client contacts is incomplete, however, as those contacting the service are a selected group and as such not sufficiently representative of all users. Only after a survey based on a selection representing all citizens can a fairly accurate picture be drawn. The reliability is enhanced by repeating the survey using the same question. Such surveys were done in 2001 and in 2003.

The surveys were carried out by the market research company Taloustutkimus Oy as part of the Omnibus Study, where a nationally representative sample of Finns aged 15-79 is subjected to a computer-supported interview face-to-face. For pension matters, the interviewees were aged 20-64 and numbered about 800. The interviewees were shown a list of pension information and services related to pensions, and asked item by item if they might need it within a year if the information or service were available on the Internet. The questions were:

- I check if all my employment contracts have been entered into the register and that the data are correct.
- I estimate the amount of my own pension
- I obtain information about pension benefits, for instance about the eligibility criteria
- I want personal advice and information in my own case
- I look for information about the effect of work abroad on my pension provision.
- I file my own pension application.
- I look for lectures, training, or study material.
- I look for general information about the pension scheme (for instance statistics, studies, reports).
- I look for information on current pension topics, for instance pension contributions, indexation, legislative reforms

The background variables included all the general social background variables as well as use of the Internet. The results were analysed both as percentages with t-tests and through a multiple-variable analysis. All the information sectors and most of the services were included in the first version of the Tyoelake.fi portal, but the electronic pension application will be included in the version in 2006. A complete pension estimate including employment in both the private and the public sectors will perhaps not be taken into use until 2009.

In short, the results (Jääskeläinen, 2004) show that the willingness to use the Internet is connected to, on the one hand, familiarity with using the Internet and, on the other hand, with age. When nearing retirement age the need for different pension services is greatest. One fourth of Finns aged 50-64 thought they might well also need electronic pension services in the near future. The entitlement criteria for a pension and the bases for its calculation as well as current topics are more important information for them than for others. About half of the age group is familiar with the Internet.

The needs for pension services among the middle-aged are more specific than among those nearing retirement age. The checking of one's own employments is the most important pension service for the age group. Since about 75% of the age group is familiar with the Internet, it can be estimated that every third needs some electronic pension services. In the younger age groups, too, the opportunity to check one's employment data in the register was the most sought-after service. The youngest respondents were further interested mainly only in the effects of work abroad on pension accrual. For the young age groups using the Internet is natural in all pension services.

In the 2003 survey the respondents' opinions on using the banks' authentication services for the pension scheme were also ascertained. As a principle this is a question of rare cooperation between the private and the public sector in developing an Internet service. Statutory pensions are considered public services even though in Finland the implementation of private-sector earnings-related pension provision is the responsibility of private pension providers. Then again, the activities of financial institutions are definitely a matter for the private sector, as seen, for instance, in the fact that the banks sell personal pension insurance. The vision or fear of the data of a financial institution selling personal pension insurance and of a pension provider carrying out a public obligation being transferred from one to the other through a common authentication service would impair the trust in the data protection of the pension scheme.

The results show that a quarter (25%) of respondents think the use of bank codes a good solution and just as many think it is a bad solution. It is worth noting that every second respondent immediately formed a clear opinion either for or against. Half of the respondents fell into the middle categories, with equal proportions for and against (16% and 18%). Only 16% could not state their opinion. Simplified, the opinions on the use of bank codes divide the population just as do the opinions on other technical innovations. The first to try out innovations are young men living in the south of Finland. The usage spreads rapidly over the whole country from south to north so that the last to adopt the innovation are those living in the north, and there more often woman than men.

## FUTURE TRENDS

In 2003, the Tyoelake.fi services had about 200,000 visits. The following year (i.e., in 2004) the number of visitors was some 30% higher than during the first year. In all, the Tyoelake.fi service has during its first two years of existence been used by 15-20% of the potential users (i.e., of the Finnish population aged between 20 and 64 years). The service has not yet met the level of demand indicated by the demand survey. The main reason is probably that the service is not well known by all citizens who use the Internet. Minor reasons are probably prejudices against using banks codes in interactive services.

The success of the first stage of the cooperation project has created good opportunities for further development. The planning of the next stage is ongoing. The objective is an online pension application service and its connection to the processes of the investigating institution. By means of the authentication solution now achieved, the opportunities arose for creating a controlled electronic process for pension applications, too: on the initiative of the party insured to the authorised pension provider's pension adjudicator and further to the payment of the pension into the individual's bank account.

The intention is to implement the first version of the old-age pension application in the Tyoelake.fi service in 2006. Those reaching retirement age (63 years) then are those born in 1943. Since many are already retired and some do not use electronic services, filling in applications over the Internet may not at first be very frequent. In the long term it can be assumed that electronic services related to pension applications will be used by every other citizen.

## CONCLUSION

It can be said that in Finland, the period in e-government of interactive services that reach all citizens really started when the authentication solution in the Tyoelake.fi service was taken into use at the end of 2002. An authentication service was rapidly taken into use in the Web services of certain large pension providers. The pension providers were able to develop additional services making use of the authentication service for their own clients. In February 2003, the National Board of Taxes, the Social Insurance Institution, and the Ministry of Labour concluded an agreement on the matter and one year later they had implemented the same mode of authentication in their own services.

## KEY TERMS

**Authentication:** The verification of the identity of a person or process. Determines a user's identity, as well as determining what a user is authorised to access (e.g., a financial database or a support knowledge base).

**Identification Card (ID Card):** A secure network key for all online services requiring the identification of a person, such as all government and many private-sector services. The card enables the service provider to reliably identify the user. In addition to the card, a card reader is needed for online use.

**Identification Service:** A standardised identification service approved by the data protection authorities and sold by a service producer to other service producers. The service producer receives remuneration for the service either from the user of the service or from another service producer. The service may function on the Internet or through mobile devices.

**Network Competency:** Knowledge of networked information sources and services plus their skilled utilisation.

**Online Banking, Telebanking, Electronic Banking, Web Banking:** Includes various services related to the payment of invoices, account information, securities trading, loan application and loan information as well as opportunity for electronic communication with the bank and vice versa.

# Performance Reporting on United States Digital Government

**Patrick R. Mullen**
*University of Illinois at Springfield, USA*

## INTRODUCTION

Starting in the 1980s, Australia, Canada, New Zealand, and the United Kingdom faced serious economic problems, such as economies dominated by government spending and high budget deficits. Further, government studies in the four countries found that government organizations lacked accountability for achieving program results and that there were many constraints to increasing such accountability. In response to these problems, each of the countries embarked on comprehensive reforms intended to increase the accountability of the civil service for the effective and efficient management of government programs. In exchange for increased accountability for results, the countries provided program managers with more flexibility in their use of resources. The studies and subsequent reforms in these four countries proposed results-oriented management reforms that were subsequently adopted in the United States (U.S.).

The approaches these countries took to implement results-oriented management reforms included departments and agencies establishing and communicating a clear direction by defining their missions and goals through strategic planning, establishing annual objectives that were directly linked to missions and goals, measuring performance to assess how well objectives were being met, and reporting on progress. The countries derived a number of key lessons from their experiences in developing performance measurement systems. These lessons focused on enhancing the usefulness of performance information to management for improving program results. The countries sought to reinforce this focus on results by holding agency management accountable for the results that agencies were trying to achieve. For example, the countries used performance agreements between different levels of management to ensure accountability for achieving agreed-upon performance goals. Cunningham and Harris (2005) discuss how performance reporting has been implemented in Canada, the United Kingdom, and three states in the United States. This article discusses how performance-reporting requirements in the U.S. are intended to promote a results-oriented management and decision-making process within Congress and the executive branch, as well as accountability to the American public, specifically for digital government programs.

## BACKGROUND

Recognizing the magnitude of modern challenges facing the federal government, Congress has encouraged a more performance-based approach to program management and accountability within the federal government, enacting the Government Performance and Results Act of 1993 (GPRA), perhaps the best-known performance-based law. GPRA requires agencies to develop strategic goals, which explain what results are expected from agencies' major functions and when to expect those results. Such goals are an outgrowth of the mission and are very often results, or outcome, oriented. GPRA also requires agencies to develop annual reports to Congress. These reports include (1) strategic plans, which define missions, establish results-oriented goals, and identify strategies for achieving goals; (2) performance plans, which articulate goals for the upcoming fiscal year that are aligned with long-term strategic goals; and (3) performance reports, which measure performance toward the achievement of the goals in annual performance plans. To be most useful, program managers should consider the reports developed in response to GPRA when they write the performance reports required by specific information technology (IT) and e-government laws discussed in this article.

Some of the first IT performance-based laws, focusing on the importance of using IT to improve government operations, were the Paperwork Reduction Act of 1980 (reauthorized in 1995), the Computer Security Act of 1987, and the Clinger-Cohen Act of 1996. Congress recognized the growing importance of e-government in 1998 by enacting the Government Paperwork Elimination Act. It requires federal agencies to use IT in order to provide the public, when practicable, the option of submitting, maintaining, and disclosing required information electronically. The E-Government Act of 2002 includes promoting the use of the Internet and other IT to provide government services electronically; strengthening agency information security; and defining how to manage the federal government's growing IT personnel needs. In addition, this law established an Office of Electronic Government within the Office of Management and Budget (OMB), to provide strong central leadership and full-time commitment to promoting and implementing IT and e-government.

*Table 1. IT performance-based laws and purpose*

| IT law | Purpose |
|---|---|
| Computer Security Act of 1987 (CSA) | • Improve the security and privacy of sensitive information in federal computer systems |
| Paperwork Reduction Act of 1995 (PRA) | • Minimize the public's paperwork burdens<br>• Coordinate federal information resources management<br>• Improve dissemination of public information<br>• Ensure the integrity of the federal statistical system |
| Clinger-Cohen Act of 1996 (CCA) | • Improve federal programs through improved acquisition, use, and disposal of information technology resources |
| Government Paperwork Elimination Act of 1998 (GPEA) | • Require federal agencies to provide the public, when practicable, the option of submitting, maintaining, and disclosing required information electronically |
| Government Information Security Reform Act of 2001 (GISRA) | • Directs federal agencies to conduct annual IT security reviews<br>• Inspectors general (IGs) to perform annual independent evaluations of agency programs and systems and report results to OMB<br>• OMB to (1) report annually to Congress on government wide progress and (2) issue guidance to agencies on reporting instructions and quantitative performance measures |
| E-Government Act of 2002 (E-Gov) | • Promote the use of the Internet and other IT to provide government services electronically<br>• Strengthen agency information security<br>• Define how to manage the federal government's growing IT human capital needs<br>• Establish an Office of Electronic Government, within OMB, to provide strong central leadership and full-time commitment to promoting and implementing e-government |
| Federal Information Security Management Act of 2002 (FISMA). (FISMA is Title III of the E-Government Act and updates GISRA) | • Lay out a framework for annual IT security reviews, reporting, and remediation planning<br>• Streamline the government's information resources, close security gaps, and create more public-centered Web sites |

## LAWS FOR PERFORMANCE-BASED MANAGEMENT AND ACCOUNTABILITY

GPRA—or "the Results Act"—is a key performance-based law for management and accountability. Prior to enactment of GPRA, policymaking, spending decisions, and oversight had been severely handicapped by a lack of (1) sufficiently precise program goals and (2) program performance and cost information. GPRA sought to remedy that situation by following private sector best practices, requiring agencies to set multiyear strategic goals and corresponding annual goals, to measure performance toward the achievement of those goals, and to report on progress made.

Digital, or e-government, is the use of IT and the Internet to transform federal agency effectiveness—including efficiency and service quality. Several U.S. laws contain IT and e-government performance-reporting requirements, including the Paperwork Reduction Act, the Computer Security Act, the Clinger-Cohen Act, the Government Information Security Reform Act (GISRA), and the E-Government Act. In instituting IT performance-based laws, Congress followed private sector best practices, as with GPRA, enabling agencies to more effectively manage IT requirements. Under IT performance-based laws, agencies are to better link technology plans and IT use to program missions and goals. To do this, agencies are to (1) involve senior executives in IT management decisions, (2) establish senior-level chief information officers (CIOs) who are to evaluate IT programs on the basis of applicable performance measurements, (3) impose much-needed discipline on technology spending, (4) redesign inefficient work processes, and (5) use performance measures to assess the contribution of IT to the achievement of mission results. In addition, laws such as the Computer Security Act of 1987, as amended in 1996, address the importance of ensuring and improving the security and privacy of sensitive information in federal computer systems. IT performance-based laws, including purposes, are summarized in Table 1.

The Clinger-Cohen Act (CCA), like the acts discussed above, imposes rather detailed reporting requirements on federal agencies (Mullen, 2005a, 2005b, 2006). The CCA requires OMB to do the following:

- Issue directives to executive agencies concerning capital planning and investment control, revisions to mission-related and administrative processes, and information security
- Promote and improve the acquisition and use of IT through performance management
- Use the budget process to (1) analyze, track, and evaluate the risks and results of major agency capital investments in IT and information systems and (2) enforce accountability of agency heads
- Report to Congress on the agencies' progress and accomplishments

CCA also requires additional reports to Congress from OMB, agency heads, and GAO.

The Government Paperwork Elimination Act (GPEA) of 1998 authorizes OMB to provide for acquisition and use of alternative IT by federal agencies. Alternative IT includes (1)

*Box 1. E-Government Act (E-Gov) provisions*

- Directs OMB to establish an interagency committee on government information and to issue guidelines for agency Web sites
- Requires federal courts to establish Web sites with information about the court and cases being presented
- Requires federal agencies to adhere to uniform security standards for information
- Creates an IT interchange program between the private and public sectors
- Authorizes government wide use of share-in-savings contracts, which permit agencies to pay contractors using savings realized through technological improvements
- Requires federal agencies and OMB to submit reports to Congress

electronic submission, maintenance, or disclosure of information as a substitute for paper and (2) electronic signatures in conducting government business through e-government transactions. The law calls for the director of OMB, in conjunction with the National Telecommunications and Information Administration, to study the use of electronic signatures in e-government transactions and periodically report to Congress on the results of the study.

The Government Information Security Reform Act (GISRA) is intended to do the following:

1. To provide a comprehensive framework for establishing and ensuring the effectiveness of controls over information resources that support federal operations and assets
2. To recognize the highly networked nature of the federal-computing environment, including the need for federal government interoperability and, in the implementation of improved security management measures, ensure that opportunities for interoperability are not adversely affected
3. To provide effective government-wide management and oversight of related security risks, including coordination of information security efforts throughout the civilian, national security, and law enforcement communities
4. To provide for development and maintenance of the minimum controls required to protect federal information and information systems
5. To provide a mechanism for improved oversight of information security programs in federal agencies

The E-Government Act (E-Gov) was passed to enhance the management and promotion of e-government services and processes. To increase citizen access to government information and services, the law created an office with the position of Administrator of E-Government and Information Technology within OMB—which oversees information resources management (IRM), including development and application in the federal government—and established a broad framework of measures that require the use of Internet-based IT. The act also authorizes $45 million for an e-government fund (and additional amounts in following fiscal years), to pay for IT projects aimed at linking agencies and facilitating information sharing. However, actual appropriated funding has not exceeded $5 million in any fiscal year. Title III of the E-Government Act is also referred to as the Federal Information Security Management Act (FISMA). FISMA updates GISRA by laying out a framework for annual IT security reviews, reporting, and remediation planning. The act is designed to streamline the government's information resources, close securities gaps, and create more public-centered Web sites. E-Gov provisions are listed in Box 1.

As shown in this section, there are many reporting requirements affecting federal IT and e-government.

## FUTURE TRENDS

In their efforts to develop useful performance reports for congressional users (or other types of users), those preparing the reports need to keep in mind that there are clear limits to the amount of information decision-makers can handle cognitively. This harkens back to the days of Herbert Simon, but also addresses one of the frequent failures of budget reform—failing to take into account legislative branch input and sensitivities. Just as importantly, when proposing performance measures, the would-be implementers need to factor end-use into the equation. As noted by Berman and Wang (2000),

*Stakeholder (or political) capacity concerns the nature of support for performance measurement... There is widespread agreement that management reforms require support from top management. Support from elected officials is critical because it forecloses back channels, legitimates reforms and new performance expectations, and helps ensure funding for new efforts. In this regard, some states, such as Minnesota, mandate the use of performance measures by counties, often as part of county budgeting and strategic planning.* (Berman & Wang, 2000, p. 410)

Another frequent problem in developing useful performance reports is the failure to link performance measures and cost data. This reflects, among other things, an unwillingness to reveal cost and the belief that "cost-effectiveness" may not be as important as perceived or actual service quality. Again citing Berman and Wang (2000), "The lack of support, especially from legislatures, is a commonly cited reason for budget-reform failure ... Elected officials are reluctant to give support when they view it as a ploy by bureaucrats to "technicalize" their operations and thereby avoid legislative scrutiny." Ammons (1999, p. 106-107) also noted this pitfall of performance reporting when he said,

*The problem is this: unless a government ties its performance measures* meaningfully *into management systems—unless those measures are something more than decorations for the budget document, as superficial reporting practices have been called derisively—any enthusiasm for measurement will quickly lose its luster, and probably deserves to. Officials moving toward a results orientation are well advised to think about application of performance measures right from the start. Think about application at every stage. Measurement flourishes—and deserves to flourish—only if it is used and is useful.*

It is worth noting here the fact that while cost data were a cornerstone of the Hoover Commissions of 1949 and 1955, nearly six decades later we still can't "merge" GPRA with the CFO Act by successfully linking performance information with budget/financial information. Although linking costs to performance goals is not a requirement of GPRA, both GPRA and the CFO Act emphasized the importance of linking program performance information with financial information as a key feature of sound management and an important element in presenting to the public a useful and informative perspective on federal spending. The committee report for GPRA suggested that developing the capacity to relate the level of program activity to program costs, such as cost per unit of result, cost per unit of service, or cost per unit of output, should be a high priority. GAO's 2003 survey of federal managers asked, for the first time, the extent to which federal managers had measures of cost-effectiveness for the programs with which they were involved. Only 31% of federal managers surveyed reported having such measures to a great or very great extent. This was lower by at least 12% than the results for any of the other types of measures associated with GPRA asked about in the survey.

The president's Management Agenda has set an ambitious goal for performance budgeting, calling for agencies to better align budgets with performance goals and focus on capturing full budgetary costs and matching those costs with output and outcome goals. All this suggests that agencies will need to develop integrated financial and performance management systems that will enable the reporting of the actual costs associated with performance goals and objectives along with presentations designed to meet other budgetary or financial purposes, such as the accounts and program activities found in the President's Budget and responsibility segments found in financial statements. However, of the six agencies GAO reviewed for a 2004 comprehensive study of GPRA's implementation over the last decade, only the Department of Education's report clearly linked its budgetary information to the achievement of its performance goals or objectives. Education's report laid out, using both graphics and text, the estimated appropriations associated with achieving each of its 24 objectives. In addition, the report provided the staffing in full-time equivalent employment (FTEs) and an estimate of the funds from salaries and expenses contributing to the support of each of these objectives (GAO, 2004, p. 65).

## CONCLUSION

The purpose of reporting requirements is to strengthen management controls and processes to increase agency accountability. The information required in reports to Congress is intended to be a valuable resource for Congress. It can use this information in carrying out program authorization, oversight, and appropriations responsibilities, as well as to ensure the public a more accountable and responsive government. An excessive number of reports on different issues within an agency are not likely to get the attention of busy congressional decision-makers or the public. One consolidated report—containing useful and understandable information dealing with an agency's performance management, financial management, and IT issues—is more likely to fulfill the intent of laws with reporting requirements: to produce useful information that had not previously been available. The information in a user-friendly, one-volume report, as envisioned by Congress with passage of the Reports Consolidation Act of 2000, is much more likely to be read and acted upon. To be most useful, each report should be readable (include an executive summary and be as brief as possible) and easily available on agency Web sites (Mullen, 2005).

## KEY TERMS

**E-Government:** The use of information technology (IT) and the Internet to transform government agency effectiveness—including efficiency and service quality.

**Performance Agreements:** Written agreements made between different levels of management to ensure accountability for achieving agreed-upon performance goals.

**Performance Measurement:** The ongoing monitoring and measurement of program accomplishments, particularly progress towards pre-established goals. Program or agency management typically conducts it.

**Performance Plan:** Annual reports in which government agencies articulate goals for the upcoming fiscal year that are aligned with their long-term strategic goals, and are to be linked to the program activities displayed in their budget presentations.

**Performance Report:** Annual reports in which agencies measure performance toward the achievement of the goals in their annual performance plans. If a goal was not met, the report is to provide an explanation and present the actions needed to meet the unmet goal in the future.

**Reporting Requirements:** Statutory provisions requiring the President (or head of government) or government agencies to submit specified information, often on an annual or recurring basis, for the purpose of assisting legislative oversight.

**Strategic Goals:** Explain what results are expected from government agencies' major functions and when to expect those results. Such goals are an outgrowth of the mission and are very often results, or outcome, oriented.

**Strategic Plan:** Annual reports in which government agencies define their missions, establish results-oriented goals, and identify the strategies that will be needed to achieve those goals.

# Portals for the Public Sector

**Jörn von Lucke**
*German Research Institute for Public Administration Speyer, Germany*

## INTRODUCTION

The term "portal" is traditionally associated with doors and gates. Room and front doors are used as simple entrances into a building or a room. Larger gates are constructed for the passage of vehicles. In ancient times the word "portal" was used mostly for monumentally designed entrances of buildings, castles, palaces, or cities, and triumphal arches. With the success of the World Wide Web (WWW) in the middle of the 1990s the term "portal" has a new meaning in a completely different context. Commercial providers of online services, search engines, and directories of Web-based links renamed their services as portals or starting points for the Internet. The providers of these portals were able to list their shares on stock exchanges with great success. Yahoo!, a commercial provider of directory services for the WWW, increased its share price steadily over 4 years since the initial stock exchange listing in 1996, which resulted in a true portal euphoria among investors until 2000. Merrill Lynch published a study in November 1998 about the internal use of portals and corresponding technologies in the enterprise, predicting unusually high growth rates and return on investment rates for such projects (Shilakes & Tylman, 1998). Many stock companies were able to increase their share price significantly just with the announcement of a portal strategy. Companies also began to rename their existing Web pages, online shops, and electronic markets as "portals," entirely in the sense of superb entrances, although most of these services had no real portal functionality. Everyone just wanted to participate in the portal success. But only a few participants had an exact idea of the meaning behind the term "portal."

## BACKGROUND: PORTALS AND PORTAL TECHNOLOGIES

Portals are easy-to-use, secure, and personalizable access systems with which users receive access to information, applications, processes, and persons which are available on the systems covered by the portal with consideration to their respective access authorization. Access to a portal can take place according to the multichannel principle, via different media and access channels. Portals are therefore not restricted to Internet technologies. Access would also be possible with other communication technologies and channels. The direct electronic channel, the speech-telephonic channel, the personal channel and the written channel are the most important ones (von Lucke, 2005).

The direct electronic channel has a special role for all channels, because it offers all users direct access to the systems covered by the portal. Therefore, it is the foundation for any portal access via other channels. Users of the electronic channel utilize modern information and communication technologies for receiving services electronically via internal data networks, the Internet, an extranet, and an intranet, via interactive digital television, or mobile phone data networks. Using the speech-telephonic channel, there is a telephone conversation between the user and an agent of a call center, for example, who has desktop access to the electronic channel and who can read the results on the telephone. Using the personal channel, there is a personal conversation with an agent in his or her office or at his or her counter, who also has direct access to the electronic channel. Even written inquiries can be answered by any agent, who has access to the electronic channel. The integration and coordination of the different channels are tasks of the multichannel management. This includes all required measures for the involvement of the four distribution channels into the demand and production processes.

Portal systems have integrating components so that the Internet Web site, the call center and the offices could make use of the same knowledge databases and profit from the experiences of the other distribution channels. This multichannel portal concept reduces the menace of the digital divide because the whole population will be reached via the portal, independent of the communication channel (von Lucke, 2004, pp. 80-81).

Different functions are associated with portals. A row of portal functions corresponds to a conventional entrance area which opens rooms behind it. References are given, what or who is where. Personal information is given, security examinations are undertaken, access authorization is controlled, inquiries and orders are taken, purchases are delivered, and payment processes are completed (Reinermann, 2002, p. 129). Other functions have to do with the access to systems in the background, their integration, and the uniform presentation corresponding

to the expectations of the user. So-called *portal technologies* secure these functionalities. Behind these are software technologies, which have already been available for a longer time, but whose combination in a portal offers users real additional value for the first time. Portal technologies need to be differentiated into which are essential and which are optional technologies. Portal management, access services, presentation, navigation, and integration are essential portal technologies. They are core components of each portal, independent from which access channel is used or how the systems are integrated. Personalization, publishing services, document management, process management, security services, search and research services, analytical services, and collaboration services are optional. Therefore portals are not only genuine access points. They can offer additional services through the portal technologies. Sometimes portal technologies are sold separately. Sometimes they are bundled with other portal technologies in software packages in order to be marketed as autonomous portal systems. Various applications and technologies can be included in these systems. Therefore portal technologies can be allocated in completely different systems. At the moment there are providers of original portal systems whose software includes the basic functionality for the operation of a portal, and there are providers of classic software applications which enhance their products with portal functionality (Correia, Biscotti, Wurster, & Dharmasthira, 2005; von Lucke, 2004, pp. 81-82; Phifer, Valdes, Gootzit, Underwood, & Wurster, 2005).

## PORTALS FOR THE PUBLIC SECTOR

The connection of the portal concept with the public sector leads to the development of portals for the public sector. These are portals which are designed for use in the public sector. Such a concept corresponds to the basic consideration of one-stop government services. It lends itself to the concept of one-stop government which tries to integrate different public services independently from their ownership by a local, subnational, national, or international agency in one point of contact and in one process. In this sense, portals for the public sector are easy-to-use, secure, and personalizable access systems, with which users receive access to information, applications, processes, and persons from parliament, government, administration, justice, and public corporations. These are available on systems of the public sector which are covered by the portal, with consideration to their respective access authorization. Access to the portal can take place according to the multichannel principle via different media and access channels. The concept is therefore not restricted to the Internet and can be transferred to the complex reality of the public sector.

Portals for the public sector can be subdivided into self-service portals and mediator portals. While self-service portals allow users (employees or citizens) direct access, mediator portals are self-service portals for mediators of the public sector, which offer them additional background information and mediator-specific working directions. They support administrative mediators in call centers, citizen agencies, and citizen shops, but also mediators like social workers, physicians, or other mentors for citizens. Like any other portal they can be used as a central front-end system for users and as a central communication and integration platform for the background computer systems (von Lucke, 2004, pp. 83-84).

## CHARACTERISTIC STAGES OF PORTALS FOR THE PUBLIC SECTOR

From the current point of view, four consequential development stages for portals can be observed. They are similar to the development stages for one-stop government (Hagen & Kubicek, 2000).

In the first stage, *simple entry point* portals simplify the access to information and public services through specially prepared orientation and signpost information. They refer to the corresponding services and lead the users to the responsible agencies and employees. They have the function of a gateway.

Portals of the second stage serve purely for information collection and diffusion. They are used for the provision of information, which is collected from different sources, bundled, prepared in simple terms and presented. Citizens use these so-called *information collection points* portals in order to get an orientation and to inform themselves about a special subject.

Portals of the third stage, the so-called *service center*, offer a seamless access to public sector information and selected public services. They allow the completion of transactions with all those agencies, which are integrated in this public sector portal. Public databases and registers are already integrated in these portals to a point that deposited data can be inserted into forms automatically and appropriately.

With an increasing networking of these single service centers there will be a *service cluster* of portals, which can communicate and cooperate collectively. Users get access to all available information and transaction services via these service clusters, independent of the provider. In the ideal scenario, all relevant participants would be

included in a cluster. These clusters enable the creation of totally new workflows and value-added chains in the public sector. They permit to bundle once-divided public services into new packages. Consequently transaction services gain significance with the public, while the providing agencies lose it. This is the fourth development stage of public sector portals. At the same time, it might be the starting point for a complete reorganization of the public sector organization (von Lucke, 2004, pp. 88-89).

## IDEALISTIC TYPES OF PORTALS FOR THE PUBLIC SECTOR

There are a lot of different portal types found in the public sector worldwide (Accenture, 2004, pp. 42-56, 61-105; Accenture, 2005, pp. 40-47, 53-97; Bent, Kernaghan, & Marson, 1999, pp. 13-100). Some of them are accessible to the public, while others are only for the internal use of an agency. Some public sector portals are designed around existing organizations while others are planned for special target groups, around methods or around objects (von Lucke, 2005).

For an outlook on idealistic types of portals for the public sector, publicly accessible portals around institutions of the public sector are a good starting point: Agency portals are designed around a certain agency or administrative unit, like a municipal office, an authority, a department, a ministry, a public institute, a public corporation, or a public foundation. Once designed as information collection points, they are developed increasingly into service centers, through which citizens and businesses can complete legally binding processes with the agency. Cross-agency portals are planned, built and operated jointly by several agencies. They try to bundle services from several agencies in one portal. Cross-agency portals can be formed in addition to the existing agency portals. They should not replace these agency portals, but rather supplement them. Government portals are designed with regard to a certain government entity. This might be the portal for the municipal government, the county government, the state government, the national government or the supranational government. As a portal to all institutions of a special government entity, it should include at least links to all of its agencies, departments, and other institutions, but could also contain specific information or public services. Cross-government portals are planned, built, and operated jointly by several governments of the same horizontal level. Vertical cross-government portals are realized and run by several government entities of different (vertical) levels of government. This enables a collaboration of national, subnational, and local level of government in one portal. Citizens and businesses are mostly interested in these portals, because they might offer one window to the whole public sector without knowing who is responsible for a special public service.

Another starting point for classifying portals is the interest of the users. While the above-classified portals integrate only public information and services, portals centered around user interests should include public, private, and third sector information as well as services. Topic portals are arranged around certain topics or subjects, with special reference to the public sector. There are a lot of potential topics which might be interesting for the users. Audience portals bundle all the relevant information and services for special target groups in one portal. The life event principle is a third arrangement concept and stands for the orientation of information, services, products, and processes toward target groups and toward their special requests in certain moments or phases of their life, from cradle to grave. In conjunction with citizens, these events are known as “life events” while for businesses the term “business event” is used. Life event portals bundle all relevant information, services, and processes around one or more life events of a citizen while business event portals do the same for one or more business events of an enterprise (BASIS, 2001). Portals for the public sector which are designed completely around its users and their needs mean a fundamental change of perspective for public administration. No longer is an orientation within the public sector important, but rather an outside orientation, tailored on the needs of citizens, businesses, and other agencies and organizations is required.

Another starting point for categorizing publicly accessible portals is a method, which uses a portal as the central communication component. Process portals open the gate to the steps of processes and the processes of value chains, so that the users have a personalized access to relevant processes. Project portals utilize project management software so that certain project targets can be reached better and so that the involved persons have one central communication platform, while at the same time they are relieved from routine project activities. Project portals support during the phases of project definition, project planning, and project execution. Knowledge portals help to organize a knowledge management system within a government agency or across several agencies. These portals assist in coordinating the knowledge of the teams, departments, and the agency. Search services and personalization functions support employees doing research. Learning portals bundle educational and training services as well as background information about courses, programs, exercises, and exams into virtual learning communities.

Finally, publicly accessible portals around objects like register portals, geoportals, and document portals open the access those objects, for example, to public registers, public geographical data, and public documents.

The portal concept can also be used within agencies and government entities. Intranet portals for departments, agencies, and government entities as well as extranet portals belong to the group of internal public sector portals around institutions. Internal portals around the needs of public sector users like employee portals or portals for mediators are not fixed to one institution. They try to bundle all relevant information and services from different sources for an internal use. The concepts of portals around methods and portals around objects can also be used for an internal purpose but the access to those portals is restricted. All these internal portals are normally planned, built, and operated by the internal information technology department. They are not open to the general public.

## FUTURE TRENDS: HIGH-PERFORMANCE PORTALS

The utilization spectrum for portals in the public sector is very broad. But in any portal-based administration the capability for action will depend crucially on these portals. Long-term outages and system crashes, which would take hours, days, or weeks, could incapacitate any agency and would be a risk for security, law, and order. If agencies want to use portals for crucial government processes, it must be guaranteed, that these portals meet the quality requirements for reliability, performance, availability, response time, security, and scalability. Even if these requirements vary from agency to agency, they are rarely fulfilled by simple portals of the first or second generation without additional quality mechanisms. This is the field of high-performance portals.

There are remarkably high requirements for high-performance portals. They have to manage high user numbers and transaction volumes in peak periods, simultaneously and with extremely low down times. Thousands of simultaneous inquiries must not overtax the system. High-performance portals should offer maximum reliability to guarantee full operational services day and night via all distribution channels. This means high expectations for the performance of the portal system. Responses to inquiries must return fast, be usable, and possess high quality for the inquirer. Users expect real-time processing without perceiving any delays. Internal availability mechanisms guarantee that access is always possible. High availability can be reached through redundancy, distributed systems, fail-over functions, and fault tolerance. Because high-performance portals are based on the multichannel principle, results can be delivered via different distribution channels, directly or indirectly via a mediator. Besides access services, their duties include security services, directory services, personalization, and single sign-on. Security services should secure all data and resources. This includes access and user control systems with registration, activation, authentication, and authorization as well as encoding, signature, and identification services. Directory services are used for user administration and can be the starting point for segmentation, individualization, and personalization of the portal. For personalization of the user interface, its content and services, any user must register himself or herself with his or her real name and his or her real identity, while for individualization the user always remains anonymous. With single sign-on one login per session is sufficient to access all services bundled by the portal. High-performance portals are in one line with the development from entry points and information collection points to service centers and service clusters, in which most portal technologies are integrated. High-performance portals must be scalable and open for several clients using the fundamental portal system for different portals at the same time without influencing each other. In addition to these technical requirements, they also have to meet the legal requirements for data protection and data security (von Lucke, 2001, pp. 293-300; von Lucke, 2004, pp. 84-86).

In the coming years high-performance portals will open an entire series of new applications which previously were unthinkable due to technical and organizational restrictions. The portal concept allows, for example, the bundling of all public services in an electronic government service portal; new models of personal data storage with the introduction of electronic administration files, citizen files, and document safes; new account models with the introduction of citizen accounts, business accounts, tax portals, and payment portals; more transparency in the public health sector with health portals and health care files; as well as more citizen participation with personalized community portals (von Lucke, 2005).

Regarding these considerations, high-performance portals are a very crucial instrument for government and administration. They have the potential for a sustainable redesign of the public sector. Only high-performance portals offer the high-quality standards secured by service-level agreements that agencies demand for the substitution of established procedures and practices. But only if these portals can contribute something to an immense improvement in fulfilling their tasks, agencies will be ready for a change. Their potential is more than just the digitalization of existing procedures. High-performance portals can lay the foundation for new public

agencies, push the internal networking, force the reorganization of the public sector, set new accents with centralization and decentralization concepts, as well as improve the citizen involvement. At the same time, they can reorganize the contact with citizens and customers, improve self-services, introduce new service delivery concepts, and start with pro-active services (Millard, Iversen, Kubicek, Westholm, & Cimander, 2004, pp. 27-45).

## CONCLUSION

Portals and high-performance portals offer a new, innovative concept for bundling information, services, products, and processes. Portal technologies open room for new public services and a broad reorganization of the public sector in general, which had been unrealistic in the past. Together they can make a significant contribution to the further modernization of government and public administration. Within the public sector there are many different portal types, which might be attractive for citizens, business, agencies, or government entities. While simple portals can be built in a short period, the development and the implementation of high-performance portals are much more complex and therefore will take a longer time and more financial means. Regarding the perspective and the potential benefits, it is definitely worth for any public sector institution to move on this way.

## KEY TERMS

**Agency Portal:** Public sector portal that is designed around a certain agency or administrative unit, like a municipal office, an authority, a department, a ministry, a

public institute, a public corporation, or a public foundation. (Web-based example of an agency portal: http://www.whitehouse.gov)

**Audience Portal:** Public sector portal that bundles all the relevant information, services, processes, and points of contact for a special target group. (Web-based example of an audience portal: http://www.students.gov)

**Business Event Portal:** Public sector portal that bundles all the relevant information, services, processes, and points of contact around one or more business events of an enterprise. (Web-based example of a business event portal: http://www.basis.ie)

**Cross-Agency Portal:** Public sector portal that is planned, built, and operated jointly by several agencies. These portals try to bundle services from several agencies into one portal. (Web-based example of a cross-agency portal: http://www.fedstats.gov)

**Cross-Government Portal:** Public sector portal that is planned, built, and operated jointly by several government entities of the same (horizontal) level to realize synergy effects. These portals try to bundle services from several government entities into one portal. (Web-based example of a cross-government portal: http://www.acol.ca)

**Employee Portal:** Internal portal of a government agency for its employees, not open to the general public, planned, built, and operated by the internal information technology department. It might include an electronic desktop, an administration information portal, an intranet portal, and an employee self-service portal.

**Government Portal:** Public sector portal that is designed with regard to a certain government entity like the municipal government, the county government, the state government, the national government, or the supranational government. (Web-based example of a national government portal: http://www.belgium.be)

**Life Event Portal:** Public sector portal that bundles all the relevant information, services, processes, and points of contact around one or more life events of a citizen. (Web-based example of a life event portal: http://www.oasis.ie)

**Life Event Principle:** Classification principle that stands for the orientation of information, services, products, and processes toward target groups and toward their special requests in certain moments or phases of their life, from cradle to grave. In conjunction with citizens, these events are known as "life events" while for businesses the term "business event" is used.

**Portal:** Easy-to-use, secure, and personalizable access systems, with which users receive access to information, applications, processes, and persons which are available on the systems covered by the portal, with consideration to their respective access authorization. Access to the portal can take place according to the multichannel principle, via different media and access channels. Portals are therefore not restricted to Internet technologies while the so-called Web-based portals (Web portals) are focused on the World Wide Web.

**Public Sector Portal:** Easy-to-use, secure, and personalizable access systems with which users receive access to information, applications, processes, and persons from parliament, government, administration, justice, and public corporations. These are available on systems of the public sector which are covered by the portal, with consideration to their respective access authorization.

**Topic Portal:** Public sector portal that is arranged around certain topics or subjects with special reference to the public sector. (Web-based example of a topic portal: http://www.environment.gov.au)

**Vertical Cross-Government Portal:** Public sector portal that is planned, built, and operated jointly by several government entities of different (vertical) levels of government. These portals try to bundle services from several government entities into one portal. (Web-based example of a vertical cross-government portal: http://www.ch.ch)

# Postal Services and ICTs in Japan

**Yuko Kaneko**
*University of Yamagata, Japan*

## INTRODUCTION

Postal service organization has a long history of exploiting ICTs in its business operation as a government ministry, then as a public corporation from April 2004. In the business world, ICTs play a central role of promoting operational efficiency and customer services as well as fostering new businesses for further development. The Japanese postal service organization will be privatized in October 2007 and privatized companies will be forced to make further use of ICTs.

In this article, the use of ICTs in the postal services will be described with a view to clarifying the relationship between the incentives of introducing ICTs and the institutional arrangements, namely a government ministry and a public corporation.

## BACKGROUND

The modern postal service was created by the national government in 1871. Three categories of services, namely postal delivery service, postal savings service, and postal life insurance service had been provided by the government (Ministry of Posts and Telecommunications, MPT) for about 130 years.

In the late 1950s, the government started its government-wide undertaking for the management reform of administrative affairs. Coincidently, the first computer in the national government was introduced by the Meteorological Agency in 1958. During the 1960s, improvement in the efficiency and efficacy of public administration were made through the use of computers (ECHMCA, 2001). Since 1960s, as one of the reform measures, MPT had been introducing ICTs into its postal service operation to improve the operational efficiency and customer services (MPT, 1972).

As a result of "Hashimoto Reform," the drastic restructuring of central ministries and agencies was conducted in January 2001. MPT and the other two ministerial-level organizations were merged to become the Ministry of Internal Affairs and Communications (Kaneko & Horie, 2000). At the same time, the unit in charge of conducting postal services was detached from the internal units of the ministry to become the Postal Services Agency, an external agency of the Ministry of Internal Affairs and Communications. Japan Post, a new public corporation, was established to carry out postal services in April 2003 as a successor to the Postal Services Agency.

The institutional arrangement of the Japanese postal services once was a ministry for more than 130 years and became a public corporation. In the following, the outcomes of the ICT strategies taken by MPT will be described. Then, on-going efforts by Japan Post will be mentioned in the future trends.

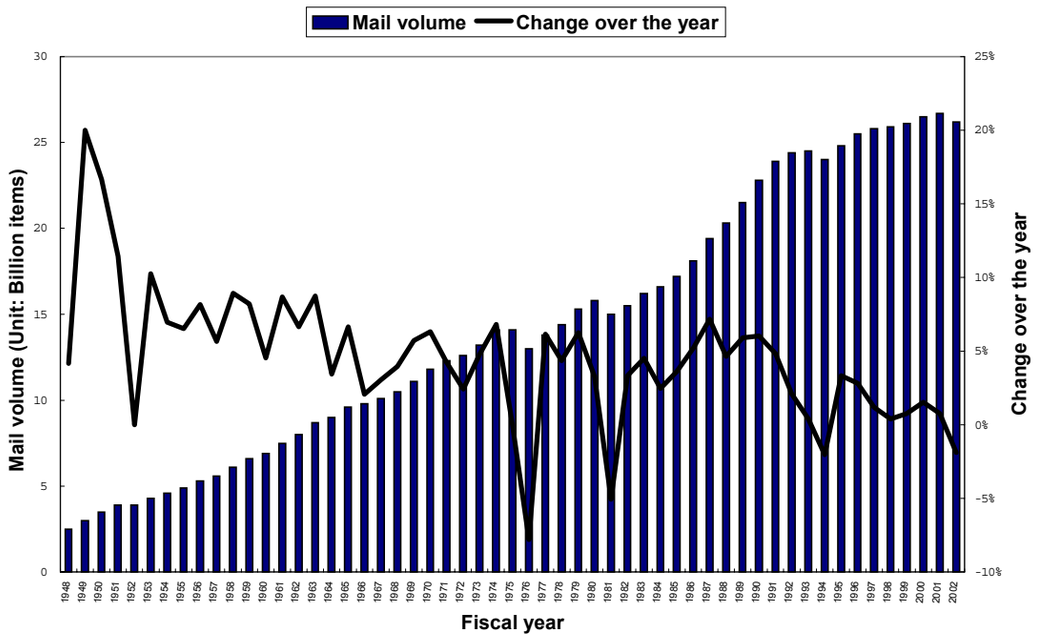
## ANALYTICAL FRAMEWORK

There are some theories concerning the use of new technologies in society. One of them is the technology acceptance model (TAM). TAM is an information systems theory that models how users come to accept and use a technology. The other prominent theory is the diffusion of innovation theory formalized by Everett Rogers (Rogers, 1995). Rogers stated that adopters of any new innovation or idea could be categorized as innovators, early adopters, early majority, late majority, and laggards, based on a bell curve. Each adopter's willingness and ability to adopt an innovation would depend on their awareness, interest, evaluation, trial, and adoption. Some of the characteristics of each category of adopter include:

- **Innovators:** Venturesome, educated, multiple information sources
- **Early Adopters:** Social leaders, popular, educated
- **Early Majority:** Deliberate, many informal social contacts
- **Late Majority:** Skeptical, traditional, lower socioeconomic status
- **Laggards:** Neighbors and friends are main info sources, fear of debt

The categorization of adopters in the diffusion of innovation theory is used in describing the use of ICTs in postal service operation in Japan. Japan Post provides transportation services and financial services. These two categories of activities are quite different so that two separate headings are set up to describe the ICT use in the postal services.

*Graph 1. Trends in mail volume 1948-2002 (MPT, 2000; Japan Post, 2004)*



## POSTAL DELIVERY SERVICE AND ICTS FROM 1960s TO 2003

### Business Outline of the Postal Delivery Service

The postal delivery service is by its very nature a transportation activity collecting mail and parcels posted in mailboxes or accepted at the post offices, sorting them according to where they are to be sent, transporting them to the delivery post offices nearest to the addressees and delivering them to the addressees themselves.

The total number of items mailed in fiscal 2003 stood at 25.6 billion. This number is almost the same as that of France (Japan Post, 2004). The volume of mail continued to grow from the 1950s through to the mid-1970s when the oil crises struck Japan which had a negative effect on the items sent. After that, the Japanese economy recovered and the volume of mail sent also began to increase steadily. In the early 1990s, the volume leveled off as results of the development of the Internet and the severe competition in the parcel delivery market.

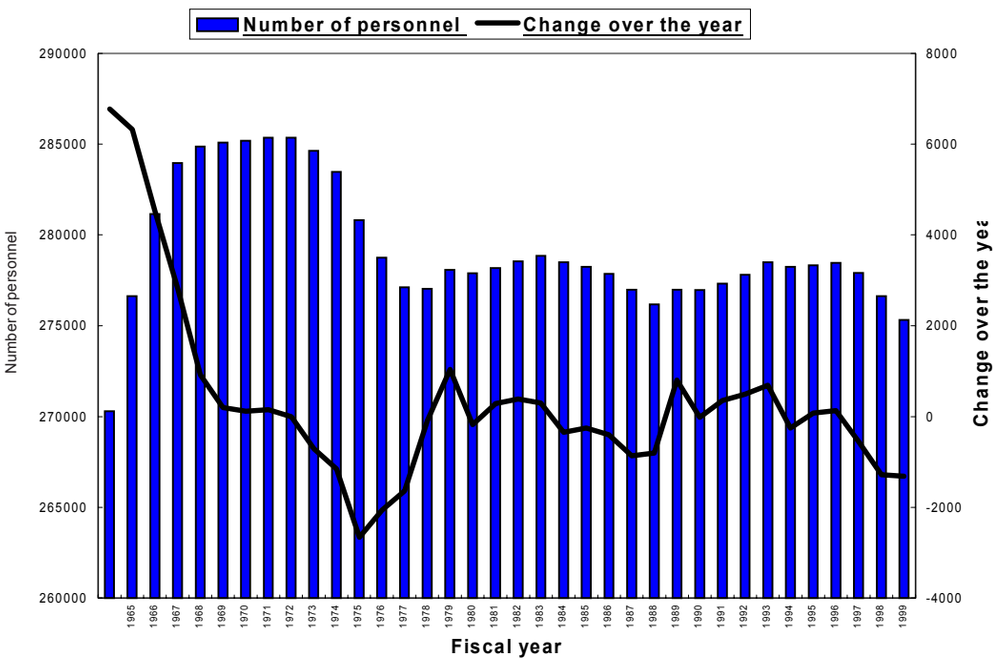
### Introduction of a Five-Digit Postal Code System

A five-digit postal code system was introduced in 1968. In this system, automatic postal code reading and sorting machines were installed in sorting mails according to the addresses. The machine was originally developed and custom-made for the use of MPT and was a product with advanced ICTs (MPT, 1972). It cost lots of money to develop the machine. At that time, there weren't any private transportation companies to introduce such machines in Japan. In this context, it can be said that MPT was an innovator in adopting ICTs according to the diffusion of innovation theory. The development of the machine served two purposes. One was to improve the operational efficiency of postal delivery service. The other was to promote the use of ICTs in society. MPT had dual roles. It was not only in charge of providing the general public with postal services but also responsible for policy-making and implementation in the ICT field. It seems that such dual nature promoted the introduction of ICTs in postal service operation.

Around 1960s, the mail volume continued to increase and a labor shortage was expected. This situation also forced MPT to introduce the automatic postal code reading and sorting machines in the postal delivery service. With this system, customers were requested to write five-digit postal codes as an appendage to addresses shown on mail.

Automatic postal code reading and sorting machines were put into operation in the post offices with collection and delivery functions. Many machines were installed even though their prices were relatively high.

*Graph 2. Trends in number of personnel in the post offices 1965-1999 (Organizational Chart of the Government of Japan, 1965-1999; Administrative Management Agency; Management and Coordination Agency)*



After the introduction of the five-digit postal code system, mail volume continued to increase by about five percent every year until 1975. At the same time, MPT could minimize the number of personnel required to deal with the increased mail volume. Before 1968, the annual net increase in the number of personnel was more than five thousand, but from 1969, that figure fell to about one hundred, a remarkable decrease. It can be said that introduction of the five-digit postal code system improved productivity and forestalled a demand for additional personnel.

## Introduction of a Seven-Digit Postal Code System

During the 1970s and 1980s, the mail volume steadily increased, except for in 1976 and 1981, when the oil crises occurred and plunged the Japanese economy into a deep recession. As a result of this recession, tax revenue decreased while the government spent its financial resources on measure to revive the economy. Consequently, the government incurred huge financial deficits in the early 1980s. In order to reconstruct public finances without increasing taxes, government-wide administrative reform efforts were initiated (Kaneko, 1996). Among these administrative reform measures, aggressive personnel reduction plans were decided on by the cabinet and MPT was forced to cut back its personnel even as the mail volume continued to increase. From around 1990, the rate of increase in mail volume fell to less than three percent, partly because of the development of the Internet and partly due to fierce competition in the parcel delivery market. The decrease of mail volume meant the decline of income from the postal delivery service.

Under such circumstances, further improvements in productivity and efficiency were needed. To cope with this challenge, the seven-digit postal code system was introduced in February 1998. Seven-digit postal codes are allocated to even smaller address areas than before, so that the reading and sorting machines can sort mail according to delivery routes. Before the introduction of seven-digit postal code system, postal workers sorted mail by hand, according to delivery routes. Such automatic mail sorting system according to the delivery routes was first introduced in the U.S. Japan is the second country to introduce the system. Only German, Singaporean and Dutch postal service agencies have introduced the same kind of system (H. Uchida, personal interview, October 14, 2005).

New reading and sorting machines were developed and installed to enable the seven-digit postal code system. One such machine reads zip codes and names of addressees, converts the read data into barcodes, which are then printed on the mail, reads barcodes, and re-

*Table 1. Workforce reductions and installation of new machines (Japan Post, 2003a)*

| Fiscal year | Cumulative full-time jobs eliminated | Jobs eliminated during the year | Number of new machines installed | Number of post offices with new machines |
|---|---|---|---|---|
| 1998 | 3,195 | 1,664 | 623 | 388 |
| 1999 | 4,610 | 1,415 | 727 | 458 |
| 2000 | 5,150 | 540 | 858 | 564 |
| 2001 | 5,693 | 543 | 1,000 | 674 |
| 2002 | 6,209 | 516 | 1,085 | 702 |

orders the mail according to the delivery route. Yet another machine uses OCR (optical character recognition) to read zip codes, names of addressees, barcodes, and sorts all larger mail measuring up to 40cm long, 30cm wide, and 3cm thick, and weighing up to 1kg (Japan Post, 2003a). The new machines were custom-made. Thanks to the development of ICTs and the introduction of competitive bidding, the initial average purchase cost of ¥280 million was down to ¥60 million in November 1999 and ¥30 million in July 2000 (T. Hama, personal interview, October 3, 2002).

The seven-digit postal code system enabled further reductions in the number of full-time jobs, resulting in the elimination of 6,209 jobs from fiscal 1998 to fiscal 2002 (Japan Post, 2003a).

## Major Issues in Introducing the Seven-Digit Postal Code System

By now, postal delivery service is going well along with the seven-digit postal code system. However, MPT encountered some obstacles in the early stage of the introduction. Major issues are described (H. Uchida, personal interview, October 14, 2005).

## Technical Instruction Tends to be Given Less than Needed

New machines were developed by the joint work by MPT head office and the contractors. At the time of installation, technical staff of the head office and the experts from the contractors usually visited the post offices to hold instruction and guidance sessions on the use of new machines. After the new machines were put in full operation, the head office has made it a rule for the technical staff to make a regular visit to the post offices to inspect the operation.

The instruction and guidance sessions as well as regular inspections had to be held during the midnight because the sorting of the collected mail is usually done during that time. This meant that simultaneous sessions or inspections were to be held at different post offices so that it was rather difficult to dispatch enough number of technical staff to respective post offices.

## Promoting the Use of Seven-Digit Postal Codes

MPT would not have made most of the seven-digit postal code system without seven-digit codes written on the mail surface. Therefore, MPT carried out several measures to promote the use of seven-digit codes. Roughly speaking, there were two approaches. One was to promote the use of seven-digit codes by the big business accounts and the other was to promote the use by the general public.

## Promotion Measures for the Big Business Accounts

Before full operation of seven-digit postal code system, MPT requested the big business accounts such as public utility companies sending massive mail of bills to change the postal code data stored in their customer information data-bases. In a usual case, these big accounts print the postal code and address of each customer on their billing mail by making use of their customer information data-bases. Additional work had to be done on the side of the big accounts. MPT introduced the discount postal charge system to be applicable to the accounts that print the seven-digit codes on their mail.

## Promotion Measures for the General Public

The next challenge was how to promote the use of seven-digit codes by the general public. In Japan, we have the custom of exchanging new year's cards. Persons who usually do not write letters or post cards write and send a lot of new year's cards around late-December. In introducing seven-digit code system, MPT held a public relation campaign of writing the postal codes of the senders on the new year's cards before the full operation of the system, in the autumn of 1997. As the senders of the new year's cards write their seven-digit codes on the cards, the receivers of the cards can write the seven-digit postal codes of the senders when they write letters next year. In using seven-digit codes, the customers can simplify the writing of the address. They can only write the names of the block and the street numbers together with seven-digit codes. Furthermore, original codes can be given to big business accounts and in this case customers need only to write the postal codes and names of addressees on the mail.

As results of these undertakings, 72.8% of the mail posted in the mailbox had seven-digit codes with them according to the survey conducted in 12 February 1998 (MPT, 1998). Further efforts were taken and the February 8, 2001 survey showed that 97.1% of all mail had seven-digit codes printed or written on them (Postal Services Agency, 2001).

## POSTAL FINANCIAL SERVICES AND ICTS FROM 1970S TO 2003

### Business Outline of the Postal Financial Services

MPT had been providing postal financial services (postal savings and postal life insurance services) from 1875. The postal savings special account and the postal life insurance special account were established separated from the general account of the government. Until April 2001, the funds deposited in the postal savings special account were compulsorily re-deposited to the Trust Fund Bureau of the Ministry of Finance. The funds were to invested or loaned to the public corporations and local governments based on the program decided by the parliament (Fiscal Investment and Loan Program, FILP). MPT could invest the insurance and annuity premiums deposited by the customers rather freely. In this sense, MPT was a financial institution with limited investment means (Japan Post, 2003b; MPT, 1972). After the FILP reform in April 2001, MPT could invest the money without restriction but a seven-year interim measure has been conducted. This is one of the reasons why the fairly large amounts of postal savings and insurance funds are invested in the government bonds.

The current Postal Savings Balance was ¥227.4 trillion and there were 75.8 million life insurance and annuity policies in force, with a total insured amount of ¥187,842 billion as of fiscal 2003 (Japan Post, 2004).

In the following, ICT use in the postal savings service is mentioned for reasons of space.

### Construction of Online Network

The use of ICTs in financial institutions began in the mid-1960s in Japan. Private financial institutions, especially banks, started to construct online computer networks together with various business operation systems in the headquarters, local branch offices, business centers etc., and to exchange data and information for greater efficiency in operation and labor saving. In the early 1970s, CDs began to be installed and ATMs took the places of CDs in the mid-1970s for enhancing customer services (FISC, 2005).

On the other hand, MPT was rather slow to construct its online system. MPT started to construct a computer networking system linking the headquarters, regional offices, business centers and post offices in the late 1970s, in order to improve customer services and streamline and modernize operations, keeping pace with the private banks. Online depositing and withdrawal services for ordinary savings started in1978. Services via ATMs began in 1981. The postal savings online network linking post offices throughout Japan was completed in 1984. This network system is one of the world's largest in the financial service field, connecting about 20,200 post offices and ATMs and CDs. The total number of ATMs and CDs is 26,483 as of fiscal 2003 (Japan Post, 2004).

According to the diffusion of innovation theory, in the financial service sector, the private banks can be identified as innovators in constructing online network for their business operations. On the other hand, MPT had willingness and ability to swiftly construct its online network for its postal savings service as a government ministry with responsibility of promoting the use of ICTs in society. However, an external circumstance as well as an internal condition forced MPT not to be an innovator of adopting ICTs (M. Aida, personal communication, October 18, 2005). As the external circumstance, there was the deep-rooted criticism from the private financial institutions. They denounced that MPT delivered the same kinds of financial services that the private sector could provide, hence ruined the business opportunities of the private sector. This circumstance hindered the advancement of ICT use in postal savings service. MPT was required to take a prudent step toward ICT introduction. The internal condition that hindered a swift construction of the online network was the vast number of post offices. Enormous investments were needed to construct online network connecting more than 20,000 post offices. In fact, it took more than five years to construct online network linking post offices throughout Japan (Japan Post, 2003b).

Because of these reasons, it can not be said that MPT was an innovator in constructing the online network together with the other operating systems. Rather MPT remained an early adopter in the early stage of ICT exploitation.

### Improvement of Customer Services by Collaboration with Private Banks

From the 1970s to the late 1990s, private banks continued to construct inter-bank networks and inter-industry networks for enhancing customer services and streamlining business operations (FISC, 2005). MPT had been ex-

cluded from these networks. After the economic bubble collapsed, the private banks became suffering from the non-performing loans. A lot of tax money was spent to rescue the banks with huge bad loans. More efficient business operation came to be needed in managing private banks. They started to close local branch offices. On the other hand, they were eager to increase the service delivery channels. Under these circumstances, MPT and some private banks agreed to connect their online networks to allow customers to withdraw cash from the bank accounts at the post office ATMs as well as from the postal savings accounts at the bank ATMs. This ATM/CD tie-up service was started in January 1999. After that, many banks sought to cooperate with MPT and as a result, the postal savings network was connected to 1,917 private financial institutions as of July 2003 (Japan Post, 2003b). In this context, MPT can be identified as an innovator in widening delivery channels by use of ICTs.

The debit card service was started in Japan in January 1999, involving the postal savings and seven other financial institutions as well as eight affiliated retail venders. This service enables cash-free payments for purchases made at retail outlets. 1,564 financial institutions and 223 companies participated in this service as of June 2003 (Japan Post, 2003b). In launching this service, MPT played a substantial coordinating role (M. Aida, personal communication, October 18, 2005). MPT should be identified as an innovator in this field.

The Multi-Payment Network is an online network to allow customers to pay their bills and taxes through counters, ATMs, cellular phones, and personal computers at any time and place. This network is regarded as one of the indispensable infrastructures for an electronic government. To construct this network, the Japan Multi-Payment Association was established in May 2000 involving major billing bodies and financial institutions including MPT. MPT was also in charge of realizing an electronic government; therefore it took the initiative of advancing the construction of the network. The services were started in October 2001. Postal Services Agency started multi-payment network services in January 2002 (Japan Post, 2003b). The postal savings organization has become an innovator and initiator in this field.

## Improving Operational Efficiency

By making use of advanced ICT in processing transactions, MPT had been improving the efficiency of its operations. Over the past ten years (fiscal 1993-2002), with a new transaction processing system, approximately 3,600 permanent positions were done away with while the number of transactions handled increased (Japan Post, 2003b).

# FUTURE TRENDS

From April 2003, MPT was transformed into Japan Post. Before the establishment of Japan Post, the establishment committee of Japan Post was organized to deliberate the medium-term management goals, management plan and other management standards. The committee suggested some crucial points to be taken into consideration in developing ICT systems under Japan Post (ECJP, 2002).

After Japan Post was established, strategies to exploit ICTs together with the restructuring of internal organizations were regarded indispensable to ensure the competitive edge of Japan Post as well as to support the corporate executives to decide overall management strategies. In order to implement this policy, some restructuring of internal organizations was conducted in July 2004. A new corporate ICT department was created and a new branch in charge of ICT matters for postal savings and life insurance services was established (Japan Post, 2003b; Japan Post, 2004).

The predecessor of Japan Post, Postal Services Agency was in its nature a unit inside a ministry and had to comply with the strict rules of the government organizations concerning personnel and financial management that are suitable for an internal organization of a ministry with policy planning functions. On the other hand, Japan Post is no longer an internal organization of a ministry, therefore more flexible rules of personnel and financial management can be applied. For example, a performance based pay system was introduced and the usual rule of preparing the budget on an annual basis has been relaxed. Such rule changing has affirmative effects on the introduction of ICTs (H. Uchida, personal interview, October 14, 2005).

In contracting out the system development, MPT often took private contracts with the specific companies. This was partly because the scale of the systems was too large for ordinary firms to accept orders and the substantial work periods were very limited due to the annual-based budget. After the corporatization, the principle of annual-based budget was relaxed and Japan Post can place orders extending several years. This measure lowered the risk bearing on the contractor's side; therefore the contracted prices were down greatly. Japan Post also made it a rule to take open bidding procedures and the procurement prices were decreased substantially (H. Uchida, personal interview, October 14, 2005).

Concerning the postal lobby, they ceased to explicitly submit demands after Japan Post was established with Mr. Ikuta, a prominent former CEO of a major marine company as its president. After the general election held in September 2005, more than half of the pro-postal candidates were defeated and now the postal lobby has lost their powers.

The Postal Service Privatization Law and other related laws were passed through the parliament in October 2005. Japan Post will be disbanded in October 2007 and split into four private entities, undertaking postal delivery, postal savings, postal life insurance and over-the-counter services under a private holding company (Kaneko, 2005). This means that the current operation systems should be divided among four companies. Business operation systems for the postal service company, the postal savings company, and the postal life insurance company may be relatively easy to reconstruct. On the other hand, lots of new business operation systems must be developed for the over-the-counter service company. Furthermore, the present corporate-wide operation systems of personnel, financial and account management must be divided into four parts, each corresponding to each company. These works must be completed by the end of September 2007.

## CONCLUSION

It seems that the institutional arrangements affected the level and range of ICT use in postal service operation. As a government ministry the Japanese postal service organization could introduce the most advanced ICTs in the monopolistic market, postal delivery market, but had to take prudent steps in the competitive market, the financial market for individual citizens. It can be identified as an innovator of ICT use in the postal delivery service. But it could not become an innovator in constructing computer networks for the postal savings service. After the online network was completed, it could be an innovator in collective undertakings of various actors in society for more convenient customer services and more efficient operation in the financial market. As a public corporation, Japan Post can develop its information systems more freely at less cost as strict legal restrictions for the government ministry were lifted. Thus, the institutional arrangements including legal regulations, organizational goals and management principles can affect the speed and extent of ICT introduction in an organization. Currently, business operation depends heavily upon its information system. Privatization and division of business involves the review of the whole system, the modification of existing systems and the development of new systems. Development of appropriate information systems is one of the key elements for the successful privatization of the postal services. How Japan Post will carry out these demanding works may show us the relationship between the ICT use and institutional arrangements of activities.

## KEY TERMS

**Debit Card Service:** A service enabling the cash-free payment of purchases made at department stores, local shopping districts, convenience stores, gas stations, and travel agencies that are the members of the Japan Debit Card Promotion Association. This is done by withdrawing funds from the customer's postal savings account or bank account and depositing them into the vendor's account using a cash card.

**Japan Post:** A public corporation newly established in April 2003 based on the law. Its mission is to deliver universal postal services to the general public. This means that the citizen who lives in the most remote area can use the postal services. To carry out this mission, the post offices are located even in the scarcely populated areas.

**Ministry of Posts and Telecommunications:** A ministry established in 1886 when Japan adopted the Cabinet system. It was responsible for delivering postal services as well as implementing regulations in the telecommunication area and promoting the use of information and communication technologies in society. This ministry was combined with the Ministry of Home Affairs and the Management and Coordination Agency to make the Ministry of Internal Affairs and Communications in January 2001.

**Multi-Payment Network:** An online network linking between billing bodies (such as private companies, municipal entities and government offices) and financial institutions to allow customers to pay their bills and taxes through counters, ATMs, cellular phones and personal computers at any time and place. The Multi-Payment Network is regarded as one of the key infrastructures to realize an electronic government in Japan. The network service was started in October 2001. The service was widened in January 2004 with government offices and municipal entities participating. 1,361 financial institutions participated as of July 2005 and 42 billing bodies participated as of October 2005.

**Postal Code System:** A code system to be added for each address of mail or parcel. Each code is allocated to some address area. Customers are requested to write postal codes as an appendage to addresses shown on mail. In Japan, a five-digit code system was first introduced in 1968 and a seven-digit code system was introduced in 1998. In the processing and delivery of mail, the postal code written on mail is read by a machine and automatically sorted according to the code. This system not only enables sorting mail quickly and speeding its delivery, but also makes it possible to reduce the cost of mail sorting.

**Postal Services:** Three services that the Japanese postal service organization has been providing for more than 100 years. These are postal service, namely mail and parcel delivering service, postal savings service, namely providing depositories and money transfer services and postal life insurance service, namely selling convenient life insurance policies and annuities. There are three separate branches in the head office but the most of the post offices deal with three services in a merged way.

**Reading and Sorting Machine:** A machine to be used in the postal code system. It can read the postal code and automatically sort mail according to the address. This machine is put into operation in the post offices with collection and delivery functions. ICTs are utilized in the development of this machine. This machine was originally developed and custom-made for the use of the Ministry of Posts and Telecommunications.

## INTRODUCTION

Various aspects of the Eastern European transition have been extensively researched over the past 15 years. Only recently, studies of democratization have begun to specifically recognize and reflect the context of the information age in which they are taking place. This claim particularly applies to the late and ongoing transitions in the Western Balkans along the new borders of Europe. The least researched aspect of their democratization refers to the modernization of their civil service, particularly through the lenses of the informatization (Frissen, Bekkers, Brussaard, Snellen, & Wolters, 1992) of their administrations and development of e-government as an important element of transparent governance. This is a gradual and uneven development, yet it initiates institutional change toward having friendlier administrations that were hardly conceived at the beginning of the transition.

## BACKGROUND

Recognizing the relevance of the external EU (European Union) framework in developing national e-government policies, this article departs from the question of how the informatization of administration affects late transitional societies in the building democratic governance. It specifically focuses on problems and actors' choices in pursuing domestic e-government policies in times of major strategic realignment from isolation to Euro-Atlantic integration: What explains the gap between aspirations, policy development, and implementation?

By definition, governments' pursuit of national information-society policies (NISPs) includes e-legislation, e-technologies, e-space, e-commerce and e-business, e-education and e-health, and last but not least e-government; it posits EU standards in the normative reforms of the candidate and aspirant states. NISPs build on technological, organizational, legal, and administrative innovations that profoundly change life in the spheres of work, politics and government, and society (Soete, 1996). We look at the case of Serbia and Montenegro because it exemplified a promising late starter among transitional countries in the region, but had experienced unforeseen problems along the way and failed to maintain the policy pace set by its neighbors. We also take Slovenia as a benchmarking success case as it is the only ex-Yugoslav country that became an EU member (in 2004) and achieved notable results in the building of the information society and functional electronic government. Many scholars think that information-society development in transitional societies positively contributes to the building of democratic governance and advancement toward consolidation because it enables the development of modernized, outward, transparent, and friendlier e-based administrations.

## ARGUMENT

This article argues that the state-led informatization of government may even slow down rather than accelerate the first stage of institutional development in late transitional societies because it increases the levels of transformational complexity. Investments in information society building may increase returns only if the top policy entrepreneurship is combined with deep techno-organizational overhaul of institutions, broad societal preparatory work, and the accumulation of the critical mass of new knowledge. Informatization rests on prior complex, vertical, and horizontal systemic and organizational change. This includes the most difficult aspects of soft reforms, that is, the strengthening of human capacity, serious learning, and attitudinal and cultural change. Such reforms cannot be fulfilled immediately after the breakdown of the old regime (particularly in competition with other state priorities). This is not linear, but a time-consuming, interchangeable process of substantive structural change where informatization creates cycles, stages, and instruments for the deepening of democracy and the advancement of citizen-centered governance.

## KEY EXPLANATORY FACTORS

a. External standards, internal contrasts: One country, two states
b. Regulatory framework: Complex requirements and leadership problems
c. Converging strategic areas: Public-administration reform, telecommunications reform, EU accession strategy, free access to public information
d. Paradoxes and missing points

## EXTERNAL STANDARDS, INTERNAL CONTRASTS

After more than a decade of wars, exclusion from virtually all international organizations, and the NATO (North Atlantic Treaty Organization) military intervention, Serbia and Montenegro became members of the South Eastern Europe Stability Pact (SEESP) and soon resumed the chairmanship of the Electronic SEE Initiative. Serbian envoys specifically lobbied to join this group. Europe was setting the pace of constant informational change, so its argument was that the Balkans (traditionally perceived as a turbulent region) cannot possibly reconnect and reduce the digital distance unless there was a mechanism that would allow institutional access to the activities the EU was undertaking. Through this electronic niche, a small group of national politicians of the new generation launched a spirit of genuine modernization and a sense of cooperation to this ever-troubling region. The comprehensive eSEE Agenda was adopted by all member states, and the goals and timelines were set. The agenda served as a mechanism to mirror the Lisbon documents and to transfer the activities undertaken by Europe (eEurope 2002, 2005; eEurope Plus Agenda and the G8 Okinawa Charter) on the Balkan non-member countries; they were to develop NISPs as basic platforms. However, 3 years later, all signatory countries developed such a document except Serbia. Why?

### One Country, Two States

Serbia and Montenegro are two federal units but technically two states; Serbia has over 10 million inhabitants while Montenegro has 620,000. With minimal joint functions and even different currencies, they lead separate policies in virtually all aspects of public life, including information-society development. In spite of the existence of the common international framework, eSEE, Serbia and Montenegro took separate paths in developing their NISPs. In the rush toward full state independence, Montenegro formally appeared more productive as it adopted its (lengthy) strategy in June 2004; however, subsequent normative work is stalled or duplicated, which is why controversies in Montenegrin ICT development call for a separate analysis. As an example, Montenegro could not automatically implement the Federal Law on Intellectual Property, but had to (re)write it as its own.

Serbia, which was perceived as a leader of the eSEE initiative, experienced a controversial development. Its late-reforming prime minister was the powerful motor force behind this experiment because he strongly believed that the e-based modernization of economy and society would pull Serbia out from the dark age and economic backwardness in a relatively short period of time. This is why no efforts were spared in this early period to put things in motion and get on information society tracks. This was a classical state-led, top-down initial push, with the presumption that the opening of the market with the basic positive regulation would take care of the rest. However, his tragic assassination in March 2003 interrupted this process and deeply destabilized the country. In this crisis, which led to early parliamentary elections and regime change, many of the reform processes were discontinued, while others, like informatization, lost priority. Only very recently, recognizing the country's international obligations, policy-development activities were revived with notable urgency. Public awareness about this is still very low and neglected.

## REGULATORY FRAMEWORK

Between 2000 and 2004, no single administrative law has been passed. Millions of donor money was spent and training was organized, but there were no results in the domain of adopted strategies, policies, and standards, let alone implementation. Some excellent drafts ended up on bureaucrats' shelves, while incidences of personal vanity got in the way of national informatization. It took the subsequent Serbian government another couple of years to start revisiting the national eSEE obligations and passing critical laws. Although the key strategic document, the National Strategy for Information Society Development, was planned for adoption by the end of 2005, it was long overdue and nowhere near adoption in mid-2006.

National action plans contained an extensive list of activities regarding the creation and implementation of legal infrastructures for IS in accordance with the Acquis Communitaire. This required the drafting and adoption of legislation on e-commerce and e-signatures, the ratification and implementation of conventions on cyber crime, and the protection of privacy and intellectual property rights by 2004's end. Ultimately, states were expected to establish benchmarking systems and national implementation mechanisms, starting with the formation of cabinet-level state bodies for the information society. For example, 3 years prior to entrance into the EU, Slovenia (in its capacity of the EU candidate) formed the Ministry for Information Society in 2001 to ensure leadership and policy coherence in this domain. Results were notable as next to Estonia, Slovenia was best rated among all candidate states (although its new government abolished the IS ministry). In Serbia and Montenegro, however, elites are still debating about the single best suitable institution for the national IS governance because the existing ones are inadequate and fragmented. Differences are more political than technical.

The primary research among policy actors shows their shared views on the key problems in getting the normative impediments out of the way: (a) the lack of institutional and human capacity of the state to lead and synchronize horizontal action in the areas of regulatory framing, (b) scarce resources and competing priorities (such as the Hague Tribunal and Kosovo) and the (temporary) loss of top political will to push for administrative modernization, and (c) the gap between the awareness of the few and the perception of the many. While some new statistics show that 20% of the population in Serbia used the Internet in 2005, other reports indicate that little has in fact changed singe 1997, when more than 40% of the population was functionally illiterate (i.e., have not finished elementary school) (Perazic & Belic, 1997). It is not just the issue of intrasocietal digital polarization; it is the mere ignorance and literacy divide. Poor access, meager population awareness, and poor (e-)literacy and democratic culture on the citizens' side, have to be addressed with the same attention as the administrative incapacity for significant e-development on the government side. This also suggests the soft areas in which policy attention should immediately concentrate if intentions about building information society are serious. Those are: modern primary and secondary education; specific administrative training, cheaper computers and access to high-speed Internet, and finally, general awareness raising. Without these groundworks, none of the high-policy promises made in the nice documents and laws make any sense and have no social value because the basis for their implementation is missing. As this preparatory work takes time, these points support the argument that informatization may slow down the process at this stage before the turnaround momentum of critical usage and exponential growth is reached.

## CONVERGING REFORM STRATEGIES

The *Public Administration Strategy* was one of the first official documents passed by the government of Serbia (in early 2005) that recognized the use of the Internet as the new medium that will enable citizens to directly access public information and interact with public offices (Ministry of Public Administration and Local Self Government of Serbia [MPSALG], 2006). The strategy rests on five principles: decentralization, depoliticization, professionalization, rationalization, and modernization; the latter is of immediate relevance to e-government development. The stated key objective of the public administration modernization is

*to enable citizens to exert influence on public life; this is envisaged through the introduction of information technologies into the work of public administration on both central and local levels. ICTs will enable full electronic accessibility of diversified services based on the principle of full transparency; this will also enable citizens to express publicly their attitudes towards the functioning of their public administration and carrying out of public assignments. Internet usage in this way, increases the role of (Serbian) public sector as a citizen-oriented service. The process of further democratization of the society is impossible without modernization and this is why these two sides must be carefully balanced and harmonized.*

This document recognizes the new reality of the information age in which the Serbian public sector promises to transform itself into a friendly e-based administration; however the implementation time span of 4 years (2004-2008) seems unrealistic given that the inherited administration is highly centralized, politicized, inward oriented, aloof, and perplexed. While the action plan seems very ambitious and focused on four main groups of activities—decentralization (four laws to be adopted by 2006), professionalization (10 laws and regulations in the pipeline), internal organization and modernization (assessment, change, electronization, and monitoring), and human resources management—the educational dimension seems inadequate. The reform period starts without a clearly designated educational center, academy, or institute that would be in charge for modern training and retraining. There are no updated, modern, standardized curricula, and what exists is donor driven and unsystematic. The PAR strategy recognizes this problem, but plans to form the training facility by 2006's end; this means that (in the ideal scenario) it could not be operational before 2007, which is too late for the pace envisaged by the strategic documents. Commonsense logic presumes a prior systematic production and employment of the new generation of professional and career civil servants so that they would constitute the input to the reform process, not the very last output.

The *Information Society Strategy* is one of the key converging documents that are still in preparation. Here, e-government is one of the areas in which rapid development is mandatory. In addition to special training for future e-literate professional civil servants, another critical element of the action plan is the enablement of online access to every school in Serbia. The fulfillment of this objective clearly requires coordination with reforms in the educational sector, which has not been systemically established as of yet. Currently, only universities and colleges in Serbia are connected to the Internet through the academic network, yet experts agree that for the exponential growth in the use of the Internet, it has to become accessible in every school. Montenegro has

already developed online access and a training plan for all 160 schools in that republic, and it is now working on the development of didactical software and teachers' training. The exponential growth in Slovenia, for example, happened when the first generations of ARNES (Scholarly and Academic Network) users matured and switched to the commercial use of the Internet for professional and other purposes outside the immediate educational realm. This was a huge leap in the number of users in Slovenia from 18% to 48% of the population in 4 years. The question is, could Serbia reach the same level of usage (nearly 50%) in a few years if it follows the same logic?

The *Telecommunications Strategy* is another crucial, yet missing document that should formulate the vision of the competitive telecommunications market in Serbia. How is this relevant for e-government? Without a strategic decision on the characteristics of the main government electronic network system, the creation and the functioning of integrated portals (particularly the standard delivery of e-government services with different levels of complexity) hasn't been possible. To avoid monopolization in the e-government affairs, Slovenia, for instance, developed the H-Kom, the state-managed network functional only for government purposes, not for commercial use. Another key element is the full coverage of the national territory with a digital signal, which is now only partially met (75% coverage; on related statistics, see Government of Serbia Statistical Office, 2006; *Internet World Stats*, 2006).

The *EU-Accession Strategy* was passed by the Serbian Parliament in early summer of 2005 as the first formal document that explicitly specifies the fields and the tasks on the country's way to EU membership. The first draft of this document had no word on e-government; only after the last minute intervention of experts and NGOs was this oversight corrected. Under the chapter on public-administration reform and modernization, this strategy now contains a section on the information society and e-government. From now on, it would be logical that these two groups of activities converge into an integral policy platform.

The Commissioner for Access to Public Information is a newly instituted, independent body that falls into the category of the keepers of democracy together with the Ombudsman. As it represents the instrument of public watch, it is an important institution that ensures the citizens' right to seek and obtain information from any government body that is financed with public money. This office was envisaged as the backbone of the future system of democratic governance, accessible (online and off-line), particularly minorities and underprivileged groups. Slovenia sees its commissioner as one of the most important information-society institutions and a powerful instrument of transparent democratic governance.

## PARADOXES

Judging by the normative and institutional dynamism, one would have to significantly lower information-society expectations in Serbia. This particularly refers to the Web-based contents and e-government services (G2G, G2B, and G2C) at all levels of complexity (information, interaction, transaction, and transformation). Between 2000 and 2005, most government institutions did develop Web sites. Business-to-business communication was, for instance, almost fully digitalized in 2003 (SMMRI, 2003). Also, around 30% of Serbian municipalities have developed partial e-services and continue to improve them and educate their staff through various decentralization programs supported by USAID, EAR, OSCE, and other donors (*Standing Conference on Towns and Municipalities of Serbia*). As a result, there is an incremental growth of G2C information and in some cases, interaction. There are hundreds of unsystematic, semi-interactive Web sites, growing in numbers as we move from top to bottom levels of government. Some of them offer open forums for citizens' comments to drafted laws (most of the republican ministerial sites), but the citizen's virtual engagement remains very low because of the still poor electronic awareness and computer literacy. Municipal governments sometimes provide electronic answers to citizen's inquiries in real time; however, this is an exception, not a standard. In most cases, services are still paper-based, off-line, and delivered by arrogant and incompetent staff, distant from the concept of the citizen-centered service. What can one make of this informational disorder?

Arguably, there is a positive side of the normative inertia: The state did not regulate the field because it fell short of the expertise, capacity, and techno-infrastructural means to do it; however, it did not prevent the donor-driven and homegrown bottom-up e-government activity that mushroomed in an attempt to modernize and upgrade the quality of the local life in Serbia. While there was no one to push the central government to get organized, there was no one to stop the local government from getting online. This is why there are e-government islands rather than a system. The number of domains doubled between 2003 and 2005 from 13,000 to 26,000. One could easily criticize the contents and the layouts of those Web sites because they are unsystematic and not very user friendly. However, given the total lack of a regulatory framework, no systematic training, no governing body, no

clear policy that would give direction in this field, and poor funding, it is a true miracle that even this quantum of content and service exists.

## MISSING POINTS

Local experts think that e-government cannot technically function as long as the integrated information system of the republican governmental bodies is missing. It should normally comprise three basic databases on (a) citizens, (b) firms, and (c) spatial information. These three databases configure the information infrastructure of the Republic of Serbia and now exist separately. All necessary information for the one-stop-shop services could be composed based on these three core groups of data. Until then, citizens will continue to be exposed to endless repetitive and costly procedures rather than have the state do the search of its own database for the information it already possesses. In the case of Slovenian development, one-stop-shop electronic service was the direct outcome of the enactment of Article 139 of the law on general administrative procedures: An administrative office must not seek the information from the citizen if it hast he retrieval capacity and access to that information through the back-office. While the combination of new rules and technology in Slovenia results in sparing seekers of government services from unnecessary hassle, Serbian citizens do not see those benefits yet.

Secondly, the fragmentation of the political system limits the potential effects of informatization on the quality of policy and governance. Sectors are not horizontally linked, and there is no systemic obligation for ministries to cooperate on lower levels of the policy process. Thus, instead of information sharing and value adding to ideas and initiatives, a silo system prevails. Without synergy in this domain, the use of information as a resource is limited while informatization seems superficial and technical rather than substantive.

The third missing element is the lack of a comprehensive educational and training system. Such a system would rely on facilities (training centers) that would produce new generations of professional career civil servants and policy makers. The fourth missing point is the normative system that would sensibly detect anomalies and paradoxes, cut the red tape, and spare the citizens from front-desk harassment and humiliation, loss of time, and undue process. There is no person, office, or body in charge to draw a typology of anomalies and regulatory paradoxes—from systemic laws to the lowest procedures—and in this way the country cannot begin to undo this vicious circle. Last but not least, no systematic tracking or research of Internet use, users' profiles, and preferences exists on the national level. The 2002 census omitted the question about the number of PCs in households. Some subsequent surveys now measure that but are still sporadic, market driven, and often contain conflicting data.

## SOME CONCEPTUAL PERSPECTIVES

We argued that informatization can even slow down the state-led e-based modernization of government because of the complexity of preconditions; it also creates instruments and conditions for the deepening of democracy. Space limitation reduces the following conceptual analysis to two debate groups: governance and new public management (Pierre & Peters, 2000), and agency-structure-function discourse (Giddens, Pierson, &Thelen, 2000; Lichbach & Zuckermann, 1997; Mahoney & Rueschemeyer, 2005). The first group of debates deals with internal and external reasons of administrative change, while the agency-structure-function debate looks at the unintended outcomes and increased returns of institutional change. How do they explain our case?

In the past 25 years, transitional scholarship has gone a long way from emphasizing national factors (O'Donnell & Schmitter, 1986) to recognizing the unpredictability of external environments in which major political overhaul takes place (Schmitter, 1996). The turn of the millennium marked more sophisticated approaches to transitional subjects, particularly in understanding the dynamism of Fourth Wave democratization (Whitehead, 1996) and administrative changes in the former Eastern Block. Students of postcommunist societies (Baker, 2002) conclude that public service can in itself be an instrument for, and of, democracy. New features of administrations for a democratic kind of governance are the professionalism of civil service, modernization, and competence rather than hierarchical dismissiveness to citizen needs. Baker illuminates our discourse by arguing that Fourth Wave transitional problems coupled with EU enlargement opened the way to the information-age type of solutions. What are these solutions?

In the recent study on the revitalization of public service, Snellen (as cited in Peters & Savoie, 2000) argues that, in spite of all risks involved (invasion of privacy, service depersonalization, lack of access), ICTs are recognized as core technologies of the 21st century public administration. Fundamental changes in these technologies are pervasive and will have a revolutionizing influence on the structure and the functioning of modern public administrations. ICTs already impact big and small

issues: legal issues in which automation enables the integration of multiple aspects of policy creation (decision-support platforms) with computer-generated policy implementation (such as welfare state), and local ones, in which local political agenda is empowered by the decentralizing features of ICT networks. Finally, on the individual level, change refers to street-level bureaucrats whose role vis-à-vis citizens will be replaced by one-stop-shops government portals that integrate the front and back offices and provide life-event services.

The end of the 20th century marked a paradigm shift in the mainstream public-administration literature from dominantly inward-oriented structural functionalism (Heady, 2001) toward a citizen-centered governance discourse (citizen as a subject, not an object of administration). Peters and Pierre (1998) highlight this debate, which centers on the question, Does the state have the capacity to continue to govern as in the past? While the new public-management literature delegitimizes the state in favor of the private sector, governance literature (Anttiroiko, 2004; Pierre & Peters, 2000) treats the state as not entirely impotent. It loses the capacity for direct control but exerts more influence instead. The capacity of government to coordinate, negotiate, and bargain becomes critical. This interaction is more network-like than top-down; interdependence (central-local levels) replaces hierarchy, while citizens are viewed as both users and stakeholders, that is, active participants and coproducers in the policy process.

The case of Serbian administrative and informational reform shows the opposite trend: The state has not yet developed any capacity to share the political space, build genuine partnerships, and engage in the governance process. It does not demonstrate the substantive opening and changing of attitudes; citizens are not aware of their changing position, infrastructure development is unsystematic, and sporadic electronization does not automatically revolutionize procedures but rather reinforces the existing anomalies. Clearly, imported laws and good intentions alone cannot do much about gaining a friendlier administration. Thus, at present, we can discuss Serbian democratic and electronic governance only in hypothetical terms.

Structural functionalists (Giddens & Lukes, 2000) and new institutionalists (Mahoney, Pierson, & Thelen, 2000) deal with the dilemma of unpredicted outcomes that the process of historical change may bring. Pierson (2000) focuses on the institutional reproduction and increased returns that history brings, but others argue that factors responsible for the rise of the institution may not be the same that sustain it over time. Institutional development does not preclude increased returns; that is, the beginning does not necessarily predict the outcome. Indeed, in the Serbian case, the beginning was ambitious and pushed by the prime minister and his expert government; the interruption was unexpected and it eventually led to the reversal of internal processes. Political paralysis paired with the loss of leadership and the weakness of the ICT business sector caused the state's subsequent inaction in regulating e-space. Yet, it also kept the state from interfering in the homegrown electronization of local governance that proved to be a useful disengagement. In spite of the initial institutional design by the EU standards for information-society development, historical events and official inertia altered the early development.

## FUTURE TRENDS

Serbian policy planners gave 3 to 4 years of time to the state administration to modernize and transform into a professional public service. Yet, the training facility that would produce new public servants ready to resume new roles was still nowhere in sight in mid-2006; some initiatives to build a Western-Balkan regional administrative center or academy under the EU patronage came up, yet without details and firm timelines. Given that wider popular understanding of e-government and the democratic potential of the Internet ranges from modest to insignificant, 3 to 4 years seem unrealistic to generate organizational, attitudinal, and cultural changes on both sides. The Stabilization and Association negotiations began in October 2005, with some national political hopes oriented in that direction. However, without urgent steps toward modernization, robust awareness raising, explicit and visible leadership, and credible commitment from the highest ranks of government, the idea of e-Serbia may remain off-line for some time.

## CONCLUSION

The capacity to implement policies is a true measure of consolidated reforms in transitional societies. Thanks to EU standards and foreign donor assistance in Serbia and Montenegro, modern state strategies are being developed without modern institutions to carry them through. Yet, when it comes to the implementation of policies, quality documents are not enough. Research shows that in Serbia, the dominant current approach to informatization looks more like superficial automation than the comprehensive systemic reform that cuts across institutional boundaries and enables meaningful and systematic exchange of information. Existing inward practices are being replicated rather than revolutionized, while information as such is not treated as a democratic and policy-planning resource. Malina (as cited in Hague & Loader, 1999) argues that the use of ICTs to democratize the activities

of the state is an ideal. ICTs will serve the cause of democratization only if a prior will for strong democracy is established. This is a critical point that highlights the contrast between the earlier period in Serbia and Montenegro in which this kind of will was clearly established, and the subsequent era where such deep changes in the mentality of governance did not find powerful-enough internal political recognition and leadership support.

## KEY TERMS

**Consolidation:** This is a highly disputed concept that marks the end of the period of institutional instability in transition, and when democracy as a system of governance becomes safe from reversal. Linz and Stepan (1996) say that consolidation means that "democracy is the only game in town" and posit five criteria for measurement: developed civil society, political society, economic society (market), stateness, and the rule of law. Huntington's condition is the two turnover test, where there are two consecutive peaceful changes of democratically elected governments. Modern consolidated democracies increasingly build the sixth element information societies as technologically advanced modes of economic, political, and societal governance.

**Democratic Governance:** This is an advanced concept of democratic rule envisaged as an interactive relationship between state, society, and market, forwarded by the citizen-centered body of scholarship. Deep structural, organizational, administrative, and behavioral transformations make state and society interact more democratically through partnerships. Administrative definitions of governance (Peters & Pierre, 1998; Pierre & Peters, 2000) posit that the state loses the capacity for direct control but

exerts more influence instead. The capacity of government to coordinate, negotiate, and bargain becomes critical. This interaction is more network like than a top-down approach, and civil servants regain a long de-emphasized policy role. Their professionalism, attitudes, skills, and e-literacy become critical.

**Democratic Transition:** This is a complex process of regime change from authoritarianism and totalitarianism to democracy. The term democratic specifies the end toward which society and new institutions are developing, while transition refers to the movement or interval from one sociopolitical order to another. O'Donnell and Schmitter (1986) and Schmitter (1996) characterize it as a process of twists, turns, and paradoxes with high instability of institutions and overall governing conditions. The ongoing debate between structuralists and rationalists focuses on dominant driving forces of transition: Structuralists emphasize institutions as key determinants of change, while rationalists think that modern politics promotes agency as the equally important variable in shaping political outcomes. Thus far, technology has not been widely recognized as an equal force of democratic change.

**E-Governance:** While e-government focuses primarily on the provision of information and transaction-type service to citizens and businesses as customers, e-governance refers to the changing role of the citizen as a public actor and policy coproducer (Abramson & Morin, 2003). E-governance focuses on modernizing and transforming government to be able to engage in an innovative dialogue with citizens on policy and other open issues. It is growing into a backbone of democratic citizenship because it enables the individual to get mobilized and networked from home on selected priority issues, not necessarily someone else's agenda. In the 21st century, we witness a significant growth of e-government technology that will enable such advanced and complex interactions including e-voting. This concept may remain a techno-optimistic utopia in societies that work harder on infrastructural access than on the building of citizens' awareness and e-literacy. In some aspects, concepts of e-governance and information-society governance are increasingly converging.

**E-Government:** This is a concept of advanced organization and provision of government services based on the digital channels of communication and interaction between citizens, businesses, and state. It grew from the supply of Web-based information on government activities to highly complex transactions. Digital government does not automatically mean smart or friendly government. It only becomes such when policy makers become committed to the greater good of delivering better public services and information through digital or electronic means. The standard types of e-government services are G2G, G2B, and G2C; the levels of complexity differ from information and interaction to transaction and transformation. One-stop shops and life events are advanced services centered on the real needs of clients, customers, and citizens; their design is based on dominant demand patterns: building permits, emergency procedures, and the issuance of various documents and certificates. Here, the most important change is the 24-hour availability and accessibility of the self-service government with a single-window access point (Snellen, 1992; Vintar, Kunstelj, Decman, & Bercic, 2003).

**E-Government Measurement Criteria:** Europe's benchmarking criteria for e-government evolve and become more sophisticated rapidly (Electronic Intelligence Unit [EIU], 2004). They measure (a) connectivity, infrastructure, and Internet access; (b) the legal and business environment (laws that facilitate public- sector service delivery through electronic means); (c) educational skills (including e-specific); (d) government policy and vision; (e) the stage of e-democracy or e-governance, which is the employment of electronic means to promote public participation in governance; (f) the development of online service delivery for citizens and businesses; and (g) the existence of a functional cabinet-level governing institution.

**Friendly Administration:** Friendly administration serves the purpose of the participatory democracy. It is the motor force of democratic governance because it enables an advanced interaction of citizens and administration (which is presumably decentralized, professional, and modernized). Citizens are viewed as both users and stakeholders, that is, active participants and coproducers in the policy process; bureaucracy can no longer serve its own purpose, but has to transform into a competent and efficient service for the public. Legacies of authoritarian rule leave the heaviest heritage in administration. This is why the Fourth Wave transitional experience posits the reform of administrations as one of the critical preconditions for the overall democratization of society.

**Information Age:** According to some historians, the information age started with the discovery of print (Guttenberg); others argue that it began with the discovery of the telegraph (Samuel Morse in 1837) or the more advanced telephone (Bell) that marks the expansion of Western civilization since the 1850s. Most definitions, however, refer to the information revolution that erupted with the Internet. It is a term and concept applied to the period when the movement of information became faster than physical movement and culminated at the end of the

20th century. Information became not only a top commodity and a backbone of the knowledge-based economy, but an instrument of democratization and tremendous social change. In the last 10 years of global Internet use, the number of users went from 1 million to nearly 1 billion in 2005.

**Informational Policy Entrepreneurs:** Transitional politics in the information age opens space to new policy entrepreneurs. These people hold significant technomanagerial skills and ICT literacy, while being politically sophisticated and located close to power. They respond to the increasing demands for a more robust role of agency in national e-development because of the limited capacity of transitional structures to quickly adapt and manage complex internal and external changes. Rationalists define policy entrepreneurs as people (agents) who invest their resources in serious deliberation to push issues or "pet proposals" upward on the political agenda. They diffuse ideas as wide as possible to ensure widest visibility and are also responsible for pairing solutions to political problems (Kingdon, 1995). In postcommunist settings, informational entrepreneurs are very scarce and indispensable. They are either imported from the diaspora or temporarily supplied by donors to launch the process of rapid learning and attitudinal change. They meet fierce resistance from the parts of structure that will be most affected by modernization, professionalization, and rationalization.

**Information Society (IS):** European definitions view the information society as a society where low-cost information and transmission technologies are in general use. The use of information and data is accompanied by organizational, commercial, social, and legal innovations that will profoundly change life both in the world of work and in society generally (Soete, 1996). Progress in ITs and communications is changing the way we live, work, interact with government, and do business. Information (at the speed of light) is affecting the way people interact and is also requiring the traditional organizational structures including government to transform and be more flexible, participatory, and decentralized. In addition to e-government, the IS concept encompasses e-learning, e-health, e-legislation, e-business, e-infrastructure, and e-space.

**Informatization:** Economists view *informatization as the core transformative process of the information age, based on* the penetration of ICTs in all aspects of life and economy. Public-administration scholarship defines informatization as a set of complex developments, processes, and systems that affect public administration in a radical way (Frissen et al., 1992). It encompasses multiple elements: (a) the introduction of IT in shaping processes of automated information supply, (b) the (re)arrangement of flows of information for efficient supply, (c) the change of the organizational structure in which IT is introduced, (d) the development of specific information policy in organizations, and (e) the introduction of expertise and leadership in this field. The informatization of government is associated with four types of organizational rationality: political, legal, economic, and technoprofessional. Public administration is linked to all four types of rationality.

# Promoting Citizen Participation via Digital Government

## INTRODUCTION

The advent of digital government unveils new opportunities in how government can address citizens' needs and requirements in innovative ways. One of the growing citizens' demands toward government today is the participation in policy making. This is reflected in a recent Organisation for Economic Co-operation and Development (OECD) (2001) report entitled *Citizens as Partners*, which concludes that "governments are under pressure to adopt a new approach to policy making—one which places greater emphasis on citizen involvement both upstream and downstream to decision-making" (p. 71). Digital government, enabled by information and communication technology (ICT), may help government in addressing such needs of citizens through network-based ICT applications.

ICT, particularly the Internet, may enhance citizen participation in several ways: By offering capabilities that transcend time and space limitations, ICT has the potential to overcome barriers of large-scale citizen participation. One of these barriers is the difficulty to achieve the desired level of face-to-face interaction during off-line participation (e.g., public meeting) (Adams, 2004). In off-line participation, citizens need to take turns to voice their opinions within a limited time frame. This often results in poor deliberation, a situation where the consequences of various policy options and views of others are not weighed carefully and sufficiently (Mathews, 1994). The mass communication and information exchange capabilities afforded by the Internet may be especially useful in enhancing participation of citizens in policy deliberation.

Despite the potential of ICT to enhance participation, it is vital to motivate citizens to participate. It is ironic that, while citizens increasingly demand for more participation, studies reveal that citizen participation has been declining in recent years (e.g., Lyons & Alexander, 2000). The paradox suggests that there is a need to investigate the factors that can lead to participation of citizens in policy making. Toward this end, we begin with a review of extant literature from political science to identify pertinent theories that may help explain citizen participation. As citizen participation via digital government is enabled by ICT, we also explore pertinent ICT features that may support participation.

## BACKGROUND

Citizen participation has long been one of the major research themes in political science. Several theoretical perspectives have been devised to elucidate antecedents of citizen participation in the offline context. Among the three widely employed perspectives are socioeconomic theories, rational choice theories, and social capital theories. We will discuss these theories in turn, and attempt to illuminate the links among them.

### Socioeconomic Theories

Socioeconomic theories are at root a sociological account of citizen participation (Parry, Moyser, & Day, 1992). This theoretical strand attempts to explain participation in terms of the individual's socioeconomic characteristics that shape his or her attitude toward participation. These characteristics include the individual's age, education level, and financial status. The socioeconomic theories (e.g., Verba & Nie, 1972) hold that individuals who are older, better educated, and wealthier are more likely to participate than those who are younger, less educated, and poorer. The logic is that an individual's advantaged socioeconomic characteristics would shape his favorable civic attitudes toward participation (Verba & Nie, 1972). While initial thinking along this perspective held that individuals with advantaged socioeconomic characteristics are more likely to participate, subsequent research questioned such propositions and the mechanisms behind the effects of socioeconomic factors (Verba, Schlozman, & Brady, 1995). Past studies have also shown that the general rise in education level does not necessar-

ily lead to increased electoral participation (e.g., Lyons & Alexander, 2000). These limitations have led to refinements in socioeconomic theories in terms of including a more comprehensive set of participation factors and the mechanisms linking individual's socioeconomic characteristics to participation.

Along this vein, Verba, Schlozman, and Brady (1995) developed the civic voluntarism model, which aims to specify "in detail how socio-economic position is linked to political activity" (p. 19). Cited as the most widely employed participation theory (Seyd, Whiteley, & Pattie, 2001), the model considers resources, motivations, and mobilization as antecedents of participation. Resources that include time, money, and civic skills bridge the individual's socioeconomic characteristics to their participation. In other words, individuals with better socioeconomic characteristics are more likely to participate because they possess the resources to do so. Motivations are conceptualized as individual and group incentives as well as a sense of political efficacy (Verba et al., 1995). Individual incentives include the ability to influence specific policies that an individual would like to see implemented, whereas group incentives include an individual's identification with a group (e.g., political party). Last, mobilization refers to the extent to which individuals are influenced by people around them to participate. Citizens may be persuaded by their friends or family members to, say, sign a petition or join a political party. Civic voluntarism model has been found to be considerably robust in explaining different types of political participation (e.g., voting, contacting authorities, and attending political meetings) (e.g., Pattie, Seyd, & Whiteley, 2003; Verba, Schlozman, & Brady, 1995). However, a limitation of the model is that it does not specify clearly the political institutions that may shape citizen participation (Rubenson, 2000). For instance, it may be useful to know whether existing political institutions support the formation of civic associations that generate mobilization, or whether there is an education system in place that promotes civic skills inculcation.

## Rational Choice Theories

Rational choice theories of participation see citizen participation as a rational activity to maximize benefits and minimize costs of participation (e.g., Olson, 1965). They propose that individuals are by nature economically rational actors, who base their decision to participate on cost–benefit calculation (Pattie, Seyd, & Whiteley, 2003). Benefits from participation include the ability to influence policy outcomes, whereas costs include the effort and financial resources required to participate. Additionally, the perceived benefits from participation are closely tied to one's political efficacy. In contrast to the socioeconomic perspective, rational choice theories consider the broad civic orientation of individuals of minor importance when compared to the benefits and costs of participation.

Rational choice theories have been criticized for not being able to explain electoral participation. In an election where many actors are involved, the likely influence that an individual has on the outcome, and thus the potential benefit, is extremely small. Considering the cost required to vote (e.g., time and effort), a truly rational actor may choose not to vote. However, we do see people participating in elections. Explanations have been offered in terms of the sufficiently low cost of voting (e.g., Verba, Schlozman, & Brady, 1995) that renders rational cost-benefit calculation unnecessary (Aldrich, 1993). This suggests that rational choice theories may be more appropriate for situations of participation where high potential benefits and costs are involved.

Arguing that the benefits for participation are too narrowly conceptualized in traditional rational choice theories, Seyd and Whiteley (2002) developed a general incentives model that incorporates incentives related to altruistic concerns and social norms. The resulting general incentives model encompasses five incentive types for participation: collective, selective, group, expressive, and social norms-derived incentives. Collective incentives are derived from policy goals that are available for all to enjoy regardless of whether one participates (e.g., tax reduction). This is in contrast to selective incentives that are restricted to participants, which include the gratification obtained during the participating process (e.g., enjoying interactions with others) and the privatized outcomes from participation (e.g., political career advancement). Selective incentives also include ideological incentives prompted by similar beliefs shared by members in a group. Group incentives and expressive incentives are related to individuals' attachment to a group (e.g., political party). Group incentives have to do with individuals' perception about the efficacy of the group as a whole to bring about desired social change, whereas expressive incentives are grounded in a sense of loyalty and affection to the group. Finally, social norms-derived incentives refer to the influence of other people on the individual's willingness to participate, and are similar to the concept of mobilization in the civic voluntarism model. The drawback of the general incentive model is that it does not consider the socioeconomic characteristics of an individual (e.g., education received) that shape the individual's civic attitude and skills toward politics. Another limitation of the model is its lack of consideration of the influence of political institutions on citizen participation.

## Social Capital Theories

Social capital theories (Coleman, 1988) are adapted to explain citizen participation from a social network perspective. This line of theories examines how network of ties and its features influence citizen participation. This signifies a departure from socioeconomic theories and rational choice theories whose focus is on individual-level antecedents of participation. One of the most widely cited works from this perspective is Putnam's (1993) study of Italian regional government.

The core concept of the theory, that is, social capital, refers to the connections among individuals that form networks of civic engagement, and the resulting norms of reciprocity and trust arising from the networks (Putnam, 1993). Social capital is intimately rooted in the associational life that exists within a community. Associational life is an outcome of civic engagement, or people's connection with the life of their community (Putnam, 1993). Instances of association life are having membership in hobby groups, neighborhood amenities, and charitable organizations. The main premise of this perspective is that a community with a rich associational life has a distinct advantage over a community with an impoverished associational life. As Putnam (1993) explains, "Civic associations contribute to the effectiveness and stability of democratic government … both because of their 'internal' effects on individual members and because of their 'external' effects on the wider policy. Internally, associations instill in their members habits of co-operation, solidarity and public spiritedness. … Externally … a dense network of secondary associations both embodies and contributes to effective social collaboration" (pp. 89-90). Features of social capital (norms of reciprocity and trust) also "reduce incentives to defect, reduce uncertainty, and provide models for future co-operation" (Putnam, 1993, p. 177). The existence of social capital, thus, may provide an environment favorable for citizen participation.

The social capital line of theories applied toward citizen participation has been criticized to suffer from tautological problems (e.g., Milner, 2002). It has been argued that the main factor posited to contribute to social capital production, that is, associational life, is also considered to be the socially desirable outcome of social capital. However, it should be noted that the associational life that contributes to social capital is nonpolitical in nature (e.g., citizen's taking part in hobby groups), whereas the favorable outcome is the political participation of citizens (e.g., voting). Since the direction of causality is from nonpolitical to political social capital, it does not constitute a serious tautological problem. Another criticism is that the theory does not consider the influence of individual's motives on participation (e.g., the benefits that one may obtain from participation). Even in the presence of social capital, individuals' intention to participate may be undermined if there is no attractive benefit to do so. Therefore, a combination of the different theoretical perspectives is likely to address the limitations of a single perspective.

## ICT and Citizen Participation

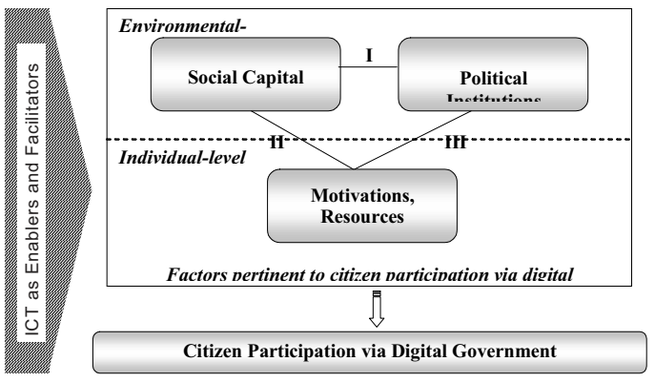
Political scientist Benjamin Barber (1998) claims that the most important question for future democracy is the meeting of ICT and democracy. ICT may support information and communication aspects that are both important to citizen participation. Citizens need various types of information in order to take active part in democratic processes (Wolfinger & Rosenstone, 1980). Through communication, citizens can broaden their understanding of a political issue by exchanging information, views, and feelings with other citizens (Gross, 2002).

Two ICT features may be particularly pertinent in supporting the information and communication aspects of citizen participation: communality and connectivity. Communality refers to the availability of a commonly accessible pool of information enabled by ICT (e.g., online forum) to all participants (Fulk, Flanagin, Kalman, Monge, & Ryan, 1996). Connectivity is the ability of ICT that enables individuals who share common goals and interests to easily communicate with each other (Fulk et al., 1996; Kumar & Benbasat, 2002). Previous literature has indicated connectivity and communality as two features of ICT that are germane in the context of collective action (Fulk et al., 1996). Communality helps to build up repositories of information that facilitate participant's access to relevant information. It also supports information exchange activities among participants that are vital to achieving policy deliberation. Connectivity, on the other hand, helps enable two-way communication between participants. ICT such as online forums and online chat record text messages posted in structured format along with the message poster. This allows individuals to easily identify other participants with similar goals and interests by directly observing their messages posted and responding to them.

# TOWARD A UNIFIED VIEW

An in-depth assessment of the off-line participation theories reveals the commonalities that they share as well as their complementary relationships, in that each of the theories is strong in certain aspects but lacking in others. An attempt at synthesizing the theories led to the identification of three classes of factors pertinent to citizen participation: motivations, resources, and social

*Figure 1. Framework of factors pertinent to citizen participation via digital government*



capital. The review of the theories also points to the need to consider political institutions. Figure 1 depicts our framework that integrates factors pertinent to citizen participation via digital government. Additionally, the framework also includes features of ICT as enablers and facilitators of citizen participation.

At the individual level, citizen participation may be determined by whether there are motivations for individuals to participate. These motivations are derived from the general incentives model and civic voluntarism model, and include collective, selective, group, expressive, mobilization/social norms-derived incentives, and a sense of political efficacy. Another class of individual-level antecedents to citizen participation is the resources possessed by individuals to participate. These factors are derived from the civic voluntarism model and consist of time, money, and civic skills. Beyond the individual-level factors, social capital and political institutions may also play a part in influencing citizen participation via digital government. Both classes of factors function at the environmental level. Social capital consists of networks of civic engagement, and norms of reciprocity and trust that exist in the community, whereas political institutions serve as the settings where political participation takes place.

The individual-level, social capital, and political institutions factors operate together to influence participation (Figure 1: links I, II, III). Political institutions that are supportive of civic association formation may encourage the development of strong networks of civic engagement (Figure 1: link I). A community with strong networks of civic engagement, where citizens actively participate in civic associations, exposes citizens to more political cues and opportunities (Rosenstone & Hansen, 1993). This makes them more likely targets of mobilization to participate (individual-level factor) (Figure 1: link II). Further, political institutions with an education system in place that promotes the shaping of individual's organizational and communications abilities may also help develop citizen's civic skills (another individual-level factor) (Rubenson, 2000) (Figure 1: link III).

## FUTURE TRENDS AND CONCLUSION

This article provides readers an integrative framework of factors that are pertinent to citizen participation via digital government. Features of ICT that may be particularly relevant to participation are also highlighted. The resulting framework (Figure 1) implies that future efforts to promote citizen participation via digital government should adopt a more holistic approach that takes into consideration the joint effects of individual-level factors (motivations, resources), environmental-level factors (social capital, political institutions), and ICT features on citizen participation. Accordingly, implementation strategies should be crafted in such a way that the different factors are carefully designed to attain citizen participation in a coherent manner, while exploiting the relevant features of ICT.

Some efforts are already headed in this direction. One notable example is community electronic networks, which provide citizens of a community (e.g., town, region) access to technologies (Internet, electronic mail, etc.), government information and contact of government officials, community services, and community-oriented discussion (Sullivan, Borgida, Jackson, Riedel, Oxendine, & Gangl, 2002). A well-known example of a community electronic network is Santa Monica's Public Electronic Network (PEN), which aims to promote citizens' access to technologies and foster a sense of community within Santa

Monica. In terms of political institutions, community electronic networks signify government's commitment to support and encourage civic activities with the help of ICT. Community electronic networks may also help in the development of social capital (Blanchard & Horan, 1998) through providing citizens an additional channel to interact with other members in the community.

Community electronic networks can be integrated into digital government efforts to create favorable conditions for citizen participation. Based on our framework (Figure 1), future efforts should exploit the positive impacts of community electronic networks (e.g., signification of supportive political institutions to citizens and increased social capital) by linking them more closely to the individual-level antecedents of participation. For instance, the community electronic network can serve as a platform to inculcate civic skills and generate mobilization of participation to citizens. ICT that offer connectivity and communality features (e.g., online forums) should be more fully tapped on to provide citizens with easier access to participation information and improve two-way communication for policy deliberation (Kumar & Vragov, 2005). Further, formal procedures for incorporating citizen's input into policy outcomes should be established to enhance attractiveness of participation incentives for citizens. Overall, our work serves to inform both theory and practice of how citizen participation via digital government can be enhanced.

## KEY TERMS

**Civic Skill:** Individual's organizational and communications abilities that can facilitate his or her political activities.

**Collective Incentives:** Incentives derived from policy goals that are available for all to enjoy regardless of whether one participates.

**Communality:** The availability of a commonly accessible pool of information enabled by ICT to all participants.

**Connectivity:** Ability of ICT that enables individuals who share common goals and interests to easily communicate with each other.

**Expressive Incentives:** Incentives that are grounded in individual's sense of loyalty and affection to a group.

**Group Incentives:** Incentives prompted by individual's perception about the efficacy of a group as a whole to bring about desired social change.

**Political Efficacy:** Individual's perception that political change is possible, and that the individual citizen can play a part in bringing about this change.

**Political Institutions:** The settings where political participation takes place.

**Selective Incentives:** Incentives restricted to participants that include gratification obtained during the participating process, privatized outcomes from participation, and ideological incentives prompted by similar beliefs shared by members in a group.

**Social Capital:** Relational resources having to do with connections among individuals that form networks of civic engagement, and the resulting norms of reciprocity and trust arising from the networks.

**Social Norms-Derived Incentives:** Incentives for individual to conform to the influence of other people to participate.

# Protecting Citizen Privacy in Digital Government

**Jerker Danielsson**
*Norsk Regnesentral—Norwegian Computing Center, Norway*

## INTRODUCTION

Protecting the privacy of citizens is a critical issue in digital government services. The right to privacy is widely recognized as a fundamental human right, as stated in Article 12 of the Universal Declaration of Human Rights (United Nations, 1948). The first definition of *privacy* was given by American lawyers Warren and Brandeis (1890), who defined it as "the right to be let alone." However, the right to privacy has been recognized for millenniums. The Hippocratic oath (n.d.) dates back to around 400 B.C. and instructs medical doctors to respect the privacy of their patients.

During the last three decades, many countries have passed privacy legislation, the Swedish Data Act from 1973 being the first national privacy act in the world. During the 1970s, many countries adopted data protection acts (Fischer-Hübner, 2001). In 1980, OECD published its privacy guidelines with the purpose of reducing the potential privacy problems incurred by cross-border trade (OECD, 1980). The European Council adopted Directive 95/46/EC in 1995, and all member states are required to implement national privacy legislation in compliance with this directive (European Union (EU) Directive 95/46/EC, 1995).

Privacy is under increasing pressure in the digital age, and the introduction of digital government services may escalate this development. The way government has been organized until now, with separate departments with their own "silos" of personal data, has inherently provided some privacy protection. In such a distributed environment data matching is expensive and resource consuming. This form of privacy protection is referred to as "practical obscurity" in Crompton (2004, p.12). Some examples of threats to privacy related to the development of digital government are as follows:

- Data collection capabilities increase as new technology for continuous and automatic data collection is introduced. Examples of such technologies include digital video surveillance, biometric identification and radio frequency identification (RFID).
- Data processing capabilities are rapidly increasing. The very existence of large amounts of stored personal data, together with the availability of sophisticated tools for analysis, increases the probability for misuse of data.
- There is a trend towards integration of formerly separated governmental services, including physical offices. Providing a single point of contact is more user friendly, but it may also provide an attacker with a single point of attack.
- Outsourcing of services (e.g., customer relationship management) is increasingly popular both among companies and governmental organizations. Those who deliver such services to many customers have a unique opportunity to gather personal information from many different sources. If services are outsourced across country borders, and perhaps in several layers, responsibilities soon become unclear.
- Even if the organization responsible for stored personal information does not have malicious intents, one cannot expect all its employees to be equally trustworthy. Disloyal employees are a severe threat when increasing amounts of information are stored.
- Tax records and other public records made available on the Internet enable efficient searches and aggregation of information about individuals. Identity thefts and fraud are common uses of information gathered in this way.

## BACKGROUND

Several aspects to privacy exist. Rosenberg (1992) identifies three: territorial privacy, privacy of the person and informational privacy. The main concern in digital government is *informational privacy*, which encompasses the control of collection, storage, processing and dis-

semination of personal data. *Personal data* is defined in EU Directive 95/46/EC (1995) as any information relating to an identified or identifiable natural person, referred to as the *data subject*.

One way to protect privacy is to focus on the individual and give each citizen tools to prevent personal data from spreading. Numerous services exist, for example, for anonymous surfing and e-mailing, and technologies for cookie management and encryption of communications. Such technologies, which give people a way to take direct control over their privacy, are important and their use should be supported whenever possible.

In the context of digital government, we choose to focus on organizations—in particular, governmental organizations—and how these can protect the privacy of the citizens whose data they process. That is, regardless of whether the individual chooses to use such technology as mentioned above to take control of his or her own privacy, how can organizations provide protection of citizen privacy?

Many government organizations have a legitimate need for collecting and using personal data in the provision of services. The right to privacy must, of course, be balanced against other rights and duties in society, but even so, governmental organizations should have a strong interest in protecting the privacy of citizens. The cost savings expected from introduction of digital government will not be realized unless a sufficient amount of citizens start using the new services, but citizens are less likely to start using new services that are not regarded socially acceptable. New services must, as a minimum, comply with legislation, but should also address the perceived threats they impose to be socially accepted.

To understand what privacy is really all about, one may start by studying the privacy principles that form the basis of modern privacy legislation in the EU member states and many other countries. In legislation, there are, of course, many exceptions to the general principles, but the intention of the legislation is to follow these principles to the extent possible. Table 1 discusses what in our opinion are the most important privacy principles.

An important issue in a discussion of privacy is against whom you need to protect the data. Against outsiders—that is, hackers and other attackers—you will use traditional information security measures. But insiders also constitute a serious threat. Insiders are employees or others with legal access to the systems who might use their access rights to misuse personal data, either on purpose or because they do not know better. Against this insider threat you need solutions to ensure enforcement of the privacy principles described in Table 1.

## PROTECTING CITIZEN PRIVACY

Government organizations need to take a structured approach in protecting the privacy of the citizens they serve. It is important to base one's actions on rational grounds. The converse approach—that is, ad-hoc collection and use of personal data—represents a severe threat to privacy.

*Table 1. Privacy principles*

| |
|---|
| • **Personal data should not be used for other purposes than those the data was collected for.** That is, the purpose of use of the data should be specified at the time of collection and should only be changed if the data subject consents. Enforcement of this principle is a major challenge, since common systems for access control do not take into account such properties as purpose and consent.<br>• **The amount of personal data collected and stored should be minimized.** Organizations should not collect more personal data than really necessary for the purpose and should delete data that are no longer necessary. In addition, they should, to the extent possible, reduce the identifiability of data; for example, by using pseudonyms.<br>• **The individual should be in control of his or her own privacy.** That is, he or she should be empowered to decide what is an adequate level of privacy weighed against the services he or she can get. Consent from the data subject is required if the law does not explicitly allow the data processing and, even more importantly, the data subject has a right to withdraw such consent at any time. Individuals have a right to be informed of which personal data exists, which purposes it is used for, who it may be transferred to and how it is secured. In addition, data subjects should have the possibility to demand correction or deletion of personal data.<br>• **Collectors and users of personal data are responsible for data quality.** That is, they have an obligation to ensure that the data is correct, up to date, complete and relevant for the purpose. Further, if errors are detected, they should take the steps necessary to minimize the damages caused for the data subjects—for instance, by distribution of incorrect information to others.<br>• **Adequate information security is a prerequisite.** An organization needs good technical solutions and operational routines to maintain security. In addition, an organization that transfers personal data to third parties must make sure that the receiver also has an adequate level of data protection. |

It is important that each government organization analyzes its need for personal data and the risks associated with their processing, so that adequate controls can be put into place to ensure a high level of privacy to citizens. A one-size-fits-all approach is not feasible, since organizations have different needs and risks associated with their processing of personal data.

An adequate level of information security forms the basis, but government organizations should take a number of additional steps to ensure proper privacy protection. These steps are addressed in the following subsections. Note that these steps are not necessarily conducted one after the other. Indeed, one would expect them to be carried out iteratively and often simultaneously.

## ANALYSIS OF DATA NEEDS AND PRIVACY RISKS

The first step is to analyze the organization's need for collecting personal data by answering the question of which personal data is needed for different purposes: in the provision of services, to comply with legislation and to ensure accountability.

Personal data collected merely to comply with legislation or to ensure accountability, and which are not needed to provide services to citizens, should never be accessed under normal circumstances. The need for personal data in day-to-day service provision should be further detailed by analyzing the needs of different users and by assessing the possibilities for using pseudonyms or less granular data. Ideally, users should not have access to more identifying data than is strictly necessary for the task at hand. One may, for instance, assess whether it is actually necessary for a user to know the identity, address or exact birth date of the person whose application or case is being treated. If not, one should deny access to such identifying data, or the data should be replaced with a pseudonym or less exact data; for example, birth year instead of full birth date.

The concept of pseudonymity is defined in Hansen and Pfitzmann (2005). Replacing a person's identity with a pseudonym enables linking of personal information in the domain where the pseudonym is valid without revealing the person's true identity. A person can be associated with many pseudonyms used in different domains. If the same pseudonym is used in too many domains, it may lose its value, because it might become possible to infer the true identity it corresponds to.

After analyzing data collection and usage practices, government organizations should analyze the risks of misuse associated with their collection and use of personal data. Examples of threats that may constitute risk include, among others, illicit profiling, disclosure of personal data to third parties and illicit access to personal data of known persons.

Privacy risk analysis is a special branch of the risk analysis field, and one that has drawn little attention so far in the research community. One exception is Zuccato (2003), who discusses the problem of measuring the value of information assets in privacy risk analysis.

The identified risks can be mitigated both by technological and procedural means. In this context, we focus mainly on technological means. In the next sections we discuss how privacy risks can be mitigated by designing countermeasures into applications and system infrastructure.

## DESIGN FOR PRIVACY

Designing for privacy encompasses the application of privacy-enhancing technologies (PETs) to address privacy requirements in system design. Privacy requirements arise from the need to mitigate identified privacy risks and to provide system support for ensuring that users do not have access to more data than is strictly necessary for the task at hand.

Privacy concerns should be addressed early in the system development process. A lesson can be learned from the security field, where it has been proven over time that security cannot be bolted onto an information system as an afterthought; it must be designed into it.

Government organizations should plan to move incrementally towards an information technology system consisting of applications and infrastructure integrating PETs while taking the installed base of legacy systems into consideration. To support this migration, organizations will benefit from establishing privacy functionality or services in their system infrastructure. Examples of such functionality are data quality assurance functionality, inventory systems for managing the personal data stored by the organization, systems that give access for data subjects to information about the personal data stored, privacy aware access control and audit tools (Arnesen & Danielsson, 2003).

As stated above, design for privacy encompasses the application of PETs, such as pseudonyms and pseudo domains (Hes & Borking, 2000), configurable granularity, client-controlled data (Wayner, 2004) and so forth, in system design.

Pseudo domains as a means to protect privacy have been proposed by Hes and Borking (2000). In each pseudo domain a data subject is identified by a unique pseudonym. Pseudo domains are motivated by the fact that some functions in an organization may not need to

have knowledge of information that directly identifies data subjects, typically the data subject's name or identity number. Some work can equally well be carried out when data subjects are identified by pseudonyms. Additionally, different functions can be provided with different pseudonyms for the same data subject, preventing unauthorized linking and matching of information.

Configurable granularity refers to system support for granting users access to different levels of granularity of personal data based on their need. For example, one user may need (and therefore, have access to) the full address, while another user may only need (and have access to) the postcode of the applicant while processing an application.

Client-controlled data refers to client-encrypted personal data where the client is in sole control of the encryption key. This technique can also be used to let the user of a service control the linkage between pseudonym and identity (Wayner, 2004).

Several projects have explored implementation of privacy in specific contexts. PISA[1] is one such example, exploring the use of PETs in the context of intelligent software agents, and Yu and Cysneiros (2002) discuss how to design for privacy and other competing requirements in multi-agent systems.

## POLICY SPECIFICATION

The privacy policy of an organization documents how personal data should be used by the organization, including who has access to which data and under what circumstances, and for how long personal data is retained before being deleted, or made anonymous and aggregated for further use as statistics.

The privacy policy of an organization reflects the maturity level of its data protection practices. At the first level, the privacy policy of the organization focuses on compliance with applicable data protection legislation, but the organization does not put much effort into analyzing its need for collecting and using personal data. At the second level, the organization has analyzed its need for personal data and enacted a policy it can enforce and that takes the need into account. In analyzing its need, the organization has also formulated a privacy goal/vision that it aspires to gradually move towards as it replaces its legacy systems with new privacy enhanced systems. At the third and last level, the organization allows its customers influence on which personal data are collected and how they are used.

Organizations should assure themselves that their collection and use of personal data is compliant with applicable data protection legislation. Some work has been done on assessment of privacy impact and compliance with privacy legislation. The Canadian Privacy Impact Assessment guidelines (Treasury Board of Canada Secretariat, 2002) and the Dutch Privacy Audit Framework (The Dutch Data Protection Authority, 2001) are notable examples of such work. They both provide means to identify weaknesses in the target system with relation to privacy legislation compliance. Furthermore, the EU project GUIDES[2] has produced guidelines to the EU privacy directive for e-businesses (GUIDES, 2002). The guidelines elucidate the legislation and give examples and best practices on how to ensure compliance with the legislation.

The privacy policy should be communicated both externally and internally; externally it works as a promise and internally it works as a basis for enforcement.

Examples of policy languages are Enterprise Privacy Authorization Language (EPAL) (Ashley, Hada, Karjoth, Powers & Schunter, 2003) and Platform for Privacy Preferences (P3P) (Cranor, Langheinrich, Marchiori, Presler-Marshall & Reagle, 2002). The policy may leave room for defining customer-specific policy rules based on each customer's preferences. A P3P Preference Exchange Language (APPEL) is a language for specifying personal preferences (Cranor, Langheinrich & Marchiori, 2002).

A prerequisite for enforceable privacy policies is the existence of ontologies or vocabularies that describe data categories, user roles, purposes of data access, conditions and obligations in a machine-understandable form. These vocabularies may be local or domain specific; for example, the health sector may adopt a common domain-specific vocabulary.

## ENFORCEMENT OF PRIVACY POLICY

Enforcement of privacy policy may encompass, among others, providing data subjects access to information about the data stored about them, ensuring data quality and that retention times are upheld, and controlling that personal data is only accessed in compliance with the privacy policy. A privacy policy may be breached both as an effect of acts with malicious intent and carelessness. Awareness building is important to limit carelessness by insiders. In many cases, technology can be used to provide automated enforcement.

Data quality can be ensured in many ways; for instance, by validating input according to defined rules, checking the data against other available registers or by encouraging the individual data subjects to access the information stored about themselves and making it easy to correct errors.

Another area where technology can be used is in controlling access to personal data. Organizations make a promise when collecting personal data. They have an obligation to see that the promise is upheld and personal data is not misused. Hence, the decision to allow access to personal data should not be up to the discretion of users. Instead, control of access to personal data should be mandatory, not discretionary. Access control should ensure, among others, that personal data is only accessed for the purposes that the data subject has consented to and ensure that any obligations incurred through the use of data are executed. An example of such an obligation is notifying the data subject of data access. Access control solutions are also necessary if fine-grained individual preferences are to be taken into account.

In addition to access control, technology support and processes for audit are important to detect privacy violations. Audit provides a safety net in case other security mechanisms fail. Audit is necessary to detect misuse through false statements of the purpose of data processing. Manual routines for inspection of logs, or more or less automated detection of privacy breaches through special privacy violation detectors should be implemented. In addition to an internal audit, enabling citizens to make extensive use of their right to information about their stored personal data and its usage may prove a powerful tool for control, as well as quality assurance and trust building.

## CONCLUSION

Government organizations should take a structured approach in protecting the privacy of citizens. Here we have given an outline of a number of steps that organizations should go through to facilitate this aim. In short, organizations should analyze their current collection and usage of personal data and evaluate the types and amount of data collected and used, whether the collection is "needed and worth it" and whether pseudonymized data or less granular data is sufficient. Additionally, organizations should analyze the risks of misuse associated with their data collection and usage practices. Furthermore, organizations should design for privacy. That is, they should incorporate PETs in their applications and system infrastructure. Finally, organizations should document their usage of personal data in a privacy policy and this policy should be enforced.

Government organizations have a moral responsibility to protect the privacy of citizens. An insufficient focus on privacy followed by a perceived erosion of privacy may result in an aversion among citizens to use new digital services and, as an end result, affect the legitimacy of government organizations. To hinder this development, it is important to take a proactive approach to privacy protection.

## KEY TERMS

**Anonymity:** The state of being not identifiable within a set of subjects (Hansen & Pfitzmann, 2005).

**Data Subject:** The person to whom personal data pertains.

**Personal Data:** Any information relating to an identified or identifiable natural person (EU Directive 95/46/EC, 1995).

**Privacy-Enhancing Technologies (PET):** Technologies for protecting or facilitating the protection of personal data.

**Privacy Policy:** The privacy policy of an organization documents how personal data should be used by the organization, including who has access to which data and under what circumstances, and for how long personal data is retained before being deleted or made anonymous and aggregated for further use as statistics.

**Pseudo Domain:** A domain in which data subjects are identified by unique pseudonyms.

**Pseudonym:** An identifier of a person other than the person's true identity.

# A Prototype Study on Electronic Rulemaking

**Gloria T. Lau**
*Stanford University, USA*

**Kincho H. Law**
*Stanford University, USA*

## INTRODUCTION

The making of government regulations represents an important communication between the government and citizens. During the process of rulemaking, government agencies are required to inform and to invite the public to review the proposed rules. Interested and affected citizens participate by submitting comments accordingly. Electronic rulemaking, or e-rulemaking in short, redefines this process of rule drafting and commenting to effectively involve the public in the making of regulations. The goal of the e-rulemaking initiative is to integrate agency operations and technology investments; for instance, the electronic media, such as the Internet, is used as the means to provide a better environment for the public to comment on proposed rules and regulations. Based on the review of the received public comments, government agencies revise the proposed rules.

With the proliferation of the Internet, it becomes a growing problem for government agencies to handle the comments submitted by the public. Large amounts of electronic data (i.e., the public comments) are easily generated, and they need to be reviewed and analyzed along with the drafted rules. As such, part of e-rulemaking involves a non-trivial task of sorting through a massive volume of electronically submitted textual comments. For example, the Federal Register (2003) documented a recent case where the U.S. Alcohol and Tobacco Tax and Trade Bureau (TTB) received over 14,000 comments in seven months, majority of which are e-mails, on a flavored malt beverages proposal. The call for public comments by the TTB included the following statement:

*All comments posted on our Web site will show the name of the commenter but will not show street addresses, telephone numbers, or e-mail addresses.* (2003, p. 67388)

However, due to the "unusually large number of comments received," the Bureau announced later that it is difficult to remove all street addresses, telephone numbers, and e-mail addresses "in a timely manner" (2003, p. 67388). Instead, concerned individuals are asked to submit a request for removal of address information as opposed to the original statement posted in the call for comments. The example shows that an effortless electronic comment submission process has turned into a huge data processing problem for government agencies. Fortunately, the advance in information and communication technology (ICT) can help alleviate some of the barriers in e-rulemaking. This article will discuss a prototype of a comment analysis system, which classifies public comments according to related provisions in the drafted regulations. The automated relatedness analysis system can potentially save rule makers significant amount of time in reviewing public comments in regard to different provisions in the drafted regulations.

## BACKGROUND

In the field of legal informatics, most research efforts focus on enhancing the search and browse aspect of legal corpus, whose targeted users are legal practitioners. Merkl and Schweighofer (1997) suggested that "[the] exploration of document archives may be supported by organizing the various documents into taxonomies or hierarchies that have been used by lawyers for centuries" (p. 465). Indeed, a hierarchical organization of relevant public comments and drafted provisions can extend the benefit to industry designers, planners, policy-makers and interested individuals as well.

Berman and Hafner (1989, p. 928) observed that legal rights of individuals are "severely compromised by the cost of legal services," and as a result suggested the potential of artificial intelligence (AI) to improve legal services. Rissland, Ashley, and Loui (2003) also noted that "the law offers structure and constraints that may enable AI techniques to handle law's complexity and diversity" (p. 6). Researchers have studied extensively the application of AI, in particular, knowledge-based systems, to the *understanding* of the law (Bench-Capon, 1991; Brüninghaus & Ashley, 2001; Schweighofer, Rauber, & Dittenbach, 2001; Thomson, Huntley, Belton, Li, & Friel, 2000; Valente & Breuker, 1995; Wahlgren, 1992). In

comparison, the application of ICT or AI to help the *making* of the law is rather new.

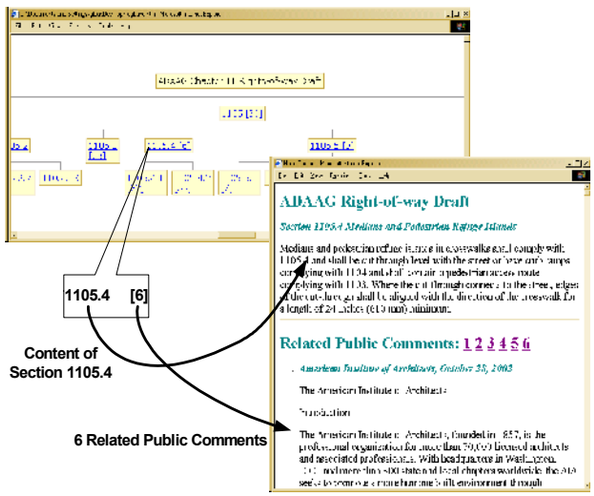
Nonetheless, ICT *can* help streamline the development of regulatory policy in several new directions (Coglianese, 2003). One suggestion is to integrate rules with other laws, such as using ICT to "link all the traces of a rule's history, both back to the underlying statute and back to past or related rules, facilitating improved understanding of legal requirements" (Coglianese, 2004, p. 88). Previous work has shown that such an application of ICT is indeed possible. A framework for comparisons among regulations from multiple sources has been developed, with successful examples of related provisions automatically linked (Lau, Law, & Wiederhold, 2003a, 2003b). This article will exploit the use of the developed comparison framework to implement a prototype to aid the e-rulemaking process.

## AUTOMATED ANALYSIS OF COMMENTS FROM E-RULEMAKING

In order to help screening and filtering of public comments, a prototype regulatory analysis system has been developed to automate the comparison between the drafted rules and their associated comments (Lau, Law, & Wiederhold, 2005). The prototyped e-rulemaking scenario incorporates public comments submitted to the U.S. Access Board, who released a drafted chapter for the Americans with Disabilities Act Accessibility Guidelines (Access Board, 1999), titled "Guidelines for Accessible Public Rights-of-way (Access Board, 2002)." The drafted chapter was less than 15 pages long. However, over a period of four months, the Board received over 1,400 public comments which totaled around 10 megabytes in size, with some comments longer than the draft itself. To facilitate understanding of the comments with reference to the draft, we have developed an automated system to perform a relatedness analysis.

Each piece of comment is compared with individual provisions from the draft. Characteristic features, such as conceptual phrases (Dörre, Gerstl, & Seiffert, 1999), are automatically extracted for the computation of the degree of similarity between provisions and comments (Bishop, 1995). The organizational structure of regulation is also exploited to review hidden relevance between neighboring provisions and references, similar to citation analysis and link analysis in the Web (Brin & Page, 1998; Garfield, 1995; Kleinberg, 1998; Page, Brin, Motwani, & Winograd, 1998). The results of this analysis are related pairs of provision from the draft and individual comment. Figure 1 shows the developed framework where users are given an overview of the draft along with related comments.

*Figure 1. Comparisons of drafted rules and public comments in e-rulemaking*



As shown in Figure 1, the drafted regulation appears in its natural tree structure with each node representing sections in the draft. Next to the section number on the node, for example, Section 1105.4, is a bracketed number that shows the number of related public comments identified. Users can follow the link to view the content of the selected section in addition to its retrieved relevant public comments. This prototype demonstrates the use of a regulatory comparison system on an e-rulemaking scenario to help review drafted rules based on a large pool of public comments.

To conceptualize the use of a comparison framework on e-rulemaking, we present some interesting results here. Figure 2 shows a typical pair of drafted section and excerpts of an identified related public comment. Section 1105.4.1 in the draft established the requirements for pedestrian refuge islands in situations where there lacks adequate signal timing for full crossing of traffic lanes. Using the prototyped system, we found that one of the reviewers complained about the same situation, where in the reviewer's own words, "walk lights that are so short in duration" should be investigated. This example illustrates that our system correctly retrieves related pairs of drafted section and public comment. We also observed from this example that a full content comparison between provisions and comments is necessary, since title phrases, such as "length" in this case, are not always illustrative of the content. Automation is clearly desirable, as it would otherwise require much human effort to conduct a full content comparison to sort through piles of comments.

*Figure 2. Related drafted rule and public comment*

**ADAAG Chapter 11: Rights-of-way Draft**

**Section 1105.4.1: Length**

Where **signal timing is inadequate for full crossing of all traffic lanes** or where the crossing is not signalized, cut-through medians and pedestrian refuge islands shall be 72 inches (1830 mm) minimum in length in the direction of pedestrian travel.

**Public Comment, October 29, 2002**

I am a member of The American Council of the Blind. I am writing to express my desire for the use of audible pedestrian traffic signals to become common practice. Traffic is becoming more and more complex, and many traffic signals are set up for the benefit of drivers rather than of pedestrians. This often means **walk lights that are so short in duration** that by the time a person who is blind realizes they have the light, the light has changed or is about to change, and they must wait …

*Figure 3. Comment intended for a single provision only*

**ADAAG Chapter 11: Rights-of-way Draft**

**1109.2 Parallel Parking Spaces**

An access aisle at least 60 inches (1525 mm) wide shall be provided at street level the full length of the parking space. The access aisle shall connect to a pedestrian access route serving the space. The access aisle shall not encroach on the vehicular travel lane. EXCEPTION: An access aisle is not required where the width of the sidewalk between the extension of the normal curb and boundary of the public right-of-way is less than 14 feet (4270 mm). When an access aisle is not provided, the parking space shall be located at the end of the block face.

**Public Comment, August 26, 2002**

1109.2 Parallel Parking Spaces. An access aisle at least 60 inches (1525 mm) …

1. **This section** needs to be clarified (i.e., where is the access isle located?) that is, "will it be on the driver side or passenger side?"

2. The following is more of a question/concern about this requirement: …

I would really appreciate, if you could **forward this comments to the right individual** and hopefully get a response back …

The pair of highly related provision and comment shown in Figure 3 suggests that a comparison between drafted provisions and comments is indeed the right approach. This commenter started by citing Section 1109.2 in the draft, followed by a list of suggestions and questions on Section 1109.2. Our system gathered the relatedness between Section 1109.2 and this comment through different features, such as the shared phrases. This piece of comment is a representative example of a lot of comments that are written similarly: comments that are concerned about a single provision in the draft. Thus, a comparison between drafted provisions and comments is important to help rule makers focus on the most related comments per provision.

## FUTURE TRENDS

Based on the observations of results shown in the previous section, there seem to be room for improvement for an e-rulemaking portal. The example in Figure 3 shows that the public might find it helpful to submit comments on a per provision basis, in addition to a per draft basis. With enabling technology, it should be possible to develop an online submission system that allows for both types of comment submission. It saves participants time to paraphrase or cite their concerned provision. It also saves rule makers time to locate related comments either through human effort or an automated system.

Comments submitted on a per draft basis can still be analyzed and compared with the entire draft to identify any additional relevant provisions. In the example of Figure 3, the commenter also suggested that it is important to forward the comments to the right person. An extension of this relatedness analysis framework could be developed to automatically inform any assigned personnel in charge of reviewing the provision within government agencies.

Regulations are frequently updated by agencies to reflect environmental changes and new policies. However, the desynchronized updating of regulations seems to be problematic, especially when different regulations reference one another. We observe that there is a need for consistency check among multiple sources of regulations citing each other as references. For instance, in the domain of accessibility, Balmer (2003) pointed out that the "ADAAG references the A17.1 elevator code for conformance. Since 2000 there has been no section of the A17 that references lifts for the disabled. Therefore ADAAG references a non-existent standard … if ADAAG is to reference the A18 then the A18 should contain the requirements for this application" (p. 10). In previous work, we have developed a semi-automated reference extraction parser, which can potentially be extended to locate cross citations and check for consistency of rulemaking (Kerrigan, 2003; Lau, 2004).

A public comment submission portal, an automated comment routing system and a reference tracking tool are just a few examples of the potential technology impact on the making of the law. E-rulemaking provides a rich research platform for a multi-disciplinary study involving social scientists, policy makers, computer scientists, and interested and affected citizens. Improvements and innovations of an integrated e-rulemaking system are much needed to help various parties to locate, retrieve, review, and validate regulations.

## CONCLUSION

This article has demonstrated a potential use of ICT on policy making, in particular, the communication between government agencies and the public via comments on proposed rules. A short discussion is given on the observed impact of e-rulemaking on the efficiency of government agencies. This translates into a significant increase of workload for rule makers, as the drafted rules need to be analyzed, compared, and revised based on the generated public comments. One of the main barriers to e-rulemaking, namely the vast amount of public comments received through the Internet, is concretized using a recent drafted regulation as an example. We proposed to perform a relatedness analysis on the drafted regulation and its associated public comments to streamline the process.

A prototype relatedness analysis system is demonstrated to compare a drafted regulation and its associated public comments. Documented and reported here are selected examples of results, which also inspired some potential future research directions. By screening through the public comments and sorting them according to their relatedness to provisions in the draft, it helps rule makers to review and revise the draft based on the comments. It helps interested and affected individuals to focus their concerns and suggestions to drafted rules. The use of ICT on the making of regulations can undoubtedly facilitate the editorial job of policy-makers and enhance public understanding of rulemaking.

## KEY TERMS

**Academic Citation Analysis:** It is the analysis of the citation pattern among scholar publications and literatures. For instance, CiteSeer is a scientific literature digital library that provides academic publications indexed with their citations (Bollacker, Lawrence, & Giles, 1998).

**Characteristic Feature:** Features are the evidences that identify relatedness. Examples include conceptual phrases such as "access aisle," and domain-specific terminologies such as chemical names and symbols. Often, features are constructed by hand based on some understanding of the particular problem being tackled (Bishop, 1995).

**E-Rulemaking:** During the process of rulemaking, government agencies are required to inform and to invite the public to review a proposed rule. E-rulemaking redefines this process in which the electronic media, such as the Internet, is used to provide a better environment for the public to locate, retrieve and comment on proposed rules.

**Feature Extraction:** Feature extraction is an important step in repository development when the data is voluminous. In particular, in the field of information retrieval (IR), software tools exist to fulfill the task of feature extraction to recognize and classify significant vocabulary items (Bishop, 1995).

**Link Analysis:** The popularity of the Internet has led to extensive examinations of different types of hyperlink topology and fitting models (Calado, Ribeiro-Neto, Ziviani, Moura, & Silva, 2003; Gurrin & Smeaton, 1999; Silva, Ribeiro-Neto, Calado, Moura, & Ziviani, 2000). Google's PageRank algorithm (Brin & Page, 1998; Page, Brin, Motwani, & Winograd, 1998) and the HITS (Hypertext Induced Topic Search) algorithm (Kleinberg, 1998) both exploit the hyperlink structures of the Web, similar to the heavy cross-references in the legal domain.

**Relatedness Analysis:** A comparative analysis among regulations and supplementary documents that identifies similar or related materials by computing a similarity score. Although the term relatedness appears more appropriate, the phrase "similarity score" has been used in the field of Information Retrieval (IR) traditionally.

**Similarity/Relatedness:** Psychologists Gentner and Markman (1997) suggested that "similarity is like analogy (p. 45)," based on the concept of analogy defined by Johannes Kepler (1609/1992). In the comparative analysis of regulatory documents, we define similarity/relatedness to describe elements of texts that are alike in substance and/or connected by reason of a discoverable relation.

# Public Authorities and the Local Information Society

**Tommi Inkinen**
*University of Turku, Finland*

**Jussi S. Jauhiainen**
*University of Oulu, Finland*

## INTRODUCTION

This article focuses on the role of public authorities in the creation of local information societies (LIS). The analysis is conducted with reference to strategies, policies, and actions of public authorities with the aim of promoting information and communication technologies (ICTs) at the local level. Although the article relates to broad issues relevant today throughout the western world, we narrow the empirical examples to Finland.

To begin, we provide a brief account of documents that guide LIS policies. Our focus is on the *discursive* formation and *strategic* guidance of LIS. For example, several European Commission documents highlight the positive relationship between economic growth, competitiveness, and knowledge-intensity as a means for success in global competition. On the national level, we discuss the current Finnish government strategy for the promotion of the information society (Government of Finland, 2003).

Second, we offer insights into how discursive strategies for the LIS are implemented through *practical* activities. Two examples discuss the relationship between public authorities and citizen, business and governance-oriented LIS. In particular, it is essential to consider the connections and disparities between written policy strategies and everyday practices. The first topic focuses on the Tampere Region, recounting a case of LIS promotion through enhancing interaction between citizens and public authorities. In the second case, we discuss the Multipolis technology network. It is an example of LIS policy targeted to support private-led technology development in the more remote localities of northern Finland.

## BACKGROUND

Information, technology and knowledge and their production, transformation, and distribution have become part of our daily lives. Consequently, everyday language has incorporated new concepts such as information society (IS) and knowledge (based) society (KS). The former adopts the progress of technology as the core question, whereas the latter focuses on promoting the capabilities of citizens through learning, knowledge creation, and creativity (e.g., Florida, 2002).

The IS and KS, in their particularities, have been addressed by several scholars (e.g., Castells, 1996; Kellerman, 2003; Mansell & Wehn, 1998; Mitchell, 2000; Schienstock, 2004; Simmie, 2001; Webster, 2004). The roots of the IS are connected to market economy and growth. The majority of theories[1] on the IS highlight global competition, circulation of capital and flexibility in locating economic activities. Where IS researchers tend to observe societal issues from a macro perspective with a strong technical emphasis, their KS-oriented colleagues prefer to concentrate on the intertwined relations between innovation processes, technological development in organisations, and the significance of information as a fundamental element in knowledge creation. Colloquial use of the term information society has deflated the concept through the attribution of a wide variety of meanings and responsibilities. In this article, we use the term (L)IS to refer to the contents suggested by both IS and KS. Conceptually, IS and KS are analysed profoundly in other articles in this volume.

Our key interest lies in the local conditions and actions promoting both economic and social dimensions of the IS. In LIS practices, the significance of "local" is commonly narrowed to the level of municipalities. However, exclusive focusing on municipality as the spatial category for local disregards the position of LIS as a process with an active presence beyond the local. Therefore, we highlight the processes of LIS formation and how the IS, present at different spatial scales, transforms and transfigures local realities (see LIS definition at the end of the article).

We argue that public authorities discursively create a flexible definition of the information society in which ICTs play a fundamental role. Public authorities are mostly responsible for the continuous presence of IS in the

media, at least in Finland. In fact, Finland is a case of particular interest due to the "Nokia syndrome" plaguing the national IS discourse. As a result of the production and rapid proliferation of wireless technology, Finland was taken off guard by its new position at the top of the global information society (World Economic Forum, 2003). Public authorities were happy to accept credit for this fluent conversion from a traditional industrial society to an information society. Retrospectively, they claimed a causal relationship between the emergence of the IS and public investment in education, research and development in particular technological fields (Miettinen, 2002).

In the 1990s public authorities began to actively promote the IS as the key economic strategy for Finland. Castells and Himanen (2002) represented Finland as an example of a socially coherent and welfare-oriented IS with high level of social security. However, during the early 2000s, the growth of the ICT production and development sector has slowed down in Finland and the attraction of the "Finnish model for the information society" has waned somewhat. In everyday life, the penetration of ICTs and especially their active use has not increased as expected (ITU, 2005).[2] Nevertheless—or perhaps consequently—public authorities stress the significance of the technologies themselves in the promotion of LIS.

## STRATEGIES AS DIRECTIVES FOR IS DEVELOPMENT

On the global scale, the IS became a top priority in public policy in the early 1990s, when the US government published its *National Information Infrastructure* report (NII, 1993). Almost simultaneously, the "Bangemann" report was published highlighting the essential role of technology for the competitiveness of the European Union (European Commission, 1993). The strategy guideline reports of these two economic superpowers were followed by various national IS or "technology-driven" growth strategies. In Finland, the lead up to the current IS strategy began in 1994 with the publication of the TIKAS report by the Ministry of Finance. Soon after regional authorities started to produce their own IS strategies.

There are several possible ways to approach IS strategies. The first challenge is to define the appropriate spatial scale. There exists a vast amount of data concerning ICT-related indicators on the national and regional level of the European Union. However, such data on the spatial diffusion of ICTs and related infrastructure is rough and only describes certain technical prerequisites of IS. The rapid diffusion of continuously changing devices has the consequence that such data rapidly becomes outdated. A comprehensive comparative analysis of the presence of ICTs in the localities of EU-25 would require enormous effort. Furthermore, such extensive description would not be sufficient, as ICTs and their usage cannot be observed exclusively as technological phenomena: they are strongly influenced by the social context. For this reason, in the present study we choose to concentrate on Finland and describe findings in the practical promotion of LIS.

The Information Society Programme[3] is one of the four major policy programmes adopted by present Finnish government. In this way, concerns relating to IS development concerns are addressed on the same level as issues regarding employment, entrepreneurship, and public participation policy, which constitute the other three programme dimensions. In certain innovation policies and programmes, contacts between the public and the private sector are frequent (Lemola, 2003). Yet, the significance and substance of a general IS policy programme in Finland has been questioned. For example, in autumn 2004 a director of a major ICT-company gave a statement that co-operation between public IS policies and private enterprises in Finland is currently "more or less non-existent" and that the national IS Programme is but a collection of fancy ideas and words with no concrete substance that might induce co-operative action.

The regionalisation of IS in Finland occurs in a number of different ways. One significant regional policy tool is the Centre of Expertise Programme initiated in 1994. The mission of the current 22 centres around Finland is to make use of international high-level knowledge and competence for entrepreneurial activities, to improve the regions' development resources, and to create new employment opportunities. The local centres aim to improve the basic conditions for new innovations, product development, and commercial activities (Centre of Expertise Programme, 2004). Several centres focus on technology improving the competitiveness of technology firms in private technology parks.

As described, the fundamental goals of IS strategies are very similar on the EU, national and regional levels: the main components generally consist of economic competitiveness, regional equality and improved social life of citizens enhanced by the usage and implementation of ICTs. In Finland, local and regional authorities state similar goals in their regional and local IS strategies. The aims of regional authorities can be observed through a three-way categorisation based on their primary object of interest: the *citizen*, *business,* and *governance*-oriented IS (Table 1).

We use the above categorisation in our analysis of two LIS cases. The first case concerns the Tampere Region (Pirkanmaa), which is the second largest functional area in Finland, the largest being the capital area (Helsinki region, Uusimaa). The second case observes localities in the area covering the northern half of Finland

*Table 1. Categories for LIS target groups*

| |
|---|
| **Citizen-Oriented LIS:** The aim is to promote the use of ICTs by improving the computer literacy of the population and providing households with technical facilities such as broadband connection. However, the strategies of Finnish public authorities are often too broad and rarely provide clear guidelines for obtaining the goals |
| **Business-Oriented LIS:** The aim is to increase the national (and regional) competitiveness in technology and this way to contribute to the national economy. The total turnover of high-tech firms in Finland is larger than that of medium-tech enterprises (Statistics Finland, 2004). However, the distinction between high, medium and low technology enterprises is not clear. The national statistics have a tendency to label a relatively large portion of activities as high-tech, which may cause some distortion in the number of "knowledge intensive" industries |
| **Governance-Oriented LIS:** The aim is to improve the necessary institutional relations between authorities and citizens and to enhance the use ICTs to facilitate and accelerate the processes of enhancing e-democracy and e-governance. This can also be a step forward in transparency of governance. Despite the strategies, a systematic breakthrough in fast and interactive use of ICT in public services has yet to occur in Finland. |

with the city of Oulu as its functional centre. The citizen- and governance-oriented examples are from Tampere and the business-oriented example from Oulu. The cities of Tampere and Oulu have been named among the ICT hotspots of Europe (e.g., ESPON, 2004). Relevant information on the areas is available in: <http://www.pirkanmaa.fi/english/> and <www.multipolis.com>.

## EXAMPLES OF LIS ACTIVITIES IN FINLAND

### Public Service Provision to Citizens

The first empirical example concerns the eTampere[4] programme, an extensive (in terms of funding and number of development activities) LIS development project in Finland. eTampere is a network organisation. The projects under "the eTampere umbrella" are conducted through institutional organisations operating in the fields of technological development and research, local business promotion, e-business research and citizens' service provision.

The role of the public authority, the city of Tampere, is to provide seed funding for the whole eTampere network and to offer easy-to-use e-services for citizens. In the service provision, the aim is to introduce new ICT-mediated practices for citizens' communication with public officials and to integrate more citizens into the LIS. Several initiatives have been launched to promote e-inclusion. These include the eTampere smart card, the Internet bus, improvements in the city's Web and educational services produced in co-operation with various education providers.

A city Web site can be defined as the user interface through which the ordinary citizen can interact with public officials and gain relevant information on the city. The Tampere Web site fulfils many of the functions (information provision, interaction, feedback and electronic transaction) pointed out in the volume edited by Anttiroiko, Mälkiä, and Savolainen (2004) regarding online services. In this regard, e-services in the City of Tampere are rather highly developed in terms of information provision, interaction, and feedback. The main challenge still lies in enabling online transactions for the whole range of communication between citizens and public administration.

It is important to highlight the role of education in the LIS development. The eTampere programme provides educational services to citizens. The services are designed for different target groups including the elderly and disabled persons. The educational services have proved very popular and constitute one of the key elements in the local e-inclusion project. Yet from a broader perspective, active incorporation of ICTs into elementary education (and levels beyond it) is essential in the promotion computer and Internet literacy.

We present three central conclusions concerning the public sector provision of LIS services to citizens. First, Web sites require frequent updating and usability testing. These requirements are met by the Tampere portal at <www.tampere.fi> that has become an extensive information source for citizens. At present, the most central concerns to be addressed in order for interactive e-governance to really take off concern the interoperability of the databases of different public actors. Second, the provision of ICT training to citizens is an important method of LIS creation. This cannot, however, bring large scale results unless the computer and the Internet

are firmly integrated into teaching on all levels of the educational system. Third, the creation of digitised local governance is still in its early phase. Important problems in this respect concern the standardisation of public digital authentication (signature), legislation (e-security) and database combining (privacy).

## Citizen and Social Usages of E-Services

So far we have demonstrated innovative actions provided by the local public authorities to promote LIS. To gain a more comprehensive picture, we must consider citizens as clients of LIS. The Information Society Institute, the eTampere sub-programme responsible for social IS research, carried out an extensive survey[5] on citizen perspectives on LIS. The questionnaire included 99 statements and questions on areas such as the digital divide, use of public sector services and citizens' abilities to interact with public authorities via the Internet.

The results clearly indicate various areas of further development. More than one in four (28.2%) Internet users experienced difficulties in interaction with public authorities via the Internet. If the whole sample is considered (including non-users of Internet), the figure increases to nearly half of the population (46.2%). The citizens demand better and more accessible e-services and activities from local public authorities: almost two out of three (62.4%) Internet users agreed fully or somewhat with the statement that public authorities should more actively promote the citizens' ICT skills through provision of free or inexpensive training.

Statistical testing indicated that the most important explanatory variables, in the explanation of IS attitudes and levels of know-how, are general technology usage levels (computer and Internet usage time per day) and socio-economic conditions (age, basic and professional education, current employment and income): the higher the person's socio-economic position, the better their ICT and IS skills are and the more positive attitudes they display towards the IS. Location is also significant: in remote areas, a higher proportion of people suffer from the digital divide.

From these examples, we draw three major conclusions. First, many groups are still unable or unwilling to use the Internet or other e-solutions such as smart cards. Second, public authorities should upscale their e-service provision. Third, public opinion clearly supports the promotion of IS through education and service provision. However, not all solutions are in the hands of local authorities. For example, the problems of digital authentication (digital signature) are national and it is not purposeful for local authorities to create their own 'local citizenship' authentication systems. The citizen-oriented LIS is highly dependent on the development in national IS legislation and administration. Thus, the challenges of LIS service provision are increasingly related to co-operation between different organisations, both public and private, present at different spatial scales. The development of LIS is profoundly intertwined with the development and guidelines of national policies and ICT infrastructure. The possibilities of local actors to promote LIS on their own are limited if national and supranational policies and decisions lag behind or fail to support local initiatives.

## Business-Oriented LIS: Clustering and Networking High-Tech in Northern Finland

The third empirical viewpoint concerns business-oriented IS at the local level and the role of public authorities in it. We examine the case of Multipolis network, an example of regional innovation policy improving the development of technology-related enterprises, products, and activities in a group of localities. The results presented here derive from an survey conducted in spring 2004 regarding high-tech enterprises outside the Oulu urban region in 14 localities including a total of 137 high technology enterprises and 116 other enterprises as clusters located most often in privately-led technology centres (Jauhiainen, in press).[6]

The aim of this public authority policy, called Multipolis, is to maximise the utilisation of technology know-how in northern Finland and to expand the technology-related expertise and knowledge from the highly developed Oulu urban region to other localities in the north. The concrete aim is to create 15,500 new jobs and 400 new enterprises in the high technology sector.

Multipolis is an example of triple-helix (e.g., Cooke, 2004; Etzkowitz & Leydesdorff, 2001) approach in the LIS promotion. The funding for Multipolis comes mostly from the public sector, partly from the Oulu Region Centre of Expertise programme that is part of the nationally funded regional policy. The network is managed by a public sector consortium. The method of Multipolis is to foster the triple helix approach by enhancing co-operation between and among high-tech enterprises, universities, other higher education units, research laboratories, other technology enterprises and regional developers within the Multipolis network.

Multipolis promotes LIS directly due to its spatial concentration on selected localities in which public sector funding and activities (including specialised education and training) enhance private-led technology development and create a fruitful environment for economically

viable innovations in high technology. After four years of implementation, the main result for the high-tech enterprises is the enhanced social networking and cooperation between the enterprises. Also, cooperation between high-tech enterprises and education providers has increased. However, despite the original goals of the network, its impact on product innovation in ICTs and other technologies as well as job creation has been modest (Jauhiainen, in press).

The connection of Multipolis to the national IS programme is evident. However, the connection of this business-oriented LIS to citizen- and governance-oriented LIS is weak. A real challenge is how to improve and embed innovation capacities locally for a more sustainable business-oriented LIS and to move from strategies to practice.

## CONCLUSION AND FUTURE TRENDS

There are several points to be made concerning the relationships between public authorities and the creation of LIS in Finland. First, a conceptual clarification with regard to the use of the concepts IS and LIS in various strategies is necessary. At the moment the IS is not a clear concept but a flexible collection of visions, ideas and ideologies that often operate on the assumption that the development of ICTs will necessarily lead to a knowledge-intensive IS.

Strategies address the question of IS in different ways: technology is portrayed as a tool for economic growth and national competitiveness, mobile communication technologies are seen to provide opportunities for a more transparent and equal society, or the IS is seen as a means for creating employment. The strategy documents for (L)IS studied in this article share a common techno-optimism (and sometimes utopian) promising significant improvements in the lives all Finns (or EU citizens). The documents rarely display any scepticism or constructive criticism.

When IS practices are studied at local level, the picture becomes more real. At least in the Finnish case, there is a gap between the strategic discursive promotion of LIS and its practical implementation. The discourses evoke images of gigantic techno-optimistic leaps, whereas practice consists of modest small steps, for example, of providing access to information networks, arranging for a more comprehensive and even distribution of technologies and providing e-inclusive educational services. The implementation of IS strategies is slower than estimated, and it takes a long time for the practices to enter people's everyday lives.

The gap between policy goals and short-term outcomes derives partly from too messy and ungrounded conceptualisation of IS, its goals and its possibilities. For example, in the case of northern Finland, the local specialisation in high-tech activities makes the localities more vulnerable and dependent on external resources than they were before.

The second issue is measuring the efficiency in achieving the goals of IS strategies. Too much attention has been paid to the spatial distribution and quantity of technological devices and infrastructure. At this point, the use of the technologies and, in particular, the contents used should be brought to the focus: do the contents serve to promote LIS–or do they amount to just another technical organising of local society? Detailed qualitative data is needed to gain an understanding of the LIS that is currently being created by public authorities through multitude of policies and projects. Understanding these relationships requires detailed knowledge of local circumstances, the profound study of which is thus necessary for successful policy evaluation.

## KEY TERMS

**Digital Divide:** Refers to differential access to ICTs between individuals on the basis of supply, know-how or economic attributes. Digital divides exist on all spatial levels from neighbourhoods to the international level. The term is commonly used to describe the differences between industrialised and developing countries regarding information society and usage of ICT. However, more emphasis should be paid to micro-level developments as well as to themes related to ICT policies and gender, age and ethnicity as modes of inclusion and exclusions in the information society.

**Finnish Information Society Model:** Was suggested by Manuel Castells and Pekka Himanen as socially coherent information society in which public information society policy guidelines play an important role in the situation of simultaneous prosperous economic development and high-level public social services.

**Local Information Society (LIS):** Is a spatially bounded territory, often municipality, daily working area or an administrative region in which public authorities, sometimes in cooperation with the private sector, promote information society in which citizens take actively part of. LIS is enhanced with fostering the usage of ICT and premises of the ICT industry.

**Public Authorities:** Include the organisations and staff of public administration. Public authorities form the overall governmental structure of a state divided most commonly to local, regional and national jurisdictions.

**Public E-Service:** Is a service provided by public authorities to citizens via technologies such as the Internet, mobile phone, smart card, and so forth. Public e-services range from passive information provision to more comprehensive interactive governance processes within the digitalised operating environments.

**Regional Innovation System:** Is a location and context bound framework for innovation producers that are located within a specific geographical area. Actors within this framework thrive to common goal of regional development through innovative actions. Regional innovation system requires actors from all sectors of society: public authorities, private companies, and educational organisations such as universities.

## ENDNOTES

[1] See, for example, the IS classification by Webster (1995, p. 6-25): (1) technical aspect, (2) economic

aspect, (3) occupational aspect, (4) spatial aspect and (5) cultural aspect. Technological development is central for each aspect and it has an impact on both individual and societal levels.

[2] The rate of mobile phone subscriptions per population in Finland is 90.1%, 50.9% of population use the Internet, and there are 2.3 persons per each personal computer. However, the penetration rate of broadband connections was only 12.8% in 2004 (ITU, 2005).

[3] The general goals of the Finnish IS policy programme are: "The information society programme will focus on the utilisation of the opportunities offered by the information society. The aim of the programme is to boost competitiveness and productivity, to promote social and regional equality and to improve citizens' well-being and quality of life through effective utilisation of information and communications technologies … Programme aims to maintain Finland's status as a leading producer and user of information and communications technology. … In addition, the programme will build up citizens' confidence in information society services by improving data security and protection of privacy." (Government of Finland, 2003). Further information is available at <http://www.tietoyhteiskuntaohjelma.fi/en_GB>. This quotation indicates that the role of information technologies and their usage is central to the national IS strategy.

[4] For full information on the eTampere project, see <www.etampere.fi>. The Web site provides the goals, the operational structure, and the history of the project.

[5] The sampling method was a two stage random sample (clustered regional selection and systematic random household selection). The sample size was 2,000 and the response rate 53.1% (1,061 questionnaires were returned). The dataset with full description is available at the Finnish Social Science Data Archive <www.fsd.uta.fi>.

[6] Northern Finland is the home of some one thousand high-tech enterprises, of which three out of four are located in the Oulu urban region. Semi-structured telephone interviews were conducted with 172 technology enterprises outside the Oulu urban region.

# Public Network Access Points

## INTRODUCTION

The Internet is changing dramatically the way people live, work, communicate, recreate, and participate in public life. But the growth and penetration of the Internet are far from being distributed equally around the globe. In developed countries, the Internet today reaches substantial proportions of the population (e.g., Finland [50,7 %], Germany [56,2 %], the United States [68,8 %]), but in developing countries, Internet penetration often is very low. In Africa, 29 countries still have an Internet penetration of less then 1% (Internet World Stats, 2005).

The unequal access to information and communication technologies (ICTs) today often is called the digital divide. This catchy label stands for a multidimensional phenomenon and describes disparities in access to ICTs along various axes and at various levels. Disparities can be found not only in who physically has access to new technologies and who does not, but also in the distribution of the skills required to use the new technologies in an effective way (Hargittai, 2002; Warschauer, 2003). At the next level, disparities can be found in bandwidth and content available to different groups. These disparities are found among countries (global divides) and among different groups within countries (national divides). Although the existence of a digital divide in one or the other form is clearly accepted among scholars, the dimensions, dynamics, and relevance of this phenomenon are still being discussed strongly (for a more detailed discussion, see Cammaertes, Van Audenhove, Nulens & Pauwels, 2003; Compaine, 2001; Mossberger, Tolbert & Stansbury, 2003; Norris, 2001; Warschauer, 2003; ).

One of the main strategies that is used to spread access to new technologies is the implementation of public network access points (PNAPs) that provide shared and, therefore, cheaper access to communities with low incomes. PNAPs can be defined as physical spaces where people can access ICT for personal, educational, economic, and democratic development without having to own the necessary hardware and software.
