This article will give an introduction to PNAPs, starting with a short look at the emergence of this access model, which can be traced back to the early 1980s. After that, the different models that have evolved over the years in different regions of the world will be described briefly before taking a closer look at the role that PNAPs can play in the context of e-governance. Finally, some critical issues like sustainability, content, and management will be discussed before conclusions are drawn.

## BACKGROUND

The PNAP scene that we see today is a very diverse and fragmented one. A variety of different models have evolved over the last 25 years, some of which can be found around the globe in places like cyber cafés; others exist only in specific regions such as village kiosks, which can be found only in rural areas of developing countries.

One of the first organizations that showed the importance and impact of public access to ICTs was the NGO Playing to Win (PTW) in the United States, which implemented the Harlem Community Computing Center in 1983 (Miller, 2000). Similarly, there have been many programs in other countries, like the Community Access Program (CAP) in Canada, which tried to foster development at the community as well as the individual level by offering public and shared access to ICTs.

In rural areas, one of the first documented projects that offered public access was the Vemdalen Telecenter in Sweden, which was implemented in 1986 (Fuchs, 1998). The Vemdalen Telecenter offered access to new technologies to individuals and to small-scale businesses in the region. This successful project was replicated soon after its implementation in many European countries in order to ensure access to new technologies, especially for people and small businesses in rural areas. In particular, the idea of supporting small and medium-sized businesses by providing shared and, consequently, cheaper access to otherwise expensive new technologies was often the driving force behind the establishment of similar projects in other industrialized countries in the mid-1980s and early 1990s. These models, which were based on shared use of technologies, have been considered powerful tools for the diffusion of the Internet and network-related skills in developing countries. Thereafter and since the end of the 1990s, these models have been implemented widely in Africa, Asia, and South America, mostly with the help of organizations like ITU, IDRC, USAID, and UNESCO.

Since then, a variety of different models have evolved. There have been several attempts to classify the different models, like those developed by Gomez, Hunt, and Lamoureux (1999), Colle (2000), and Lachmayr (2003), who classified them according to size, management-mode, or target group. The following section will give a short overview of the most common models that are based on the previously cited works.

## TYPOLOGY OF PNAPS

There are at least six main models of PNAPs, which differ from each other in various aspects. However, they have to be seen as just theoretical, as PNAPs in reality often appear as a combination of different models.

### Village Information Kiosks

Village information kiosks often are extended STD/ISD phone shops that have one or two additional computers connected to the Internet via dial-up connection or any other narrowband type of connection like UHF or VHF radio transmission. Recently, as in the case of the SARI project, advanced wireless technology (WLL) also is being used (Jhunjhunwala, Ramachandran & Bandyopadhay, 2004). The village kiosk usually offers phone calls; Internet connectivity; information services; health-related, educational, and e-government services; along with some other computer-related applications like word processing, scanning, or printing. But according to Colle (2000), the main focus of these centers is communication-related. One of the most interesting aspects of this model is the management mode, as it is run mostly by private entrepreneurs, such as the SARI-project, where local entrepreneurs can open a village kiosk with an investment of $1,000 US (Jhunjhunwala, Ramachandran & Bandyopadhyay, 2004). Some of the biggest problems can be seen in the task of achieving sustainability, creating awareness for the offered services, and accommodating the low educational levels of the rural population, but despite these problems, this model seems to be highly interesting in the spread of the use of ICTs into rural areas in developing countries.

### Telecenters

According to Gomez, Hunt, and Lamoureux (1999), telecenters are one of the most common PNAP models implemented in developing countries. They usually are equipped with five to eight computers, use a broadband connection, and offer more advanced services than the village information kiosks. There are examples of telecenters that are run by private entrepreneurs, but mostly, they are implemented and managed by NGOs, as the initial and operational costs are too high for private entrepreneurs in developing countries. Telecenters also can be found in developed countries, where often they are part of a regional development strategy. One of the main tasks of telecenters is the development of skills; especially in developed countries, these centers often are used to support people in gaining computer-related skills, which enables them to make online job searches and prepare application materials (Chow, Ellis, Walker, & Wise, 2000).

### Multipurpose Community Telecenters

The multipurpose community telecenter model is set up with 10 to 20 computers. It offers more than just basic access to the Internet and often focuses on educational issues and community development. It is equipped with the latest technology and offers top market applications like videoconferencing, e-governance, and telemedicine in rural areas. In many ways, this model is similar to telecenters; the main distinction is its size and the services that it offers. Because of its size and the variety of services it offers, a multipurpose community telecenter is implemented and run only by NGOs or governments. These centers often aim not only at enabling access and training but often also are part of broader community development strategies. Whereas this model has become quite common in the developed world, especially in urban areas, it seems to be oversized and too expensive to work effectively in developing countries.

### Civic Access Centers

Based in schools, universities, libraries, post offices, or other civic buildings, Civic Access Centers often offer the general public access to computers and network connections, just as some schools or universities offer the general public access to their equipment at certain times (Proenza, Bastidas-Buch, & Montero, 2001). In most developed countries, like the United States, Germany, Japan, and Australia, libraries offer their customers free Internet access as an additional service. These centers usually neither publicize their services very openly nor concentrate on training or education (Gomez, Hunt, & Lamoureux, 1999). However, in some regions of the world and for some groups, especially in the developed world, these centers seem to be an important access point, as home access or other public access places may not be available (Gordon & Gordon, 2005; Erikson, 2005). Civic access centers can be seen as a necessary government service to the general public, as citizens have the right to

access information and new services and as these centers become the most basic way to ensure that people at least have the possibility to access them.

### Cyber Cafés

Cyber Cafés are commercial, market-driven phenomena that occurred in the early 1990s with the diffusion of the Internet in most urban cities of developed countries, especially in the US. According to Stewart (2000), they should not be seen just as an additional access point to the Internet but rather as a new public space and part of temporary culture. They have played an important role in spreading knowledge about the Internet and have served as an access point for specific communities (e.g., students) in the early days of the Internet, but today, with the diffusion of home Internet access in developed countries, their importance has been considerably reduced. However, the situation is dramatically different in developing countries, where they have become almost ubiquitous. Cyber cafés in developing countries, especially in urban areas, are mushrooming and serve as a critical part of society (Haseloff, 2005).

### Mobile Access Solutions

There are other various projects, where access points are mobile in order to reach distant rural communities, like the Internet on Wheels project in Malaysia, where a bus equipped with modern technologies brings the Internet to remote areas by using a satellite connection. There are other similar projects, for example, in India and South America. All these projects have a mobile unit that temporarily brings network technology to remote and unconnected rural areas. But the important word is *temporary*. Temporary means that the facility will be available to the rural communities only for a short time and only occasionally. Such projects may be very helpful in creating awareness about new technologies, but they cannot be seen as long-term solutions.

The previous examples provide an idea of various possible models. But despite all these differences, PNAPs have some common features: they offer network access to people who can't afford to have the necessary hardware and software at home, who can't afford to pay the monthly connection fees, or who just need support in order to use the new technologies. There are major differences between PNAPs in developing and developed countries, as well as between rural and urban areas within a country. Generally, PNAPs play a much bigger role in developing countries, where they are not just an additional access point but often the only access point with which to access ICTs.

## PNAPS AND E-GOVERNANCE

There are several common services and applications available in the different PNAP models. Some, like e-mail, are ubiquitous; others, like telehealth, are found only in a few projects. PNAPs usually offer the following:

- New and cheaper modes of communication
- Educational information and applications
- Job and job-search information and applications
- Microfinancial/e-commerce information and applications
- Health/telehealth information and applications
- Recreation

In addition to these applications, PNAPs are an important and effective delivery point for new e-governance applications. At present, there are different applications available in some projects, including mainly the following:

- Government information and schemes
- Government services and applications
- Online payments
- Communication with politicians (using e-mail, chat, or Webcam)
- Digital land mapping
- Election and party/candidate information
- Civil rights/legal and social information

PNAPs have to be seen as an important delivery point for any possible e-government service, and as of today, PNAPs are a necessary tool in order for various groups to access these services, as they have no alternative access point. From a democratic point of view, e-government services only can be introduced if all citizens theoretically have a possibility to access them. As Internet access at home or at work is far from being available to the total population, even in the most developed countries, PNAPs in this context need to be seen as necessary institutions for the delivery of e-government services, at least until universal home access is reached.

## DISCUSSION

The implementation of PNAPs, especially in developing countries, is a difficult and controversial task. On the one hand, it often is criticized that marginalized rural communities are more in need of water pipes than data pipes (Greis, 2004); on the other hand, such projects can have a strong impact on marginalized communities, if they are implemented according to their needs. The most critical

issues determining the success of PNAPs can be seen in the management mode, sustainability, and creation of local relevant content and applications.

## Management

Arunchalam (2002) suggests a bottom-up approach, in which communities are involved from the planning stage on. He also points out the need for involving the local community in managing centers at the village level. Generally, these centers can be managed in two forms: either a center run by an organization or by a local entrepreneur. Recently, most of the newly implemented projects are based on the entrepreneur model, but there are several problems that need to be considered. Jhunjhunwala, Ramachandran, and Bandyopadhyay (2004) discuss the role of the entrepreneur. Their main findings are the following:

- The entrepreneur is a critical factor for the success of PNAP projects.
- The entrepreneur needs special training to develop a variety of needed skills, technically, socially, and economically, as he or she is the interface between the local community and technology.

In addition to the entrepreneur model, other forms of management can be successful, as long as they follow a bottom-up approach, evaluate and respect the needs of the communities, and do not place technology above the people, as technology is merely a tool.

## Sustainability

The most critical issue determining the success of PNAP projects is the task of reaching sustainability. Especially in a long-term view, sustainability determines whether these projects continue to remain after the implementation stage. There are many projects that failed because sustainability could not be reached, and a successful PNAP project needs to develop clear strategies regarding sustainability. In order to achieve sustainability, several services and applications need to be offered; it has been demonstrated that these necessarily do not have to be network-related. In this context, governments and organizations need to support such projects, either financially or by developing services that can be offered in PNAPs.

## Local Relevant Content

The content available on the Web is growing every day. From a Western point of view, there is enough free and easily available content on the Web to fulfill the needs of most users, but the situation is dramatically different for rural and marginalized communities in developing countries (Warschauer, 2003). One has to bear in mind that most of the content is produced in and for developed countries. Content not only needs to be in the local language but also needs to target the needs of rural communities. It is not enough to translate existing content into different languages, as the needs of rural communities differ significantly from those in developed countries. Therefore, a critical factor regarding PNAP projects is the production of local relevant content (Gurstein, 2003). An important question in this context is who will produce this content, as the commercial sector doesn't target these markets because of the lack of revenues. In the future, organizations like the United Nations and governments need to play a stronger role in creating content, as it is not enough to provide just technology and connectivity. Taking a look at PNAP projects all over the world shows that, until today, a variety of interesting and valuable content has been produced, but there is a lack of exchange and networking among various projects. Especially governments and development organizations need to focus more strongly on this aspect in order to make technology useful for marginalized and rural communities.

# FUTURE TRENDS

If one takes a look at the PNAP scene today, it can be seen that PNAPs have become a global phenomenon. On the one hand, the commercial sector, like cyber cafés, has spread to almost all urban areas, and in countries like India and Turkey, PNAPs projects can be found even in bigger villages. They already serve a crucial role for Internet users and have become an important institution. On the other hand, organizations and governments have implemented development-oriented projects in many rural areas of developing countries. The significance of such projects in the future depends strongly on the spread of home Internet access, and in many developing countries, PNAP projects will remain significant only for small groups, as access to the Internet at home or at work may reach considerable proportions of the population in the future. But for developing countries, the situation for the major part of the population is dramatically different: PNAPs in developing countries will remain the only way to have access to the benefits of the network revolution for substantial parts of the population. In India, Mission 2007 plans to implement an information kiosk in every village until 2007. This ambitious goal gives an idea of the future significance that such projects can have.

## CONCLUSION

Public network access points (PNAPs) can play an important role in bringing the benefits of network technology to underprivileged communities by providing access and, equally important, by providing training to people in order to enable them to use the technologies effectively. Especially with the growing number of e-governance applications, from a democratic point of view, PNAPs are needed for people who don't have access elsewhere.

Today, these models are implemented as projects on a global scale in almost every region of the world. However, such models never should be seen as solutions to reduce poverty, unemployment, or other structural problems in rural areas. One should not forget that the widening gap between those who have access to clean water and those who don't is much more dramatic in its outcomes than the so-called digital divide. Technology only can act as an effective tool, never as a solution to structural problems. PNAP models always have to be part of overall community development programs, which include structural, environmental, and gender issues and involve the communities in its development and management. If these issues are considered, PNAPs in the future can become important institutions, especially in developing countries, which not only help to bridge the digital divide but also foster community and individual development.

## KEY TERMS

**CorDECT WLL:** An advanced wireless access system integrating voice and data services. This technology was developed by Midas Communication Technologies, the IIT Madras, and Analog Devices, USA.

**Cyber Cafés:** Commercial institutions that provide Internet access on a pay-per-view basis. Today, they are found in urban areas all over the world.

**Digital Divide:** Refers to the gap between those people who have access to new technologies, especially the Internet, and those who do not. Inequalities, however, are not restricted to physical access, and the current debate also covers the unequal distribution of skills to effectively use new technologies, the unequal distribution of content and applications for different communities, and the differences in the motivations of people to use new technologies.

**Public Network Access Point:** A physical space where people can access ICT without owning the necessary hardware and software and where they can achieve training in the needed skills to effectively use this access for personal, educational, economic, and democratic development.

**Universal Access:** Refers to allowing everyone in a country to have access to basic telecommunications that work within a reasonable distance and at a reasonable cost.

**Universal Service:** The principle of providing affordable basic telecommunications services for all households in a country.

**Village Kiosk:** Small shops that have one or two computers and that offer Internet access and communication and information services in rural areas of developing countries.

**VoIP:** A technology for transmitting voice, such as ordinary telephone calls, over packet-switched data networks.

# Public Sector E-Commerce

P

**Christopher G. Reddick**
*The University of Texas at San Antonio, USA*

## INTRODUCTION

Electronic commerce or e-commerce has the potential to streamline existing functions and services in the public sector by reducing transaction costs or the cost of doing business. This article provides an overview of some of the critical e-commerce issues for the public sector focusing on its impact on reducing transaction costs.

## BACKGROUND

E-commerce in the public sector has been defined as any process or transaction conducted by a government organization over a computer-mediated network that transfers ownership of or rights to use, goods, services, or information (Stowers, 2001). Public sector e-commerce has also been defined as the subset of e-government involving the exchange of money for goods and services purchased over the Internet by citizens and businesses (Reddick, 2005). The main aspect that defines e-commerce is transactions between government and citizens or businesses involving the exchange of money. Therefore, e-commerce is the use of the Internet and the Web to transact business. More formally, e-commerce is digitally enabled commercial transactions between and among organizations and individuals (Reddick, 2004b).

Generally speaking, one definition of electronic government or e-government refers to the use of technology, particularly Web-based Internet applications, to enhance the access to and delivery of government information and services to citizens, business, partners, employees, other agencies, and entities (GAO, 2001). E-commerce is a subset of e-government, is more restrictive in that it focuses on government transactions over the Internet. E-commerce is one way for government to reduce transaction costs and hence save budgetary resources, an especially critical function in fiscally restrained governments as witnessed by some of the transactional services offered online.

## E-COMMERCE TRANSACTIONS

Survey data on the U.S. state government use of e-government was compiled by this author and was taken from the Center for Digital Government (2003) (Table 1). The 2002 data indicates that the top five most popular online services were job searches (done by 48 states), unclaimed property searches (46 states), college admissions (45 states), legislative tracking (45 states), and personal tax filing (43 states). Other interesting observations were that driver's license renewals were done in eight states and auto registration renewals were provided in 18 states. Therefore, many of the top services involve information searches such as online job searches and unclaimed property search.

The results in Table 1 indicate that e-government has changed the traditional way of advertising for a government job. It has also made it much easier for citizens to locate lost property. The college admissions process has been streamlined because of the Internet. In terms of e-commerce and transactions being completed online, filing personal taxes, for instance, was done in almost all of the states. This article focuses on the development of transaction-based e-commerce, since e-commerce is not possible unless there is a transaction between two parties over the Internet. A model of e-government adoption can be used to explain the evolution of e-commerce.

There are several stages of e-government growth. In the first stage, there is the cataloging of information on government Web sites (Layne & Lee, 2001). In this stage, there is no interaction with the citizen or business, just the presentation of downloadable forms or Web content for users. Most governments are in this stage of development because they have their own government Web sites disseminating information to the public. However, e-commerce is not prevalent in this stage because there are no transactions taking place between the user of the government Web site and the agency providing information or services.

The second stage is the transaction phase (Layne & Lee, 2001). There is some initial evidence in the United States suggesting that e-government has entered the transaction-based phase of e-government adoption (Edmiston, 2003; Holden, Norris, & Fletcher, 2003; Layne & Lee, 2001; Reddick, 2004a; Reddick, 2004b; Reddick, 2005; Wang & Rubin, 2004; West, 2004). This phase is where e-commerce comes to life. Governments make available working databases that support online transactions such as renewing a driver's license or filing taxes (Table 1). As a result of putting live databases online, govern-

| 18 | Business Registration | 18 | | | |

*Note: UCC = Uniform Commercial Code; Top five e-commerce services in bold*

ments can cut back on staffing offices since citizens and businesses now have the option of going online for selected services. There is, of course, still the problem of the digital divide where certain groups, such as minorities, elderly, low income, and those with disabilities do not have as much access to the Internet or are not as Web savvy, although this gap is shrinking over time (U.S. Department of Commerce, 2002). Besides the important issue of the digital divide, this article examines transaction costs theory and its impact on e-commerce adoption.

## TRANSACTION COSTS THEORY

One of the reasons for the adoption of information technology, and especially the Internet, is the reduction of transaction costs. Information technology helps government decrease in size because it can reduce transaction costs—the costs incurred when government buys on the marketplace what it cannot make for itself (Fountain, 2001; Laudon & Laudon, 2003; Thurmaier & Chen, 2005; Williamson, 1985). The principle idea of transaction cost theory in its application to e-commerce is that governments incur transaction costs when they conduct business. Simply stated transaction costs are the costs of making an economic exchange. The costs in government transactions include search and information costs, bargaining costs, and policing and enforcement costs (Thurmaier & Chen, 2005).

Information technology with the aid the Internet can also reduce internal management costs. According to the agency theory, the government can be viewed as a "nexus of contracts" among self-interested individuals rather than a unified entity (Horn, 1995). In this theory, a principal (e.g., departmental manager) employs "agents" (employees) to perform work on his or her behalf, however,

agents need constant supervision from management because they will tend to pursue their own interests rather than those of their managers. Information technology permits public organizations to reduce agency costs because it becomes easier for managers to oversee a greater number of employees, when the number of middle management and clerical workers is reduced. Other issues of e-commerce that should be discussed address impacts from management, policy, and technology capacity.

## STATE PUBLIC SECTOR E-COMMERCE ISSUES

The National Electronic Commerce Coordinating Council (NECCC) in conjunction with the Center for Digital Government addressed some of the issues that state governments will face in the implementation of electronic commerce (NECCC, 1999). These issues are common to e-commerce at most levels of government. There are four areas: enterprise administration, technologies, management, and policy. Each area will be briefly discussed along with its key issues (Table 2).

In terms of enterprise administration, some issues in this category are leadership and governance (Table 2). An enterprise approach to governance is recommended to maximize efficiencies and create a sense of empowerment in the implementation of new business processes. Leadership and vision at the executive level are critical elements of successful e-commerce (GAO, 2001). A second issue in the enterprise administration category is privacy. There should be informed consent at the point of collection, limiting collection to required elements, allowing subjects to view and correct information, obtaining consent for any additional use of information. The third issue in the category is security. In implementing security solutions, governments should support open standards and choose commercially accepted technologies. The fourth issue in the enterprise administration category is electronic payments. Governments need to explore the full range of electronic payment mechanisms for both inflows and outflows including credit cards, debit cards, electronic funds transfer, micropayments, electronic wallets, and e-checks. Laws must be in place to support new and emerging technologies such as digital signatures, electronic records management, and electronic payments (NECCC, 2002).

Another important issue in state use of e-commerce is technologies (Table 2). Governments have been trying to create a "single face" by re-engineering their Web sites into service delivery mechanisms (i.e., Web site portals). The two general models prevail: a government-funded approach that uses an appropriation of the state budget and a self-funded model (Johnson, 2003). Each service offered on the Web portal may have its own financial model, advertising revenue, convenience fees, and documented cost savings that all contribute to an overall financial strategy. A second issue in the technologies' category is applications developed from electronic commerce. By leveraging a standards-based infrastructure and browser-based tools, government agencies can streamline their internal processes and applications, enabling employees to use self-service tools. A third issue in the technologies' category is infrastructure. The most common challenge to almost any information technology project is funding. Governments must figure out how to pay for their e-commerce projects. The fourth issue in the category of technologies is standards. Consistent standards are important in order to ensure interoperability, compatibility, and shared usage of electronic commerce resources.

Management is the third category of successful e-commerce, and I argue that it is the most important issue (Table 2). Some of the existing literature supports the conclusion that more effective management leads to greater e-government adoption (Holden, Norris, & Fletcher, 2003; Reddick, 2004b). Funding is one of the issues in management that has its own set of challenges. There are three main funding and financing models for government Web site portals (Johnson, 2003). In the

*Table 2. A selection of e-commerce issues for governments*

| Enterprise Administration | Technologies | Management | Policy |
|---|---|---|---|
| • Leadership and governance | • Portals | • Funding | • Digital divide |
| • Privacy | • Applications | • Marketing | • Economic development |
| • Security | • Infrastructure | • Personnel and training | • Taxation |
| • Electronic payments | • Standards | • Economies of scale | |

traditional model, monies are appropriated from the general fund and sometimes charge-back pricing occurs. The second model is the infrastructure finance model. The funding scheme is from debt proceed funds generated from the sale of state or local government bonds. The third funding model is the Internet based approach. The funding stream for this model is either advertising and or transaction-based revenue. Another often-overlooked issue in the category of management of public sector e-commerce is marketing. Edminston (2003) suggests that if e-commerce is to become successful, governments will be required not only to build and maintain useful Internet Web sites and portals, but also to educate their constituents about the availability of online public services and the benefits of using digital government resources. The third issue in the category of management is personnel and training. Some of the issues involved with electronic commerce and training include the short lifecycle of technology and the variety of technologies. Both of these require management to make strategic decisions regarding technology training. The fourth issue in the management category of e-commerce development is economies of scale in service provision. Since governments obviously have limited goods to sell to the public or business, one would expect to see the most e-commerce applications in the areas where funds exchange hands—taxes, licenses, permits, and procurement (Stowers, 2001).

The fourth category is electronic commerce policies and one key issue in this category is the digital divide (Table 2). There is a large group of citizens and small businesses without access or any real knowledge of the tools required to use the Web as a medium for conducting affairs (Edmiston, 2003). The second issue in the policy category is that of economic development. When private businesses can do everything online from obtaining permits to renewing licenses, the government offering these services is considered business friendly. The last issue in the policies category is taxation. If an Internet business has no physical presence in the jurisdiction, the company is not collecting sales tax, paying business license fees, property tax, real-estate tax, income tax, or employing local citizens (Nesbary, 2000).

## FUTURE TRENDS

Public sector e-commerce in the future will increasingly expand as citizens and businesses grow accustomed to using online services. In addition, as some of the aforementioned issues such as management, privacy, and technology capacity receive greater attention, e-commerce should significantly expand. The potential for e-commerce to reduce transaction costs for government agencies makes it very desirable for them to accept online payments for services.

## CONCLUSION

Public sector e-commerce is different from e-government in that it focuses on citizens or businesses using the Internet to conduct transactions with government such as renewing a driver's license or filing taxes. Governments often take part in e-commerce initiatives in order to reduce transaction costs. Governments in the United States are mostly cataloging information online; there is not as much development into conducting transactions online. Some of the e-commerce issues discussed in this article that should be addressed before more transactions are completed online are enterprise administration, technologies, management, and policy.

P

## KEY TERMS

**Convenience Fees:** A fee charged to the public or businesses for the privilege of using an online government service such as renewing a driver's license online.

**Digital Divide:** Large differences in Internet access and e-commerce access among income, ethnic, and age groups.

**Digital Wallet:** Authenticates the consumer through the use of digital certificates or other encryption methods, stores and transfers payment, and secures the payment process from consumer to government.

**Government-Funded Portal:** The government uses its own funds to start up an e-commerce Web site.

**Micropayments:** Part of a digital wallet function. Used for payments under $5 anywhere on the Web based on credit cards.

**Privacy:** Includes both the claim that certain information should not be collected from the Internet at all by governments, and the claims of individuals to control the use of whatever information that is collected about them.

**Public Sector E-Commerce:** Public sector e-commerce is defined as the subset of e-government involving the exchange of money for goods and services purchased over the Internet by citizens and businesses.

**Security:** Educates and trains users, keeps management aware of security threats and breakdowns, and maintains the tools chosen to implement security on a government Web site.

**Self-Funded Portal:** Private vendors pay for the start-up costs of an e-commerce Web site and recoups their costs of investment through online transaction charges and subscription fees.

**Web Site Portal:** Is an integrated gateway into a government Web site and provides visitors with a single point of contact for online service delivery.

# Radio Frequency Identification as a Challenge to Information Security and Privacy

## INTRODUCTION

New technology has continuously changed the face of computing, and each change has involved an improvement in computer architecture and information processing. There are strong indications that the next paradigm shift in information technology will be kicked off by tiny radio frequency identification (RFID) tags. These lowly devices are being ushered in by corporations like Wal-Mart to facilitate business logistics, but other uses are waiting in the wings. As usual with any technology, criminally-minded individuals have been quick to exploit smart tags for their own purposes. Thus, it is in place to take a look at the dark side of RFID technology to see how it may affect the security and privacy of citizens.

## BACKGROUND

Information security work is a relentless struggle against evil. Previously, a balance was sought chiefly between usability and security, but recently a new axis has been added, namely, social control and privacy. However, this is still a simplification that does not reflect the so-called real world sufficiently well, considering that there are more aspects to it than those four. For example, there is the three-way relationship involving the individual, organization, and technology that should be taken into account, not to mention certain business aspects.

On the road to the information society, we have passed through the agricultural and the industrial society. The large-scale application of computers and wireless communications are characteristics of the automation society, a precursor to the information society (Anttiroiko, 2003). Despite the progress we have made, it appears that taking small steps is not enough in order to get to the destination. What is needed is a comprehensive change at the global level.

One impulse that triggered a wave of change across the globe was the Universal Bar Code which, although originally designed to facilitate supply chain management, inventory management, and product identification, will inevitably affect most aspects of information processing and business. Behind this impulse was a decision taken by Wal-Mart in the 1970s to stop handling goods that are not bar coded. Now the company has issued a similar demand: all products must have an RFID (radio frequency identification) tag by the end of 2005.

RFID tags are computer chips that broadcast a 96-bit code that can be used to uniquely label individual items, rather than just product types (as does the UBC). RFID systems comprise a transponder, or tag, that responds to wireless signals produced by a transceiver, or tag reader, which also powers the tag. Readers identify tags placed in all products by referring to an associated database. A typical reading distance, without line of sight, is two to eight meters.

Product identification tags come in two varieties: the first one is placed on packaging, while the other type is placed on the product. For obvious reasons, the latter type is much more likely to put personal privacy in jeopardy.

Little attention was attached to reading devices such as Wal-Mart's prior to 2004, when international RFID frequency ranges were determined. As a result, each continent now has its own specific standards. Even more importantly, each tag is equipped with circuits for two different frequency ranges (Want, 2004).

Mobile phones are also getting new features. For example, the city of Oulu introduced a new parking pay system which can be accessed through cell phones. In autumn 2004, a new mobile service was presented enabling cell phones to be used as automated readers for RFID tags.

*Table 1. Basic rights of citizens in the European union*

| • Freedom of expression and information (article 11) |
| • Workers' right to information and consultation within the undertaking (article 27) |
| • Right of access to documents (article 42 |

## LEGAL STANDARDS WITHIN THE EUROPEAN UNION

In our society, citizens and organizations have rights and responsibilities regarding information. A continuous debate focuses on fundamental individual and communal liberties and rights, although no general solution that all parties would find satisfactory is in sight.

Citizens of the European Union have at least the following basic rights presented in Table 1 (European Commission, 2000).

To ensure that these rights are respected, information security solutions must be well balanced. It is impossible to stop progress or even slow it down, for technological innovations, which inevitably create new challenges, possibilities, and threats, are part and parcel of our society and lifestyle.

## INFORMATION SECURITY DEMANDS

Discussions on information security often begin with a reiteration of the dimensions of the so-called CIA model, to wit, Confidentiality, Integrity, and Availability (Anttila, Kajava, & Varonen, 2004; BSI, 1993; Canadian Royal Mounted Police, 1981; ISO, 1995, 2001; Longley & Chain, 1989; Parker, 1981; Schweitzer, 1990). In terms of RFID tags, these dimensions are essential, but even more important is another, less discussed, dimension: Traceability. Most people are aware of its existence, thanks to its application in mobile phone tracking systems and satellite surveillance systems. Despite the advantages that traceability offers, there is also a downside, for tracing the position of an individual may violate the individual's personal location privacy and constitutional rights.

Another challenge that such surveillance gives rise to, involves the right of authorities to use a person's cell phone to locate him, for example, when a mishap is suspected to have occurred.

Satellite surveillance is a more convoluted phenomenon. Can it be justified by reason, or is it just a matter of the stronger side dictating the rules? Moreover, as satellites know no national boundaries, which national legislation should be observed? Harmonizing legislation in any area is a daunting task, and information security is no exception. To give an example of the range of approaches, we could cite a case from the late 1990s. An armed robbery took place on an Italian motorway, but the perpetrators were caught thanks to a photo taken by an American surveillance satellite, revealing their car's licence number. At the same time, a debate raged in Finland over the right of the police to acquire telephone data on two men suspected of involvement in drug trafficking.

## INVESTMENTS AND EXISTING APPLICATIONS

Although the spirit of the times seems to be that the pervasive introduction of RFID systems is a thing of the future, big players are already jockeying for position. IBM and Hewlett-Packard, for example, have invested $250 million and $150 million, respectively, on RFID-related research projects.

Some projects are no longer on the drawing board. In the Japanese city of Osaka, city authorities have launched an initiative in which schoolchildren in certain parts of town are equipped with RFID tags. These tags are placed in their clothes, bags, or name tags and are used to keep track of the children's whereabouts. RFID readers are positioned at the school gate and other critical places along the way to school.

This decision indicates that the children's parents and local authorities set more value on security than privacy. Strictly speaking, though, this is not completely true; after all, they are only creating a more extensive surveillance network around their children, while keeping their own privacy intact.

Another area where RFID technology has been applied for years is the satellite surveillance of expensive cars. Should one of these cars be stolen, locating it is generally not a difficult task. Moreover, owners are within their legal rights to install RFID tags on their cars in order to protect their property.

*Table 2. Information security and privacy-related concerns, expressed in conjunction with RFID tags*

| |
|---|
| • Maintaining the privacy of citizens in the novel situation |
| • Prevention of crime in the traditional business world |
| • Utilization of this new technology by criminals |
| • Expansion of surveillance technology |
| • Potential introduction of a new, epoch-making person identification system |

RFID technology will undoubtedly revolutionize business logistics, allowing businesses to better manage inventory, fight counterfeiting, gauge-marketing efforts, and so on. Simultaneously, it will also affect other aspects of society. One example of this is their proposed use in passports and other identification documents. As a matter of fact, this little component is thought to represent the decisive invention that takes us to the Information Society.

## PRIVACY CONCERNS ASSOCIATED WITH RFID

Several information security and privacy-related concerns, not to say challenges, have been expressed in conjunction with RFID tags in Table 2. Most of these challenges are not yet factual, as current RFID systems are mainly trial systems. However, before the large-scale introduction of this technology, issues such as these must be addressed.

The dark side of RFID tags begins at the moment a customer picks up a tagged product from a shelf. For example, in an effort to thwart shoplifters from stealing Gillette's Mach 3 razor blades, the supermarket chain Tesco installed cameras that snap a security picture whenever a package is picked up. Following this line of development to its logical conclusion means that, very soon, when we are dithering whether to buy product A or B, all our musings can be recorded.

The threat is by no means over when the shopping cart passes the store's reading device (McCullagh, 2003). In some cases, checkpoint clerks may delete the tag's contents, but this procedure may also erase important product information (such as user instructions). However, should these tags not be removed, they will remain in the product throughout its lifecycle, all the way to the refuse dump. This means that anyone with an interest in following the route of the product may do so using, for example, a cell phone.

RFID tags contain two circuits operating at different frequencies. Both are designed for a particular purpose. With a reading range of up to three meters, without line of sight, readers at stores are able to communicate with one of these circuits. The other one responds to another type of reading device, such as a cell phone, which can be used by the customer at home to read the product's washing instructions, for instance. This device has a range from zero to about 10 centimetres.

Defining dedicated operating frequencies solved the first problem hindering the large-scale adoption of smart tags. At the next stage, these tags are beginning to be used in applications other than business logistics. A case in point is the stance taken by the parents in Osaka, Japan, to use RFID tags to monitor their children. The next step, however, is much more cumbersome as it involves extending surveillance from children to adults. Installing reading devices and tags in working places is a particularly knotty issue.

## COUNTERMEASURES

Several ways have been suggested for countering the threat on privacy imposed by RFID. Of these, the simplest one involves introducing an opt-out capability which allows consumers to identify tags and remove them.

Another alternative is the use of so-called blocker tags which prevent tagged goods or people from being tracked outside the store. Blocker tags turn the tables on criminals as they operate on a principle that is one of hackers' favourites: denial of service. Tag readers usually read the 96-bit code one bit at a time, checking whether any tags in the vicinity have a 1 in that position and then whether they have a 0. Then the same query is made concerning the next bit. Having gone through the code, the reader is then able to identify the tags. A blocker tag, however, confuses the reader by responding to all queries, rather than just to its own specific 96-bit string.

Government regulation is absolutely necessary for applications such as passports, for who would want their identity and nationality to be identified by non-authorities. Some form of government regulation has also been suggested for commercial organizations for fear that they will not be able to self-regulate the use of RFID technology.

## RFID AND THE INTERNET

RFID has capabilities than can be exploited for the prevention of crime, for example, some products come with a tag that functions as a type of theft alarm. Nevertheless, professional criminals are already using reading devices, like cell phones, to detect what products shoppers are carrying and selection their targets on the basis of that information. Some walk around residential areas with readers trying to locate suitable targets to burgle.

Examples such as these clearly illuminate the dark side of RFID technology. But to properly understand the extent of the threat, we must consider the progress of telecommunications. Most homes are now connected to the Internet, but the rapid development of ad hoc networks and ubiquitous computing exacerbate the problem.

On top of the risks attendant on wired communication, wireless communication has a host of problems specific to it. A central factor is its dependence on the reliability of communication networks. Take industrial automation systems, for example, which increasingly utilize public networks, although the security features of these systems do not always correspond to present-day requirements. At another level, homes are no less vulnerable to threats than industrial automation systems. An ever greater number of homes are connected to the Internet through a multitude of electric appliances and devices, including set top boxes for TV. And this trend will continue at an increasing speed as refrigerators, microwave ovens, burglar alarms and air conditioning systems, among myriad others, are acquiring Internet capabilities.

As for ad hoc networks, RFID introduces a definite new threat. Ad hoc networks do not have a conventional support server or power source, they take their resources from wherever these are available. The first hitch is that, because devices in ubiquitous, or ever-present, computing environments are equipped with small power sources, they will inevitably lose their efficiency. Another risk involves the case presented earlier, in which criminally minded individuals prowl a neighbourhood with scanners to spot future prey. Currently, they may use their cell phones as scanners to read the value of their victims' possessions through a window. In the not so distant future, they may not even have to leave their dens to do that; they simply use the Internet for that purpose. Luckily, at the moment of writing, this is still a science fiction fantasy.

Referring back to the privacy-related concerns or challenges presented at the beginning of this chapter, the final item on the bulleted list was "potential introduction of a new, epoch-making person identification system." RFID tags are well suited for that purpose, particularly when fitted under the carrier's skin. Its current value as such, however, is only as good as the installer's reliability. But in the long run, there is no doubt that personal identification will be a central factor in the Information Society, to the point that it will be the main task of neural networks.

All the examples on the potential misuse of RFID technology point in one direction: we must change our approach to it. Attention has thus far been focused on the smart tag component, now we must turn the tables and concentrate on the readers. Smart tags can, after all, be deactivated or erased, but how dangerous can readers be, especially those installed in cell phones?

## SURVEILLANCE TRANSLATES INTO PRESSURE

Mere knowledge of the existence of RFID tags is enough to make people feel uncomfortable; not many people cherish the idea of being constantly watched (Kajava, 1999). A good example of similar effects produced by a simpler technology is provided by traffic cameras. If new technology is to be introduced for monitoring or surveillance purposes, there will be a lot of resentment, unless an effort is made to alter the public's perception of the system's function. Traffic cameras, for example, are often experienced as a way of controlling drivers, not as a means of increasing traffic safety. The same applies to any type of monitoring. Security professionals have always emphasized the use of security functions to enhance overall security. By avoiding difficult situations, it is possible to steer clear of trouble, but an even stronger effect is achieved by the deterrence function. If someone performs a forbidden activity, they know that they will be caught and punished. A situation with transparent surveillance is one in which an electronic (or other) system is in charge of monitoring a place, but the system is superintended by humans, who can intervene and deal with problem situations (Kajava & Varonen, 2001). A case in point is a video recording surveillance camera covering a work station.

Inexpensive RFID components will be strewn in various places in our environment to serve a variety of applications. They will not solve current problems per se, but they will usher in a new networking ideology based on self-organizing ad hoc networks (Savola, 2004). Also smart tags themselves will undergo some form of evolution, from today's passive components to independent computing devices, albeit with a lower capacity than computers. Potentially constructed using paper-machine technology, they push the door wide open for ubiquitous computing.

With the advent of RFID technology, surveillance is also becoming a ubiquitous function. And as the information security dimension will be omnipresent, carriers of

identification tags stand to lose a large portion of their privacy. It may be doubted, however, whether even this development will bring about a perfectly secure or safe society. The basic paradox is that it is highly unlikely that more than a small percentage of employees actually ever even consider engaging in an illegal activity. Professional criminals often have a completely different background and are less susceptible to such surveillance. For example, criminals know how to break the data protection systems of typical end-users. Thus, the function of such systems is actually to protect the data of one employee from other employees. Hackers can always work their way around protection schemes.

Should surveillance through the use of RFID tags become a reality at the predicted scale, business life and society at large would be permeated by surveillance technology. One justification for this trend is that humans are the weakest link in the security chain. The existence of one susceptible person in a company may compromise the entire organization's security strategy. In our day and age, any large organization is quite likely to have on their payroll at least one employee, who is unpredictable in this respect, through the use of drugs or otherwise. This would seem to offer a fairly strong justification for installing stronger monitoring policies.

## CONCLUSION

Introducing RFID technology encompasses a host of unforeseeable consequences, some for the good of society, others rather less so. International commerce sets such high demands that the price of RFID tags must necessarily be very low. This will serve to extend their application range far beyond business logistics. And therein lies the promise and the threat of this new technology. RFID tags can be used to provide information on the product, including price, user instructions, and so on, but they can also be used for more sinister purposes, such as oppressive surveillance by retailers, marketers, and manufacturers.

Measures have been suggested to counter the ill-effects of this new technology, including government regulation, use of tags with an opt-out capability (or, alternatively, opt-in capability) and blocker tags.

We set out to explore the effects of a new, inexpensive technology, and particularly its dark side from the viewpoint of personal security and privacy. It seems that the road of exploration has taken us to a largely uncharted territory, which may even turn out to be the outskirts of the real Information Society. Getting there, however, requires solving the problems associated with one of the key technologies of the future: RFID.

## KEY TERMS

**Information Security:** Securing data and information in terms of confidentiality, integrity, and availability (CIA model).

**Privacy:** Right of individuals and organizations to control the collection, storage, and dissemination of their information or information about themselves.

**RFID:** Radio frequency identification.

**Surveillance:** Careful watching of a person or a place, usually because a crime is expected or has happened.

**Tag:** Multilaminate structure that houses RFID electronics.

**Traceability:** Ability to review in retrospect what happened during an activity.

**Ubicomp:** Ubiquitous computing, or ever-present computing; making computers available throughout the physical environment.

**Usability:** Extent to which users are able to access data and information.

# Radio Frequency Identification Technology in Digital Government

**Les Pang**
*National Defense University, USA*

## INTRODUCTION

Following technical strides in radio and radar in the 1930s and 1940s, the 1950s were a period of exploration for radio frequency identity (RFID) technology as shown by the landmark development of the long-range transponder systems for the "identification, friend or foe" for aircraft. Commercial use of RFID appeared in the 1960s, such as electronic article surveillance systems in retail stores to prevent theft. The 1970s were characterized by developmental work resulting in applications for animal tracking, vehicle tracking, and factory automation.

RFID technology exploded during the 1980s in the areas of transportation and, to a lesser extent, personnel access and animals. Wider deployment of RFID tags for automated toll collection happened in the 1990s. Also, there was growing interest of RFID for logistics and having it work along side with bar codes. In the beginning of the 21st century, the application of RFID technology has been ubiquitous and now it is practically part of everyday life (Landt, 2001).

## BACKGROUND

Similar to bar coding, RFID tags provide information about goods, products, conveyances, animals, and people in transit. However, unlike bar coding which tracks product lines, RFID technology uses radio frequencies to automatically detect individual units and the information about these units. Use of radio frequency eliminates line-of-sight requirements and permits wireless detection.

RFID offers a number of advantages over the current bar-code technology which uses universal product codes (UPC). Codes in RFIDs are long enough so that each tag may have a unique code whereas a specific line of products are limited to a single UPC code. The distinctive nature of RFID tags results in an object that can be individually tracked as it moves from location to location. For product items, this characteristic can help retailers reduce theft of specific units and other forms of loss. Although functionalities provided by this technology far surpass those provided by bar coding, it does not mean that RFID will replace bar codes because of cost considerations.

RFID technology ensures better inventory control which leads to improved supply chain operations. The U.S. Department of Defense (DOD) has required its roughly 40,000 suppliers to put RFID tags on pallets and cases as well as on single items costing $5,000 or more beginning January 1, 2005. Wal-Mart has required that its top-100 suppliers provide the tags by 2005 for tracking merchandise, materiel, and goods.

RFID technology extracts information from tags, also known as transponders, wirelessly and automatically. Consider an arrangement of antennas connected to reader, which in turn is connected to a computer. When a tag enters the radio frequency field, it derives power from radio frequency signal. This energy allows a tag to transmit data, typically an identity, often in the form of an electronic product code (EPC). Unlike bar codes which tell you that a carton contains product XYZ, EPCs can specifically identify one box of product XYZ from another box of product XYZ.

This information is fed to a reader via the antenna. The reader interprets the information and translates it into binary format before relaying it to the connected computer. The computer can perform an action based on data received—this could be simply identifying existence of an item or adding or deleting it from its inventory. In some cases, the computer can also send a message back to the tag (Shahi, 2004).

RFID technology has clearly emerged as an approach to support e-government strategies aimed at improving citizen services, security operations, government-to-business interactions, and internal government operations. This article explores the potential of RFID technology in achieving quantum-level improvements in the realm of digital government particularly at the federal sector.

## APPLICATIONS OF RFID

Applications of RFID technology were researched and actual and potential uses of the technology for digital government were identified and categorized into the following functions:

- Delivery of citizen services

- Security applications
- Business-to-government interactions
- Internal government operations

Applications identified were specifically those that have been or can be implemented by a government entity including the military.

## Delivery of Citizen Services

### Improving Drug Safety

The Food and Drug Administration is investigating attaching RFID tags onto pharmaceutical drug labels. These tags will help pharmacists and technicians find where on the shelf a drug is stored and the length of time the drug has been there. This system can also help when there are drug recalls and for verifying expiration dates (Sun Microsystems, 2003).

In another application, RFID tags are being embedded in lids of medication bottles and vials to ensure patient medication compliance. The RFID can be programmed to remind the patient when the next dose is due and tracks and records the time the patient opens the bottle to remove the tablet or capsule. The data can then be retrieved by a reader for review by the physician, researcher, or pharmacist. This approach can be applied to Veterans Administration hospitals, military hospitals, and other government medical facilities (Information Mediary Corporation, 2004).

### Reducing Traffic Congestion

Toll facilities operated by state government transportation agencies are equipped to read RFID tags mounted on vehicles. Examples of electronic toll collection systems include Virginia's SmartTag system, the EZ-Pass system in the northeast United States, and California's FasTrak system. The tag is linked to a prepaid replenishable account that is debited when paying the toll. These tag-equipped vehicles no longer need to stop and pay the toll, thereby reducing traffic congestion at these locations.

### Improving Postal Services

RFID tags can be used to improve the flow of mailed packages. An RFID-enabled conveyor system was developed that is able to sort packages with 100% accuracy and at a speed of 200 packages per minute. This success shows that RFID can be used instead of bar codes for this type of operations (Collins, 2003b). Also, the U.S. Postal Service is investigating the placement of RFID technology on postage stamps in order to track and locate mail quickly (Sun Microsystems, 2003).

### Preventing Auto Theft

German companies developed a holographic windshield label that will make it difficult to conceal the identity of a stolen car. The high-security windshield label is difficult to counterfeit because of the hologram technology. This label allows police to view electronic data verifying the ownership and operating status of a vehicle. If a criminal attempts to transfer a label to a stolen car, the RFID label is disabled because the connection between the antenna and chip will be decoupled (Anonymous, 2002a).

### Ensuring Tire Safety

Michelin, the tire manufacturing company, has begun testing RFID tags embedded in tires for tracking purposes to ensure compliance with the United States Transportation, Recall, Enhancement, Accountability and Documentation Act (TREAD Act) in the wake of the Firestone and Ford Explorer fiasco. The Act requires carmakers to closely monitor tires starting with the 2004 model so the tires can be recalled promptly if a problem occurs (Anonymous, 2003a).

### Improving Transit Operations

Washington, DC's public transit system uses an RFID-based smart-card system called SmarTrip. Used by more than 360,000 of its Metrorail travelers, a card-carrying passenger can stroll by a reader at the entrance kiosk of one station and the value of the card is displayed. When it is scanned past the exit kiosk of another station, the cost of the trip is automatically calculated and deducted from a prepaid account. This helps the passenger avoid waiting in line for purchasing paper fare cards. These cards can also be used to pay commuter parking lot fees and bus trips within the regional network.

In Bogotá, Colombia, 23,000 transit buses carry RFID tags ensure that the buses are distributed throughout the city and avoiding congestion located at major thoroughfares (Collins, 2004e).

### Improving Highway Safety

The Federal Highway Administration is looking at using RFID technology in its goal to reduce road fatalities in the United States by 50%. The agency has funded companies to develop dedicated short-range communications (DSRC) technology, a complement to RFID systems, for issuing

alerts to drivers about impending intersection collisions, rollovers, weather-related road hazards, or warning a driver that his or her vehicle is going too fast to safely negotiate an upcoming curve. This high-bandwidth technology can also be used for downloading road maps and a possible replacement for automatic toll collection systems (Collins, 2004b).

### Improving Food Safety

One of the futuristic uses of RFID tags has been its capability to work with "smart" appliances. For example, RFID technology will allow a refrigerator to track the expiration dates of the food it contains and notify its owner when it does expire. This is an area that may be of interest to the Food and Drug Administration for ensuring food safety at commercial sites (Brown, 2002).

### Facilitating Financial Transactions

The use of RFID technology to facilitate payments can be used at government-operated recreational areas and parks, museums, food concessions, and other government-sponsored facilities. The private sector has been pioneers in this area with their novel applications of tag technology particularly in retail establishments.

### Improving Luggage Flow

McCarran International Airport in Las Vegas is applying RFID tags as part of its effort to overhauling its baggage-handling systems to support federal security regulations and reduce incidences of lost baggage. The system which currently uses bar-coded labels is expected to improve in terms of expediting the flow of baggage using RFID (Joachim, 2004).

## Security Applications

### Access Control

Many buildings and other secure locations are using contactless RFID tags as physical access cards. Often in the form of smart cards, these credit card-sized systems contain a microprocessor embedded in it.

### Anticounterfeiting

The Internal Revenue Service is investigating embedding RFID tags into currency to reduce counterfeiting. In addition, euros may get RFID tags to stop counterfeiting. These tags will also have the ability of recording data such as details of the transactions involving the subject paper note. This would prevent money laundering, track illegal transactions, and also prevent kidnappers demanding unmarked bills (Sun Microsystems, 2003).

### Personal Identification

China will issue over a billion RFID-based personal identification cards to each of its citizen. Three million handheld RFID readers would be issued to the police to give them the ability to scan the information contained in the cards (Winer, 2004).

Another way personal identity can be ascertained is through VeriChip, a small RFID chip about the size of a grain of rice. Each VeriChip contains a unique identification number which is used to access a database consisting of personal information. It is implanted just under the skin not unlike receiving a shot and it is scanned with a scanner. Because of this approach, the developers claim that the VeriChip cannot be lost, stolen, misplaced, or counterfeited. This chip can be used for personal identification. In October 2004, the Federal Drug Administration approved the device to give medical personnel instant access to patient records (Feder, 2004).

### Livestock Tracking

Vermont Senator Patrick Leahy told a Georgetown University audience that he had firsthand experience with RFID technology from his own involvement in a Vermont pilot program tracking cattle to thwart outbreaks such as mad cow disease (Swedberg, 2004).

### Improving Port Security

Pilot studies are being conducted that test RFID technologies in combination with satellite tracking systems, gamma ray image scanning devices, and Web-based software to make sure containers at U.S. ports hold what they are supposed to contain (Rosencrance, 2002).

### Making Children Safe

RFID tags embedded in wristbands have been used in various amusement parks in the United States and Europe to track the location of children. Parents who can rent these wrist bands for their children can locate their children to 5 feet of their actual location using a distributed network of sensors. This child-tracking system relies on a combination of active RFID tags and Wi-Fi access-point triangulation (Anonymous, 2004e). This approach can be used at government-run facilities frequented by children such as art galleries, museums, and zoos.

### Improving Firearm Safety

A Belgian subsidiary of the firearm company, Smith and Wesson, implemented a RFID firearm system which would make a firearm operational only to the individual implanted with a corresponding microchip (Gossett, 2004).

### Detecting Counterfeit Drugs

The Food and Drug Administration recommended the use of RFID technology to create a "pedigree" for a drug—a secure record documenting that the drug was manufactured and distributed under safe and secure conditions. The agency predicts that RFID can be used to track all individual drugs by 2007 (Food and Drug Administration, 2004).

### Tracking Inmate Movements in Prisons

RFID technology promises to locate prisoner movements in real time. At the Ross Correctional Facility in Chillicothe, Ohio, inmates wear wristwatch-sized transmitters that track them within the prison. These devices can also detect whether prisoners have removed them and can send an alert to prison computers (Best, 2004).

### Securing Library Books

San Francisco Public Library system approved plans to tag library books with RFID chips to prevent theft of the books and track its use (Stanley, 2004).

## Business-to-Government Interactions

### Improving Supply Chain Management

RFID technology promises improved product availability and reduce processing costs. Private sector retailers Wal-Mart, Target, and Albertson are mandating its suppliers to put RFID tags on cases and pallets. The DOD is requiring suppliers to place passive RFID tags on pallets and cases starting in 2005. As an incentive to suppliers that tag their shipments, the agency is introducing a fast-track billing process enabled by the faster processing of deliveries (Collins, 2004c).

### Tracking Airline Parts

The Air Force and the Federal Aviation Administration might want to consider what Boeing and Airbus are planning to do with RFID technology. These two major airline manufacturers are initiating a number of forums for customers and suppliers to prepare the airline industry for the use of RFID technology to identify major airplane parts (Roberti, 2004a).

### Improving Asset Management in Hospitals

Managers in military hospitals and other government medical facilities may want to look at RFID-based asset-management solutions. One RFID provider will tag and track 10,000 pieces of mobile medical equipment at three Virginia hospitals (Collins, 2004d).

### Tracking Vehicles in Secure Areas

A new RFID-enabled yard management system is being developed that will let operators of shipping yards and quarries automatically track vehicles as they enter, travel through, and exit facilities (Maselli, 2004).

### Tracking Containers

A provider of wireless asset-management systems is integrating optical character recognition technology with RFID tags to replace the manual processes terminal operators now use to track the container from ship to terminal and vice versa. The provider expects to process a container more efficiently, at a higher volume and with lower costs (Anonymous, 2003b).

## Internal Government Operations

### Tracking Wounded Soldiers

RFID technology was used for tracking wounded soldiers who were involved in the war in Iraq. The U.S. Navy's Fleet Hospital in Pensacola, Florida, tested a system involving RFID wristbands which store the soldier's identification and medical information regarding his or her condition and treatment as he or she moves from the battlefield to a hospital. The U.S. Navy is also using RFID technology to track the status and location of prisoners of war, refugees, and others arriving at the hospital (Anonymous, 2003).

### Tracking Combat Rations

The Department of Defense simulated the tracking of combat rations throughout the entire supply chain from "vendor to foxhole." The agency showed how data could be aggregated and encoded on a special tag with a temperature sensor for the quality control of the combat rations (Anonymous, 2004c).

### Improving Internal Services Management

The U.S. General Services Administration mandated RFID technology to assist in managing data on government buildings, fleets of cars, and products. The driving factors are cost reduction and improved efficiency. The agency intends to cut cycle times and provide rapid response to customers through the use of this technology (Sun Microsystems, 2003).

### Tracking Media

Government agencies have a tremendous storehouse of media that it must track for retrieval purposes. Playboy TV is deploying RFID to track master tapes at its British headquarters where tapes are edited for broadcast over the English and European cable and satellite networks. Tracking tapes in the library used to be a difficult task at Playboy—they spent hours searching for tapes throughout the building. By tagging each of its 11,000 videos, Playboy is experiencing highly reduced search times (Collins, 2003a).

## ISSUES

With the implementation of any new technology, issues can arise stemming from its use. RFID technology is no exception. This section will focus on four key concerns surrounding the tags—privacy, system reliability, interoperability, and cost.

### Privacy

The issue of privacy revolves around retail use of RFID technology. There is concern that RFID tags affixed to consumer products remain operational after the purchase of the product. Although intended for short-distance use, these tags have the potential of being interrogated from great distances by someone with a high-gain antenna, thereby allowing, for example, the contents of a house to be scanned at a distance according to some experts. Therefore, key concerns involve the consumer not being aware of an affixed tag, the consumer not being able to deactivate the tag, and the capability of reading the tag at a distance without the knowledge of the consumer. If the purchased item was paid by credit card, theoretically it would be possible to link the items purchased to the consumer's identity.

German retailer Metro came under fire by privacy advocates who discovered that RFID tags were embedded in the store's loyalty cards. They also found that RFID tags on products sold at their store cannot be completely deactivated after purchase. "Customers are misled into believing that the tags can be killed at a special deactivation kiosk, but the kiosk only rewrites a portion of the tag, while leaving the unique ID number intact." Outraged German citizens were demanding that Metro put an immediate end to the trials (Associated Press, 2004).

Privacy groups such as Consumers Against Supermarket Privacy Invasion (C.A.S.P.I.A.N) are trying to get legislation introduced into Congress to outlaw RFID tagging. Others are applying market pressures to encourage businesses to behave responsibly.

Government is responsible for maintaining the public trust of the citizens. If the government uses RFID tags in ways that violate of privacy standards, public trust is breached and there will be considerable ramifications.

### System Reliability

Some observers indicate that antitheft RFID systems are capable of being set off by odd things such as items of personal electronics or bits of metal. One claim was that a child activated these systems because he happened to generate the exact frequency of electromagnetic energy.

Early applications of RFID technologies were not successful. Early tests conducted for the Department of Defense showed that tags on liquid-filled containers could not be read reliably but this problem has been corrected. Tagging liquid-filled containers (such as cartons of bottled water or shampoo) is still a challenge but tags that will work on virtually any surface or container are now available (Anonymous, 2004c).

Practitioners have identified other problems with RFID technology. There is considerable delay when an encoded tag cannot be read. Some imply that it is not ready for high-volume processes yet. There are also middleware issues that need to be addressed in order that the RFID tag system to be compatible with the database management system (Sliwa, 2004).

Activists against the technology state that RFID could be bad for health reasons. In a future world where RFID readers are ubiquitous, people would be continually bombarded with electromagnetic energy. The long-term health effects of chronic exposure to this constant energy are not clearly known to researchers (Anonymous, 2003b).

### Interoperability

Based on interviews with senior executives across the globe, the system infrastructure presented by the diverse and competing RFID vendors are often incompatible. Many countries have not agreed on common standards, frequencies, and power levels for RFID tags and readers (Collins, 2004c).

Significant differences in the numbering scheme for the RFID tags have surfaced. The EPCglobal, the industrial consortium for RFID technology, envisioned that all companies would use a single EPC numbering scheme. However, the DOD, the biggest customer migrating to RFID technology, prefers using its "Unique ID" numbering system accepted as one of the EPC standards. Other industries are also seeking to use their own unique numbering systems so that companies within those industries will not have to spend much to modify their software systems (Anonymous, 2004d).

One of the biggest challenges involves integrating the data received by the RFID with an organization's backend systems. This occurred to 7-Eleven when the company piloted an effort to use a RFID stored-value card inside the corporate headquarters in Dallas and at a store in Plano, Texas (Levinson, 2004).

### Cost

Companies are also concerned about the cost of RFID tags and how much they will have to spend to comply with mandate such as those posed by Wal-Mart and the DOD. A related question is how to allocate the cost of deploying RFID systems and tagged products among the different players in the supply chain (Collins, 2004d).

The cost of the tag is roughly $0.50 to a dollar; many in the industry say that the price must come down to $0.05 for it to be economically viable (Carroll, 2004).

## FUTURE TRENDS

RFID, as with many other technologies, proceeds through a maturation cycle. It is now being overhyped as the solution to many problems. It may not prove to have a place within an organization's infrastructure, culture, or financial budget.

Nonetheless, it is exciting to see the number of actual and potential ways this technology can help in improving and streamlining business processes. The future looks very bright for RFID technology. For example, RFID promises to bring a new level of usability and functionality to cell phones. By inserting an RFID reader into the unit, it will allow mobile services, ticketing, payment transactions, and exchanging business cards by simply touching two cell phones together. Employees can send real-time attendance logs and automate routine reporting tasks over the cellular network.

## CONCLUSION

As this technology matures, sufficient attention must be made toward the issues identified here, namely, privacy, system reliability, interoperability, and cost. People need to feel confident that their personal privacy is protected whenever RFID tags are used and that information is not being distributed to unauthorized parties. People need to know that RFID systems are reliable enough for mission-critical applications such as financial transactions. Instead of a multitude of incompatible standards, there needs to be a common basis for RFID systems to work with each other without going through tedious effort. The RFID tags should be economical so that they could be used on a widespread basis and offer substantial value to both businesses and ultimately consumers.

## KEY TERMS

**Active Tag:** A tag with a power source such as a battery that can be used as a source of energy for the tag's circuitry and antenna.

**Bar Codes:** A collection of lines of different weights and spacing that can be read by a computer input device.

**Passive Tag:** A tag that does not have a power source such as a battery. Power is supplied by the reader. When radio waves from the reader meet a passive tag, the coiled antenna within the tag forms a magnetic field. The tag draws power from the field and energizes the circuits in the tag. The tag next transmits the data encoded in the tag's memory.

**Reader:** A device which is capable of "interrogating" or reading data from a tag. The reader has an antenna that emits radio waves; the tag responds by sending back its data.

**Tag:** A portable device which is capable of receiving data from or transmitting data to a reader. It holds a microchip combined with an antenna in a compact package. The antenna picks up signals from an RFID reader or scanner and then returns the signal typically with some additional data. RFID tags can be very tiny such as the size of a large rice grain or as large as a paperback book.

**Transponder:** A combined receiver and transmitter whose function is to transmit signals automatically when triggered by a reader or an interrogator.

**VeriChip:** An implantable radio frequency identification (RFID) microchip for human use.

# Record Keeping for Digital Contracts

## INTRODUCTION

A challenge in electronic commerce is to keep proper records of business contracts made over the Internet. A common type of contract is a purchase order that a buyer places on a vendor using the Web or a private network. The government has to step in to adjudicate disputes if and when they arise. It is in the public's interest, therefore, that formal and indisputable methods are developed for recording contracts digitally.

On June 30, 2000, the Electronic Signatures in Global and National Commerce Act (E-sign Act) was passed in USA, and it legalized electronic signatures in contracts. This paved the way for the rapid growth in electronic commerce which is estimated to be $3.2 trillion in the USA (Freeman, 2004). With this sizable business, it is very likely that disputes involving electronic contracts arise.

In this article, we suggest a few models and processes for creating and storing authentic contract documents so that future disputes can be settled more effectively.

## BACKGROUND

Disputes could be about any aspect of a contract. They could be about the quantity, the price, or the quality of the product or service stated in the contract. In the former case, the dispute may concern the exact wording of a clause in the contract. If the contract is in digital format, then we have to make sure that the contract has not been altered by any of the parties. In a hard copy, alterations can be easily detected, but in a digital format, alterations can be difficult or impossible to detect. One way, almost an ideal way, to avoid alteration is to use digital signatures (Anthony, 2004; Freeman, 2004; Landau, 2000). A digitally signed electronic document cannot be altered or forged. The scheme will work as follows: The buyer sends a digitally signed purchase order, usually with an expiration date, to the seller which declares the buyer's offer to pay for the goods or services mentioned in the order. When the seller accepts the order, the seller digitally signs and dates the order that is already signed by the buyer. The seller then sends a copy of the doubly signed document to the buyer. Now both parties have a doubly signed unalterable document and there can be no dispute about the content of the contract. This scheme is practicable when both parties are rich enough to possess public keys necessary for digital signatures. In practice, though, the buyers of consumer products such as personal computers may not have public keys and will not be able to sign documents digitally. Yet, they would like to be able to place purchase orders over the Web without fear of fraud. Also, the seller, usually a large corporation, should be able to accept as many orders as possible without fear of dispute.

Another case is a large buyer who purchases many types of products from many small suppliers. In this case too, a third party can keep the records of all contracts so as to minimize disputes.

In this article, we provide a few approaches to generate and store electronic contracts between a customer and the business. These approaches differ in the following aspects: average dollar worth of the sales transaction, likelihood of default or a lawsuit, and the technical infrastructure with which the business operates.

## MAIN FOCUS OF THE ARTICLE

In this section, we present a few models in which a third party stores the contracts so as to minimize the chances for disputes. The third parties may be certified by some governmental authority, or an international authority, so that credibility of such an entity is established. To avoid the need for additional governmental expenses, existing trade authorities can be entrusted with this task of certifying third parties.

## Single Seller, Multiple Buyers

In this scenario, a large seller receives orders from thousands of buyers digitally, say, through a secure Web page created for the purpose at the company's Web site. After the product is delivered against an order, it is possible that the buyer disagrees about some aspect of the order. To minimize such complaints, the seller hires a third party to receive and store the contracts. The steps involved in this scenario are:

1. The seller publicly announces products and prices, on its official Web site
2. A buyer places a purchase order which is received by the third party, rather than the seller
3. The third party sends the order to the seller and gets it digitally signed by the seller
4. The third party sends the digitally signed copy to the buyer
5. If the buyer accepts it, the buyer makes the payment, usually through a credit card authorization
6. The third party stores the digitally signed purchase order and the buyer's credit card authorization for a predetermined length of time, so it can be retrieved in case of dispute

## Single Buyer, Multiple Sellers

A large buyer such as a manufacturing company may place purchase orders on hundreds of suppliers for thousands of materials. Suppliers could be in different countries. The buyer hires a third party to store the contracts in order to minimize disputes. The steps involved in this scenario are:

1. The buyer sends a digitally signed purchase order to the third party
2. The third party sends the digitally signed order to the seller
3. If the seller accepts the order, the seller sends an acceptance notice and a credit card authorization for payment to the third party
4. The third party stores the contract and the acceptance notice with credit card authorization for a predetermined length of time, so it can be retrieved in case of dispute

## Call for Quotes

In this case, the buyer calls for quotes for a project from many potential contractors. Usually, a deadline for submitting quotes is specified, the quotes are sealed, and all quotes are opened at once at a predetermined time. Disputes can still arise about some aspects of a quote. The buyer can hire a third party to receive and process the quotes so as to minimize the chances of disputes. The steps here are:

1. The buyer announces a Call for Quotes at an official Web site
2. Contractors send their password-protected quotes to the third party, and receive an acknowledgment of receipt. (A pdf file of the quote can be password protected reliably). Contractors who have public key facility may digitally sign their quotes for added security
3. Contractors communicate their passwords to the third party at a predetermined time, so that their quotes can be opened
4. The third party communicates all quotes to the buyer, and stores them for a predetermined length of time

## Government-Hired Third Party

Sale of real estate and automotive vehicles are required to be registered with the government. For economic reasons, a government may hire a third party to store sales documents in a way that is amenable to public access, or protected access by authorized parties. The steps here are:

1. The buyer and seller both pay a fee and ask the third party for a document to be stored according to government specifications. Payment of fees is taken as acceptance of the document version
2. The third party stores the document for a predetermined length of time and provides public access to it via a Web site. If the document is to be protected in such a way that only those with a password can access it, the third party implements such protection

## Independent Third Party Service

In this model, a document that involves two or more parties is stored by the third party for a fee. Payment of the fee is considered acceptance of the document version by all parties. The steps here are:

1. The third party announces its services via a Web site
2. Each of two or more parties pays a fee to the third party to store a document for a predetermined length of time with password protected access. One or more of these parties may digitally sign it for further security

3. The third party stores the document with password protected access via its Web site

## FUTURE TRENDS

A fundamental requirement of the proposed models in this article is the use of a third party whose authority is well established. Just as Key Distribution Centers (KDC) are authenticated in the practice of public key cryptology (Koblitz & Menezes, 2004), the third parties in the models above are to be authenticated by a governmental body. Indeed, a KDC itself can serve as a third party to store commercial contracts. Additionally, governmental trade regulatory authorities can be entrusted with the task of certifying third parties.

A second important aspect of the models is the use of digital signatures. Many improvements are taking place in this area, the most promising one being quantum cryptography. While current algorithms such as RSA (Rivest, Shamir, & Adleman, 1978) or DES (NIST, 1993) have been secure so far, they are not guaranteed to remain so in the future. A breakthrough in the theory of computation or a leapfrog improvement in the speeds of computers could thwart current algorithms. On the other hand, quantum cryptography is based on objective uncertainty and therefore is not subject to the same threats (Bennett, Brassard, & Ekert, 1992).

It is also possible to use the emerging schemes for multi-signature and proxy signature for creating and storing secure documents (Hsu, Wu, & He, 2005). Such schemes can reduce the number of steps involved in the processes described in this article.

Further improvements to the Internet and telecommunication can strengthen the models suggested in the article, due to better and more secure access to the Web.

## CONCLUDING REMARKS

Business-to-customer information systems process orders electronically without much manual intervention. Processing such orders usually involves a legal contract between the business and the customer, which confirms that both parties agree to the terms and conditions of the transaction. This contract needs to be captured and electronically saved by some agent so that any disputes that arise later can be properly addressed. Currently, the business itself is carrying out this process. This practice is unsatisfactory not only because it is unilateral, but also because there are no standards for fraud-free record keeping. Lacking a standard, each business has devised its own way of generating, and storing the contracts. Not even a set of guidelines for systematic generation and storage of electronic contracts exists.

In this article, we have presented a few models for generation and storage of electronic contracts. These models involve cryptology, digital signatures, and authentication. Business managers can devise suitable strategies for managing their contracts based on how the model parameters apply to them.

## KEY TERMS

**Data Encryption Standard (DES):** A Federal Information Processing Standards (FIPS) approved cryptographic algorithm for encrypting and decrypting text.

**Digital Signature:** A method for authenticating digital information using public key cryptography.

**E-Sign Act:** Refers to the Electronic Signatures in Global and National Commerce Act passed in 2000 by the U.S. Government that legalized digital signatures.

**KDC Authentication:** The process by which the integrity of a Key Distribution Center (KDC) is established.

Usually carried out by a governmental body, the authentication enables the use of public keys.

**Key Distribution Center (KDC):** A facility that generates and distributes public and private keys for encryption and decryption.

**Public Key Cryptography:** A scheme that allows users to communicate securely without having prior access to a shared secret key, by using a pair of cryptographic keys, designated as public key and private key,

**Quantum Cryptography:** An encryption/decryptions scheme which uses the objective uncertainty of quantum properties of subatomic particles and therefore expected to be secure forever. Current public key cryptography, on the other hand, relies on intractable mathematical problems, and may become insecure in the future.

# Regulatory Ontology–Based Interagency Information and Service Customization

## INTRODUCTION

The government services needed by citizens or businesses often require horizontal integration across autonomous government agencies. The information and services needed are typically scattered over different agencies in diverse formats, and therefore are not interoperable. This results in the so-called "stove-pipe" service and information paradigm, which raises a number of challenges. First, the service consumers, both citizens and businesses, face the challenging task of locating relevant services and information from a large number of documents scattered at different locations on the Web. Therefore, it is beneficial to have a system to locate and integrate available services that are tailored to individual preferences and needs according to regulations. Second, due to the fact that information is not shared among the different agencies, service consumers are required to reenter certain data repeatedly to obtain interagency services. Service integration should allow sharing among agencies.

Digital governments have been evolving with different focuses in terms of information and transaction services. The evolution has shown at least four different stages. At the first stage, with the Internet and the WWW, governments digitized paper forms and started to disseminate information with static Web pages, electronic forms, and data displays. The focus of this initial stage has been to make information digitally available on the Web. The transaction services tended to resort to off-line paper-based traditional methods (e.g., by submitting the printed form with a payment) such as by credit cards.

In the second stage, governments started to provide services for the citizens by developing applications for service delivery and databases to support the transactions. The citizens and businesses can "pull down" the needed services and information through "active" interaction with individual agency Web sites separately, as in self-services. In both of these stages, the digital government efforts did not consider what other government agencies have been doing and how their services may be related to other agencies' services. The information and service consumers need to "visit" each agency separately and actively search for information and services. The digital government up to this stage mimics the physical government, and citizens and business entities navigate digital boundaries instead of physical boundaries for complex services, such as business registration or welfare benefits. When agency interactions are needed, data and forms are forwarded in batch mode to other agencies through paper or fax, where the data is reentered, or the digital data captured from a form is forwarded in a file via CD-ROM or a floppy disk. The streamlining of business processes within individual agencies may have been achieved, but not the streamlining of business processes across agencies.

In the third stage, digital government agencies strive to provide seamless, integrated services by different agencies with sharing necessary information. The services and documents are organized such that they are easily identified and the consumers do not have to scour large amounts of information for the right ones. This stage of digital government is characterized as one-stop portal stage. In the fourth stage, the governments create digital environments where citizens' participation is encouraged to define government policies and directions. The services up to the third stage are often enforced by government regulations and policies. These very rules and policies can be modified by citizens' participation. In this fourth stage, digital government efforts focus on developing collaborative systems that allow collaboration among government agencies and citizens in order to reflect the constituents' inputs.

Today's digital governments characterized by "self-service" and "one stop portal" solutions, between stages

two and three, need to provide front-end (citizen-facing) tools to deliver relevant, customized information and services, and a back-end (processing) infrastructure to integrate, automate, manage, and control the service delivery. The service integrations vary according to user requirements and need to be dynamically achieved in an ad-hoc manner with personalized processes as end results.

## BACKGROUND

Web-based electronic commerce applications or digital government services applications support the interaction between different parties (customers or citizens) and management of data involved in the process. In Electronic Commerce, integrating a variety of available applications creates value-added services for customers and new business opportunities for providers. The integrated applications allow comparative shopping services where customers have a uniform interface for different stores. The integration of complementary services allows one-stop services, such as airline, train, hotel, and car rental services as one service. The application integration faces a number of challenges, such as diversity of applications, disparity of interfaces, and heterogeneous data and API formats. In addition, the integrated services may be loosely coupled involving different participants, playing different roles, in an ad-hoc manner, involving different flows, and complicating the coordination. Thus, the discovery of available services for flexible customization and coordination is required. There are a variety of technologies and standards for solving these issues.

- **Database Schema Integration:** Heterogeneous data formats in each application need to be integrated for integrating autonomous business applications. ERP solutions such as SAP R/3 or EAI (Enterprise Application Integration) use consolidated common data and message exchange models (e.g., XML) for enterprise-wide and cross-enterprise application integration (Lee, Siau, & Hong, 2003)
- **Middleware Approaches:** Invoke a set of software libraries (components) to locate the needed application components and data. CORBA (Common Object Request Broker Architecture) (Vinoski 1997) is an example. The client makes high-level requests for objects and the CORBA middleware locates necessary components and implementation objects
- **Workflow Systems:** Have been used for interorganizational processes or virtual enterprises where processes span multiple organizational boundaries and are composed of loosely coupled cooperating workflows executed in different organizations (Alonso et al., 1999; Casati & Discenza, 2000; CrossFlow, Georgakopoulos, Shuster, Cichocki, & Baker, 1999; van der Alst 1999). The workflow systems typically include components for the modeling and specification of virtual business processes, their execution, process monitoring and analysis, and message communication among process participants
- **Agent-Based Integration:** An agent is a software module having local decision-making capabilities and intelligence to perform specialized tasks by interacting with users, other agents, and information sources. It communicates with other agents to locate the needed services to fulfill the requests from the user or another agent (Wiederhold, 1992). The information and services are integrated by tasks performed by a set of agents
- **Web Service Composition:** The growing trend for B2B or enterprise application integration is using Web services that are platform independent. Each service is published with a set of descriptors about its input, output and behaviors. A set of XML-based standards is used to describe these Web services (WSDL–Web Service Description Language), to be published in a public repository (UDDI–Universal Description, Discovery and Integration), and to be invoked via SOAP (Simple Object Access Protocol). Individual Web services are composed for integration and customization and can be specified in BPEL (Business Process Execution Language) (Hull & Su, 2004).

Using these technologies, one may integrate the applications, services, and business processes, but putting these services together remains mostly manual. Web service technologies try to automate the service identification and discovery utilizing the Web service descriptors such as input and output matching, which are mostly syntactic descriptors. More semantic and pragmatic approaches may be needed for automatically identifying the needed component services for integration and customization (McIlraith, Son, & Zeng, 2001).

## ONTOLOGY-BASED CUSTOMIZATION

Consider an entrepreneur, John, who wants to develop an open lot to start a new automobile repair shop as follows:

*Scenario: The open lot is located in an environmentally sensitive area near wetlands and a river in the New Jersey Meadowlands designated as "Light Industrial and Distribution B zone."* (HMDC, 1999) *John will have*

*to find out all the relevant permits from different agencies and forms to fill out.*

*He will first visit the Websites of the New Jersey Department of Environmental Protection (NJDEP) to see if the lot falls in a wetland according to the Freshwater Wetlands Map, Tidelands Claims Maps and County Soil Survey of Natural Resource Conservation Service. If the wetland is verified, he needs to know that Army Corps of Engineers Section 10 or 404 Permits are applicable and determine whether NJDEP Waterfront Development Permit, Stream Encroachment Permit, Water Quality Certificate and Riparian Grant are needed. This is in addition to the task of deciding whether the zone-specific permits for the business type need to be obtained from NJMC (NJ Meadowlands Commission).*

*After this, John needs to obtain all business registration-related permits and certificates. He will need to look at Web resources on the business location, business type, and labor relations in order to identify all tasks, such as registration at the Department of Taxation, employer ID service at the Labor Department, and other services from the Division of Commercial Recording, Division of Community Affairs, Department of Environmental Protection, Department of Public Health and Safety, Division of Unemployment and Disability Insurance, Division of Worker's Compensation and others. John has to visit each agency's Web site and extract relevant documents.*

As shown in the scenario, the services provided by agencies for developing and opening a business define an inter-agency process, composed of individual services from each agency, in a way that the services are highly customized to meet the requirements and preferences of a particular individual. The relevant information and services should be automatically identified and gathered from different agency sites and integrated into a logical sequence. The composition of the inter-agency service needs to be dynamic, not static, and automatic rather than manual, to deal with diverse situations and contexts of each citizen.

The determination whether two government services can be integrated or not is often based on government regulations. Our approach is to develop an integrated comprehensive knowledge base of services and regulations for front-end customization tools (Chun, Atluri, & Adam, 2002; Chun, Atluri, & Adam, 2002a) which allows the relevant information to be "presented" according to the citizen's needs and preferences, and a decentralized workflow system for back-end process management (Atluri, Chun, Holowczak, & Adam, 2002) which promotes data sharing, and autonomy of agencies. The regulatory knowledge is represented as *ontology* that is used to automatically generate service integration and customization for the NJ State government and NJMC to deliver services for small and medium size businesses.

## Interagency Service Integration and Customization

The information needed for an entrepreneur differs based on the location (e.g., lot and zones), spatial features of the lot (e.g., wetlands, flood plain), development type (e.g., residential vs. commercial), and business type (e.g., gas stations), etc. The developers need to be aware of the regulations to meet the requirements for opening a new business. This compliance knowledge is captured as a regulatory ontology (Figure 1) where each concept node is associated with relevant regulatory rules. For example, the node "wetland" is associated with a rule (R0 in figure 1) with a condition-action pair (If the lot is within 100 meters of a river, obtain water front permit). The required compliance service "waterfront permit" from the DEP is identified as soon as the lot is identified as wetland. A regulatory rule functions as *actionable knowledge* (i.e., when the condition of the rule is met, the action is carried out). In the new business registration interagency process, the service of obtaining the certificate of incorporation is required for an incorporated business structure (R1 in Figure 1). The resulting customized interagency service is represented as a workflow and presented to the user (Figure 2).

## Regulatory Information Customization

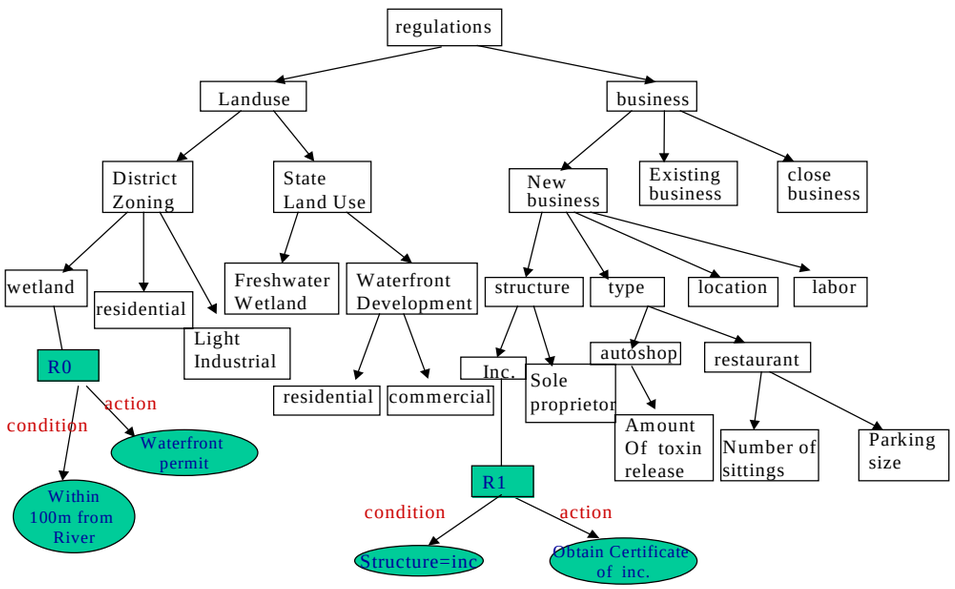
In addition, the regulatory information for a land developer can be customized through the use of the regulatory rules ontology. As the developer chooses one business type (e.g., the permitted zone for the particular business types are presented) (e.g., only commercial and light industrial zones (Figure 3)). A choice of a particular location (e.g., lot 20 in industrial zone) triggers the location-specific regulatory information and presented to the developer to show what rules are relevant. For instance, if the developer chooses a lot near a riverbank, the "Waterfront development regulation" is presented to the developer (Figure 4).

The visualization of customized information and services allows the citizen to have a road map for navigating different agencies. Since the composite interagency service is designed as a workflow built on the Web-based services, the services can be executed one after another by forwarding the relevant data from one agency to another.

## Prototypes

A prototype system, MyNJBusiness, generates an interagency service workflow customized for each business and entrepreneur to register a new business for the NJ

*Figure 1. Regulation ontology*



State government (CIMIC, 2001). This interagency service involves several agencies within the State government such as Office of Information Technology, Department of Taxation, Department of Commerce, Department of Environmental Protection, and Department of Labor, etc. Another prototype system, the Meadowlands Coastal Permitting Assistant (MCPA) (CIMIC, 2003), was developed and deployed at NJMC to customize an inter-governmental permit service that is composed of services from separate government agencies, such as the federal US Army Corps of Engineers, the state government agency NJDEP, the regional agency NJMC, and 14 local governments. The customization system takes user preferences and constraints and tailors their services accordingly.

## FUTURE TRENDS

One of the challenges in our approach is to develop a comprehensive ontology, which requires expertise in the domain. The regulation documents are immense. One approach is to build an ontology semi-automatically using text and other information cues combined with statistical methods (Alani et al., 2003; Degeratu & Hatzivassiloglou, 2002; Gal, Modica, & Jamil, 2004). For a full-blown system, one needs to employ automated text extraction methods. A second challenge is to automate updating of the rules and services. The government environments are dynamic. Each agency implements new policies, services and programs as mandated by law, which requires updates of the ontology systems. Each agency can need to monitor the changes and update the regulation ontology as a new rule becomes available or an old one becomes obsolete (Atluri & Chun 2003; Chun, Portscher, & Geller, 2005).

With the emerging technologies in Web Services (W3C, 2004a) and Semantic Web (Berners-Lee, 2001), especially OWL-S Web Ontology Language for Services (W3C, 2004), Web services can be invoked and dynamically discovered and composed using semantics provided by an ontology. The regulations ontology can automate the dynamic discovery and composition of services in alignment with these new technologies (Chun, Atluri, & Adam, 2005a; Maximilen & Singh, 2004).

## CONCLUSION

In this article, we have addressed the issue of providing customized interagency and intergovernmental information and services. We achieve the customization by using a knowledge base of regulations. The regulatory knowledge scattered in separate agencies' documents and Web pages is modelled with ontology of concepts, classes and subclasses, and actionable rules with conditions and actions. A customization system using the ontology of

*Figure 2. Integrated service workflow*

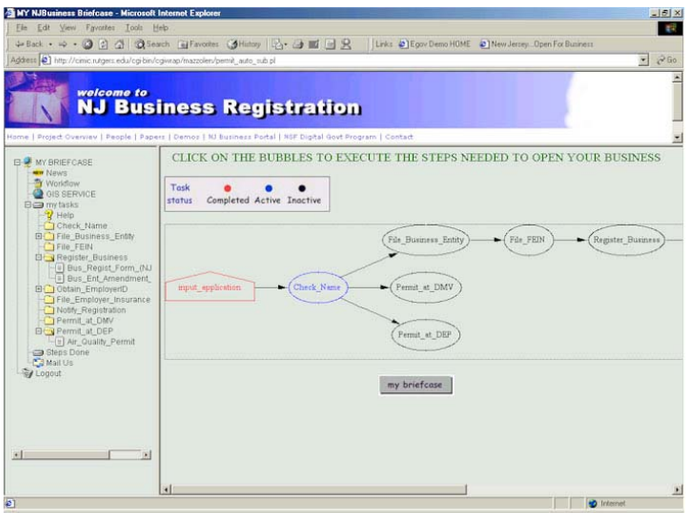


*Figure 3. Customization by zoning rules*

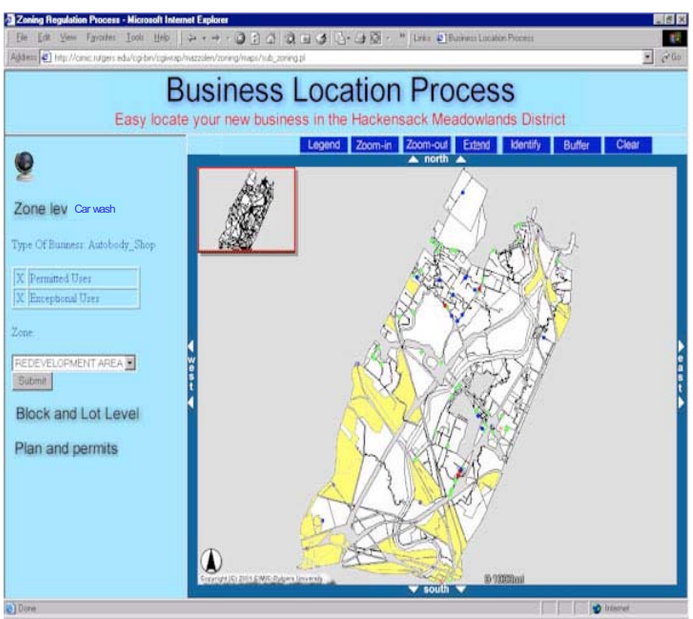

these rules discovers and generates an interagency workflow with information and services tailored to the citizen's preferences and needs and government rules. Online government systems using the regulatory ontologies can automatically achieve seamless integration of individual services.

## KEY TERMS

**Actionable Knowledge:** Explicit knowledge and information, typically presented in the form of rules, that allows the decision maker or a system to recognize some important relations and to perform an action, such as targeting a direct marketing campaign, or composing an integrated services.

**Interagency Information:** Information or data from multiple agencies, that is required for consuming interagency services.

**Interagency Service:** A government service that is composed of services from multiple autonomous individual agencies.

**Interagency Service Customization:** On-the-fly service integration composed of services from multiple government agencies that are required by the citizen's or business's preferences and constraints.

**Portal:** A Web site that hosts a broad array of resources and services, with personalization, single sign-on, content aggregation from different sources, such as email, forums, search engines, news, weather information, stock quotes, phone and map information and online shopping malls. It provides infrastructure for application systems to seamlessly aggregate and integrate back-end processes and systems, and deliver cross-enterprise services and information. The government portals facilitate the connection with citizens, businesses, employees, partners, and other government entities.

**Ontology:** The study about what kinds of things exist—what entities there are in the universe. It derives from the Greek onto (being) and logia (written or spoken discourse). It is a branch of metaphysics, the study of first principles or the essence of things. In information technology, an ontology is a working model of entities and their relationships in some particular domain of knowledge or practices (hence, domain ontology). Ontology provides a set of concepts and vocabulary in a given domain with a typically hierarchical structure containing all the relevant entities, the relationships among entities and rules that govern the uses of entities. Ontology helps humans and programs to share information and knowledge. Every concept within an ontology hierarchy can be described by assigning attributes–for instance, color is an attribute of concept "car." Attributes allow more complex relations to be modeled–for example, an instance attribute or a class attribute can describe an instance or a class of the concept, respectively.

**Self-Service:** A mode of finding and extracting the needed data and information through direct interaction with Web resources provided by government agencies.

**Stovepipe Systems:** Applications developed to solve very narrow problems within departments or within an organization that are not easy to interoperate with other systems.

**Workflow Management System:** A computer system that manages and coordinates the execution of the flow of work (tasks) among participants, according to procedures (dependencies) among a number of tasks.

# Reusability in Governmental Electronic Services

R

**George Lepouras**
*University of Peloponnese, Greece*

**Costas Vassilakis**
*University of Peloponnese, Greece*

## INTRODUCTION

Reusability in the everyday life is the capacity of using existing objects or even concepts again in the same or other contexts. When applied to information systems reusability is the capability of using the same parts of an application in other applications or in other contexts. As defined by IEEE (IEEE, 1990), *reusability* is the degree to which a software module or other work product can be used in more than one computing program or software system. Although rapid application development environments such as MS Visual .NET™ (Visual .NET, 2005) and Delphi™ (Borland Delphi, 2005) have to some extent employed reusability of components to aid the fast implementation of software applications, the extent to which existing objects can be used again in the implementation of new software systems is usually limited to basic building blocks of the interface. One problem that hinders reusability of larger building blocks is the fact that once a component which encompasses a number of objects is built it also encapsulates algorithms (sets of well-defined instructions that perform a task) in the form of code that define the functioning of the component. Tight coupling between the program logic and the program code makes portability of the component between applications difficult, when even small modifications in the program logic are required. A second problem that hinders reusability is that even when the same component can be directly used between applications, recognizing that such a component exists and retrieving it, is not an easy task.

Reusability plays an important role in software development industry. If a set of well-defined components is available, valuable resources can be saved by utilizing again these components. As Rich Seely observes (2003) "as part of that cost-saving message, Gartner recommends vendors and consultants focus on reusability of Web services applications and components."

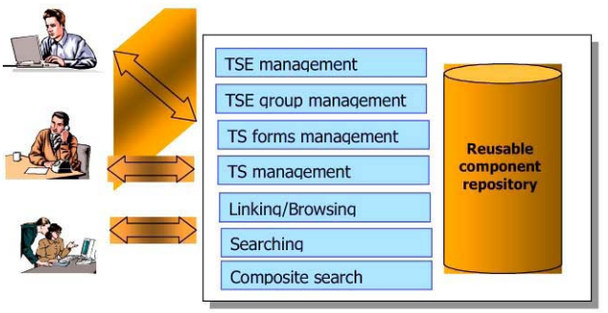
## BACKGROUND

Electronic government is an area where a lot of development effort is lately devoted to. Electronic government aims to promote the use of electronic means, mainly electronic services to facilitate communication and interaction between civilians or businesses and the government. According to the European Commission (European Commission, 2000) "transaction services, such as electronic forms, are perceived as the future of electronic government."

An electronic transaction service is usually the electronic counterpart of an existing service, implementing the business process logic involving the filling and submission of forms containing the necessary data, the processing of these data according to rules derived from laws and regulations and finally the return of a reply to the user.

In order to implement transactional electronic services, the collaboration between a number of experts is required. To this end, reusability can help by minimizing the effort needed for developing online transactional services. Electronic government offers a prominent area for the application of reusability since services offered to citizens from the same or different public authorities have common parts that could be reused between their electronic counterparts. However, in order to have effective reuse of components the two main problems previously described have to be solved. Back in 1995, Dusik and Katwijk (1995) identified the importance of a software development environment in which reuse, in various forms, would be an integrated element. As Gall, Jazayeri, and Klosch (1995) noted, the goal for reusability should be to create a software development process based on the "use" rather than the "reuse" of standard components. The approach used during the SmartGov project (2001) involved the design and implementation of an e-service development environment that would enable developers and domain experts to use components that they or other users had created to create their own transaction services.

*Figure 1. Introducing the reusable component repository*



## SMARTGOV APPROACH

In contrast to simple information services, transaction services allow users to submit their data and in response, the public administration performs a service such as the issuing of a certificate or the tax clearance. Transaction services allow the user to perform common services online, implementing thus one of the main objectives of the electronic government, namely the facilitation of the interaction between civilians and businesses with the public authorities.

To be able to implement reusability effectively, one has to start by decomposing a transaction service to its basic building elements. In the first level, an electronic service consists of a number of forms the user is required to fill in. In the case of short documents, one form may be enough, where for lengthy documents, more than one form may be necessary. A form itself may comprise of several *areas*, and each area commonly contains individual *fields*, which are conceptually interrelated. The term *field* denotes the equivalent of a paper form field, which in the electronic service may be implemented as text input field, selection list, radio button group, etc.

For example, in a tax return form, distinct areas may be dedicated to collecting data regarding the taxpayer's personal details, income, and expenditures. Form fields are the individual elements that citizens need to fill in, either by direct typing of data in the area pertaining to the field (e.g., typing *13765* in the input area of the *Zip code* field) or by selecting one of the available field options (e.g., *Yes* or *No* for the *Do you own the house you live in?* field). Fields usually come complete with *labels* (i.e., descriptions of their purpose on the form). In some cases, the number of fields needed for some purpose cannot be predetermined. As Shaw pointed out (1995), 90% of most applications code goes into system or administrative code, like user interface code and back-end processing. Thus, reusability of objects combining the visual part of the field and the inherent processing logic is crucial. Objects greatly increase software reusability and simplify the software development process (Fan, Stallaert, & Whinston, 2000).

As noted earlier for a reusability approach to be effective two issues have to be tackled: the tight coupling between the logic and the program code (i.e., between what we aim to achieve and the code that implements it) and the implementation of suitable mechanisms for retrieving components. The first issue can be solved by providing facilities to customize components without the need for completely rewriting the program code while the second can be solved by offering mechanisms for locating components pertinent to the tasks at hand and mechanisms for publicizing components to other user.

To facilitate these tasks, a *reusable component repository* is introduced, complemented with tools enabling users to browse, query, populate, and customize its contents. The repository approach is illustrated in *Figure 1*.

In the proposed approach, the idea of a basic building block is introduced. A *transaction service element* (*TSE*) is the equivalent of paper based form field. However, in contrast to a simple field, the TSE has more into it. A TSE can have a multilingual label, the field for inputting data, validation checks for checking the conformity of data to rules, instructions, documentation, or even legislation that applies on the field. The component repository holds *templates of TSEs* and *of groups of TSEs*. The transaction element management (TSE management) facility enables users to create templates of reusable TSEs. A reusable TSE template contains exactly the same information as an individual transaction service element, but is not directly used in transaction services. Instead, users create *instances* of this template and customize it to suit the needs of particular circumstances, since a TSE need not appear identical in all its occurrences. For instance, a TSE representing a person's VAT number may appear in a tax return form as "Taxpayer's VAT number" in the area for personal details, as "Landlord's VAT number" in the section in which housing expenses are declared and as "Employer's VAT number" in the incomes section. Besides the changes in labels, the validation checks associated with each occurrence may need to be customized (e.g., the Taxpayer's VAT number is always mandatory while the landlord's VAT number is mandatory only if housing expenses are declared; the employer's VAT number may need to be verified to correspond to an enterprise, rather than an individual). Once a TSE template has been instantiated and (possibly) customized, it can be used within a form of a transactional service. Note that customization is still possible after the establishment of the link between the instantiated TSE and the transactional service. A similar approach is used for TSE groups (i.e., users create in-

stances of generic TSE groups), which can then appropriately customize for use in services.

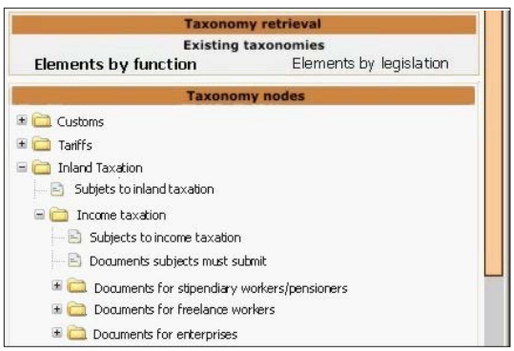
In the approach adopted by SmartGov it was not considered appropriate to introduce the concepts of transaction service form templates and transaction service templates, respectively, since the cases in which whole forms or whole transaction services will be reused are less frequent than the cases in which TSEs or TSE groups will be. Instead, for transaction service forms and transaction services a *clone* facility has been provided, which creates exact duplicates of the source object. The developer can then customize any component of the cloned object.

So far, the notion of the reusable component repository has been described. However, the presence of a repository containing customizable objects does not automatically guarantee the effectiveness of the reusability approach. It has to be complemented with tools that will allow efficient management of the components. As already stated, for such a repository to be useful it is of the essence to provide efficient navigation and searching facilities that will allow users to locate the elements they want to view or modify. Moreover, when new services are created or existing services are modified, it is very desirable to be able to *reuse* existing components implementing the needed functionality. For instance, most services have a special form or form area in which the personal details of the service user are displayed; when creating a new service, it is beneficial to re-use this form from en existing service, since development resources and time are saved, testing has already been done and uniformity across services is achieved.

Braga, Mattoso, and Werner (2001) have proposed the use of an *ontology* to aid retrieval of components that exist in distributed repositories. As defined in Noy and McGuiness (2001), an ontology is a formal explicit description of concepts in a domain of discourse (called classes or entities), properties of each concept describing various features and attributes of the concept (called slots, roles or properties), and restrictions on slots (called facets or role descriptions).

In the SmartGov approach, a simpler yet efficient navigational scheme was used based on *taxonomies*. According to WhatIs?Com Online Encyclopaedia (WhatIs, 2005), a *taxonomy* is a classification according to a predetermined system, with the resulting catalog used to provide a conceptual framework for discussion, analysis, or information retrieval. The basic difference between an ontology and a taxonomy is that an ontology defines not only the concepts (the classes) but also their properties, as well as possible restrictions on how the classes and properties can be instantiated. In a taxonomy, concepts are classified hierarchically, with each concept being a separate node in the hierarchy. Nodes appearing in the lower level of the hierarchy are known as leaf nodes. Under this scheme, an organizational taxonomy is built with broad categories at

*Figure 2. Taxonomies for navigation in the repository*



the first level, which are refined into smaller categories at the second level and so on, until the desired level of detail is reached (usually 5-7 levels) (Fraser, Adams, Macintosh, & McKay-Hubbard, 2003). Platform users that create elements can link them at any category node, either leaf or non-leaf; linkage of elements with nodes can also be modified at a later stage. Users needing to locate an element, start from the top node of the taxonomy and drill down the categories (Figure 2). Once an element is reached and displayed, the navigational facilities should allow the platform user to move to any other element linked to the current one; for example, if a field is displayed, the user should be able to view the form(s) that this field appears on, the groups it participates in, the validation checks it is involved in, examples illustrating its usage, legislation pertaining to it and so on. The information enabling the platform to display these links has been already entered by the relevant stakeholders, either as an indispensable part of the element definition (e.g., when defining a form the user selects the fields that should appear on it; the definition of a validation check references the involved fields and so forth), or as express linkage (e.g., linkage of legislation and documentation to elements). Linkage may also be implicit and derived by the context of actions (e.g., if the user selects the "Create an example" action when editing a form), the example will be linked with the form being edited.

Finally, the organization may want to define multiple taxonomies, as is the case in Figure 2. With multiple taxonomies, different classification schemes can be supported to facilitate the work of users with diverse expertise or interests. In the example of Figure 2, two taxonomies are used: the "elements by function" taxonomy is addressed to domain experts specializing on different taxation items, and the "elements by legislation" taxonomy, addressed to legal advisor. While support of different taxonomies is beneficial for users that try to

locate elements, it places an extra burden for element authors, since a link must be established for each distinct taxonomy. Semiautomatic classification schemes may alleviate this problem.

The search mechanism allows users to enter *patterns,* which are matched against the contents of the repository, and the components that qualify with respect to the matching are included in the result. The search pattern may include free text search, either in all sections of elements or in specific ones (e.g., labels, descriptions, author, keywords, content [for document-type elements only, i.e., examples, documentation and legislation] or any combination); users may also designate and the type of the desired result (e.g., *fields only*, or *examples and legislation*).

One issue that must be addressed with searching within the repository is that standard search engines examine *individual objects* whereas when searching the repository the information stated in the search pattern may be dispersed across several repository elements, perceived however by the querying user as a single entity. For instance, if the user enters a query requesting objects containing *all the words* "Name," "Surname," "Address," and "Id number," there may exist no single object containing all these words and, consequently, a standard search engine would produce no results. However, users would *expect* a field group "Personal details" to be retrieved by the query, because its elements *collectively* satisfy the search criteria. In order to tackle this issue, a modified search engine should be used for searching the repository. The modified search engine flags that an element matches a pattern if either the element itself or any of its *contained elements* matches the pattern. The "containment" relationship is defined as follows: *transactional services* contain *forms*; *forms* contain *form element groups* and/or *individual form elements*; and *form element groups* contain *form elements*. The containment relationship is also transitive, e.g. if a form element is contained in a form, it is transitively contained in any transactional service containing the specific form. Finally, validation rules, examples, and documentation are directly "contained" in any element they are linked to. Another complementary facility that can be used during searching is a dictionary of synonyms. If for example, the user searches for "Surname" and an object with description "Last Name" exists, the dictionary can help in retrieving this object.

## FUTURE TRENDS

Although the use of taxonomies can help in managing and reusing code, an ontology can offer a richer and more complete image of the organization which produces the service. To this end, know-how acquired from the SmartGov project can be used to incorporate ontologies as a mechanism for semantically managing reusable components. Furthermore, since the organization can change in time, a versioning system for the ontology can be introduced which will allow finding the elements that become obsolete as well as the history of the changes.

## CONCLUSION

It is widely recognized today that reuse reduces the costs of software development (Mili, Mili, & Mili, 1995). However, in order to efficiently implement reusability, a system is required that will enable the management of code fragments according to their logic. In the framework of the SmartGov project a knowledge based platform was implemented that allows semantic classification of transactional service elements, fast and easy copying and modification of existing code and management of the service logic by means of taxonomies. The proposed approach has been proven (SmartGov Consortium, 2004) to offer a viable and efficient solution to implementing transaction services by means of reusable components.

## KEY TERMS

**Clone (Function):** A function which copies all aspects of an existing object including visual appearance, parameters and links to code affecting its behavior, creating thus an identical copy of the original object.

**Field:** The term field denotes the equivalent of a paper form field. Although in a paper-based form a field is usually a box that the user has to fill in, in an electronic service the same field may be implemented as text input field, selection list, radio button group, etc.

**Ontology:** An ontology is a set of concepts for a certain domain, connected together with inheritance relationships and each of them having a set of attributes.

**Pattern (Search):** A string containing alphanumeric and possibly special characters (such as wildcards) used as a target to search for. In the simplest case the string contains a word (or part of it), while in other cases it can contain multiple words or regular expressions.

**Reusability:** The extent to which a software module of an existing application can be used in other applications and/or in other contexts.

**Reusable Component Repository:** A repository that can hold reusable components. To be usable the repository is complemented with tools that allow the managing of components (i.e., the storing, categorizing, retrieval and dissemination of components).

**Software Module:** A software component that performs a well defined function and is independent of other components.

**Taxonomy:** A hierarchical classification of concepts for a certain domain. The main difference between a taxonomy and an ontology is that the taxonomy lacks the set of attributes for each concept. In a taxonomy concepts are classified hierarchically, with each concept being a separate node in the hierarchy. Nodes appearing in the lower level of the hierarchy are known as leaf nodes.

**Transaction Service Element (TSE):** *Transaction Service Element* (*TSE*) is the equivalent of paper based form field. However, in contrast to a simple field the TSE has more into it. A TSE can have a multilingual label, the field for inputting data, validation checks for checking the conformity of data to rules, instructions, documentation, or even legislation that applies on the field.

**TSE Template:** A TSE template is the equivalent to the a class definition in object oriented programming. It can be instantiated to a TSE or modified to create a new TSE template.

# Revamping the Administrative Structure and Processes in India for Online Democracy

**R. B. Jain**
*University of Delhi, India*

## INTRODUCTION

There is a talk of e-governance all over the world. India has also not remained oblivious of these developments. E-governance implies a smoother interface between government and citizen. Peoples' expectations from e-government have gone up very high. They see the new technology as a panacea to improve their living conditions. With the application of IT initiatives in certain states of India and at the union level, there has been some overall improvement in the transparency and accountability of the government. However, it must be remembered that technology cannot deliver everything. It is only a tool and an enabler to accomplish certain objectives—perhaps more quickly. E-governance has both a narrow and a broad perspective. In a narrow sense, it is focused primarily on public service delivery through Web site and Internet, while in a broader sense, it stands for all kinds of ICT (information and communication technology) applications in different stages of policy making, formulation, implementation, and evaluation (Snellen, 2005). E-governance sometimes may also make it harder, rather than easier, to achieve more information-driven, boundary-crossing reform such as improved delivery of public services (Heeks, 2002).

## THE BACKGROUND

One of the prerequisites for the success of e-governance is the issue of structural and procedural reforms in the existing system of government and administration. Such reforms must be an all-embracing endeavor, touching all aspects of government. Only then can it have any impact on the objectives sought to be attained through introducing e-governance. With the increasing complexity of human activities, growing population, consequent changes in demographic and socioeconomic structure, the forces and pressures of globalization, satellite and communication revolution, consumerist culture, and technology-savvy world, governmental functions can no longer be carried in the old traditional manner. Governments need to change themselves according to changed times on a continuing basis. However, the change process is generally slow because of the vast dispersed government structure and functions and proverbial resistance to change. The government of India is no exception, where the reform processes are further complicated, due to divergent views and policies pursued by different sets of governments (federal, state, and local), and by different political groups sharing power in different coalitional setups. With low literacy levels and strong differences of caste, community, region, religion, and ethnicity and where people are not well informed despite a well-developed press and electronic media, problems of e-governance are further aggravated by the fact that in India, opinions are much more influenced by the glamour and personality of the individual leader rather than his vision or the ideology of the political party/parties competing for political power. Thus, the result is political compromises in policies, rather than a consensual policy perspective for the general public good. Consequently, the processes of reforms also get politicized.

## ADMINISTRATIVE REFORMS AS A PRECONDITION FOR SUCCESSFUL E-GOVERNANCE

The system of administration in India has undergone a number of structural and procedural changes since its colonial days (see Jain, 1976, 2002). However, for achieving the goals of good governance at the present juncture of the Indian polity, the need of the hour seems to be to adopt a normative model of *good management approach* towards public administration. This should include (a) a more strategic or result-oriented (efficiency, effectiveness, and service quality) orientation to decision-making; (b) replacement of highly centralized organizational structures with decentralized management environment integrating with the new Panchayati Raj and municipal institutions, where decisions on resource allocation and service delivery are taken close to the point of delivery; (c) flexibility to explore alternatives to direct public provision which might provide more cost effective policy outcomes; (d) focusing attention on the matching of authority and

responsibility as a key to improving performance, including mechanism of explicit performance contracting; (e) Creating of competitive environments within and between public service organizations; (f) strengthening of strategic capacities at the center to steer government to respond to external changes and diverse interests quickly, flexibly and at least costs; (g) greater accountability and transparency through requirements to report on results and their full costs; (h) service-wide budgeting and management systems to support and encourage these changes; (i) breaking the growing nexus of bureaucrats, politicians and criminals to restore public confidence in public management system amongst the citizenry; (j) adapting of innovations and evolving suitable mechanism to eliminate corruption at both political and administrative levels and strengthen citizens' grievance redressal system; (k) downsizing of bureaucracy and improving the system of delivery at the cutting edge of administration by replacing the existing archaic bureaucratic procedures by absorbing some appropriate precepts inherent in the philosophy of new public management; (l) effectively utilizing the fruits of technical revolution and the information management system for an effective and quick public service delivery system; and (m) making improvements in the working atmosphere of the government institutions and offices to reflect a new work culture and a changed administrative behavior incorporating the principles of transparency, responsiveness, accountability, participative, and citizen-friendly management.

## E-GOVERNANCE AS A TOOL TO ADMINISTRATIVE REFORMS

E-governance is an effective tool linked to the processes of administrative reforms. It can catalyze the reform process, reduce overheads, and enhance the credibility of government agencies, which can in turn bring more investments in various sectors that can directly or indirectly help the poor by providing education, ensuring good health and creating new jobs, apart from strengthening governmental transactions. E-governance, if implemented properly, can bring in efficiency, cut delays and red-tape, and improve transparency. However, it requires a strong political vision and courage by the top leadership to ensure reforms to revamp the existing structures and processes for the implementation of e-governance and bring about the necessary transformation (see Gupta et al., 2004).

Public governance consists of multiple networks: organizational, human, and electronic, which work together to produce policies, service and knowledge. Delivery of service and making and implementation of policies is increasingly spread across various levels of government. Managing across levels of government is an increasingly important aspect of network management (Wolf, 2004).

As has been pointed out one of the basic objectives of e-governance is to make the government organizations flatter and leaner to ensure quicker decision making to respond faster to emerging situations and be productive and reliable. In many developing economies it is observed that the policies made by different sections or agencies of the government fail to gel with each other in the first go and therefore create confusions initially among the citizens. The e-governance model is likely to help achieve accountability of individuals and their post execution verification by the apex policy-making body of the government. A comparison between required attributes and the attribute of the present day processes would give the reformers an indication of what they should do to bring the necessary change (Gupta et al., 2004).

Among the prerequisites for e-governance is the requirement of achieving effective coordination in a dynamic environment, where authority, responsibility and among people are distributed. It involves a major organizational transformation. It brings changes of the types that are technology driven but which cover wider aspects of organization such as coping with new organizational structures and skills, new forms of leadership, and perhaps even a redefinition of purpose (Ibid).

A third requisite is to redefine administration's social technologies in order to remain relevant to a more participative more interactive and more informational era. A radical and effective reform becomes a necessity to prepare the government capable of adapting changes, which is not an easy task, because there are resistances at all levels. A strong leadership is needed with vision and commitment to spearhead reforms towards e-governance (Ibid).

Fourthly, in many democratic developing countries, the model of e-government will at least put a pressure on political parties to give priorities to an issue which is more important for well being of its citizens than meeting the narrow political objectives of the political parties. This is so because e-governance will make the decision-making process transparent as well as make government information accessible to the public (Ibid).

Perhaps the most important challenge for the construction of an efficient e-government is the management and funding of information technology. This includes recruitment of qualified workers, their retention and compensation. Employee empowerment and training of employees at all levels of organization is the precondition to introduce the new technologies. Insisting on the computer literacy is the need of hour at all levels of government. The most important performance criteria for computerization of administration would be levels of public

satisfaction with service delivery, improvements in productivity and efficiency and increased skill levels of government employees in handling information technology (Pardhasaradhi, 2004)

The purpose of information communication technology (ICT) is to promote good governance in three basic ways: (a) by increasing transparency, information and accountability; (b) by facilitating accurate decision-making and public participation; and (c) by enhancing the efficient delivery of public goods and services (Ibid). It is particularly helpful in establishing a two-way information communication network vertically an horizontally across the public and administrative system and helps in reinstalling and reinforcing credibility and people's faith in the government. Efficiency of e-governance can be understood from the level of empowerment he citizen enjoys in accessing and making choices about government information system and services provided regarding increased transparency and accountability in government business and dismantling of administrative hierarchical structure (Ibid).

## UNDERSTANDING THE NATURE OF E-GOVERNANCE REFORMS

While e-governance cannot entirely replace manual governance, even its limited applications are good enough to affect day to day living. It can fulfill roughly speaking, the four purposes for which citizens generally interact with the government; (1) paying bills, taxes, user fees and so on; (2) registration formalities, whether of a child's birth or a house purchase or a driving license (i.e., in the state of Tamil Nadu in India, one can download 72 application forms); (3) seeking information; and (4) lodging complaints. E-governance can reduce distances to nothing, linking remote villages to government offices in the cities, can reduce staff, cut costs, check leaks in the governing system, and can make the citizen-government interaction smooth, without queues and the tyranny of clerks. It is only through electronic governance that transparency and accountability can be obtained in government procedures and can lead to quick delivery of services to the citizens. With these goals in mind, a number of e-governance programs have in recent times been implemented at the states and union levels in India, some of which are discussed in the following paragraphs. There are also proposals for the ICT to be used in a strong way to provide planning tools to the local bodies.

For example, the *Gyandoot* program of the government in the state of Madhya Pradesh provides to the people a number of services to the people at a nominal price. The services include: online registration facility, copies of land records, and agriculture produce auction center rates. Karnataka, another state of India, has applied IT in the areas of (1) education, wherein transparent common entrance test, recruitment, transfers, and payment of salary of teachers is computerized; (2) development and use of the support system to keep a track of the chief ,minister's (CM's) decisions, instructions, the constituency management system, and summarized data on major projects in health, housing, and other social sector schemes. Other e-governance-related programs are *Bhoomi* (land records project in rural areas in states of Karnataka and Maharashra at 189 locations), CARD in the state of Andhra Pradesh at 230 locations provides for payment of property taxes and issue of land titles), *Nondini* (computerized registration operational in 12 sub-registration offices in Banglore), Secretariat Local Area Network, *Khazane* (account of all the payments of the state), E-lottery and Yuva.com, and so forth. The state of Kerala has launched an e-governance project known as FRIENDS (fast, reliable, instant, and efficient network for disbursement of services) for availing a long range of public services like payment of taxes and utility charges, renewal of licenses and to obtain the latest information on government programs. The state of Andhra Pradesh is also implementing e-governance through a project known as SMART (simple, moral, accountable, responsive, transparent). The central government has also introduced a computerized system of administration in a limited way in the departments of railways, planning commission, human resource development, and rural development ministries, University Grants Commission, passport departments, and so forth (Jain, 2005; Bhatnagar, 2004). Despite these well intentioned initiatives taken by the center and the states, the system would not yield desired results unless the prerequisite of revamping of administrative structures facilitating these programs are established and education and training infrastructure are developed to enable people to derive the maximum benefits out of these efforts.

But it must be remembered that e-governance is only a tool for good governance. It cannot be effectively implemented without the appropriate structural and procedural innovations designed to assimilate it. It cannot succeed independent of responsive officers, and it has to be owned by the political leadership. Otherwise it will only be a bureaucrat's game (*India Today,* 2000). How to rebuild the system of governance on these new premises without the majority of population even being literate is a real challenge for all concerned with adopting new innovations in the performance of the government (Jain, 2002).

It is ironical that despite India having the highest degree of IT development amongst the developing countries, it has the poorest of its application in governance.

One of the main reasons for this phenomenon is that Indian population is digitally divided. One part of citizens is highly aware and educated, and technologically competent to understand and utilize the digital technology, while the other section, comprising of a majority of citizens is illiterate and technologically ignorant. There is a need to bridge this gulf and create a digitally literate population. Experiments have been made in some states of India to bridge this gap through the setting up of electronic kiosks in rural and other remote areas with the cooperation of the private sector to provide services to citizens at nominal costs. This program, known as *Drishtee*, (literal meaning vision—Kiosk-based e-government for rural India) has been extended recently to five Indian states, brings e-government services to rural India using kiosks run and maintained by entrepreneurs who charge a small fee for access. *Drishtee* combines social activism with market solutions in order to alleviate the problems of poverty and weak government and help those isolated by distance and lack of resources (International Institute for Infrastructure and Development).

This concepts needs to be further developed and implemented vigorously, which hopefully will make the fruits of e-governance not only being utilized by a majority of the vast illiterate population, but also make it self-sustaining. The government of Andhra Pradesh is now embarking on a project to develop 22,000 such kiosks throughout the state.

## FACTORS AFFECTING E-GOVERNANCE REFORMS

For affecting e-governance reforms, two important elements deserve specific mention: people and technology. Since the initiative for e-governance has to come from government itself, government needs to be proactive. E-governance also means that people have access to computers and also must be proficient in operating them. Thus, reforms, aimed at implementing e-governance in a country, are worthwhile and have a great chance of success only if people are comfortable with new age machines. Also, security of data is a major concern, as e-governance involves exchange of valuable information over the network. Hence, a legal framework to deal with any breach of that security and security measures for the data has to be in place for any e-governance initiative to be successful (Gupta, et al. 2004).

Another bottleneck in the way of e-governance is the perennial problem of resistance to change from the bureaucracy and the lack of political will on the part of the leadership. These have been critical factors in the failure of many reform efforts in the past and also in the various e-governance initiatives. These factors have led to a lack of long-term commitment and funds needed for changeover to e-governance. At the same time it, is important that there is a change in the attitudes of the employees responsible for operating the e-governance mechanism. The traditional attitude of the governors toward the governed will not help promote the concept of e-governance, nor will it secure help and cooperation from the private sector. The need for changing the mindset and psyche of the civil services is of prime importance if the fruits of the use of IT in governance are to be fully utilized through the cooperation of the private sector.

Finally, publicity campaigns through electronic and print media in local languages, which could give all information and explain in simple terms the likely accruable benefits through such initiatives, are highlighted and publicized and are of utmost importance. The publicity campaign should be carried out in the common language of day-to-day conversation and should also provide information about the location and at what costs such services are available. Political and bureaucratic leadership need to mobilize to provide what can be called technologically-enabled governance, for which it is necessary to sensitize the realm of peoples' awareness through forums of interaction, education, and networking.

## FUTURE TRENDS

It is a well-known fact that India suffers from an absence of governance, and most people in India do not have any access to government or political authorities. The question is how much of e-governance could enable good governance and bring the government nearer to the people. A popular joke that prevails around India is that e-governance means only election governance, as all political parties plead for their introductions during elections, but does little by way of implementation after elections. Notwithstanding the political and bureaucratic apathy to its expansion in critical aspects of the functioning of government and aversion to private sector participation in these areas, there is a big scope of public-private partnership in India for providing services to citizens deep down to the rural level. One has to learn lessons from different countries in this respect. But for this, it is necessary to have changes in the infrastructure of the administrative system and in the attitude of the civil services. This can be done if the concept of the CEO is borrowed from private sector and if its autonomy of functioning with same emoluments and perks is adopted in the civil services. Qualified and expert specialist personnel from the private sector could also be seconded to

the civil services. Poor infrastructure in public administration has further hindered the process of decision making in implementation of projects through e-governance. If properly developed and implemented, governments both at the union and state levels in India and can very fruitfully adopt the techniques of e-governance in three key areas, where substantial reforms are urgently needed: (a) development of a police network throughout India; (b) reforms in the judiciary and legal systems to reduce delays in the finalization of billions of civil and criminal cases pending for judgments in the courts throughout India; and (c) delivery of essential services to citizens at all levels.

## CONCLUSION

In the background of India's experiences to bring in an era of e-governance, this article attempts to reiterate that e-governance is something more than moving government services online. It is to make government more interactive and participative with the public. While the rising expectations of the public and the compulsions of the government to improve its service delivery system and removing public grievances are some of the important factors behind the reforms for e-governance, the primary issues that the e-governance reformers need to consider carefully are those of structure and processes of administrative reforms, literacy and technical training in handling equipment, data security, maintenance of the system to prevent failures, continuous updating, attention towards authenticity of data collected, analyzed and used, and adaptability to new technology. E-governance furnishes a great instrument and an opportunity to bring efficiency, economy, effectiveness, and equity in the government operations along with accountability and transparency. Despite the fact that India has embarked upon a series of reform measures in its public administration system, mostly in its methods and procedures. (For a detailed study of these reform measures see Jain, 1976, 2002). E-governance has received attention only recently (Oracle, n.d.). The introduction of e-governance poses a formidable challenge in a pluralist democracy like India, which despite being technically very well developed in comparison with other transitional societies, has a great illiterate and semiliterate population with limited means for technical equipments. Hopefully, a discussion of India's efforts and experiences toward e-governance, its successes and failures, (for details see Kumar, 2004), and the kind of reforms and innovations needed in its administrative structures and processes as a prerequisite to its installation, would be of some interest to other transitional and developing societies, embarking on a path of e-governance.

## KEY TERMS

**Administrative Reforms:** A process through which governments affect changes in their administrative structures, personnel, or processes for better efficiency and performance. These can be undertaken by the concerned officer to meet minor problems or bottlenecks in administration arising on a day-to-day basis or after the recommendations of a study group, expert committee, or a high-powered reforms commission, suggesting comprehensive and far-reaching changes in the administrative system after a detailed study and deliberations.

**E-Governance:** Defined as the process of enabling transactions between concerned groups and the government through multiple channels by linking all transaction points, decision points, enforcing/implementation points, and repositories of data using information and communication technologies (ICTs) to improve the efficiency, transparency, and effectiveness of a government.

**E-Government:** A process of reform in the way the government works, shares information, and delivers services to external and internal clients through harnessing external and internal clients.

**Governance:** Defined as the manner in which power is exercised in the management of a country's economic and social resources for development.

# The Role of E-Government in Rebuilding Bosnia-Herzegovina

**Meliha Handzic**
*Sarajevo School of Science and Technology, Bosnia-Herzegovina*

## INTRODUCTION

The world is currently experiencing a period of major change. The emerging new world is variously referred to as the third wave, the information age, the information society, or the knowledge-based economy. Regardless of the terminology used, what matters is that the new social, political, and economic world is globalized, based on the production, distribution, and use of knowledge, and is heavily reliant on information and communication technology (Handzic, 2004a). It is also characterized by increased complexity, uncertainty, and surprises. Some analysts like Raich (2000) think of it as a period of living in the centre of the "Bermuda Triangle" where individuals, organizations, and societies have to deal with the increasing turbulence and speed of change in order to progress.

The rise of the information society has brought major changes in citizen and business expectations, as well as organizational structures, cultures, and work processes. To remain responsive to the changing needs of their constituents, governments increasingly have to adopt information society tools and working practices. Essentially, they have to use information and communication technology (ICT) as tools in private and public sector renewal, develop information industry, maintain high level of professional expertise in ICT, provide opportunities to use information society services and have information infrastructure capable of providing such services. The purpose of this article is to explore how these processes are helping in rebuilding Bosnia-Herzegovina.

## BACKGROUND

As any other country, Bosnia-Herzegovina (BiH) cannot stay out of the way and isolated from current world trends. Its transformation into a modern knowledge-based economy and information society is viewed by BiH government as the key for its prosperity or even survival in the global competitive environment. There is also a recognition that only as an information society can the country decrease the existing divide between different social groups and individuals, and ensure progress and a future for all its citizens. Finally, there is a recognition that, in order to catch up with more advanced countries, the transition of BiH from an industrial to an information society will require proactive and accelerated application of information and communication technologies (Policy of Information Society Development in Bosnia and Herzegovina, 2004).

In addition, BiH transformation to a modern information society is seen as a strong means of rebuilding the confidence and regional collaboration destroyed by the 1992-1995 war. More importantly, the development of an economy and governance based on the application of information and communication technology is identified as the only plausible path that will enable BiH to take a worthy place within a united Europe (Policy of Information Society Development in Bosnia and Herzegovina, 2004). Finally, there is a widespread agreement among the international and local community that the transformative processes should not happen haphazardly, but rather by using experiences from other countries to direct and develop these processes (Strategy of Information Society Development in Bosnia and Herzegovina, 2004). Of particular importance is harmonization with European processes (Handzic, 2004b).

The transformation of public administration in the direction of e-government is one of the key segments of the overall process of building an Information Society in BiH. It is also a crucial pre-requisite for the integration of BiH into the European Union. Therefore, it is important to understand what courses of action, development factors and activities are being undertaken related to the reconstruction of public administration, and how successful they have been so far.

## INVOLVEMENT OF THE INTERNATIONAL COMMUNITY IN THE E-GOVERNMENT STRATEGY DEVELOPMENT

The EU defines e-government as the use of information and communication technologies (ICT) combined with organizational change and new skills in order to improve

public services and democratic processes and strengthen support to public policies (http://europa.eu.int). In the broadest sense, the expected impact of e-government is simply better government. More specifically, e-government promises better policy outcomes, higher quality services and greater engagement with citizens and private sector. Typically, e-government initiatives focus attention on effective collaboration among institutions, enhancing customer focus and building relationships with business partners. However, e-government benefits to the quality of life, industrial competitiveness, and society can only be realized if administrations change the way they operate.

E-government has only recently received systematic attention, and is now becoming a positive factor in the long-term development of BiH. Several factors have been identified that contribute to the stronger attention given to e-government issues in the post-war rehabilitation and development of BiH (eSEEurope, 2004). One is an understanding of the beneficial role ICT could play in the interaction between government, citizens and business. The other is active involvement of a number of international bodies in creating standards, models, and best practices. Most notable among these are the United Nations Development Programme (UNDP) and the European Union (EU).

E-government development effort in BiH is based on a number of important initiatives. These include the 1995 G7 government online initiative, the Feira 2000 eEurope Action Plan, eEurope+ plan for informatisation of EU candidate countries, the global initiative for the Information Society under the auspices of the United Nations, the eSEEurope Agenda for the Development of the Information Society adopted by the Southern European countries, and the Poverty Reduction Strategy Paper (PRSP). These initiatives have raised awareness and paved the way for the start of the BiH national Information Society Development. The following are some major steps undertaken in this process presented in chronological order.

First, the ICT Forum was started with support from UNDP to develop situation assessments and preliminary recommendations in a number of areas relevant to the use of ICT in development. It was divided into seven round tables that covered the most important aspects of ICT usage and development. The Forum and its round tables gathered more than 100 local experts from various fields, as well as hundreds of participants of public discussion in entire BiH. Based on their conclusions and recommendations the ICT Forum issued a variety of reports in late May 2003, including: (1) Millennium Development Goals and The Information Society; (2) Infrastructure for an Information Society, (3) Policies for an Information Society; and (i4) Information and Communication Technology for an Information Society–Final Recommendations and Conclusions. These documents provided a basis from which the BiH national Information Society Development proceeded in fast and effective manner

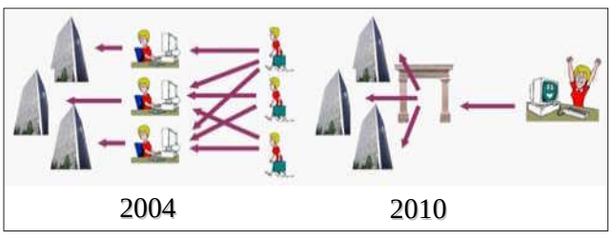
As the next step, the Government of Bosnia and Herzegovina and the UNDP entered into a Memorandum of Understanding (MOU) on Information Society Development. The parties undertook to formulate a joint Project Document that outlined the process, expected key results, and a time-frame relating to the development of the Information Society. This MOU formed the basis on which UNDP was supporting the development of a comprehensive policy for an Information Society in BiH, a process taking place at the expert level and with public participation but under the overall guidance of the Council of Ministers. The idea initiated on the international level was diffused by media to ensure the widest possible visibility, support, and continuity of the process.

The actual development of a BiH national information society (IS) strategy started in October 2003. An expert group consisting of both government and non-government members produced the document "Policy for Development of Information Society in Bosnia and Herzegovina." That document serves as a framework in accordance with which future legislation, acts, and other regulations will be passed in the process of building and development of an information society. It also serves as a baseline upon which future decisions will be taken on development directions, action plans, and priorities at the level of Bosnia and Herzegovina and its entities.

Starting from the Policy document, larger expert groups developed the documents "Strategy for Development of Information Society in Bosnia and Herzegovina" and "Action Plan for Development of Information Society in Bosnia and Herzegovina." Both documents cover five key development pillars identified by the Policy document (e-education, e-governance, ICT Industry, ICT Infrastructure, and e-Legislation). The Strategy document includes a short review of current sector status, defines the vision for the period 2010-2015, and provides a set of strategic recommendations for achieving the envisioned status. According to the strategy document, the action plan defines a set of concrete actions (initiatives, large development programs, projects, pilot projects, etc.) that should be implemented during the period 2005-2010, in order to achieve the goals defined by the strategy paper.

By the end of 2004, all three papers were officially accepted by the BiH Council of Ministers, as well as the representatives of the international community. Before that, the documents passed extensive public and expert debates and consultations. The second conference on Information Society gathered over 400 participants including government officials, local and international ex-

*Figure1. E-government in BiH Present*



perts, as well as leading industry companies. Based on participants' suggestions, expert panels produced technical and very specific suggestions on both the strategic and the operational aspects of IS development. Through this approach, policy and strategy development was more inclusive and participatory.

In sum, European and other initiatives provide a global framework for e-government development in BiH. Late adoption and transfer of best international know-how helps the country to learn from others, and thus avoid repeating the same mistakes. In addition, experiences of others under similar circumstances show that the participatory consultative process followed ensures a quality and realistically feasible strategy. However, the lack of coordination among many different players and agendas, coupled with the complex state structure and public administration organization of BiH, seriously hinder the e-government implementation success, as shown in the next section.

## CURRENT E-GOVERNMENT IMPLEMENTATION STATUS AND FUTURE ACTION PLAN

The e-government strategy of BiH envisages that the country's transformed public administration will provide its citizens, business partners and non-governmental organizations with improved quality, availability and efficiency of services; increased operational effectiveness and knowledge sharing among institutions; improved dialogue with citizens and their greater involvement in the democratic process; and improved government transparency (Radivojevic, 2004). It will also create pre-requisites for integration of BiH into the European Union by 2010.

However, several major obstacles exist in introducing the concepts of e-government in BiH. Current legislative and judicial systems are not well equipped to take up the challenge of e-governance. At present, there are 146 municipalities in BiH, 10 cantons, two entities (Federation of Bosnia and Herzegovina—FBiH and Republika Srpska—RS), District Brcko and state level government. Such a complex structure produces various problems in terms of e-governance. For example, there are 13 parliaments with power to define laws (sometimes contradictory to each other); principles and practice of governance in one municipality (or canton) are often very different than in another; there is low tendency towards making common databases or towards connecting the databases; there is almost no electronic communication, horizontally or vertically; there are no accepted standards relating to software and hardware systems; there is no state level plan for informatization of state administration; existing electronic governance support systems are not well connected and cannot give the reliable and timely information to citizens. In short, the eSEEurope (2004) report claims that there is no implemented e-governance concept in BiH at all, while the System Review of Public Administration Institutions in BiH (2004) interim report identifies only isolated cases of e-government.

Other obstacles include lack of equipment and financial support, and the profile and number of employees in administration (one employee per 350 citizens as opposed to 2000 in developed countries). This is a serious problem in all structures in the country. However, one can speculate that the blame for the huge gap between the capacity to design the top level Information Society development strategy and incapacity to implement it does not lie solely in weaknesses of Bosnian institutions. The current situation is also one of the consequences of the 1992-1995 war, as well as of the post-war arrangements set by the Dayton peace agreement. In such an environment, it is hard to implement new systems that are efficient and concentrated on citizens. A concerted effort of both the international and local community will be required to address these issues.

According to Wimmer (2001) an effective e-government may be possible only if the country has adequate public administration legal regulations, modern and safe ICT implementation and people skilled in ICT use. Deficiencies in these areas found in BiH are not unique but rather a common malaise of all transitional societies. However, because BiH is a protectorate rather than an independently governed state, the international community should bear at least some responsibility for failing to provide adequate means of bringing their decisions to execution faster.

The general review of ICT use in public administration (System Review of Public Administration Institutions in BiH, 2004) indicates low digital literacy of employees, low internet access and no official access points. With respect to digital literacy, only about half of the employees can use personal computers, BiH administration does not recognize ICT workplaces, and institutions

do not employ adequate specialists. Furthermore, those working on information systems development, implementations and maintenance are not well trained. This situation is expected to change soon as a result of the establishment of the world class international university in BiH namely Sarajevo School of Science and Technology (SSST). In partnership with the University of Buckingham from UK, SSST (http://www.ssst.edu.ba) provides specialist degrees in Computer Science and Information Systems that will produce the workforce suited to the Information Society.

With respect to internet access, the World Bank World Development indicators (http://www-wds.worlsbank.org) reveal that 61% of governance institutions do have access to the internet, but only 4% are connected by cable connection; institutions are using the services of almost 40 different ISPs; government Web pages have no real and up-to-date information useful to citizens; there are no official places where citizens can find accurate and secure information on the local economy, state administration, history and so forth; public institutions do not use the electronic media to transparently inform citizens of annual investment plans, procurement, budgets, etc.

Nevertheless, there are some notable initiatives and projects related to e-Governance development. Two projects of strategic importance have been recently implemented: CIPS—Citizen Identification Protection System (2003) and Treasury information management system (Deloitte Touche Tohmatsu, 2004; Runko, 2002). Other important implemented projects include customs administration, elementary municipal systems, Web portals offering at least basic information to citizens, introduction of electronic databases etc.

## FUTURE TRENDS

The majority of implemented projects are consistent with the realisation of the first phase of the e-government action plan focusing mainly on information management and the formation of basic registers. Such electronic records enable a fairer and wiser society by providing evidence, protecting individual rights and preserving social capital (Handzic, 2004a). The next three phases of the plan emphasize aspects of interaction, integration and transformation aimed at making these electronic records more visible and usable to citizens and business partners as illustrated in Figure1.

Another visible symbol of BiH government commitment to new approaches to development will be the creation of a specific Agency for Information Society (AIS). The main goal of AIS will be to provide a government-led stimulus to change and speed up its transformation in partnership with OHR, UNDP and CoM. In particular, the Agency will have to ensure the effective connection between two previously largely unconnected areas of information and communication technologies as a major information society development tool. It will also have to provide a coherent framework to a number of currently uncoordinated international, private and public e-initiatives and e-policies. In short, the Agency will be main coordinating agent in BiH Information Society (and thus e-government) strategy implementation.

## CONCLUSION

The main objective of this article was to explore the place of e-government in transforming a society through a case study of Bosnia-Herzegovina (BiH). The article starts by introducing the global, regional, and local context in which the development of e-government is taking place. The analysis indicates that it is characterized by a unique and complex public governance structure of BiH and high involvement and influence of the international and European community.

The article identifies two important aspects of e-government development process in BiH: (1) global framework for the transition into an information society (including the transformation of the public sector towards e-government) and (2) harmonization with the European process. Together, they should enable the change of culture and institutions to take place in a controlled manner and thus facilitate the creation of conditions conducive to innovation and value creation. They should also provide BiH with a rare opportunity of applying best international practice to avoid costly mistakes.

At the same time, the article warns that the present complexities of the local context seriously hinder the e-government implementation effort. The general observation is that there is a lack of appropriate legislation and coordination to guide the process, as well as a lack of adequate technology and human resources. Yet, an effective e-government may be possible only if it has adequate public administration legal regulations, modern and safe ICT implementation and customers skilled in ICT use. The good news is that there exist some isolated examples of e-government at work (e.g., CIPS and Treasury systems) and a realistic action plan. This incremental implementation plan is expected to result in a fully transformed (i.e., electronic, interactive and integrated) government usable by citizens and business partners by 2010. Overall, it appears that BiH is placed firmly on the path towards e-government, with a slow beginning, but a promising future.

## KEY TERMS

**E-Governance:** Evolutionary process of re-engineering of business processes and reform of the work of administration/government that goes beyond the introduction of information and communication technologies.

**E-Government Action Plan:** According to the strategy document, the action plan defines a set of concrete actions (initiatives, large development programs, projects, pilot projects, etc.) that should be implemented during the set period of time, in order to achieve the goals defined by the Strategy paper.

**E-Government Policy:** A basic document in accordance with which the future legislation, acts and regulations are passed in the process of building and development of e-government, and upon which future decisions are taken on development directions, action plans and priorities.

**E-Government Strategy:** A document that explores the current situation, defines the vision for the future, and provides a set of strategic recommendations for achieving the envisioned status.

**E-Government:** The use of all information and communication technologies to facilitate the daily administration of government; Internet-driven activity that improves citizen access to government information, services and expertise to ensure citizen participation in, and satisfaction with the governing process.

**Information Society:** A society in which the economy and governance are based on know-how, and heavily reliant on information and communication technologies.

**Knowledge Economy:** An economy in which the main source of wealth and growth is knowledge.

# The Role of E–Parliament in Hungary

R

**Eszter Kertészné-Gérecz**
*Hungarian National Assembly, Hungary*

## INTRODUCTION

The supreme legislative power of the Republic of Hungary is the unicameral National Assembly, which has 386 members.

The 1990 political changeover expedited the development of democratic institutions and substantially increased their importance. Besides the traditional media, electronic information has assumed an increasingly important role (European Commission, 1999).

The change of paradigm in the management of information is made necessary by the recognition that knowledge supports politics. Parliamentary work is one of the main sources of this. Thus, Parliament and its standing committees function as systems acquiring and processing information. These systems have so far tried to produce information from largely unstructured data in the course of written and verbal communication.

According to the new paradigm systematisation of the knowledge of the organisation and the environment will generate the knowledge base which will be suitable for upgrading the quality of political and professional processes (Hungarian Government, 2003).

The work in Parliament, the utterances of politicians are in the forefront of public attention. Therefore the staff of the Office of the National Assembly should provide access to current and accurate information on a continuous basis. In the information age this is a serious challenge for Parliament. This is why it has become necessary to determine the demands that electronic Parliament (e-Parliament) has to meet, and to devise ways for their gradual and systematic satisfaction.

## BACKGROUND

This case study is aimed at describing the concept of e-Parliament in Hungary, its implementation, achievements and future plans. The following topics are addressed:

- The political and legal background of the development of e-Parliament
- The development of the information technology background of e-Parliament in Hungary
- Social dimensions and relations of e-Parliament

## THE POLITICAL AND LEGAL BACKGROUND OF THE DEVELOPMENT OF E-PARLIAMENT

At the end of 1999 the European Commission published the first eEurope Action Plan followed by eEurope 2002 and eEurope 2005.

On January 1, 2001 the Hungarian Parliament established the Informatics and Telecommunications Committee, a standing committee which has proved to be very useful in shaping the legal environment for an information society since its inception.

In 2001 Parliament subscribed to the goals specified in Chapter 3 of E-Government, the Electronic Government programme under the eEurope initiative, and became a part of the tasks outlined in the Action Plan.

Following its integration into the European Union on May 1, 2004 Hungary must realise the goals of the eEurope Action Plan approved by the Member States. The Action Plan aims to develop modern online public services (e-government) as well as a dynamic environment for e-business in all EU Member States by 2005.

This can be achieved through widespread availability of broadband access at competitive prices and a secure information infrastructure. To this end, Hungary launched the Public Network Programme in 2004, which makes broadband access available to all of the public institutions.

Launched in November 2004, the Internet Based Administrative Services system (XR) was a major step forward on the path to electronic public administration (Hungarian Act CXL of 2004).

The launching of e-government services was facilitated by the E-Government 2005 Strategy and Action Plan, which was drafted and put to social debate by the Centre for Electronic Government of the Prime Minister's Office at the end of September 2004 as part of the Information Society Strategy of Hungary.

The Centre for Electronic Government operates the Hungarian government portal at www.magyarorszag.hu, which serves as a point of entry to government services and offers interaction in certain matters. In addition, the portal presents news and information about the Government and the country, and provides the largest Hungarian database on the European Union (Hungarian Government Decree No. 44/2005 & 193/2005).

The Dialogue Forum is a particularly important feature of the portal. Unlike other online forums, it only accepts real names to log on. The operators expect people will formulate their opinion in a more deliberate fashion if they have to give their name.

The Ministry of Informatics and Communications and the Inter-ministerial Coordination Committee for Information Society envision submitting to the government the Hungarian Information Society Strategy before the end of 2004. Upon the request of the Ministry of Informatics the ministries and organisations concerned have prepared their respective sub-strategies, which contain, among others, programmes regarding the electronic signature and the smart card.

At its session on July 4, 2005 the Hungarian National Assembly passed Act XC of 2005 on the Freedom of Electronic Information with effect of January 1, 2006 except for some of the provisions, which will enter into force as of July 1, 2007. Implementation at the level of the Office will be ensured by the internal Rules and Regulations developed in 2005, which provides for the rules of disclosure of data of public interest, and of the provision of electronic information. Some of the contents of the Rules require expansion of the e-Parliament project.

## THE DEVELOPMENT OF THE ICT BACKGROUND OF E-PARLIAMENT IN HUNGARY

Today, processes supporting the work of Parliament are inconceivable without ICT support.

The Hungarian Parliament deployed its first major ICT investment between 1990 and 1992 with the involvement of American and EU (PHARE) funds. Currently the Office of the National Assembly operates nearly 1500 PC and laptop workstations and is equipped with reliable and up-to-date network and servers.

Based on the Oracle database management system, the Information System of Parliament (PAIR, by its Hungarian acronym) and the system in the assembly rooms have become an integral part of Parliament's everyday work and processes. Events related to the work in Parliament, documents and drafts are keyed in as part of the office routine and are made available for queries.

Even the early stage of development of Parliament's IT system included electronic information provided to citizens as a fundamental goal. The domain name of the Office of the National Assembly was registered by the Internet service provider on June 22, 1994. As a result Parliament has operated its own Web site on a continuous basis since 1995. The content has gradually been expanded as a result of upgrading of the IT system of Parliament.

The information system relying originally on static Web pages was replaced by dynamic data base query in 1998. This ensures that citizens can continuously monitor the functioning of Parliament, the events in plenary sessions including the votes and the committee meetings as well.

Further milestones in upgraded Internet services included regular live Internet broadcast of the plenary sessions from the beginning of the 2002 term as well as the option to search and play digitalised video recordings of speeches delivered in plenary sessions.

Annual review of the ICT strategy and full-fledged consolidation and upgrading of the medium term plan for 2005-2007 was concluded in December 2004. The plan allows for further expansion of the e-Parliament project by adding new tasks, which are handled by means of widely accepted modern IT solutions.

## SOCIAL DIMENSION AND RELATIONS OF E-PARLIAMENT

The role of e-Parliament should be explored in the context of the social dimensions and relations of the electronic Parliament, which has been developed in an integrated system. Based on the functions and operation of Parliament, the social dimensions and connections can be classified as follows:

- Parliament's relations with citizens and civil organisations
- The system supporting MPs' work
- Parliament's internal processes and the system supporting decision making
- Relations with other branches of power and to administrative and social agencies
- Relations with foreign Parliaments

### Parliament's Relations with Citizens and Civil Organisations

The relationship between Parliament and citizens is instrumental in terms of the exercise of democratic rights. Accordingly, the Office of the National Assembly gives a high priority to this issue. In this effort, in addition to traditional solutions, it makes use of electronic devices which meet the expectations of an information society.

A home page with an up-to-date content is a key tool of electronic information. It offers citizens and civil society organisations a clear picture of the structure and functioning of the National Assembly, its role within the legal order and society as well as of its fundamental task of legislation and related events. In Hungary citizens and

civil organisations show a keen interest in the information offered on the Web site of Parliament, a fact proven by statistics of Web site hits (Enyedi & Tamási, 2001.).

The Hungarian and English content of the Web site www.parlament.hu differ as bills, proposed amendments and other documents including the minutes of plenary sessions are only available in Hungarian.

Besides queries related to data parliamentary work in the stricter sense, the expert system and data base of the National Assembly, the Web site also provides information in the public domain in the following areas:

- The structure and functioning of Parliament; information on the legislative process;
- Information on the legislative plan of the National Assembly (bills, submitted, schedule of deliberations, and expected enactment);
- Additional information related to Parliament (for instance calls for projects from the civil sector);
- Electronic access to all the services of the Information Centre of the National Assembly.

The introduction of a video server brought a major enhancement in the quality of electronic information from the change of government in 2002. The system provides live broadcast of plenary sessions via the Internet, and stores the digitalised speeches delivered in plenary, which can be searched according to different parameters and replayed at any point in the future.

Although Parliament does not deal with citizens' affairs, nor are bilateral transactions typical, the possibilities for online interactive electronic contacts should be explored along with demands and requirements regarding such services. Our surveys show that civil organisations are mainly interested in information provision, simple communication and queries (Pethõ, B. 2002).

## The System Supporting MPs' Work

The Office promotes the work of MPs and experts by providing appropriate ICT infrastructure on the one hand, and by applications available via uniform and standardised user interface (intranet, Internet, e-mail, CD-server, etc.) on the other hand.

The Office installed an electronic mail system in January 1995 available for MPs and office staff. The MPs' e-mail addresses are public which allows citizens to get in touch with their representatives.

In the first stage of e-Parliament formulated in 2001, MP's had to be provided with the possibility of distance work. The major upgrading that took place parallel with the 2002 change of government as a result of preliminary developments enabled MPs to join the work processes of Parliament from their home or external office, or to be able to work from their home (Molnár, L. 2002).

The security of distance work is guaranteed by an intelligent smart card, which is suitable for storing *X.509* digital certificates. It supports safe login through MS Windows, authenticates and encrypts correspondence, and will append electronic signature to certified documents to be introduced in future (PKI compatibility). In the event of loss or theft of the card the laptop cannot be used by an unauthorised person.

Four hundred laptops have been purchased in order to support distance work. This went hand in hand with creating the conditions for efficient distance work including individual broadband access for all MPs.

A basic requirement of distance work relying on laptops was that laptops could be used in an office environment, in sessions, and on other premises to suit the choice of the user. Essentially, laptops should be able to function as mobile offices supporting secure distance work. Thus a data transfer system had to be devised which ensures MPs secure connection to the internal information system of the National Assembly.

Formerly, materials required for the preparation of decisions in plenary sessions or in the committees were delivered by courier. This was an extremely costly service and had the added drawback that MPs often received documents outside their scope of interest and sometimes ended up having to plough their way through mountains of papers virtually impossible to process. The e-Parliament project had to remedy this situation. For this reason, the most important task of Stage II of e-Parliament was to replace the physical courier service with the electronic e-courier.

As a first step to determine the specifications of e-courier, the earlier courier delivery practice was surveyed and analysed. This was followed by defining the content of the electronic courier service together with the most appropriate technological solution. The trial run of the electronic courier started in September 2003. Presidential Decree No. 2/2004 on the definitive introduction of the electronic courier entered into effect as of September 1, 2004.

Pursuant to the provisions of the Presidential Decree, the electronic courier service must be activated from the main menu of Parliament's Web site (www.Parlament.hu). This greatly facilitates the use of e-courier: all the MP needs to do is to connect onto the Internet without having to log in on the internal network via VPN. At the same time this also means that e-courier is public domain, the only exception being committee documents for deliberation or information, which the submitter intends to send exclusively to committee members. Such documents are supplied to MPs by either e-mail or traditional delivery.

The e-courier is a prime paper-saving tool for supplying, and providing access to, and information on, documents needed for the MPs in their legislative work, lists of their submission, as well as other documents and materials of an informative nature.

Making materials required for legislative work available to MPs electronically via the Internet has resulted in the revamping of working methods and procedures, which not only brought a significant positive change in the life of Parliament but also opened new vistas of public information as citizens can access the documents deliberated in Parliament in the same structure and with the same content as MPs (European Commission, 2005-2006).

## Parliament's Internal Processes and the System Supporting Decision Making

Once e-Parliament has been fully implemented, information will be generated electronically in parliamentary work processes; they will be stored in an Oracle database, and all information-related activities will be preceded by planning, and will be carried out by continuous updating of events.

In addition, e-Parliament must provide electronic connection between MPs, parliamentary groups, committees, officers and secretariats as well as electronic inter-committee connection.

Office tasks related to legislation (deadlines, consultations and other administrative duties) as well as IT support of work processes require further development.

The organisation and conduction of plenary sessions, the work of chairpersons and registrars are supported by modern installations in the assembly rooms (amplifiers, electronic voting system, etc.). This system also ensures connection between the Video studio and the Parliament's ITC system.

Internal communication is supported by the online electronic telephone book of Parliament. This system is at the same time a central organisational and personnel database, which provides consistent data for the central data directory and all related applications, handles user authorisations as well as help desk support for users, and provides data for the government data directory as a one-stop shop.

The goals of e-Parliament include the creation of a paperless office. Based on international experience, this has not yet been achieved anywhere. It is, however, indispensable that each work process can be carried out without a paper base. Identifying materials that are unnecessary for certain MPs, and discontinuing their printing was a realistic objective. In addition, the handling of documents, which need to be read while session is in progress, will be made easier.

In order to meet the goals it was first necessary to define the scope of new documents, or those prepared earlier by a word processor, which should be digitalised, then put on records, with the original signatures as certified true copies.

A special technology was developed to ensure digitalisation, storage and search ability of documents. It files all documents submitted (input of metadata in the database). This is followed by digitalisation; then the documents automatically become accessible and can be queried from the Web host server.

Introduction of the electronic signature will bring a dramatic change in electronic document management. The legal framework has already been provided for in the Act on Electronic Signature.

The first real-life application of the electronic signature was in conjunction with the statement of property submitted by the MPs in 2005. This task is undertaken by means of XML tools. The project includes XML technology as well as electronically signed document management.

An important development project for 2005 and 2006 is the uniform structure for handling Web contents accessible via the intranet, extranet and Internet through a portal system. The portal under development will coordinate all the interfaces and applications that have been developed so far. Distance work, documents with various levels of authorisation and different applications will be handled in a transparent format from a unified platform, and can be tailored to suit the individual user.

## Relations with Other Branches of Power and to Administrative and Social Agencies

In the course of preparation of legislation and policy debates, there are intensive connections between government agencies and non-governmental organisations on the one hand, and different structural units of Parliament, specifically the standing committees on the other hand (West, 2005.).

A key element is the development of digital relations with government institutions, parliamentary secretariats, the State Audit Office and other agencies, organisations and branches of power related to the National Assembly. These relations are supported, besides an intranet and the Internet, by an extranet system, which has been in operation since 2000. It provides a private Web-based service to designated users of the government's network. In 2005 substantial development efforts were targeted to this area as a result of which we reached almost 100% paperless

document handling due to the upgrading of the data content of the extranet and enhancement of its operation.

A major step forward has been taken in the e-Parliament project in the electronic management of bills submitted to Parliament by the government. Efficient and close cooperation with the Ministry of Finance should be mentioned specifically in the electronic exchange of bills on taxes, final settlement and the budget, as well as of the complex tables in annex to the bills.

The government set up a special working group to promote implementation of the Act on the Freedom of Electronic Information. The aim is to achieve transparency of parliamentary procedures and the government's legislative programme from the point of view of citizens. At this juncture cooperation between e-government and e-Parliament is presented and their point connection determined (Hungarian Act XC of 2005).

## Relations with Foreign Parliaments (Primarily Those of European Union Member States)

When determining the tasks to be implemented in the context of the e-Parliament project the question of what kind of electronic connections would be required in order to liaise with foreign parliaments, in particular the European Parliament, the National Assemblies of EU Member States, and with EU executive bodies.

The main platform of connection is the Internet and the electronic mail. These are also the main channels to liaise with various organisations, professional associations and institutions.

In the course of preparation for EU accession, then following accession, liaising with the Hungarian organisations in charge of EU affairs and with Members of the European Parliament (MEPs) has become so intertwined that it is impossible to draw a clear line between domestic and international duties. This is reflected by the following IT tasks, which need to be tackled in conjunction with EU accession:

- From September 2003, still in preparation for accession, European Union documents were supplied only electronically, via the Interim E-Mail System, to the Ministry of Foreign Affairs, whose job it was to forward the e-mails to the ministries concerned and also to the National Assembly. The Office had to devise a system, which provides a designated group of experts in the Foreign Office and in the Committee on European Integration with access to these documents for study and analysis.
- By the end of April 2004, an IT system had to be developed which was suitable for the management of EU documents received by e-mail. This application presented a special development task as interpretation of the metadata of the masses of electronic mail and their uploading to a database could not have been undertaken by traditional methods, thus special robot software was developed to meet this function. The software made it possible that from the moment of accession all pieces of EU legislation could be uploaded to the database of Parliament. Relying on a database, the system had to provide access to MPs, committees and office staff with different levels of authorisation thought a user-friendly Web-based interface.
- The system must support the storage and queries of documents generated in the process of consultations, with links to relevant EU projects and documents.
- Documents received in different languages and formats should be made available in all the formats received. While most of the documents are non-Hungarian, a Hungarian search function should be supported.
- MEPs, who reside alternately in Brussels and in Hungary, raised the need to access specialist materials, documents, official e-mails, and so forth. related to the Hungarian legislative process.

## FUTURE TRENDS

Parliament submitted plans for 2005 in conjunction with the e-democracy programme of e-government, in accordance with the goals formulated in the medium term ICT strategic plan for 2005-2007 of the Parliament. The plans contain further development of current e-Parliament projects and define new projects to be included in the programme.

In 2005 IT projects of strategic significance have been launched, which will provide the most efficient IT tools and support to promote parliamentary procedures and to assist Members of Parliament following the change in the parliamentary cycle in 2006. In this respect mention should be made of electronic administration, which includes parliamentary work processes from handling electronically submitted and certified documents to immediately uploading data that are of general interest to a Web site with search ability at different levels of sophistication.

Taking into consideration citizens' information demands, a longer-term goal can be to provide online access to legislation as published in the Official Journal of Hungary, and possibly in the official journals of specialised areas. The electronic content would have the same legal

effect as the printed version in the Official Journal, which is currently regarded as the attested text. It is to be noted that to our knowledge, this has not yet been achieved at the level of the European Union.

Based on the experiences, an electronic document management system should be developed along with the rules of access to information. PKI-based digital signature and electronic date and time marking should be used to ensure and record the authentication of senders and the time of transmission.

## CONCLUSION

E-Parliament has envisioned meeting expectations related to e-government and e-democracy on the basis of the tenets of eEurope formulated at the end of the 20th century, applying state-of-the-art means available at the beginning of the 21st century. Efforts have been made to serve citizens without being impersonal, so that human and social relations can be fostered to high standards of quality, in keeping with the requirements of an information society.

To this end, the main goals should be carefully conceived and implemented step by step, involving the user groups concerned.

The further development of e-Parliament is inseparable from the provisions of the Information Society Strategy of Hungary. It is continued in keeping with the spirit of the strategy and is closely linked to other ongoing projects related to the creation of electronic public administration.

## KEY TERMS

**E-Democracy:** A co-operations among citizens, academic, media, commercial and government sectors. New forms of public/private partnership need to be explored and developed in order to realise the democratic potential of new information technology and networks.

**eEurope Programme:** Defines the most important elements of the information society in national and European level like education, culture, social security, public health, public administration, and so forth.

**E-Government:** Goals to achieve better and more inclusive government which means improved services and policies, increased transparency, inclusion, accessibility and accountability or greater participation in decision making.

**E-Parliament:** The entirety of parliamentary work processes and services, which support the legislative activity of the MPs by means of state-of-the-art applications and provide citizens with up-to-date information on parliamentary work.

**European Public Administration Network:** Provides possibilities for the exchange of experience in national e-government activities and deeper analysis of selected topics and offers a forum to all member states to present their activities.

**Hungarian Information Society Strategy (HISS):** The vision, plans and actions through which Hungary will take

the path of a new development and modernisation. The strategy intends to achieve the development of a knowledge-based economy and a modern information society in Hungary, on both state and local levels, within ten years. Its has six key objectives: (1) enter the age of information, as intensely and innovatively as possible; (2) provide a comprehensive vision for the construction of a knowledge-based economy and an information society; (3) promote the growth of competitiveness and successfulness of the Hungarian economy; (4) demonstrate that information and communication technologies are not mere opportunities but effective tools; (5) have a long-term plan and programme for the development of the information society, approved by the government and reflecting the adoption of European values; and (6) provide guiding principles and an organisational framework for designing coordinated plans and operative programmes for developing the information society.

**Social Dimension of E-Parliament:** The relations within Parliament and citizens, civil organisations, other public administration, social agencies and foreign parliaments, supporting MPs' work, Parliament's internal processes, and decision making.

# Role of ICT in Establishing E-Government System for Disadvantaged Communities

**Hakikur Rahman**
*Sustainable Development Networking Programme, Bangladesh*

## INTRODUCTION

Information and communications technologies (ICTs) are playing an increasingly vital role in the daily lives of all communities by revolutionizing their working procedures and rules of governance. ICTs offer a unique opportunity for governing elite to overcome the crisis of representative democracy, as ICT and the Internet empower civil society to play its role more effectively and facilitate the performance of governments' main function-serving the people who elect them (Misnikov, 2003). In the realm of government, ICT applications are promising to enhance the delivery of public goods and services to common people not only by improving the process and management of government, but also by redefining the age-old traditional concepts.

Community networking groups and local government authorities are well placed to campaign for greater inclusion for all members of the community in the information society. Possible areas to target include the provision of technology at low or no cost to groups through community technology centres or out of hours school access. There are many possibilities and local government must take a significant role in these activities (Young, 2000).

Information society is based on the effective use and easy access of information and knowledge, while ICT for development (or ICTD) is not restricted to technology itself but focusing on manifold development and diverse manifestations for the people to improve their well-being. ICTD has deep roots in governance, is part of governance and has effects on governance patters and practices at both central and local level.

By recognizing these facts, UNDP focuses on technologies to end poverty at WSIS Cyber Summit 2003, and emphasizes on ways that new technologies can help lift more than one billion people out of extreme poverty (UNDP, 2003). Apart from the four Asian IT giants (Korea, Rep., Hong Kong, China, Taiwan, China, and Japan), most of the Asian countries have fallen under the "low access" category of the Digital Access Index. This has also been referred in the WSIS Cyber Summit 2003, until now, limited infrastructure has often been regarded as the main barrier to bridging the digital divide (ITU, 2003). Among the countries with ICT spending as share of their GDP, Sweden, UK, The Netherlands, Denmark, and France (8.63, 7.97, 7.39, 7.19, and 6.57% respectively during 1992-2001) remain at the top (Daveri, 2002, p. 9), while countries like Bangladesh, Greece, Mexico, Niger, and many more remain at the bottom (EC, 2001; ITU, 2003b; Miller, 2001; Piatkowski, 2002). In a similar research it has been found that in terms of average share of ICT spending GDP, New Zealand, Sweden, Australia, USA, and UK (9.3, 8.4, 8.1, 8.1, and 7.8% respectively during 1992-1999) were among the highest (Pohjola, 2002, p. 7), though most of the countries in the Asian and African regions remain below the average of 5%. The disadvantaged communities in the countries staying below average in ICT spending seem to be lagging in forming appropriate information-based economy and eventually fall behind in achieving proper e-government system.

The e-government system in those countries need to enhance access to and delivery of government services to benefit people, help strengthen government's drive toward effective governance and increased transparency, and better management of the country's social and economic resources for development. The key to e-government is the establishment of a long-term dynamic strategy to fulfill the citizen needs by transforming internal operations. E-government should result in the efficiency and swift delivery and services to citizens, business, government employees and agencies. For citizens and businesses, e-government seems the simplification of procedures and streamlining of different approval processes, while for government employees and agencies, it means the facilitation of cross-agency coordination and collaboration to ensure appropriate and timely decision-making.

Thus, e-government demands transformation of government procedures and redefining the process of working with people and activities relating to people. The outcome would be a societal, organizational, and technological change for the government and to its people, with IT as an enabling factor. E-government should concentrate on more efficient delivery of public services, better management of financial, human and public resources and goods at all levels of government, in particular at local level, under conditions of sustainability, participation, interoperability, increased effectiveness and transparency (EU, 2002).

ICT brings pertinent sides more closely by prioritizing partnerships between the state, business and civil society. A few East European countries have became economically liberal with the high level of foreign direct investment per capita and at the same time became ICT-advanced regional leaders in terms of economic reform. These countries also present the region's most vivid examples of partnerships and collaboration. They have clearly manifested the importance of the public-private partnerships, transparent bottom-up strategies, involvement of all stakeholders, total governmental support, capturing economic opportunities, and enabling electronic mediated businesses, responding to the challenges of globalization.

## BACKGROUND

Electronic government refers to public sector use of the Internet and other digital devices to deliver services and information. As the e-government industry expands worldwide, the complexity and specificity of online services continues to develop. Many nations have sites devoted specifically to e-government, on which they present new initiatives as well as offer listings of services available online. For example, Taiwan, Singapore, and the United States have highly developed portals, which serve as gateways to a plethora to a plethora of government services as well as directories to other specific government sites (West, 2004).

Definitions of e-government range from "the use of IT to free movement of information to overcome the physical bounds of traditional and physical-based systems" to "use of technology to enhance the access to and delivery of government services to benefit citizens, business partners and employees." The common theme behind these definitions is that e-government involves the automation or computerization of existing paper-based procedures that will prompt new styles of leadership, new ways of debating and deciding strategies, new ways of transacting business, new ways of listening to citizens and communities, and new ways of organizing and delivering information (Pascual, 2003). E-government is a sub-set of the broader phenomenon of e-governance, and can be understand as the application of information technology's tools and techniques to the workings of government for the workings of government for the benefit of its "customers"—citizens and businesses—as well as for itself (Scacco, 2003).

With the proliferation of easy-to-use Internet and Web technology, many federal, state and local governments now provide the necessary instructions and forms for specific services. This facilitates citizens with direct interaction with the desired government service. However, this first phase of digital government efforts has resulted in a fragmented conglomeration of services and information sources (Chun, Atluri, & Adam 2002).

In ways, governance systems are not always neutral to ICTs; they may sometime support or sometime obstruct the application of ICTs for development. The era of the global information society, as brought about by the technological advancement and globalization in trade and economy may create challenges to the society, restrict the development of grass-roots communities; contests the business accomplishment and create barrier to the professional development if congenial policies have not been adopted by the government.

Governance, participation, and inclusion stand to benefit from the networking opportunities and access to relevant knowledge across distances. ICT can finally bridge local, regional and central governments, although it is difficult to separate the work of central government from overall governance practices. If a common platform of e-governance may be initiated, it does not matter much whether the central government provides nation-wide services or a grass-roots telecenter in a remote area services local villagers.

However, the central government need to review regularly its citizen services, retaining only those that are a clear public good, while outsourcing (whether fully or partially) to the civil society and private sector those that are too expensive or difficult for the government to administer or that would simply be better and faster delivered by non-governmental organizations.

### Aims of E-Government

The aim of the e-government policy is to set the enabling framework for the government administration to effectively and efficiently utilize ICT opportunities and to guide the forward move in the right ICT direction along an accelerated path in contributing towards the economic and social upliftment of the nation. It will enable the citizen to be a beneficiary in the global information economy and would create the framework for an e-society to support their economic, learning, and personal needs (e-Sri Lanka, 2003).

E-government may be set to accomplish the following goals that move beyond mere efficiency of government processes to that of overall reform and development:

- Better business environment
    - Technology is a proven catalyst in increasing productivity and economic growth, especially in rural and underserved communities (Konrad, 2002) (remote and disadvantaged). The use of

ICT in government and the establishment of e-government infrastructure assist to create a business-friendly environment at the grass root level. These can be achieved by streamlining the interactions and improving the interfaces between government and business focusing SMEs. By eliminating redundancies in procedures and emphasizing immediate and efficient delivery of services, e-government creates the atmosphere to attract the investors/investment

- Strengthened governance
  - Promoting transparency and accountability in government through the proliferation of ICT in management and operations opens opportunities for better mobilization of resources, efficient decision making and good governance
- Enhanced public participation
  - E-government facilitates swift delivery of information. Mass dissemination of information assists empowerment of citizens and facilitates informed decision-making. Eventually, citizens are made to be more actively involved in the policy and decision making processes of the government
- Improved productivity and efficiency of government agencies
  - Re-engineered management processes and procedures, efficient delivery of services, increased productivity of the bureaucracy, and increased savings are the inherent benefits of e-government system

With its emphasis on the use of information technology in the delivery of services, e-government presents a government agency with the opportunity to re-think how it delivers services. Specifically, e-government offers the agency the opportunity to: examine its current operations and procedures, identify business processes and practices that can be streamlined, implement those streamlined business processes, and implement new technologies that enhance those improvements. In the processes of streamlining business operations, a properly implemented e-government solution provides the agency with the opportunity to focus its resources on service delivery efforts that are most efficiently provided through direct contact versus other means (Pascual, 2003).

The success of efforts in achieving e-government lies in the way that technology is utilized and managed by the public sector. ICT as the enabling tool and with effective deployment it could facilitate the desired results in the long run. Systems, processes and procedures constitute the framework for the usage of ICT. However, the critical factor for the delivery of the desired results is the willingness of the public sector and the citizen to use and adapt to new technology-based environments (e-Sri Lanka, 2003). The government agencies should find innovative ways of working in fulfilling the needs of the people within the information society.

## METHODOLOGY

Stripped down to its bare essentials, e-government is concerned with leveraging and distributing knowledge more effectively government to citizen (G2C), government to business (G2B), and inter-departmentally within government (G2G) (Smith, 2004), including government-to-employee (G2E) relationships.

A country needs to focus on the following areas from the unified perspective of national governments, the telecom industry, and economic perspectives by:

- Making a connectivity breakthrough by expanding networks outside the urban areas
- Developing Web-based online services for the general public
- Providing large-scale Internet and capacity development training for the general public
- Identifying information and content needs and generating local content for social groups, entrepreneurs, farmers and communities
- Encouraging the development of need-based and bottom-up ICT strategies within a defined framework
- Making telecom sector a national priority
- Reforming telecommunications' legal and regulatory frameworks to facilitate nationwide network expansion, lower tariffs, affordable Internet access, higher teledensity, faster application of advanced technologies (broadband and wireless), increased openness and competitiveness in the markets
- Creating a regulatory environment in the telecom industry

The government should have clear concept on the formation of an information society with positive impact on the national economy. The transitional information society need to include the following strategies:

- Modernization of public administration and services
- Improvement in quality of life through the implementation of information technologies in the areas of education, health, environment and communication
- Development of an information technology sector and form a National Task Force to intensify conge-

nial atmosphere for establishment of an information society
- Modify the educational system by including digital content (E-government Strategy, 2002)

E-government services focus on four aspects: citizens, the business community, government employees, and government agencies. E-government aims to make interaction with citizens, businesses, government employees, government agencies in more convenient, user friendly, transparent, inexpensive and effective way.

In e-government system individuals can request for a particular government service and then receive that service through the Internet or some computerized mechanism. The government service can be delivered through one government office, instead of many (as one-stop-service), a government transaction can be completed without direct in-person contact with the government employee.

The following sub-sections would like to constitute the main thrust of this chapter, describing a few parameters that may assist to enhance the e-government system in disadvantaged communities.

## Improved Collaboration

Governments will have to explore new relationships among government agencies as well as partnerships with the private sector and NGOs to ensure quality and accessibility of e-government. Agencies may have to overcome traditional reluctance to work with each other to maximize benefits of scale in e-government projects. Collaboration among government entities, private enterprises and NGOs can assist policy-makers in crafting meaningful reforms and can expedite the implementation of e-government. Private sector experts, who deeply understand topics such as e-commerce, information technology, marketing and management, can advise government policy makers (Sakowicz, 2003).

In this context, four dimensions of e-government may be broadly categorized:

- **E-Services:** Electronic form of delivery for government information, programs, strategies, and services.
- **E-Management:** Information systems supporting the management and administrative functions of public institutions, including data and information management, electronic records maintenance and intra departmental information flow.
- **E-Democracy:** Assist to set agendas, establish priorities, make important policies and participate in their implementation in more deliberate ways (such as e-consultation or e-voting).
- **E-Commerce:** This concept is linked to the business side of government interaction (e-procurement—exchange of money for governmental goods and services conducted over the Internet/Intranet).

## Extensive Participation of Common People

E-government is the use of ICT to transform government by making it more accessible, more effective and more accountable to the common people. By this definition e-government does not mean putting more computers on the desks of government officials. Rather, it concerns the relationship between government officials and people. The reformation may include:

- Providing greater access to government information by making laws, regulations, forms, data collected by the government to be made accessible online; promoting civic engagement by enabling the public to interact more conveniently and interactively with government officials
- Increasing government accountability by making its operations more transparent, thereby reducing the delay in decision making and also reducing opportunities for corruption infiltration; supporting development goals by lessening the time and expense of small business entrepreneurs in their dealings with government, and by providing rural and disadvantaged communities with information and communications capabilities
- E-government is not any more a phenomenon limited only to the richer countries. Some of the most innovative uses of the Internet in governance are emerging from the developing world, as ICTs are increasingly being used to streamline government and connect it more closely with the people en masse it is intended to serve

## Increased Economic and Societal Participation at the Grass Roots

Introducing e-government is a necessity in the contemporary economy. Its advantages are known, recognized, and incontestable. For this reason, the question is not if, but how, to implement and promote e-government in transitional economies by taking into account the significant discrepancies between the capacities of developing countries and those of more developed countries. These include both economic and social factors, not least of which

is the relative absence of necessary specific habits and skills for the successful advance of technology.

The effectiveness of e-government solutions differs according to the stakeholders they address, whether common people of the community, business entrepreneurs or legal entities. The distinct challenge applies to reaching people in general. There are common thoughts of favoring business-oriented e-government applications over people-oriented ones.

However, implementation of an integrated e-government requires resolution of a few practical issues, like, breaking of monopoly on the fixed telephone market; the capacity development for the Internet service providers; raising of computer illiteracy for the government staffs; easy availability of modern payment instruments in electronic form; and the application of electronic signature law.

In developing countries, access to information infrastructure remains always inadequate, and progress on telecommunications policy reforms are lagging behind. Yet there is an opportunity for leapfrogging the new technology can provide better, cheaper links to the grass root stakeholders, while competing global operators can provide low-cost long distance communications. Adopting new technologies, developing countries can deploy telecommunications at lower costs per capita than the industrial world and rapidify poverty alleviation processes (Rahman, 2003).

## Enhanced Transformation

E-government is about transforming the way government interacts with the governed (government, business, people). The process can neither be easily accelerated nor simply can be manifested. It requires a coherent strategy, beginning with a thorough review of the nation's current regulatory environment and the ability of the population to make use of the planned technologies.

The primary motivation for e-government reforms should not be targeted to merely save money or reduce staff. While this can be a valuable output, the savings incurred from e-government initiatives should be the benefit the businesses and people utilizing the improved system are enjoying, rather than the government agencies have invested initially. In order to realize the long-term benefits of the transformation, governments should develop a citizen-centric model involving key stakeholders outside of government- businesses, trade associations, researchers, professionals, academics, CSOs, CBOs, and NGOs.

The success of e-government transformation is not just about the automation of existing processes and inefficiencies. It is the creation of new processes and new relationships between governed and governor. The use of ICT should not be treated as just a cost- or labor-saving tool and simply allotting government officials with computers or automating manual records. E-government is a solution that can revolutionize the process of government within itself. Therefore, government leaders planning e-government projects should first examine the function or operations which they want to apply through ICT.

E-government requires strong political leadership within the government. In order to achieve successful e-government transformation, there must be officials at all levels of government who understand the technology and the associated policy goals with proper motivation to carry out reforms. Strong leadership can ensure the long-term commitment of resources and expertise as well as the cooperation of discrete factions within the system.

## CASE STUDIES

A few case studies have been described in this section to illustrate cases in countries that have successfully adopted policies in their national ICT policies or taken approaches to implement the policies, focusing disadvantaged communities.

Bangladesh, being one of the developing country has integrated the societal participation at the grass root level. Relevant article from Bangladesh ICT Policy is added next for reference (ICT Policy, 2002):

- **3.10:** Social Welfare.
- **3.10.1:** Nation-wide ICT systems will be implemented for rural development activities, agricultural, horticulture, fisheries and livestock extinction for youth, technology guidance for rural enterprise, micro level planning, and so forth. Communicates and user groups or beneficiaries would be actively encouraged to participate in all such activities.
- **3.10.3:** Non-government organizations will be encouraged to establish centers at the village level for providing hardware/software or other support services. At the sometime the Government will use both the formal and nonformula channels to disseminate information about the application, advantages to communities of the use of ICT.

e-Sri Lanka takes a comprehensive approach to using ICT for overall development by promoting the growth of this promising sector, and more importantly by using ICT as an enabler for all the key sectors in the economy and society (World Bank, 2004a). The vision of e-Sri Lanka came about in response to the observed impact in India of the use of technology in development, and in transform-

ing government. It is a concerted effort by the Sri Lankan government to design and implement a comprehensive, nationwide strategy to harness the potential of ICT for the achievement of broader socio-economic goals (Development Gateway, 2004).

*Objective of the e-Sri Lanka Development Project is to promote: (i) use of ICT to enhance growth, employment, and equity through affordable access to means of information and communication; (ii) access to and use of public information and services on-line by citizens and businesses; and (ii) competitiveness of private sector, particularly of knowledge industries and Small & Medium Enterprises (SMEs)*. (World Bank, 2004b)

The Indian experience in e-government can be seen to be evolved in three phases. The first from the late 60s, or early 70s to the late 90s; second from late 90s to 2000; and the third 2000 onwards. The very recent trend of e-government systems in India achieved tremendous success in forming a homogeneous community across the country.

*In the first phase, efforts to develop e-government were concentrated on the use of IT for in-house government applications with a principal focus on central government requirements as defense, economic monitoring and planning, and certain data intensive related to elections, conducting of national census, and tax administration (GOI, 1985). In the second phase, the implementation of the national IT Task Force and State Government IT policies symbolized a paradigm shift in e-governance policies towards using IT for a wider range of sectoral applications reaching out to a large number of people in rural as well as urban areas (Madon, 2003). The third phase has seen the ultimate development of e-government systems in India, reflecting visionary implementation of India Vision 2020 and e-India. Another example for India can be the Government of Kerala's recent policy focus on establishing front-end computerization to trigger the administrative reform, even before the automation of departmental records.*

A statement made by Abraham Sotelo, the coordinator general of the E-Government Programme of Mexico has been quoted here, "E-Government is intended to strengthen the framework of professionalism in public service as well as lower government costs. It will help create a more deregulated government and eliminate a lot of paperwork and bureaucracy. The main objective is to create a high quality government service that is also honest and transparent" (World Report, n.d.).

Among many other successful e-government approaches implemented or adopted globally, IT2000 of Singapore, Digital 21 of Hong Kong, Malaysia Vision 2020 of Malaysia, and Mauritius Vision 2020 of Mauritius are to name a few.

## FUTURE PROSPECTS

E-government offers the potential to bring citizens closer to their government. From 2001 to 2004, e-mail interactions through government Web sites have increased from 73% to 88%. In e-government rating, North America scored 39.2, while Asia has only 31.6 in 2004. Despite this progress, there are still a diverse issues that hinder their ability to reach their full potential in terms of accessibility and effectiveness, especially in many developing countries (West, 2004).

E-government is an expensive tool requiring strong and enduring political will. Without the active commitment of government leaders, states are not assured the allocation of financial resources, the adoption of an appropriate legislative framework or even the most basic human investment in planning and implementing e-government. One strong indicator of political will is the degree of involvement of high level decision-makers in e-government implementation (Misnikov, 2003).

While the myth prevails that all e-government/e-governance initiatives are always costly, this is not true. The implementation cost of e-governance projects may seem expensive, but the cumulative social and economic outcome is much extended. However, there must be efforts and investment plan on the government side to create an effective e-government for providing direct value-added e-services for citizens.

Utilizing ICT to develop e-government will ultimately need to re-engineer government processes and transform governance. It is not enough to deliver services efficiently and effectively by following steps to accomplish certain procedural requirements. It has to simplify government processes altogether, change the concept of governance, and thereby transform the overall relationship between government and people. Increased information access and transparency in government processes leads to greater accountability and credibility, as online or computerized processes remove discretion from government officials and provide monitoring facilities.

Designing security systems for a digital government's multidomain environment requires balancing between providing convenient access and monitoring permissions (Joshi et al., 2001). Developing an evolutionary architecture to integrate large heterogeneous systems poses another challenge. Although these systems support vertical applications, exporting their services requires reengineering their technological services and adminis-

trative processes. The goal is to establish an architecture that coordinates information exchange among government information systems while maintaining each organization's autonomy (Mecella & Batini, 2001).

## CONCLUSION

The integration of ICT into development processes and delivery mechanisms of public and private services necessitates social mobility learning, vigorous planning, local level initiation and the sharing of local and international experience on best practice as pre-requisites. Effective monitoring and evaluation is also a must. It is a proven truth that no blueprint plan will sustain for long with the dynamic changes in ICTs and the degree of adaptation and innovation needed to exploit these technologies.

The strategies, standards, and guidelines on e-government schemes should form part and parcel of the policy and serve as the detailed blue print for the strategy development. The updated policy together with the set strategy is expected to increase productivity, competitiveness, cooperation, and foster innovation in the public sector to leapfrog in the knowledge economy. Successful implementation of the policy would assist the government to be more responsive and accountable to the citizen and achieve greater transparency by providing benefits of increased efficiency and fostering the trust of the citizen for greater cooperation towards the development efforts.

Good governance (including fighting against corruption and for greater transparency) has been identified as a "missing link" both in poverty alleviation efforts and equitable and inclusive economic growth. Its basis lies in good governance: strengthening the diminishing the growing disparities among its members (Misnikov, 2003).

Developing countries cannot expect positive outcomes by following the strategies and building the institutions that served the developed countries in the industrial era. The development challenge in the 21st century will be entirely different to the development challenges of the past century. Indeed, all countries, whether developed or developing, will need to recognize the scale of changes currently underway and design new strategies for these realities (Clarke, 2003). Disparities in rural-urban infrastructure and in hierarchies of economic development are acute in most developing countries and tend to broaden with ICT development, due to high costs of ICT infrastructure deployment in rural areas and also due to limited profit potential of rural markets (Proenza, 2002).

Despite occasional setbacks, digital government projects now appear firmly on the road to fulfilling their promise of making civil and political processes more accessible than ever (Elmagarmid, & Mclver 2001). However, it is estimated approximately 35% of e-government projects in developing countries are total failures and approximately 50% are partial failures (FairfaxDigital, 2004).

Ideally, the ICT tools offer an unprecedented opportunity for community to access information over any geographical distances and across any sovereign state borders. Opportunities for networking and knowledge sharing are also unlimited, regardless of its perseverance. Furthermore, ICTs position in governance systems and practices are becoming widely participatory and inclusive, with endless economic opportunities. Time has come to look backward, take a good view, breath a while, and re-think on strategies, policies, and planning on the developing countries acting locally, regionally and globally along this hopeful road to success and prosperity.

## KEY TERMS

**Community Networking:** A form of network that brings together the practices of community development, community-based research, health, education, and insights from fields such as sociology, feminism, or library and information and management sciences.

**Digital Divide:** The digital divide is a social issue referring socio-economic gap between communities that have access to computers and the Internet and those who

do not. The term also refers gaps that exist between groups regarding their ability to use ICT effectively, due to differing levels of literacy and technical skills, as well as the gap between those groups that have access to quality, useful digital content and those that do not.

**E-Government:** E-government refers to the use of information and communication technologies to improve the efficiency, effectiveness, transparency and accountability of government.

**ICT:** It is the convergence of information technology, telecommunications and data networking technologies into a single technology, and it is the electronic means of capturing, processing, storing and communicating information.

**ICTD:** It is a term for information and communications technologies for development, an initiative aimed at bridging the digital divide (the disparity between technological "have" and "have not" geographic locations or demographic groups) and aiding economic development by ensuring equitable access to up-to-date communications technologies.

**Information Society:** A society in which economic and cultural life is critically dependent on rapidly developed information and communications technologies and it is integrated by complex communication networks for exchange of information.

**Information Systems:** Also known as management information systems (MIS) is the formal study of the information systems within an organization, consisting of the network of all communication channels. An information system is comprised of all the components that collect, manipulate, and disseminate data or information.

# Securing an Electronic Legislature Using Threshold Signatures

**Brian King**
*Indiana University—Purdue University Indianapolis (IUPUI), USA*

**Yvo Desmedt**
*University College of London, UK*

## INTRODUCTION

Today a significant amount of research has focused on trying to apply the advances in information technology to governmental services. One endeavor has been the attempt to apply it to "electronic voting." Unfortunately, while questionable secure e-voting technology has been widely deployed, the same cannot be said for cryptographic based ones. There is one type of "voting" which has received only limited attention concerning applying these technology advances, the type of voting that takes place within a legislative body. At first glance, it may not appear difficult to institute electronic voting in a legislature, for it may seem that one only needs to apply the traditional security mechanisms that are used to safeguard networked systems, but as we soon outline there will be significant security risks associated with an electronic legislature. One of our concerns is that entities may attempt to implement an electronic version of a legislature without realizing all the risks and implementing all the needed security mechanisms. In fact, there have been occasional instances of some entities attempting to create some electronic/digital form of legislature, for example (Weidenbener, 2004).

In any legislative vote, the legislature's ability to pass or to not pass legislation should be interpreted as the legislature deciding whether to "sign the proposal" into "law." Thus, "law" is a signature; anyone can verify that a "proposal" is a "law" by applying the signature verification procedure. As we move towards electronic applications of governmental services, it is only natural when this is applied towards legislatures we will replace the "written law" by a "digital signature" (here the use of the term law can be replaced by any internal regulation and a legislature by any regulatory body). The underlying aspect of the article is the security considerations that need to be applied when this is implemented.

The question *why consider an electronic legislature* is important. The fundamental reasons for applying today's information technology to government and its services have always focused on that it would bring improved services and allow greater accessibility of government to its constituents. An electronic legislature would most certainly improve the legislative service. It will allow for the legislators to be *mobile*, they will no longer need to be tied to the legislative house to provide representation. Many industrial employers allow their workers to telecommute to work, it is a realization by the employers that these workers are valuable, as well as a recognition that the workforce and the time constraints on the workforce has changed. In many cases, without this option, these workers may leave the workplace. This same reasoning of a valued worker should be applied to our legislators. Further, it does not make sense that today we would allow a subset of the legislature to make and pass laws due to absenteeism, especially in light that many of the required mechanisms to bring about a mobile "electronic legislature" are available. One can argue that by allowing legislators to occasionally telecommute will provide an improved workforce (this argument is motivated by the same reason that private industry utilizes "telecommuting"). We also observe that an electronic legislature should provide the constituents greater access to their legislators. A final argument for an electronic legislature is that it will provide continuation of government in the case of some drastic action like a terrorist attack. In the fall of 2001, the legislative branch of the U.S. federal government came under two attacks. The first attack was performed by Al Qaeda operatives (who it is speculated intended to fly one of the planes into the U.S. capital), and a second attack by an unknown entity who contaminated parts of the U.S. senate (and it offices) with anthrax spores. This second attack was successful in that it denied the Senate the ability to convene for several days. Although such terrorist's attacks on the legislative branch may appear novel, at least in the U.S., such attacks have been precipitated in other countries for some years (PBS, 2001). The U.S. government has recognized the need to develop a means for the continuity of government in the wake of such disasters (Continuity of Government Commission, 2002), one such solution is to utilize an e-legislature.

The concept, model, and a protocol for an e-legislature was first described in Desmedt and King (1999). In Ghodosi and Pieprzyk (2001), the authors described an alternative, which required the use of a trusted administrator. Later in Desmedt and King (2002), we pointed out the weaknesses and disadvantages of the system in Ghodosi and Pieprzyk (2001) and clarified some aspects of the protocol in Desmedt and King (1999).

## SECURITY CONCERNS

One reason to be concerned about the security of an electronic legislature (e-legislature) is that one can "view" the e-legislature as a "network." Represent the legislators as computers/hosts and their communications as the network communications. All problems that affect a network can affect an e-legislature; however there are several more reasons to be concerned. First observe that as a "law making body," an e-legislature and the results derived from its communications need to possess a high integrity. In addition, the participation of members from the legislative body will dynamically vary from time-to-time. Further, since the decisions made by the body (i.e., law) are determined by some fixed percentage of those members present/active, there will need to be some *"transfer of power"* which allows this percentage of the legislators present to pass legislation. For example, suppose that the legislature makes decisions based on majority rules and that the original legislature contains 50 members. Thus 26 legislators are required to approve a proposal into law. Later we have seven legislators absent. At this time, 22 legislators are needed to pass legislation. Thus, there will need to be some mechanism that allows the original body to transfer signing power from the 50 to the 43 (so in the latter case 22 can pass legislation). This in turn becomes a great risk to the integrity of the legislature. The reason is that a legislature is a political body and their members will certainly act this way. The moment at which a transfers needs to occur will be the moment when the risk to the integrity of the legislature is the highest (unless mechanisms are enacted to ensure the integrity).

## THRESHOLD SIGNATURES

As we have described earlier the mechanism that is used to pass a "law" is equivalent to creating a signature, whereas the "legislature" will construct the signature. This is done as a collective body. The first realization question is "how do we model this construction" in an electronic legislature. We could of course provide each legislator with a public-key/private-key pair (Menezes, van Oorschot, & Vanstone, 1996), and when a legislator wishes to vote on a proposal they sign it. If enough legislators sign the proposal then the proposal becomes "law." The problem is that this is unsuitable. First the essence is that this system of law making is generated by a "group-decision," hence the signature should be a *signature created by a group* and not individually signed. There are several other reasons why it is not reasonable to have each legislator individually sign, one is the procedure of verification. To verify that the proposal has been passed one will need to verify each of the individual signatures using each of the individual public-keys, and then they will need to verify that a suitable number of legislators have signed[1]. Since the verification of a law can take place at various times by various parties, there would be a need to "securely store this information concerning who was present and how many." This information would need to be authenticated; hence some signature may need to be applied. But no one party can sign this information otherwise they would possess a power, concerning the signature of proposals (making law), that others don't possess. Thus we need a *signature created by a group* to authenticate this information, but we were trying to avoid such a signature. Consequently, a signature created by a group is required and so we should make the signature of a proposal a "group generated signature" which is called *threshold signatures*.

The next question would be "how do we generate this signature generated by a group?" The solution is to use a cryptographic tool called "threshold secret sharing."[2, 3] The tool is such that a *distributor*[4] generates a single "legislative signing key" and divides it into shares—one for each of the legislators, so that any $k$ of the legislators can reconstruct the signing key[5]. Here $k$ is the quorum number. When a proposal is considered each of the $n$ legislators decide to vote on it. If they decide to vote "yes" they create a *partial signature* by applying the signature generation function with their share. This process of using a threshold secret sharing scheme within a signature scheme is called threshold signature sharing or threshold signatures, for short.

Consider a legislative body $P_1,\ldots,P_n$. They each possess shares of the signing key, so they collectively possess the signing power, for which when a proposal is made this body has the power to sign it into law (as long as a quorum of legislators are present). The number of legislators present will vary from time to time. As long as a quorum $k$ exists (a pre agreed minimum number of legislators needed to be present), a proposal can be passed, according to some fixed percentage (threshold), for simplicity we will assume a simple majority vote. i.e. a $k_t$ out of $n_t$ vote where $n_t$ represents the number of legislators present at time $t$, and $k_t = n_t/2+1$; and so we must transfer from a $k$ out of $n$ vote to a $k_t$ out of $n_t$ vote.

We can support the dynamism of legislator attendance by doing the following: select any $k$ of the legislators present at time $t$. Have each of them independently play the role of a distributor and *share their partial signature* in a $k_t$ out of $n_t$ manner using threshold secret sharing. Then each of the $n_t$ legislators has received $k$ shares. Each of them (for convenience) compresses these $k$ shares to one share.

## NECESSARY REQUIREMENTS TO SECURE AN E-LEGISLATURE

The first requirement is that the "law" is created by having the legislators "partially sign a proposal" and that the signature (law) is generated by using threshold signature sharing. Such a signature is created by using the single legislative key. No one entity possesses this key, but rather this key is shared to the participants by using threshold secret sharing.

Second as the legislature changes in size the transfer of signature power from the original body must be made to the body that is present. This sharing of signature power needs to be temporary. For example suppose the original legislature contains 50 parties. Thus 26 legislators are required to approve a proposal into law. Later 7 legislatures are absent. At this time 22 are needed to pass legislation. At sometime later 49 are now present. Consequently 25 are required to pass legislation. If we permanently shared the secret signing key, then 22 would still be able to sign. We could "ask/require" that these members destroy their old shares. But this would require that 49-22=27 destroy their old shares, the irony is that we require more people to be honest than what the current threshold is (which is 25). If legislators send "shares of their share" to the others[6], then these legislators can continue to use this information to sign later messages into law (those that occur at later times). In fact they can impersonate this legislator in future votes. Temporary sharing is achieved by having $k$ participants $P_{i\_1}, \ldots, P_{i\_k}$ transfer *their partial signatures* instead of their power to sign. Consequently the "transfer of power" (also called "sharing of shares") needs to be message-oriented, and so it is achieved by *sharing partial signatures*.

Third, observe that a few of the $k$ (out of the $n_t$ participants $P_{i\_1},\ldots,P_{i\_k}$ could defeat the process by not properly transferring their power (shares). This would be especially true if the message (law) was such that they had a vested interest that the law should not be passed. Thus, as the transfer of power ("sharing of shares") is message oriented, there is a need for the set $P_{i\_1}, \ldots, P_{i\_k}$ to transfer power blindly (i.e., encrypt the message before sharing).

Fourth, the participants $A_t = P_{i\_1}', \ldots, P_{i\_k\_t}'$, when given an opportunity to act on legislation must know that the outcome ("sign" or "not sign") is a result of their decision and not a result of bad faith on the part of the participants $P_{i\_1}, \ldots, P_{i\_k}$ who had transferred them the power to sign (these are the legislators who "share their shares"). Signature generation should be such that if a signature is not generated then we should be confident that the only possible reason for this was that there were not enough "yes votes." We shouldn't have to wait until voting time to find out that this "sharing out shares" was not fair. Hence, the participants $P_1', \ldots, P_{n\_t}'$ (the legislators who are present at time $t$) need to be able to verify that they were actually given the power to sign that message.

Fifth, no set of participants should gain any information about a motion made during an illegal session, a session where either cheaters have been discovered or the number of legislators present is less than the quorum $k$. Otherwise, they could use this knowledge, to act in later sessions. The point is that cheaters should not benefit. Further cheaters maybe motivated by their political affiliation, and attempt to cheat so that their colleagues benefit, hence no one should benefit. This provides another reason to blind the motion.

Sixth, in a *receipt-required* version of an e-laws protocol, for each legislator belonging to $A_t$ there must exist a record as to how that legislator voted. Note that if each legislator sends a validated partial signature (which we interpret as a valid vote) then this provides a receipt that the legislator voted in favor of the message. We could use the lack of a validated partial signature as a "no" vote.

Lastly, we assume that the network is sufficiently reliable connected, even to overcome any disruption by malicious parties.

## AN OUTLINE OF A SECURE E-LEGISLATURE PROTOCOL

The following is an outline of a verifiable democracy portocol. We omit all technical details, for technical details of the protocol we refer the reader to Desmedt and King (1999).

### Verifiable Democracy Protocol: A Democratic Threshold Scheme

During the set-up, the legislature is empowered with a secret key so that any k out of $n$ legislators can compute the secret signing key. If $n_t >= k$ we proceed with the protocol (we have a quorum), if $n_t < k$ then there are not enough legislators to pass the legislation.

At any time $t$, a message/proposal $m_t$ may be proposed. $A_t$ represents the set of participants present at time $t$, $n_t = |A_t|$, and $k_t$ represents the threshold (the minimal number of participants required to sign).

## Set-Up Phase

### Legislative Key Generation

A secret key K is distributed to the $n$ participants so that a "blinded message/proposal" can be signed in a $k$ out of $n$ threshold manner. In addition to distributing shares of K this distributor generates auxiliary information[7] which is used later to verify "partial signatures." (For example if the protocol utilizes RSA signatures (Rivest, Shamir, & Adelman, 1978) a "test message" is generated and the distributor broadcasts all $n$ partial signatures of the test message. The test message and partial signatures of test message play an important role in the verification of future partial signatures (Gennaro, Jarecki, Krawczyk, & Rabin, 1996). This can be performed by a trusted third party or by the participants using a protocol such as Desmedt and King (1999) and Ghodosi and Pieprzyk (2001).

## Use for Each Law-Proposal

### Blinding Message

The participant $P^*$, who proposes message $m_t$, blinds $m_t$ before they present it to the legislative body $A_t$.

### Transfer of Power: Partial Signature Generation TPSG

As long as $n_t$ exceeds (or equals) $k$, the message will be considered for signing. If so, $k$ participants in $A_t$ are chosen and they generate partial signatures for the blinded $m_t$.

### Transfer of Power: Partial Signature Distribution TPSD

Each of the $k$ participants share out their partial signatures in a $k_t$ out of $n_t$ manner to $A_t$ (we will refer to these $k$ participants as *partial signature distributors*). Each participant in $A_t$ has received $k$ shares, whereupon they compress the $k$ shares of the partial signature to one share. In addition to distributing partial signatures, the partial signature distributors will also distribute auxiliary information which allows the legislative body $A_t$ to verify the correctness of the partial signatures of the blinded $m_t$. If enough valid shares of the signatures have been obtained at this stage, then this will allow one to obtain the signed law. Details of this are now described.

### Transfer of Power: Partial Signature Verification TPSV

The auxiliary information provided in TPSD is first verified by each legislator in $A_t$. Upon verification the auxiliary information is used by each legislator to verify the correctness of their share of the partial signature of the blinded $m_t$. The verification procedure is devised so that with overwhelming probability it can be determined that a recipient has received a valid share this is achieved via a "verification and complaint" protocol. If a verification fails then a complaint will be raised, at that time a cheater has been detected, what remains is a protocol to determine whether the cheater is the "partial share distributor" or the "complainer." The consequence is that the completion of this stage with no complaints implies that the signature power for the message has been transferred to $A_t$ so that any $k_t$ can sign the message. If the cheater is the partial share distributor, it is removed and one proceeds without that party, which is possible due to the sharing technology.

### Unblind the Message

The message is revealed to the legislature. Who reveals the message? $P^*$ could. Or if one utilizes a trusted chairperson as in Ghodosi and Pieprzyk (2001), then the trusted chairperson could reveal $m_t$ (this protocol has several problems, for more details we refer the reader to Desmedt and King (2002)—for example the use of a trusted chairperson is rarely if ever utilized in a legislature). In Desmedt and King (1999), the protocol utilized RSA signatures and so the legislators themselves could unblind the message without the legislators revealing their partial signature of $m_t$.

### Decision: Vote on $m_t$

The legislators decide whether to vote for or against $m_t$.

### Partial Signatures Sent PSS

If any legislator wishes to vote for the by now known $m_t$ they send their share of the partial signature of the blinded $m_t$.

### Verification of the Signature: Determining the Passage of $m_t$. PSV

If $k_t$ or more participants have sent their partial signatures then the message may be passed. If so, the combiner

selects any $k_t$ of the sent partial signatures and verifies the correctness of these partial signatures using the ancillary information provided within this protocol. For each one of these invalid partial signatures the combiner selects one of the remaining partial signatures sent and verifies it. If the number of valid partial signatures is less than $k_t$ then the message $m_t$. is automatically not passed. We have adopted a receipt-required version of the verifiable democracy protocol. The partial signature sends (PSS) together with the partial signature verification (PSV) implies $k_t$ "valid votes."

Who can play the role of the combiner? Any person, collection of people, or even the legislators.

### Message Passed

The message is passed if a signature of $m_t$ can be constructed and the $k_t$ "yes votes" can be verified using the auxiliary information. A vote for $m_t$ is a valid partial signature.

A comment about the verification steps TPSV and PSV in the protocol. The verification procedure TPSV and PSV may utilize different verifiable secret sharing schemes due to the amount of information the senders TPSD and PSS, respectively, know. In TPSD the senders know the shares of the secret key, whereas in PSS the senders know partial signatures. Whether TPSV and PSV require different verifiable sharing schemes may depend on the threshold signature scheme that is used.

## CONCLUSION

The importance of developing an electronic legislature with high integrity requires a careful consideration of the e-legislature protocol. We have provided several requirements that such a protocol will need to possess to ensure this integrity. We have also provided a high-level outline of an e-legislature protocol. One of our main concerns is that one may attempt to implement an e-legislature without giving careful consideration to the security risks, potentially handing over democracies to hackers.

## KEY TERMS

**Digital Signature Scheme:** A digital signature scheme is a is a public-key cryptographic tool which allows a party to provide origin authentication to a message. It consists of two schemes, a signature generation scheme, where a party can "sign" a message with their private key and a verification scheme where any party can verify the authentication of the signature by using the public-key.

**Threshold Secret Sharing:** A cryptographic tools which allows one to distribute pieces of a secret key to n participants so that: any k of the n participants can

collectively reconstruct the secret key and any set of participants with less that k member cannot generate any information about the secret key.

**Verifiable Secret Sharing:** A secret sharing scheme for which there exists a mechanism which allows the shareholders to verify the correctness of their shares, without requiring them to reconstruct the secret key. That is, by utilizing this mechanism they can be assured that their shares can construct the key without requiring them to reconstruct the key.

**RSA Cryptographic Primitive:** A public key cryptographic primitive that can be used for both public-key encryption and digitally signing. The primitive is such that the public value N is generated by selecting two large, secret distinct primes p and q and setting N equal to their product. Two parameters e and d are determined by: (1) selecting e so that gcd of e and (p-1)(q-1) is 1, and (2) computing d so that e*d =1 mod (p-1)(q-1). Encryption of message m is equal to me mod N and decryption of C is performed by computing Cd mod N.

**Partial Signature:** When utilizing a threshold signature scheme, a partial signature is the data generated by a participant by signing a message using their share of the private key (secret key).

## ENDNOTES

1 Recall that this "suitable number" is dependent on some fixed percentage of those legislators that are present/active.

2 One method to construct a threshold sharing scheme is to utilize a polynomial construct method within a field (Shamir, 1979).

3 The importance of using threshold sharing to construct a group signature was independently developed in Boyd (1989) and Desmedt (1988).

4 Technology exists to avoid the need to rely on a single distributor, that is, using several distributors.

5 Of course the legislators will never reconstruct the signing key, what they will do is, use this information to construct a signature.

6 Rather than sharing out their partial signatures, the participants could share out their shares of the secret signing key.

7 This ancillary information will be broadcasted to all, that is, public record. The nature of the ancillary information is dependent on the verifiable sharing scheme that is used. In Desmedt and King (1999) we utilized the RSA signature scheme (Rivest, Shamir, & Adelman, 1978), so the ancillary information was based on this assumption of RSA and using a verifiable secret sharing scheme for RSA.

# Skilling for E–Government

**Helmut Drüke**
*Capgemini Germany Ltd., Germany*

## INTRODUCTION

Implementing e-government in local, regional, or central administration represents a far-reaching modernisation of governing the public affairs. Therefore, in training it is not sufficient to train users in new programs as in the case of f.i. further training in a new office application. To understand and actively influence the restructuring that, by necessity, goes along with the introduction of e-government a broader approach in e-skilling is needed.

For Grabow, Drüke, H., and Siegfried (2002), e-skilling is one of the ten factors for success in local e-government. Schelin (2004) goes into the same direction when she points out: "With the era of digital government upon us, Federal, state, and local governments need to prepare their elected officials and employees to handle the multitude of changes incorporated into digital government. However, the lack of training opportunities, as well as the lack of research dedicated to training for digital government, is ominous for successful digital government endeavour ..." (Schelin, 2004, p. 273).

Whereas Schelin in this encyclopaedia, presents the content and methods of an advanced training module this contribution focuses on the competencies that are required to enable the different user groups to be up-to-date for the new challenges that are ahead of them.

In accordance to that approach in the first chapter the basic challenges that different user groups have to face when being confronted with e-government as a comprehensive modernisation concept.

## BACKGROUND: E-GOVERNMENT AS A COMPREHENSIVE MODERNISATION CONCEPT

In local e-government these secular developments of the last few decades are drawn together, e.g. the rapid progress of information and communication technology (Garson, 1999; Grönlund, 2000), globalization (Carnoeiro, 2000, Valenzuela, Vázquez, & Lorente, 2001), the declining importance of ideologies[1] (OECD, 2000), new opinions on the reasons for efficiency in organizations (Baldwin & Clark, 1997; Daft & Lewin, 1993; Harrison, 1994; Kogut & Bowman, 1995) and a changed understanding of the relationship between the state and society (Carnoeiro, 2000; United Nations, 2001)[2].

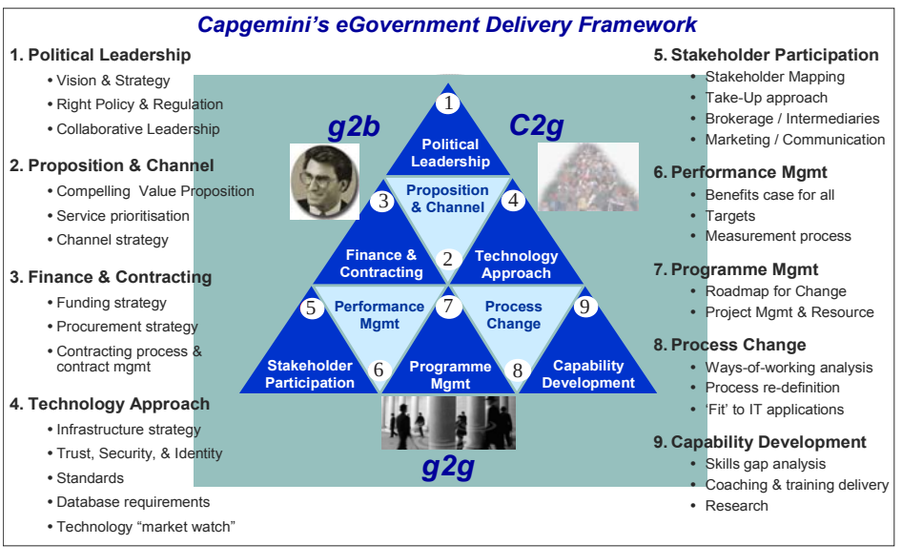
As the OECD (2003) phrases it, the main effect of e-government is "simply better government by enabling better policy outcomes, higher quality services, and greater engagement with citizens and by improving other key outputs identified. Governments and public administrations will, and should, continue to be judged against these established criteria for success" (p. 12).

E-government has a high global priority. The subject is regarded as a central national task: programs, strategies, and institutions are being established or adapted. This high awareness in itself encourages the development of local e-government. In a sense, e-government creates a second chance for administrative reform. This is partly because some of the same subjects are on the agenda and partly because the establishment of the virtual town hall, if it is done systematically, also involves modernizing the administration.

Strictly speaking, e-government even goes a step further, because it aims to restructure the internal processes from the customer's perspective to a far greater extent than was planned in the administrative reform. According to Hill (2002), e-government also goes beyond the previous administrative reform in its greater focus on services (e.g., its life episode approach with integrated services) process improvement by e-government and a "reinvention" of administrative action with new organizational forms and new methods of service to the public.

The use of information and communication technology lends great support to the administration in all reform processes. As a result, it will be possible to put the goals of administrative reform back on the agenda—goals such as increasing the effectiveness and efficiency of the administration, citizen and customer orientation, a greater service quality and an increase in the transparency of the tasks, improved working conditions for the administrative staff, reminding staff of the goal of pooling subject and resource responsibility in a coherent e-government project and transforming this into fresh motivational impetus and renewed activity.

*Figure 1. The e-government delivery framework*



## THE E-GOVERNMENT DELIVERY FRAMEWORK

A proven concept to understand the structural factors influencing e-government conceptualization and implementation on any level be it local, regional, national, or supragovernmental, is the Capgemini eGovernment Delivery Framework which will be explained in the following.

The "eGovernment Framework" captures the main building blocks of e-government with all in all 29 subcategories which cover the main aspects that have to be taken into consideration when building up e-government. The categorization starts from the fundamental assumption that e-government is more about organization than about technology. Only if perceived as a comprehensive modernisation concept e-government can generate the massive results it can have. Any of the aspects is indispensable when e-government is led to a success.

- **Political Leadership:** Comprehends the foundation of any e-government project on a solid and well-communicated vision and a clear strategy. Rules for all participants are made clear and the leaders execute a collaborative style of cooperation with internal and external process participants.
- **Proposition and Channel:** Deals with the processes to address the different user groups. The main questions here are: what is the value proposed to different user groups, which services are to be prioritized according to what criterion. A multi-channel strategy should be implemented.
- **Finance and Controlling:** Asks for the strategy and concepts to organize the supply chain in e-government (funding, procurement, contracting).
- **Technology Approach:** Assembles the aspects to use the right technology such as middleware, security, standards, interoperability.
- **Stakeholder Involvement:** Broaches the issue of the appropriate ways and concepts to involve the main stakeholders into e-government projects during the whole life cycle.
- **Performance Management:** Asks for the methods, instruments and tools to measure the economic, societal and political impacts of e-government.
- **Program Management:** Covers the classical project management issue.
- **Process Change:** Explores the central role that business process reorganization plays in e-government.
- **Capability Development:** Touches the issue of permanent further training of both the individuals and the organization to cope with the demanding challenges that e-government poses.

This cascade of features ensures a structured and comprehensive coverage of the topic and provides a basis for skilling. With the aspects laid out in the e-government delivery framework generic as well as specific require-

ments and contents of skilling for different user groups are given. Generic skills and competencies would comprehend project management, performance measurement, financing, and contracting and the like. Specific issues are strategy, proposition and channel, technology, process change or stakeholder participation. In other articles, the requirements for different user groups are described along the perspective elaborated in the theoretical concept of another article.

## COMPETENCIES FOR DIFFERENT USER GROUPS

Involving the employees in the set-up of e-government is indispensable. Even councils and heads of administrations must be motivated—if needed—to support the overall e-government project. Online offerings—posted on the Internet with the best intention—serve their purpose only when accepted by and encountering interest among citizens and local businesses. Achieving this on a sustained basis assumes an easy Internet access and a certain level of "Internet literacy."

Qualification is therefore needed by several groups. As for the own staff, councillors, and heads of administrations, this need can be identified with a survey. The evaluation of the results provides then the basis for planning and implementing measures.

In view of the citizens and all small and medium-sized companies, supporting measures for qualification and competency improvement help to avoid a "digital divide" in the society.

### E-Skilling for the Staff in the Public Administration

Without know-how of and active support from the employees, e-government is not feasible. Their ideas and tips are needed. But it is also important that they recognise and understand the radical changes e-government brings about in terms of processes, responsibilities, content-based and psychical requirements, and social interrelations. Motivation and qualification measures help to get employees out of their (in case of innovation, "classic") role of affected people and turn them into actively involved staff.

Essential are the capabilities and skills needed to deal with the new possibilities in a targeted fashion and positively influence the general conditions in the own professional sphere of action. Conveying and strengthening relevant competencies represents the overriding objective of all development measures for human resources.

E-government, in the first place, means increased electronic support in the execution of tasks. The use of information and network technology—Internet, Extranet, and Intranet–requires relevant competencies and qualifications. The widely available knowledge of Office applications may serve as a basis; they are, for example, also a prerequisite for acquiring the European Computer Driving License. In addition, the employees need to master corresponding functional applications, groupware, content management, and document management programs for e-government.

Overall, it is about improving the employees' capabilities and skills of handling the new technical possibilities and positively influencing the general conditions in the own professional sphere of action. Conveying and strengthening relevant competencies represent the overriding objective of all development measures.

These competencies include social skills, personal skills, and media skills:

- *Social skills* in terms of ability to understand and shape the own social environment
- *Personal skills*, meaning the ability to establish and maintain working relationships in the professional arena, develop as individual, co-operate with others, and lead as manager
- *Media skills* as technical-practical capability and skill, including critical reflection on benefits and limits of technology (systems)

Qualification measures must be planned systematically and incorporated into the human resources development. This also includes the systematic capture of strengths and weaknesses of each employee and the entire work area. The related training must allow for various methods and be based on a target agreement within the administration. The works council must be involved in the planning activities. For the operational implementation, a qualification plan—relating to both the work area and individual employee—must be developed.

Moreover, the human resources systems should be aligned in a way to better respond to the requirements resulting from the introduction of communal e-government. Within the scope of the possibilities given in public administration, incentive systems and career planning must also be aligned.

E-government changes processes and organizational structures. It reshapes activities, forms new work groups, and rearranges obsolete work areas. As a consequence, some competencies become obsolete, other and new qualifications become relevant. With e-government, virtual worlds of work arise, particularly in form of extranet co-operations and in corporate-like networks. Tele-working and work forms with new time management will emerge, which in turn requires new competencies.

More than before, employees need co-operation and communication skills as well as process chain orientation when performing sub-tasks. Internal and external customer orientation becomes a principle of action.

In projects, employees must increasingly work together with internal and external partners; especially co-operations with external players will rise. These can be own operations, "hybrid forms" of formally independent companies, but factually depending on the administration, or even "classic" private enterprises. The orientation in such co-operations is aggravated by the variety of interests, attitudes, experiences, and content requirements.

The working process must be designed as an environment that nurtures learning to support competence development via active learning or "learning by doing." This particularly includes (informally arranged) possibilities to exchange experience with problems around new applications and administrative procedures with colleagues, managers, and IT managers and search and get help during daily business. Executives are invited to expressly encourage their staff to do so.

More formal activities such as the involvement in projects on the changes in the working process and/or the continuous development used by larger employee groups are meant to enhance their competencies and increase their motivation. The practice in Tameside (United Kingdom) demonstrates the benefit of a continuous training vs. a training that is being carried out only when it is urgently needed.

*To date, over 1,000 Tameside staff have completed the 'Continual Improvement' training program, and IT training in the region of 1,200 delegate days is provided annually each year by the in-house training team. This training is predominantly for front-line staff to equip them with basic IT skills. More than 1,000 staff have been trained in the tools and techniques of statistical process control and systems.* (Socitm & I&DeA, 2002, p. 147)

The employees must be addressed differently; therefore, different measures must be planned and taken. This results from the wide range of objective prerequisites, such as task, formal and effective qualification of the employees, and subjective factors, such as attitude towards work, profession, and changes. Accordingly, the qualification strategy will have to contain differentiated qualification plans in terms of content and time.

In the human resources development trainings, the whole set of state-of-the-art methods and instruments should be used, including e-learning, the self-directed learning handled in tele-operation via standardised learning programs. In an e-government strategy, "classic" and new methods are integrated in the "blended learning" concept.

In some foreign municipalities, the enhancement of competencies is addressed with employee rotation from the original work area to another municipality (like in Tampere/Finland), or from public administration to a private business (like in Liverpool, UK) or privatised company. In Tameside (UK) teams of employees work in other municipalities for about three months for the general IT introduction and co-ordination between back-office and front-office when introducing e-government. "In order to maximise the transfer to recipients, a certain amount of technical expertise will be needed to tailor the Web site and associated software for local conditions and to ensure it is further maintained and develop thereafter. To facilitate this technical staff from partnership, Councils will be seconded to work in Tameside for a period of around 3 months, during which time they will become familiar with software and do the initial tailoring work. It is also likely that staff from TMBC will be seconded to other partner LAs [Local Authorities, HD] to facilitate joined up working within the partner LAs. At the end of this period, the Web site will be installed and developed within the mentoring council.

During this same period, a parallel secondment of staff for up to 3 months will take place to familiarise staff with the toolkits, templates, and processes for implementing e-government via a front office. This is vital work in re-engineering processes to ensure front and back offices work in concert to improve services to the citizen." (www.idea-knowledge.gov.uk)

## E-Skilling for Management of Public Administration

Also, the executives must acquire competencies, qualifications, and capabilities on e-government. First, they are requested to enhance their media competence and align it with the new need. They must be able to handle new programs, specific applications, group ware services, and database systems. Second, they must understand the applications and functionalities to an extent enabling them to take decisions on the resource allocation and task distribution in their work area—even if they do not personally use these applications and functionalities.

Third, the executives will have to control on their own the restructuring of the information and knowledge management inevitably resulting from the introduction of communal e-government.

The competencies specifically required by the introduction of e-government also include the application of control techniques: both in terms of an in-depth understanding of project management and business tools of controlling, the evaluation and success control. Particularly required in times of changes is the ability to motivate

the staff and build teams. Executives need leadership competence also to steer change processes in large-scale projects and for change management. Last but not least, managers must recognise, convey, and consider in their action the significance of gender-specific vocational training.

The further training concept of Espoo (Finland) is exemplary under the aspect of the transfer of competencies and capabilities for e-government: "Top management in the city administration have been given training in the use of management support systems. In addition, they were due to attend e-management training for about 112 days in 2002. This training program was fairly comprehensive, divided into five major thematic areas:

- Introduction into digital environment and models
- Management of change and the utilisation of interaction and openness in the net
- Networking and strategic partnerships
- Provision of services and products in the net and management of customer relations (changing customers, CRM, learning from customers etc.)" (Anttiroiko, 2005, p. 46).

In times of change, the ability to motivate the employees and to organise team working is especially required. The competence to lead people and to control change processes in big projects as well as in overall change management is needed. The council of the Finnish town of Tampere has passed a comprehensive training concept for public managers that focuses on computer skills as well as on management skills. The description of the major topics of activities underlines the broad perspective on the e-skilling that is required for management. "Financial management (budgeting, costs, planning the income statement); partnerships, shares; risk management; human resource management: how to manage information, the role of incentives and motivation, policy of wages and salaries, labour relations: labour relation laws, system of collective agreements, local contracts, and negotiations." (http://www.tampere.fi)

## Skilling for Companies

The first—and doubtlessly reasonable—question is why public administration should invest into further training for private companies at all.

To facilitate and support further training for private companies is a need especially in the case of small and medium-size companies. Only using state offers these actors can take full profit out of e-government services. Take-up of e-services or the building of virtual cooperation networks by using e-government technology is underdeveloped among small firms in handcraft as well as in the service sector. These potential users are systematically disadvantaged in terms of market observation, market entry, and defending their market position but are not able to reap the potentials given by e-government to address just these issues.

Therefore, public bodies and authorities should present wherever they can—as in the case of schools, libraries, and adult training facilities—measures for further training. So, it is possible to simplify the technical processes of access and of usage of e-services and adapt the content of e-skilling to the special needs of this group.

The so-called "power users" defined as users with frequent online contact are expected to have little problems with medial competencies to use e-government services. In the professions like freelancers in the tax sector, in the legal sector or in retailing online contacts with public administration have become quite normal.

## Skilling for Politicians

Politicians and especially parliamentarians and—on the local level—councillors must be enabled to take well-founded strategic decisions on e-government and use applications on their own.

Qualification measures must first aim at giving the parliamentarians and councillors a comprehensive overview of the e-government project, its opportunities and risks, prerequisites and general conditions. In their role as users, the parliamentarians and councillors must be instructed in enhanced Office systems, council information systems, knowledge management system etc.

In the use of Internet to improve the work of politicians Estonia has achieved a level that is unique worldwide. Since August 2000, the meetings of the cabinet have been carried out with the help of the Internet. One result is that the files are prepared more focused and another result is that cabinet members that in the past could not take in the government meetings because of their absence can now be involved due to the linking up via Internet. Tallo observes that "in the cabinet room you won't find any paper—but instead a LCD for each minister" (p. 46).

## Managing the Digital Divide by E-Skilling

Motivating and qualifying the citizens and private economic players are important tasks to make them familiar with e-government. These groups may not be excluded from the acquisition of the relevant knowledge. This, on the one hand, is a political task, as the digital divide must be put into a perspective. On the other hand, the investments in e-government must pay off, which requires a

wide participation of a large share of the population (or in other words: achieving economies of scale in e-government assumes a high number of users).

Citizens and private economic players should acquire the competencies needed to use applications in e-government, above all media competence. In recreational facilities with supported PCs, homes for the aged, youth clubs, housewife clubs, immigrants' hangouts, culture clubs, schools, adult education centres, and libraries, the public administration has the opportunity to exert direct influence on contents, human and financial resources.

In Liverpool (UK), resources are made available for learning in education facilities, at publicly accessible places, and online.

*The three city learning centres in Liverpool are a key element of the Excellence in Cities initiative and have a major impact on learning in city schools by providing a focus for the very best in education for young people. They provide outstanding local facilities, which are improving education standards and skill levels, so promoting employment opportunities and enabling the social inclusion agenda. The centres are linked into the community grids for learning and give students low cost online access and central learning resources, from home, from libraries and from other public access points.* (http://www.idea-knowledge.gov.uk)

When implementing education for citizens, there are no limits to imagination. In Okoyama, Japan, former teachers are mobilised as "information volunteers" for IT education:

*The information volunteers are the lecturers for the IT class for the citizens and/or support the citizens' IT use. With the collaboration of the private sector, educational institutions and welfare organs, the information volunteers are publicly recruited at the earliest possible date among the retired ex-public officers, ex-private company employees, and from other relevant institutions.* (Fujita, 2005, p. 226)

In Tameside, UK, different population groups are specifically addressed in a systematic qualification concept:

*There is a commitment that all citizens of Tameside who want to work should be qualified to the European Computer Driving Licence standard: as a part of this initiative a junior version of this qualification is being implemented in primary schools. Additional funding has been secured to develop the Tameside passport to learning; an Internet-based individual portal that will provide a managed learning environment to take people from basic skills through to further and higher education.* (Ferguson, 2005, p. 179)

The problem that some classes of population with a low level of education cannot be activated to visit measures for further education is addressed by the innovative organisation concept of the Internet bus. In Tampere, Finland, the Internet bus offers non-mobile population groups the possibility to use the Internet, e-government applications, and further education:

*The city has provided extra resources for training providers. From the city's point of view, the special target groups are senior citizens, minorities, inhabitants of suburbs and children, whose teaching in computer skills have been increased in schools. The city itself has contributed to this area by the Internet bus called Netti-Nysse. It can be booked free of charge for any group wishing to learn to use the computer and to utilise the Internet. The bus itself has two parts: in the front, there is a computer room with 11 computers with the mobile and W-LAN connection to Internet, and in the back, there is small auditorium with a data projector, screen, and comfortable chairs.* (Anttiroiko, 2005, p. 48)

A similar solution is followed also in Liverpool, UK: "LCC [Liverpool County Council] launched an ICT bus in May 2002 to deliver ICT taster sessions across the city. The bus has full Internet access through wireless connectivity. The idea behind the project is to provide access to IT systems and the Internet and wherever access to services may be deemed difficult, or where there are large numbers of Liverpool residents. The bus is visiting places such as shopping centres, residential homes, schools, and institutions." (http://www.idea-knowledge.gov.uk3).

## INNOVATIVE METHODS FOR INNOVATIVE ADMINISTRATION

In the people development trainings, the whole set of state-of-the-art methods and instruments should be used, including e-learning, the self-directed learning handled in tele-operation via standardised learning programs. In an e-government strategy, "classic" and new methods are integrated in the "blended learning" concept.

When selecting the methods for further training the guideline must be according to the actual discussion in didactics: it is not about results but about initiating activities and processes. Only as part of a mixture of methods it is acceptable to have the classroom-based delivery and the classic tuition from the front. Learning, instead, has to be implemented as an inherent part of the everyday activity on the job. To achieve that an environ-

ment that fosters learning has to be set up characterised by learning with the task, acceptance of trial and error, failure tolerance and the application of mentors or tutors.

Organisational measures also make sure that learning is not perceived or misunderstood as something that distracts from "actual" work, as boring or luxury. In the face of tight budgets, learning on the job—being more cost-convenient than classic seminar classes—has good realisation chances.

To jointly clarify questions and issues of general interest, a "time-out" of five to ten minutes can be planned. With regular quality and training circles of only ten minutes per day in the core time, continuous learning can be easily integrated into every-day work. With graphical illustrations, for example, on the relationship between difficulties encountered and solutions developed over a specific period of time, progress in problem solving can be made clear.

Hardware and software, learning environment, trainers' team, training methods, and learning atmosphere must be co-ordinated and updated. Devices and programs used in training measures should by no means be technically outdated. When selecting trainers, it should be made sure that they have practical experience with the use of hardware and software in work environments, in addition to theoretical knowledge.

A gender-specific learning environment must be created: women "learn differently"; the specific conditions relevant for many women, such as childcare and part-time activity, must be addressed.

With growing levels of online usage at the desktop and at access points in libraries and learning resource centres, e-learning can increase access to end-user ICT training, whether for a formal qualification such as the European Computer Driving License (ECDL) or for new systems training like CRM (customer resource management). Many high street banks for example have begun to provide e-learning on their Web sites to educate customers on their services.

E-learning covers a broad set of applications including online training and education (e.g., Internet and Intranet), computer-based training including CD-Rom and digital collaboration. It can provide major benefits to public administration at a time when the need is greatest. E-learning can underpin rapid transformational change by quickly delivering targeted training and consistent messages right across an organisation in a way that gets into peoples heads.

## FUTURE TRENDS

From the analysis it comes quite clear what the future trends are. Firstly, the front-loading approach, for example, the learning once for all in primary school or in academic institutions, belongs doubtlessly to the past. Who does not get into constant learning will get keep on the running in terms of the skills and competencies needed to be an asked-for employee. Secondly, e-learning will expand and gain in importance compared to the traditional learning method. Blended learning is not only a fashionable expression but the appropriate description of the approach that is needed to keep up with the growing demand for learning.

What is not so clear are two other points. The first is if the digital divide as the gap between those that can and will work with the computer and have the abilities to make full profit also from e-government can be relativised. The second is if in training concepts for e-government the whole range of aspects and themes especially dealing with the comprehensive claim of e-government will be considered in the future. The risk is that as before skilling sticks to the traditional understanding of learning in IT as learning how to use new software.

## CONCLUSION

Theoretical considerations make clear that e-skilling is essential in order to make e-government a success. E-government as a comprehensive modernisation concept for local, regional, and central administrations is likely to change structures, habits, and living patterns profoundly. For those who want to take part in it and want to play an active role in the change process the training in new skills and new competencies is essential. And for those who continue to be reactive or tend to exclude themselves from the new area of living it is the state's task to avoid digital divide and make sure that no major group of the population stays out of the circle.

Empirical evidence that has been laid out widely in this contribution proves that e-skilling works as long as decision-makers in public administration are led by the broad perspective on e-government. Examples from the most advanced countries such as Finland and United Kingdom are likely to get into the process of exploring innovative methods and measures. E-skilling is a success factor for the implementation of e-government as long as it is conceptualized systematically and with a spirit of engagement. Money is not necessarily a hindering factor to organise a systematic e-skilling process. In Estonia, the KOOK@World foundation established by Estonian companies "trained over two years more than 100,000 Estonian people in the use of PC and Internet. That equals more than ten percent of the adult population. As a consequence, the Internet penetration increased significantly." (Tallo, 2004, p. 46)

## KEY TERMS

**Blended Learning:** Means the combination of learning in class (in a personal contact) and of learning assisted by a tele-coach (online over the Net) (e.g., in self-learning centres). "Blended Learning" includes assisted learning, a pedagogic-didactic approach, ensuring an environment that nurtures learning, mentoring, and mitigates the threat of self-isolation.

**ECDL:** The European Computer Driver's License certifies to a user that he is in possession of basic skills to work with the computer that every employee in Europe needs. The ECDL is an initiative of the Council of European Professional Informatics Societies (CEPIS ) in cooperation with the European Union (EU). The activity is organised internationally by the ECDL foundation in Dublin (Ireland). Since the European Driver's Licence is a certificate that is accepted all over Europe, only

authorised training institutions are allowed to carry out the ECDL examines.

**Media Skills:** Stands for a) technical-practical capability and b) skill, including critical refection on benefits and limits of technology (systems).

**Personal Skills:** Comprehend the ability to establish and maintain working relationships in the professional arena, develop as individual, co-operate with others, and lead as manager.

**Social Skills:** The ability to understand and shape one's own social environment.

## ENDNOTES

1 "The collapse of ideology no longer allows governments to use stock ideological responses to society's problems. Instead, governments should learn to mange flows of present and past perceptions" (OECD, 2000, p. 36).

2 "There is growing discomfort with existing arrangements of government. Citizens demand greater democracy and transparency. Communities seek more autonomy. Business leaders point an accusing finger at the lazy pace of governments. Interest groups are prodigious in showing displeasure with the way governments resolve their disputes and issues. The media are eager to report dissent and nurture mistrust. Lack of effective governance ranks high on the list of major societal concerns" (Carnoeiro, 2000, p. 93).

# Social Critiques of Electronic Voting

**Andrew Ó Baoill**
*University of Illinois, USA*

## INTRODUCTION

The use of computers in the electoral process—to count punch-card ballots, or to maintain a register of voters—has been in place in many countries for some time. We now see many countries move to more thoroughly integrate computers into the voting experience, by introducing what are commonly known as "electronic voting" systems. The use of such systems in public elections combined with the role of voting in creating and maintaining democratic institutions requires that we pay attention to the impact that changes to the electoral process have on the construction of the public nature of elections.

## BACKGROUND

The essential characteristic of an electronic voting system, as discussed here, is that voting takes place through the use of a computer or specialized electronic interface—commonly called direct recording electronic (DRE) equipment. Such systems usually also collate votes and calculate results through electronic means, but this latter characteristic is shared with other systems not considered here (Cranor, 2001). In restricting ourselves to systems with an electronic interface, it is important to note essential differences between electronic voting in polling stations, voting in kiosks, and remote Internet-enabled voting where voters can vote from any Internet-enabled computer (Chen, Roberts, & Gibson, 2002). Although all three forms constitute electronic voting and introduce computing technologies to the voting process, they have quite different impacts.

Media attention to electronic voting often focuses on system failures, and expert-driven critiques of the technical shortcoming of the various systems, such as the need for a voter verified audit trail (VVAT). Social critiques, if considered at all, are often relegated to anecdotal accounts of the ease of use (or lack thereof) of the system. However, much of the rationale put forward for the transition to electronic voting presumes a social critique, such as arguing that "the practice of voting … has not kept pace with social and economic change" (Pratchett, 2002, p. 4). It behooves us, then, to interrogate the social impacts of electronic voting, given particularly the centrality of voting to our social and political structures. In doing so we focus on three main aspects. First, we examine general social critiques of technological development and the implications of these for discourse around electronic voting. Second, we examine the impact of electronic voting on the public nature of elections. Third, we examine issues of usability and participation. There is, necessarily, overlap between these various areas–both questions of public space and usability can be understood to turn on the issue of accessibility and inclusivity–but these headings provide a convenient point of departure for a consideration of the questions to be addressed.

## EXPERTIZATION AND TECHNOCENTRIC DEBATE

Much analysis of electronic voting stems from a neutral conception of technology, divorced from any consideration of the cultural context of technology's production or consumption. Linked to this is a belief that any problems with the implementation of a technology are technical in nature, and can be addressed by technical fixes. This frame can be used, for example, to explain debate over the need for—and means of implementing—a voter verified audit trail in electronic voting systems. Alternative approaches arise from those who view technology as existing primarily within a cultural framework. Kling, for instance, challenges the "tool" metaphor, arguing (1996, p. 20) that "part of what is required … is a willingness to examine computer issues as part of a larger socio-technical system, not just as a component." For such theorists an exclusive concentration on, for example, cryptography, or questions in computer science has at least three troubling aspects. First, it ignores issues that cannot necessarily be considered within a technological frame, such as the nature of the public-private divide or the interplay of technology and culture. Such issues form the basis of the remaining sections of this article.

Second, a neutral conception of technology is tied to a view that newer, more "high-tech" solutions are somehow necessarily better, by virtue of their novelty and innovation. Such an approach doesn't accommodate a belief that a technology may be "sufficiently advanced" or that technological innovation is not synonymous with

progress. One report, for instance, chides voting processes (Pratchett, 2002, p. 4) explicitly for having "changed very little in over 100 years." Illich has criticized the cycle of obsolescence that emerges in a society where:

*Periodic innovations in goods or tools foster the belief that anything new will be proven better….The "better" replaces the "good" as the fundamental normative concept.* (Illich, 1973, p. 74-75)

Illich is wary of a situation where "a few corporate centers of decision-making impose compulsory innovation on the entire society" (1973, p. 73) and concerned with the manner in which a certain form of technology gains what he calls a "radical monopoly" over the accepted range of approaches to social innovation. Efficiency and speed, modernization, an image as a technologically advanced society: all become aims in themselves, irrespective of whether they are needed to address identified problems. A more techno-skeptic approach would prompt greater scrutiny of, and skepticism about, the rationale for introducing electronic voting, asking, for instance, whether its introduction is focused on a necessary change, or whether it is the most effective solution to identified problems with the existing system. To what extent might electronic voting circumscribe or influence the possibility of future choices, such as–to take a topical issue in the U.S.—the introduction of instant run-off voting?

Third, full engagement with the issues raised within a technocratic framework frequently requires a level of expertise and knowledge that serves to exclude most people from discussion concerning matters of great public importance. In a similar vein, Mercuri notes in relation to electronic voting that:

*Electronic balloting and tabulation makes the tasks performed by poll workers, challengers, and election officials purely procedural, and removes any opportunity to perform bipartisan checks. Any computerized election process is thus entrusted to the small group of individuals who program, construct, and maintain the machines.* (Mercuri, 2001)

## PUBLIC-PRIVATE DIVIDE

Apart from the purely functional matter of electing officials, elections are seen by some to act as a legitimating ritual (Hoffman, 2000; Oostveen & van den Besselaar, 2004), serving as a symbolic process that both acknowledges and, in doing so, creates the "public." One can usefully ask how adoption of electronic voting—particularly Internet voting—might affect the significance of voting as "a symbol which unite [sic] people in a common commitment toward democracy" (Monnoyer-Smith & Maigret, 2002, p. 283). There seem to be two related issues at play in such a critique. First, by removing the solemn, and sometimes arcane, aspects of the ritual of voting we risk obliterating the cultural markers that identify an election as an important social act. Some observers (Schaffer, 2002) go so far as to suggest that moves designed to "clean up" elections may, perversely, be linked to disenfranchisement and demobilization. Second, voting becomes increasingly refigured as an individual act. Barber already criticizes the existing system of secret voting in representative democracies:

*Our primary electoral act, voting, is rather like using a public toilet: we wait in line with a crowd in order to close ourselves up in a small compartment where we can relieve ourselves in solitude and in privacy of our burden, pull a lever, and then, yielding to the next in line, go silently home.* (Barber, 1984, p. 188)

With Internet voting we do not even need to attend a public place, thus reducing even further the social nature of the act of voting. However, this is also true with absentee or postal ballots, and so this criticism, as leveled at Internet voting, is perhaps best understood as one of remote voting generally. Barber's dislike of the secret ballot is, it should be noted, somewhat unusual, but it does raise the question: why secret? The secret ballot was introduced to protect individual voters from coercion and manipulation, and to prevent vote selling. Remote voting, in which oversight by election officials is absent, and where it cannot be assumed that voters will be free from intimidation or observation, removes these protections. Thus there are concerns (Oostveen & van den Besselaar, 2004, p. 6) that "with remote voting…family members, colleagues, or employers may try to influence the voter's decision…Internet voting is expected to substantially increase the scale of these problems."

For Jürgen Habermas elections and similar systems are the necessary but fallible "legal institutionalization of the general conditions of communication for a discursive formation of will" (1992, p. 450)—necessary because in practice we need some means to move from debate to action, fallible because of temporal and other constraints under which voting occurs. Systems put in place for holding elections should encourage the discursive, reflective formation of opinion by individuals, rather than an "unpolitical follower mentality" (Habermas, 1992, p. 450) where people act only for their own personal short-term preferences. In this context, processes that make voting more convenient for individuals, but which diminish the social, deliberative and discursive elements of the electoral process are doing both the voter and society a

disservice. Given the limited amount of discourse occurring under contemporary systems, as described by Barber, it is legitimate to ask whether electronic voting will actually have a significant negative impact in this regard. Consider the limited communication undertaken by political activists outside polling stations in many jurisdictions. Does this qualify as discourse that is no longer possible with remote voting, or is it purely ritual? Would Internet voting encourage voters to be more reflective, searching out information on candidates as they vote, or encourage them to view voting as no different from buying an item online? A further question, that of public access to source code for software used in electronic voting systems has also been raised, entangling the electoral system in debates over open source software, free software, and the privatization of core public services (Commission on Electronic Voting, 2004; Ó Baoill, 2004).

## USABILITY AND PARTICIPATION

The introduction of electronic voting has often been enthusiastically received by disability advocate groups, in part because such systems often include features that enable blind voters to cast their vote in private, without assistance from a third party—something that is not generally possible with older manual systems—and other features that improve the ability of voters with disabilities to participate in the electoral process. As a result of the newfound equality of access these systems provide, advocacy groups have also sometimes opposed the addition of VVAT functionality to DREs, as the paper record generally returns blind voters to requiring an intermediary to participate in the voting process. It should be noted that not all electronic voting systems include features that facilitate use by blind voters, something that can in turn lead disability advocacy groups to withhold support (Commission on Electronic Voting, 2004).

Others support electronic voting on the basis that it can reduce or eliminate the unintentional casting of invalid votes by individuals. In certain cases, however, public debate has highlighted dissatisfaction with systems that also disrupt the possibility of intentionally casting a blank or invalid vote (a "spoilt" vote). In Ireland, debate on the planned introduction of a DRE system led to public outcry at the seeming removal of the ability to cast a spoilt vote (Commission on Electronic Voting, 2004; Ó Baoill, 2004). It is accepted that most spoilt votes result from inadvertent error. However, the debate in Ireland resurrected attention (Ó Baoill, 2004) to a "case [in which] a puppet character is reputed to have "secured" more ballot papers in Tallaght (a large suburb of Dublin) than one of the three candidates during the national Presidential election in 1990" something viewed as indicative of social discontent in that area. Can an intentional "spoilt" vote be a valid social statement? Debates such as this show that voters and "pollsters"—those "in charge of collecting and elaborating the poll results, or…otherwise involved in voting systems and processes"—often "have different expectations of how a polling system should perform" (Oostveen & van den Besselaar, 2004, p. 7). This highlights the importance of research such as that of Oostveen and van den Besselaar, where voters are asked to articulate what they believe to be the important issues arising from electronic voting.

The issue of computer proficiency also arises, with some professing concern that "the voter population will include people with little or no computer experience" (Larsen, 1999, p. 57). Given the heterogeneous target user group—comprising all those eligible to vote–any existing "digital divide" across race, gender, or other, lines offers potential for a distortion of participation rates and subsequent results (Oostveen & van den Besselaar, 2004). Some proponents hope to mitigate any negative impact of this through the use of multi-channel delivery with remote voting possible through mobile phones, digital television, and other interfaces, while maintaining the option of voting in a polling station for "the foreseeable future" (Pratchett, 2002). The Indian DRE system is frequently cited (Commission on Electronic Voting, 2004, p. 316; Gill, 2001) as being successful despite large numbers of voters who are illiterate or have little or no computing experience, though some argue (Mercuri & Camp, 2004) that the system "made it easier for partisan operatives to commandeer and control entire polling booths." Mercuri addresses some specific issues that arise in the case of remote Internet voting:

> *Off-site Internet voting creates unresolvable problems with authentication, leading to possible loss of voter privacy, vote-selling, and coercion. Furthermore, this form of voting does not provide equal access for convenient balloting by all citizens, especially the poor, those in rural areas not well served by Internet service providers, the elderly, and certain disabled populations. For these reasons, off-site Internet voting systems should not be used for any government election.* (Mercuri, 2001)

To approach the issue another way, and using the case of one vulnerable social group for whom electronic voting might have an impact—those with learning disabilities–careful design may, for example, reduce the risk of inadvertently spoilt ballots, a tangible benefit, though electronic voting cannot be expected to be a cure-all (Bell, McKay, & Phillips, 2001) since barriers to voting for this group go beyond what might be addressed by

electronic voting. In addition, *remote* voting might facilitate voting by this group, but would also remove the protection from coercion that a polling station provides.

It is important also to ask whether it is possible to examine usability divorced from more general societal questions of equity and cultural diversity. To the extent that usability can be usefully addressed, we must also ask what the practical impact of improved usability might be. Some governments, for instance, have seen electronic voting and remote voting as means to address falling participation rates (DETR, 1998, Wilson, 1999). However there are conflicting reports regarding the impact of such approaches, from estimations of "relatively insignificant" impact (Mercuri, 2002) to "indications [of] higher voter participation" (Chen et al., 2002). Done (2002) examines a 2000 presidential preference election in Arizona in which remote Internet voting was available and finds a significantly higher rate of participation than the previous (1996) election. The increase in remote paper voting was, however, almost as much as the number who used remote Internet voting and Done acknowledges that the increase resulted from a "combination of outreach, legal argument, process, and technology" (2002, p. 8). Overall the research available indicates that "e-voting on its own is unlikely to stimulate greater levels of democratic engagement" (Pratchett, 2002, p. 8) with at least one study finding postal ballots to have a significantly greater impact than remote Internet voting (Norris, 2003). Also significant—particularly in light of our earlier discussion of the social ritual conception of elections—is the claim (Internet Policy Institute, 2001, p. 24) that "previous reforms designed to make voting more convenient … have had very little if any impact on turnout levels and virtually none on the composition of the electorate."

While convenience and increased usability can benefit specific user groups such as the blind or those with learning difficulties as discussed above, they do not appear to have an impact on general issues of voter engagement and involvement. Hoffman asks whether the increased convenience of Internet voting would "outweigh the possible further erosion of the "civic ritual" of physically casting your vote at your local polling place" (2000, p. 221), bringing us back to our earlier discussion of the public nature of voting and forcing us to consider how to balance benefits for particular groups against losses for the overall population.

It has also been suggested that remote voting might have an impact on voter behavior other than merely on participation rates (Oostveen & van den Besselaar, 2003), and some work has been done on tools to measure this impact (Hammer & Traugott, 2004). Internet voting could have a significant impact; Hoffman (2000), for instance, draws attention to the "disintermediating" function of the Internet, which could effectively erase the current delay between receiving information and acting on it by voting. While some have seen benefits for, for instance, smaller political parties, in integrating an information portal or "lobby space" into a remote voting interface (Chen et al., 2002), Hoffman clearly worries that such developments might reduce reflection, inducing more knee-jerk reactions, and endangering both the deliberative and representative nature of current democratic systems. One's personal approach to these questions must inevitably be informed by one's own conception of the role and function of democracy (Barber, 1984). However, researchers such as Norris show (2003) that acceptance of the benefits of the Internet for the campaign process need not require that one support the use of computers or the Internet in the voting process.

## FUTURE TRENDS

The theoretical questions that have been raised, and the evidence to date, suggest that there is plenty of room for fruitful debates in this area. More research is needed on the impact on turnout of various innovations—including changes in technology and changes in the location of voting (kiosk voting, remote voting). Such research should attempt to identify the relative contribution of different factors—distinguishing, for example, the impact of remote voting in general from that of Internet voting—and be awake to the various demographic components that may further influence (changes in) participation rates. Given the attention paid to the purported ease of use of DREs and Internet voting there is also space for comparative, systematic research on the relative usability of various systems (Caltech/MIT Voting Technology Project, 2001, p. 72), which will, of course, depend in turn on factors such as the electoral system in use and cultural and social settings.

Further, there have been calls (Hammer & Traugott, 2004) for researchers to identify impacts other than simply the "top line" one of participation. Does electronic voting have an impact on voter behavior—such as participation in "second tier" ballots? What impact might changed usability for vulnerable groups—either improved, for the blind, or declining, in the case of the computer illiterate—have not only on results, but also on the electoral process and the greater political environment? What impacts do DREs and remote Internet voting systems have on the potential for discourse in and around the voting process–what opportunities are gained, what lost? The unique role of elections also suggests that this area would provide particularly interesting material for examinations of free and open-source software—with issues of privatization, commercialization, intellectual property, security of a

crucial application, and expertization all arising in this single case.

## CONCLUSION

The political momentum behind the introduction of electronic voting has often been strong, often driven by a sense that existing systems are anachronistic and inappropriate for our current society, or by a belief that electronic voting will provide an improved usability that will combat apathy and declining participation rates. Social research in the area would indicate that, as Norris notes, "technological quick fixes, while superficially attractive, cannot solve long-term and deep-rooted civic ills" (2003, p. 10). Rather, we should ensure that changes to these important systems are made in light of a holistic consideration of social and cultural effects.

## KEY TERMS

**Electronic Voting System:** A voting system in which voters record their votes by means of an electronic interface, or DRE.

**DRE (Direct Recording Electronic Voting) Device:** A piece of equipment that allows voters to record their vote directly into electronic form. It can thus be differentiated from systems in which voters record their votes in, for example, paper form, with the votes later being collated and counted using an electronic system.

**Kiosk Voting:** The concept that voting might be possible in public places that would not have the trappings of a full traditional polling station. This is often thought of as being enabled by Internet voting, and might supplement, or be a transitional step to, remote Internet-enabled voting.

**Remote Internet-Enabled Voting:** Remote voting system in which the voter casts their vote on an Internet-enabled computer, which in turn transmits the vote over the Internet to a central server. Such a system might use a secure website or a specialized software application on the voter's computer.

**Remote Voting:** The situation where a voter need not attend a special venue, such as a polling station, in order to vote. Examples include postal ballots, remote Internet-enabled voting, and voting using alternative channels such as mobile phone messaging services.

**Voter Verified Audit Trail (VVAT):** A generally paper-based system run parallel to an electronic voting system that provides an independent record of the votes cast. One such system would involve a paper ballot being printed after the voter casts a ballot on the electronic system, allowing the voter to accept (verify) or reject that paper record.

## INTRODUCTION

Building any online system or service that people will trust is a significant challenge. For example, consumers sometimes avoid e-commerce services over fears about their security and privacy. As a result, much research has been done to determine factors that affect users' trust of e-commerce services (e.g., Egger, 2001; Friedman, Khan, & Howe, 2000; Riegelsberger & Sasse, 2001). Building trustable e-government services, however, presents a significantly greater challenge than e-commerce services for a number of reasons. First, government services are often covered by privacy protection legislation that may not apply to commercial services, so they will be subject to a higher level of scrutiny. Second, the nature of the information involved in an e-government transaction may be more sensitive than the information involved in a commercial transaction (Adams, 1999). Third, the nature of the information receiver is different in an e-government context (Adams, 1999). Some personal information, such as supermarket spending habits, might be relatively benign in an e-commerce situation, such as a loyalty program (supermarket points, or Air Miles, for instance), but other information such as medical records would be considered very sensitive if shared amongst all government agencies. Fourth, the consequences of a breach of privacy may be much larger in an e-government context, where, for example, premature release of economic data might have a profound effect on stock markets, affecting millions of investors (National Research Council, 2002).

E-government services also involve significant privacy and security challenges because the traditional trade-offs of risks and costs cannot be applied as they can in business. In business contexts it is usually impossible to reduce the risks, for example of unauthorized access to information, or loss of or corruption of personal information, to zero and managers often have to trade-off acceptable risks against increasing costs. In the e-government context, because of the nature of the information and the high publicity, no violations of security or privacy can be considered acceptable (National Research Council, 2002). Although zero risk may be impossible to achieve, it is vital to target this ideal in an e-government service. In addition, government departments are often the major source of materials used to identify and authenticate individuals. Identification documents such as driver's licenses and passports are issued by government agencies, so any breach in the security of these agencies can lead to significant problems. Identity theft is a growing problem worldwide, and e-government services that issue identification documents must be especially vigilant to protect against identity theft (National Research Council, 2002). Another significant challenge for e-government systems is protecting the privacy of individuals who traditionally have maintained multiple identities when interacting with the government (National Research Council, 2002). Today, a driver's license is used when operating an automobile, a tax account number is used during financial transactions, while a government health card is used when seeking health services. With the implementation and use of e-government services it becomes possible to match these separate identities in a manner that was not being done before, and this could lead to new privacy concerns.

## BACKGROUND

Trust is a cognitive process and behavior that people use every day to make decisions, reassure themselves, judge information, confer authority, take or assign responsibility under uncertainty, and simply to get out of bed in the morning (Luhmann, 1979). It's one of the building blocks of society (Bok, 1978; Misztal, 1996) and it is necessary for effective day-to-day cooperation. It is worth noting that the decline (or otherwise) of public trust in government is not necessarily universal, and is a phenomenon worth much further study. That said, trust in some governments has been studied extensively, particularly with regards to

the decline of trust in public institutions (for example, see Thomas, 1998; Uslaner, 2001), as well as the apparent increase in trust in government in the U.S. post-September 11th (Chanley, 2002). As well, the link between political and social trust has been extensively studied (see for example, Newton, 2001).

Recently, as evidenced by this volume, there has been an upsurge in bringing government closer to the people by making services, ideas, decision makers, and procedures available to people using information and communication technologies (ICTs). One of the laudable ideals of this work is that, by increasing citizen participation in government, the crisis of confidence (trust) can be answered and to some extent reversed. That is, if citizens have more of a say in running their country than an election every few years, they will feel more connected with government, and thus trust it more (e.g., Advisory Committee to the Congressional Internet Caucus, 2001). Trust is a multidimensional concept and addressing it completely would result in a book on its own. Here we will introduce trust issues in digital government by briefly defining what trust actually is, both in terms of social trust and trust in the digital sphere, then what digital government projects can do that address trust issues, pointing out some of the pitfalls and problems associated with the work.

## DEFINING TRUST

Trust, although not always a mainstream research topic (Misztal, 1996), has in recent years become much more fashionable. Ironically, this is in large part due to the influence of the online world, where in the late 1990's the Internet boom resulted in a need to understand how trust worked in online situations, so that people would ultimately spend more money (for excellent examples of studies in this area, see Cheskin, 1999, 2000). Fortunately, the later dot-com bust did not significantly reduce this need to understand trust, and developments in the area have led to better experiences for people using Web systems, better designed interfaces, and an increased level of sophistication of both information providers and information users.

While there is an *interest* in trust, there remain almost as many definitions as there are researchers in the area. It may not be necessary to have a precise definition if we can agree that trust exists (Bok, 1978; Misztal, 1996). Nevertheless, we have developed an operational definition of trust that is very useful (Marsh & Dibben, 2003, p. 470): "Trust concerns a positive expectation regarding the behavior of somebody or something in a situation that entails risk to the trusting party."

*Table 1. The layers of trust*

| Trust Layer | Description |
|---|---|
| Dispositional (Basic) | The basic disposition of a person to be trusting or not (and how trusting) |
| Learned (General) | A person's general tendency to trust, or not to trust, as a result of experience. Based on dispositional trust |
| Situational (Contextual) | A person's trusting judgment in a specific context or situation, based on dispositional and learned trust |

The important points are that there is a judgment involved, as positive expectation, that there is free will on both sides to behave in certain ways, and that there is an element of risk.

Our work has also led us to describe trust as a *layered* phenomenon (Marsh, 1994; Marsh & Dibben, 2003). The different layers of trust (see Table 1) are utilized in different ways and together determine how trust will be used in particular situations. For example, in an unfamiliar situation, dispositional trust is of the greatest importance because no experiences are available to the trustor. In a familiar situation, people can rely on past experiences to make a learned judgment. And in a specific situation encountered before, trustors can make situational decisions that are specific to the context. Clearly, the more information available the better, although ironically, complete information by definition removes the need to rely on trust.

In the digital world, trust is both the same as it is in traditional face-to-face interactions, and it is different. Whereas people may be quite adept at assessing the likely behavior of other people and the risks involved in the physical, face-to-face world, they may be less skilled when making judgments in online environments. For example, people may be too trusting online, perhaps routinely downloading software or having conversations in chat rooms without realizing the true behaviors of the other parties and the risks involved. People may also have too little trust in online situations, perhaps dogmatically avoiding e-commerce or e-government transactions in the belief that such actions cannot be done securely, at the cost of missed opportunities and added inconvenience. As with any new thing, there is a process of building knowledge and awareness, and it is the responsibility of governments to make sure that its digital persona is trustable and to a large extent inviolable from a security point of view.

## CHALLENGES

There are several trust challenges that must be addressed when designing and implementing interactions and tech-

nologies for digital government. As has already been noted, the level of trust that people have in the Internet and online technologies can be scarce and fragile. While digital government may have an advantage over other online services because of the mandatory nature of some digital government interactions, such as filing taxes (Warkentin, Gefen, Pavlou, & Rose, 2002), it still faces significant challenges. The following list summarizes some of the challenges and opportunities for digital government projects that are related to the nature and presence of trust.

## Understanding

There remains a lack of understanding of trust in the digital sphere, a lack of appreciation of the needs of e-government within government (it's not just a Web site), and a corresponding lack of understanding of the needs of government in the developers of digital government services. Huge strides have been made recently to overcome these hurdles, but a key recommendation in any digital government endeavor is to *fully understand the needs of all parties and fully appreciate potential goals and outcomes* (Fang, 2002; Marchionini & Levi, 2003; Pardo, 200l; Schorr & Stalfo, 1998; Warkentin et al., 2002).

## Responsibility

Increasing the responsibility of the citizen for taking part in the democratic and governmental process is potentially a very good way of enhancing their trust in that process. Government, however, has added responsibilities of its own, including timeliness, enhanced clarity, and efficiency in delivery. Thus, a key recommendation in this respect is to *make clear beforehand what is expected in any transaction or a continuing set of transactions by each party of the other* (Fang, 2002; van Gompel & Steyaert, 2002).

## Expectations

More than anything else, it is important that the expectations of citizens be managed and treated with care. Putting government services online does *not* necessarily mean citizens can video-conference with their representatives, but often, you'd be led to think so with the fanfare that surrounds government online services. As well, the younger citizens, those to whom such technologies can be more accessible, have their own expectations of performance and availability. What is key here is to *realize, communicate accurately and live up to the performance and behavior that is expected, and manage external expectations accordingly* (Allen, Juillt, Paquet, & Roy, 2001; Schorr & Stalfo, 1998).

## The Digital Divide

Not everyone owns a computer, and fewer have fast Internet access. This lack of access, through lack of availability or resources, is the quintessential digital divide. Thus, *it is unreasonable to assume everyone will be able to access digital services through a computer in the home or library*—there remains a danger that some citizens will become increasingly disenfranchised. Thus, digital government is not a 100% solution (Institute for Social Research, 2002; van Gompel & Steyaert, 2002).

## Security

The Internet is not always the safest place. Viruses, spam, spyware, and phishing are some of the many security risks to online citizens. Any and all of these have a direct and tangible effect on trust. As an example, consider the following: a citizen checks her e-mail and has a message from the government requesting that she confirm your tax details. She follows the link and goes online to file her taxes, fills in the necessary fields, including identification number, address, pension details, and so on, and submits the form. But the site is a fake and her details, her personal identity, is now lost. The effect on trust could be massive, and just because it's not the government's fault won't make it any better. The utmost care is needed to manage this trust so that citizens are protected, and feel protected. Part of this is in the communications, thus, *citizens should be kept informed, up to date and aware of their rights, responsibilities, and risks when interacting online with a government, and governments should manage (and be seen to manage) their online security with the utmost care* (Joshi, Ghafoor, Aref, & Spafford, 2001; Medjahed, Rezgui, Bouguettaya, & Ouzzani, 2003; Rezgui, Ouzzani, Bouguettaya, & Medjahed, 2002).

## Delivery Methods: Accessibility and Design

Some citizens have skipped the computer altogether and now use mobile PDAs and cell phones. Still others have fundamental interaction challenges such as blindness. These differences of accessibility are important and *trust can be built by providing for and opening services digitally to the differently abled.* Avoiding fancy interaction techniques that can get in the way of assistive technologies is mandated here. The final concern, while not so much a divide, is the capability of the device being used, which may well be the citizen's only access to digital government—screen size, memory, interaction means, and so on, are all important here. Thus, it is

imperative that *digital government technologies fully grasp and accommodate the differing means of accessing them* (Marchionini & Levi, 2003).

## SOLUTIONS

The issue of building trust has most often been studied for e-commerce transactions (e.g., Rielgelsberger & Sasse, 2001) but the lessons are also applicable to e-government. One of the most important factors for building trust in e-commerce is the visual design of the interface, and users often make rapid trust decisions based on a shallow analysis of the appearance of a Web site (Fogg, Marable, Stanford, & Tauber, 2002). A visual appearance that is clean, uses pleasing colors and graphics, is symmetrical (that is, balanced in appearance), and is professional looking is usually rated as more trustable. Other design factors that can build trust are the amount of information provided to the user, such as the information on how a system operates and the status of any processing. This transparency of operations can be particularly important for e-government systems because users may not understand the internal procedures and policies that are involved in a government service. Predictable performance can also be an important factor, with systems that respond rapidly and consistently instilling higher levels of trust.

The most important factors for determining the level of perceived risk in e-government transactions are the sensitivity of the information involved and the receiver of the information. As previously discussed, users will perceive situations to be more or less risky depending on the nature of the personal information that is involved and the eventual destination.

Halabi (2002) has recently summarized some simple design principles for e-government interfaces. The most important is usability, which is the ability to perform the necessary tasks with ease. If users cannot accomplish the tasks they set out to perform, the service will not be accepted or used. There are a number of usability test methods that can be used to assess problems in this area, and human factors researchers have developed a number of user-centered design techniques that can improve usability (e.g., Nielsen, 1993). Kossak, Essmayr, Winiwarter (2001) have illustrated how these techniques can be applied to e-government services.

The second factor is providing transparency through comprehensive information. For example, if an e-government service for paying parking tickets does not provide detailed information about how quickly the payments are processed, users may not trust it in fear that they will incur further penalties. A related factor is feedback and reassurance. The interface should ensure that users receive acknowledgement when information is received, and a capability to track the processing of requests or transactions will often reduce apprehension.

Another useful resource for building trustable e-government interfaces is the research results on Web site credibility. B. J. Fogg (2002) has summarized this research into a set of design guidelines that are very relevant to e-government services. Perhaps the most important is to make the site useful. This means providing the information and services that the users really want, rather than what the government wants to provide. In a sense, this can be thought of as government adopting something of a business model in its online provisions. A related principle is to make it usable, as was discussed above. A second principle is that the service should clearly identify itself as a legitimate organization, which means using the appropriate government logos and appearance. Third, the interface should show the real people behind the site, rather than providing a faceless corporate look. Although showing the names and faces of individuals may not be possible in a large government bureaucracy, putting some kind of human face on the interface will be important for building trust. A related design guideline is to make it easy to contact the service organization (e.g., by telephone or e-mail), and this is related to the flexible access design goal discussed above. Fogg's research also supports the importance of a professional look and feel, which includes layout, typography, colors, images, and consistency. The most colorful design is not always the most appropriate and it is important to match the visual design to the site's purpose. It is also important to avoid errors, including typographical errors and missing links. Even the smallest errors can decrease the credibility of a site. Finally, providing up-to-date and dynamic information that is clearly time-stamped is important for building trust and return visitors.

## FUTURE TRENDS

Not all is challenge, however. The opportunities provided by digital government are many, and this volume brings them to light. One of the interesting things about trust is that, once it is present, it can be leveraged in different directions. For example, once citizens trust the government with their information in one way, there may be a place for government to attempt to use the trust in other forms. Consider early warning systems for natural disasters—if government knew who of their citizens was in a threatened area, and had details as to how to contact them (exit scans of passports, cell phone/text messaging details, and so on), such systems could be enabled and save lives. However, the lack of trust that exists in government

today precludes such tools because citizens are not comfortable with the thought of their information being manipulated in this way. (It's worth pointing out here that privacy laws in various countries are not an indication that citizens trust their governments and industries, rather the opposite.) Trust can be won, and once won, leveraged, but it will take time. Digital government provides decision makers with excellent tools for building trust, such as accessible online interactions, timely information provision, and well thought-out service provision.

## CONCLUSION

Trust is a basic building block of human societies, and a scarce resource that must be nurtured and built over time. Trust will be crucial for the success of any e-government enterprise. But trust is also a resource that governments have less of now than ever before. Digital government, the provision of services and new modes of interaction by government for citizens, presents an opportunity to win back trust simply by increasing participation and familiarity with government. But if people do not trust a service, they will not use it. Worse, if they use it and are let down, they will be extremely hard to win back. Getting it right the first time is vitally important because second chances are scarce and costly.

## KEY TERMS

**Digital Divide:** The situation whereby those able to afford computers and associated equipment can have better services or experiences than those without.

**Human-Computer Interaction:** The study of how computer user interfaces can be designed to better accommodate (real) people.

**Identity Theft:** Where a person's personal details are gathered so as to enable another to impersonate them. Often achieved through non-technical means such as dumpster diving, but susceptible to phishing and other hack attacks such as spyware.

**Phishing:** Impersonation of a Website (usually an e-commerce site) with the purpose of stealing personal information (bank details, passwords, etc.) and then using them for fraudulent purposes.

**Security:** In computational terms, making computers and networks capable of withstanding attacks from within or outside.

**Spyware:** Small malicious programs downloaded onto personal computers that watch activities such as keystrokes and send details to others to allow fraudulent use (i.e., passwords).

# Strategic Importance of Security Standards

## INTRODUCTION

### E-Security and E-Privacy Issues

Even before September 11, 2001, security and privacy was a concern to nearly 80% of the current and potential Internet users around the globe, according to survey released by the Information Technology Association of America (ITAA) (Poulsen, 2000). The survey, commissioned by the American Express Company, randomly polled 11,410 people in 10 countries, and found that nearly half of the respondents enjoyed some form of Internet access. As might be expected, most of the world's Internet users utilize Internet for e-mail, browsing, and entertainment. However, fewer than 28% do some shopping online, and 24% use the Internet for banking and financial transactions. But when Internet users and nonusers of many countries were asked if they agree with the statement, "I am or would be concerned about security and privacy issues when purchasing or making financial transactions online," 79% agreed. Prior to the tragedy of September 11, 2001, U.S. citizens also expressed legitimate concerns toward the issues of privacy and security, with an 85% showing. The poll released by the Information Technology Association of America also illustrated that approximately 80% have doubts about the U.S. government's ability to maintain computer security and privacy. Hence, protecting operating systems is a major strategic concern if the success of e-government as a whole is to reach its potential. Although most of these issues are typically not discussed in relationship with e-government, the need for trusted computing systems within e-business and computing systems can be made as an effective argument that all these issues affect e-government systems as well. Secure computing systems issues in terms of e-government are just as important.

The scope of this article is to present a description of one the most generally known security certifications; namely, the trusted computer system evaluation (TCSEC) and its commercial implementation procedure in the commercial product evaluation process and discuss the influence of this evaluation/certification on the incidence of hacker attacks on e-business. As evident by the abundance of marketing literature of different operating systems for e-business that frequently refers to its security strength ranked against popular security certifications, it is very common to rank commercially available operating systems against TCSEC evaluation and/or certification criteria. This article will also explore where the many operating systems stands on this particular evaluation. In essence, given the vulnerabilities exposed after September 11, 2001, strategic security managers should be deeply concerned that the e-business platform they are responsible for contains the highest security standards to prevent any type of potentially harmful hacker attacks. Managers need to have a working knowledge of TCSEC security evaluation/certifications to become better informed when choosing the e-security platform for e-government/e-business.

Essentially, the selection of a particular operating system for e-government/e-business have as much to do with factors ranging from existing skills, existing infrastructure, and economic reasons all the way up to political and strategic reasons. In dealing strategically with modern e-business environments, one of the most important factors that management must consider when choosing an operating system for their e-business platform is the security strength to resist computer hacker attacks on the operating system. If, for example, during different hacker attacks, one of the major aspects of these attacks is a certain operating system, as opposed to other systems, then this is a clear message to management to build in proper safeguards in the proposed operating system (Smith & Rupp, 2002a, 2002b). Certainly some of the reasons for frequent hacker attacks may probabilistic in terms and not random events, since Linux and Windows operating systems are more frequently used for e-commerce than other systems. So, it is not surprising that there are practically few reports of successful hacker attacks against operating systems that run e-business platforms (Smith, 2005; Smith & Lias, 2005; Smith & Offodile, 2002).

### Strategic Imperative for Proper IT Management Practices

#### Renewed Focus on Security in the E-government Environment

According to Dunn (2001), computer crime incidents more than doubled in a single year, creating a virtual crime wave

across computer systems all over the world. For example, more than 21,000 incidents, up from nearly 10,000 in 1999, were reported in 2000 to Carnegie Mellon University's Software Engineering Institute—which tracks online criminal activity in the United States and provides assistance and advise to victims (CERT/CC statistics 1988-2001, 2001) (This is 5 years old, get the most recent data from the same site.). For example, in the first quarter, record numbers of more than 7000 incidents of cyber crime were posted. As of total incidents reported (1988-Q3 through 2001) has climbed to a record high of 82,465 (CERT/CC statistics 1988-2001, 2001) (Rewrite). The Internet Fraud Complaint Center (IFCC)–which was initially established by the FBI and the National White Collar Crime Center in May 2000, reported increasing amounts of Internet fraud as well (The Internet Fraud Complaint Center (IFCC), 2001). IFCC offers a central repository for complaints related to Internet fraud, works to quantify fraud patterns, and provides timely statistical data of current fraud trends. The Internet Fraud Complaint Center has reported a total of more than 20,000 complaints from its inception until early November 2000 (The Internet Fraud Complaint Center (IFCC), 2001) (Old data). Unfortunately, in addition to fraudulent transactions, cyber crime ranges from hacking to stealing credit card numbers and planting viruses (Dunn, 2001). The apparent need for strategic management information systems and its proper management to combat these recent and significant increases in cyber crime should be of high priority in the minds of e-government administrators.

Considering that humans cannot be in more than one place at a time, the need for software agents and its document security is on the rise. In order to conduct profitable transactions in the increasing number of electronic marketplaces, an individual user needs to keep tack of the ever-changing offer, demand, and price situations in a secure environment. An encouraging new way of fulfilling this strategy is with the use software agents that represent their human principals at the marketplace, having these agents conduct a whole business transaction in a satisfying way.

A software agent is a computer program which functions continuously and autonomously in an environment in which other processes take place, and other agents exist. In today's environment, agents are known as shopbots, but they are most widely used for information retrieval, while negotiations are not supported. If there is a market world existing without a centralized institution and a common goal, agents will be free to act fraudulently, or cheat in negotiation. In order to reduce the risks related to financial loss in the marketplace due to a fraudulent agent, a mechanism is needed to obtain earlier information concerning the agents' previous transactions- his reputation. The reputation of the agent can be described as good or bad based on the amount of document sharing and former transaction partners apply the rating. A good reputation means that the agent has kept commitments, and an agent having a bad reputation is expected to behave non-cooperatively, or not keep commitments.

The main aspects of a sound security framework, if open to all software agents would be: Authentication, privacy, and non-cooperation. In the occurrence of the authentication issue, the human owner of the agent may choose to mask their identity. In addition, the same person can utilize several different pseudonyms, which in turn may lead to the phantom bidder. Access to change pseudonyms frequently should be unavailable; thus allowing future partners a chance to gain reputation information. The privacy issue is the second area of concern in insecure networks like the Internet, even though confidential communications are subject to prior authentication. Lastly, software agents involved in the marketplace are free to behave in a non-cooperative way.

In order to limit the ability of agents to act irresponsibly, a prototype system called Avalanche was developed, implementing a private key that will digitally encrypt agent messages (Bagner, Evansburg, Watson, & Welch, 2003; Chen, Chen, Lin, 2003; Kang & Han, 2003). The developers believe that this will knock down the barriers that exist for new Internet-based business cooperation. With the help of Avalanche, the development of fast, flexible, and adaptive markets will extend beyond static catalog Web sites and closed auction communities, where transactions amongst unknown agents can create new market opportunities.

In order to take advantage of these new market opportunities, there are numerous research efforts suggesting the need for effective management practices for IT infrastructure and its successful applications. In particular, Ross, Beath, and Goodhue (1996) researched the objectives for successful strategic IT management practice and found the following practices: (1) Bottom aligning IT products and services with the firm's strategic objectives, (2) Delivering solutions faster, and (3) Providing high-quality, cost-effective measures. Ross, Beath, and Goodhue (1996) also found that the process of segregating support costs for non-standard technologies promoted IT-business unit communication that aided in the identification of outdated standards and established priorities for new standards (p. 34). They discovered that shared risk and responsibility are built on this shared communication and mutual respect through the interaction of people and associated IT assets.

In addition, Kossek and Ozeki (1998), make the insightful observation that "The need to develop a global perspective on human resource management has been part of the managerial landscape for well over a decade, but there is no consensus about what tools to use" (p. 2). Kossek

and Ozeki found through their research that there are at least three challenges facing global managers: (1) Deployment, (2) Knowledge and information dissemination, and (3) Identifying and developing talent on a global basis. These important relationship assets include business partner ownership of and accountability for all IT projects, as well as top management leadership in establishing IT priorities. These relationships, especially concerning types of automatic identification and data capture systems assets; also interact with both the human elements and the technology assets to form the IT-assets model proposed by Ross, Beath, and Goodhue (1996). Although these assets are distinct, they are mutually reinforcing. Although not every firm will choose to make IT a strategic asset and provide the proper level of protection, even though every firm that finds itself information-dependent will encounter situations in which competitors develop IT applications that become competitive necessities. IT applications that become competitive necessities are further demonstrated by research by Evans and Wurster (1997). Evans and Wurster have suggested that since current availability of large quantities of information has changed operating processes, company executives are being forced to re-think the strategic fundamentals of their businesses and their methods of competing in the marketplace.

Firms not directly involved in disseminating information through a product line are also directly involved with the economics of information, such as capturing, storing and processing information relative to their business during the process of designing, producing, marketing, delivering and supporting their products. In the process of disseminating this information to achieve strategic goals, as suggested by Evans and Wurster (1997), there is a trade-off between richness and reach. "Reach simply means the number of people, at home or at work, exchanging information" (p.73). Richness is defined in three ways relative to the aspects of the information: (1) bandwidth or the amount of information that can be moved from sender to receiver in a given time; (2) customization or the degree to which the information can be customized; (3) interactivity or that dialogue is possible for a small group, but to reach millions the message must be a monologue. The traditional belief in a corporation is that communication cannot be rich and broad simultaneously. However, the rapid advancements in net technologies now allow everybody to communicate with everybody else. "The explosion in the number of people and organizations connected by networks" is "freeing information from the channels that have been required to exchange it, making those channels unnecessary or uneconomical" (p. 74).

This change in economics of information can be responsible for deconstruction of the value chain, requiring firms to fundamentally re-think their strategy. For example, newspapers are built on a vertically integrated value chain and are ripe for upheaval. "Journalists and advertisers supply copy, editors lay it out, presses create the physical product, and an elaborate system delivers it to readers each morning" (p. 75-76). Anyone with a computer can access the latest news from many sources at anytime without the need to purchase a daily newspaper. Through the use of a computer it is also possible to submit, pay for, update, search through, and respond to advertisements electronically and conduct e-governmental services. This deconstruction will require new brand strategies and that "new branding opportunities will emerge for third parties that neither produce a product nor deliver a primary service" (p. 81). They suggest that "assets that traditionally offered competitive advantages and served as barriers to entry will become liabilities" (p. 82), and that it will be very difficult for managers to act on these implications.

## NEED FOR SECURITY IN E-GOVERNMENT

### National Computer Security Center (NCSC)

The National Computer Security Center (NCSC) is entirely a subsidiary of the National Security Agency (NSA) of the U.S. government. This organization is essentially in charge of dictating guidelines for computer security at a very high level. The NCSC generally publish security guidelines in several books (rainbow series) and regularly updates them on a continuous basis. A major focus at the Computer Security Resource Center (CSRC) is on working with government and industry to establish more secure systems and networks by developing, managing and promoting security assessment tools, techniques, services, and supporting programs for testing, evaluation and validation. The CSRC addresses such areas as: development and maintenance of security metrics, security evaluation criteria and evaluation methodologies, tests and test methods; security-specific criteria for laboratory accreditation; guidance on the use of evaluated and tested products; research to address assurance methods and system-wide security and assessment methodologies; security protocol validation activities; and appropriate coordination with assessment-related activities of voluntary industry standards bodies and other assessment regimes (Security Testing, 2001). Prominent among these publications are the Orange book, which deals with security systems in stand-alone operating system, and the Red book, which deals extensively in networking. In dealing with e-business platforms, even

that the red book for networked computers is the basis of the Internet, the Orange book that deals with the server provides the basis security infrastructure where the e-business site actually runs.

Recently three significant events have increased the security importance of U.S. standards like the TCSEC. The first and obvious one is that on the exponential explosion of e-government. The other is the permission from the U.S. government to export SSL encryption technology to almost all countries allowing secure connection around the globe putting increasing security focus on the server side of the e-business in a global scale. The third, and most profound, is the national and international consensus on the need for security safeguards in the wake of the tragic September 11, 2001 event.

Therefore, trust is a key component of eBusiness and all online users should be able to evaluate the reputation and the trustworthiness of Web sites that they initiate transactions with. Trust transcends separate technological and business aspects. Authentication, e-security, and users' authorization are chiefly technological and are the key areas where electronic signatures and trustworthiness is established. Such factors as reputation, e-privacy, reverse logistic, customer support, and service all directly effect business transactions.

A trusted third party is necessary in establishing the identities and standards of the verification system. Many firms take advantage of public key infrastructure where a person's public key could be accredited or verified by other users or companies. This works as long as all the users have integrity. Standards should be used for electronic signatures, preferably one that is open source and is the result of one vendor succeeding in competition over or combining with several others, or a set of common keys between various systems will enable e-businesses to have a verification "Rosetta Stone" of bona fide verification and transactions. Although people trust reliability, excellence, urgency and kept promises, there must be sufficient safeguards build into the technologies so that people can trust them without verification through face-to-face interaction. Many customers routinely pay many of their bills at various vendor Web sites, from Sprint PCS to Duquesne Light, and do not worry about their transactions because of established reputations for trust reliability.

## Components of the Trusted Computer System Evaluation (TCSEC)

The trusted computer system evaluation criteria classify systems into four broad hierarchical divisions of enhanced security protection. They provide a basis for the evaluation of effectiveness of security controls built into automatic data processing system products (Department of Defense Standard, Department of Defense Trusted Computer System Evaluation Criteria, 2001; Hasselbring & Weigand, 2001). The criteria were developed with three objectives in mind:

a. To provide DoD (Department of Defense) components with a metric with which to evaluate the degree of trust that can be placed in computer systems for the secure processing of classified and other sensitive information
b. To provide guidance to manufacturers as to what to build into their new, widely-available trusted commercial products in order to satisfy trust requirements for sensitive applications
c. To provide a basis for specifying security requirements in acquisition specifications

With respect to the first purpose evaluations can be delineated into two types: An evaluation can be performed on a computer product from a perspective that excludes the application environment; or, it can be done to assess whether appropriate security measures have been taken to permit the system to be used operationally in a specific environment. The former type of evaluation is done by the Computer Security Center through the Commercial Product Evaluation Process that uses the trusted computer system evaluation criteria. The latter type of evaluation, those done for the purpose of assessing a system's security attributes with respect to a specific operational mission, is known as a certification evaluation. It must be understood that the completion of a formal product evaluation does not constitute certification or accreditation for the system to be used in any specific application environment. On the contrary, the evaluation report only provides a trusted computer system's evaluation rating along with supporting data describing the product system's strengths and weaknesses from a computer security point of view. The system security certification and the formal approval/accreditation procedure, done in accordance with the applicable policies of the issuing agencies, must still be followed-before a system can be approved for use in processing or handling classified information. Designated approving authorities (DAAs) remain ultimately responsible for specifying security of systems they accredit.

The trusted computer system evaluation criteria will be used directly and indirectly in the certification process. Along with applicable policy, it will be used directly as technical guidance for evaluation of the total system and for specifying system security and certification requirements for new acquisitions. Where a system being evaluated for certification employs a product that has undergone a commercial product evaluation, reports from that process will be used as input to the certification

evaluation. Technical data will be furnished to designers, evaluators and the designated approving authorities (DAA) to support their needs for making decisions.

The scope of these criteria is to be applied to the set of components comprising a trusted system, and is not necessarily to be applied to each system component individually. Hence, some components of a system may be completely un-trusted, while others may be individually evaluated to a lower or higher evaluation class than the trusted product considered as a whole system. Though the criteria are intended to be application-independent, the specific security feature requirements may have to be interpreted when applying the criteria to specific systems with their own functional requirements, applications or special environments—communications processors, process control computers, and embedded systems in general. The underlying assurance requirements can be applied across the entire spectrum of ADP system or application processing environments without special interpretation.

## Nomenclature of the Criteria

Concurrent with DoDs efforts to address computer security issues, work was begun under the leadership of the National Bureau of Standards (NBS) to define problems and solutions for building, evaluating, and auditing secure computer systems. The criteria are divided into four divisions: D, C, B, and A ordered in a hierarchical manner with the highest division (A)—reserved for systems providing the most comprehensive security (Department of Defense Standard, Department of Defense Trusted Computer System Evaluation Criteria—December 1985. 2001). Each division represents a major improvement in the overall confidence one can place in the system for the protection of sensitive information. Within divisions C and B there are a number of subdivisions known as classes. The classes are also ordered in a hierarchical manner with systems representative of division C and lower classes of division B being characterized by the set of computer security mechanisms that they possess. Assurance of correct and complete design and implementation for these systems is gained mostly through testing of the security- relevant portions of the system. The security-relevant portions of a system are referred to throughout this document as the Trusted Computing Base (TCB). Systems representative of higher classes in division B and division A derive their security attributes more from their design and implementation structure. Increased assurance that the required features are operative, correct, and tamperproof under all circumstances is gained through progressively more rigorous analysis during the design process.

Within each class, four major sets of criteria are addressed. The first three represent features necessary to satisfy the broad control objectives of: Security policy, accountability, assurance, and documentation—which describes the type of written evidence in the form of user guides, manuals, and the test and design documentation required for each class (Department of Defense Standard, Department of Defense Trusted Computer System Evaluation Criteria–December 1985, 2001).

## Requirements of Each Level

The classes of systems recognized under the trusted computer system evaluation criteria are as follows. They are presented in the order of increasing desirability from a computer-security point of view (Department of Defense Standard, Department of Defense Trusted Computer System Evaluation Criteria—December 1985, 2001).

1. **Class (D): Minimal Protection:** This class is reserved for those systems that have been evaluated but that fail to meet the requirements for a higher evaluation class
2. **Class (C1): Discretionary Security Protection:** The trusted computing base (TCB) of a class (C1) system nominally satisfies the discretionary security requirements by providing separation of users and data. It incorporates some form of credible controls capable of enforcing access limitations on an individual basis (i.e., ostensibly suitable for allowing users to be able to protect project or private information and to keep other users from accidentally reading or destroying their data). The class (C1) environment is expected to be one of cooperating users processing data at the same level(s) of sensitivity
3. **Class (C2): Controlled Access Protection:** Systems in this class enforce a more finely grained discretionary access control than (C1) systems, making users individually accountable for their actions through login procedures, auditing of security-relevant events, and resource isolation
4. **Class (B1): Labeled Security Protection:** Class (B1) systems require all the features required for class (C2). In addition, an informal statement of the security policy model, data labeling, and mandatory access control over named subjects and objects must be present. The capability must exist for accurately labeling exported information. Any flaws identified by testing must be removed. The key distinction between C-level and B-level security is in the notion of access control. For example, in a C2 (DAC) system, owners have absolute discretion about

whether or not others have access to their objects. In a B-level, or mandatory access control (MAC) system, objects have a security level defined independently from the owner's discretion. For example, if you receive a copy of an object marketed "secret," you cannot give permission to other users to see this object unless they have "secret" clearance. This is defined by the system independent of your discretion. MAC involves the concept of data labeling, which is the creation and maintenance by the system of security "labels" on data objects, unalterable by users (except in certain cases under system control and auditing). An administrator can get access to anyone's objects, although it may require some programming to do so, that is, the user interface would not expose this power.

5. **Class (B2): Structured Protection:** In class (B2) systems, the TCB is based on a clearly defined and documented formal security policy model that requires the discretionary and mandatory access control enforcement found in class (B1) systems be extended to all subjects and objects in the ADP system. In addition, covert channels are addressed. The TCB must be carefully structured into protection-critical and non-protection-critical elements. The TCB interface is well defined and the TCB design and implementation enable it to be subjected to more thorough testing and more complete review. Authentication mechanisms are strengthened, trusted facility management is provided in the form of support for system administrator and operator functions, and stringent configuration management controls are imposed. The system is relatively resistant to penetration.
6. **Class (B3): Security Domains:** The class (B3) TCB must satisfy the reference monitor requirements that it mediate all accesses of subjects to objects, be tamperproof, and be small enough to be subjected to analysis and tests. To this end, the TCB is structured to exclude code not essential to security policy enforcement, with significant system engineering during TCB design and implementation directed toward minimizing its complexity. A security administrator is supported, audit mechanisms are expanded to signal security-relevant events, and system recovery procedures are required. The system is highly resistant to penetration.
7. **Class (A1): Verified Design:** Systems in class (A1) are functionally equivalent to those in class (B3) in that no additional architectural features or policy requirements are added. The distinguishing feature of systems in this class is the analysis derived from formal design specification and verification techniques and the resulting high degree of assurance that the TCB is correctly implemented. This assurance is developmental in nature, starting with a formal model of the security policy and a formal top-level specification (FTLS) of the design. In keeping with the extensive design and development analysis of the TCB required of systems in class (A1), more stringent configuration management is required and procedures are established for securely distributing the system to sites. A system security administrator is typically supported.

## CONCLUSION

As evident from these classifications, it is important to understand strategically how IT applications and their security configurations are interconnected and become competitive necessities for successful e-government operations. Hence, current availability of large quantities of information has changed operating processes; company executives are being forced to re-think the strategic security fundamentals of their businesses and their methods of competing in the marketplace. The issue of e-privacy/e-security in an e-government environment is based on the tenets of building trust. Only through a persuasive discussion of privacy agreement on ethics can universally accepted standards can be implemented. By pitting the most fervent opposing issues, that the manager must protect itself and its resources against the employees' privacy rights and the fact that home life and work life are more greatly overlapping than ever before with customers, a compelling need to reach a balance or win-win situation with trusted systems. Hopefully, a discussion of the security-relevant portions of a system, the Trusted Computing Base (TCB), as they related to the widespread availability of trusted computer systems for use in e-government applications, will result in increased consumer confidence and loyalty. The never-ending quest for growth among businesses demands that trust evaluations and/or audits must be consistent and the benefits and detractors continually updated to allow a fair assessment of the e-government environment and of what is best for computer users.

## INTRODUCTION

The question of electoral participation has today become a major issue for the future of democratic systems. In the USA and Europe, voter turnout continues to fall. Faced with this strong erosion of political participation, the watchword is mobilization.

In this connection, several proposals, chiefly technical in nature, have been put forward to curb this rising voter absenteeism. For example, several projects have been developed with a view to putting in place new voting procedures, including among others, telephone voting, postal voting, computer voting, Internet voting, using pre-perforated cards, mobile phones or digital terminals installed in public places (shopping centres, public buildings, etc.).

## BACKGROUND

In the face of this multiplication of new experiences, it is in the interest of democracy to examine, in a rigorous and objective way, such developments, based on empirical material provided by the political entities that have tested one or more new voting methods. However, the relevant information is often dispersed among various governmental and electoral authorities and available solely in the political entity that initiated the experiment. It is therefore appropriate to summarize the main experiments carried out and the main lessons to be learned from them.

It is not possible, however, to review all the experiments or to cover every new possible voting technique, as this would require far more than a short article. Consequently, we will focus solely on USA and Europe, and on two forms of e-voting that are computer voting and Internet voting. Actually, there is a debate on the validity of this distinction. For some, the appropriate distinction is between attended e-voting and unattended e-voting. The previous supposes that the voter go to a polling station to cast a vote, while, for the later, the voter can cast his vote from any place where there is an electronic device connected to a network transferring the vote to the electoral authorities.

In this article, we do not follow this line of argument. The core distinction is between computer voting and Internet voting. In the previous, voters go to a polling station to cast a vote on a computer that is not connected to any network. In the latter one, the vote is cast through any electronic device connected to a network transferring the vote to the electoral authorities. Unlike unattended e-voting, the connected electronic device used can be in a polling station. The choice in this article is related to the fact that when there is a connection to a network (in the polling station or not), it has crucial consequences for the security of the system.

Within this framework, we will address only the most interesting experiments in terms of the issues involved in such changes. To that end, we have used public and semi-public documents[1], as well as scientific studies, for the purpose of our evaluation. On that basis, we will set out the details of the main experiments in this area, before highlighting the lessons learnt and problems revealed by those large-scale tests.

## COMPUTER VOTING

The most significant breakthrough in the use of NICT in the electoral process concerns computer voting. In numerous countries, regions and cities, its use is becoming increasingly widespread.

In The Netherlands, computer voting has become common practice for voters. At the last Dutch general election in May 2002, 95% of the Dutch municipalities

provided electronic voting machines (Nederlandse Ministerie van Binnelandse Zaken, 2003). Citizens in the Netherlands use touch panels to vote. In Belgium, since 1994, computer voting is used in several municipalities. At the last federal elections in 2003, computer voting had replaced paper-based voting in 34.1% of the country's cities (44% of the population)[2]. Florida is also noteworthy in this regard. A touch-sensitive screen was one of the voting solutions used in that state in the 2004 presidential elections to avoid the voting imbroglio of 2000. Finally, in various countries, including UK, computer voting is one of the new voting methods currently being tested (Office of the Deputy Prime Minister (ODPM), 2002)[3].

The success of computer voting cannot be explained in terms of convenience, since voters still have to go to a polling station to cast their vote. Therefore they do not save any time, or very little time. Moreover, observers agree that computer voting does not improve strongly the level of voter turnout at elections (MORI, 2003). Moreover, it is even possible that the queues caused occasionally by technical problems have discouraged certain electors.

The main advantages of this new voting technique correspond to objective such as ensuring the accuracy of counting and avoiding errors and spoilt ballots. With regard to the risk of fraud or malpractice when counting votes, computer voting is considered less vulnerable to "rigging" than paper-based voting or voting using preperforated cards. This security criterion is particularly important in countries where trust in the authorities is far from absolute (Saltman, 1998). In addition, and that is undoubtedly the main argument, computer voting avoids the problem of votes being invalidated because of voter errors such as double voting and spoilt ballots (Independent Commission on Alternative Voting Methods (ICAVM), 2002).

Nevertheless, those positive arguments are sometimes called into question by the assessments made in countries using computer voting. As regards the security and secrecy of the ballot, various problems have arisen. First of all, the elector identification and voting processes are often linked, which undermines the principle of ballot secrecy. Consequently, in Belgium and the Netherlands, the authorities have decided to separate the two processes. In Belgium, voters identify themselves to the chief returning officer of the polling station and are then given a magnetic card to vote. After they have cast their vote, the card is transferred to an electronic ballot box before being wiped and reused (Federal Ministry for the Interior, Belgium, 2003).

In addition to those initial technical reserves, there is the problem of the material impossibility of checking votes. In most cases, votes are counted by the computer as soon as the vote has been validated. That helps considerably to speed up the vote counting process and reduce costs in terms of human resources. However, recounts are then impossible. In order to overcome that problem, various solutions have been proposed, notably the "ticketing" solution, where a voting ticket is printed by the computer and collected in a sealed ballot box. Ticketing has been tested for instance in Belgium. It makes it possible to have a recount, either in the case of a problem or on a random basis in respect of a small percentage of votes. In other countries, the source code is given to the electoral authorities to allow the auditability of the voting system.

Finally, voting machines remain subject to technical uncertainties. Any failure can result in long queues, which may dissuade citizens from voting. In that case, the result is, of course, the opposite of that desired by the authorities (Detry, 2001).

From this initial survey, it can be observed that experiments with computer voting have dampened slightly the enthusiasm of the supporters of this new voting technique which is supposed to enhance considerably the security and rapidity of electoral arrangements.

Moreover, in addition to the reserves regarding counting, secrecy and accuracy highlighted during the various computer voting experiments, it also imposes a heavy financial burden on the authorities, because of the need to invest in equipment. Furthermore, the equipment cannot be used for other purposes (ICAVM, 2002). In addition, the changeover to computer voting cannot be seen as a purely technical operation. It is necessary, in any event, to adapt electoral laws accordingly (Bourgaux, 2001). However, that stage is very often neglected (Detry, 2001). As a result, in Belgium, legal proceedings have been instituted on several occasions against the legislator. (EVA, 2003).

In addition, the introduction of computer voting has an impact on the electoral results themselves. Research carried out by the *Vrij Universiteit Brussel* (VUB) has shown that the positioning of candidate lists in columns on the screen tends to favour the candidates placed at the top and bottom of the column (Deschouwer, Buelens, & Heyndels, 2000). For example, the 2004 Brussels regional elections, when there were sometimes as many as 88 candidates on each French-speaking list, highlights the pertinence of that aspect.

It appears from a survey of the public and private reports on computer voting in Belgium, the Netherlands and UK, that the success of this method does not necessarily mean that this change in voting methods has been accepted unreservedly.

## INTERNET VOTING

Of all possible uses of NICTs in the electoral process, Internet voting is undoubtedly the one which carries the most hopes. However, it is also the most debated and the most controversial. At the current time, Internet voting, or remote electronic voting, is not used widely in any country. In most cases, only limited experiments with pilot projects have been conducted. Nevertheless, the number of such projects is sufficient to provide a very satisfactory empirical basis from which some initial lessons can be learned.

In Europe, The Netherlands carried out Internet voting tests during the 2004 European elections (Figueiredo, 2003). In Spain, 15 000 voters from the village of El Hoyo de Pinares (Avila, North of Madrid) used Internet voting for a referendum (Mohanty, 2003). Three different tests were carried out in France in 2002 and 2003 (McMahon, 2002). Some Swiss cantons have also experimented with the use of remote Internet voting, notably Neufchatel, Zurich and Geneva (Trechsel, Mendez, & Kies, 2003). As part of the Cybervote project, financed by the European Union, three Internet pilot projects have been carried out in Germany, Sweden and France (Cybervote, 2003). Finally, in the United Kingdom, Internet voting was part of the new voting techniques tested recently. Outside Europe, it is mainly in the United States that Internet voting is being tested. In 2000, democrats in Arizona also used Internet voting during their primary election.

In this regard, three types of Internet voting can be distinguished (Internet Policy Institute, 2001). First, there is Internet voting at the polling stations, which is very similar to electronic voting, apart from the collection of data. The second method concerns Internet voting using kiosks installed in public places, such as libraries, schools and supermarkets. Finally, Internet voting from any computer connected to the Web is the freest method currently being tested.

The first problem related to Internet voting, concerns security. The principal risk is vulnerability to viruses and hacking, highlighted in particular in the Netherlands (Figueiredo, 2003). The second main problem concerns identification. As mentioned above in the case of computer voting, experience has demonstrated the need to separate the voter identification operation from the voting operation strictly speaking. Although that is possible when a voter goes to a polling station, the same separation is not possible in the case of remote voting. There is, therefore, a real risk of identify theft and various options are currently being examined in order to reduce that risk. For example, in UK, the recommendations are based on multiplying identification criteria (PIN code, date of birth, digital ID certificate). However, none of those procedures can guarantee absolute security in the case of remote voting.

In addition, from a technical point of view, several authors have stressed that a transitional period will be necessary for the introduction of Internet voting. Given the recent problems encountered with some pilot projects, various British experts consider that any plans to extend Internet voting must be implemented gradually. Changes in this regard cannot be introduced in the space of one election, not only because of the need to train the people supervising the electronic operations and acquire the necessary equipment, but also because of the need to familiarize electors with the method (ICAVM, 2002).

The second category of comments made concerning Internet voting concerns the reserves regarding the conformity of this new voting method with legal criteria for democratic elections. First of all, there is the question of ballot secrecy. Internet voting, like any form of remote voting, raises the question of how to guarantee that voters, without the protection offered by the privacy of the polling booth, are not subjected to any outside pressures when voting (Watch & Birch, 2002). The aim of secrecy is to protect voters from such influences.

Another problem is the question of equality. The issue here is not the principle of “one man, one vote” (OMOV), but rather the principle of equal access to voting. Numerous observers and academics have denounced what is commonly referred to as the digital divide. In their view, the introduction of remote Internet voting would accentuate the gap between different social classes (rich and poor; people having minimal qualifications and those having received higher education; young and old, visual impaired persons). This affirmation is based on several empirical observations. According to Norris, although Internet access is increasing in Europe, it continues to be more widespread among younger people and people with a higher level of education (Norris, 2002). Consequently, those groups would be more inclined to vote if Internet voting become the rule.

This digital divide seems to be confirmed by several national experiences with Internet voting. For example, in Arizona, young people and people having received higher education made the most use of Internet voting during the democratic party’s primary elections in 2000 (Solop, 2001). Although the electoral participation of young people in the 18-24 age group was low (2.1%), 75% of the people who declared that they had voted via the Internet were young people (Gibson, 2002). The British experience was the same (ODPM, 2002, p. 4-6). In California, it is the 55 and over age group that is the most opposed to Internet voting (Secretary of State, 2000).

Finally, it is necessary to reiterate that the main aim of considering new voting methods, including Internet voting, was to make it cheaper for electors to vote in order to achieve a higher voter turnout. However, it would appear that the success of Internet voting in this regard is somewhat mixed. In the canton of Geneva, fewer than 5% used Internet voting (Trechsel, Mendez, & Kies, 2003). In Great Britain, where electors had the choice as to which voting method to use, 41% of electors preferred to vote by post compared with 2.9% for Internet voting, 1.5% for telephone voting, 0.7% for voting by SMS and 0.2% for voting by electronic polling booth (British Electoral Commission, 2003). On the other hand, in Arizona, the use of Internet voting in the Democrats primary elections was 7.23% higher than in the previous presidential election.

Nevertheless, the mixed results in terms of electoral participation are not accompanied by a strong rejection among voters of this voting method. In UK, at the end of the pilot projects, a survey showed that 59% of the citizens having used Internet voting declared that it was "easy" or "very easy" (MORI, 2003, p. 46). In Switzerland, 91.6% of Internet users are in favour of Internet voting (Trechsel, Mendez, & Kies, 2003). In France during the Cybervote project, 22% of Internet voters said that their level of confidence in Internet voting was reasonable, while 68% said that it was high (Cybervote, 2003, p. 64). It would appear, therefore, that the low use of Internet voting stems not from the risks associated with this voting method, but rather from the lack of apparent advantages for voters in using it. In this regard, other remote voting methods, such as postal voting, are for the time being more popular (EGov Monitor, 2003).

## FUTURE TRENDS

Electronic voting is at a turning point. After a first experimentation stage, it is now being more widely used in several democracies. Computer voting received a satisfying appreciation from electoral authorities. As a consequence, several political entities using this form of e-voting are considering its generalization. Such evolution is for instance under consideration in Belgium. The main stumbling-blocks in that respect are related to security and re-counting issues.

By contrast, experiences of Internet voting raised more hopes, but also more fears. The digital divide, as well as security issues (hackers, frauds …) lead most countries to adopt a more sceptical stance towards Internet voting. None of the countries presented in this article has serious projects to generalize Internet voting. The sole form of Internet voting under consideration is computer voting in a polling station connected to the Internet.

## CONCLUSION

It would appear from the two parts of our analysis above concerning the various national experiences, that several conclusions can be drawn as to the advantages, drawbacks, and questions raised regarding the application of NICT to the electoral process. Both in the case of computer voting and Internet voting, the lessons learned can be grouped into three categories.

The first concerns technical considerations, and in particular voting secrecy. The various "wide-scale" tests have highlighted two major problems in this area. The first concerns the vulnerability of the hardware used, from the point of view of not only technical failures, but also hacking and viruses. In addition to that, there is the more fundament issue of voter identification. First of all, it is necessary to ensure the security of the procedure to avoid identity theft. In addition, there is a clear need to separate the identification and voting processes. Without those guarantees, the principle of ballot secrecy will be undermined.

The above reflection on voter anonymity leads to the second category of comments, namely compliance with the legal principles associated with any democratic election. First of all, as we have discussed, is the guarantee of ballot secrecy, where over and above the question of identification, there is also the difficulty of avoiding social pressure on the elector, which is a risk as soon as the vote is cast outside the *ad hoc* booth.

The second major legal principle which requires attention in the light of the national experiences concerns the principle of equality among voters. In particular, the use of IT methods, and all the more so in the case of Internet voting, raises the question of equal access for all social categories. This affects in particular people who are less familiar with IT systems (older people, people with a lower level of education, economically disadvantaged groups, etc.).

Finally, various socio-political questions have also been emphasized. The main ones concern the effect of the new voting methods on voter participation in elections. In this regard, the figures are mixed. In certain cases, no impact was observed, while in other cases a slight increase was recorded. In any event, computer voting and Internet voting attract are neither strongly supported nor virulently rejected. However, the majority of voters acknowledge the ease of use of the new methods. Likewise, no strong expression of distrust has been noted. Nevertheless, the use of Internet voting or computer voting is still relatively limited, when other options such as paper-based voting or postal voting are available. The explanation seems to lie with the fact that voters find it difficult to perceive any added value in the two voting methods discussed in this article.

Solutions are however conceivable with regard to the observations noted and questions raised. However, it is important to be particularly attentive in this regard, both as regards political decisions and academic research. As long as the necessary legal guarantees are not in place and ballot security ensured, these new voting methods will continue to be at a disadvantage compared with paper-based voting which has proved its worth over numerous decades. However, the social acceptance and resultant legitimacy of the new voting methods depend on these questions of effectiveness and added value. Without that, computer voting and Internet voting will continue to be disputed. Moreover, by extension, the whole electoral process will be called into question. There can be no doubt that no democracy can afford such a malaise.

## KEY TERMS

**Attended Electronic Voting:** Form of electronic voting requiring that the voter go to a polling station to cast a vote.

**Computer Voting (or Automated Voting):** Form of electronic voting by which electors vote by following the instructions on the screen of a computer installed in a pooling booth, instead of by using a ballot paper.

**Digital Divide:** Several social groups (older people, people with a lower level of education, economically disadvantaged groups, visual impaired persons) have a more difficult access to IT. As a consequence, the introduction of IT in the electoral process would put certain categories of voters at a disadvantage, depriving them de facto of their right to vote.

**Electronic Voting (or E-Voting):** The use of one of more electronic means to vote and/or to process votes.

**Internet Voting:** Form of electronic voting by which electors vote by using a computer connected to the Internet. This operation can be take place in a polling booth, via interactive kiosks installed in public places, or from any computer connected to the Web.

**Ticketing:** Form of computer voting where a voting ticket is printed by the computer and collected in a sealed ballot box, in order to improve confidence in electronic voting and, eventually, recount in case of contest.

**Unattended Electronic Voting:** Form of electronic voting not requiring that the voter go to a polling station to cast a vote; the voter may cast a vote from any computer connected to a network transferring his vote to electoral authorities.

## ENDNOTES

1 We have avoided using reports drawn up solely by private companies involved in electronic voting, because of the risk that they might put their business interests before other considerations.

# Successful Implementation of an E-Government Project

**Giseline Rondeaux**
*Lentic—University of Liege, Belgium*

## INTRODUCTION

Challenged to multiple pressures, the administration developed many initiatives aimed at modernizing its practices and offering the citizen customer (Thomas, 1999) a faster and better-quality service (OECD, 1996). From this perspective, the use of information and communication technologies (ICTs) is presented as an essential means of modernization (Poullet & Van Bastelaer, 1999). However, the declarations of intent sometime seem to be difficult to translate into efficient projects integrated in civil servants' daily work practices. A lot of case studies focus on best practices or analyze the reasons of failure of several e-government projects. There are fewer studies that position upstream and try to identify the key success factors of the introduction of ICTs into public services regarding their acceptance and appropriation by internal users.

## BACKGROUND

A review of the literature devoted to micro-analysis of e-government projects shows a primacy of perspectives focused on the impacts of these projects (on organization performance or services offered to citizens). Indeed, we note that the large majority of studies mentioned in the literature are centered on the effects produced by the introduction of ICTs into administrations or on individuals concerned with the change. They particularly consider work organization, frequency rate and use of the suggested systems. Other types of approaches are less frequent. Although several authors mention its interest, research focused on the context of e-government projects' implementation remains limited. Far from simply fitting into a reproduction process (automation of existing tasks or processes), ICTs are carrying certain organizational presuppositions (Alsène, 1990) that cannot be congruent with the context in which they are developed. In this respect, it appears essential to consider the specificities of the particular context of public administration. Several authors (Jae Moon, 2002; Jae Moon & Norris, 2005) stress the importance of considering contextual specificities, showing that some institutional factors can contribute to the adoption of e-government or have technical implications on project design (Riedl, 2003). Similarly, Heeks (2003, 2005) identifies "design-reality gaps" as potential explanations of e-government failures: According to him, success or failure of the e-government project depends on the size of the gap between current realities of the situation (the context of the project) and the design proposal for new e-government projects.

In addition, there is a need for considering nontechnical factors (representations, attitudes, motivations, reactions, etc.) in the analysis of innovation processes. We observe that the process of e-government project management, the way they are introduced within the administration, do not constitute the majority of researches. The technological project management or the changes that such projects suppose were certainly approached (Alsène & Denis, 1994; Boddy & Buchanan, 1986; Rhodos & Wield, 1985), but seldom in the context of the public administration. We can quote in particular Grabow et al. (2002), and Ho and Pardo (2004), but the latter do not identify specific success factors for public administrations. Adopting a more upstream position, Jae Moon and Norris (2005) explore the effect of managerial innovativeness in municipal government on the adoption of e-government and its outcomes. Their study finds an association between managerial innovation orientation and the adoption of e-government at the local level. Nevertheless, it does not focus specifically on e-government project management, but on government management in a larger perspective. The management style adopted can be considered as a potential success factor of the e-government project. Some studies (Eddowes, 2004; Heeks, 2003) examine both the relevance and availability of methodologies and techniques suited to the implementation of e-government or propose techniques to reduce the risks of e-government failures.

In this context, we propose to consider these two dimensions simultaneously (consideration of the context and process of project management) and illustrate their influence with two case studies carried out in Belgium. The central question of the analysis is the effective use of digital projects by the internal actors of the administration, their satisfaction and their appropriation of proposed tools. Within the framework of this article, we will only develop the intra-administration perspective, and

will not consider the aspects linked to the relationship with the citizen.

The analysis of uses shows a frequent shift between desired uses (i.e., the initial purposes assigned with a project) and the effective uses, or the way in which the tools are used on a daily basis. This observed shift often leads to an acknowledgement of failure of the project or, at best, an under-utilization of the system. ICTs, which are too often considered as simple technical objects, are carrying organizational changes and are the result of interactions between their users and the context of implementation. Consequently, we can usefully mobilize the contextualist analytical framework, whose specificity is to understand organizational phenomena by considering the elements of the context likely to influence them. Accordingly, we refer to the approach proposed by Pettigrew (1985, 1987, 1990), in which he articulates the *content*, referring to the dimension submitted to the change (here: the e-government project), its *context* (factors likely to influence the content and its evolution) and the *process* (the complex interplay of power relationships among various actors concerned with the transformation of the organization).

Consequently, our analysis focuses on the factors that influence, and even structure, the uses, from the design of the project to its effective implementation within the organization. This analysis, combined with empirical observation, leads to formulation of some management observations relative to the necessary consideration of the context and the management process likely to optimize the uses of the installed tools.

This text is based on two case studies carried out within the framework of two research projects in public administrations. The first study examines the modernization of an inter-departmental human resources database managed by a central federal department, was generally perceived as a failure: Users did not use the proposed tool and showed no appropriation of it, and this under-utilization led to its abandonment. The second analysis, the development of a municipal intranet aimed at easing and stimulating the interactions between the different administrative services of the town, was a genuine success in terms of utilization, appropriation and satisfaction of the users.

The common point between these two cases is their aim to inter-connect and stimulate the collaboration and exchange of content between various departments of the same political decision level.

We use a qualitative methodology for both cases, consisting on one hand of interviews with the promoters and originators of the project as well as internal users within the administration, and a documents analysis on the other hand. For each of the two cases, we will present:

- The contextual variables, whose consideration supported the success or, on the contrary, whose non-consideration can be identified as a factor of failure, or at the very least a source of difficulties in the setting of the project
- The processual variables, namely, dimensions which, when were integrated in piloting and the setting of the project, supported a successful introduction of ICTs into the administration and *a contrario* when they were neglected, led to an under-utilization and then consequently an abortion of the system. These variables are mainly focused on the consideration of the actors and their interests, and the power games surrounding the project.

## CASE STUDY 1: THE MUNICIPAL E-ADMINISTRATION

These municipal authorities simultaneously set several e-administration projects both for the citizens and personnel. We will focus only on the projects intended for the latter (internal tools, back-office tools) or on the internal aspects of the projects developed for citizens (not the interfaces between citizen and civil servants).

This local administration has been involved for several years in many projects related to the introduction of ICTs, wishing to be perceived as an up-to-date administration. This wish, held by the burgomaster, was relayed at the political level, and was also made effective through collaboration with the private sector. This collaboration was translated in a computing equipment acquisition at very low cost for the administration.

In terms of equipment, the municipal authorities were equipped with several workstations in a local network (Intranet) with high capacity (an optical fiber installed by the municipality), connecting all services and establishments of the municipal authorities, based in several villages. All systems were developed simultaneously in the same computing environment, with the same ergonomics. This total standardization of the computing environment aimed at an easier appropriation of the various applications that will allow, in the long term, the mobility of agents in the various administrative offices.

The ICT process of these municipal authorities has led to the installation of an Autonomous Office to accompany the process, to free bureaucratic constraints more easily. Thus, the authorities decided to create a public limited company, whose objective was computing and communication in the municipality and, later on, the marketing of what was developed by other administrations.

The autonomous office was directed by a board of directors (majority of administrators designated among

the municipal advisers), which appointed a management committee in charge of everyday management. The fact of having actors from inside the administration convinced of the utility of the ICT projects had a facilitating effect. These municipal actors (high level) act as an interface and link the Office and municipal authorities closely. The statute of this Office enables it to recruit people within a different statutory framework, more flexible than that of municipal authorities (contracted personnel). In addition, the entire dedication of employees from the autonomous office to their ICT projects made it possible for civil servants to benefit from these projects without having extra work load due to their installation and maintenance.

Since the beginning of the e-administration project, an analysis of the administrative existing procedures was carried out by a mixed think tank composed of municipal personnel and a team of computing consultants. The civil servants were interviewed by an external consultant, so they could express themselves about their daily tasks, difficulties and so forth. This consultation was controlled by project management professionals who made it possible to express the requirements and translation of the requirements in logical and technological language.

The civil servants were mobilized into working groups, and took part at the various stages of setting up the project. They were asked to give opinions, which were actually taken into account. They learned how to look at their work practices from a new angle. A general long-term innovating dynamics was born and allowed a real mobilization of the actors. The promoters of the projects (i.e., the office) tried to adapt workstations according to the users' degree of ability to use the new tools.

The philosophy behind the project was that each worker was able to do the same job as before but using new tools. The development of the teleservices and teleprocedures consequently (almost) did not result in job rotation or major organizational changes. However, the ICT projects highlighted the possible time savings. The reorganization of the services resulted in the strengthening of the back office. Liaison officers were placed on the level of the various services to ease the projects implementation.

At the beginning, the majority of the municipal personnel had only very few computing competences; thus, they did not have particular skills for ICT implementation in their working methods. The introduction of the software was done progressively, starting with relatively simple applications, and supported by training. Thus, starting from a basic level, the municipal agents saw their computing competences increase, which they could use very quickly in their daily work.

The first software installed on the municipal network were electronic messaging and shared agenda. As soon as all of the civil servants (100 people) were plugged in the network, the use of e-mail was completely opened: The rules of e-mail use were deliberately very flexible. A great confidence was granted to the users to support the in-use self-training and especially the appropriation of this tool. The information and familiarization of the users to the added value of the projects in their daily work were developed throughout the project. Stress was laid on accountability, transparency, flexibility, saving of time and increased efficiency. In parallel, these projects provoked few fears or rejection on behalf of the municipal agents, insofar as they were not threatening for their jobs and did not cause major upheaval in the nature and quantity of work. On the contrary, most of the agents were shown to be very motivated to take part in the process, insofar as this resulted in more accountability and autonomy in their work. In response to expressed needs, several administrative procedures were digitized. However, the information management and mail management procedures are still subjected to the same cycle of approval (official channels). They were not reduced at the time of this digitalization. The approval cycle, however, became more transparent. In short, the internal e-government projects can be considered as successful, not in terms of innovation and process reengineering, but in terms of appropriation, effective use and users' satisfaction.

## CASE STUDY 2: THE HUMAN RESOURCES (HR) DATABASE

This administration supported the project for a certain time to build a database (DB) whose aim was to gather various data **as** several data on the personnel of various federal public services. HR information gathered for this DB was to come from several departments distinct from the promoter of the project. The users of this DB, also data suppliers, are very different in terms of size, equipment and means. Their practices regarding the DB are also much diversified: Whereas some large administrations provide a large amount of data without facing difficulties, other administrations, smaller, less equipped or whose personnel is less qualified, provide partial data or encounter problems to conclude this task. In the latter case, the head of department does the work according to his availabilities, whereas the task to be achieved is often decentralized on the level of smaller units in the first case. In the same way, the heterogeneity of the users' needs in terms of HR data also involves a variable use of the DB. The bureaucratic organization and the inter-departmental compartmentalization led to a phenomenon of computing "territoriality." The computing baronies rest on networks or computing tools that developed in the course of time within the various departments of the same

administrative entity. These developments were carried out in parallel by means of internal personnel, without any dialog between the teams in charge of the development design. As a result of this, the systems composing the same administrative entity are often not compatible (in most of the cases, the work of setting compatibility is in hand). The birth of the computing baronies tends to limit the possibilities of effective and efficient electronic exchanges.

The existence of parallel but non-compatible systems, the will of each service to keep control on its own tools, but also the absence of constraining coordination mechanisms is likely to slow down the possibilities of devolution of the networks, which would make it possible to establish electronic relations between administrations (of the same ministry) linked according to a "supplier-customer" model.

In this case, the situation seems divided between two contradictory tendencies: On the one hand, an administration implements its own HR policy in a decentralized way; on the other hand, the project developed by the administration is an HR database, with statistical vocation, centralized within a general service of administration. To not consider this situation goes against the success of the project. The extent to which this situation seems problematic actually carries out with the statute granted to the DB as a statistical tool or HR management tool. This ambiguity around the purposes of the system caused considerable questions from data suppliers: Does the tool aim only at data collection? Is it also used to exert a form of control on the administrations? What about their autonomy, consequently? What are the respective roles of the users, data suppliers, managers of the tool and political "supervisors"?

Anxious to preserve their autonomy, to locally manage their own data with their own system, the administrations using the system showed much resistance to the tool and its use. The development of this tool, instituted by Royal Decree, was carried out without holding a preliminary consultation of the users, who are also information providers. The latter are, thus, in charge of additional workload (to provide information) without having had the opportunity to express their needs or questions as to the relevance of such a project. Although this DB can indeed cover interesting aspects for the various services concerned, the absence of familiarization and analysis of preliminary needs did not make it possible to highlight these advantages. The users, thus, regard this project as a useless constraint, an extra workload deprived of the least element of motivation. Moreover, the users supplying the data did not receive any clear and precise information on the various possible uses of the DB, nor profited from training to the use of this software. As a result: They sometimes waste a lot of time trying to understand how to use it in an optimal way. The lack of incentive to establish collaboration, the absence of preliminary identification of the user's needs, while at the same time those users occupy a central place as data suppliers, led to a slow asphyxiation of the project. Less and less data received and poor-quality data were the most visible signs of the progressive failure of this project. In such a context, the introduction of a technological innovation is obviously not recognized as a success: The civil servants, seeing their workload weighed down by contribution to a tool without perceiving its added value, boycotted the project. A few months later, the project was abandoned.

Literature and the reading of these cases show that an e-government project is more likely to be successful if the project manager considered two dimensions during its design and implementation: the specificities of the context and the actors in presence. Though we examine both these dimensions successively, we do not pretend that they are independent. To the contrary, the contextualist model asserts that the contextual and processual variables are closely linked, the one possibly being a reply to the other. It is, thus, very hard to really isolate the one dimension from the other.

## CONSIDERATION OF CONTEXTUAL SPECIFICITIES

The context in which the introduction of projects based on ICTs appears to be an element of prime importance. Specificities of the public sector cannot be ignored in the design and implementation of e-government projects.

First, the civil servants' work depends on the political supervision of their administration. Political time is fast and short, contrary to administrative time. The management of the public sector, thus, is confronted with a double temporality and fragmentation of the decisional capacity. Moreover, the work organization and decision-making are subjected to particular lawful systems, such as year-limited budgets, making strategic management in the medium- and long-term more random than in the private sector. The law on public markets, for example, adds an element of complexity in the equipment policy because of the lengthening of deadlines and constraints that this law implies as regards the choice of the supplier. Being conscious of this potential source of difficulties, the municipal e-administration set up the Autonomous Office as an answer to a contextual fact. This allowed a faster decision-making process and more freedom regarding the statutory framework.

Civil servants profited for a long time from a particular statute, initially intended to ensure a certain independence compared to the political world. However, this has some limit, particularly in terms of accountability. In addition, the current coexistence of personnel under the

statute and a growing number of contracted personnel also raises particular questions in terms of HR management. Again, the setting up of an Autonomous Office next to the municipal administration facilitated the avoidance of such a problematic situation by enabling more flexible recruitment policies to hire computer scientists.

Finally, several organizational dimensions have to be considered, particularly in bureaucracies. Public organizations, frequently characterized by centralization and compartmentalization, present situations of systems incompatibilities and difficulties to network. This appears particularly in the HR DB case, where the equipment heterogeneity constituted one of the important threats to the project.

The following list summarizes the contextual specificities important to consider.

- Dependence on political supervision
  - Double temporality
  - Fragmentation of decisional capacity
- Particular lawful systems
  - Year-limited budgets
  - Law on public markets
- Administrative statute
  - Limits in terms of accountability
  - HR issues due to the coexistence of personnel under statute and contracted personnel
- Bureaucratic organization
  - Centralization
  - Compartmentalization
  - Systems incompatibilities and computing baronies

## TAKING ACTORS INTO ACCOUNT

Contextual specificities can be considered as given, and they have to be taken into consideration. Furthermore, it is a matter of looking at the actors' interventions: The mobilization of these dimensions by actors, following their interests, implies that the context is not always simply an objective data, but can become a construct. In other words, the environment constitutes a constraint for the action but is also built by various categories of actors. As Nizet and Pichault note (1995), the organization and environment are created together through processes of social interactions of the members of the organization. This is not without impact on the way in which ICTs will be perceived and used:

*The bureaucratic structure and the internal procedures of the large organizations (organization, principles of management, the particular system of gratification of the agents, etc.) the attitude and the reactions of the users with regard to the technological innovations influence a bureaucracy slows down in particular the diffusion of new technologies.* (Bretschneider & Wilmer, 1993)

In addition, the organizational actors, whomever they are, do not involve themselves in a change process—only if they perceive this as potentially positive for them in terms of values or interests (Crozier & Friedberg, 1977; Nizet & Pichault, 1995). Moreover, if this change is not perceived as a judgment of their practices (Peters & Savoy, 1998), actors are more likely to embrace change. The HR DB project completely neglected these aspects by proposing a tool without real usefulness for them. Besides, some of them were already equipped with more effective software or did not need to use one.

Power games also influence people's behavior. Because of power relations existing between actors in any organization, various constructions of the context are often conflicting; that is, interests of the various actors being generally divergent. In an organization with centripetal tendency, as it is the case for many public administrations, users are likely to adopt more defensive attitudes and/or withdrawal (Agro & Tavernier, 1999).

The way the project will be introduced and especially the methods of users' involvement appear of capital importance for the implementation of an e-government project. Various stages appear crucial in this respect. Some are frequently evoked in the literature relating to computing project management, but seem seldom used within the framework of a digital administration. Let us quote a design of the project, first of all based on a rigorous analysis of the needs and not on the only expression for the will of a political actor or fashionable trend.

The HR DB case shows that the neglect of this stage can drive to under-utilization or even a boycott of the proposed tool. This DB met no needs and had no added value in the users' work. Due to this inadequacy, the users did not enter the required information and the project ran lower every day.

The e-government project will ideally take place in a plan of total development. Indeed, integration of the project in an organizational strategy and a broader policy of communication appear essential. The promoters of the project will be attentive in particular with current work practices and organization and the potential reorganization of the work processes that this kind of project imply. In the e-municipality, the project was designed to not disrupt the work processes, and it is probably one of the success factors of this project in terms of appropriation and users' satisfaction. To the contrary, HR DB promoters did not consider the work practices in use; this had negative effects on the users' opinions of the tool and on their later participation with it.

In addition, the information and familiarization of the users to the finalities of the project and its added value, and the training of these users to the implemented applications, without a doubt constitute a critical factor for later uses of the system. The presence of driving actors exclusively dedicated to the project, and having necessary competences, also seems a facilitator, as was the case in the municipal e-administration. The HR DB case is a counterexample in this respect, since its finalities were the subject of questions or even worries and, consequently, generated much resistance.

Project managers will bear in mind the need to involve various actors (decision makers, users, technical experts) at various key times of setting up the project, supporting a bottom-up approach. Several works (Agro & Alii, 1995; Bijker, 1992; Flichy, 1995) contributed to show the importance of the "social construction of technologies," underlining how decisive emergent uses, alliances, communication, users' involvement strategies, and so forth are. Such reports result in thinking the innovation like an "*interessement*" process (Latour, 1992) considering technical, social, economic or organizational dimensions.

The following list summarizes which dimensions linked to the actors should be considered during the piloting process.

- Analysis of needs
- Integration in a total development plan (organizational strategy, broader communication policy)
- Attention to current practices and the reorganization of work
- Information/familiarization of users (finalities, added value)
- Training
- Presence of competent driving actors dedicated to the project
- Involvement of a different kind of actors (decision makers, users, technical experts) at various key times of setup
- Interactive approach

## CONCLUSION

As one sees it through this contribution, many obstacles can draw up in front of an e-government project. Considering some dimensions of the context and project management cannot certainly guarantee without the slightest doubt the success of the project, but can, however, constitute key factors of success. One of the essential conditions for an e-government project to be successful, according to us, is that the administration that undertakes such projects is ready to question its procedures, organizational practices and, in particular, its pre-existent modes of control, even the preliminary draft itself. ICTs, to deploy their full potentialities and be adopted by users, must open spaces of freedom, innovation and discovery to them. In this way, they will not be perceived as being an additional layer of constraint to usual bureaucratic operations. The harmonious implementation of the e-government project and its finalities in its specific context thus supposes to consider this last, and identification of the space left at the disposal of the project pilot to circumvent the principal constraints or solve the inherent difficulties. The style of management adopted by the persons in charge for an e-government project plays a decisive part in the orientation of the process. A central element within all stages of the process is to make users understand the utility and added value of the project in their daily working lives. To convince the users, it is necessary to involve them in the process. This axis is essential for better comprehension, acceptance and use of the system (Rondeau & Chouakri, 1993). However, the choice of such project management is better suited to long-term processes, and even if the implementation is a lengthy process, it will contribute to the maintenance of the project in the long run and perpetuate its uses.

## KEY TERMS

**Centripetal Tendency:** Tendency that characterizes organizations whose capacity is concentrated at the strategic top and in the hierarchical line, as it is the case for many public administrations.

**Computing Baronies:** Phenomenon of computing "territoriality" due to bureaucratic organization and compartmentalization. It appears as networks or computing tools developed in parallel without any dialog between the teams in charge of the design, and thus often are incompatible.

**Contextualist Analytical Framework:** Theoretical model proposed by Pettigrew, based on a change model that articulates three central dimensions: the content of change, the change process itself and, in particular, the contexts (both internal and external) where change happens.

**HRM:** Human resources management.

**Interessement Process:** Measures aiming at favor investment (or mobilization) of all the parts in presence in a project.

**Key Success Factors:** Factors that, when considered, can favor the project success and, when neglected, can lead to project failure.

**Users' Involvement:** Various practices that associate users in the tools' conception and development processes. These practices lead to a better consideration of needs. They also constitute a good means to soften resistance to technical and organizational changes that accompany the introduction of ICT projects.

## INTRODUCTION

Business transactions require involvement from both customers and suppliers. This is the case whether the transaction takes place on-line or off-line or whether the transaction is businesses to business (B2B), businesses to consumers (B2C), or businesses to administration (B2A). At the beginning of the e-commerce era attention focused mainly on business to business and business to consumer relations. Today attention has shifted and the possible commercial benefits resulting from e-commerce with the public sector are now also on the agenda (Andersen, 2004; Coulthard & Castleman, 2001). Regardless of whether e-commerce is performed in a private or a public context, it is commonly assumed that e-commerce can lead to shortening of transaction time, lowering of costs, increased transparency, improved sharing and maintenance of enterprise information, and an increased internal and external efficiency of the organization (Zwass, 2003).

In this article we will focus on and use the term e-procurement to refer to the use of electronic means in purchasing processes. These processes include seeking information about goods and services and ordering and paying of goods (Andersen, 2004). A number of issues concerning e-procurement have been studied recently. Among these issues is the required architecture of e-procurement systems (Liao et al. 2003), the tendering process in e-procurement (Liao et al., 2002), and the possible economic gains achieved from public procurement portals (Henriksen & Mahnke, 2005.

Common assumptions for these studies suggest a pool of suppliers willing to offer goods and services through e-procurement channels as well as a concurrent demand for goods and services in e-procurement channels among public sector institutions. In the Danish context there has been some reluctance to adopt e-procurement among the public sector institutions (Henriksen & Mahnke, 2005). Whether this reluctance to adopt e-procurement is caused by the classic problem of who is to embark the marketplace first: buyers or suppliers (Bakos, 1991) is still to be decided. In this article the focus is on the challenges that suppliers to public sector institutions face. In recognition of the broad scope of issues that suppliers have to consider when including e-procurement in their business activities, a model has been developed for assessing e-maturity. The model is designed to embrace two aspects of e-maturity: the technological aspect and the organizational aspect. Whereas this article is conceptual in nature, the proposed assessment model is empirical, estimated in earlier work by Henriksen, Kerstens and Andersen (2004b).

## MATURITY MODELS FOR E-PROCUREMENT: FILLING THE ONTOLOGICAL VACUUM

The terms "maturity" and "immaturity" are often used to characterize a state of a given level in a continuous process. The terms are used relative to their objects, for example, "e-commerce is still in an immature state." This use of the term "immature" in relation to e-commerce creates an ontological vacuum since both the term and its object are somewhat fuzzy. The concept of e-commerce represents a plethora of aspects both related to organizational and technological issues as well as to business functions and supportive activities (Zwass, 2003). Adding the notion of maturity or immaturity does not strengthen the ontology of the concept. Some qualitative and/or quantitative measures to determine what characterizes different degrees of maturity are necessary.

There are a number of academic disciplines that use the term maturity and then develop maturity models as classification schemes. In the field of *software process improvement* the capability maturity model, a measure of maturity, is used to determine how structured the soft-

ware development process is (Paulk et al., 1995). Within the field of *business economics*, examples of explicit usage of the term maturity are found in the product life cycle concept (Lancaster & Massingham, 1993; Robson, 1997).

In the *information systems field* the term maturity is also familiar, for instance in the context of the "Stages of Growth model" (Galliers & Sutherland, 1991). The stages of growth model illustrates the organizational stage in a development process where the organizational usage of IT is measured. Whereas Galliers and Sutherland (1991) decomposed maturity into six stages with each stage characterizing the presence of particular attributes of the organization, the strength of the stages of growth model is in its focus on IT *and* organization. This overall typology of technology and organization is used as a point of departure in the further development of an e-maturity model where focus is on the organizational and technological capability and the readiness of suppliers to engage in e-commerce.

Before discussing some often used classification schemes based on maturity models, it should be acknowledged that not all researchers agree on the suitability of "evolutionistic" development models as a means for measuring IT capabilities in organizations (e.g., see King & Kraemer, 1984). Acknowledging this critique of maturity models, we stress that the four levels of our proposed model outlined in the following section do not appear as distinct stages in a practical setting. The four levels rather represent discrete points in a continuous development process in the organization. The four points should therefore be used as indicators for positioning the organization in the e-commerce landscape and not be regarded as absolute measures.

## THE FOUR MATURITY LEVELS

Our proposed assessment tool has four levels reflecting the four *stages* of maturity. The first level of maturity refers to a situation where the supplier has not realized any need for e-commerce. No changes due to shifts in environment or technology developments have affected the behavior of the organization. However, due to pressure from business partners some e-commerce actions may have been implemented.

At the second level the supplier uses one e-commerce channel, often an e-shop. Limited resources are invested and only small organizational adjustments have been made. Most business routines are still carried out manually.

The third level is characterized by an explicitly formulated e-commerce strategy where critical success factors have been outlined. More channels are used and the organization has changed some business routines. Investments in e-commerce are seen as opportunities for cost reduction and, at the same time, seen as a way to free resources for more service oriented tasks.

At the fourth level, the supplier uses several e-commerce channels. Individual customer support has a high priority. Manual routines are replaced by fully automated procedures. The aim is to achieve full integration of data internally in the organization and also to be able to provide integration of data to customers. E-commerce is now seen as a tool to increase customer and employee satisfaction.

## THE PARAMETERS OF THE ASSESSMENT TOOL

Each of the four maturity levels is assessed through estimation of a series of parameters. In the subsequent sections the seven parameters of the tool for assessment of e-maturity of a supplier are presented. The parameters are primarily based upon Galliers's *stages of growth model* (Galliers & Sutherland, 1991) and upon the *CIVO-VIDS (abbreviations for capabilities, interactivity, values, orientation-volume, integration, depth, spread) variables* (Andersen, Juul, & Larsen, 2001; Andersen, Juul, Henriksen, Bjørn-Andersen, & Bunker, 2000). The parameters have subsequently been adjusted specifically to assess e-maturity with respect to e-procurement. Each of the seven parameters is divided into four levels of e-maturity where each level represents a certain degree of maturity ranging from *immature* to *mature* e-commerce commitment. The seven parameters are described briefly in the following sections.

The parameter *strategy* relates to the visions and goals of the organization. Strategy is typically outlined by top-management with explicit expectations towards e-commerce. *Strategy* is thus an indication of the ambitions of a supplier with respect to e-commerce. A clear strategy is essential for achieving success in connection with all projects involving major organizational change (Davenport & Short, 1990), especially in connection with e-commerce projects (Rajkumar, 2001; Kalakota & Robinson, 2001; Neef, 2001). Kalakota and Robinson (2001) suggest a classification of strategy based upon the attitude of management towards technological advances and new market opportunities. According to this classification, the attitude can be categorized as: *visionary*, *pragmatic*, *conservative*, and *skeptical*. These correspond to the four strategies outlined by Ackoff (1974).

The parameter *e-commerce model* is defined as the specific electronic relation used to connect suppliers to customers. Based on the degree of innovativeness and the extent to which the applied *e-commerce model* is

*Table 1. Supplier strategies (Adapted from Ackoff, 1974)*

| | Passive | Active |
|---|---|---|
| Planned change | Inactive strategy<br>"Sceptical" | Proactive strategy<br>"Pragmatic" |
| Situated change | Reactive strategy<br>"Dynamic conservative" | Interactive strategy<br>"Visionary" |

*Table 2. Maturity levels and estimation parameters*

| Parameter | Level 1 | Level 2 | Level 3 | Level 4 |
|---|---|---|---|---|
| **Strategy** | *Sceptical*<br>No belief in the possible technological opportunities created by e-commerce | *Dynamic conservative*<br>Small investment and resource allocation<br>seen as a way to create value | *Pragmatic*<br>Result orientation where e-commerce incentives must fulfill the expectation | *Visionary*<br>Market leader where<br>e-commerce initiatives are independent of other companies |
| **E-commerce model** | *Conventional sales channel*<br>On-line presence | *Single channel (experimental)*<br>Often in the form of an e-shop | *External e-commerce models as a pilot project*<br>A single channel is expanded with distribution of e-catalogues to e-procurement systems and/or e-marketplaces | *Multiple digital channels*<br>Full use of and integration of e-procurement, e-marketplaces, and e-shop |
| **Process** | *No change*<br>Manual processes<br>Employee intensive sales process | *Adjusted*<br>New tasks are incorporated in the old process which is still dominant<br>Mostly manual tasks in the sales process | *Streamlined*<br>Eliminate unnecessary operations<br>Processes are streamlined<br>Reduction in process cycle time | *Innovative*<br>Process vision<br>Re-engineering<br>Value-added re-design of the sales process to gain more value<br>Dramatic changes<br>Incorporating new business opportunities |
| **E-catalogue** | *Digital catalogue*<br>Distributed via off-line means<br>Infrequent up-dating | *Content management*<br>Make internal product information external and available to customers<br>Manually prepared | *Automatically generated*<br>Frequent and online updating<br>Supports different standards | *Customized*<br>Contains product information based on customer demand<br>Is digitally handled |
| **Integration** | *No integration*<br>Printing of orders and messages<br>Manual handling | *Low integration*<br>Conversion of e-mail to ERP-system<br>Few document types<br>Manuel typing of data<br>Few entities | *Medium integration*<br>Replicating order information as a batch process between ERP and the e-commerce model.<br>No external integration<br>Several document types<br>Automatic<br>Many entities | *Full integration*<br>Digital transaction of information to ERP-systems<br>Buzz-talk (all document types)<br>Real time<br>Integration to the customer |
| **Organization** | *Conventional order-handling*<br>Do not use technological opportunities | *Parallel tasks*<br>Much manual typing of data<br>Employees create externally understandable product information<br>Transaction based operations | *Tasks related to product information on customer demand*<br>Education of the sales force<br>The employees learn new tasks and procedures in the e-commerce process<br>Reallocation of employees and reduction of the sales force | *Account management*<br>The sales force support different e-commerce models<br>CRM |
| **Management/ control** | *Individual*<br>Enthusiastic employees<br>Generally no recognition of needs | *IT department*<br>e-commerce is seen as an IT project | *Marketing*<br>e-commerce is seen as a commercial project | *Executive*<br>Interorganizational<br>e-commerce coordination |

functionally integrated (Timmers, 2000), four types of *e-commerce models* of relevance for suppliers of goods to public sector institutions can be identified: *online presence, e-shop*, *e-procurement*, and *e-marketplaces* (Rajkumar, 2001; Neef, 2001).

The parameter *changes of sales processes* includes all the different activities, routines, and procedures which occur in connection with sales activities. *Sales processes* can be divided into two main groups of processes: negotiating framework agreements and carrying out sales operations (Andersen, 2004). The extent to which the sales processes have changed with the introduction of e-commerce can be used as a general measure of the improvement of the effectiveness of the sales processes.

Hence, this can also be used as a measure of the decrease in the duration, as well as the costs, of the cyclical sales processes. The changes of sales processes which the supplier has undertaken to accommodate e-commerce can be categorized as: *no change, adjusted*, *streamlined*, and *innovative (*Ambeck & Beyer, 1999).

The parameter *e-catalogue* comprises a supplier's digital product information which can be divided into four stages: *digital, content management, automatically generated,* and *customized.* The digital catalogue is a basic representation of goods distributed via digital media, often in the form of a CD. In the next stage, where the supplier employs *content management*, more effort is put into the user interface. This is often a major challenge for suppliers (Heywood et al., 2002) because the product information is usually spread among several different systems and because the information can be difficult to understand for many customers. *Automatically generated* e-catalogues provide buyers with systematic product searching facilities. Continuous and precise electronic up-dating of the e-catalogue is automated. The most developed level of the e-catalogue is where the catalogue is *customized* to fulfill the particular needs of individual customers.

The parameter *integration* refers to the extent to which back-office systems are integrated with the front-office systems, and the flow of information (e.g., sales orders between internal organizational units of the supplier, as well as external autonomous units) is adequate and coordinated (Andersen et al., 2000). The parameter is measured on a scale with four levels, ranging from *no integration* to *full integration*.

The parameter *organizational changes* is a measure of the number of changes that occur in the organization as a consequence of e-commerce implementation. The parameter also includes possible down-sizing and shifts of responsibilities between various departments due to e-commerce. When sales procedures are digitized, new employee skills are required and job profiles may change. This, in turn, may lead to staff changes, employee replacements, the need for employee training, as well as new recruitment strategies. Likewise, the organizational culture is assessed, for example, down-sizing is likely to have negative effects on the organizational culture, thereby causing resistance from the employees towards the introduction of e-commerce. The scale of maturity with respect to organizational change ranges from conventional task handling to account management.

The parameter *management and control* measures the degree to which e-commerce is considered to be an integrated part of the organization by top-management, the marketing department, or the IT-unit, etc. The assessment of the parameter can be made by investigating the allocation of resources for e-commerce projects, the priority of e-commerce projects, and whether or not the e-commerce projects have got a strategic, tactic, or only operational status within the organization. Likewise, it is of major importance to know whether the e-commerce projects have been carried out as a result of managerial dispositions, whether decisions are made on departmental levels or initiatives are taken by a few enthusiastic employees. The scale concerning management and control comprises the following four parameters *individual, IT department, marketing,* and *executive.*

## DISCUSSION AND CONCLUDING REMARKS

The focus of this article is to identify a tool for measuring the maturity of e-procurement for suppliers of goods and services to public sector institutions. One issue that is compelling to discuss in this context is whether or not e-maturity is of higher importance in business-to-administration relations compared to business-to-business relations. The public sectors' e-procurement has characteristics which, in our view, require a high e-maturity level from the suppliers. An issue to be kept in mind is that public sector institutions purchase goods in order to provide a variety of services to citizens who are often very dependent on the services provided, for example, health care and education. Supplies of for example medicine in health care have to be in place when there is a need for it, though lack of supplies impedes production processes in the business environment it is rarely a matter of health or vigour if supplies are not in place as might be the case in the hospital system. In addition, many "production units" in the public sector are very dependent on basic supplies, often representing a marginal value compared to the cost of running the service. An illustrative example of this situation is in hospital service. The cost of rubber gloves is marginal compared to the cost of running the hospital, not mentioning the personal costs of cancellations due to a situation where the hospital runs out of stock of rubber gloves. This is apart from the fact that public institutions have close budgetary control and pay political attention to reducing costs (Henriksen & Mahnke, 2005). This requires advanced IT systems which are expected to improve efficiency. Although e-auctions as e-Bay has become a popular channel for procurement in the private households (Frei & Rodriguez-Farrar, 2001) because they provide an ideal competitive environment both for buyers and suppliers. However, based on the above-mentioned considerations on the requirements for timely delivery of supplies, e-procurement via e-auctions is not a suitable option for many public sector institutions.

Due to the need for controlling procedures, purchasing is ideally suited to electronic procedures (Liao et al., 2003). This requires transparency in all business processes, ideally through full integration of data. Public sector institutions buy commodities, which are mostly purchased repeatedly (e.g., office supplies, provisions, and nursery supplies). Ideally, e-procurement is supported by CRM systems (customer relationship management systems). CRM systems can furthermore support punctual delivery, often crucial due to the type of services performed by public sector agencies (e.g., eldercare, where nursery supplies have to be in place). These conditions speak in favor of highly structured processes within the suppliers' organization. The suggested parameters indicate that an organization operating at e-maturity level 4, where integration, customization, and real-time updating of product information is a must, has to be highly structured.

The point of departure in this contribution has been the individual supplier operating in the market. No distinction has been made between whether this market is the traditional market or if it is an electronic market (e-marketplace). In an e-marketplace suppliers and buyers are linked via electronic means typically based on an Internet interface where buyers log in and perform their transactions based on e-catalogues provided by suppliers. One trend which as been observed in the Scandinavian context is that the public sector takes its suppliers into an e-marketplace (Moe, Andersen, & Henriksen, 2005). By chosing this apporach the public sector can negotiate framework agreements embracing all institutions in a given unit. This approach is beneficial for buyers because it provides transparency and standardized purchasing information. The implication of the switching to e-marketplaces for the suppliers is that it is crucial that they operate on level 4 parameters in our e-maturity model with respect to the technological attributes.

Level 4 parameters are closely related to the technological attributes of e-maturity. However, given that organizational support and consensus are needed, powerful IT-systems alone will not be enough. It is therefore be stressed that the e-maturity model should be seen as a holistic framework, where organizational issues cannot be separated from technological issues.

## KEY TERMS

**E-Auction:** Defined as online organized processes of buying and selling by offering bid, taking bids, and selling products and services.

**E-Commerce:** Commercial activity that takes place by digital processes over a network as direct cabling, third party vendors (EDI), internet or mobile network.

**E-Marketplace:** A digital platform that enables multiple sellers and buyers to enter, perform business transactions, and exit.

**E-Procurement:** Digital business-to-business purchase and sale of supplies and services.

**Maturity Model:** Characterize a state of a given level in a continuous process.

## INTRODUCTION

An electronic government (e-government) is essentially an amalgam of interconnected heterogeneous information systems belonging to both government agencies and public and private sectors with a goal of modernizing the government's highly fragmented service-centric information infrastructure by improving information flow and the decision-making process (Joshi, Aref, Ghafoor, & Spafford, 2001a). The e-government environment also embeds the nation's critical infrastructures, that are required for providing the nation's basic services to the citizens (PDD, 1998), such as energy, telecommunications, banking and finance, and transportation facilities. The intricate connectivity of systems and their increasing dependence on IT dramatically magnifies the consequences of damages resulting from even simple system faults/accidents and intrusions, as well as natural events (fire, earthquakes, etc.), also collectively called *disruptions* (Ellison et al., 1997). A key challenge for such an infrastructure is to ensure continuous service availability to prevent financial losses, loss of prestige, endangerment of citizens' lives, and disturbances in national socio-psychological structures adversely effecting governance and democracy (Ellison et al., 1997; Gibbs, 1994; Moore, Ellison, & Linger, 2001). While it is essential that the e-Government infrastructure is resilient to disruptions, an even bigger concern is the protection of critical infrastructure components within the e-government. In essence, the e-government infrastructure should have the capability *to provide services in a timely manner, irrespective of disruptions*, a capability known as *survivability*.

## E-GOVERNMENT SYSTEMS SURVIVABILITY

The e-government survivability infrastructure should support both the intricate interdependence of government programs at different levels and between government and the private/public sectors, and address the need for continuity of its services in presence of disruptions. While such disruptions are inevitable in an e-government, key to its success lies on the effectiveness of mechanisms for detecting and responding intelligently to disruptions, which is a daunting challenge. Intelligent distributed capability is required to detect and counter both structured and unstructured disruptions that can be either in the form of intrusions or faults. Intrusions refer to the illegal access to a system by an intruder, whereas faults refer to the causes of physical failure of a system. Intrusions can be detected with the help of intrusion detection systems (IDS). IDSs report *anomalies* in behavior or recognize intrusion *signatures*. Faults can be detected but more importantly, methods for fault tolerance have to be implemented in the system. Fault tolerance is the ability of a system to withstand physical failure.

A survivability system needs to employ a combination of intrusion detection/prevention and fault tolerance methods. Separation between faults and intrusions, which have been studied separately, does not leverage the synergy existing between the two areas. This increases the overall cost of deploying measures against them, as well as the complexity of the overall system. Newly emerging coordinated, distributed intrusion detection techniques, coupled with data mining or stream mining tech-

*Table 1. Threats and their intent (Alexander et al., 1999)*

| Threat level | Actor | Intent |
|---|---|---|
| National security threats | Information Warrior (Cyber-soldier) | Reduce decision making capability at the national level, National chaos and psychological terror |
| | National intelligence (Cyber-spy) | Information leakage for political, military and economic advantages |
| Shared threats (government & Private sector) | Cyber-terrorist | Visibility/publicity, chaos, political changes |
| | Industrial espionage | Competitive advantage |
| | Organized crime (Cyber-crime) | Revenge, retribution, monetary gain, institutional/political change |
| Local Threats (Hacktivism) | Institutional hackers | Monetary gain, thrill/challenge, publicity/prestige |
| | Recreational hacker | Thrill, challenge |

niques show promise in improving the survivability capability of a large infrastructure like that of an e-Government system by facilitating real-time detection of and responding to disruptions.

## Disruption Categories for E-Government Systems

Disruptions to e-government services can be divided into two categories—*cyber disruptions* and *critical infrastructure disruptions*. Cyber-disruptions include cyber-terrorism, like NIMDA and the Code Red worms, and information warfare. Potential "*info weapons*" that can be used to launch an attack on an e-government include computer viruses, logic bombs, worms, Trojan horses, etc. (Alexander & Swetnam, 1999; Denning, 2001; Garfinkel & Spafford, 1997). Various attacks on systems include denial of service attack, virtual sit-ins and blockades, rootkits, etc. (Denning, 2001). The attacks using these malicious tools range from simple hacktivism, which refers to active hacking activities with the intent to disrupt normal operations but not causing serious damage, to the more damaging *cyber-terrorism* and *information warfare* (Alexander et al., 1999; Denning, 2001), which have become growing concerns post 9/11 era. Information warfare refers to the large-scale malicious activities launched by independent individuals or attackers hired by terrorists or belonging to rival countries. Cyber-terrorism is a more dangerous form of cyber-disruptions that can cause severe damage to the nation's systems (Denning, 2000). Even a simple, hour-long coordinated hacking activity that affects the country's air traffic system, a critical infrastructure, can have very drastic consequences for government operations. In a few years, the cyber-threats to the country is expected to be worse than the physical threat (Alexander et al., 1999).

*Critical infrastructure disruptions* could be some malicious attack, accident, or disaster causing critical infrastructure malfunction, which becomes a national concern. Protection of critical infrastructure is an important issue, because any disruption in their functioning would cause nation-wide chaos, for instance, the North-East Blackout of 2003 in the United States and Canada—a power failure over the Northeastern regions of the United States and Canada in 2003 that caused many systems dependent on the electrical grids to fail disastrously. The damage was estimated at almost U.S. $5 billion (Anderson et al., 2003).

Table 1 shows various threat levels and the criminal intent behind them (Alexander et al., 1999). At the highest level, we see national security threats, which are essentially aimed at the nation's critical infrastructures. Threats common to both government and non-government agencies include cyber-terrorism and e-espionage. Finally, there are frequently occurring hacking incidents that can create huge losses within an e-government environment. An alarming issue is the lack of awareness and ability to identify cyber-threats. Newer spamming and phishing attacks make survivability function more difficulty to implement (GAO, 2005).

At present, there is no nationally coordinated defense and survivability capability to detect and counter strategic and well-coordinated act of cyber-terrorism against the nation and to ensure the continuity of e-government services under cyber-siege. The U.S. National Infrastructure Protection Center (NIPC) is a program started by the Clinton administration in 1998 with an intention to maintain public and private sector infrastructure from disruptions of any sort and perform vulnerability checks regularly as preventive measures. Other nations such as Canada (PSEPC) and New Zealand have also taken to emergency preparedness and critical infrastructure protection. The Critical Infrastructure Protection project focuses on the impediments to the security and protection of the assets and addresses *public-private cyber-security cooperation, industry-academia consortium, knowledge management long-term high-risk cyber-security research.*

## AN ADAPTIVE E-GOVERNMENT INFRASTRUCTURE SURVIVABILITY FRAMEWORK AND ITS CHALLENGES

The key e-government survivability challenge is to synthesize a unified adaptive survivability framework (ASF)

*Figure 1. The adaptive survivability framework*

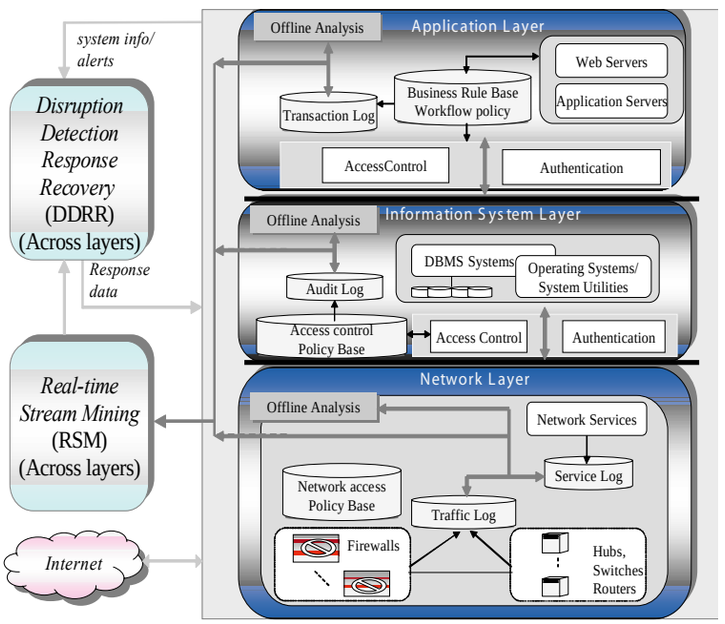

*Figure 2. The adaptive disruption detection, response, and recovery module*

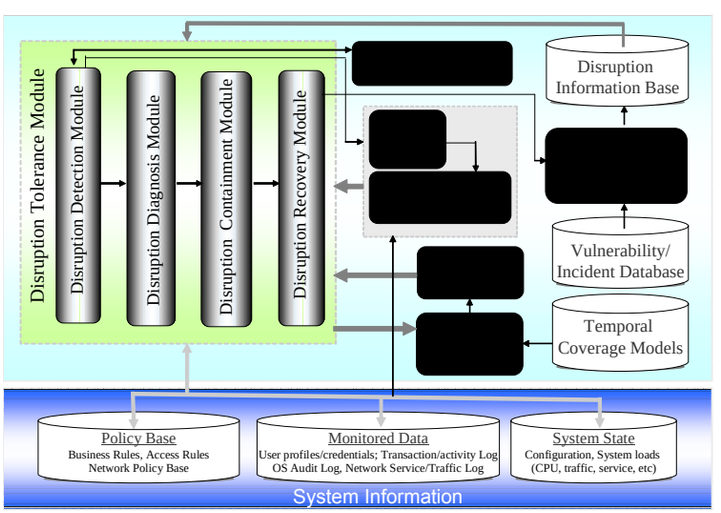


by integrating the best of breed, synergistic techniques in the fields of vulnerability analysis, intrusion detection, containment and response, and fault tolerance. In particular, these techniques for network, system, or application layers need to collaboratively work to generate a survivability framework that provides the following capabilities:

1. Efficient diagnosis of disruption, pinpointing the cause and determining or predicting its impact on the system. The diagnosis should provide support for choosing the best possible mechanisms for timely prevention, control, and recovery from a single, or multiple concurrent disruptions

2. Isolation of the effect of an impending or ongoing disruption, facilitating quick recovery and high availability of system functionality while the system is being disrupted
3. Utilization of prior knowledge in adapting to faster, more effective and economical methods of disruption tolerance. Adaptation also occurs in response to unpredictable environmental conditions

In this section, we present such an ASF for a generic system. A nation-wide extension of its key functionality is crucial to create an overall coordinated e-government survivability capability. The key component of the ASF is the adaptive, disruption detection, response, and recovery ($AD^2R^2$) module, (see Figure 2) which is responsible for correlating the events across the three architectural layers to efficiently detect the disruptions in the system and respond to them.

The three layer architecture captures a general separation of components within an application environment and include information resources (databases, files), utilities (SSH, Web service, FTP), computational resources (CPUs), and communication links (betwork card, routers, switches, etc.) organized at different layers. These components interact with each other to perform various activities, represented as transactions or events. Figure 2 depicts the functional architecture of the $AD^2R^2$. The thick arrows indicate the information exchange between each module, whereas the thin arrows indicate inter-module information exchange. The disruption detection module (DDM) analyzes system data to identify ongoing/impending disruptions with the assistance of the disruption classifier module (DCM). A set of predictive parameters are used by the disruption diagnosis module (DDiaM) to construct the containment boundary around components that have been affected by disruption. The disruption recovery module (DRM) is responsible for response and recovery actions. The coverage computation module (CCM) computes coverage for each of the four phases, and thus facilitates the determination of the efficiency and efficacy of the individual modules as well as the entire system.

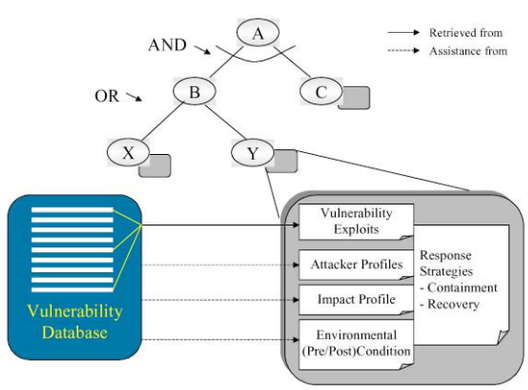
## Disruptive Information Base

A key challenge for the ASF entails the identification of taxonomic features of general classes of disruptions and representing them efficiently, in a disruption information base (DIB). Various publicly available databases related to security vulnerabilities and incidents, such as those maintained by the US-CERT, CERIAS-VD (Meunier & Spafford, 2002; Song, Mandujano, & Meunier et al., 2000), and BUGTRAQ, are available that contain volumes of vulnerability information that needs to be properly used to generate a knowledge base of disruptions. These databases provide important information related to known software vulnerabilities, such as the impact of the exploitation of a flaw, the types of objects that are directly or indirectly affected by the exploitation, and the fixes that are available. Existing characterization of attacks and intrusions are ad-hoc, unstructured and restricted. For example, a denial of service attack does help us to understand the nature of the attack, however, what impacts it has on different parts of the target system is vague. Furthermore, a unified classification of faults and intrusions is needed.

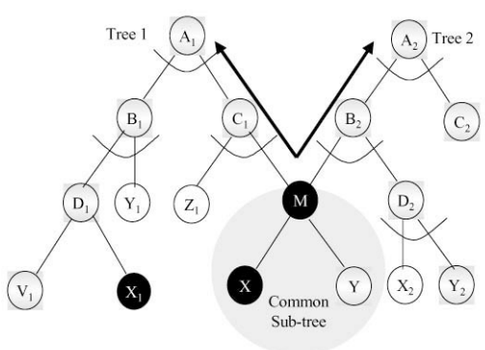
A promising approach is the representation of the disruption classes using AND-OR trees (Schneier, 2000). The root of a disruption tree represents an ultimate attack goal or a major system failure and its children represent different disruptions that must collectively (*AND*-decomposition) or alternatively (*OR*-decomposition) occur for the major disruption to occur. For example, Figure 3(a)

*Figure 3. A disruption tree (a) with associated information (b) with a common sub-tree*

*a.*



*b.*



depicts a simple attack tree for attack type A. The model can be expanded to include two key parameters that are associated with each node in the disruption tree, and are computed by the parameter computation module (PCM):

- $P_s(d|D)$—Probability of occurrence of disruption $d$ given the occurrence of disruptions $D$
- $T_m(d|D)$—Propagation time of $d$ given the occurrence disruptions $D$

Computation of $P_s$ and $T_m$ is based on monitored real-time data. The trees need also be augmented with the following information: (1) system vulnerabilities, (2) attacker profile, (3) system state, (4) impact profile, and (5) response strategies. In particular, a crucial issue is an efficient modeling of attacks and attackers, which is the function of the attacker profiler module, to capture attack objectives and strategies. Determining efficient and cost-effective countermeasure against a disruption will depend on the $P_s$ and $T_m$ values associated with the disruption node and the cost the response strategies. In scenarios where two disruption trees have a common node, (e.g., node M in Figure 3(b)), choosing the response strategy will involve more complicated decision-making. For a robust ASF, it is crucial that the DIB contain detailed information about response strategies for each disruption class.

Most existing classification schemes focus primarily on classifying security vulnerabilities. Attacker modeling has been addressed in (Avizienis, Laprie, Randell, & Landwehr, 2004; Bagchi et al, 2000; Ellison et al., 1997; Moore et al., 2001), but no formal model has been proposed. Some model checking approaches have been used to generate attack/fault trees (Moore et al., 2001; Schneier, 2000). However, these models rely on exhaustive knowledge of system states and have serious complexity problems.

## Adaptive Disruption Detection, Response, and Recovery

Development of a real-time collaborative disruption detection framework that analyzes monitored data and the disruption trees is another significant challenge for an ASF. Multiple detectors should be employed at different architectural levels and their results correlated to detect disruptions accurately. Traditional intrusion detection techniques lack real-time capabilities essential for timely response in emerging systems because of the need to analyze a huge amount of log data. In such a case disruption, management requires real-time continuous monitoring and intelligent analysis of event data streams to detect impending/ongoing disruptions.

### Real-Time Mining of Transactional Audit Trail for Disruption Detection

Stream mining, a newly emerging data analysis and mining paradigm, encompasses mining potentially infinite amount of continuously arriving data at a variable rate. Mining event data streams poses many new challenges as such streams differ substantially from traditional data. While traditional databases assume that exact mining results can always be obtained as data elements are synchronized, streams data is often lost, stale, or intentionally omitted for processing reasons and so mining results must be computed with incomplete information. Furthermore, traditional databases assume that applications require no real-time services whereas event data streams are real-time by nature. Therefore, the challenging task of mining such streams is to develop online incremental data mining techniques that operate on incomplete data, or alternatively, data summaries, yet that can obtain "good" results. Research in mining data can significantly enhance real-time detection.

### Disruption Diagnosis and Containment

The goal of the DDiaM is to identify and enforce a *disruption containment boundary* (DCB) so as to prevent the propagation of disruptions. Once the DDiaM identifies that one or more of the sub-goals in the disruption sub tree have been achieved, it queries the DIB to determine the propagation time for a higher-level goal and the post-condition of the particular phase of the disruption to construct the DCB. DCBs may be composed of services, a node, a layer within a node, a component/sub-component within a layer. The diagnosis will also obtain the latency of the detection mechanism that triggered the diagnosis phase.

### Response and Recovery

This phase recovers the system from the effect of the disruption and/or initiates counter-measures, and prevents future disruptions. Response may involve downgrading the trust level of the system. Vulnerability prevention in an automated manner is difficult. The recovery infrastructure also provides feedback to the disruption tree. If the suggested recovery from the current DIB is not successful, alternate recovery strategies are attempted and the node in the disruption tree is re-labeled with the successful recovery strategy. A key challenge is handling multiple simultaneous disruptions as it requires analyzing the dependencies among different disruption classes.

### Cost-Based Adaptability and Coverage Computation

Another key challenge is the development of various cost-based recovery strategies that can be used to recover the system's normal or good state after a system disruption has been detected. These techniques will aim to achieve an acceptable level of survivability in presence of ongoing disruptions. It is crucial to develop cost-based models for adaptively guiding the response to system disruptions, based on risk analysis. The CC module computes coverage for each of the four phases facilitating the determination of the efficiency and effectiveness of the different modules. The CC module needs to be augmented by cost-based models to adaptively guide the response capability of the system. The key challenge is ensuring that acceptable values of key metrics such as survivability are achieved at the desired cost.

Several IDSs exist in the literature, such as in (Habib, Hafeeda, & Bhargava, 2002; Kerschbaum, Spafford, & Zamboni, 2000; Kumar & Spafford, 1994; Reynolds et al., 2002). Some work on isolation of sub-systems targeted by attacks through cutting the connections to them has been shown in (Reynolds et al., 2002). There have been several systems that provide adaptive fault tolerance in distributed systems through a middleware layer. Chameleon (Kalbarczyk, Iyer, Bagchi, & Whisnant, 1999) and AQuA (Ren et al., 2003) are two recent examples that focus on tolerating different classes of faults. Some existing adaptive intrusion detection systems include (Hinton, Cowan, Delcambre, & Bowers, 1999; Ragsdale, Carver, Humphries, & Pooch, 2000).

## CONCLUSION

In this article, we have presented the e-government infrastructure survivability challenges and motivated that the success of an e-government system is dependent on how resilient it is to the continuous onslaught of intrusions and faults, as any disruption can have severe impact on national security and effective governance. It is crucial that an e-government system has a coordinated, adaptive capability to analyze, diagnose, and timely respond to impending/ongoing infrastructural disruptions. We have presented an adaptive survivability framework for a generic system that integrates the synergy among different technologies to synthesize coordinated and efficient defense capability. Such a framework needs to be implemented to create a dependable, secure, and survivable e-government infrastructure.

## KEY TERMS

**Critical Infrastructure:** An infrastructure containing systems, assets, and services which a country's economy and society depend on.

**Disruption Containment:** Controlling the propagation of the effects of a disruption to other parts of the system.

**Disruption Signature:** A sequence of events by which a disruption can be recognized.

**Disruption:** A system failure or intrusion that prevents the normal operation of a system.

**Intrusion Detection Systems:** Systems that can identify ongoing/impending system intrusions by recognizing intrusion signatures or anomalous system activities.

**Stream Mining:** An emerging data analysis and mining paradigm that can be applied to potentially infinite amounts of continuously arriving variable rate, real-time, asynchronous event data streams.

**Survivability:** The ability of a system to maintain its functionality even when disruptions occur.

# Tax Proposal Service of the Finnish Tax Authority

## INTRODUCTION

Taxation is one of the key functions of any state. Without a working tax collection system, any state would have big difficulties in fulfilling its responsibilities. Even though taxation is a service with negative demand (Kotler, 1997) at an individual level, most taxpayers admit that taxation needs to be done. As an unpleasant issue, it should be taken care of as efficiently and with as little effort as possible needed from the taxpayer's side.

Our article, as well as the tax proposal system to be introduced, focuses solely on the personal income tax. The idea of the tax proposal system is to take away the hard work from the taxpayer: He or she does not have to work out anything for the taxation purposes in the normal case. The taxpayer's role is rather to accept the taxation information and decision that is given to him or her, or to demand changes to the taxation. In that case, he or she has to deliver the evidence. In the long run, the Web-based interfaces are too on the Finnish tax-authority's (shortly referred to as taxman in the rest of this article) development list.

Taxation is a very information intensive activity. It needs the support of huge information and other systems. Introducing changes to this environment, which is also heavily regulated, is a demanding task. Yet the efficiency and effectiveness of the taxation system is a key success factor for any state, and innovations are needed in a constantly changing environment.

As many countries try to create Web-based tax return arrangements (Vassilagis, Laskaridis, Lepouras, Rouvas, & Georgiadis, 2003), Finland has chosen another strategy to streamline the taxation process. In Finland, the interface to the final taxpayer, to the individual, remains so far paper-based, but massive system integration between the systems of the tax authority and the various payers of salaries and other income to the final taxpayer has been established.

In this article, we tell how the Finnish tax proposal system works, how tax authorities have been able to develop and introduce the tax proposal system, and what kind of benefits it has brought to the taxman and to the taxpayers.

We represent that the tight information system integration in one governmental agency does not give competitive advantage. The integration has to go much deeper and wider into intergovernmental networks (G2G) and government to business networks (G2B) (Scholl, 2004).

Our main conclusions are:

- Citizen-oriented process design and system development can give efficiency and effectiveness benefits for administration too. The Finnish approach of first streamlining the taxation processes and regulation and then later giving electronic access to the taxpayer to the taxation data is sensible.
- To get the systems automated and processed streamlined, has meant that the very structure, process and basis of taxation has been changed in some details. A Finnish success factor has been that political decision makers have let this happen.
- The Finnish approach has been possible because of a wide nationwide consensus and co-operation. The selected approach has benefited from the trust the taxman and other authorities enjoys in the society. The new system further strengthens the goodwill of the taxman among taxpayers. There is a positive interaction going on.
- Adam Smith's over 200 years old principles of good taxation are easily implemented with computerized taxation methods.
- The massive system integration effort on the background has cost a lot, not just to the taxman but to the employers and many other parties too. However, all parties have seen the increased efficiency of taxation worth the investments.
- Information systems with clear strategic advantage take years if not decades to mature. This has too been the case with the Finnish taxation system.

## BACKGROUND

Finland has been number one in the list of less corrupted countries for years. In Table 1, countries which are less corrupted are listed. Citizens trust the Finnish public administration in general and the authorities have understood that trust generation and maintenance demands an ongoing process which has to be catered for (OECD, 2003).

The trust towards authorities in general and the taxman in particular has been a key success factor in Finland. Citizens can be sure that everyone is taxed on the same basis of rules and that the paid money will go to the intended recipients. The outcome of taxation is public, and anyone's paid taxes and the key figures leading to the taxation are public data that can be accessed by anyone. As compared to many countries with federal structures, Finland has it easy: there is just one taxation basis. In addition, citizens and companies conform to laws relative literally. The size gives some flexibility too: in Finland there are only 5.3 million inhabitants.

Finland has also performed well in the lists comparing ICT infrastructures in different countries, as presented in Table 2.

Table 2 is based on relatively gross data on some basic network technologies. Deeper in the background is the fact that Finland is a cashless society, where all parties are used to electronic money transfers. These always leave behind the documentation needed even for the taxation purposes. At a concrete system level, employers are, for example, used to EDI-type and later Web-based connections to banks and have the needed expertise and infrastructure. It has not been a big step to adapt the same resources to connections to the systems of the taxman. The well-functioning Finnish banking network is a cornerstone for the tax-related money traffic (Kallio, Mallat, Riipinen, & Tinnilä, 2005). Currently all taxation related money transfers are made by electronic account transactions.

The system we discuss here is a result of a long development. If we take a historical perspective, Finland has been able to collect the best parts (and maybe some of the worst too) of the administrative systems of both the Swedish and Russian empires, as Finland has been a part of both empires before the independence gained in 1917.

Another part of the development is evolution of information systems. Already as early as 1947 the first punch card-based computers were installed to the Finnish tax authority premises. In the 1980s a real investment boom occurred, and ICT investments in the Finnish taxation grew 18-fold in the period between 1980 and 1987 (Lehtinen, 1995).

One essential issue to develop taxation systems is the Finnish labor market system and the large-scale cooperation within it. Government has traditionally taken part in the income settlement negotiations which are not focused on wage issues only. Taxation and developments in working life have also been topics for many years.

In Finland, labor union membership fee is directly deducted from wage of the labour union members[1] by the employer and employees can deduct the fee from the taxes. The clearance of these union membership payments has then been sent to labor union and to the tax authority. Again here we have detail that has been contributing to the system integration built.

What anyway is maybe the most important development is the system integration between the different taxation interest groups. Those are banks, employers, private pension institutes and other government agencies (especially Population Register Centre, National Board of Patents and Registration and Social Insurance Institution).

## CHARACTERISTICS OF GOOD TAXATION

Adam Smith (1723-1790) was one of the first to pay attention to good taxation principles. His recommendations for good taxation still hold today (Smith, 1993):

- **Equity:** Every subject of the state ought to contribute towards the support of the government, as

nearly as possible, in proportion to their abilities; that is, in proportion to the revenue which they enjoy under the protection of the state.

- **Certainty:** The tax which every individual is bound to pay ought to be certain, and not arbitrary. The time of payment, the manner of payment, the amount to be paid, ought all to be clear and plain to the contributor, and to every other person.
- **Convenience:** Every tax ought to be levied at the time, or in the manner, in which it is most likely to be convenient for the contributor to pay it.
- **Economy:** Every tax ought to be so contrived as both to take out and to keep out of the pockets of the people as little as possible, over and above what it brings into the public treasury of the state.

## THE FINNISH TAX PROPOSAL MODEL

The functioning of the Finnish tax system is described in Figure 1.

The basis of the system is that the employer collects the income tax directly from the salary, and the employee just gets to his or her bank account the net income, also the income without taxes.

On the basis of the earlier income and many other factors every citizen is given an individual tax-withholding rate that the employer uses for the tax-collecting purposes. This system is psychologically easy to accept: you as a taxpayer in principle never owe to the taxman.

The tax money collected by the employer goes monthly to the tax authority with a notification. Whether or not this happens orderly is not a headache of the employee, the final taxpayer. In addition and for security purposes employers make a yearly notification.

In Finland there are two electronic possibilities to send statutory employees' notifications. Big and medium size companies have sent their wage and collected tax information mainly through XML-based broker systems that are integrated into the TYVI application. For firms with 1-5 employees a new Web-based system Palkka was published in 2005. The electronic notifications carried by these systems are called Employees' e-notifications.

The tax authority forwards the collected tax to the tax recipients, also state, municipalities, parish, and Social Insurance Institution.

The hard part of the system is the collection of data from other sources. Citizens, for example, collect incomes from capital investments, and enjoy many different taxable social benefits. The taxation system too allows citizens to draw reductions on taxes. The most important reduction is interest of the mortgage. Information on all these issues should be collected in order to make the tax proposal exact.

After processing all this information, the tax authority yearly, in May, sends the tax proposal to the taxpayers. This comes in as classical mail. The tax proposal contains a comprehensive and detailed list of the taxpayer's income, reductions on tax, paid taxes and other relevant data connected to taxation, and a final

*Figure 1. The Finnish Tax proposal flow of activities*

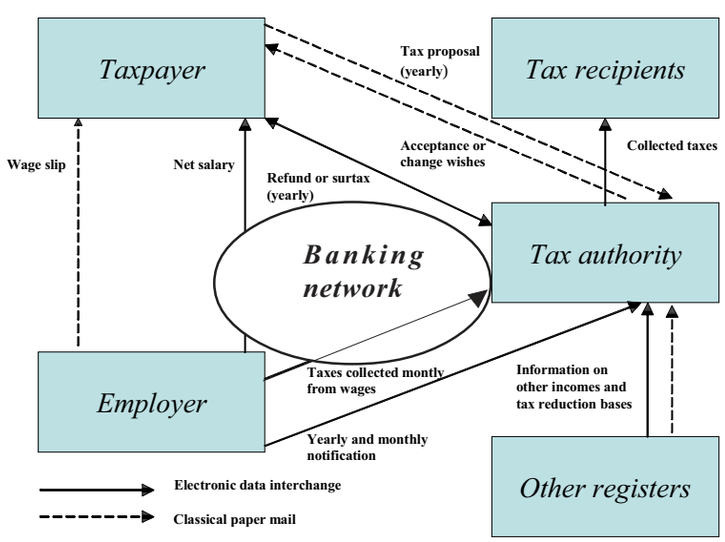

*Table 3. Some statistics about Finnish personal taxation (National Board of Taxes, 2003, 2004)*

| Year | Taxman's Used Person-Years | Cost of Personal Taxation for the State | Number of Tax Proposals Sent | Tax Proposals of Total Personal Taxation Cases | Returned Tax Proposals of Sent Tax Proposals | Number of Employees' E-Notifications Received by Taxman |
|---|---|---|---|---|---|---|
| 2000 | 6, 265 | 95 M• | 3, 002, 000 | 70 % | 25 % | 540, 000 |
| 2001 | 6, 270 | 102 M• | 3, 037, 000 | 70 % | 26 % | 725, 000 |
| 2002 | 6, 323 | 112 M• | 3, 094, 000 | 70 % | 24 % | 1, 420, 000 |
| 2003 | 6, 297 | 109 M• | 3, 127, 000 | 70 % | 24 % | 1, 980, 000 |
| 2004 | 6, 300 | 110 M• | 3, 140, 000 | 71 % | 25 % | 3, 136, 573 |

calculation based on those. If the taxpayer accepts the tax proposal, he or she does not have to do anything. If he or she wants something to be changed, he or she can apply for that. Currently 70% of all tax returns are made with tax proposal method. Only one quarter of tax proposals were returned to the tax authority.

Depending on the final outcome, the taxpayer will get the tax refund back to his or her bank account later or will get a bill on the unpaid part of the taxes (surtax)[2]. The goal of the taxman is to minimize these transactions, and often they are not needed at all. The tax collection mechanism is quite accurate: average tax refund was 450 • and surtax 930 • in 2003. The net effect of this is only 2.1% of wage earners total taxes (National Board of Taxes, 2003).

Taxes are collected very efficiently in Finland. The costs of collecting one Euro of personal income taxes costs just 1.43 cents for the taxman (National Board of Taxes, 2004).

In Table 3, we have some information on the Finnish taxation system key figures in years 2000-2004 in the field of personal taxation. As can be seen, the amount of used man-years has remained quite constant. Costs have anyway risen partly because of investments in information systems. During this period, the tax proposal system has been established, and no further coverage was aimed at, because the system had to be tested and fully integrated. For the taxation of year 2005, a full 100% coverage is aimed at. This means for example that taxpayers with entrepreneur income will be included to the system. As can be seen from the table, during the period 2000-2005 employers have taken into use electronic systems for delivering employee notifications to the tax authorities, their amount is more than fivefold in year 2005 as compared to year 2000.

There is a principal discussion whether the taxpayer should anyway sign the tax proposal and return it, or not. Currently this is not demanded if no changes are demanded by the taxpayer, but demanding a signature would put the taxpayer more in charge of the issue, and would stress that it is at the very end also his/her responsibility that the taxation is right performed.

## CONCLUSION

If you automate a messy system, you get an automated mess. The Finnish government has given a lot of priority to the streamlining of the taxation processes. Taxation data must first be brought to a high quality level. Giving Web-based access to deficient data would just add to confusion and extra work.

To get the systems automated and processed streamlined, has meant that the very structure of taxation has been changed in some details. A Finnish success factor has been that political decision makers have let this happen. The ministry of Finance has been able to keep the needed development process on the right track, even though different political ambitions regarding taxation have emerged now and then.

The taxation system is a very visible and concrete part of public administration for the citizens. If it is performing well the citizens' general acceptance of and respect for the public administration is increased. The selected approach has benefited from the trust the taxman enjoys in the society, and the new system further strengthens the goodwill of the taxman among taxpayers. There is a positive interaction going on. Citizens find taxation-related tasks a nuisance, and are happy to get rid of them. This can of course just happen in an environment where the citizen can be sure that the taxman is not trying and going to betray him or her is some way. A part of this is that the mistakes even negative to the tax collector are too automatically corrected.

The massive system integration effort on the background has cost a lot, not just to the taxman but to the employers and many other parties too. However, all parties have seen the increased efficiency of taxation worth the investments. The most costly way would be having everything on just papers, and coming back to the issues again and again because of deficient information flows. This situation of the time before computers is something no one wants to return to.

Information systems with clear strategic advantage take years if not decades to mature. The Finnish tax-

proposal system has been constructed over decades, and small but planned steps have finally allowed the current level of sophistication.

We can take a look at the system evaluating it on the basis of the recommendations by Adam Smith presented above. Our conclusions here are:

- **Equity:** The goal of bringing 100% of citizens to this system will make citizens very equal. Every wage earner will be handled with the same rules by the system.
- **Certainty:** The tax proposal system will increase certainty as everything is verified against different registers.
- **Convenience:** The system is very easy for the taxpayer. In the best case, he/she has to do nothing.
- **Economy:** When fully operating the system should reduce errors and double work efficiently, and so contribute to the economy of taxation.

The Finnish tax proposal case proves which benefits can be achieved when having tight BtoG and GtoG integration. It shows too how citizen can utilize e-taxation without a Web-based tax return system.

## FUTURE TRENDS

The Finnish income tax system is not ready. Certain goals for the future system are already published; some are still at an idea phase. The goal for the taxation on year 2005 is to expand the coverage of the tax proposal to cover the whole of the population. To obtain this, reporting on occasional incomes and rights for tax reductions to the systems must still be developed. Same tax legislation has to be chanced in order to be corresponded with new process.

The tax process innovations haven't decreased dramatically the amount of tax personal. The Finnish tax authority's aim is achieve 5 000 employees level by year 2012.

The vision of the future is a tax-account, like the one we have in banks. Citizens, as well as the tax authority, would have real-time on-line accounting of due and paid taxes, and a balance would be visible all the time. Taxpayers could arrange their payment schedules themselves and inform themselves of their tax account status all the time through Internet. A prerequisite for this would be good working systems for citizen identification on the net, say through an ID-card. A lot of further system integration work is needed on the tax authority's side, as well as issues with re-engineering process, tax legislation, and organization.

## KEY TERMS

**Employees' Notification:** Employers deliver information of paid taxes and wages at individual employee level. Employee identification is made with a personal ID code. Electronic declarations are forwarded by TYVI or Palkka systems and they are called Employees' e-notifications. In Finland these notifications are made on a monthly and yearly basis.

**Government to Business (G2B):** Rationalizes exchange of information and transactions between government and business, the government being the more active part. G2B is also referred to with acronyms g2b or GtoB.

**Government to Government (G2G):** Inter- and intra-governmental transactional and informational system integration. The aim is to create new services and rationalize governmental processes. G2G is also referred to with acronyms g2g or GtoG

**Palkka:** Payroll and statutory declaration system for small size employers. Employers with 1-5 employees can pay their wage, tax, insurance, and pension payments with the system. In the same way they can make the declarations. The service is free. A Web-based application.

**Tax Proposal:** Precomplemented citizen's tax declaration delivered by the tax authority.

**TYVI:** Statutory authorities' declaration system for big and medium size employers. Provides companies with an electronic channel for making statutory declarations to authorities, insurance, and pension companies. The information transfer is based on XML-technology. Most of Finnish payroll applications are integrated into it.

**Extensible Markup Language (XML):** A computer language, designed to improve the functionality of the Web by providing more flexible and adaptable information identification. XML is a formal specification of the World Wide Web Consortium.

## ENDNOTES

1 Labor union membership is voluntary in Finland, but the membership rate is very high in most professions.

2 It might be worth noting that in Finland, every citizen and company has a clear identity marked with unique identification code. This is even given to foreigners having a permanent stay in Finland. Further, citizens have no difficulties in having a bank account and giving its number to the tax authorities. Every citizen too has a permanent address. These conditions might not be available in all countries.

# Technological Innovation in Public Organizations through Digital Government

**Charles C. Hinnant**
*U.S. Government Accountability Office (GAO) and Center for Technology and Information Policy (CTIP), Syracuse University, USA*

**Steven B. Sawyer**
*The Pennsylvania State University, USA*

## INTRODUCTION

The rapid adoption of computer networks, such as the Internet and the World Wide Web (WWW), within various segments of society has spurred an increased interest in using such technologies to enhance the performance of organizations in both the public and private sectors. While private sector organizations now commonly employ electronic commerce, or e-commerce, strategies to either augment existing business activities or cultivate new groups of customers, organizations at all levels of government have also begun to pay renewed attention to the prospects of using new forms of *information and communication technology* (ICT) in order to improve the production and delivery of services. As with many technologies, the increased use of ICT by government was in response not only to the increased use of ICT by government stakeholders, such as citizens or businesses, but also in response to a growing call for governmental reform during the 1990s. As public organizations at the federal, state, and even local level began to initiate organizational reforms that sought to bring private sector norms to government, they often sought to employ ICT as means to increase efficiencies and organizational coordination (Gore, 1998; Osborne & Gaebler, 1993). Such attempts to reform the operations of public organizations were a key factor in promoting an increased interest in use of new forms of ICT (Fountain, 2001). This growing focus on the broader use of ICT by public organizations came to be known as *digital government*.

The term, *digital government,* grew to mean the development, adoption, and use of ICT within a public organization's internal information systems, as well as the use of ICT to enhance an organization's interaction with external stakeholders such as private-sector vendors, interest groups, or individual citizens. Some scholars more specifically characterize this broader use of ICT by public organizations according to its intended purpose. Electronic government, or *e-government,* has often been used to describe the use of ICT by public organizations to provide programmatic information or services to citizens and other stakeholders (Watson & Mundy, 2001). For example, providing an online method through which citizens could conduct financial transactions, such as tax or license payments, would be a typical e-government activity. Other uses of ICT include the promotion of various types of political activity and are often described as electronic politics, or *e-politics*. These types of ICT-based activities are often characterized as those that may influence citizens' knowledge of, or participation in, the political processes. For instance, the ability of an elected body of government, such as a state legislature, to put information about proposed legislation online for public comment or to actually allow citizens to contact members of the legislature directly would be a simple example of e-politics.

However, ICT is not a panacea for every organizational challenge. ICT can introduce additional challenges to the organization. For example, the increased attention on employing ICT to achieve agency goals has also brought to the forefront the potential difficulty in successfully developing large-scale ICT systems within U.S. government agencies. For example, the Federal Bureau of Investigation's (FBI) recent announcement that it may have to scrap its project to develop a Virtual Case File system that was estimated to cost $170 million (Freiden, 2005). The adoption of new ICT is often marked by setbacks or failures to meet expected project goals, and this characteristic is certainly not limited to public organizations. However, adherence to public sector norms of openness and transparency often means that when significant problems do occur, they happen within view of the public. More significantly, such examples highlight the difficulty of managing the development and adoption of large-scale ICT systems within the public sector. However conceptualized or defined, the development, adoption, and use of ICT by public organizations is a phenomena oriented around the use of technology with the intended purpose of initiating change in an organization's technical and social structure. Since the development and

adoption of new ICT, or new ways of employing existing ICT, are necessarily concerned with employing new technologies or social practices to accomplish an organizational goal, they meet the basic definition of technological innovations (Rogers, 1995; Tornatsky & Fleischer, 1990). If public organizations are to improve their ability to adopt and implement new ICT, they should better understand the lessons and issues highlighted by a broader literature concerning technological innovation.

## TECHNOLOGICAL INNOVATION AS A THEORETICAL FOUNDATION FOR DIGITAL GOVERNMENT

Since the adoption and use of ICT by public organizations can be considered a form of technological innovation, studies examining various aspects of the development, adoption, and eventual routinization of new technologies may illuminate the social and technological factors that influence digital government initiatives and strategies. Researchers often describe technological innovation in terms of loose overlapping stages or steps. Some conceptualizations of the innovation process include up to five progressive stages: awareness, matching, adoption, implementation, and routinization (Tornatsky & Fleisher, 1990). Other researchers have collapsed these five stages into just two broad phases, initiation and implementation, because each of the two stages is influenced by different factors (Damanpour, 1991). The initiation stage includes activities such as problem perception, information search, attitude formation, and the attainment of resources. Implementation includes activities such as modification of the technology or practice, the adjustment of necessary organizational practices or operations, early use and more routine use of the innovation. Regardless of the actual number of stages in the innovation process, it is important to note that the process may, or may not, occur in a linear fashion, and all innovations may not experience each stage. In fact, some research specifically highlights the occurrence of setbacks, and even reversals, with regards to the innovation process (Rogers & Agarwala-Rogers, 1976; Tornatzky &Fleischer, 1990).

While the broader process of technological innovation is often described in terms of stages, the interaction of the actual technology with the social and technical factors of the organization plays an important role in how the innovation will progress. A technology's particular characteristics strongly influence whether or not a particular technology will be adopted and implemented by a particular organization. While studies of innovation have examined numerous technologies, relative advantage, ease-of-use, and compatibility of the respective technology seem to be repeatedly linked to whether or not a particular technology will be adopted by an organization (Tornatzky & Klein, 1982). The extent to which a particular technology alters current organizational processes or outputs also plays a key role in the innovation process. So-called, radical innovations usually involve a major transformation of an organization's processes or outputs, and/or significantly impact the organization's key stakeholders (Dewar & Dutton, 1986; Ettlie, Bridges, & O'Keefe, 1984). Radical innovations are clear departures from an organization's technological norms and, therefore, generally experience more risks for failure or setbacks than do technological innovations that involve only slight changes in an organization's current technological environment.

Several key types of organizational factors seem to influence the process of technological innovation. These include awareness or knowledge of the innovation, available resources, ties to the external environment, and organizational structure (Rogers & Agarwala-Rogers, 1976). During the initial stages of the innovation process, the organization must detect some need to use a new technology to alter organizational processes and performance, and must be aware of the potential advantage of employing a particular technology. This awareness may come in the form of personnel within the organization or from external experts, but the organization must be able to both detect the need to undergo technologically grounded change and match that need to a new technology that already exists or will be developed. Once the need for a technological innovation exists, the organization must then have enough resources to acquire the technology and integrate it into organizational processes. Resources may come in the form of expertise already possessed by an organization's personnel, existing technologies and technical infrastructure, or the financial assets required to attain such resources from outside the organization itself.

In addition to the role of knowledge and resources, an organization's structural arrangements can also play an important role in successfully adopting and developing new technologies. For instance, organizations with high levels of structural complexity, less formalization, and low centralization tend to adopt more technological innovations than do organizations with high levels of formalization and more centralized structural characteristics (Damanpour, 1991; Duncan, 1976). This does not mean, however, that such factors automatically promote the successful implementation of new technologies, since in some situations successful implementation often requires the resources and support of key organizational personnel, such as senior managers. Such support and attention might be available more readily in organizations with more formal and centralized organizational structures because senior managers may play a more central, and visible, role

in supporting organizational initiatives (Rogers & Rogers-Agarwala, 1976; Wilson, 1989).

Closely tied to the issue of organizational structure is how closely the organization is tied to its external environment. An organization that is tied closely to its external environment through legal or market mechanisms may more readily perceive performance shortfalls and, therefore, have a heightened awareness for the need for technological innovations. In addition, such ties to the external environment may also facilitate awareness of new technologies that may be applied in an attempt to implement technologically based change. Furthermore, organizations that have relatively porous boundaries with their external environment, and which are accountable to stakeholders within that environment, will be more likely to be innovative than organizations with more stringent boundaries. Organizations will, in fact, attempt not only to adapt to meet demands emanating from its external environment, but to control them (Thompson, 2004).

Taking these broad points into consideration, an organization's ability to successfully adopt, implement, and use new forms of technological innovations, such as ICT, seems to be an interactive result of various socio-technical factors arising from the technology, resources, organizational structure, and ties to the external environment. It is important to note that technological innovation is not an inevitable process that must take place or that must successfully move through a progression. An organization may never initiate the innovation process or the innovation may end at any one of the stages. Furthermore, it is important to understand that organizations may not make decisions in a hyper-rational manner during the innovation process. They act within a form of bounded rationality that results from limits in information about the innovation process and their ability to process what information is available (March & Simon, 1958; Simon, 1976).

## APPLYING KNOWLEDGE OF TECHNOLOGICAL INNOVATION TO STRATEGIES OF DIGITAL GOVERNMENT

Studies of technological innovation have already led to more specific theories of innovation that focus on the acceptance of ICT by individual users. For instance, the Perceived Characteristics of Innovating (PCI) draws upon Rogers' theory of innovation diffusion (1995) to develop a means to evaluate an adopter's perception of ICT (Moore & Benbasat, 1991). The research on technological innovation covers a broad group of specific technologies and an array of socio-technical factors that influence the innovation process. An evaluation of the literature highlights some important factors to consider with regards to the adoption, development, and implementation of ICT within public organizations. It is apparent that public organizations must consider the characteristics of the specific ICT, as well as factors such as knowledge, resources, structural arrangements, and the external environment.

## Characteristics of Digital Government ICT

With regards to digital government, the characteristics of the actual ICT play a significant role in the progression of the innovation process. While the use of Internet-based technologies, such as hypertext markup languages (HTML), extensible markup language (XML), browser software, and even wireless networks are now almost ubiquitous characteristics of modern computing, the broader configurations of such technologies occur in a variety of ways, depending on the respective objective or task. For example, essentially the same basic component technologies can be used to develop an intranet for communication and data processing within an organization's environment or can be constructed to disseminate information to stakeholders external to the organization through some form of extranet. While there have been a steady stream of new technologies that facilitate the technical systems development inherent in using ICT to accomplish organizational tasks, the degree to which such technologies are significantly different from preexisting information systems, or the way in which such systems are used, may play a significant role in how such innovations are perceived and adopted within public organizations. ICT applications that are clear departures from an organization's existing ICT infrastructure or that seek to accomplish core tasks in different ways may experience more difficulty and resistance during the innovation process. For example, many public organizations have adopted Enterprise Resource Planning (ERP) systems that were originally designed as modular software systems intended to improve the administration of business functions, such as budgeting, procurement, and human resources. The software modules are connected to a common database that is used to centralize information and improve organizational decision-making (Sawyer & Southwick, 2002). The awareness and adoption of such systems has been quite popular among public organizations at all levels of government, however many implementations have experienced significant difficulties because such systems are departures from existing ICT systems and are often difficult to integrate within preexisting business procedures and norms (Sawyer & Tapia, 2002).

## Knowledge of ICT

The extent to which an organization is aware of how new ICT may be applied to accomplish organizational goals is an important factor in the initiation of the innovation process. As mentioned previously, digital government in its broadest sense is not a new phenomenon. Public organizations have been using ICT for many years in order to carry out key tasks, such as data processing. The extent to which organizational actors, such as managers or technical experts, seek out new ICT in order to achieve goals is an important contributing factor to the innovation process. For example, managers may consider the adoption of new forms of ICT as a means of addressing problems within their scope of responsibility. Their interest in adopting new ICT may be viewed as a response to a perceived organizational need or their own more narrow need to enhance information processing or communication within the organization. Simultaneously, the perceived ease of use and overall usefulness of ICT to such managers may also increase the adoption and implementation of new technologies (Bugler & Bretschneider, 1993). Knowledge of new ICT applications is also closely tied to the extent to which organizational personnel seek out and receive ICT-related information from sources external to their normal work environment. Organizations whose personnel interact with professional associations, educational institutions, consulting firms, or vendors of ICT products tend to be more aware of how ICT may be used to address organizational tasks.

## Resource Availability

With regards to digital government innovation, an important enabling factor is the sufficient availability of organizational resources to adopt and implement the ICT in question. With regards to the adoption of ICT, resources may come in several forms, including sufficient personnel with knowledge of the ICT of interest, the status of existing ICT systems, or even sufficient time to adopt and implement the ICT, in addition to ordinary organizational activities. Significant problems often arise out of the lack of sufficient financial resources to obtain the hardware and software systems of interest or the necessary personnel resources to oversee the implementation of the new ICT innovation. Public organizations are often reluctant to use budgetary funds to invest in new ICT innovations when they may be already earmarked for existing organizational activities. For example, Hinnant and O'Looney (2003) indicate that financial costs are a factor in whether or not local governments were interested in adopting advanced ICT practices, such as personalization of online services. Other research has indicated that organizations are more likely to adopt new ICT systems or practices when the financial resources are at least partially provided above and beyond normal budgetary expectations. For example, the Commonwealth of Pennsylvania created the Technology Investment Program (TIP) in the late 1990's to assist agencies with additional funds to upgrade systems that were potentially vulnerable to year 2000 problems and to cooperatively adopt ICT systems that were being championed by the governor's Office for Information Technology (Hinnant & Sawyer, 2003). Such funding schemes reduced the risk for individual public agencies to both initiate and implement new ICT systems. However, unless such funding programs are protected from the possibility of government revenue shortfalls, they may be greatly diminished or eliminated altogether.

## Organizational Structural Arrangements

An organization's administrative arrangements play an important role in how successful public organizations will be during the innovation process. A classic depiction of public organizations is of highly bureaucratic structures with high degrees of centralization and formalized procedures. If this stereotype is true, public organizations may have more difficulty adopting new forms of ICT, especially if they do not clearly enhance the accomplishment of tasks core to the generation of services. After all, public organizations develop bureaucratic structures and formal routinized procedures at least in part due to the need to produce services in a stable and equitable manner. In such cases, public organizations will be weary of new ICT that might initially disrupt the production of public services (Wilson, 1989). However, in situations where public organizations see new ICT as a clear means of improving organizational processes or improving the production of services, public organizations may be more likely to positively perceive the new ICT system or application.

Taking such expectations into account, it is also important to highlight the interaction between ICT and an organization's structure. As a technology oriented toward altering information flows either within or across organizational boundaries, ICT may in and of itself, influence a public organization's formal and informal structure. For example, Kraemer and King (1986) found that the new ICT reinforced preexisting social arrangements or shifted power towards higher levels of management. In other situations, power may be shifted down and outward within the organizational hierarchy to those who more closely understand and manage the new ICT (Kreamer, King, Dunkle, & Lane, 1989; Kraemer & King, 1986). With the adoption of newer forms of ICT that make use of wide-area networks such as the Internet or WWW to expand

communication, organizational structure may be altered in unexpected ways. For instance, end users may increase their capabilities through a heightened ability to access and transfer information both within and across organizational boundaries through the use of the WWW or Internet. However, the underlying planning, development, and maintenance of an organization's information systems, and information assets, by centrally located ICT managers may once again centralize power within the public organization. Such findings indicate that structure plays an important role in the ability of public organizations to initiate and fully implement new forms of ICT; however, the ultimate reciprocal effects are difficult to accurately predict.

## The External Environment

The broader external environment within which a public organization resides also plays a role in how the innovation process unfolds. Economic and political actors within their external environment often heavily influence public organizations (Bozeman, 1987; Rainey, 1997). As already mentioned, the financial resources available to a public organization are one factor that influences the process of technological innovation. Since the budgets of most public organizations are directly or indirectly influenced (through tax revenues) by the vigor of the greater economy or political decisions regarding fiscal policy, their ability to adopt and implement new forms of ICT, to an important extent, is influenced by the external economic environment. Similarly, the adoption and implementation of ICT by public organizations are also influenced by the actions of political actors such as elected officials, political appointees, citizens, and businesses external to their organization. For example, the initial adoption and successful implementation of new inter-agency criminal justice database systems were linked to a consistent level of support from public officials who hold key elected or appointed positions within the government (Hinnant & Sawyer, 2003). In a similar manner, businesses, interest groups, or private citizens, as actors who either impact the generation and delivery of public services, or which receive those services, can each influence the adoption of ICT. Interest in the adoption of new online practices by cities and counties has been linked to a perceived need or demand for such practices by the citizens within the local government's jurisdiction (Hinnant & Sawyer, 2003). In addition, many governments are adopting ICT systems to streamline the procurement processes that are used to buy goods and services from the private sector (Moon, 2002). As in the case of organizational structure, the adoption and use of specific ICT by government is not only influenced by external actors, but may also help shape the use of ICT by those actors.

At a broad level, the process with which ICT is adopted and implemented by public organizations is not a straightforward and linear process. While it is safe to say that the factors discussed: ICT characteristics, technical knowledge, resources, structural arrangements, and the external environment all influence the process with which new ICT are adopted and implemented, the process is more interactive and nonlinear than presented here. For instance, relatively early studies of personal computers in local government indicated that computer applications with greater public visibility and less uncertainty with regards to cost were more likely adopted (Perry & Danziger, 1980; Perry & Kraemer, 1979). Similarly, public managers may seek to use new forms of ICT, such as a portal on the WWW, to communicate more easily with external stakeholders, but find their efforts limited by budgetary limitations imposed by the economic environment (Gant, Gant & Johnson, 2002).

# FUTURE RESEARCH ISSUES: BROADER ISSUES OF ICT AND TECHNOLOGICAL INNOVATION FOR DIGITAL GOVERNMENT

The use of technological innovation as a theoretical basis for examining the adoption and development of digital government by public organizations seems valid, but it is important to understand that public organizations are only parts of a greater institutional framework of government. In essence, attention should be paid to the extent to which ICT alters traditional institutional arrangements and the extent to which such technology potentially improves governmental performance. One means of achieving such study is to consider an institution's technological core as architecture, or a set of ICT design decisions, that bring together different elements of ICT systems into a more coherent whole. Therefore, architectural innovation might take a broader view of how innovation and change within and between subunits, such as organizations, influences the overall performance of broader institutional relationships and performance (Agre, 2000, 2003; Henderson & Clark, 1990).

In addition to examining the broader connections between ICT, innovation, and government institutions, more attention needs to be paid to the differences between the actual goals and limitations of employing ICT in public, versus private, organizations and institutions. Government faces many challenges with regards to realizing the potential of digital government activities. One challenge that is often discussed concerns citizen and stakeholder access to ICT. While private sector firms only have to market and provide services to set groups of

customers who may buy or make use of a specific good or service, government must be accountable to broader segments of the population. For example, some citizens have adopted ICT, such as the Internet, WWW, or wireless technologies, for their daily use. However, some demographic groups have been found to have more limited access to the ICT that digital government often relies upon or may have insufficient technical skills to fully make use of such technologies (Agre, 2000, 2003; Thomas & Streib, 2003). Issues of access may serve to, in some ways, limit the ability of public organizations to adopt new ICT, especially if adopting ICT is intended to enhance communication or provide services to citizens or other external stakeholders. However, if external users adopt new ICT at high levels themselves, they may actually serve as a means to drive innovation on the part of public organizations.

Other challenges to developing digital government innovations also exist. Many governments are being forced to deal with technical and administrative issues that arise from the employment of ICT itself. For example, employing ICT to deliver services to the public requires more attention to issues, such as information assurance, ICT systems security, and overall organizational accountability. If public organizations wish stakeholders, such as citizens and private sector firms, to be willing participants in digital government activities, it must provide assurances that such information-intensive activities are well planned out and relatively secure from potential abuse. In essence, governments must seek to promote trust on the part of participants in the innovation process (Welch, Hinnant, & Moon, 2005).

## CONCLUSION

If the adoption of ICT by public organizations and their broader institutions of government is to lead to the benefits of improved efficiencies in the production and delivery of public services, public organizations must develop a clearer understanding of the social and technical factors that influence the process of technological innovation. The failure of large-scale ICT projects is not uncommon in either the private or public sector. However, the openness and transparency of public sector activities, as well as broader issues of accountability to the public at large, will always bring any failures or shortcomings within the innovation process to the light of public scrutiny. While this may cause some public sector organizations to be more apprehensive to undertake the development and adoption of new ICT, a greater lesson is that public organizations must pay special attention to identify and address possible problems within the innovation process itself. Furthermore, while the ICT inherent to current incarnations of digital government practices may be an important driver of change, its impact within the greater social structure of organizations or institutions is often difficult to anticipate. As public organizations increasingly look to digital government as a core part of their operations, they must seek a better understanding of how the factors within the innovation process interact together and, ultimately, impact the adoption and implementation of ICT.

## KEY TERMS

**Architectural Innovation:** Innovations that involve a significant redesign of an organization's architecture. For instance, architectural innovation may require reconfiguring the technological components or systems of an organization or network of organizations in order to produce a significantly different aggregate arrangement.

**Digital Government:** The development, adoption, or use of ICT by government organizations and actors.

**Electronic Commerce (E-Commerce):** Conducting business and communication transactions over electronic computer networks. This may include the selling of goods and services, as well as the transfer of funds from customers. This may also include inter-firm (business-to-business) transactions, as well as intra-firm computer-based activities.

**Electronic Government (E-Government):** The use of ICT, such as the Internet and WWW, by public organizations, such as government agencies, to provide information and public services to citizens and other government stakeholders.

**Electronic Politics (E-Politics):** The use of ICT, such as the Internet and WWW, by political actors, to inform and facilitate public participation in the political process.

**Information and Communication Technology (ICT):** Devices, applications, or practices that facilitate information processing or communication processes.

**Internet:** A large system of interconnected computer networks composed of backbone networks, mid-level networks, and local networks. This includes networks owned and managed by public, private, and nonprofit sector organizations.

**Radical Innovation:** Technological innovations that are clear departures from an organization's current technological norms and, as a result, are perceived to impose significant risks if adopted and implemented.

**Technological Innovation:** The development and introduction of knowledge-derived tools, artifacts, and devices by which people extend and interact with their environment (Tornatzky & Fleischer, 1990).

**World Wide Web (WWW or Web):** A hypertext-based client-server system that is one component of the larger Internet. The hypertext-based format of the WWW allows users to navigate through the system by using graphical user interface software known as browsers.

# Teledemocracy

*Auburn University, USA*

## INTRODUCTION

Up until very recent times in Western political philosophy, theory, science, and discourse, the words predominantly used to describe the democratic pole of Aristotle's political continuum were *direct democracy*, *indirect democracy*, *social democracy*, and, in Aristotelian terms, *republic* or *representative democracy*.

The latter half of the 20th century, however, saw dramatic changes in democracy around the world in its spread, variation in form, and in the use of the word. In fact, there have been a number of books in recent years that have discussed a wide array of models or degrees of democracy (Held, 1996; Sartori, 1987). Phrases such as *participatory democracy*, *managed democracy*, *strong democracy* (Barber, 1984), and *semidirect democracy* (Toffler & Toffler, 1994) are just some of the clusters of terms now used to define particular kinds of democracy that exist or are theorized to be better forms of it.

Also, as the 20th century drew toward a close, there was a virtual consensus among Western political scientists that a potentially dangerous schism has grown between the citizens of both representative and social democracies and their governing elites. Indicators of such are public-opinion polls that manifest an increasing discontent with the political class and politicians (usually termed *alienation*) and a general decline in voter turnout (albeit with occasional upticks).

Most of this dissatisfaction with, or alienation from, various forms of representative democracy is considered to be due to the growth of the influence of those who lavish large sums of money on the public's representatives in these political systems. Another widely perceived cause of this gap between the people and their governments is the inertia of bloated, entrenched bureaucracies and their failure to acknowledge the wishes of the general public in policy implementation. Both of these phenomena seem to be present in all modern, industrialized, representative democracies, and they even seem to become manifest in the youngest, least industrialized countries as well. For example, in the fall of 2004, Cerkez-Robinson (2004) reported that the turnout in the Bosnian national election had fallen precipitously because most Bosnians are tired of repeated fruitless elections.

As this complex problem in modern representative democracies seems to have become systemic, a potential technological solution has also come upon the scene. This involves the previously unimaginable proliferation of information and communications technologies of the late 20th century and early 21st century. This new and rich mixture of rapid, electronic, interactive communications has been seen by many political thinkers and actors as an excellent medium by which to close the gap between the people of representative democracies and their elected and administrative officials.

This has led to a plethora of new adjectives and letters to prefix the word *democracy*, each referring to some theoretical or experimentally tested improvement in the present and future forms and practices of both direct and/or indirect democracy using ICTs. Thus, in the past decade or so of reinventing government (Osborne & Gaebler, 1992), we have come to learn of such new ideas and ideals of democracy as *electronic democracy* (or e-democracy), *digital democracy*, *cyberdemocracy*, *e-government*, and *teledemocracy* (Becker, 1981; this listing is far from exhaustive.)

Taken together, they demonstrate that the future of democracy around the world is in flux, that there is a broadly perceived need by those in and outside government for some changes that will ultimately benefit the general public in various aspects of governance, and that these new technologies are seen by many as part of the solution. As alluded to above, there are numerous experiments and projects along these lines that have been completed, many are in progress, and there are multitudes to come that probably will be a part of any such transformation in the future of democracy on this planet.

## BACKGROUND

In December 1981, I wrote an article for *The Futurist* that was titled "Teledemocracy: Bringing Power Back to People." I had not heard, seen, or remembered reading the word before using it, and some scholars told me that it was too vague and unclear to be of much use. Nonetheless, I have continued to use it in numerous contexts, as have some others (Arterton, 1987; Ytterstad et al., 1996).

This article will attempt to clarify how I originally employed it, how I modified it over the years to bring about greater clarification, and where it stands now and into the future. This is necessitated by the fact that others have come to either misinterpret or misrepresent the essence of the concept as it was originally conceived and since refined by myself. I will also point out how my usage of teledemocracy can be distinguished from the generic use of some other related concepts like e-government, digital democracy, and so forth. Finally, I will point out how some others are using it or a more generic term, more or less in line with my original and/or revised definition.

In the original 1981 article, I referred to the phenomenon of burgeoning citizen abstention in most democracies, which was apparent well before then (Levin, 1960). I also acknowledged a number of experiments in using interactive television and the increasing use of national referenda in some Western social democracies on major issues. In addition, I made reference to new methods of scientific deliberative polling that were proving to be successful in stimulating thoughtful survey results in lieu of conventional scientific public-opinion polling (using random-digit dialing methods), which produced a superficial, top-of-the-head, oft-cited but equally oft-disparaged public opinion.

Here is the way I defined it at first:

*Teledemocracy—the term coined for electronically aided, rapid, two-way political communication—could offer the means to help educate voters on issues, to facilitate discussion of important decisions, to register instantaneous polls, and even to allow people to vote directly on public policy.* (Becker, 1981, p. 6)

Some others have agreed that this was, indeed, the first usage of this term. In 1997, a thesis at a university in Germany written by Martin Hagen stated that

*the oldest concept of electronic democracy is "Teledemocracy." Developed in the 1970s, it became the first widely accepted concept of electronic democracy in the 1980s. While it is impossible to trace who first coined the term "teledemocracy," it was used by Ted Becker...in the late 1970s.*

A European Union report on May 31, 2001, that is on the Internet noted that the term teledemocracy was originally coined in 1981 (http://www.eucybervote.org/Reports). A Spanish Web site that also reported the results of a thorough search on the word is also in agreement on the original coinage.

As time passed and I became aware of further developments in this field, I continued to revise and clarify what I meant for teledemocracy to include that was entirely consistent with the original coinage. In 1986, in a book chapter called "Teledemocracy Emergent," I came up with what I believe to be a somewhat clearer definition:

*The great difference in feeling and perception between protagonists and antagonists of teledemocracy does not stem from any problem with definition. Quite simply, teledemocracy is the use of telecommunications technology to promote, improve, and expand (a) direct, pure democratic forms such as town meetings, initiative, referendum and recall; and (b) the citizen information and feedback functions of indirect democratic forms such as republics, where the population elects various legislative and executive officials to plan, promulgate, and carry out public policy. In other words, teledemocracy would include such novel phenomena as "electronic initiatives," "electronic town meetings (ETMs)," and "electronic public hearings."* (Becker, 1986, p. 264)

In essence, this was a lexical definition based on the developments in using ICTs in ever new ways to help the public become better informed, thoughtful, and active citizens so as to "generate a more democratic republic and a stronger system of direct democracy in the future" (Becker, 1986, p. 267). By implication, through the addition of the word thoughtful, the idea of two-way was expanded to include multilateral discourse among many people and to crystallize that teledemocracy was not limited to two-way TV interactions. This should have been manifested from the fact that in the televote method of scientific deliberative polling that was the major empirical basis of the concept of teledemocracy, the randomly selected respondents were encouraged to discuss the contents of the survey brochure with friends, relatives, coworkers, and family before deciding and voting (Campbell, 1974; Slaton, 1992).

Unfortunately, the ideological foes of this definition and vision (and the experimental phenomena upon which it is based and to which it often refers) are many and well placed, and do not have the same democratic values in their view of the role of the public in a representative democracy. These opponents of teledemocracy particularly entertain extremely negative views of direct democracy or more direct citizen engagement in any governmental activity. Thus, one of their ploys has been to misrepresent the definition of teledemocracy as being one in which (a) citizens are isolated in their homes to vote electronically and do not in any way deliberate together (Elshtain, 1982) and/or (b) representative democracy must be replaced by direct electronic democracy.

In his book that describes and analyzes many of the same projects conducted or discussed by Becker and others cited above, Christopher F. Arterton (1987) con-

fuses teledemocracy with something he calls plebiscitary democracy. In other words, it is his claim that the concept of teledemocracy refers exclusively to, and is synonymous with, citizen empowerment through and in direct democracy, a view that it is incorrect. This inaccurate assertion of what the concept means was highlighted by the fact that he titled his book (which was the first to use this word as a title) *Teledemocracy*. Thus, this tactic has aided those opposed to the phenomena defined by the word teledemocracy by distorting its original meaning since anyone only familiar with Arterton's book would think his definition was the actual definition, which it is not. So, it is crucial that the encyclopedia on this general subject be the ultimate definer of what the original and refined concept of teledemocracy actually means—according to the person who coined the term and has been using it longer than anyone else alive today (2006). The general and fundamental underlying theme in the concept of teledemocracy, then, is empowering the public via ICT in obtaining a wide variety of information and opinions, thinking about it, talking and listening to other people's views about it, deliberating on the issue(s), and then having the power to make a decision (vote, opinion) that will be injected into some official process of planning, prioritization, agenda setting, policy making, or policy implementation in either an influential or binding way.

Often included, and sometimes exclusively such, are face-to-face meetings and experiments in which random or stratified (and in rare cases self-selected) samples of the citizenry come together to listen to a full range of information and opinions, and then deliberate on one or more issues that will bind officials to adhere to their considered opinion (called planning cells in Germany and consensus panels in Denmark, which are well covered by the mass media). These are encouraged by the full definition of teledemocracy; however, they are just one method in a mélange of empowering techniques that in some way utilize modern ICTs to enhance the inclusion of more citizens in any face-to-face process and/or to expedite and facilitate consensus in very large meetings (thousands of people in one place at one time, or multiples of that being interfaced via satellite communications). The reader is invited to see an advanced model of this at http://www.americaspeaks.org and to become familiar with Listening to the City as a sophisticated, working model of 21st century teledemocracy and how it is designed and operates.

All this is made quite clear in the most recent advance on this definition to be found in Ted Becker and Christa Slaton's work *The Future of Teledemocracy* (2000). In that work, we define teledemocracy in another complementary way as a "comprehensive 21st century democratic political communications system" that is both lateral and interactive, using all available methods of ICT at the time as well as facilitation techniques to improve citizen participation in either representative or direct democratic processes (pp. 178-197).

## THE MAIN DISTINCTION IN THE DEFINITIONS IS IDEOLOGICAL

The main difference between the concept teledemocracy and other similar-sounding concepts like digital democracy, e-government, and deliberative democracy could be construed as a matter of emphasis, or it may be a matter of ideology. I believe it is the latter.

In my viewing of scores of other Web sites that use any of these phrases, the most pervasive ilk devises and tests ways in which electronic technologies, particularly the Internet, can improve representative governmental services in order to make governance more efficient. Thus, these sites accent such things as putting governmental services online, letting constituents talk to their representatives or other governmental officials, using the Internet as a grassroots tool to help design and run campaigns for candidates and issues, and, on occasion, having the government consult with the citizenry in nonbinding ways.

Perhaps one of the most advanced Web sites along these lines is that of the International Teledemocracy Centre at Napier University in Scotland (http://itc.napier.ac.uk). It has been online for many years now and combines highly innovative uses of digital democracy and e-democracy into its concept of teledemocracy. In looking through it, however, one is struck by its operational definition of teledemocracy being limited to expanding and strengthening the bonds between citizens and their representative system via consultations and petitions. Although its work is excellent and admirable, it shows how the preponderance of the work being done in the name of teledemocracy and its allied concepts is very much ideologically aligned with Arterton (1987) and similar authors in avoiding more direct democratic approaches to citizen empowerment that actually make, or have measurable direct impact on, major public decisions via a combination of face-to-face meetings and the complementary use of ICT.

Thus, as far as the originator of that concept is concerned, when properly used, teledemocracy is an umbrella concept that can be used in all kinds of citizen empowerment in all kinds of democratic practices (surely including ways to make direct democracy more effective, expansive, and binding at all levels of governance) using a wide array of innovative technologies and techniques, electronic and otherwise. And yes, I believe this should be done, which makes the term teledemocracy an ideo-

logical, as well as scientific, term. It was that way from the beginning and no amount of ignoring, misrepresenting, or tinkering can change that fact. If it does not truly empower the citizenry, then call it something else.

## FUTURE TRENDS AND CONCLUSION

The empirical phenomena that were originally defined and refined as the concept of teledemocracy continue to flourish and grow, though not under that rubric. There is an increasing myriad of projects and experiments around the world that test and develop new ways of engaging citizens in meaningful face-to-face or electronic (or some combination of both) deliberative meetings, where the results of such are quickly conveyed to government officials either to be part of their decision-making processes or implemented as policy. (An excellent recent example is the Citizens Assembly of British Columbia.) Many of these are now being aggregated under the concept of deliberative democracy.

In light of the popularity of that term, which seems to include all of what I meant by teledemocracy, the person who coined the concept teledemocracy and put up the first Web site devoted to such projects (Teledemocracy Action News + Network, TAN+N at http://www.auburn.edu) now reports on the further evolution of authentic citizen empowerment in *The Journal of Public Deliberation* at http://www.services.bepress.com and http://www.auburn.edu/jpd. In reality, then, teledemocracy seems to be verbally morphing into deliberative democracy.

## KEY TERMS

**Deliberative Democracy:** A transformation in representative democracy in which representative groups of citizens are encouraged to participate as planners, lawmakers, and/or implementers of policy through complex deliberative processes via face-to-face meetings, electronic meetings, electronically enhanced meetings, or some combination of both.

**Direct Democracy:** Where citizens can act directly as lawmakers or planners through either facilitated or free elections and where their decisions become the law or the plan without being filtered afterward through any other officials other than, perhaps, the courts to see if their decisions are constitutional.

**E-Democracy:** Electronic discussions among citizens in which the results of their deliberations are given some force in the decision making of officials or in which their votes count in some way to make laws, plans, or regulations.

**E-Government:** The use of modern ICT by governments to allow citizens to access information from the government, to discuss issues and/or problems with officials, and to carry out administrative tasks, like getting licenses or paying fees, through electronic ICT.

**Electronic Town Meeting (ETM):** A comprehensive bringing together of large numbers of citizens to discuss

some important issue or problem using electronic technologies to help them set priorities, set agendas, or inform officials of any consensus or majority opinion that may be formed by the discussion. It is a method used in e-democracy, teledemocracy, and/or deliberative democracy

**Participatory Democracy:** A theoretical concept that includes more specific manifestations such as deliberative democracy, direct democracy, e-democracy, electronic town meetings, and teledemocracy.

**Representative Democracy:** A form of indirect democracy in which citizens elect others to represent them as lawmakers in deliberative processes. E-government is a new way for representatives to send information to the citizens and to allow citizens to access the government for administrative purposes.

**Scientific Deliberative Polling:** A new method of feedback from the public to its representatives. This method of surveying citizens about their opinions on important issues selects the respondents by random or stratified methods so as to make certain that all major demographic groups within the polity are represented within a small margin of error. The respondents are given information and opinions, and time and encouragement to talk among themselves before coming to a final opinion.

**Teledemocracy:** Another concept closely allied to that of deliberative democracy, representative democracy, and direct democracy that uses e-democracy, electronic town meetings, and scientific deliberative polling in order to empower citizens to directly affect or make laws and administrative decisions.

# The Telehealth Divide

**Mary Schmeida**
*The Cleveland Clinic Foundation, USA*

**Ramona McNeal**
*University of Illinois at Springfield, USA*

## INTRODUCTION

In the United States, the public is accessing the Internet to provide information and deliver services, and to interact with citizens, business, and other government agencies (Bimber, 1999; Pardo, 2000; West, 2003, 2004). As with any change between citizen-government interactions, e-government is accompanied by speculation on its impact to both citizen and government. E-government capability of continual service delivery can make government efficient and transparent to the public (Norris, 1999; West, 2003), and more responsive to public needs through fast and convenient communication options (Thomas & Streib, 2003). It permits quicker material update than traditional distribution methods (Pardo, 2000).

However, other literature suggests e-government will not live up to these prospects. A separation exists among citizens that use and do not use the Internet. This separation is based on a number of factors, including inequalities in Internet access "digital divide" and technological skills, along with psychological and cultural barriers. Literature extensively shows the differences in United States Internet use to fall along important socioeconomic and demographic factors, such as age, race, education, and income (Mossberger, Tolbert, & Stansbury, 2003; Neu, Anderson, & Bikson, 1999; Pew Internet & American Life Project, 2003c; U.S. Department of Commerce, 2002; Wilheim, 2000). E-government may create inequalities in the delivery of government information and services.

Telehealth is a specific form of e-government aimed at improving the accessibility and quality of healthcare, and reducing service costs (Schmeida, 2004a). It relies on electronic information and telecommunication technology innovation (H.R. 2157, 2001). As nations contend with expensive healthcare, the promise of better healthcare service delivery at a reduced cost has made teleheath an increasingly attractive policy option in the United States and internationally.

Telehealth advancement greatly reflects the dramatic changes in the telecommunication industry. In the 1990s, we witnessed considerable advancement, such as the use of digital technology—interactive video and Internet. Interactive video, for example, can link doctors and medical students afar improving medical education. Rural citizens can interact with specialist(s) through interactive video rather than traveling great distances for a medical consultation. The Internet can bring health related information into the home for better healthcare decision-making.

Telehealth can be conceptualized as both an administrative reform policy and regulatory policy. As a hybrid policy type, it mostly exhibits the characteristics of administrative reform, such as e-government (McNeal, Tolbert, Mossberger, & Dotterweich, 2003; Schmeida, McNeal, & Mossberger, 2004) driven by the goals of cost reduction and increasing efficiency, paramount to telehealth adoption and implementation. Administrative reform policy does not involve the direct and coercive use of government power over citizens and are therefore associated with low levels of conflict (Ripley & Franklin, 1980). Regulatory policy, on the other hand tends to be politically salient among citizens as well as controversial among the actors within the policy community.

Traditionally, those interests who are regulated have been important players in the policy process. Important telehealth players are physicians, nurses, pharmacists, and health insurers. Since telehealth straddles both administrative and reform policy areas, it is difficult to predict the actors that will play the greatest role in assisting or impeding its implementation. Execution of regulatory policy is highly volatile and controversial with shifting of alliances and players. However, administrative policy innovations are low salience, and as some regulatory policies it involves technical issues, often driven by professional networks and elected officials.

## TREND STUDIES ON INTERNET USE AS A HEALTHCARE TOOL

Although policy actors, cost containment and advances in technology are driving the adoption of telehealth, its

impact is contingent on factors, such as Internet access among members of the public. The Internet provides information on various health and medical-related topics through government sponsored and private sector Web sites. Today, more Americans are conducting Internet health and medical-related searches. On an average day, about six million people get online to search for medical-related information (Pew Internet & American Life Project, 2002) for better decision-making on self-care and helping others (Pew Internet & American Life Project, 2003b). Across different health and medical issue topics, Pew (2003b) found online searches for information on a specific disease or medical problem leads the topic areas searched. In addition to using the Internet for health information searches, about 30% of e-mail users have e-mailed their doctors and other health professionals, thus bridging the gap between patient and doctor, particularly specialists over great distances. This elementary form of telehealth (information search, and doctor and patient correspondence) exemplifies the potential of telehealth. Yet, while becoming a commonly important healthcare tool, not all citizens including those most in need of online health and medical-related information (the elderly and poor) are taking advantage of the online services (Schmeida, 2004b).

Research on demographic groups using the Internet to search for health information is sparse and does not establish with any certainty what factors matter in predicting who is taking advantage of this form of e-government (Schmeida, 2004b). However, multivariate statistical research on computer and Internet access does exist and may help us better appreciate the barriers facing the utilization of telehealth. Mossberger, Tolbert, and Stansbury (2003) find both an Internet access and skills divide, indicating inequalities in home Internet access, e-mail use and computer ownership. The research suggests there are gaps based on race/ethnicity with whites more likely than African-Americans and Latinos to have Internet access. Inequalities were also found on education and income with higher income being associated with greater Internet and computer access and ownership. Age was also an important factor with young persons more likely to be connected (pp. 32-35). Compounding the access divide are differences in technological skills. Mossberger et al. (2003) find a skill divide exists closely mirroring the access divide with the poor, older, less educated, and non-whites less likely to have technical skill, that is, technical competence or information literacy. As important as having access at home are the technical skills for computer operations and information literacy to locate and effectively use computer information.

## A TELEHEALTH DIVIDE MATCHING THE DIGITAL ACCESS DIVIDE

Do those who are least likely to have computer and Internet access match that of a potential telehealth divide? Based on literature showing disparities in Internet access and use (Mossberger, Tolbert, & Stansbury 2003; Pew Internet & American Life Project 2003a; U.S. Department of Commerce 2002), it is expected that disparities in Internet use for health searches would also exist. Using the 2000 Pew Internet & American Life (2003b) survey data and controlling for demographic factors with regression analysis, Schmeida (2004b) found several factors important in explaining which citizens are searching for health and medical information online.[1] Persons who are young, white, with a higher education and income, are more likely to search for information online.[2] Also, females and household healthcare givers are more likely to conduct searches than males and non-caregiver.[3] The findings suggest that older persons, who face more health-related problems, ironically are less likely to take advantage of these telehealth services. However, females are more likely to search online, as might be expected since they have been more active in health searches in the Pew Internet & American Life Project (2003b) study and are more likely to be caring for another person(s) at home.

Unexpectedly, race (Asian Americans and African-Americans) was not a significant predictor of a telehealth divide, differing from previous studies showing these minority groups are "have-nots" in Internet access at home. On the state level, McNeal et al. (2003) found racial diversity was not a significant predictor in percentage of state government Web sites providing services to state residents. While, Schmeida, McNeal, and Mossberger (2004) found state racial context mattered in influencing implementation of telehealth policy. This suggests that minority context may matter more for telehealth implementation. Latino (who were found significantly less likely to search for online health information) contextual barriers to computer literacy, such as entrenched resistance to acquiring computer skills (Stanley 2003) may be factors for further research.

## CONCLUSION

The policy implementation literature directs us to examine factors, such as political actors, the need/ demand to contain costs and increase healthcare efficiency, important to explaining the adoption and implementation of telehealth. To understand the impact of this policy, we

cannot, however, lose sight of factors, such as public Internet access and use. Research statistically controlling for demographic factors on telehealth use is limited. However, using regression we control for these factors and with certainty find disparities between demographic groups searching for health information on the Internet. A telehealth divide exists and in general mirrors the contours of the digital divide. As with the digital access divide—those who are least likely to have a computer and Internet access at home are the poor, less educated, older, Latinos and African-Americans (Mossberger et al. (2003) face barriers in taking advantage of services made available by telehealth. That is, persons who are poor, less educated, older, and Latino are least likely to search online for health information than others (Schmeida, 2004b).

Persons most in need of online health information are not accessing it. These findings suggest a dilemma, those in greatest need of information, such as, the poor and elderly are not seeking it online. The ramifications are significant suggesting the "advantaged" will obtain superior healthcare and treatment than the "disadvantaged." As advanced technology replaces labor-intensive information specialists, for example, the U. S. Centers for Medicare & Medicaid Services (2004) Web site, parity between demographic groups is essential. As literature suggests that e-government will not live up to the prospects of efficiently improving healthcare for all people, our findings show that indeed e-government maybe creating inequalities in the delivery of government information and services.

Effective information technology use depends on user knowledge and skills. Technical competence, information literacy and basic literacy are required for the information age for effective use of telehealth. Today, public access cites, such as computer technology centers are giving individuals both access to computers and educational opportunities to overcome literacy barriers (Mossberger, et al. 2003). Bridging the gap may be progressed by community services and educational opportunities, yet evolving. The adoption of telehealth reminds us that with adoption of any new policy, it must be evaluated on more criteria then efficiency. Criteria, such as equality in costs, benefits and risks must also be considered.

Although this article considers policy diffusion among the United States, it has implications for the international community in terms of lesson drawing. As the literature reminds us, countries often look to their neighbors for policy ideas (Bennett, 1997; Wolman, 1992) for emulation. This has proven to be the scenario between the United States and many other nations, all-searching to improve the health of their citizens while facing rising heathcare costs.

## KEY TERMS

**Centers for Medicare & Medicaid Services Web site:** A United States government Web site that provides information to needy groups on Medicare and Medicaid services, state children's health insurance, and clinical laboratory testing.

**Digital Access Divide:** Disparities between groups on demographic factors, such as gender, age, income, education, race, and ethnicity in accessing digital information technology, such as on the Internet.

**Telehealth:** The term is often interchanged with telemedicine. There is no consensus on its definition. However, the United States Congress defines it as the use of electronic information and telecommunications technologies to support public health and health administration, long-distance clinical healthcare, patient and professional health-related education (H.R. 2157, 2001).

**Telehealth as an Administrative Reform Policy:** As an administrative reform policy, telehealth is highly technical, not political charged although it may be conflictual in the policy community. Unlike regulatory and re-distributive policies, it does not involve the direct and coercive use of government power over citizens. Telehealth behaves mostly as an administrative reform, with its policy goals emphasizing greater efficiency in terms of cost savings.

**Telehealth as a Regulatory Policy:** Although regulatory policy may be politically salient among citizens, telehealth may be conflictual within the policy community. The regulatory aspects in this policy area may engage the participation of networks of healthcare interest groups, such as nurses, pharmacists and physicians. A moderate level of conflict over the issue may lead to some interest group activity by those who are liable to be covered by state regulations.

**Telehealth Divide:** Disparities between groups on demographic factors, such as gender, age, income, education, and race in using digital information technology, such as the Internet to search for public and private health and medical-related information online.

**Telehealth Policy:** An electronic government policy that uses the Internet to improve accessibility of public and private and non-profit healthcare services in rural and urban areas, while improving the quality of services at a lower service cost.

## ENDNOTES

[1] Similar question as the Pew survey is asked but demographic factors are controlled for by using negative binomial regression analysis: Have you ever looked online for any information on any of the 16 health and medical issues?" The 16 issues are: specific disease or medical problem; certain medical treatment or procedure; experimental treatments or medicines; alternative treatments or medicines; diet,

nutrition, vitamins, or supplements; exercise or fitness; prescription or over the counter drugs; immunizations or vaccinations, how to quit smoking, problems with drugs or alcohol; depression, anxiety, stress or mental-health issues; environmental health hazards; sexual health; particular doctor or hospital; health insurance; and Medicare or Medicaid insurance. Our dependent variable is a count of all "yes" responses to each health and medical issue topic, ranging from 0 to 16. An individual who has searched for all 16 medical issues is coded as 16 and someone who has looked for no medical issues is coded 0 (Pew Internet & American Life Project, 2003b).

[2] Age is in years, while education is a 7-point Likert scale measuring the last grade or class completed in school. Income is measured on an 8-point scale measuring the total family income from all sources before taxes in 2001 ranging from less than $10,000 to $100,000 or more (Pew Internet & American Life Project, 2003b).

[3] Household healthcare giver is defined as either a primary or secondary healthcare giver to a member in their household (Pew Internet & American Life Project, 2003b).

# The Information Society and the Danger of Cyberterrorism

**Giampiero Giacomello**
*Università di Bologna, Italy*

## INTRODUCTION

Computers have always caused psychological uneasiness in the human brain. That a computer is the closet thing to a thinking machine can be discomforting. That average users have little understanding of the complexity and intricacies of how computers and software operate only add to the distress. Networked computers further increased the puzzlement of human beings. The media (suffering from the same poverty of information as the public) have picked up catchwords like *cyberwar, netwars, cyberterrorism*, and *cybercrime.* Speaking of Electronic Pearl Harbors and comparing modems to bombs have only contributed to increasing the level of media hysteria and confusion in public opinion. Schwartau (1994) is a classic example. Imagine that poorly informed journalists start telling the general public that ruthless hackers (hired by terrorists) could take over the power grid and shut it down, or cause patients' death after their medical records have been compromised. The mere suspicion that terrorists could perform such acts would be enough to fueling the fear factor, which regularly happens as a result of this crying wolf.

Under these circumstances, cyberterrorism seems like a nightmare come true. As Embar-Seddon (2002) noted, the word terrorism brings together two significant modern fears: the fear of technology and the fear of terrorism. Both technology and terrorism are significant unknowns and unknown threats are generally perceived as more threatening than known threats. To some extent, cyberterrorism does not need to be manifested itself in any significant way because many already believe it to be real. This article will try to dispel some of the myths of cyberterrorism, such as the contention that terrorists could remotely take control of critical infrastructure and thus bring a country to its knees. In fact, today, cybercrime and economic damage caused by hackers are far more real and serious threats than terrorists. Misdeeds are more likely to be committed by disgruntled insiders than skilled outsiders (Randazzo et al., 2004).

There is no commonly accepted definition of terrorism, hence cyberterrorism has been variously interpreted. For example, Sofaer et al. (2000) defines it as "intentional use or threat of use, without legally recognized authority, of violence, disruption or interference against cyber systems" (p. 26), resulting in death or injury of people, damage to physical property, civil disorder, or economic harm. The probability, however, that cyberattacks may actually cause victims is extremely low. Furthermore, Sofaer et al. tends to exclude states from committing terrorist acts, which is also debatable. Hughes (2004) observes cyberterrorism as a diverse set of technologies whose purpose is to scare people, but scaring people without getting anything in return is simply useless. Paraphrasing a working definition of terrorism, I would identify cyberterrorism as the use of digital means to threat or undertake acts of organized violence against civilians to achieve political advantages. Perpetrators then could be nonstate groups or sovereign states. Terrorists spreading scary stories to terrify the populace via the Internet would also qualify.

Finally, because of cost efficiency, information and communication technologies have blurred the distinction that long existed between the noncombatant and the combatant spheres. The technology on which the military now rely is exactly the same commercial off-the-shelf hardware and software products that civilians have in their homes and offices (Department of the Army, 2003). Military and civilians alike use largely the same computer networks, which were designed for ease of use and not for hardened communications. During the Cold War, dual use technology (civilian hardware and software) was considered "dangerous" because it could help the Soviets close the gap with the West. Paradoxically, dual-use technologies are now "good." One of the many downsides of such a situation is that if terrorists hit computer networks, in theory, they could hit multiple targets: the economy, law enforcement agencies, emergency services, and (albeit to a lesser extent) even the military. For terrorists this scenario would be a dream come true. Reality, however, is substantially different.

## BACKGROUND

The first report to highlight vulnerabilities and risks for societies highly dependent on computer networks was the Tengelin report, in the 1980s (Tengelin, 1981). Soon

*Table 1. National critical infrastructures (Source: personal elaboration based on Randazzo et al., 2004, Wenger, Metzger, and Dunn, 2002, Commission of the European Communities, 2004)*

| E.U. | United States | Australia | Canada |
|---|---|---|---|
| Finance | Banking and finance | Banking and finance | Financial services |
| Communications and information technologies | Information and telecommunications | Communications | (Tele) Communications and Information services |
| Energy, oil, gas | Food, energy, water | Energy and utilities | Energy and utilities |
| Transport | Transportation and shipping | Transport and distribution | Transport |
| Government | Postal, emergency services, defense industrial base, continuity of government | Other critical government services (e.g., defense and emergency) | Safety |
| Food and water | Agriculture | | Safety |
| Healthcare | Public health | | Safety |

sociologists began to explore "the world of high-risk technologies" (Perrow, 1999), where "normal accidents" might occur in risky enterprises, like nuclear power plants or air traffic control, resulting in the deaths of hundreds and crippling the lives of thousands or even millions. After the publication of the Tengelin report, more governments, in primis the U.S. federal government, became sensible to the issues. The issue of computer-dependent societies skyrocketed in the 1990s with the diffusion of the Internet.

In 1998, U.S. President Clinton signed the Presidential Decision Directive 63 (White House, 1998), the first official document to identify "critical" sectors (information and communications, electric power, transportation, oil & gas, banking & finance, water, and emergency services) for protection. Disruption in one or more of these sectors would seriously compromise the survival of the United States as a sovereign country. The U.S. government has revised and refined the list of critical infrastructures several times since 1998 (the Patriot Act of October 2001 also mentioned the necessity to protect the country's critical infrastructures). The most recent modifications were included in the *National Strategy to Secure Cyberspace* in 2003 (White House, 2003). More recently, the E.U. has also come up with a list of critical infrastructures. The items on the E.U. list resemble very closely those sectors identified by the United States government and those of other advanced countries (see Table 1).

The U.S. military first considered "information operations" in the early 1990s. The Gulf War was actually the first information war (Campen, 1992; Libicki, 1995). Information operations involve "actions taken to affect adversary information and information systems while defending ones own information and information systems" (Joint Forces Staff College, 2003, p. 1). Adversaries could be hackers, criminals, vandals, terrorists, transnational groups and nation states. Computer Network Operations are a subset of information operations and may include psychological operations, open source intelligence, *hacktivism* (Denning, 1999), and so on. Perception management (the old propaganda), via selecting bits of information may demoralize the adversary and even obtain that victory without fighting, which Chinese strategist Sun Tzu (400 B.C.) portrayed as superior to other forms of winning.

More worrisome for the United States and other advanced countries is that even non-state actors like terrorist groups could become skilled enough to launch cyberattacks. Alberts (1996) noted that such acts would entail serious consequences for information infrastructures. Among the first to explore this eventuality were RAND researchers Arquilla and Ronfeldt, (1997, 2001), who investigated "cyberwars" and "netwars." Netwars, involving "nonstate, paramilitary, and other irregular forces," would be located "increasingly at the societal end," where "military operations other than war" were (Arquilla & Ronsfeld, 1997, p. 275).

At the end of the 1990s, Nelson et al. (1999) of the Center for the Study of Terrorism noted that "the majority of literature dealing with cyberterrorism has focused principally on the vulnerabilities of critical infrastructures" (p. 3). Exercises like Black Ice or Blue Cascade (Verton, 2003) focused on disruption of critical infrastructures and penetration of supervisory control and data

*Table 2. Typologies of terrorist groups/attacks (Source: personal elaboration based on Nelson et al., 1999 and Department of the Army, 2003)*

| Type | Attack Levels | Objectives |
|---|---|---|
| Etno—nationalists/ separatists/autonomists (Basques, Palestinians, Kurds, etc.) | Advanced, structured attacks | Economic loss, major disruption of services |
| Old style revolutionary (Red Army Faction, Red Brigades, IRA, etc.) | Advanced, structured attacks | Economic loss, major disruption of services, possibly fatalities |
| Right wing extremists | Simple, unstructured attacks | Nuisance, loss of some data, service interruption |
| New age terrorists (e.g., Animal Liberation Front) | Advanced, structured attacks | Economic loss, major disruption of services |
| Religious fundamentalism terrorism | Complex, coordinated attacks | Total disruption of services, major economic losses, fatalities |
| Hackers (Script kiddies?) | Simple, unstructured attacks | Nuisance, loss of some data, service interruption |

acquisition systems in the U.S. The type of cyberterrorism that advanced countries feared the most was akin to the military version of information operations (see Table 2).

The term *cyberterrorism* conjures up an endless list of doomsday scenarios, which journalists seem to pick up at regular intervals (Anderson, 2002; Arena & Ensor, 2002; Corera, 2004; Vise, 2001). Several authors (Denning, 2001; Embar-Seddon, 2002; Giacomello, 2004; Green, 2002; Hutter, 2002; Lewis, 2002; Ranum, 2004; Schneier, 2000, 2003a, 2003b), however, have demonstrated that for the time being cyberterrorism is not a realistic threat and that resources should be focused elsewhere. The consensus among security experts is that there has never been a recorded act of cyberterrorism pre- or post-September 11. This situation contributes to perpetuating a false understanding of the nexus between computer networks and national security. Opportunity costs for misallocation of public resources are extremely high and the risk of needlessly infringing personal privacy and civil liberties are also extremely great. Furthermore, Denning (2001) reckons that for terrorists to regard strikes at computer networks as a viable weapon, the attack should be sufficiently destructive or disruptive to generate fear comparable to that from *physical acts* of terrorism. Attacks that lead to death or bodily injury, extended power outages, plane crashes, water contamination, or major economic losses would be examples. Denning concludes that, presently, more traditional forms of attacks like car bombs are far more dangerous.

James Lewis (2002) of the Washington-based Center for Strategic and International Studies has analyzed the problem of cyberterror and other cyber threats from the perspective of potential victims of cyberattacks, in the United States, Europe, or Japan. Lewis concluded that, although computer network vulnerabilities are an increasingly serious business problem, "their threat to national security is overstated" (p. 1). Likewise, cryptographer Bruce Schneier (2003a) observed that not only had the threat posed by cyberterrorism been overestimated, but also that much of the hype was coming from the U.S. government.

## THE CURRENT SITUATION: MYTHS OR REAL DANGERS?

Journalists, law enforcement officers and even private sector CIO (chief information officers) tend to attach the tag "cyber terrorist" to a variety of subjects ranging from "script kiddies" interfering with their school's computer servers to professional terrorists. Already, in the mid-1990s, Alberts (1996) reckoned that the vast majority of attacks against domestic information infrastructures in the United States were carried out by "hackers, whose motives run the full gamut from financial motives to having some fun or to some more serious forms of antisocial behavior" (chapter 6). The U.S. *National Strategy to Secure Cyberspace* (White House, 2003) indicated as a primary concern "the threat of organized cyber attacks capable of causing debilitating disruption" (p. 6). But the same document also pointed out that the required technical sophistication to carry out such an attack was "high" and that the likelihood of the U.S. suffering a severe cyberattack was difficult to estimate.

The type of cyberterrorism that Nelson et al. (1999) worry about (outsiders taking over computer networks

*Table 3. Typologies of targets and damage (Source: Giacomello, 2005, 2004)*

| Type | Target | Damage | Fatalities | Personnel Required |
|---|---|---|---|---|
| (a) Perception management/ Propaganda | Image and self—confidence of the enemy | Psychological | None | One to three? |
| (b) Web defacement/ Taking over credit card and banking accounts | Private companies, banks, stock exchange, and so forth | Economic/ psychological | None | Two to several |
| (c) "Breaking things and killing people" | Air control /power and water distribution systems, and so forth | Human/physical/ economic and psychological | Yes | Several |

and sabotaging water distribution or 911 emergency systems) is not the one that has spread over the Internet. Rather, it is a cyberterrorism, which Thomas (2003) calls "cyberplanning" and Nelson et al. define as "support" of cyberterrorism, that is most widely found on the Internet. This cyberterrorism includes communications, recruiting, and propaganda, open source intelligence, and so on. Credit card fraud and other financial scams are also frequent. In many instances, cyberterrorism is very much like cybercrime: But is stealing credit-card numbers to use them for self-financing a terrorist act or cybercrime? Experts already agree that cybercrime is a bigger threat than cyberterror (Coren, 2005). Or, it might be that people overplay the risks of cyberterrorism, but then underplay the risks of cybercrime (Schneier, 2003b)? If one notes that the private sector in the United States and other advanced countries owns the largest part of the information infrastructure, these arguments are hardly surprising.

Further studies have confirmed the consistency of these arguments. According to the U.S. Computer Emergency Response Team statistics, until now, viruses, and worm attacks have caused denial-of-service or distributed-denial-of-service disruptions with massive economic losses in some cases but no physical destruction. If the main targets of those attacks had been the management systems associated with critical infrastructures, the potential physical damage would have been considerable. But that was not the case. Indeed, Randazzo et al. (2004) have shown, in a study for the U. S. Secret Service, that banks and other financial institutions are much more likely to be hit by cyberattacks. Moreover, Lewis (2002) also demonstrated that the most devastating impact of cyberterrorism would be on the *American economy* although the growth of cybercrime is likely to have longer lasting and more widespread consequences.

Institutional investors and financial markets are extremely sensitive to any news that may have even some remote effects on the world economy. A coordinated attack that, on the one hand spread false business information and, on the other, temporarily blocked communications to and from a few major banks or stock exchanges could seriously damage the economies of several advanced countries. Such an eventuality would certainly be an attack on a critical infrastructure. The motives of the perpetrators would be the real watershed to qualify them as terrorists or criminals. Cyberterrorism may certainly have overlapping features with cybercrime, but currently, these attacks are more likely to be motivated by ransom or financial scams than by political demands (Randazzo et al., 2004). In other words, behind these acts there are criminals, since politically-motivated terrorists are still a rarity in this field.

As terrorists could learn the same methods to raise money for their causes or engage in serious economic warfare, several countries consider the Council of Europe (CoE) Convention on Cybercrime a pivotal tool in tackling cyberterrorism. After September 2001, several European countries, along with the United States, Canada, Japan, Russia, and Australia signed the CoE Convention. The Council includes as members all EU countries along with Russia, Ukraine, Croatia, Turkey, and other Europeans. Negotiations for the convention started in 1997. With the rising awareness of the Clinton administration on protecting critical infrastructures, in 1998the FBI became actively involved in the drafting of the convention, since the United States, along with Canada, Japan, and South Africa decided to join the negotiations (as "observers"). The goal of the convention was to provide all member countries with some common definitions of what cybercrime should be, allowing better coordination of legislation and law enforcement. Within the general framework of the convention, all the members were supposed to adopt domestic legislation on the matter over time. Differences of opinion and of legal systems made negotiations sluggish however.

Most Council members quickly signed the convention in November 2001, following the 9/11 attacks. At a time when the United States was harvesting any ideas and tools to fight terrorism, it was hoped that the convention could help fight cyberterrorism. The convention entered into force in July 2004 (Council of Europe, 2004), but only for the eight states that actually ratified it. The E.U., Japan, and the U.S. did not ratify. Unlike the United States, the current emphasis of the E.U. and of other advanced countries seems to indicate that they want to continue considering cyberterrorism as a form of "crime" rather than a national security threat (Giacomello, 2005). Europol, the European Police force, for example, is tasked with primarily fighting cybercrime, with cyberterrorism conceived of as a "subsection" of the former. The same conclusion seems to apply to the newly founded European Network and Information Security Agency, which will focus on cybercrimes, with cyberterrorism being just one of them.

## CONCLUSION

Over three years after September 2001, terrorism is still a priority for many countries, but the surge in cyberterrorist attacks predicted in the wake of 9/11 has failed to materialize. In the meantime, interest in and instances of the less "glamorous" issue of cybercrime has risen sharply. While there are certainly some risks, the probability that external attackers could disable or seriously disrupt information infrastructures is, for the time being, still quite remote. Disgruntled insiders keen to extract revenge or organized criminals seeking ransoms are much more real threats. For societies highly dependable on computers, the other concrete risk is that attacks on networks will be launched to "multiply" the effects of conventional attacks in a war between states. In fact, offensive digital tools *will* be used, in the next war, to disable and destroy other countries national information infrastructure, to disrupt the economy, and interrupt utility distribution. Since the switches, routers, hardware, and software upon which civilians and the military rely are the same, civilians are likely to suffer considerably if such events to materialize.

While Americans and (to a lesser extent) Europeans, Canadians, Japanese, and Australians were devoting their resources to develop capabilities to fight the next cyberwar against state actors, terrorists have once more surprised them. Not only did terrorists not disrupt computer networks, but they have learned how to use the Internet and other digital technologies to ensure that their messages and declarations reach a wider audience and are reported with a resultant cascade effect in the Western media (Weimann, 2004). The negative balance should also register that governments have come to believe that there is an inevitable trade-off between civil liberties and security and that it is the latter that should prevail.

Online government surveillance has increased, but there is no hard evidence that this solution will raise the quality of intelligence gathering or the overall safety of societies. Democracies are reconsidering civil liberties and spending vast amounts of money but to foster the wrong cybersecurity. On the brighter side, however, independent experts (Lewis, 2002; Ranum, 2004; Schneier 2003a,) have shown that there are good solutions to protect societies and their infrastructures. Hopefully, policy makers will soon start to listen, if they understand that computer networks, with their economic and psychological position in modern societies, are too important to be left (only) to governments.

## KEY TERMS

**Computer Networks Operations:** A subset of information operations; imply attacks to and defense of networks only through digital tools.

**Critical Infrastructure:** Utility and communication networks without which the physical and economic survival of a society would be impossible.

**Cyberplanning:** The use of the Internet to communicate, gather open source intelligence and spread their political messages by terrorist groups.

**Cyberterrorism:** The use of digital means to threat or commit acts of organized violence against the civilians to achieve political advantages.

**Hacktivism:** The use of computer networks by activist hackers to spread propaganda or to alter perception management in the public.

**Information Operations:** Actions taken to affect adversary information and information systems while defending ones own information and information systems.

**Perception Management:** The selection of bits of factual information to adversaries in order to manage their perceptions and behavior.

# Theory-Based Models of E-Government Adoption

**Craig P. Orgeron**
*Mississippi Department of Information Technology Services, USA*

## INTRODUCTION

Too often, citizens view government as hopelessly ineffective and lacking in skill to deliver services in the same way that a bottom-line-focused private-sector business is able to effectively do. This view often informs a marked decline in political participation and a lack of confidence in the ability of public-sector agencies to effectively and efficiently solve problems (Hetherington, 1998; P. Norris, 1999). As a response, contemporary public administrators have been tasked with government "reinvention" as a way of increasing bureaucratic effectiveness and efficiency (Osborne & Gaebler, 1992). Some scholars have begun to view information technology as a critical component for creating a more capable government, one capable of providing better service and thus increasing citizen confidence in public-sector management (Norris, 2001). Electronic government (e-government) has in recent years attracted much attention as scholars have suggested that by leveraging cutting-edge information technology, government may reap benefits of increased efficiency, effectiveness, and citizen communication with public-sector agencies (C. Chadwick & May, 2003; Ho, 2002; Melitski, 2001; West, 2004). E-government can be defined as the implementation of information technology to supply services between public-sector agencies and citizens, businesses, employees, and other nongovernmental agencies (Carter & Belanger, 2004). E-government offers potential impact on the business of government in two fundamental, yet crucial, ways: by improving service delivery, including costs, and by improving communication between citizens and government (Fountain, 2001). Participatory forms of e-government, such as online public hearings or e-voting, are less common than informational uses or online transactions, such as tax e-filing. Carter and Belanger note that public-sector agencies at all levels of government have leveraged e-government applications to foster buying goods and services, the dissemination of critical information, and the acceptance of bids and proposals (General Accounting Office [GAO], 2001). Arguably, both the public sector and the citizenry benefit from the implementation of e-government services. As public-sector agencies reduce costs and improve efficiency, citizens receive quicker, better aligned services from a more focused and streamlined government (Kettl, 2000).

## BACKGROUND

While a large number of research studies have been conducted that analyze how public-sector organizations use information technologies for internal operational needs (Bretschneider & Wittmer, 1993; Nedovic-Budic & Godschalk, 1996; Norris & Kraemer, 1996; Pandey & Bretschneider, 1997; Ventura, 1995), and more current studies have been published that document the increase in e-government program development (Cohen & Eimicke, 2001; Fountain, 2001; Ho, 2002; Moon, 2002; Thomas & Streib, 2003), few studies focus on the question of what organizational and environmental factors drive the decision to adopt e-government features and online services. Though this research is newly conceived, the desire is for public administrators to have a reliable model from which government agencies can more fully understand what impels citizens to adopt a specific e-government application or service. Clearly, while the body of knowledge regarding e-government is burgeoning, the focus is nebulous and generally lacking in substance regarding the impact of e-government on public organizations. The lack of a rigorous model from which to measure the impact of e-government programs on public organizations represents a methodological lapse in the existing body of knowledge.

In recent years, scholars have worked to frame the new field of e-government by applying well-founded and accepted theories. Jain (2004) cites Scholl as applying stakeholder theory to analyze e-government; in addition, Jain discusses the application of network theory (Bardach, 2002) in the examination of public-sector collaboration via information technology, as well as the use of diffusion-of-innovations theory (Lazer, 2002) as a tool to understand the value information technology can offer leading-edge public-sector agencies. Additionally, various scholars have leveraged the research on user adoption of electronic commerce or e-commerce (Carter & Belanger, 2004;

Gefen, Elena, & Straub, 2003; McKnight, Choudhury, & Kacmar, 2002) to conduct research analyzing the foundational elements directly influencing citizen adoption of e-government services (Warkentin, Gefen, Pavlou, & Rose, 2002). Although e-commerce and e-government differ with respect to access, structure, accountability (Jorgensen & Cable, 2002), and mandatory relationships (Warkentin et al.), e-commerce models can be utilized to analyze the adoption of online services in the public sector (Carter & Belanger).

By leveraging the widely accepted technology acceptance model (TAM), developed by Davis (1989), various researchers have suggested a role in the user acceptance of e-commerce in the private sector (Belanger, Hiller, & Smith, 2002; Carter & Belanger, 2004; Gefen, Elena, et al., 2003; Gefen & Straub, 2000; Moon & Kim, 2001). The TAM is comprised of variables designed to measure the acceptance of software applications by an organization's employees. Carter and Belanger note that these measures have been studied and proved valid for users of varying skill sets and for multiple applications, as well as for gender (Chua, 1996; Doll, Hendrickson, & Deng, 1998; Jackson, Simeon, & Leitch, 1997; Karahanna & Straub, 1999; Venkatesh, Morris, Davis, & Davis, 2003). Similarly, Carter and Belanger document that several studies have also used TAM to evaluate user adoption of e-commerce (Gefen, 2000; Gefen, Elena, et al.; Moon & Kim). Considering the similarities between e-commerce and e-government, the constructs used to study e-commerce adoption are also applicable to e-government adoption (Carter & Belanger; Warkentin et al., 2002).

Additional research has been conducted in the area of the Web trust model (WTM). According to a 2003 survey conducted by the Council for Excellence in Government (CEG, 2003), citizens possess a firm grasp on the potential benefits that e-government could bring to the public sector, but they have "concerns about sharing personal information with the government over the Internet, fearing that the data will be misused and their privacy diminished" (p. 2). Carter and Belanger (2004) note that privacy (Hiller & Belanger, 2001; Hoffman, Novak, & Peralta, 1999) and security (Belanger et al., 2002; S. Chadwick, 2001; GAO, 2001) are recurring issues in e-commerce and e-government research. As noted by Lee and Turban (2001), a citizen's decision to actively pursue the use of online government services requires that the citizen trust the government agency providing the service, as well as trust the Web-based technology utilized to accomplish the transaction. In this vein, newly published research (Gefen, Rose, Warkentin, & Pavlou, 2005) investigates the impact of trust in information-technology adoption in diverse cultures where divergent concepts of socially acceptable behavior exist. To accomplish this analysis, this study (Gefen, Rose, et al., 2005) compares trust-related perceptions of electronic voting between the United States of America and the Republic of South Africa.

However, a recent research proposal by Mete Yildiz (2003) offers an opportunity to examine the motivations of e-government from an institutional-theory perspective. Arguably, from the vantage point of the public organization, the use of institutional theory affords the prospect of understanding the initiation of e-government projects and the impact of these projects on the government agency. Institutional theory aids in the understanding of organizational reactions to conventions of the institutional environment. Thus, institutional theory requires the inclusion of components of decision making such as concerns of legitimacy, stability, and survival (Meyer & Rowan, 1977). After cautioning the use of the "measures and methods of the institutional theory, since it is argued that the theory itself has not institutionalized yet" (Yildiz, p. 2), Yildiz argues that institutional theory may aid public-management scholars and practitioners in the understanding of e-government programs in public agencies. Yildiz suggests that from an "institutional theory perspective, government organizations go online because of legitimization needs and resulting isomorphic pressures" (p. 3). DiMaggio and Powell (1983) write of three main types of isomorphic processes: coercive, mimetic, and normative.

According to the coercive isomorphic process, public organizations have adopted and implemented e-government programs as the result of a pointed managerial directive and/or as a result of unofficial pressure by other public-sector organizations that have already begun an e-government program. In the coercive model, the decision to implement e-government would be made by political appointees and career civil servants for reasons of perceived legitimacy and anticipated efficiency. Using the mimetic isomorphic process, public organizations mimic other successful and legitimate public-sector organizations. Yildiz notes that by imitating these other organizations, which already use e-government successfully, "they enhance their legitimacy by demonstrating that at least the organization is trying to improve the conditions of its service and/or information provision" (p. 3). And lastly, using the normative isomorphic process, public organizations use e-government due to the "newly emerging professional norms of public service—online interactivity, virtual service, transparency and accountability" (p. 4).

## FUTURE TRENDS

The systematic implementation of online public-sector services is proving to fundamentally change the way citizens and businesses interact with government. E-

government offers a significant potential in seeking innovative ways to reach the ideal of government as being of people, by people, and for people. The scope of this article was to analyze theoretical foundations used in the study of e-government and, through this assimilation, bring to light a lesser discussed model for understanding e-government adoption: institutional theory. A wide variety of theoretical models have been employed in the study of e-government: from the use of stakeholder theory (Scholl, 2001) to the utilization of network theory (Bardach, 2002), as well as diffusion-of-innovations theory (Lazer, 2002), the TAM (Gefen, Elena, et al., 2003; Gefen & Straub, 2000; Moon & Kim, 2001), and the WTM (Belanger et al., 2002; Gefen, Elena, et al.; McKnight et al., 2002). Much of this research is newly conceived and is being driven by the desire of researchers to develop a systematic, valid, and reliable model from which government agencies can more fully understand what impels citizens to adopt a specific e-government application or service. It is therefore suggested that the use of institutional theory provides a basic view for guidelines and frameworks that address e-government adoption.

## CONCLUSION

Leveraging institutional theory should also conceptually give impetus for resources that enable e-government's planning, design, and implementation through reviewing the primary factors impacting citizen adoption. Specifically, the following research questions, adapted from Yildiz (2003), can be employed to guide research into e-government adoption. How are e-government projects initiated in a government organization? Which problems do e-government programs aim to solve? Who are the actors in the e-government agenda-setting processes? How do these actors affect e-government agendas? The issues of public administration uncovered by e-government need to be analyzed systematically and further studied, especially in the electronic, digital, and virtual world in which scholars and practitioners in this field are currently working. There is no doubt that e-government impacts bureaucracy in various ways. However, there exists a pitfall that public-sector organizations could embrace the approach of utilizing e-government to achieve organizational transformation; this approach views e-government as providing curt answers to complex organizational and cultural issues (Li, 2003). The employment of institutional theory affords a framework from which scholars and practitioners can begin to understand the initiation of e-government projects and the impact of these projects on the government agency.

## KEY TERMS

**Diffusion-of-Innovations Theory:** Used by Lazer (2002), the diffusion-of-innovation theory is the process by which an innovation is communicated through certain channels over time among members of a social society. According to Rogers (1995), an innovation is an idea or object that is perceived to be new.

**E-Commerce:** The use of communications technologies (such as Web-based technologies) for the conduct of business and service-delivery transactions while leaving internal or external business processes substantially unchanged.

**E-Government:** The transformation of internal and external business processes toward customer centricity based upon service-delivery opportunities offered by new communication technologies (such as Web-based technologies) to better fulfill the purposes of government to provide efficiency and effectiveness as well as fairness and equitability.

**Institutional Theory:** Used by Yildiz (2003), institutional theory helps us to explain the ceremonial conformity to rules and trends of the institutional environment. It necessitates the incorporation of bounded-rational and social aspects of decision making such as concerns of legitimacy, stability, and enhanced survival prospects.

**Network Theory:** Used by Bardach (2002), network theory refers to the analysis of social networks as a key technique in modern sociology, anthropology, social psychology, and organizational studies, as well as a popular topic of speculation and study. Research in a number of academic fields has demonstrated that social networks operate on many levels, from families up to the level of nations, and play a critical role in determining the way problems are solved, the way organizations are run, and the degree to which individuals succeed in achieving their goals.

**Stakeholder Theory:** According to Scholl (2001), the stakeholder research tradition began to unfold in the wake of R. Edward Freeman's book *Strategic Management: A Stakeholder's Approach*. Freedman demonstrated in a comprehensive fashion that the strategic management of private-sector firms could become much more effective and efficient if managerial efforts regard various stakeholders' concerns. In other words, shareholders benefit long term if other legitimate interests in the firm do not fall by the wayside.

**Technology Acceptance Model (TAM):** TAM is an information-systems theory that models how users come to accept and use a technology. The model suggests that when users are presented with a new software package, a number of factors influence their decision about how and when they will use it, notably, about its perceived usefulness and perceived ease of use (Davis, 1989).

# Third World City in the Information Age

T

**Dipankar Sinha**
*Calcutta University, India*

## INTRODUCTION

It could be one of the great paradoxes of history that the third world continues to urbanize itself at a faster pace than the developed world. At the same time, third-world cities, inevitably at the cost of the rural areas, continue to play the game of one-upmanship in proclaiming themselves the best possible hub of the information and communication technology (ICT). Such a phenomenon is natural not only because in the third world the cities are the privileged sites or spaces in which any new and progressive process or event is supposed to take root but also because the cities, the firm favorites of the policymaking elite of the third world, are supposed to be the privileged channels in the trickle-down process of development. In this process, the hinterland (the suburbs and the rural areas, mostly in that order) fall behind. Thus, a veteran scholar of third-world urbanization, T. G. McGee (1971), described third world cities either as "enclaves" (spaces meant for the elite's games surrounded by "hostile peasantry") or as "beachheads" (centers of modernization and catalysts for economic growth) (p. 13). However, cities in the third world are not monolithic entities enjoying exclusive occupation by elites and other privileged sections of society. Our real-life experience shows that third-world cities that are inhabited by nearly one-third of the world's urban population provide classic and shocking contrasts in terms of playing host to affluent, powerful citizenry on the one hand and to their underprivileged, powerless counterparts—ordinary people (the middle-middle/lower-middle classes downward) on the other hand. The latter, at best, possess only the legal attributes of citizenship, and, at worst, they are devoid of even that to remain utterly marginalized if not pulverized. It is in this setting that the third-world city opens itself up to the information age and its concomitant: digital governance.

This article limits itself to drawing attention to the fate of the third-world city caught in the vortex of the information age and the associated rhetoric of salvation. In the process, it reveals certain general indicative trends. It does not provide any fixed blueprint for immediate crisis solving, keeping in mind the variety that exists in third-world cities despite a substantial degree of commonality among them. However, it does endorse the view (Visvanathan, 2001) that to "understand … spaces being continually defined by development we need sharper tools for the analysis of symbolic space and the interrelationship between historical events and social phenomena, which bring space, time and culture together" (p.182).

## BACKGROUND: INFORMATION REVOLUTION AS SOCIAL REVOLUTION

The information age might have been initiated and propelled through spectacular technological breakthroughs, but it goes beyond the technological confines to have immense impact on the lives and lifestyles of people across social echelons (Robins & Webster, 1999). With the onset of globalization, which compresses space and time like never before, the policymaking elite of third-world countries dreams of harnessing its power to create an information society. As it is, in the information society, the socialization of technology is a must in order to put its power and to reach to the service of the people. This is what makes the information revolution a social revolution in the fundamental sense. What is seen, however, as Scott Lash (2002) so directly puts it, the information society turns into the "Disinformed Information Society" (pp.141-155). Obviously, the state has a key role in such a design in terms of its stress on thrusting an information society on the people without adequately promoting the communicative dimensions (Sinha, 2005).

Referring back to ordinary people in the third world, they continue to be marginalized and even pulverized. It is despite this fact that in almost all third-world cities (e.g., Kolkata [previously Calcutta], Mumbai [previously Bombay], Delhi, Dhaka, Karachi, Rio de Janeiro, Johannesburg, etc.), a substantial percentage of prime urban land/space is occupied by the less privileged segments. Such occupation can be found in various forms, such as pavements, public parks (originally planned for the privileged), bus terminals, railway stations, government precincts, or, for the relatively fortunate ones, *bustees, jhupries*, *favelas*—slums and shanties. Thus, one finds a widespread urban schizophrenia in the cities. However, what is more alarming, as I have demonstrated (Sinha, 1989) in the case of Kolkata, policymakers remain largely ignorant and indifferent about it. The following statement on the city-regions in the developing countries confirms this point:

*[T]he population of global city-regions are almost highly segmented in terms of social class (and) income. ... These city-regions then assume spatial forms that express ... segmentation of the rich and poor. At one extreme, one finds massive poor communities living in shantytowns,* favelas*, and* bidonvilles*, and at the other the more spacious and well-equipped communities of the middle class and the rich. ... This architecture of fear only exacerbates the fragmented character of the urban space, and generates additional problems.* (Scott et al., 2001, p. 25)

Being partially if not completely devoid and deprived of many basic amenities in life, cities in the third world with loads of ordinary people now are waiting to be catapulted to the status of what Manuel Castells terms an *informational city*. It happens amidst the hype generated by third-world rulers as well as the media that the information age is a sort of magic wand (Sinha, 2004). The magic wand is supposed to end the hitherto existing discriminations, deprivations, and exclusions. In short, the urban third world is expected to benefit immensely from the much-publicized marriage of good governance and digital governance. It particularly happens when the information revolution is conceptualized and sought to be implemented technocratically and technologically, keeping the vital issue of social negotiations out of sight. The wrong can be corrected to a considerable extent if the information revolution is treated fundamentally as a social revolution and as one stage of social development. This would demand extensive organizational innovation and restructuring. But it calls for the change in the mindset of the ICT-happy third-world policymakers, as well. For a good beginning, they might try to be conversant with the concept of informational city.

## INFORMATIONAL CITY

The information age acquires importance because the steady and rapid expansion of ICT has been a constitutive element of the globalization of capitalism, often specified as information capitalism. This leads to the point that information today has shifted to a higher status—from being a facilitator to commodity production to being a key commodity. How, then, do ordinary people in a third-world city confront this problem? A lead can be found in the way Castells (1989) conceptualizes and theorizes the informational city.

Castells (1989) defines the informational city as an urban system with sociospatial structure and dynamics determined by a reliance of wealth, power, and culture on knowledge and information processing in global networks, managed and organized through intensive use of ICT. But it is only one side of the coin. He simultaneously points out that the informational city is a dual city. Dual city, in Castells' perception is an urban system socially and spatially polarized between high value-making groups and functions on the one hand and devalued social groups and downgraded spaces on the other. The politics of a third-world city vis-à-vis the information age can be explored more specifically from these twin referents.

Ari-Veikko Anttiroiko (1999) incidentally refers to a number of items of the informational city Management, of which a select few can be mentioned for providing a more concrete scenario:

- **Main Premises:** Globalization and the information mode of development; informationalism and new welfarism; managing aspects of risk society.
- **Overall Objectives:** Welfare and quality of life; equality and equity; sustainability and diversity.
- **Operational Objective Area:** Thriving local and regional economy; strengthening human and social capital; attracting external resources; efficient and cost-effective administration.
- **Strategic Tools:** Better innovativeness; efficient utilization of institutional resources; creativity and utilization of human and social capital; informational urban policy lines.
- **Informational City Management Techniques:** New concept of informational city management; networking and creative alliances and partnerships; enhancing local investment and empowerment; city marketing and place promotion; management support systems.

Before we go more deeply into Castells' (1989) depiction of the informational city to extract its political implications, it is important that we refer to his earlier and classic work, *The Urban Question* (1977). In it, Castells produced two senses of urbanization: first, as a spatial concentration of a population on the basis of certain limits of dimension and density; and second, as a diffusion of a system of values, attitudes, and behaviors—by the name *urban culture*. While to Castells, the notion of *urban* relates to the ideological dichotomy between traditional and modern society, in his scheme, the process of urbanization, linked with the development problematic, relates to technological and economic level, to process as qualitative transformation of social structures, and to ideological function in the form of structural change presented as accumulative movement of technological and material resources of society.

No less significant is the fact that, with this backdrop, in *The Urban Question*, Castells also introduced and elucidated the concept of *collective consumption* (a concept of fundamental importance along with the concept of *reproduction of labor power*), which refers to forms of

services (e.g., mass transport, housing, health facilities) collectively provided generally by the state. Castells, in fact, established a link between collective consumption and political mobilization, which lies at the basis of urban social movements (e.g., squatters' movements, tenants' movements, etc.), aiming to challenge the existing nature of collective consumption, if the need arises, for purpose of improvement. Castells floated the concept in the particular context of labor force on which the capitalists depend for production of commodities.

However, there is reason to develop a critique of Castells' propensity to focus on the concept of collective consumption, somewhat at the cost of the process of production. The latter carries much relevance in the third-world context, which has been well explicated by scholars like Lojkine(1976) and Harvey(1973). But, with some degree of liberty, one can stretch the concept of collective consumption to include the ordinary people referred to here. One can do this on two grounds: (1) the concept refers to the collective use of certain services that also have something to do with the quality of life of individuals and with the role of the state in organizing and running the various forms of collective consumption; and (2) for a long time, this resembled the scenario in the third-world cities. A major criticism against Castells could be that the concept of collective consumption is less relevant in the case of the Western-developed states that also have large private provisions of consumption. By the same logic, the concept retains its validity in the third world. However, with the coming of the information age, the concept, which is rooted in the ideas of state welfare, was in need of revision. Castells seemed to have realized this as much as his critics, particularly Saunders (1986), who is best known for his dual state thesis. Saunders (1986) made incisive analysis of the advent and centrality of consumption practices as a reference point of urban inequality by explicating the growing split between those who can afford to purchase their services from the market and those who continue to depend on state welfare.

## INFORMATIONAL CITY AS DUAL CITY

The information age, which is based on a distinctly new mode of production and a new form of organizing power, is not without its share of risk, uncertainty, and unpredictability. Saskia Sassen (2000) refers to the "new geography of centrality and marginality" (pp. 267-280) in this context. In Sassen's scheme, the new global economy in effecting centrality binds the cities, especially the downtowns and metropolitan business centers, of the developed and the developing world, particularly through financial markets and transactions in services and investments. On the other hand, low-income city areas continue to sink. The disparity, according to Sassen (2000), is even more evident in the contrasting pictures of workers, with highly educated workers witnessing a steady rise in their incomes and low- and medium-level workers facing steady declines and disasters.

As Castells views it, the lifelines of the information age—the space of flows and networking—produce revolutionary changes, but the changes, by their very characteristics, give rise to tension created by the conflict of personal well-being and social alienation, individual fulfillment, and social disintegration. Space of flows refers to different centers linked in information space through electronic networks. Networking relates to governance based on the use of flexible linkages organized by information technology. The two give rise to a flexible form born out of placeless logic and functional footlooseness of the network state within the framework of which the government works in more and more collaboration with other governments and supranational institutions. The institutions of society and governance, particularly in third-world countries, face the unpredictability factor head on. They fail to keep pace with the changes thath find their highest expression in the global financial market—a virtual automate, in Castells' description—that affects everybody by doing things by itself without knowing why it does it. A direct and evident outcome of it can be found in the dismantling of traditional organization and patterns of work marked by stability, and the rise of various networks resting on temporary, contractual work in which individuals are constantly on the move by shifting jobs, tasks, and assignments.

With such sweeping change being inevitable, it is expected that the information age only would cause the decline of collective consumption through advocating decline in planning, thus facilitating the dominance of the market mode and privatized modes. All these are part of the process in which there is a perceptible shift from social redistribution to promotion of capital accumulation, from politics of legitimation to domination, and greater expansion of the capitalist system by accelerated internationalization of economic processes. This, in turn, creates a great cleavage between those who can afford to go by the market mode and those who are left behind to stick to the collective consumption, however emaciated it might be. When Castells theorizes on the informational city as a dual city, he has this cleavage in mind. His treatment is not superficial. As Castells explains in his reference to New York City as the dual city, it does not simply mean opposition between executive limousines and homeless people. More fundamentally, it represents an urban social structure that exists on the basis of interaction between opposite and equally dynamic poles of the new informational economy, whose developmental

logic leads to polarization of society and its social groups, creates segmentation in labor forces and occupation, isolates cultures, and segregates the uses of a shared space.

One does not have to stretch one's imagination too far to realize the graver consequences of this cleavage in the third world (cities) in which it acquires an extreme form. To quote Castells: "There will remain switch-off, wireless communities, still real people in real place, yet transformed into urban shadows doomed to haunt the ultimate urban dream of new technology" (p. 19). Castells' observation finds echo in Mike Davis (quoted by M. Irvine):

*The contemporary city stimulates or hallucinates itself in at least two decisive senses. First, in the age of electronic culture and economy, the city redoubles itself through the complex architecture of its information ... networks. ... If so, urban cyberspace—as the simulation of the city's information order—will be experienced as even more segregated, and devoid of true public space than the traditional built city.* (Irvine, n.d.)

Let us take the instances of attempted replication of the Silicon Valley in third-world cities. In terms of high-tech-sponsored spatial manifestation, such replication runs the risk of being a truncated and incomplete version of the original. Castells refers to the following five factors that led to the establishment of the semiconductor industry in Silicon Valley: (1) the presence of high-ranking universities with intense research orientation in general and in thrust areas like electrical engineering and computer sciences; (2) organized and proactive network of financial firms specializing in venture capital; (3) positional advantage as regional nodes center and nodal points in national and international network of telecommunications and air transportation; (4) pleasant environment and hosting of an industrial milieu beyond the confines of its own organization; and (5) the military market. The factors indicate that they are the products of a long tradition and exceptionally wide-ranging milieu of innovation that cannot be developed overnight in the city regions of the third world. On the other hand, it is a total package without any opportunity of being selective about its ingredients. In other words, either the third-world cities should have all such facilities in a very satisfactory, if not full-fledged, form, or they simply do not. The question is how many cities in the third world—already reeling under the strain of large-scale migration and associated problems like scarcity of livelihood, predominance of low-end, low-skill jobs and housing—are ready for a high-tech hub? The question calls for greater introspection because, as the preceding discussion shows, the difference between the thinking of being ready and being actually ready is the difference between the proverbial cup and the lip.

## FUTURE TRENDS

Urbanization policies, as one observer mentions, "have traditionally been negative in tone and intent" (Mohan, 1996, p.130). Add to it the inherent hierarchy that remains integrated to the third-world urbanization process in general and the third-world city in particular. Would not, then, the technocratic interpretation of the information age intensify the problem? One might argue that because such interpretation is couched with determination and optimism, the problem will go away. But let us assert that such technocratic optimism is part of the problem and not the solution itself. Only if its policymakers are ready to view the information revolution as a social revolution can they find possible and effective clues to establish a humane city with more equitable vision. The path is not very smooth. Then again, smoothness has never been a great attribute of urban management, as it always confronts urban politics not only in terms of physical control over physical urban space but also physical control over symbolic urban space, the latter being the instances of occupation or demonstration in prime locations in cities for a temporary period for a show of strength. The way forward, though strewn with challenges of complex nature, is to reinstate and reiterate the political, as expressed through reciprocity, conviviality, solidarity, cooperation, and not the least, simultaneously pursued competition and contest, which is a process through which challenges and negotiations emerge and sustain themselves amidst contradictions and dislocations that mark the urban scenario in the third world, in particular. Services like housing facility, sanitation, sewage, drainage and garbage removal, and public transport concern the efficient or inefficient nature of urban management. But the question is how can citizens demand a better deal in these services, if they are found in pathetic state?

The demand for the aforementioned services in the improved and better form—in the form of socially and environmentally sustainable sanitation, sewage, drainage and garbage removal and public transport—would need social struggles and protests and movements of segmented collectives of ordinary people. It could be evident in putting up roadblocks, organizing meetings and processions, or even making collective representation to the friendly or not-so-friendly city councilor by people of different neighborhoods and/or social strata. It also requires greater attention of the powers-that-be to the citizen-centric political process and greater receptiveness to criticisms and protests. All of these provide the clue that rather than being over-enthusiastic about the inherent powers of the information revolution, the need of the hour is to adopt a stance by which the technological marvels of the revolution could be integrated and recon-

ciled with more material aspects to improve the quality of life of ordinary citizens.

In addition, the local institutions, both public and private, have a key role here, but then again, they are facing tremendous challenges. There is little doubt that ICT has an intimate tie with the hyper-mobile global capital, the modus operandi of which calls for withdrawal of subsidy and weakening of public service provisions and the social sector (e.g., housing). This, as observed by scholars (Logan & Molotech, 1987), is leading to severe erosion of the autonomy of cities all over the world (including developed countries). Thus, when one thinks in terms of (urban) development in the third world, one has to rethink the locality (Peterson, 1981) in light of these new developments. It is known widely that local governments in the third world generally are weak, if at all in existence. This, from the very foundation, subverts any possible initiatives to reconcile the technological with the existing political, economic, social, and cultural milieu. However, the following excerpt, taken from a booklet titled *Are you a Councillor? This Booklet is for You* (2001), reveals that there are some attempts at the local governmental level in the urban third world to reconcile with the new reality. The excerpt shows how the elected councilors of the municipalities, the urban local body meant to administer towns, are provoked to be acquainted with ICT (more specifically, computers) in order to serve their constituencies better. The excerpt reads:

*It goes without saying, if you need to make use of a technology to the fullest, you need to be familiar with it. ... You might ask, "I don't know how a computer works." ... In reality, it is not a very difficult proposition. Leave out the examples in developed countries; some of your colleagues have learnt this technology quite well within a few days. They too did not know the basics of computers. ... Even then if you fear you are not confident ... ask for training.* (p.8)

In indicating the councilors' political positions, power, and responsibilities, the brochure concludes in this dramatic vein:

*Whether you want to continue as subservient to the traditional system in the future or assert your own rights to fulfill the genuine expectations of your electorate, the final decision is yours.* (p.8)

Such efforts need to be imparted a more broad-based character beyond the confines of the councilors. To initiate such process in more concrete terms, the imperative is to integrate a movement for technology literacy (developing the power to understand and analyze technology in terms of its positive and negative impacts) with social movements. It is unfortunate that in third-world countries, where one would find the existence of many kinds of social movements, none really goes for such integration.

## CONCLUSION

The preceding discussion, among other things, reveals the problems with the technocratic orientation of policymaking in a specific context—the deployment of ICT in the (third-world) city. Keeping in mind that technocratic rationality tends to undermine political rationality, de*myth*ifying and demystifying the information revolution through the socialization process mentioned earlier become urgent tasks. It is needed particularly in order to prevent the third-world city, which is still a space for the struggle for existence and emancipation, from being thoroughly depoliticized and from becoming a bottomless pit. It definitely involves a long and arduous struggle, but only such integration can, in turn, make both the policymakers and the people aware that the question of ICT is not simply a technological issue insofar as providing dignified and humane living to the ordinary people of the third world. It is, first and foremost, a social, cultural, economic, and political question.

## KEY TERMS

**Disinformed Information Society:** Mainly developed by social theorist Scott Lash, it refers to a cultural development made up of unintended consequences of the informationalization, which makes information ubiquitous and spins it out of control. It also leads to overload of communications, thereby subverting many of the promises and prospects of the information society.

**Dual State Thesis:** Attributes two functions of the State—(1) social investment, which aims at maintenance of goods and services in the economy with support to the profitability of the private sector firms and (2) social consumption, which supports the consumption needs of diverse groups that cannot fulfill their requirements through the market.

**Information Age:** An era marked by the advent of information as a primary resource/commodity, guided by information flow, with the consequences of spatial and temporal compression, disembeddedness, and real-time relations.

**Informational City:** An urban system with sociospatial structure and dynamics determined by a reliance of wealth, power, and culture, and on knowledge and information processing in global networks managed and organized through intensive use of ICT.

**Information Mode of Development:** The resultant change guided by development ICT-mediated communication, which contributes to radical reconfiguration of institutions and processes.

**Information Revolution:** The transformation in the nature of information, propelled by that of technology (beyond the earlier focus on the silicon chips and based on the later focus on the economic, social, cultural, and political dimensions of information and communication technology) with extensive and intensive impact on society.

**Information Society:** Primarily theorized as a post-industrial society marked by the centrality of knowledge-based services, as distinct from the industrial society in which production of goods held center stage.

**Third World:** The underdeveloped and developing countries/societies of Asia, Africa, and Latin America. The term is shorn of its pejorative connotations here.

**Trickle-Down Process:** A process characterized by the gradual diffusion, penetration, and percolation of the changes occurring at the top of the layer (in this case, the upper crust of society/economy/polity) to the lower level.

# Third-Generation Local E-Government

**Busso Grabow**
*Deutsches Institut für Urbanistik (Difu) (German Institute of Urban Affairs), Germany*

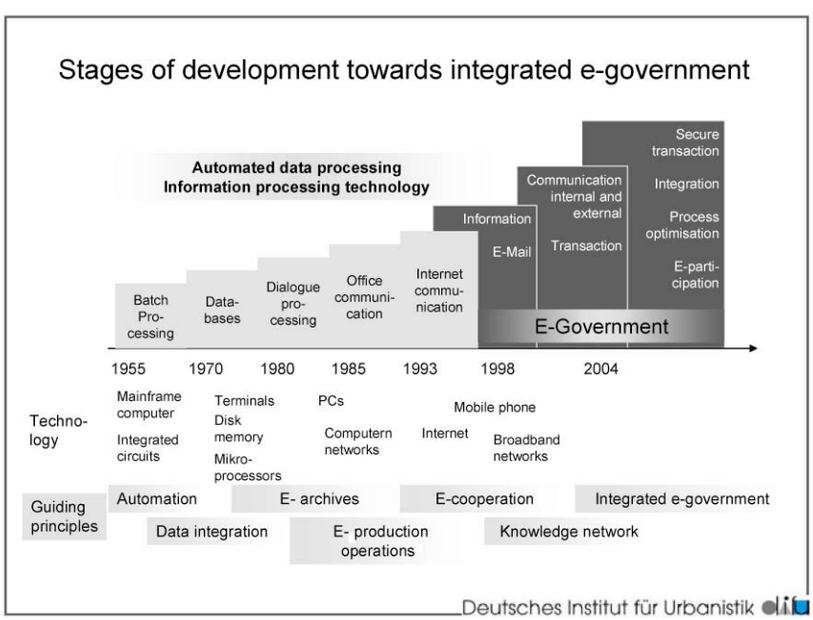
## INTRODUCTION

Local e-government reflects an ongoing process of modernization. Like all processes of innovation and modernization, the development of e-government is also characterized by various phases and cycles. These phases of development are fundamentally similar, whether they are implemented in a country that is a pioneer of e-government or a country that is among the stragglers in the electronic modernization of the administration. As to the specific mechanisms, the obstacles and the driving forces of modernization vary from one country to another. At the same time, there are differences in the introduction and development of e-government between the different levels of government. National e-government strategies and possibilities are subject to different conditions than a local e-government. The national differences and the differences between various levels of government depend on factors such as the state constitution, the institutional circumstances, work cultures, modernization strategies, IT equipment, Internet access, or financial resources (Drüke, 2005b, p. 286-291; Eifert, 2004; Socitm & I&DeA, 2002, p. 8). This is important as a preliminary remark for the limitation in the scope of this study, which is focused on Germany and specifically the local government level. However, these perspectives are naturally reflected in the international discussion about good e-government.

## BACKGROUND[1]

Before the idea of third-generation local e-government is presented in detail, the historical background and the preceding discussion of e-government in Germany must be considered. The term "e-government" originated in the English-speaking countries and has been used in German-speaking countries only since the second half of the 1990s. Since then, Administrative Science and Administrative Computer Science have tried to provide an authoritative interpretation of this artificial term. At least among German-speaking specialists, agreement has largely been

*Figure 1. E-government development stage model*



reached on a comprehensive understanding. According to this view, e-government includes *all* aspects of government and administration (public policy formation, decision-making, creation and provision of services, public participation)[2] insofar as they can be supported and enhanced by the use of information and communication technology.

So this definition follows on from the considerations and descriptions of potential from the boom era of computing in the administration, some of which were very far-sighted even then: "In future, information technology is likely to cause far more fundamental questions to be asked about the citizen-related tasks of the administration" (Reinermann, 1987). The phrases "automated data processing" and "information processing technology" were coined in the early days of computing, and they are still used alongside the term "e-government" which is so popular and therefore so eroded by constant use.

The creation of the term e-government not only marked the rise of a fashionable "Americanism" in the discussion in German-speaking countries. Instead, it represents a step across the threshold toward a new quality in the use of ICT technology in the administration, marked by the use of the Internet—today mainly in the Internet applications www and e-mail. New technical opportunities have arisen which are quantum leaps in comparison with earlier computer systems both within the administration and in contacts with the citizens. Here are just three factors:

- The internal computer networks of the administration have interfaces to the computers used by the "customers" of the administration; direct data exchange is therefore possible.
- E-mail communication allows asynchronous exchange between partners in the administration, politicians, citizens, and business people.
- Different computer systems are made compatible by "middleware" and established standards and protocols for data exchange; electronic communication and transactions can take place "across platforms."

At the end of the 1990s, the use of the Internet by local communities was mainly limited to offering information on their Web sites—it was no accident that many municipal Web sites were referred to as "municipal *information* systems." This first generation of local e-government was gradually replaced by the second generation in which the provision of information itself was supplemented by communication and transaction services: by the provision of forms on the Internet, by participation facilities on local community portals—a term which has increasingly replaced the "*information* systems"—or by the possibility of electronic interaction and transaction services. The speed with which e-government of the second generation has spread is very varied; pioneering municipalities and regions, such as those involved in the MEDIA@Komm model projects in Germany[3], which were documented in other countries, for example, in Drüke (2005a) and Socitm & I&DeA (2002)—have made considerable progress, whereas most other local communities still only provide information services.

## TOWARD THE THIRD-GENERATION E-GOVERNMENT

If supplementing information and communication services by transaction services is described as e-government of the second generation, what is the third generation? What are the fundamentally new characteristics of the next generation of e-government? What are the decisive questions and features in the transition from one generation to the next?

In the phase of transition from the second to the third-generation e-government, innovations and individual solutions are beginning to grow together as integrated and consolidated implementation concepts. So the third-generation is not only characterized by a "higher level" of the use of electronic media, it also involved consolidation processes and integration at different levels.

Each "phase transition" is a time for important and decisive steps: knowledge gained from experience gives rise to new questions (cf. next section), and new positions and insights in academic theory and practical municipal solutions are discussed in preparation for the next phase.

Before the distinctive features of the third-generation of e-government—"integration" and "consolidation"—are subjected to closer scrutiny, we must describe the way e-government is embedded in the cycle of innovation which is characterized by the introduction and application of ICT technology in a networked society; for more detail, see Lenk and Traunmüller (1999, p. 21-51), Castells (2000, p. 38-60), and other sources quoted there (cf. Figure 1).

The first visible attempts to develop the third-generation of local e-government in Germany are so far only apparent in selected pioneer regions and cities such as Hamburg and Bremen. Good examples of such pioneers in Europe, the USA, and Canada can be found in Drüke (2005a), Hagen and Kubicek (2000) and Traunmüller (2003).

When we speak of "integration" as a characteristic feature of the third-generation e-government, this means:

- Grouping of e-government services by life situations or concerns.
- Integration of electronic information, communication and transaction services.
- Integration of different options to contact the administration (citizens' office, phone/call centre,

Internet, e-mail, UMTS, etc.) (i.e., "multi-channelling")
- Internal integration of front-office and back-office so that processes are implemented electronically without discontinuity of media by the online portal where appropriate, even including specialist applications
- Integration of applications reaching beyond the local community (horizontal integration) and data exchange with national or federal state organizations (vertical integration)
- Integration of technology and organization by business process optimization
- Technical integration (e.g., by the use of powerful e-government platforms taking into account the relevant e-government standards and other widespread standards)
- Integration of the main modules which must be implemented to achieve successful local e-government (success factors)

The different forms of integration represent an immense challenge to the administration and can only be implemented step by step. At every step, care must always be taken to ensure that options for subsequent integration stages are not blocked.

Another characteristic of the third-generation e-government is that legally binding electronic transactions must be possible. According to the current legislation in Germany, a verified electronic signature is necessary for all cases in which the law requires that agreements must be made in writing. The countries of Europe have introduced different provisions based on the requirements of the EU directive on common conditions for the introduction of electronic signatures (European Communities, 1999).

Finally, using ICT and the Internet to improve participation by the citizens is also of central importance for the third-generation e-government. This goal still plays a subordinate role—compared with other goals—in practical use at the local communities. This should be changed in view of the necessity of developing the community of citizens and integrating citizen involvement in society; cf. the examples and possible fields of action in Traunmüller (2003, p. 43-84), Drüke (2005b, p. 274), and Grabow (2004c).

It is obvious that process optimization is more than just a natural consequence—it is essential if technology and the organization are to be integrated—and that optimization must be preceded by a fundamental critique of the tasks. An exact implementation of the conventional administrative processes in the electronic world would be just as unproductive as correcting typing errors on the screen with correcting fluid.

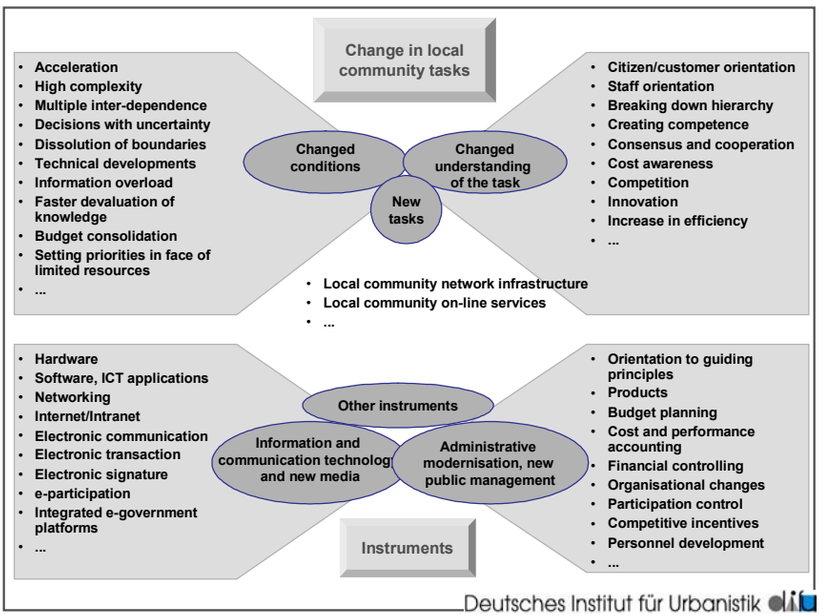
But it is not just a question of adapting the organizational processes. Instead, two fundamental and "revolutionary" modernization tasks should be combined: modernization of the administration (against the background of the guiding principles for the new public management) and e-government. Basically this means harnessing the "enabling" potential of ICT technology and the Internet for administrative modernization.

This use is all the more appropriate because of the many areas in which the changed general conditions for administrative action, certain concepts of administrative modernization and the characteristics of modern ICT technology and new media correspond to each other (cf. Overview 1). This cannot be explored in detail here, so we will focus on the concept of "acceleration" as an example: in general it can be observed that product cycles, industrial cycles and location selection cycles are increasingly accelerating. Speed is becoming a quality factor for locations, and in many municipalities this forces the acceleration of administrative processes and decisions. On the other hand, acceleration and speed are also inherent elements of the new information and communication technology and the Internet and part of their potential (automation, faster computers, fast electronic

*Table 1. The interdependence between the general conditions, the concepts of the modernization of the administration and the characteristics of new ICT technology and new media (German Institute of Urban Affairs; Grabow, 2004)*

| General conditions for administrative action and political decisions (selection) | Concepts of the modernization of the administration (selection) | Characteristics of new ICT technology and new media |
|---|---|---|
| • Acceleration/ growing dynamism<br>• High complexity<br>• Multiple inter-dependence<br>• Decisions with uncertainty<br>• Dissolution of boundaries<br>• Technological developments ⇔<br>• Information overload<br>• Faster devaluation of knowledge<br>• Setting priorities in face of limited resources | • Acceleration<br>• Parallelization of processes<br>• Leaner processes<br>• Breaking down hierarchy<br>• Reorganization<br>• Teamwork<br>• Open communication ⇔<br>• Cooperation<br>• Creating competence<br>• Innovation<br>• Increase in efficiency<br>• Competition | • Speed<br>• Parallel rather than sequential processes<br>• Reduction of complexity<br>• Networking<br>• Broad access to information<br>• Navigation aids in the information environment<br>• Self-organization<br>• Open network<br>• Informal communication<br>• Innovation |

*Figure 2. Changes in local community tasks and instruments (Grabow, 2004)*



communication, parallel processing instead of sequential processing).

On the whole, therefore, new ICT technology and media are forcing certain changes in the administration and the way tasks are carried out, and on the other hand their use is also encouraged by new approaches in the political sphere and the administration.

The reaction to the changed general conditions in local communities is a change in the understanding of tasks in the administration and the political sphere. Existing tasks are changing, new tasks are being added, old tasks are becoming disposable. At the same time, the guiding principles for the local community administration are changing (at least, this should be so in view of the current discussion on the modernization of the public administration); the goals for a local community administration which meets the requirements of today are being redefined, in keeping with the concepts defined for the new public management. In Germany these goals were initially set in the new control model of the Joint Communal Association for Administrative Simplification (KGSt) of 1993, although some of the details have now been changed.

Of course, it must be noted that the process of modernization is only progressing in small steps and with mixed success in many municipalities and local communities. For example, it is rare for all elements to be completely implemented; in most cases, modernization initially covers only isolated areas. The undoubtedly sensible basic concepts encounter various difficulties in practical implementation, and in some cases they even have negative effects—which were predicted by some critics at an early stage. But this should not hinder us from using e-government as a catalyst to give new impetus to the process of administrative modernization where it has come to a standstill. "In a sense, e-government creates a second chance for administrative reform" (Drüke, 2005a, p. 4).

## FUTURE TRENDS

In the phase of transition to the third-generation e-government, which aims to give new impetus to administrative modernization and which, as mentioned above, is a time in which important decisions must be made, the step forward to a "phase of maturity" will not be possible without answering new central questions.

These questions include the following:

- How far can the administration and the political sphere be transformed by e-government in their structures, processes and functions?
- Is the guiding principle of integration of and by e-government compatible with the different federal structures which are especially strong in countries like Germany?
- Is the design potential determined by questions about the economic efficiency of e-government?

- What are the factors which demonstrably promote the success of integrated e-government?

Initial answers to these questions are given in the issue of the Deutsche Zeitschrift für Kommunalwissenschaften (German Journal of Urban Studies) focused on "Local e-government" (No. 2;/2004). Hill (2004) has formulated a clear position on the previous core theme (i.e., the extent to which e-government) as a comprehensive modernization project, is automatically linked with administrative reform. He even heightens and extends this question by speaking of transformation rather than modernization. He rightly suggests that e-government offers considerable transformation potential for the state. This means that centralized and decentralized services must be re-examined. The role of the citizen and the joint organisation of public affairs by the state, the business community and society should also be discussed afresh in the light of e-government. This also shows that current ideas about the future of (local) e-government must be extended, and that an all-embracing discussion of e-governance is necessary.

Integration, which is a major element of e-government of the third generation, also includes the integration of applications which reach beyond the local community (horizontal integration) and data exchange with national or federal state organizations (vertical integration). If we follow the arguments presented by Hill (2004), who suggested that the decentralized performance that is typical in strongly federal states such as Germany would need to be reviewed and possibly replaced by central "overlay" administrations, this would erode one of the basic principles of the division of responsibility in a federal state. But this apparent dilemma can be overcome by pragmatic solutions. Instead of centralization, Kubicek and Wind (2004) suggest standardization in data exchange. Although they suggest that the main responsibility for the slow progress in data integration lies with federalism and local community self-administration, they show that there are good examples of harmonization in practice. These examples show that there is considerable integration potential without calling the basic principle of federal government into question. Nevertheless, this leaves the problem that "retreating" to use harmonization of data exchange as the sole instrument for integration would fail to exploit the considerable potential savings that could be achieved by central provision of services (e.g., by joint organizations acting on behalf of the local communities).

After all, economic viability in the transition to the third-generation e-government is especially important in view of the shortage of local community finance. The search for potential savings is at the top of the political agenda, and this brings up several questions: Are there any practical ways to evaluate e-government from an economic perspective? Can the further development of e-government be recommended from the point of view of economic efficiency? If both questions are answered with "Yes," does a judgement based on economic considerations lead to the right decisions, or does it in fact jeopardise the goal of the "common good?" The articles by Engel (2004) and Grabow (2004) show that discussion of these issues has only just begun in Germany. But even internationally, there seem to be very few cases in which greater insights have been attained: "In general there is little knowledge about the cost-benefit-relation, and this is severely felt as a huge gap by practitioners in the municipalities and political officials" (Drüke, 2005b, p. 276). It is obvious that far more research is needed on this subject.

But there are more answers when it comes to the success factors for integrated e-government. Whereas e-government of the second generation often only considers individual factors or solutions, the third generation is characterized by the fact that it takes the different success factors into account simultaneously at different levels and attempts to integrate them. "The long-term success of local e-government is determined in the last resort by far more factors than are often assumed. Online applications and their benefits are only one aspect. One of the main insights of Administrative Science on the subject of e-government is that the technology or the applications on their own are not the key to successful e-government. In fact, there is a whole range of factors such as organizational measures, strategic procedures, qualifications, communication, partnerships, obtaining resources, and much more." (Grabow et al., 2004). The success factors were identified, and a management concept was developed in the accompanying research to the German MEDIA@Komm model projects to offer local communities guidelines for their e-government developments.[4] The model of the success factors also serves as an evaluation grid for benchmarking in the development toward integrated e-government. It has been successfully used for an exemplary description and analysis of local e-government by reference to seven different countries (Drüke, 2005a).

## CONCLUSION

Even though this article had a double limitation in its perspective—the specific German view and the focus on local e-government—most of the points mentioned are equally applicable internationally and to e-government at all levels of the state. It is obvious that the most difficult step in the development of e-government is still ahead of us—integration at all levels including the expansion of e-government to constitute e-governance. Fundamental

decisions must be made. The discussion on the right approach is being conducted in many places. Especially in relationships with citizens and the business community, e-government of the third generation will lead to greater upheaval in the administration and the political sphere than was expected when the first municipal information systems were set up.

## KEY TERMS

**Back Office:** This is the overall term for all processes and areas in a business enterprise or public authority which are carried out in the background for the citizen or customer and are not directly visible. It includes the internal processing of applications and queries received by the administration.

**E-Governance:** E-governance stipulates the rules and negotiating processes of all participants in the process of shaping society from the perspective of the special challenges and rules of the information society (ICT technology, Internet, new networks, etc.). Public e-governance describes the specific focus of the public sector.

**Front Office:** By contrast with the back office, the processes which take place in the front office are processes in public administrative transactions which are visible to the customer. The further steps of processing the customer's request then take place in the back office of the administration.

**Life Situation Concept:** Life situations are central life events such as work, birth, marriage, relocation, starting school (i.e., subject areas which require a variety of administrative services). The life situation concept aims to provide "one stop" services for these situations.

**Multi-Channelling:** For each administrative service, the suitable distribution channels are considered in each case (personal contact, citizens' advice office, letter, fax, telephone/call centre, Internet, e-mail). The aim should be to be able to address all of the electronic processes provided in the back office via various front end channels.

**Third-Generation E-Government:** E-government of the third generation is largely characterized by integration at different levels: the integration of electronic information, communication and transaction services, of the front office and back office, by data exchange between all levels of the state, technical integration, multi-channelling and integration-based consideration of all of the success factors,

**Verified Signature:** Verified signatures are generated with a secure signature generating unit and are issued by certification service providers which must fulfil certain legal requirements. The verified signature satisfies high security criteria, it is suitable for authentication and offers a high degree of conclusive force. In civil law it can replace a handwritten signature, and in public law it can replace the formal requirement of written form.

## ENDNOTES

[1] These considerations and the fundamental remarks on third-generation e-government are mainly based on the line of argument in Grabow (2004b).

[2] This definition is based on the explanation of the term in the memorandum "Electronic Government" compiled by the Administrative Computer Science Committee of the Computer Science Society (GI) and the Information Technology Society (ITG) in the Association for Electrical, Electronic & Information Technologies (VDE) (Informationstechnische Gesellschaft, 2000).

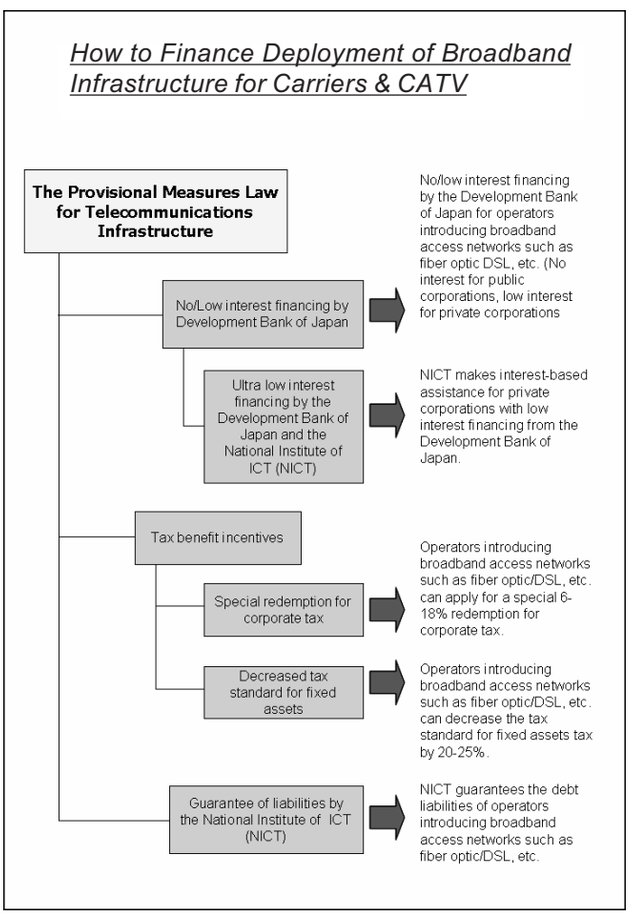
## INTRODUCTION

Japan is set to move forward to developing a broadband and ubiquitous network society as envisioned under the concept of an advanced information society. And the successful implementation of e-government in Japan will serve as the foundation to achieving this goal. How does e-government affect the government itself, the business sector and the citizens? According to a 2005 user survey by the Institute of E-Government, the two main benefits of e-government are improved accessibility to information and transaction, and greater accountability from the government.

To administer e-government in the country, the role of public sector and computerizations in various government agencies were taken into consideration. However, if computerization is limited to central government, this is of limited benefit to citizens. Thus, for communication between citizens and government, there is a need to go mainly through local government, not the central government directly. There is also a need to refer to e-municipality or e-local government, considering it of equal importance to e-government.

It is also important to take into account issues against some aspects of an information society, but being overly anxious about them causes obstacles to promoting e-government. These issues include information security problems, lack of unified management of agencies and the risk of socio-economic digital divide. As such, one of the problems that every country has to face in promoting e-government is the legal system, embedded in every democratic government. Computerization and informatization of the government is, in one respect, an effective administrative and fiscal reform, but requires legal mandates. Thus, reforms in the legal system, including regulation system, are inevitably called for.

*Figure 1. How to finance deployment of broadband infrastructure for carriers and CATV. Japan encourages the private sector by providing various incentives such as no/low-interest financing by the Development Bank of Japan, tax benefits and guarantee of liability by the National Institute of ICT (NICT).*



## BACKGROUND

Needless to say, Japan is unique in its history, culture, demographic profile, state of IT development and government structural problems, though the experiences of major developed countries are worth looking into. These include the development in member nations of Asia-Pacific Economic Cooperation (APEC) and International Telecommunication Union (ITU), wherein the author has an

*Figure 2. Fiber optic infrastructure in Japan. Carriers have been receiving support from the government, such as ultra-low interest financing (1995) and tax benefit incentives. Thus, as of 2005, almost 100% of feeder points have been covered by fiber-optic cables.*

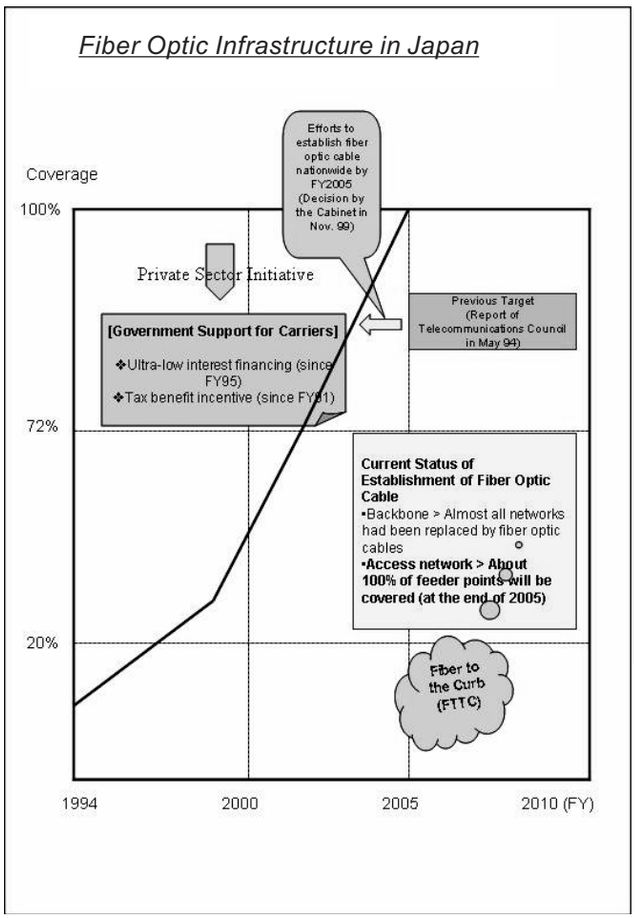


*Figure 3. Structure for promotion of e-government. The Ministerial Chief Information Officers Council, established in 2002, is the highest decision-making body. The structure was created to effectively implement the e-Japan Strategy.*

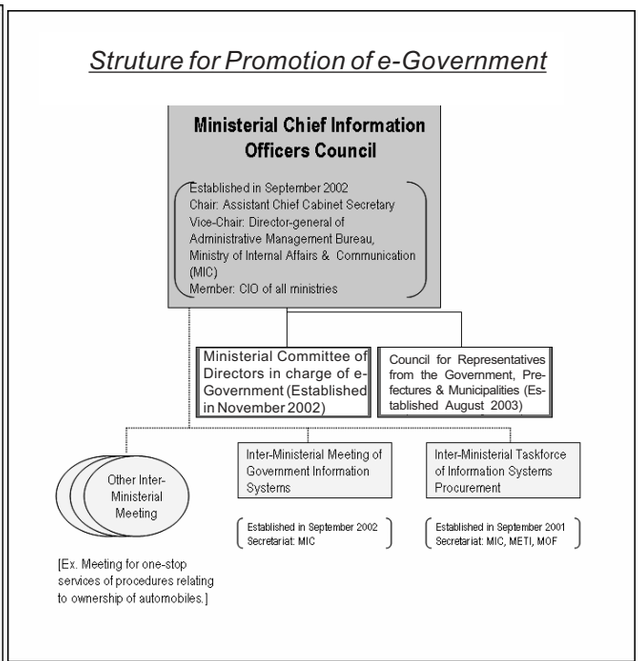


active involvement in the human resource development (HRD) sector for e-government.

To better understand the whole picture of a broadband/ubiquitous network society, it is necessary to recognize first the significance and issues of e-government, analyze the experiences and problems faced by other countries, and come up with new solutions toward the direction of e-democracy. That is, e-government is a vital key towards the success of an advanced information society.

## FORMULATION OF STRATEGIC ACTION PLAN FOR E-GOVERNMENT

The government formulated the *ICT Basic Law*, the country's basic policy framework for information technology (IT) strategies in November 2000. In compliance with this law, the *e-Japan Strategy* was announced in January 2001 to solve the digital divide, among many other issues. To effectively implement the strategy, the *IT Strategy Council* (see Figure 3) was established as the highest decision-making body. The council adopted goals to make Japan the world's most advanced IT nation within 5 years:

- to build an ultra high-speed Internet network and provide constant Internet access at the earliest date possible
- to establish rules on e-commerc
- to implement e-government
- to nurture high-quality human resources for the new era.

Under the e-Japan Strategy, priority policy areas were identified. Likewise, concrete goals were outlined, and agencies and institutions responsible for each policy initiatives were designated. These areas include:

- Establishment of ultra high-speed network infrastructure and drafting of competition policies.

- Promotion for the establishment of one of the world's most advanced Internet networks within 5 years that will enable people to have ultra high-speed access network (30-100Mbps as a standard) at affordable rates.
- Provision of high-speed, constant-access networks to at least 30 million households and ultra high-speed constant access to 10 million households. (Based on the Provisional Measures Law for Telecommunications Infrastructure)
- Nationwide installation of fiber-optic networks in FY2005. Support measures are provided, such as ultra low-interest loans, tax incentives and loan guarantees, to private telecommunications carriers.
- IT literacy education to reduce gap on digital divide.

In March 2001, the e-Japan Priority Policy Program was announced, which introduced various crosscutting issues. Under the program, the government shall promote the development of IT infrastructure to enrich public services that utilize IT in under-populated areas, remote islands and the like. This was aimed at improving people's accessibility regardless of geographic situation, thus addressing the problems of digital divide and turning it into digital opportunities. There are four issues identified, as follows:

- Promoting research and development (R&D)
  - Cooperate with the Council for Science and Technology Policy
  - Reinforce cooperation among industry, academia and government
  - Further promote R&D in areas that require public initiative· Closing digital divide
  - Addressing problems on geography, age and physical constraints to narrow the digital divide
- Dealing with new issues
  - Drawing up of solutions to emerging concerns, such as employment of highly specialized skills, particularly in IT, information security and so forth
- Harmonizing and contributing internationally
  - Compliance with international standardization of rules and specifications, dissolution of digital divide across nations.

E-government in Japan is in progress at par with other developed countries, but it has to hurdle many challenges as well. A report from the Organization for Economic Cooperation and Development (OECD), *The Hidden Threats to E-Government*, reveals that the problem is that objectives will not be achieved in developed countries due to excessive cost and time requirements. The report suggests that until an action plan for e-government has been created, its success will not be realized. Examining what convenient e-government is, this means the rising accountability of administration and the need for transparency in the political decision-making process. Among other issues, these include leadership support, funding and communication as vital keys to success. E-government portfolio performance is examined by measures of success with performance criteria as well as cost-benefit analysis.

Japan has many projects to promote e-government. These include taking into consideration the examples of advanced nations in e-government. Thus, solutions to several problems can be achieved by formulating a strategic action plan. At the same time, some concrete e-government issues are analyzed. This somehow verifies how e-government is used by the citizen, revealing aspects of high usability. Likewise, legal systems, such as the e-signature law and privacy protection law, are continuously developed and discussed to promote useful contents and deployment of broadband.

## EFFECT OF INFORMATION AND COMMUNICATION TECHNOLOGY (ICT) INVESTMENT BY JAPANESE GOVERNMENT

The Japanese government has been seriously studying the effects of ICT investment on the national economy, as discussed in its report, *Effect of ICT Investment by Japanese Government on National Economy* (March 2003). According to the report, ICT-related activities in the government will raise the GDP economic growth by 0.5% in 2004 and 2005. Likewise, they will create new employment, at 1.31 million and 1.85 million, respectively (see Table 1). The ICT sector in Japan has also created a big impact to boost its economy.

A study made by Professor T. Hasegawa of the Ministry of Economy, Trade and Industry, *Japanese ICT*

*Table 1. Estimate (MIC)*

| | Item | Year 2004 | Year 2005 |
|---|---|---|---|
| Potential Economic Growth | Effect to Economic Growth | 0.5% | 0.5% |
| Production Trigger | Production Trigger Co efficient | 1.86 | 1.86 |
| | Amount | $ 230 billion | $ 330billion |
| New Employment | New jobs by Increase of Demand | 1.31 million | 1.85 million |

*Industry for Macro Dynamic Input-Output in JIDEA Model*, listed 10 out of the 100 industries in the model under the ICT sector. These include industries involved in the production of office machines; computers; communication equipment; integrated circuits; electronic parts; and services related to communication, broadcasting and information. ICT contribution in the GDP of Japan is 12%, which is 3%-4% higher in the United States (US).

Likewise, the study reveals that the growth rate of the ICT sector is five times higher, at 1.5%-2.68%, compared to non-ICT, which has a growth rate of 0.58% in 2003-2004.

The ICT sector continues to serve as the driving force in the national economy of Japan. Under inter-industry analysis based on macro dynamics, this sector will lead in output, employment and export for more years.

## PROMOTING E-GOVERNMENT FOR UBIQUITOUS NETWORK SOCIETY IN BROADBAND AGE

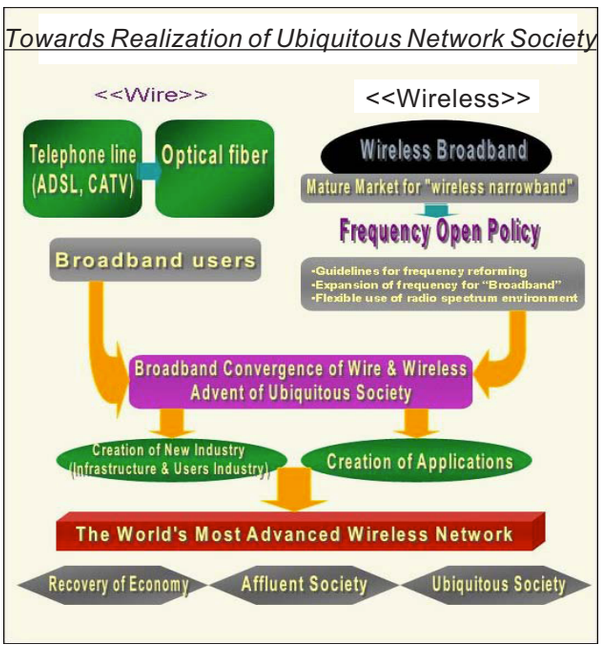
In July 2003, Japan announced the second strategy, aptly called *e-Japan Strategy II*, which echoes similar goals with the proposed ubiquitous networking society, such as:

- The shift of emphasis from the development of ICT infrastructure to the intensive promotion of ICT utilization
- The next environment of information society will be enabled by a ubiquitous network, where connection is possible anywhere, anytime, by anyone, anything (see Figure 4).

In this stage, the emphasis has shifted from the development of broadband infrastructure to the promotion of ICT utilization by end users. Structural reforms are bound to make more people, individuals and organizations actually using the online services offered by the government on the Internet. National trends and issues on ICT and socio-economic development in Japan are intertwined. Listed below are some of them:

- Promotion of e-government is essential to enhance international competitiveness.
- Application of business management models to e-government is a key for success.
- A digital society with broadband programs brings about synergy effect on regional economic development.
- Technological innovation in e-government contributes to technology-oriented community development.

*Figure 4. Towards realization of a ubiquitous network society. E-Japan Strategy II is directed towards achieving a ubiquitous society where connection is possible anywhere, anytime, by anyone and anything.*



- Information security issues are an emerging agenda in broadband.
- A chief information officer (CIO), which is a high-level HRD in ICT, is important to realize the digital opportunities.
- Strengthening competitiveness is made by increasing ICT investment in e-government.
- E-democracy could be achieved by the participation of e-people via broadband.
- Leadership is necessary to establish a national ubiquitous networking framework.

A key issue for e-government in the e-Japan Strategy is on the selection of policies that would address the extensive deployment of broadband within the short term. Studies in Japan indicate that e-government is vital to accelerate the utilization of resources in the public sector. Thus, policies on broadband for e-government are necessary to maximize the impact, particularly on the HRD in ICT. A seamless integration between public facilities and suppliers/vendors of software and hardware should contribute for the promotion of nationwide broadband networks.

A recent survey conducted by Waseda University Institute of e-Government on the status of e-government in the world shows that Japan is among the top countries. The top 10 is as follows: (1) U.S., (2) Canada, (3) Singapore, (4) Japan, (5) Korea, (6) Germany, (7) Taiwan (8) Australia, (9) United Kingdom, (10) Finland. The study also shows that the differences among the top 10 countries are actually very insignificant, and would probably decrease further in the near future.

In this survey, Japan ranks fourth, but the point difference against Canada and Singapore is very small. Japan scored very high in areas measured in the survey, such as preparedness of Internet structure, introduction of online applications and e-tax system. It got good remarks also on e-tender and e-payment systems, but need further development and patronage by the public.

Japan also scored high on optimization of existing systems and integration of network services that promote efficiency and effectiveness in the administration of public services.

Meanwhile, its Web site is in need of immediate improvement on information and documentation.

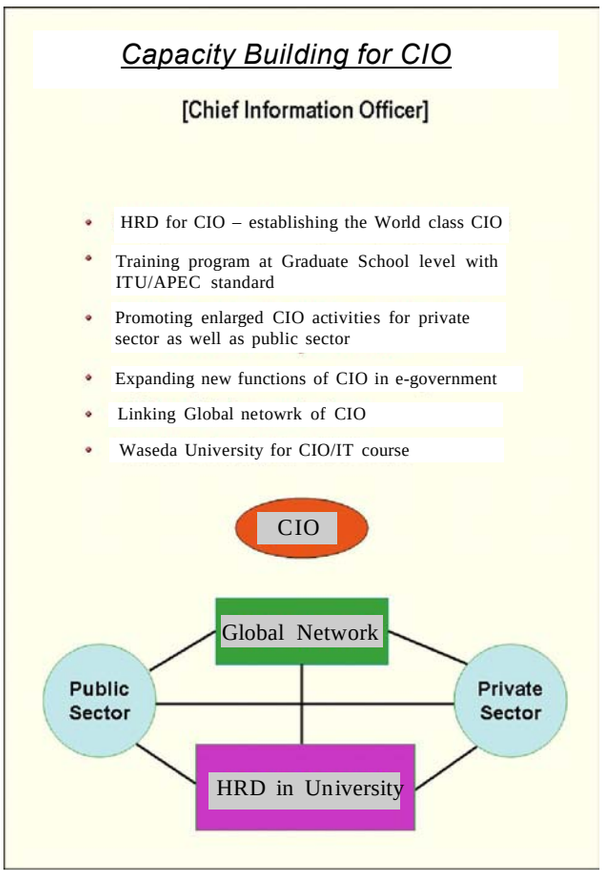
On the introduction of a CIO in its e-government, Japan scored high among the countries in the top 10. However, aside from designating CIOs in the ministry level, there is still a need to improve the quality of CIOs in its government. Further, in the promotion of e-government, Japan's efforts are marked positively, but still the problem of lukewarm support from the end users remain. Thus, the call for extensive promotion, or modification in the framework for national strategy if needed, is reiterated.

## ROLE OF CIO FOR E-GOVERNMENT

The country has been witnessing the emerging roles of CIO in both private and public sectors. As such:

- A CIO in the private sector first became popular in the early 1990s. Since then, it has been essential for companies to create an ICT strategy on cost, security and management system. However, there is a lack of understanding on the role and responsibilities of the CIO (see Figure 5).
- For the public sector, the government established the Ministerial CIO Council for coordination of inter-agency activities.
- Methodology for HRD and support systems in the private sector has led to the establishment of professional graduate schools on CIOs and the redefinition of its role and function.
- A CIO plays an important role for both public and private sectors as: top decision-maker; IT strategist; IT budget planner; specialist on risk management; promoter of business innovation; engineer on e-procurement; and key communicator. Given the many responsibilities of a CIO, it has become a very popular HRD for e-government.

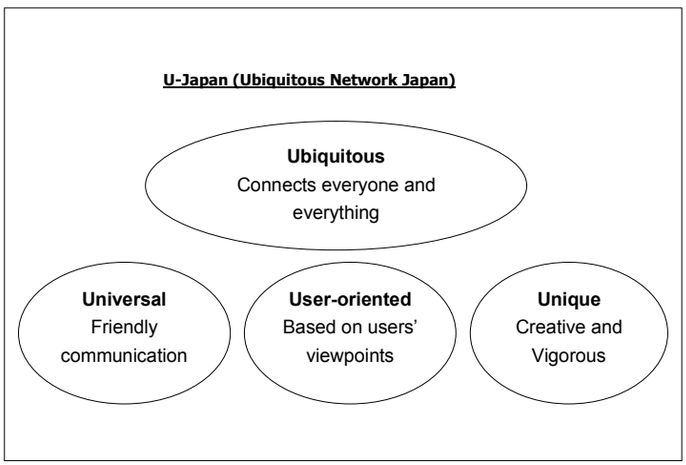
*Figure 5. Capacity building for a CIO. In response to clamor from both the private and public sectors to provide a formal education for CIOs, Waseda University has been the first school in Japan to offer a CIO/IT degree course.*



## FUTURE TRENDS

A ubiquitous Japan is envisioned as the next generation ICT society by 2010. Currently, many countries are embarking on efforts to realize a ubiquitous network society that will make possible easy connection "anytime, anywhere, by anything and anyone." In this society, people will be able to easily share knowledge and information,

*Figure 6. U-Japan. The Ubiquitous Network Japan goes beyond the deployment of broadband network that will allow connection by everyone and everything, but ensures that services online are universal, user-oriented,and unique to every needs of its citizens.*



create new values and realize a more convenient and comfortable life by changing a wide range of information.

The u-Japan Policy drafted in 2005 anticipated issues that will arise in 2010. Based on a questionnaire that determined the needs of consumers, the most important concerns are the safety and security of society. Three policy packages are created under the u-Japan to address these issues.

First is the fulfillment of a sophisticated network. Strategies include: to lay out a ubiquitous accessible environment; open radio waves; promote digital broadcasting; integrate promotion of local information; construct a new IP structure; lay nationwide broadband in equal proportions; promote a steady competitive policy; and support the Asian Broadband Program.

The second is to activate the ICT industry by acquiring opportunities for new growth and providing measure for a rapidly changing business environment. Strategies include: to promote e-business collaboration, networks with smart household appliances, and distribution and usage of content; and to revolutionize industrial organization, enhance cooperation between the public and private sectors, and nurture ICT human resources.

The third policy package will address criticisms against a ubiquitous society. To resolve these, all issues on a ubiquitous society are organized in 10 segments. Afterwards, 100 specific issues will be identified and studied to determine whether they are being tackled under current measures. These issues are prioritized and clarified to the public. Likewise, to prepare the society to better understand the concept of a ubiquitous society, basic rules are organized. At the World Summit on Information Society (WSIS) in Tunis in November 2005, the Ubiquitous Network Society was seriously discussed, as well as Internet governance and digital divide issues.

The realization of a ubiquitous network is expected to create new industries, business and markets; realize a safe and highly convenient society; and promote upgrading and efficiency in various areas, such as education, ecology and employment. The economy of Japan is expected to increase threefold, at 87.6 trillion yen in a ubiquitous-related market scale in 2010, based on the current state and prediction of the size of market created in a ubiquitous network society. Ubiquitous service solutions will expand new possibilities in the fields of business and public services.

A ubiquitous network society is consistent with the key principles of the Geneva Declaration of Principles. That is, to provide, "universal, ubiquitous, equitable and affordable" access to ICTs and to ensure that everyone can benefit from the opportunities that ICTs can offer.

## CONCLUSION

Japan has been consistent in formulating national ICT plans that allow the realization of e-government. These included the Basic ICT Strategy in 2000; e-Japan Strategy and e-Japan Priority Policy Program in 2001; and e-Japan Program in 2002, all of which addressed top priority issues, such as:

- Ensuring security and reliability of advanced information and telecom networks
- Digitalization of administration and application of IT in public sector areas
- Facilitation of e-commerce
- Promotion of education and development of human resources
- Formation of the world's most advanced information and telecom networks

The second stage, e-Japan Strategy II, which took off in 2003, faces another challenge for e-government. That is, to usher Japan in the era of a ubiquitous society by facilitating the deployment of broadband network nationwide as a backbone network by fiber optics. Core technologies that support a ubiquitous society will be developed for different layers, such as applications, networks, platforms and devices, and will expand promising industries.

The greatest challenge for e-government in Japan has been the response of the end-users. The government is firm to make every Japanese take advantage of services online. Thus, the second strategy is focused on addressing this problem by reviewing the content and application design of many government portals, especially various online services to both businesses and citizens, and to intensively promote the e-government scheme. In conclusion, Japan has already taken up the challenge of creating a ubiquitous network society by launching the U-Japan Strategy, and is prepared to overcome various issues, including technological innovation, applications and security.

## KEY TERMS

**APEC TEL:** Asia-Pacific Economic Cooperation Telecommunications.

**Broadband:** Refers to data transmission where multiple pieces of data are sent simultaneously to increase the effective rate of transmission. In network engineering, this term is used for methods where two or more signals share a medium.

**CIO:** Chief information officer.

**CIO Council:** CIO Council is the principal interagency forum to assist CIOs in realizing their mandates to ensure the rapid and effective implementation of information management and information technology (IM/IT) solutions.

**e-Japan Strategy:** Proposes that Japan take revolutionary yet realistic actions to create a "knowledge-emer-

gent society" in which all citizens can actively tap information technology and fully enjoy its benefits.

**Fiber to the Home (FTTH):** FTTH Asia-Pacific is a market development organization whose mission is to educate, promote and accelerate FTTH and resulting economic and quality-of-life enhancements.

**i-Mode:** i-mode makes your mobile phone a useful tool of everyday life. Send e-mail, surf the Internet, check the latest news, play games, shop, book airplane tickets and so much more—all with your i-mode mobile phone. With an i-mode phone display, you can get information from i-mode menu sites (programs) and Internet sites that are i-mode compatible, and can exchange i-mode mail. Simple operation, inexpensive charges and available all over Japan.

**MIC:** Ministry of Internal Affairs and Communication.

**Radio Frequency IDentification (RFID) IC Tag:** An automatic identification method relying on storing and remotely retrieving data using devices called RFID tags or transponders. An RFID tag is a small object that can be attached to or incorporated into a product, animal or person. RFID tags contain antennas to enable them to receive and respond to radio-frequency queries from an RFID transceiver. Passive tags require no internal power source, whereas active tags require a power source.

**Ubiquitous Society:** An ideal society where connection and communication is possible at anytime (24 hours a day/7 days a week) and anywhere (regardless of geographic situation), by anyone (including the very young and old, disabled, illiterate) and anything (machine to people, and machine to machine).

# Transformation of Government Roles Toward a Digital State

**Monica Zuccarini**
*University of Florence, Italy*

## INTRODUCTION

Information technologies (IT) and the new (virtual) space of dominion that they create can alter the order of the powers of the democratic states.

This article will discuss the idea that the digital state is becoming a *Virtual* state with less power of control over its territory, because the historic power of the state is being restricted by the rise of governance beyond the state. The process of globalization, as well as the larger use of digital technologies, challenges the Westphalian nation-state, changing the state's boundaries so that new forces and new actors acquire even larger space of dominion.

We will explain that the information society challenges, but does not eliminate, the effectiveness of the state. The Web, with its open spaces, extends the state's boundaries, creating new spaces of virtual dominion and changing governments structures: Actually, digital technologies affect functions of direction, control and organization of governments, and democracy quality, opening new areas of dominion for governments.

Even if some of the functions of the states, like those related to economics, are diffuse under the new globalized and virtalized world, the states still preserve most of their political and military power. And more, the regulatory role of the state is considered pivotal: In the future, national governments need to define a new code of regulation of the Internet to defend citizens' rights in the virtual space.

## BACKGROUND

The Internet creates a new space for "virtual" power, where it is not completely possible to individualize classical concepts of state and nation, rights and laws. Some scholars think the power of the state can be compromised from the pre-eminence of information and communication technologies (ICTs) (Dyson, 1998; Tapscott, 1998), imagining catastrophic scenarios and losses of power of the states: They are considered incapable to keep up with information society's innovation. In the same way, Jerry Everard, in *Virtual State, The Internet and the Boundaries of the Nation-State* (2000), examines the impact of the global growth of the Internet and links it to the fragmentation of the unitary state intervenes. Everard emphasizes that the traditional realistic approach was geared towards the identification of the state as an individual actor, embracing the Cartesian idea of sovereign identity. In relation to this analysis, Nicolas Negroponte sees in the growth of the Internet, the end of the nation state. In *Being Digital,* he argues that the four cardinal virtues of the information society—decentralize, globalize, harmonize and authorize to do—are going to subdue the Hobbes' idea of the state as a Leviathan (Negroponte, 1995). The state was seen by Hobbes as the social personification of the *corpus* of the domestic polity. By analogy, the Prince was considered by Machiavelli like the captain of the ship of the state (Machiavelli, 1975). By extension, the social organs working were the arms or limbs of the state. Establishing such boundaries, rules and laws of the state defines the identity of a nation. Indeed, the identity is the result of the process of the construction of boundaries, a manner to identify oneself from others. But, today, the ability of the Internet to break through boundaries challenges the traditional structures based on the identity of the state. This new situation changes the nature of the state's boundaries, but does not erode them. In the new digital state, the point is to rethink the manner of the construction of national identity and the meaning of identity itself, which is no longer connected to territory.

## THE STATE SOVEREIGNITY IN THE WEB

As Mattelart reminds us, "like it or not, the territory of the nation-state remains the place where the social contract is defined. It has by no means reached the degree of obsolescence suggested by the crusade in favor of deterritorialization through networks" (Mattelart, 2002, p. 609). The territory of the nation state is still the historical and functional painting of the democracy, the place of definition of the social contract. Therefore, it is quite distant from the obsolescence that the crusaders of the

Web attribute him (Mattelart, 2002). Hence, the information society challenges—but does not eliminate—the effectiveness of the state, whether in the political domain rather than in the economical arena, which before was sovereign.

The nation states that between the 12th and the 19th centuries became sovereign in the economical field (making the boundaries of the economy the same boundaries of the state) have seen to change their powers. If, before, the economy had to take the state into account, now it is the state that has to take the economy in consideration. Even if the state is continuing to develop an important role, it has lost its economical sovereignty, because the boundaries of the state and of the economy do not correspond anymore (Cassese, 2002).

If one side the Web, with its open spaces, extends the state's boundaries, creating new spaces of virtual dominion; from the other side, the process of globalization and the larger international contest moves the economical activities out of the state's territory, and this ends with the exasperation of those states familiar with their boundaries and spheres of influence. Consequently, there is an imbalance between economy and state that the governments have tried to resolve in different manners the last few years. In Europe, this has occurred through cooperation between the authority of different nations, arranged from national laws or bilateral agreement, through the transfer of government tasks to trans-national organisms (constituted on multilaterals agreement) or through supra-national organisms that absorb state functions. The extension of the government's tasks and spaces created regulation on different levels. A different model replaces the Westphalia one, according to which states are the unique subjects of international law and the principles of their sovereignty and legal equality are absolute. The state redefines its own organization and renounces the actual functions in favor of smaller regions (the so-called "inside federalism") and greater regions (the so-called "outside federalism"). For that, "it is lost also the unitary political connection of the citizen with the state, in favor of a balkanization of the belonging and of the identity" (Cassese, 2002, p. 50). Also, technology has played a crucial role opening the financial world markets—liberalization and technological change are strictly interwoven—and some national monopolies, like telecommunications and electricity, were transformed in areas submitted to national and international competition.

Therefore, the proposition—supported by the Californian ideology—that the physical space in which the states live has been marginalized or lost its importance needs to be reconsidered. The withdrawal of the state relates to some areas (especially public management and welfare) and not the whole state, which is, instead, increasing in its dimensions.

ICTs are not depriving the states of the ability to govern and reduce their sphere of jurisdiction; instead, they are opening the jurisdictional space to competition, favoring the possibility of the expansion of the states.

In countries like the United States (U.S.) and France, for example, the increase of the jurisdiction outside their own boundaries emerges in some cases, in which some acts made outside the territory were sanctioned: As in the case of Johansen in the U.S. or the Yahoo case in France, that had effects to the inside of these states. In fact, in January 2000, the Norwegian Department of the Economical Crimes arrested Jon Johansen, who published on the Internet a program enabling Linux users to visualize DVDs, activity that broke the rules of the U.S. Millennium Copyright Act on the exchange of copies of protected systems. Although Johansen had not committed an offence under Norwegian law, he was judged to have done so according to American rules. In the same way, the French government undertook a legal action against Yahoo who allowed sold Nazi souvenir in some auctions on the Internet. Even though Yahoo was located in the U.S. and, therefore, not subject to French law, Yahoo was forced to eliminate that material from its Web site (May, 2002). These are examples of how we face up to two structures of government: the government *of the Internet* and the government *into the Internet*. With the expression "government of the Internet," we mean the technical management of it: The development of protocols, the allocation of Internet names and addresses; in short, all those procedures that guarantee the functions of coordination regulated from an independent organism, the Icann. With the expression "government into the Internet," instead, we make reference toward the political management, to the governments' strategies in order to control, organize and regulate this new space of power: The government goes into the Internet to regulate it and acquire areas of dominion and control. Therefore, on one side there is a solid structure of government of the Internet—created by the American government and presumably independent—with coordination functions; and from the other side there are the national governments, whom try to enter in the government of the Internet to satisfy of the criteria of transparency and democracy.

As Rhodes reminds us, the central government is not supreme anymore. "We live in the centreless society, in the polycentric state characterized by multiple centres. The task of government is to enable socio-political interactions; to encourage many and varied arrangements for coping with problems and to distribute services among the several actors" (Rhodes, 1996, p. 653). This is why the state is called to intervene in the new dominion of the Internet, to defend citizens' rights and values. Indeed, looking at the attempts of e-democracy made up from many governments—such as e-petitions, e-voting or e-

rulemaking—it is easy to see in these experiments a strategy (or a mere instrument) to extend the institutional framework in the digital world. The point is that the state has to find a new way to rule this new space.

If the challenge of globalization asks governments to change their centers of power, the ones of the information society is to arrange the stability of the "regulators'" governments with the flexibility of a structure that has been conceived as not regulated. The nature and the architecture of the Internet is an exception to the rules that have governed during the industrial era, and now it becomes important to think towards a specific code of regulation.

## FUTURE TRENDS

The states have to deal with the government of the Internet and, therefore, with different codes and norms from those used in the off-line world. In the new space of dominion, they find themselves facing up to the necessity to define a new code of regulation of the Internet, to establish new legislative boundaries, impose new codes and defend citizens'/users' rights and liberties.

The speed and instantaneity of the Internet means for governments a smaller control on their agendas. A centralized control is possible, but governments that aspire to monitor the informative flows across the control of Internet have to deal with high costs and big problems. The nature and architecture of the Internet makes it an exception to the rules that have governed in the industrial era, and this is why it requires a different code of regulation. In parallel, the Internet also raises economical, social and institutional questions, and governments have to stand up to them.

Lawrence Lessig is right in saying that we are moving from a world in which the laws are made by governments to one in which the architecture is created by private companies, passing from lawmakers to the "code writers" (Lessig, 1999, p. 207). Nevertheless, to regulate, to transform the informal structure of Internet in a structure of formal government is an operation that needs remarkable exercises of constitutional engineering. It means to individualize tools that limit, bind and put under control the exercise of political power. For this reason, David Post has defined the issue of control of the Internet as a "constitutional moment" (Post, 1998): a constitutional moment that should keep account of an order of global powers: in which the U.S. preserves the keys of the control of the Internet, and the European Union has to deal with it (Mayer, 2000). If Rousseau believed the freedom of individuals is guaranteed by the government of laws and not of men, then to reaffirm this freedom in the virtual space, it is necessary to think about a new scheme of "free government" guaranteed from a constitution. Information-age politics does not mean to get rid of the state, nor suggest that the terms *digital state* or *virtual state* (Fountain, 2001) are synonymous with invisible state. But rather, it means to decide in what way the states and their governments can facilitate and create the kind of society we want. Today, governments have an important role to play, especially towards the technological changes that come from the information age. Only if we understand the continuous role of the states and of their governments will the information society become (or remain) democratic (May, 2002).

## CONCLUSION

In the era of the Web and of the co-modification of information, perhaps the balance of modern society is based actually on the difficult alchemy described by Nora and Minc: the dosage between a vigorous exercise of the state's institutional powers and an always greater exuberance of civil society. IT, for good or ill, will be an important ingredient of this dosage (Nora & Minc, 1978). The information revolution certainly had a strong impact on the states but, as Robert Keohane and Joseph Nye (1998) suggest, the reason why it has not transformed the world of politics is that information does not circle in the empty space but in a political space already occupied by the regulatory state—even if not all the states are in a position to maintain such authority with success. How the state will ensure a controlled exercise of power, keeping its space of regulation within and beyond the Internet, is written in the next future.

## KEY TERMS

**Californian Ideology:** A label for the ideological position taken by a loose alliance of writers, hackers, capitalists and artists from the West Coast of the U.S. in regards to the coming of the information age.

**Constitution:** The constitution is a "form" that regulates the organization of the state; it structures and disciplines the decision-making process. It is a procedure aimed to ensure the exercise of power. It's the social and political order of a society.

**Digital State:** In the idea of a state government that leads the nation in adopting digital technologies to improve services delivery.

**Internet Governance:** The term is used as a general reference for technical administration and coordination of Internet resources. It refers to the administration and management of domain names, Internet addresses (IP numbers and autonomous numbers), the coordination of technical aspects and the definition of the technical parameters necessary for the operation of the domain name system and root servers.

**Leviathan:** In Hobbes' idea, *Leviathan* is a treatise on the origin and ends of government. Leviathan is the state, whether in the form of an absolute monarch or a democratic parliament. The state exercises its absolute power to maintain a state of peace.

**Nation State:** It is a geographic/political organization uniting people by a common government. It is a state whose inhabitants consider themselves to be a nation, geographically and legally bounded under one legitimate government.

**Westphalian Model:** It is a model based on the sovereignty of the nation-state, with a minimalist role for international law and limited international intervention to deal with disputes between nations.

## INTRODUCTION: INTERNET AND DEMOCRATIC EMPOWERMENT

The advent of new information and communication technologies (ICTs), in particular the Internet, has inspired bold scenarios about a new era of democratic governance and political empowerment that these technologies of freedom make possible. Most visions and strategic frameworks for e-government posit that this paradigm of citizen empowerment can be advanced in two ways:

1. By harnessing new ICTs in order to make the provision of government services more accountable and responsive to customers' needs.
2. By harnessing new ICTs in order to decentralize and disintermediate collective decision-making.

The first path, which could be called *e-services*, is influenced greatly by the theories of new public management, the zeitgeist flavor in thinking about public administration. New public management focuses on lean government. It conceptualizes the working of public administrations as a customer-service provider relationship, where a lean management team is tasked to put our tax money to work in order to produce those few services that the market cannot deliver. E-services, in this view, will advance democratic empowerment, because they involve the streamlining of government bureaucracies; because they can be deployed more efficiently and more flexibly and can be targeted; and because they limit the scope for abusing bureaucratic power by allowing customers to take greater control of the timing, format, and monitoring of due process in public service provision.

The second path, which could be called *e-democracy*, subsumes the various plebiscitary uses of the Internet that have been put on the map by advocates of direct democracy and now are featured in many official e-government visions and strategies. Initiatives in this area include online voting, online polls, online deliberations, and use of the Internet to contact civil servants or legislators directly (Barber, 1998; Norris, 2002). New ICTs in this context are anticipated to engage individual stakeholders more directly in decision-making processes, to enhance the effectiveness of plebiscitary instruments, and to cut out intermediaries and reconnect citizens more closely with their elected representatives.

Taken together, these two dominant themes of e-democracy and e-services constitute the main paradigm for envisioning what role the Internet can play in democratic governance and what public policies should be crafted in order to make this happen.

Governments all over the world have bought into these concepts, some enthusiastically and some more reluctantly. But all of them appear to accept these dominant expectations of how the Internet ought to transform governance. E-services and e-democracy have become the public yardstick for performance and symbolic legitimacy.

Adding to their persuasiveness is the fact that e-services and e-democracy complement each other ideally. They share a more fundamental suspicion of big government and seize upon the Internet to reassert individual freedom and self determination by making governments lean and by disintermediating deliberation and decision making. This convergence in large parts of the e-government community around a techno-libertarian value framework also is aligned closely with and, thus, reinforced by similar sentiments in the Internet developers' and early adopters' communities. With regard to Internet use in the trailblazing U.S. context, Norris (2001) finds that "users proved significantly more right-wing than non-users concerning the role of the welfare state and government regulation of business and the economy". This wariness with regard to regulatory intervention is not confined to the Internet but reflects a long-standing suspicion against politicizing technologies (MacKenzie & Wajcman, 1999).

## A NEGLECTED DIMENSION: E-TRANSPARENCY

As laudable as these goals are, it is questionable whether this almost romantic vision of disintermediation and self-representation that has been fueled by the arrival of the Internet adequately captures the complexities of political claim-making and governance in a modern democratic

society and whether it presents the full range of options for the Internet to be used in this context.

It can be argued plausibly that these conceptions of empowerment and the e-government strategies that they inspire pay too little attention to the wide field of conventional practices of political engagement A number of commentators have drawn attention to the democratic shortcomings of the e-services agenda (Chadwick & May, 2003; La Porte et al., 2000). The e-democracy theme does not fully make up for these shortcomings, either. The citizen is not only customer or voter, but he or she is also a citizen who participates in public affairs predominantly via a thick, rich layer of social networks and collective entities that help to transmit preferences into political claims, that bundle interests and mobilize, that monitor government conduct, and that condense dissatisfaction into opposition.

Refined conceptual work and emerging empirical evidence on the political effect of the Internet suggest that hopes for radical dissemination and individualistic empowerment are premature. It is more likely that a messy patchwork of organizations and affiliations, and of civil society and media intermediaries will remain the predominant infrastructure for forming political claims and disciplining public power. Analyses of conceptual and comparative empirical evidence on the relationship between the Internet and the political process corroborate this claim (Agre, 2002; Bimber, 1998).

The failure to recognize more firmly the persistence of these forms of political engagement and the widespread occupation with more visionary e-services and e-democracy initiatives is deplorable. It seems to have pushed into the background a set of rather fundamental policies and initiatives that would help to make the Internet work better for democracy. This neglected area of engagement is the use of the Internet for making governance structures more transparent. This agenda, which could be called e-transparency, focuses on comprehensive information disclosure by all branches of government. It prioritizes progressive statutory freedom of information rights to make disclosure enforceable, and it places the objective to make information disclosure more effective in enabling critical scrutiny and constructive engagement in public decision making at the center of thinking about the Internet for political empowerment and practical e-government strategies.

A commitment to e-transparency is based on the recognition that what lubricates the machinery of political and civic engagement is the flow of information from and to systems of governance. Transparency is a key to good governance, political empowerment, and a functioning democratic system. The importance of transparency long has been recognized by political scientists. Dahl (1971) made an early claim in this respect from the perspective of prescriptive democracy theory. More recently, March and Olsen (1994) developed an institutional justification, while Linz and Stepan (1996) highlighted the benefits of transparency for processes of democratic consolidation. Florini (1997) and Mitchell (1998) elaborated on the respective advantages for international regimes.

## THE PRACTICE OF E-TRANSPARENCY

While all governments pay lip service to good governance and transparency, e-government strategies rarely are attuned to these commitments. In most countries' e-transparency, little attention is being given to creating an enabling legal and policy environment for e-transparency (Zinnbauer, 2004). Some countries, such as Germany, that pursue ambitious e-government initiatives have not even put in place a basic freedom of information law that would be a prerequisite for advancing e-transparency. Freedom of information laws, where they have been passed, typically sideline technology-related issues. A 2004 survey of freedom of information laws around the world found that about 80 countries have instituted or are in the process of establishing freedom of information laws, but very few explicitly consider the role of electronic information and the Internet. Just a handful of countries has clarified that freedom of information practices apply to electronic records, and even fewer have established a statutory duty to publish more expansive information online or to accept e-mail requests for documents (Banisar, 2004). This neglect is mirrored in the information disclosure policies of international regimes and multilateral development banks. Information guidelines for these institutions, if they make reference to the Internet at all, contain only vague references to electronic dissemination but do not set any explicit and, thus, enforceable standards for what should be published online, when it should be published, and in what form it should be published. This is what the author found when reviewing disclosure policies of the World Bank, IMF, UN-ECOSOC, UNDP, AFDB, ADB, and WTO in May 2004. Mendel (2003) arrived at similar results. To give another example, disclosure policies for the European Union Commission and Council only call for the establishment of an electronic register of documents that have been produced but do not mandate full-text online access (Curtin, 2003).

This neglect of e-transparency in the legislative framework also is replicated in the practice of e-transparency in many countries. A global survey of e-government in 192 countries found that on average, government Web sites achieve less than half of the maximum score for their transparency function (La Porte et al., 2001). Similarly, a

closer look at parliament Web sites around the world reveals that only 14% post the full record of parliamentary proceedings, and only 5% provide the opportunity to subscribe to mailing lists for receiving regular e-mail updates (Norris, 2000).

These shortcomings are replicated at the level of local e-government. A 2004 survey of 212 local and regional government Web sites in France disclosed that only half of the sites provided minutes or proceedings of council meetings online (Artesi, 2004).

Even the development around the arguably most ambitious initiative to integrate the Internet into freedom of information rights, the 1996 U.S. Electronic Freedom of Information Act (EFOIA), does not really give much reason for optimism. A 1998 assessment of 57 U.S. government agency Web sites by OMB Watch, a public interest group, found that compliance was very unsatisfactory. None of the examined agencies was in full compliance with EFOIA, and 25% had not even attempted to implement these compulsory provisions (Henderson & McDermott, 1998). These findings were confirmed by a follow-up study in 2000, which detected a lackluster performance of agencies and criticized that many questions about the scope of data that would fall under the act and about adequate dissemination standards remained unresolved (Halstuk, 2000). Practices in 2003 were still far from optimal, as an audit of freedom of information practices conducted by the National Security Archive, an initiative based at George Washington University, revealed. Less than half of the 35 agencies that were contacted responded to a freedom of information request in time, while three lost the request, and, overall, neither the availability of e-mail contact information nor the inclusion of electronic information in disclosure practices could be rated as satisfactory.

## TOWARD A PROGRESSIVE AGENDA FOR E-TRANSPARENCY

All efforts to devise a policy framework for Internet-enabled information disclosure should start with the recognition that transparency rules and technology use are interrelated. Technology-neutral rules in principle are desirable but tend to be too vague in practice in order to be effective. More desirable are rules and strategies that set transparency and disclosure standards with direct reference to the new information dissemination capabilities that the Internet affords. Technology-related elements for such a policy framework and e-government strategies could be grouped into the three following interrelated clusters:

1. Internet for making requests for information easier
   - Establish rights for any interested party to file information disclosure requests electronically and receive requested information in electronic format for easy perusal.
   - Publish a detailed online guide on how to make information requests.
   - Provide public access computer terminals for filing electronic requests and researching transparency information online.
   - Establish an online register of all documents produced, including the ones that are not released in full text publicly, in order to curb excessive secrecy.
   - Provide electronic information push tools that allow one to sign up for and to receive e-mail updates of new materials made available.
   - Adopt electronic data standards such as XML that allow users to process and reuse information in a flexible manner.
2. Internet for widening and deepening transparency
   - Ensure that electronic information and communications are covered by disclosure rules.
   - Set acceptable response times, update cycles, charge users with reference to the speed and efficiency afforded by electronic information management.
   - Use advanced electronic publishing technologies that help to protect privacy by allowing one to tag personal information that automatically is omitted in the online publication process.
   - Significantly expand the scope of accountability information that is required to be published proactively and mandate publication online.
   - Enable keyword searches and other advanced online search tools for accountability information published online.
3. Internet for a new quality of contextualized and discursive transparency
   - Use the power of hyperlinking in order to integrate traditional accountability information with other categories of published information such as environmental indicators for air and water quality.
   - Subject rule and policymaking processes to particularly stringent disclosure standards with mandatory advance notice and comment periods and the online publication of all draft materials before the final decision to allow for meaningful input.

- Post received comments online alongside draft documents in order to facilitate constructive deliberation.

Aspects of this policy agenda are beginning to be incorporated in innovative pilot projects around the world, albeit in fragmented manners. Some practical examples include the following:

- **Canada:** Compulsory online disclosure of hospitality and travel expenditures by ministers and senior government officials.
- **London:** Online access to air pollution data, searchable by postal code and directly linked to environmental targets and commitments set by the government.
- **Mexico:** Freedom of information law requires the establishment of public computer terminals for access to electronic information.

As these examples and the suggested policy agenda indicate, the Internet can leverage information disclosure in a variety of ways. Maximizing these benefits requires according efforts for information disclosure in a central place in e-government strategizing and practice and, at the same time, updating related disclosure rules and entitlements with direct reference to the new opportunities afforded by the Internet.

## FUTURE TRENDS: MIXED PROSPECTS FOR E-TRANSPARENCY

Devising and putting into practice such a strategy for e-transparency is by no means easy. A number of obstacles can be discerned. First, under the current terms of the governance debate, even the status quo in freedom of information practices has come under attack. A focus on lean government in combination with severe pressures on public budgets has drained funding for existing freedom of information operations. A study on the public administration in Canada, for example, found that spending for freedom of information practices typically is considered non-essential and, accordingly, has been cut, which has driven up response times significantly (Roberts, 2000). Similarly, a review of agency compliance with the electronic freedom of information act conducted by the U.S. Government Accounting Office (GAO) came to the conclusion that "information dissemination is still not an integral part of agency information resources management programs," thus giving rise to the assessment that information dissemination is an "unfounded mandate" (Government Accounting Office, 2003).

Budget cuts, insufficient funding, and a narrow interpretation of information disclosure go hand in hand with an increasing drive toward the comodification of information produced by the public sector. In the U.S., for example, administrative guidelines restrict the information services that public authorities can offer to the public on the grounds of often-unspecified concerns over unfair competition. Salem (2003) and Jensen (2003), for example, describe a prominent case in which illusive concerns about unfair competition helped to shut down access to scientific information provided by a public authority despite proven utility and cost savings. Most paradoxically, some public policies that have been passed in direct response to the digital revolution actively support this precarious development. One motivating factor behind the European Union *sui-generis* protection for databases, for example, was to enhance the commercial value of information held by the government (David, 2000). It appears not too far-fetched to speculate that this opportunity for making government information more marketable is likely to evolve into a standard activity for revenue generation for public administrations. In such a context, freedom of information only can be regarded as an annoying burden.

## CONCLUSION

E-transparency is not a very visionary project when compared to the lure of direct democracy or user-controlled online service provision as the dominant themes in e-government scenarios. The relation between novel ICTs and freedom of information often is viewed as too commonsensical to necessitate a proper normative grounding, too straightforward to require an in-depth conceptual or practical elaboration, and too banal to qualify for a prominent place in visionary conceptions of governance in the information age. This is unfortunate and misguided. It squanders a significant opportunity to make the Internet work better for democratic empowerment in authoritarian settings, advanced democracies, and international governance regimes alike. Refocusing e-government visions and strategies on the basics of freedom of information and transparency is a timely and important task, and more research on best practices, challenges, and shortcomings can make an important contribution to this end.

## KEY TERMS

**Accountability Information:** Information provided by and about institutions of collective governance for the purpose of satisfying the obligation to be answerable to the public and to submit to democratic oversight

**Comodification of Information:** The increasing practice of emphasizing the economic value of information and perceiving and treating information as an economic good that can be produced, traded, and conceptualized in legal terms just like a conventional physical commodity.

**Deliberation:** Approach for facilitating collective decision making through informed exchange of viewpoints and joint assessments of facts, reasons, and their respective importance by all affected stakeholders.

**Electronic Data Standard:** Collectively agreed upon technical specifications for how to digitally encode, process, transfer, and display a certain class of data.

**E-Transparency:** The use of Internet-related tools for making governance systems more transparent.

**Freedom of Information:** Normative presumption, often encoded as legal entitlements (freedom of information legislation), that all information produced and used by institutions of collective governance ought to be available to the public for purposes of accountability and democratic oversight.

**Sui-Generis Database Protection:** The recognition of an intellectual property right for collections of data rather than via the conventional intellectual property category of copyright, which additionally requires an element of creativity or innovation in order to constitute an intellectual property right for a specific information collection.

# Trust in Digital Government

**Neil C. Rowe**
*U.S. Naval Postgraduate School, USA*

## INTRODUCTION

The concept of trust in organizations has been an important area of recent research in sociology and management science (Sztompka, 1999). Trust is positive expectations of positive actions by others, and is important to well-functioning organizations of all sorts. Trust facilitates the effectiveness of government. A focus on trust leads to a more humanistic view of individuals within organizations than that of the traditional managerial psychology of humans solely as input-output devices whose performance must be monitored and measured.

New technology changes the form of government operations. So it is natural to ask how trust is affected by the advent of the technologies and practices of digital government, as it is affected by online security practices (Friedman, Kahn, & Howe, 2000). On the one hand, digital government should be more efficient government, and people trust more in well-run, efficient processes. On the other hand, digital government could enable governments to evade responsibility for their actions by imposing new barriers to citizens, restricting access to information more, falsifying information more easily, and providing a new set of excuses for inefficiency. Some extremists (Postman, 1993) claim that most technology cannot be trusted, but few people agree. So the issue needs to be examined at length.

## BACKGROUND

Sztompka (1999) provides a detailed analysis of trust relationships. He defines trust as "a bet on the future contingent actions of others" and enumerates six major factors supporting it: (1) reputation, (2) performance, (3) appearance, (4) accountability, (5) precommitment, and (6) contextual facilitation. Of these factors, reputation is not much influenced by whether government is digital or not. Performance and accountability are supported by virtually any digital government as well as government: Past performance of government (demonstrating that procedures are being followed) and lines of accountability (indicating that recourse is available for fixing problems) are almost always present. But digital government can improve performance and accountability by exploiting its ability to store extensive documentation. For instance, digital government can keep records (while removing identifying information to maintain privacy) to demonstrate that citizens are being treated fairly and equally. They can also track citizen interactions and requests to show that procedures are functioning properly.

Appearance is related to the user friendliness of digital government, and this can be ensured by good human interface design for the software, with phone numbers and email addresses of human contacts provided in case of problems. Precommitment (fulfilling initial steps to build trust in completing a full promise) can be accomplished in digital government by offering receipts, certificates, and other documentation at milestones while providing a service. Finally, contextual facilitation is the "culture of trust" cultivated by a government by treatment of its citizens, and is only indirectly related to digital government through its performance.

Sztompka also distinguishes between instrumental trust (related to specific goals), axiological (based on moral expectations), and fiduciary (based on legal or quasi-legal obligations). Government is generally a means to the ends of its citizens, rarely makes moral claims, but does fulfill legal obligations. Thus it concerns instrumental and fiduciary trust, the latter in regard to laws and the former in regard to everything else. (Hardin, 2002) points out other important differences between trust in government and trust in people, and suggests that government cannot actively seek the trust of its citizens but can only gain trust by acting consistently in a trustworthy manner. Levi and Stocker (2000) point out other important kinds of trust involved in citizen-government relations.

## ACCESSIBILITY OF DIGITAL GOVERNMENT

Now let us consider some specifics of trust in digital government. Digital government usually strives to increase accessibility of the government to the citizens, and this will increase trust in the government by Sztompka's factors of appearance and performance. Digital government provides good ways for government to get public feedback with surveys, complaint forms, and online discus-

sion groups. But this requires some effort by the government; a digital government designed only for efficiency may function as a "screen" keeping government officials more distant from the people, thereby decreasing trust.

Even when digital government is accessible, not all citizens may have equal access to it. A social and cultural gulf separates the computer literate and the computer illiterate because of the necessary investment in technology (Cronin, 1995). The computer illiterate are feeling increasingly disenfranchised, and this exacerbates their mistrust of a government that uses digital government technology. So it is essential that government provide technological support for access to digital government by all citizens. This could take the form of free public access devices at dispersed locations, or subsidies for the purchase of devices and software necessary to use digital government. It should also include free training in their use, because not all technology can be designed to be usable without training. Without such steps to make digital government accessible to most of a society, distrust of government will increase regardless of its efficiency.

## SECRECY IN DIGITAL GOVERNMENT

All governments keep secrets to protect themselves from exploitation by other governments and to preserve the privacy of their citizens (Yu, Kundur, & Lin, 2001). Information technology can help protect secrets. For instance, messages encrypted with today's strong encryption methods cannot be deciphered without the key no matter what incentives are offered. Other technological developments like cryptographic protocols, security kernels of operating systems, and firewalls are also helping secrecy and protecting privacy, and generally promoting trust in government.

But governments that want to keep unnecessary secrets will also find this technology helpful, and this can hurt trust in regard to Sztompka's issues of appearance and accountability. This is a political issue, however, and citizens may have different ideas than their government does about what should be kept secret (Theoharis, 1998). Governments need to legitimize themselves, and secrecy erodes legitimacy. If taxpayers cannot see what their taxes are being spent on, or militaries fail to protect a country despite their secrecy, dissatisfaction grows. Economic downturns or unpopular wars may then cause serious political stresses, and can even destroy a government, as happened in Argentina in the 1980s. The number of secrets kept by the United States government continues to increase without much justification, damaging citizen trust.

Secrecy includes prevention of correlating disparate pieces of non-secret information to infer secrets. For instance, knowledge of the average salary of female employees in a department can be combined with knowledge there is only one female employee in the department to infer her salary. However, these problems are well known by statistical agencies, and automatic checks can be made before releasing correlatable information (Adam & Worthmann, 1989).

## DELIBERATE DECEPTION IN DIGITAL GOVERNMENT

Politicians lie and equivocate on many occasions since protecting secrets and pleasing large numbers of people often requires it (Eckman, 2001; Nyberg, 1993). This accounts for some of the low trust that citizens have in governments. Thus it is important for digital government to maintain high standards of truth telling to avoid being associated with the poor reputation of politicians (and losing trust on Sztompka's factors of reputation and performance). One important principle is that digital government should mostly record and report matters of fact. Exceptions must be made for discussions and public comments on matters of policy, but even these can be made more trustworthy by ideas such as linking statements in a discussion to the raw data supporting them. World Wide Web technology makes it easier to provide such links.

A reason to be very cautious about deception by governments is that trust is subject to different laws than distrust. Josang (2001) argues that trust can decrease quickly with experience but distrust decreases much more slowly, and this has been confirmed in experiments (Rowe, 2004). This is because actions that create distrust tend to be hard to interpret as accidental. Thus a few incidents of deception (or even half deceptions) can ruin the trustworthiness that a government has taken years to build. But easy online access to validated information should reduce the ability and desire of governments to lie about matters of fact, reducing the total amount of lying that they do. And if a government that tries to limit access to important information, or lies about possessing it, it can be seen as almost as bad as if it lied about it in the first place, as citizens become familiar with the capabilities of digital government.

Another issue is that third parties besides a government and its citizens could use digital government technology for their own deceptions. For instance, vendors could insert advertising in the software they supply to a government, or trespassers could post false information on government Web pages. Such events would lower

public trust in the government. So digital government must enforce software standards and implement good information security practices.

## AUDITING

Every legitimate government must also provide safeguards to prevent secrecy from being exploited for personal or political advantage. For instance, secrecy should not be permitted to enable embezzlement, awards of contracts to relatives of government employees, or a campaign of harassment against political enemies. Audits are one way to prevent this (Mercuri, 2003). These are independent analyses of the secret data by accountants, regulators, lawyers, and other purportedly independent evaluators to confirm that policy and laws are being obeyed. Computer software is essential to auditing as it can systematically check all the details. Software can also check for bugs and loopholes, either inadvertent or deliberate, that could permit policy violations or crime (Prins, 2002). With automatic auditing, digital government can in fact be made more trustworthy than traditional government.

Auditing requires recording all changes and attestations for a key document such as a budget with indications of who made them and when; computers can easily record such information. Then if there are discrepancies, blame can be localized, and this supports Sztompka's trust factor of accountability. Such controls necessarily increase bureaucracy in government, but bureaucracy is a price that must be paid for a trustworthy government (Wilson, 2000). Bureaucracy has an additional benefit in increasing the reciprocal trust that government employees have in citizens, since it limits citizen interactions to a narrower set of activities and this can reduce the stress on government employees.

Mandated disclosure is often coupled to auditing; it can reduce the amount of secrecy used by a government and improve its legitimacy through accountability for decisions. For instance, departments can be required to disclose how they spent their budgets. Mandated disclosure can occur after a time limit. For instance, classified information in the United States must be disclosed after a period of time when it cannot compromise ongoing activities. While intelligence agencies may grumble about it, it is usually beneficial for trust in government to reveal 50-year-old information.

## AUTHENTICATION

Authentication is an accountability technique related to auditing, and includes methods for verifying the integrity of information and the identity of people (Smith, 2001). Authentication can confirm that digital documents are unmodified, which is important since it is so easy to change them. Authentication can also prove that software (including auditing software) has not been tampered with, confirming that no viruses, worms, or other "Trojan horses" have been inserted. Authentication of digital data uses methods of cryptography and "digital signatures"; public key cryptography is particularly useful because it can be used either to encrypt or to authenticate. Effective authentication methods prevent signatures from being copied from one document to another by making the signature a complicated function of the contents and date of the document.

Authentication can thus prove the author of a document, which prevents forgeries as well as later disavowal of authentic documents; this supports strong accountability. Authentication also can prove that a document in a sequence is missing, if one encrypts pointers to the previous and subsequent documents for each document. It can also identify sources of information leaks, by using steganography to embed unique hidden messages in each copy of a document, as in the pattern of spaces or line lengths (Wayner, 2002). Authentication and auditing are critical in providing trust in electronic voting (Kofler, Krimmer, & Prosser, 2003).

Authentication also helps preserve privacy of citizens by requiring credentials to access data. If a government site permits unauthorized people to read private personal information of citizens like credit card numbers, addresses, and birthdates, it will quickly lose the trust of its citizens. Even less obviously private data like who has visited a government site should be restricted to maintain good public trust. So access to citizen data should require secure authentication permitting access of a very small number of government employees.

But authentication on computer systems only works when one can trust the computer systems on which it is done. This requires that the operating system of the computer is free of security flaws, a challenge for the popular operating systems of Windows and Linux for which security flaws are being discovered all the time. An older and well-debugged version of an operating system can be selected, a very safe operating system with "security kernels" can be used, or the operating system can be put into hardware to prevent tampering. Increasing the trustworthiness of the supporting software can also increase trust in the operating system. For instance, good network security methods like encryption and well-tested communications protocols can prevent tampering with commands that cross the network, so their use encourages trust in the operating system.

## TRANSACTIONS AND FEEDBACK WITH GOVERNMENT

Digital government should include more than making forms and reports accessible to citizens; it should permit citizens to affect government processes (Slayton & Arthur, 2003), to address Sztompka's factors of performance and precommitment. Citizens should be able to file applications for business permits online, for instance. Permitting such online transactions can simplify citizen's lives, reducing the amount of time they spend in government offices and waiting in lines, and may be the only possible way to deliver services for widely scattered governments and those of developing countries with limited infrastructures. Providing such services increases citizen trust that government procedures are functioning appropriately. Online transactions can also eliminate much of the opportunity for bribes and other forms of corruption, and can remove some of the subjectivity of bureaucratic decision making by implementing some decisions with computer algorithms. This provides more fairness (Bovens & Stavros, 2002).

Digital government also permits feedback from citizens to the government to give citizens a better means to influence it. For instance, online surveys can assess citizen opinion, which is helpful even for nonrandom samples of citizens, or citizens can actually vote online. Proposed or existing laws and regulations can be subjected to comments on discussion boards, giving the government feedback about unanticipated problems, increasing the fairness of the laws and regulations and improving citizen trust in them.

## MEASURING TRUST IN GOVERNMENT

It is valuable for a government to measure by surveys the degree of trust can that citizens have in it. (West, 2004) reports that digital government as currently implemented in the United States is not fostering much trust. Welch and Hinnant (2003) surveyed Americans to determine what features of electronic government were most supportive of trust by citizens. They discovered that both "transparency" (accessibility of government by information systems) and "interactivity" (ability of citizens to control government in some way) were correlated with trust in government; but frequent American users of digital government were less satisfied with the interactivity available than the transparency, which tended to decrease their total trust level. This suggests that interactivity must get more attention in future systems if they are to be well trusted by citizens.

## FUTURE TRENDS

Digital government may be inevitable, but trust in digital government is another matter. Successful cultivation of trust by citizens is difficult for many governments today, and digital government is subject to many of the same stresses that make trust difficult. Clearly, good technical understanding, including human engineering of the interface, is necessary to implement digital government successfully, and a successful implementation is one precondition of trust. But another factor is the degree to which citizen needs are met by the technology, and that requires perceptive political leadership. It is too early to say how the trust issue will be resolved in digital governments.

## CONCLUSION

Digital government, like much technology, can either to improve government or make it worse. Digital government can provide advantages for the citizenry: Easier access to important information, more reliable implementation of procedures, and better accounting for actions including assignment of responsibility. If digital government is implemented well, these benefits should increase the trust of citizens in their government because they increase the appearance of trustworthiness, consistency of performance, and accountability for actions. But citizens are not very tolerant of incompetence in government, and digital government must be implemented with carefully designed and carefully tested technology to gain these benefits.

## KEY TERMS

**Access Control:** Limitations (usually automatic) on who can see or use something.

**Auditing:** Keeping records of processes to later confirm they were performed properly.

**Authentication:** Proving that someone is who they say they are; this is particularly important with online activities where one cannot see with whom one is interacting.

**Computer Illiterate:** Lacking knowledge of how to use computers and software.

**Deception:** Causing someone to infer a false idea; lying is one subcategory.

**Digital Signature:** Digital information attached to a digital document that proves who is responsible for it by use of a code known only to them.

**Secrecy:** Prevention of access to information, enforced for digital data with encryption.

**Steganography:** Embedding hidden messages in documents.

**Transparency, Organizational:** The ease by which the operations of an organization can be understood by outsiders.

**Trust:** Confidence that future actions by others will fulfill our positive expectations, usually entailing reduced vigilance by us to monitor those actions and freed resources by us to do other things.

## INTRODUCTION

Designers often design for themselves unless they are trained to realise that people are diverse, and that users are unlikely to be like them. The more errors that can be avoided "up front" by the right method, the less work both test-users and designers will have to put in to refine prototypes to improve their usability. Landauer (1995) points out that it is not good enough to design interactive systems without subjecting it to some form of evaluation, because it is impossible to design an optimal user interface in the first attempt. Dix Finlay, Abowd, and Beale (1998) argue that even if one has used the best methodology and model in the design of usable interactive systems, one still needs to assess the design and test the system to ensure that it behaves as expected and meets users' requirements. Nielsen's (1993) advice with respect to interface evaluation is that designers should simply conduct some form of testing.

As digital libraries (DLs)—interactive systems with organised collections of information—become more complex, the number of facilities provided by them will increase and the difficulty of learning to use these facilities will also increase correspondingly. Like the Web, DLs also provide non-linear information spaces in which chunks of information are inter-connected via links. However, they are different in character from the Web in several important respects: a DL represents a collection for a specific purpose containing text-based and/or geospatial content and has search strategies that are clearly defined and more powerful.

After a decade of DL research and development, DLs are moving from research to practice, from prototypes to operational systems (Borgman, 2002). In the digital world, real world cues such as face-to-face interactions with human librarians and thumbing through hardcopy books have been replaced by drop-down menus, search screens, and Web page browsing. In DLs, users must map their goals onto DLs' capability without the assistance of a human librarian. As a result, wide acceptance of DLs will only be achieved if they are easy to learn and use relative to the perceived benefit (Borgman, 2000).

## BACKGROUND

In recent years, government services across the world are going online, replacing old bureaucratic service lines with accessible information and services, available 24/7, directly from the desktop, using powerful new technologies like digital signatures and electronic forms, and creating a new phenomenon called "digital government." Implemented or proposed digital government initiatives in many countries are an attempt to move more of their citizens online, thus shortening the queuing lines at traditional service counters.

According to the U.S. official state government Web site (see http://dis.wa.gov/index.htm; retrieved March 6, 2005), *digital government* offers a "one-stop shop" to many government services through the state's Internet portal. It is a fundamental shift in government culture, allowing those in public policy and government to respond much more quickly. The U.S. digital government initiatives, for example, embrace the following objectives: (1) make the process of accessing government services immediate, simple, seamless and intuitive; (2) reduce paperwork within government, and reduce costs so funds can be moved into direct delivery of services; and (3)

improve service delivery to all segments of the population, whether they are connected to the Internet or not.

In Singapore, the power of the Internet and information technology is radically altering the way the Singapore government relates to her citizens and the business community. Singapore, ranked among the world's top three e-governments by World Economic Forum in 2003, and by management and technology consultancy firm, Accenture, in 2004, aims to be "a leading e-Government to better serve the nation in the digital economy" driven by the Ministry of Finance, and executed through the Infocomm Development Authority of Singapore (IDA, 2001).

Hence, the purpose of Singapore's official digital government site, eCitizen Centre (see http://www.ecitizen.gov.sg/), is to provide easier, more convenient and more comprehensive, round the clock access to government services. Citizens can access among many library information services online via *eLibraryHub*, the National Library Board (NLB) Digital Library (see http://ele.ecitizen.gov.sg/lib/lib01.htm).

The *eLibraryHub* (see http://www.elibraryhub.com), launched on September 7, 2001, aims to provide its four million individual users access to information resources and services anytime, anywhere (Chan, 2002). It is also a one-stop integrated digital library for immediate access to vast amount of information and resources. It is both a content and community portal (Chia, 2002) and caters to users from multiple environments, from individuals, businesses, professionals, corporate to community groups (Abu Bakar, 2002).

On the content side, the library resources in the *eLibraryHub* include some 13,000 electronic magazines, journals, and online databases; 10,000 electronic books and more than 700 CD-ROM and 900 video-on-demand titles. In the "Reference Library," links to resources selected by NLB's information specialists are provided. In a bid to target the information needs of niche markets, NLB has plans to create specialized libraries within the *eLibraryHub*. Its first offering launched in end-2002 is the "China Resource Library" that provides business-related information about China. Another two specialized libraries that are being planned will cater to children and teenagers.

## SETTING THE STAGE

This article reports a study conducted on the *eLibraryHub* as part of NLB's on-going efforts to improve services of the public library, in particular, for the purpose of this article, the usability of the *eLibraryHub* in meeting users' needs via the eCitizen Centre. We also hope this study would contribute to the under-studied usability research on DLs constructed by community organizations such as public libraries and hospitals, as highlighted by Borgman (2002).

The study, conducted in early 2003, evaluated the effectiveness of the *eLibraryHub*, looking at users, uses, and usability issues of the DL. It attempted to employ a quantitative approach based on questionnaire survey to evaluate the perceived value of the DL and the effect on the intention of use by users.

## Questionnaire Development

The development of the questionnaire involved an iterative process of formulation and evaluation by five peers who were taking the Master's in Information Studies course at the Nanyang Technological University, a means of obtaining feedback from a small, convenient sample of potential respondents. The purpose was to determine the relevance of the questions and the extent to which there may be problems in obtaining responses.

The final refined questionnaire was structured such that all respondents, regardless of whether they are users of the *eLibraryHub* could answer the first part comprising demographic questions.

Users of the *eLibraryHub* were then asked in the second part about their usage of the DL. For *user satisfaction*, the users assessed the resources and services of the *eLibraryHub* as well as the overall effectiveness.

The questions asked were:

- How satisfied are you of the resources used?
- How satisfied are you of the services used?
- Overall, how would you assess the effectiveness of *eLibraryHub?*

They were asked to rate their satisfaction of the resources and services on a Likert scale from "1" (most satisfied) to "5" (least satisfied) in terms of four factors: availability, accessibility, quality, and effort. The factors were based on the second major class (Class B: "Interaction") of the taxonomy derived by Saracevic and Kantor (1997). They were also asked to rate the effectiveness of the *eLibraryHub* from "1" (most useful/usable) to "5" (least useful/usable). The purpose was to find out if the *eLibraryHub* fulfilled users' needs, if there was a difference in satisfaction level for different factors, and if users found the *eLibraryHub* equally useful and usable.

To study *user intent and user perception*, six statements were presented and the users were then asked whether they agree of disagree with it. They were:

- I can obtain the resources and services I need when using *eLibraryHub*

- Using *eLibraryHub* would enable me to accomplish my task or project more effectively
- I find *eLibraryHub* easy to use
- My interaction with *eLibraryHub* is clear and understandable
- Assuming I currently use *eLibraryHub*, I intend to continue my use in future
- I intend to increase my use of *eLibraryHub* in future

The statements were adapted from the study by Hong, Thong, Wong, and Tam (2002) to determine user acceptance of the Open University of Hong Kong's E-Library. Likert scales (1-5) with anchors ranging from "strongly agree" to "strongly disagree" were used for all statements. Respondents were requested to select the category that corresponds most closely to their responses. The statements were to serve as an initial stimulus, and the response categories could be used to measure reactions and assess respondents' attitudes or opinions. Five response categories were used to allow for sufficient information without exaggerating the decision-making abilities of the respondents (Gray & Guppy, 1994).

For *user intent*, the following question "How often do you access *eLibraryHub*?" was also asked.

The purpose was to determine if the *eLibraryHub* was used on a regular basis, if users would keep using it, and even increase their usage. For the area of user perception, the purpose was to examine users' perceived usefulness and ease of use of the *eLibraryHub*.

## Protocol and Target Respondents

The questionnaires were disseminated in two modes, namely in hardcopy via person-to-person and softcopy via e-mail attachment. They were collected over a period of six weeks from March/April 2003. A total of 107 respondents completed the questionnaire, out of which 40 of them were returned via e-mail.

The completed questionnaires were checked to ensure there were no missing or ambiguous answers. A minor problem occurred for three respondents who were Macintosh users. The Microsoft Word format for the softcopy version of the questionnaire was incompatible and their replies could not be read properly. The respondents were thus requested to re-send their answers as part of the text message and not as an e-mail attachment.

The target respondents of this study were library users, namely students (tertiary level and above) and working adults, spanning the age group of 18-44. This group accounted for almost 60% of the resident library book borrowers (Yeo, 2002) and constituted more than 63% of home Internet users (Infocomm Development Authority of Singapore, 2001). They would usually need to search and find information in the course of their schoolwork and jobs. The respondents were recruited from fellow course mates and friends and were chosen on the only condition that they belonged to one of the age groups mentioned earlier.

# FINDINGS AND ANALYSIS

## Demographic Characteristics of Respondents

The sample population of 107 respondents was almost split in half by gender, with males constituting 49.6%; 75.7% of the respondents were between 25-34 years of age, and 89.7% held degree qualifications and above. The high proportion of respondents in these categories could be due to the fact that they were recruited from fellow course mates and friends who shared similar backgrounds. Majority of the respondents (65.4% of the sample) were working persons. The occupations of the working persons varied from professional, administrative and managerial, technical, sales and marketing, and service-related. The percentage of the *eLibraryHub* users was 36.4%. Below are findings on user intent, user satisfaction and user perception. More detailed analyses found in Khoo, Chan, Theng, and Buddharaju (2004).

## User Intent

Almost 95% of the *eLibraryHub* users accessed it less than once a week. 66.7% of the users agreed or strongly agreed with the statement that indicates their intention to continue using the *eLibraryHub*. However, only 35.9% agreed or strongly agreed with the statement that indicated the intention to increase their usage. This could mean that existing users are generally satisfied with the *eLibraryHub*, but more could be done to increase their usage level.

## User Satisfaction

Users rated favourably their satisfaction of the availability, accessibility, quality, and effort of use of the *eLibraryHub*'s resources and services as well as its overall effectiveness. On a scale of "1" (most satisfied) to "5" (least satisfied), the *eLibraryHub*'s services received marginally higher mean ratings (2.71 to 2.87) than the resources (2.97 to 3.03) for the four factors. Overall, users rated the *eLibraryHub* to be slightly more useful (mean=2.82) than usable (mean=2.95), where usefulness was defined as "providing useful information and ser-

vices," and usable was defined as "easy to use" in the questionnaire. This could mean that users are generally satisfied with the usefulness of the *eLibraryHub* but more could be done to improve its ease of use.

Correlation analysis was done to see which user satisfaction factors are related to overall effectiveness of the *eLibraryHub*. The Pearson *r* was calculated for each pair of variables. Statistical tests were also carried out to determine whether the calculated value of *r* is significantly greater than 0. The t-statistic was used for the test and p-values of 0.05 and below were considered statistically significant. From the correlation results, it could be observed that almost all but four correlation pairs were found to be statistically significant. For overall usefulness, the strongest positive correlations were with the *accessibility* (r=0.503, p=0.002), *availability* (r=0.490, p=0.002) and *effort of use* (r=0.462, p=0.004) of resources. For overall ease of use, the strongest positive correlations were with *effort of use* (r=0.701, p=0.000), *accessibility* (r=0.550, p=0.000) and *quality* (r=0.448, p=0.005) of the resources.

### User Perception

From the results, it could be gathered that users perceived the *eLibraryHub* as generally quite useful and easy to use. In terms of perceived ease of use, 61.5% of the *eLibraryHub* users agreed that it is easy to use and 46.2% agreed that their interactions are clear and understandable. In terms of perceived usefulness, 51.3% agreed that they can obtain the resources and services they need when using the *eLibraryHub*. However, only 33.3% agreed that using the *eLibraryHub* would enable them to accomplish their task or project more effectively. This might seem that users perceived the *eLibraryHub* as more easy to use than useful. Yet, from their satisfaction ratings, they seemed less satisfied with this perceived level of ease of use compared to the level of usefulness. This reinforces the idea that more could be done to improve the ease of use of the *eLibraryHub* for its users.

## CONCLUSION AND FUTURE WORK

This article reported a quantitative study evaluating the effectiveness of the eLibraryHub from users' perspective, looking at users, uses, and usability issues of the DL. Results showed that users rated favourably their satisfaction of the overall effectiveness and usability of eLibraryHub.

As this study explored usability issues when accessed from the *eLibraryHub* directly, but not via the eCitizen Centre homepage, it is recommended that future work should study user interactions when accessing eLibraryHub from the eCitizen Centre. The size of the sample should be increased and responses should be gathered from participants of more diversified backgrounds. Interviews, focus group discussions, or further qualitative studies could be done to obtain more in-depth information and to further examine user perceptions. The study could also be further developed to connect the perceived value of DLs with appropriate economic indicators. This could then help to provide a more tangible means of prioritizing the development and improvement of usable and useful DLs in particular, and digital government Web sites in general.

## ACKNOWLEDGMENTS

The authors would like to thank the subjects who took part in the survey, and the National Library Board for commissioning the study.

## KEY TERMS

**Digital Government or E-Government:** Digital government is providing online government services, replacing old bureaucratic service lines with accessible information and services offering a "one-stop-shop" to many government services through the state's Internet portal. It is available 24/7, directly from the desktop, using powerful new technologies like digital signatures and electronic forms.

**Digital Library:** They mean different things to different people. The design of the digital libraries is, therefore, dependent of the perceptions of the purpose/functionality of digital libraries. To the library science community, the roles of traditional libraries are to: (a) provide access to information in any format that has been evaluated, organized, archived and preserved; (b) have information professionals that make judgments and interpret users' needs; and (c) provide services and resources to people (students, faculty, others, etc.). To the computer science community, digital libraries may refer to a distributed text-based information system, a collection of distributed information services, a distributed space of inter-linked information system, or a networked multimedia information system.

**Electronic Library Services:** ISO/DIS 2789 defines them to include the OPAC, the library Web site, electronic resources, electronic document delivery and internet access offered via the library, supplied either from local servers or accessible via networks.

**Usability:** ISO 9241-11 defines usability as "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use." Usability of hypertext/Web is commonly measured using established usability dimensions covering these categories of usability defects such as screen design, terminology and system information, system capabilities and user control, navigation and completing tasks.

**Usefulness:** This is debatable. Some make the distinction between usability and usefulness. Although it is impossible to quantify the usefulness of a system, attempts have been made to measure its attainment in reference to system specifications and the extent of coverage of end-users' tasks supported by the system, but not on end-user performance testing.

# Usenet and the Proactive Ombudsman

**A. P. G. van Meeteren**
*Vereniging Internetgesprek, The Netherlands*

## INTRODUCTION

There is hardly any interest in Usenet in governmental circles at the moment. That is not surprising, given that the government's task is to organize society, while for Usenet, spontaneity is extremely important. However, it is still worth investigating whether government and Usenet can grow toward one another. Usenet can become a "public city park" of the Internet, as suggested by Stewart, Gil-Equi, and Pileggi (2004). They overlook this possibility, although Usenet meets a number of the basic conditions. It is an open, non-purposive space and "provides a place where different people cross paths, without necessarily interacting all the time" (Stewart, 2005, p. 356). The conversations in that city park can contribute to democratic decision-making or to administrative objectives, if they lead to anything. A system of order imposed from above will be suffocating. This article outlines a method of ensuring that those conversations are given a focus. Government itself can then ensure that Usenet conversations have a focus by providing and collecting information, while respecting other users, as an ordinary user.

## BACKGROUND

According to Hauben and Hauben (1997), "Usenet was born in 1979 when Tom Truscott and Jim Ellis, graduate students at Duke University in North Carolina, conceived of creating a computer network to link together those in the Unix community." (p. 39). Their idea was for computers to automatically call one another to see whether there were any changes in their Usenet databases. If there were any changes, they would be downloaded to the caller computer. Any user would be able to post a message somewhere within the Usenet system; that message would then be distributed throughout that system. In other words, people would reply to one another.

Usenet, in fact, went on to become the poor man's ARPANET (later: World Wide Web). In order to access ARPANET at that time, one needed about $100,000 and some political connections; in other words, ARPANET/World Wide Web was a system for use by large institutions. Unlike ARPANET/World Wide Web, Usenet is available to any user, as both consumer and producer of information. Moreover, Usenet allows the recipient to determine what he or she wants to receive, whereas ARPANET determines centrally what is displayed. A Usenet recipient also selects the postings he or she wishes to download and determines the format in which he or she wishes them to appear; in order to do this, he or she makes use of a "newsreader." The various contributions in response to postings can be categorised into "threads," meaning that one can see in graphic form how a particular interchange is progressing.

Initially, new communication techniques are used by the relevant experts and are only discovered by the general public at a later date. Usenet was no exception: the experts were pioneering computer users and it was not until the late twentieth century that the general public began to make use of the system. Hauben and Hauben (1997) and many others were extremely enthusiastic about the communicative power of Usenet, identifying a new democratic élan within it that created a lively and creative community. Hauben and Hauben's book was written shortly before a deterioration set in in that respect. The poor man's World Wide Web became the scene of a kind of warfare. The absence of an institutional framework was celebrated as anarchy, at the cost of the exchange of actual substance. However, a number of "old boys behind closed doors" (Lovink, 2003, p. 258) continued to believe in the communicative value of Usenet and—despite the impending "information overload" (Durlak, O'Brien, & Yigit, 1987)—made great efforts to preserve the good manners developed in the period when Usenet had been the preserve of the experts (Moreas, 1998).

## FLAME-WARS

Early users of Usenet were still building up the Usenet community, and everyone involved could make his or her contribution. The later Usenet, by contrast, is seen as a finished technical infrastructure. A number of "netiquette" rules, both written and unwritten, specify how one is meant to behave. There is no institution where further development can take place and there are no effective sanctions if one breaches the rules.

In contrast to the community spirit of the early Usenet, participants now feel that they are at liberty to express

themselves freely, with no obligations and without being held accountable. In such a climate, it is easier for "flame wars" to get started and to rage for longer. This climate of misunderstanding and quarrelling makes Usenet useless for governmental purposes.

"Flaming" means verbally abusing someone by posting angry or derogatory messages. A "flame war" is an interchange of such postings; it may go on for weeks. Such conflicts are encouraged by the fact that there are no longer any accepted bounds of behaviour, because one is dealing here with contact that takes place without the other person or persons actually being present (Köhler, 1999, p. 150; Schroth, 2002, p. 129). If one's interlocutor is in fact present, one takes account of him, either consciously or unconsciously. A Usenet poster is only required to qualify his remarks if the urge to do so comes from within himself (Hauben & Hauben, 1997, p. 25). Some posters clearly enjoy starting a flame war and then keeping it going; in some cases this leads to their bringing about the demise of an interesting newsgroup (Lovink, 2003, p. 124).

Methods are being conceived to prevent flaming. Hauben and Hauben (1997, p. 25) and Shirky (2004), for example, think that the solution is improved software. Shirky refers to a number of initiatives and ideas to set up the software in such a way as to prevent disruptive action by individuals. He calls for experimentation with such techniques so as to find a balance between the freedom of the individual and the interests of the group which that individual has joined.

Slashdot (a "virtual community" concerned with technical aspects of the Internet) makes use of a technique whereby an appeal is made to the actual group processes as a means of keeping individual behaviour within the desired bounds: "Instead of assuming that all users are alike, the Slashdot designers created a karma system, to allow them to discriminate in favor of users likely to rate comments in ways that would benefit the community" (Shirky, 2004). Slashdot allows a specially selected group of users to indicate the value of contributions for the group as a whole. Jordan, Hauser, and Foster (2003) seek the solution in constructing the World Wide Web in such a way as to restore trust between people. They hope to achieve this by taking measures to prevent the increasing fragmentation of the Web (stable identity, increased accessibility of virtual communities).

Lee (2005) notes that "... there seems to be the regular's inclination to accept relativism in online debates and flaming." O'Sullivan and Flanagan (2003) also point out that what a third party may consider to be a clear case of "flaming" can in fact be of value to the recipient of the message.

According to Millard (in Lee, 2005), the realisation that others do not want to be convinced will not mean that people will avoid clashes because "… the desire to achieve persuasion provides the initial and constant motivation for rhetoricians to perform."

## THE THREAD PRESIDENT

Flaming is a case of using improper means to get people to concede that one is right. It is in fact a kind of battle for the pulpit, a struggle to get people's attention for the fact that one is right. One tried-and-tested method of settling such a dispute is to give each speaker a certain amount of time to speak. On each occasion, each of the "truths" is dealt with separately and ultimately the listeners decide what appeals to them. This technique revolves around the chairperson who apportions the attention. Something like this can also be developed for Usenet, but suitable agreements need to be made. Within the culture of Usenet, however, there is a fear that there will be a loss of spontaneity if such agreements are indeed made. In my opinion, that fear is groundless. There will still be a lot of spontaneous ideas on Usenet; the only difference will be that they will be assigned a place in the subjective and definitely not coercive order imposed by the thread president.

In order for the system to function, the president must be in a position that is visible for all and he must have certain instruments at his disposal. Whether a thread president stifles spontaneity depends on those instruments. He (the "TP") would be allowed to assess postings by other individuals in a clearly visible manner. In this way, he would indicate the level at which he was managing "his" thread, and what he wanted to talk about. Spontaneity would not be stifled because the TP would only give directions. Despite the existence of the TP function, all the participants would continue to be involved in drawing up and enforcing the rules. Kollock (1996) believes that such involvement is vital for a community.

Each posting responding to another posting would constitute one vote in favour of a particular TP. Each member of the group would be able to become a candidate for the position of TP by simply starting a discussion. This too would allow everyone to continue to act spontaneously. The TP would not be carrying out an assignment from the group and it would be his own ambition that determined how much energy he wanted to put into his thread. In the course of his thread presidency, someone may stand out from the rest. This makes possible a greater social presence (Köhler, 1999 p. 147). The TP would influence the presentation of the postings and in that way a second channel—even a superior one–would be introduced containing evaluative information (even directed towards the person) but in an indirect and non-aggressive

manner. People would therefore be able to take note of the information and then move on to the discussion.

The evaluative TP channel would clarify what users actually mean for one another; one could then draw useful conclusions for future contacts. Common bond groups could be created, with "rewarding interpersonal relationships" then being the "main reason for membership" (Schroth, 2002, p. 172). The TP on duty would assign rewards or impose sanctions, thus creating the common bond that defines a common bond group. There would be an "expectation of something in return," a "confirmation of one's identity," and a "feeling of effectiveness" (Schroth, 2002, p. 172, quotation translated). If friends then wanted to have fun savagely flaming one another, they could do so, with other common bond groups leaving them to get on with it while pursuing their own more profound discussions. All this would be a dynamic alternative to Jordan's "Augmented Social Network" (Jordan et al., 2003). Creating a group by means of the TP system would also be a way of reducing information overflow (Durlak et al., 1987). Each TP would convert the information—the contributions to his thread–into information useful to him and to the other members of the group.

## GOVERNMENT AND USENET

### Many-to-Many

A Usenet based on a TP system would enable government to participate effectively in the options for "many-to-many" communication that have been created by the Internet, with government being just one of the many participants and not a special one. Usenet is an interesting phenomenon from the governmental point of view. In the first place, of course, that is because it is a societal phenomenon (i.e., part of society). But the main reason is that it consists of members of the public, freely and spontaneously engaging in discussion of a variety of subjects. It is discussion that everyone—including government—can follow and in which everyone–again including government as government—can basically participate. Surratt (2001, pp. 79ff) believes, for example, that this can help preserve the nation state and prevent it being submerged by globalisation.

The Internet provides opportunities for many-to-many communication. To that end, scientists and authorities are also greatly interested in the World Wide Web. What will always remain a problem is that efforts to generate many-to-many contacts take place within the framework of one-to-many contact. As Jacobson (1993, p. 197) points out,

*[t]his tendency toward control had been even more pronounced in the plans of ... governmental administration to operate interactive information systems: Political and cultural censorship are built in as a matter of deliberate design. Reciprocity, on the other hand, is excluded.*

Government will always wish to have control of the discourse, while the public will always assume that there is a wish to dominate behind the invitation to participate. Through the World Wide Web, government controls the public space in which it is itself active. Members of the public are enticed in to participate in the discourse within government's own topics and stated interests.

Another obstacle is to be found in the fact that the structure of the World Wide Web creates barriers between the various different types of virtual community. Jordan et al. (2003) refer to them as "walled castles." For businesses and NGOs, this is necessary given the restricted reasons for their presence on the Web. Government, however, is there to serve the public interest, meaning that such barriers are a major obstacle.

Usenet is not a channel for "one-to-many" communication by the institution "government"; rather, its whole point is that it makes possible many-to-many communication. Hauben and Hauben (1997) note: "The very nature of Usenet is communication…In its simplest form, Usenet represents democracy" (p. 48). Someone—anyone—makes an announcement or asks a question, doing so without any frills or trimmings. Anyone else can then reply, again without frills or trimmings. All the various participants in the communication are basically equal.

In short, interactivity within the World Wide Web takes place within an institutional framework; within Usenet, there is interactivity without such a framework. This then raises the difficulty noted by Thiedeke (1997, p. 239) that "a paradoxical feature of performative publicity is that it is simultaneously interactive but uncontrollable (quotation translated)." Performative publicity thus involves a public space within which individuals—with their own specific interests—have an influence. By making use of Usenet, government is seeking out people involved in discussion in their own physical environment and is aiming to key into the subjects that concern them. It is not necessary for the individual to be enticed in and government does not need to put any effort into presenting itself in an attractive manner. Government in fact follows the public discussion, something that fits in with the concept of democracy.

Surratt (2001) measures the quality of the efforts made by government in the context of the Internet by the attractiveness of government Web sites and the extent to which they are interactive; her focus is on the World Wide Web. In this context, I would like to ask—perhaps provocatively—whether Usenet could not in fact become the "poor government's" World Wide Web. After

all, Usenet allows for a great deal of interactivity, without the need for any great effort on the part of government as regards infrastructure. The existing infrastructure could be used and there would be no need to take steps to get people's attention.

## Changing Government

Mosco (2004) investigates the rise of myths regarding cyberspace. Referring to the division of powers, he comments:

*The rise of a horizontal society most of whose members are more or less 'jacked in' to new communication and information technologies, to networks that link people in more than traditional top-down vertical ways, will, the myth teaches, transform power as we know it.* (p. 99)

But then, for Mosco (2004), the transition would seem to mean that the myth desires an end to political power. I would go no further than to say that political power will undergo change. I in fact endorse what is argued by Surratt (2001, p. 84). We should not aim at a state organised on compact, hierarchical lines but at one that is able to respond to networks such as Usenet. When using a TP-structured Usenet, government will need to suppress its tendency to want to immediately impose top-down control. Agre (2003) also realises this: "The role of political organizations must change. An organization no longer needs to carry the full burden of organizing the collective cognition of the social group it claims to represent. (p. 65)"

The Usenet think tank cannot be forced into production via the existing vertical lines of authority. Usenet thinking is spontaneous and will come to an end if government attempts to guide it towards an intended result from a higher rung on the hierarchical ladder. The way for government to acquire a significant role in such many-to-many communication is not by means of its holding any particular position but by deploying knowledge and manpower and by means of cooperation outside Usenet that focuses on Usenet. If government wishes to make use of Usenet, it will need to do so as a kind of "street-corner social worker," at the same level as those with whom it interacts. What is involved is direct persuasiveness. A second Usenet channel created by the introduction of the TP system would make it possible to deploy that persuasiveness efficiently. The work of government would not be hidden within a mass of postings but would be visible in threads clearly labelled by TPs.

Hauben and Hauben (1997, p. 56) see Usenet as a means whereby people can influence government: "Usenet could grow to provide a forum through which people influence their governments, allowing for the discussion and debate of issues in a mode that facilitates mass participation." However, government needs to allow itself to be influenced in that way. For traditional reasons, it is "politics" that is the most obvious institution through which this could take place.

Usenet (or the World Wide Web) has provided democracy with a public space once more, one in which many-to-many contacts are possible. Such contact used to take place in locations like the *agora* of Ancient Greece and similar physical meeting places. One-to-many media such as newspapers, radio, and television did away with the democratic importance of such venues, but editorial offices are a poor substitute. Usenet (or the World Wide Web) can become a venue for democracy (Poster, 2001), allowing for broader and more differentiated participation. A consultative democracy involving all members of society becomes possible once more (Dahlberg, 2001).

But even a democratic public administration would do well to become part of this network. Doing so would be an effective addition or alternative to the collection of information and public enquiry procedures (preparation of decisions) and to providing public information and opportunities for objection and appeal (justification of decisions). Frissen and De Jong (1996, p. 19) note developments in administration in which policy is increasingly being given shape through government participation in networks, with the fundamental principles being differentiation, variety, and pluriformity. In line with this, it is conceivable that government will allow itself to be represented on Usenet by highly trained civil servants who have been assigned a position that gives them freedom to act independently. Such contact with the public does not need to lead to any radically different political structure. In my opinion, those involved in that contact will not acquire power on Usenet from their administrative position, assuming that they are not loaded down with specific responsibilities within the public space of Usenet, and assuming also that their activity within Usenet does not mean that government is bound by what they say there. I would refer to such persons as "proactive ombudsmen." An ombudsman has a critical function with respect to government, but unlike the present ombudsman, "proactive ombudsmen" would not just act subsequently if objections are made, nor would they be bound to particular cases. They would, however, be independent and they would also function as shapers of opinion. They would thus perform some of the tasks currently performed by the press; specifically, they would digest data—the contributions posted by participants—and turn that data into information. The information would then be passed on to the echelons where decisions are traditionally taken. The proactive ombudsman would work in a more targeted manner than the press does and would have immediate and public access to the echelons where decisions are prepared and implemented. He would request information

on Usenet when necessary and would himself provide information as objectively as possible. The Usenet public would thus receive relevant information as and when necessary, namely when it was ready for it, and would take part in a debate that really mattered.

## FUTURE TRENDS AND CONCLUSION

There is little interest at the moment on the part of government in Usenet as a democratic or governmental instrument. It will only be worth government showing such interest when users streamline their communication so as to make it clearer. If the described method catches on, Usenet can develop into a city park while at the same time retaining its spontaneity. It will then be worth investigating whether Usenet can play a role in the democratic and governmental process. Given the nature of Usenet, that role will need to be a submissive one, with government fostering Usenet's spontaneity and also acting spontaneously itself.

## KEY TERMS

**Consultative Democracy:** Political system that makes possible wide participation by citizens by means of performative publicity (Dahlberg, 2003).

**General Discussion with Depth:** Discussion, without an agenda, whose intention is for at least one of the participants to broaden his horizons. Positioned between a social discussion, in which it is social contact that is primary, and a discussion with a specific agenda and objective.

**Many-to-Many Communication:** System whereby an unrestricted number of parties exchange messages.

**One-to-Many Communication:** System whereby a single party gets a message across to an unrestricted number of other parties.

**Performative Publicity:** A (virtual) meeting place, accessible to all, where people can influence one another and are permitted to do so.

**Proactive Ombudsman:** Civil servant charged with contact between the Usenet public and government. He does not answer to politicians for his decisions in a direct manner. Citizens do not derive rights on his sayings.

**Usenet:** (1) System for exchanging information via the Internet. (2) The social system associated with Usenet in sense 1. (3) The people who make use of Usenets 1 and 2.

**World Wide Web:** System for making information available via the Internet by way of interlinked hypertext documents.

# User Orientation in the Provision of Online Public Services

**Karsten Gareis**
*empirica Gesellschaft für Kommunikations—und Technologieforschung mbH, Germany*

## INTRODUCTION

In the context of e-government strategies, governments typically claim that they utilize Internet technology to improve service provision and to better meet citizens' needs. However, the development of front-office e-government applications often seems to be guided primarily by supply-side factors. Many observers criticise that in practice, technological possibilities rather than user needs determine the design and provision of most public online services.

This situation contrasts sharply with the common political intention that the "user—the individual—has to be placed at the centre of future developments for an inclusive knowledge-based society for all" (CEC, 2004). At the root of this contradiction lies technological determinism: the widespread tendency to assume that certain social outcomes are in some way inherent in a technology. A determinist view implies that it is sufficient to "unleash" a certain technology in order to make its potentials for improving human life come true. It can, however, easily be shown that technological determinism is a myth and that technology, while enabling certain beneficial developments, is in no way a sufficient condition for these (Webster, 2002). Rather, society has to devise policies which effectively strive to use technology to the largest possible benefit of all.

There is, thus, no reason to be complacent about the high degree of satisfaction which users show with e-government services (CEC, 2003). A lot of research has shown that users tend to be satisfied with online public services: Lassnig, Markus, and Strasser (2004b) found through representative surveys that over 90% of citizen and over 80% of business users indicate that they would use the online channel for e-government service provision again. At the same time, however, a large percentage of potential users of e-government state that they still prefer to access government services through traditional channels (mostly face to face). Thus, a positive attitude towards online government services seems to exist only among current users, while most nonusers tend to dismiss their usefulness.

Such polarisation between users and "e-government refusers" points towards the need for better understanding of facilitators and barriers to uptake. The issue is of special relevance because the main services of public interest (which, of course, need to be defined) must be accessible to *every* citizen. Additionally, for many services there exists a public interest to have as many users as possible (e.g., education, civil participation). It become clear, therefore, that user orientation must go beyond mere accessibility and also fully address questions of motivation.

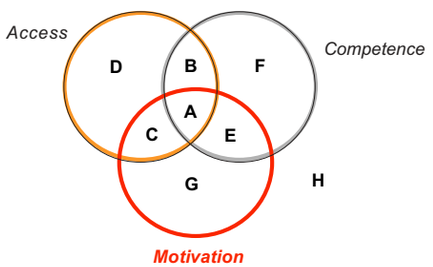
Recent evidence, from the UK especially (Curthoys & Crabtree, 2003), suggests that online availability of a core set of public services alone is unlikely to lead to strong increases in take-up of e-government. The UK government has set a target of getting all public services online by 2005, but this contrasts with low usage rates: About 70% of services were online, but many of these services were hardly being used at all. Curthoys and Crabtree (2003) suggest that encouraging more citizens to use online services should be made the "unequivocal top priority" by the government in its e-government strategy, even if this means downgrading quantitative targets.

What, then, must be done to better cope with the diversity of user needs and preferences in the development of online public services? This article outlines the main challenges related to user orientation of end-user e-government services. Disparities between citizens in the areas of access, competence and motivation appear to be of special relevance in this regard. Against this background, the article suggests a conceptualisation of user orientation of online public services which takes account of all main stages of the service delivery process. This framework may help providers of e-government services in the ex-ante assessment of online services to be developed. The final section includes some conclusions and a brief look into upcoming trends and challenges in the area.

## MAPPING USERS

Public services are defined here as front-office government services. The focus is on delivering such services using online computer connections, either entirely or at least to a significant degree. The relevant issues relate to the improvements that can be achieved in comparison to 'traditional' delivery channels. These improvements can be twofold—first, they can relate to the efficiency of

*Figure 1. Access, competence, and motivation as key factors determining uptake of e-government services (eUser, 2005)*



| Type | Description |
|---|---|
| **A** | Users of online public services |
| **B** | Lack of motivation but access and competence given, most likely from user experience at work or from basic education. Large share of "self-excluded". |
| **C** | Access and motivation given, but lack of competence. Traditional target for training measures, high probability of success of such measures. |
| **D** | Only access given, but neither competence nor motivation. Severe barriers exist before online public services will be used. Likely to apply for many older persons who live in households together with their children who provide the access. |
| **E** | Only access is missing. The bottleneck here is infrastructural equipment, which may need to be provided by the state as in the case of free public Internet access points. Also applies to many disabled who need special devices and services to access mainstream computer applications. |
| **F** | Only competence given, most likely from basic education. Motivation is likely to be the bottleneck. |
| **G** | Only motivation exists. Applies for parts of the poor population who show a strong commitment to society, but lack the means to gain competence and access to the Net. |
| **H** | None of the three conditions exist. Likely to apply to significant parts of low qualified, low-income population in the EU, including poorly integrated ethnic communities. |

service provision. Thus, e-government can provide a new impetus to address the ongoing challenge of how to raise the quality of public services; second, improvements can aim to widen the reach and reachability of these services by actively incorporating the needs of all potential users as integrative part of the whole delivery process.

Users of online public services are a highly differentiated group. This is often ignored as governments are planning the "roll-out" of public online services according to simplistic assumptions about diffusion dynamics. In reality the notion of an "average user" (as it has been applied by the United Nations (2003) for a study on e-readiness of public administrations) can be misleading because the main services of public interest must be accessible to everybody rather than only the majority (or minority?) of users whose capabilities and preferences are well represented by the statistical "average". For this reason, an analysis of barriers to uptake needs to shed more light on types of users and their specific requirements.

For the purpose of this article, the analysis carried out by Viherä and Nurmela (2001) is of special value. They have introduced the concept of communication capabilities. This comprises not only access to information and communication technologies and competence in using them, but also the *motivation* for actively doing so. Figure 1 shows how different combinations of (lack of) access, competence and motivation lead to target groups which need to be carefully distinguished when exploring barriers to uptake and devising strategies for inclusion.

In order to apply the notion of communication capabilities to usage of online public services, we need to understand what access, competence and motivation mean in the context of e-government applications.

- **Differences in Access:** Using public online services requires access to the Internet for private usage. When looking at Internet access at home, and additionally usage of public Internet access points or in educational institutions, libraries, Internet cafés, and so forth, available data quite clearly indicate that access is far from ubiquitous even in Europe. This applies, in particular, when considering that many advanced online services require a broadband access to function efficiently.

According to data from Eurostat (2005), the share of households with access to the Internet varies between 16% in Lithuania and 78% in the Netherlands. The national figures for broadband access range from 1% (Greece) to 54% (Netherlands).

Differences in access can also be the result of special requirements of users (Roe, 1995). This is because the ability to use online applications through the usual end devices (mainly personal computer) can be limited by functional restrictions. The best available estimate on how widespread these are in the EU comes from the SeniorWatch study (2002). It found that 17% of the EU population in the age group 50-59 have severe functional restrictions (with regard to either seeing, hearing or dexterity), and an additional 41% have "some" restrictions of these kinds. Persons with functional restrictions may need special equipment to be able to access mainstream Internet-based services, such as enlarged keyboards and monitors, or voice input/output. Members of ethnic minorities are often facing language barriers, if they do not feel confident enough to understand the language in which public Web sites are penned. This is where access is interrelated with the second condition for communication capability, namely competence.

- **Differences in Competence:** To properly use online public services, citizens still need to have considerable computer and Internet skills. Endowment with these skills is highly correlated with usage experience, which means that skills are obtained mainly by doing rather than by upfront methods of learning (Lassnig, Markus, & Strasser, 2004a). The share of citizens who are able to use online services can therefore be estimated by consulting national usage statistics. More direct indicators on digital literacy are available, for example, from SIBIS (2003). Available data show a strong positive correlation with household income, social grade and educational attainment, and a strong negative correlation with age.

  In addition to computer skills and ability, the notion of competence related to the use of online public services also includes competence in handling public services, irrespective of the channel through which they are received. A factor in this is literacy in the wider sense of the term, meaning the ability to grasp and process informational content. Data on literacy has been systematically collected by the OECD through the International Adult Literacy Survey (OECD, 1997). The analysis showed that "low literacy is a much larger problem than previously assumed in every [OECD] country surveyed: from one-quarter to over one-half of the adult population fail to reach the threshold level of performance considered as a suitable minimum skill level for coping with the demands of modern life and work" (OECD, 1997, p. 5). This means that low literacy levels is likely to also act as a severe barrier to take-up of online public services, as long as these require more advanced literacy skills than traditional methods of (face-to-face) provision.
- **Differences in Motivation:** Lack of motivation can here be understood in two ways: First, as lack of willingness to interact with providers of public services in general: This means a passive attitude towards public services as opposed to a more customer-like behaviour. It can be rooted in general attitudes towards society. It can, of course, also result from a low perceived utility/relevance of the service on offer. And second, as lack of willingness to use the *online* channel for the purpose of interacting with providers. As Viherä and Nurmela (2001, p. 13) point out, it is often the telephone rather than the Internet which is citizen's preferred tool for societal communication. They conclude from this that "when services and commerce are being launched to an ever-increasing degree in the network, special care must be taken to guarantee the availability of services also by telephone". Findings from SIBIS (2003) showed that even among regular Internet users, the majority would prefer to use traditional channels such as the telephone, postal mail, or face-to-face exchange rather than the Internet to obtain services from government. Underlying reasons also tend to include security concerns, which often make would-be users shy away from interacting electronically with government.

## USER ORIENTATION OF ONLINE PUBLIC SERVICES

Research has identified a number of reasons why citizens use, or do not use, specific services in general and online services in particular. Usability (see below) is only one aspect of this. Optimising usability alone, although certainly a top priority, will not necessarily mean that take-up rates of online public services will improve significantly.

The literature on user satisfaction lists a large number of quality determinants with regard to services. Most of these are derived from asking users, using focus groups or more structured methods. Johnston (1995) compiled 18 factors which had been identified in empirical research: access, aesthetics, attentiveness/helpfulness, availability, care, cleanliness/tidiness, comfort, commitment, communication, competence, flexibility, friendliness, functionality, integrity, reliability, responsiveness, and security. Parasuraman and Berry, who developed the

influential SERVQUAL methodology of measuring customer perceptions of service quality (Parasuraman, Zeithaml, & Berry, 1988), presented a set of five quality dimensions which has found wide application. These are: tangible factors, reliability, responsiveness, assurance, and empathy.

When assessing user satisfaction one needs to be aware of the fact that satisfaction is heavily influenced by expectations (MORI, 2002). Indeed, research on service quality started out in the early 1980s by suggesting that perceptions of service quality stem from a comparison of what customers feel a provider should offer (expectations) with the way the service is actually performed (Grönroos, 1982; Lewis & Boom, 1983).

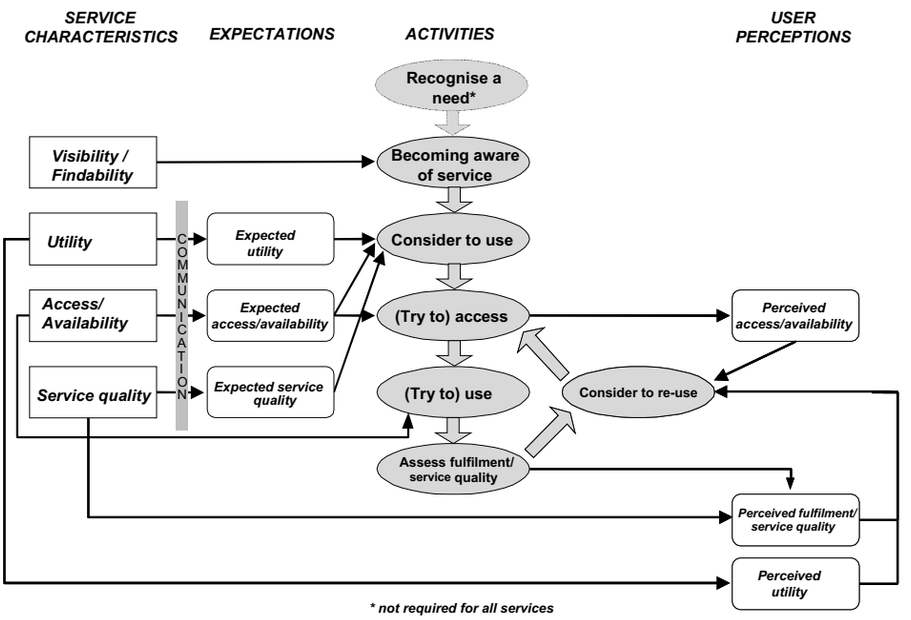
The understanding of determinants of perceived service quality has been developed for service delivery through traditional channels, mostly "people-delivered services" (Zeithaml, Parasuraman, & Maslhotra, 2001). Findings from this research need to be adapted before being applied to online services. For services that are transmitted via technological systems such as the Internet, we need to distinguish between two main components in user requirements: the service (content) component and the technology component. The latter is relevant because citizens need to be able and willing to access and apply online computer technology for using online services.

User acceptance of technology has been researched against a number of theoretical perspectives. Arguably the most important are the innovation diffusion theory (Rogers, 2003), which tries to identify the perceived characteristics which influence the adoption of a technological system by users; and the Theory of Reasoned Action (Fishbein & Ajzen, 1975), which explores how user beliefs and attitudes are related to individual behavioural intentions with regard to a technological system. Based on the theory of reasoned action, the technology acceptance model (Davis, 1989) is one of the most established models to explain the adoption of technology at the level of the individual. Davis (1989) distinguishes between perceived usefulness ("the degree to which a person believes that using a particular system would enhance his or her [...] performance", i.e., utility) and perceived ease of use ("the degree to which a person believes that using a particular system would be free of effort"). The model has been confirmed in general by a large number of replication studies (Zeithaml et al., 2001, p. 15), which explains its big popularity among researchers.

On the basis of this theoretical and empirical research, the following elements of user orientation for online public services can be distinguished:

- **Visibility/Findability:** Means the degree to which the service is known to potential users, that means awareness about the service in the target population. Visibility can be influenced/managed by providers through publicity strategies. Services are, however, also to a certain extent visible even if no promotion has taken place. Awareness might result from unintentionally coming across a service, that is, while surfing on the Internet. This relates to the definition of findability used in the context of Website promotion strategies, which can be structured to a variable degree.
- **Utility (Usefulness):** Refers to the utility of the service from the viewpoint of the individual (actual or potential) end user. Utility might be derived from the *relevance* of the service to meet particular needs of the user (i.e., in the case of many health services) and the *suitability* for personal circumstances. It also comprises the variety of tangible aspects, such as time savings, cost savings and so on resulting from the service itself (rather than the way it is delivered—see service quality below). Finally, it can also incorporate less tangible aspects, such as personal intrinsic gratification that can be derived from the fun of, for example, participating in an attractive learning experience/training course. Other social aspects such as prestige and social desirability may also play a role.
- **Access/Availability:** This is the degree to which the distribution channels and technologies employed allow all types of potential users access to the service in question. Accessibility is a function of (a) *Findability,* in the narrow sense, the ease with which the service can be located intentionally; (b) *Affordability*, the degree to which the public can afford the cost to access and use the services in question; (c) *Time independence*, the extent to which the service is accessible at any time when demand occurs; (d) *Location independence*, the extent to which the service is accessible from any fixed or mobile location; (e) *Platform independence*, the extent to which the service is accessible through various alternative systems (hardware and software); (f) *Accessibility*, suitability for persons with disabilities; (g) *Availability* of services in a way that is easily accessible for persons which belong to social minorities such as immigrants.
- **Service Quality:** Encompasses the ability of the service to fulfil the expectations of the user (i.e., lead to satisfaction with the service) with regard to a large number of attributes, as first conceptualised by the SERVQUAL school of researchers (Zeithaml et al., 2001). Adaptation for the subject of online public services, the following factors are the main determinants of service quality:
  a. **Content Quality:** That is, conformance to legislation and professional quality (correctness/

*Figure 2. eUSER conceptualisation of user orientation (eUser, 2005)*



validity, comprehensiveness, reliability, accuracy). Note that content quality is something that usually cannot be fully assessed directly by users, since they lack the professional knowledge for this. From user's viewpoint there is, therefore, a demand for signifiers that give them trust in the quality of the content.

b. **Flexibility:** Involves choice of ways in which the service is used and delivered, and choice of content (the width and broadness of the service offer).

c. **Usability (Ease of Use):** Means the capability of all supported paths towards task accomplishment, to "maximally fit" individual users' needs and requirements in the particular context and situation of use (Shackel, 1984). This includes elements of efficiency (Is the process is simple to use, structured properly, and requiring only an appropriate minimum of information to be input by the user?), learnability and memorability. Web-site-based services with a high usability contain functions that help the user find what they look for without difficulty, and allow them to manoeuvre easily and quickly back and forth between pages and functions. This requires the ability of the system to take advantage of users' skills and thereby to function well in a broad range of real world situations. Error handling, that is responsiveness in the case of technical problems (ability to get fast assistance if there is a problem or question) and system reliability (correct technical functioning of the technical equipment and related support services) are also important.

d. **Assurance/Trust:** Refers to the degree to which the service in question (and the ways it is provided) infuses trust and confidence. It is due to the reputation of the site and the services it offers as well as clear and truthful information presented. There is a close relation to what above has been defined as the professional quality of services: since end users cannot always assess quality directly, they want assurance that the content is of a certain quality. Another aspect of trust concerns protection from security threats and privacy offences.

e. **Customisation/Personalisation:** How much and how easily the service can be tailored/ adapted to individual users' preferences and needs.

## CONCLUSION

The model in Figure 2 puts the main elements of user orientation, as discussed above, in relation to the process

of uptake of a given service by a potential user. The model can be used to devise strategies for increasing service take-up, targeted at specific target groups. It distinguishes between "real" service characteristics, expectations regarding service characteristics (which are the result of the communication of "real" service characteristics through marketing, social networks, etc.), the activities of (potential) users of public services, and the perceptions which result from these activities.

Note that the figure does not differentiate between delivery/transaction channels (online vs. offline). It also tends to suggest that there is a logical progression from recognising a need via trying to access a service to using the service. Of course, at each of the steps during the process individuals might decide not to (try to) use the service if they feel that expected returns do not compare well with efforts/costs.

This article has briefly presented arguments for a strategy towards public online service provision which is guided by the needs, capabilities and preferences of potential users. It has argued that the traditional focus in e-government development on supply-side measures has been misguided. We cannot any longer assume that a high-quality online service will automatically lead to take-up by all or even the majority of the target population. The reasons for citizens not to use online public services are various and often complex. Without a better grip on the diversity of user groups and their specific attitudes and capabilities with regard to using the Internet and public services in general, e-government projects will fail to reach their targets. More and better information on user characteristics, needs, preferences, perceptions and attitudes is needed before a front-office e-government project can hope to be truly oriented to citizens.

## KEY TERMS

**Access/Availability:** The degree to which the distribution channels and technologies employed for delivering an online public service give all types of potential users adequate access to the service in question.

**E-Government Service Quality:** The ability of an online public service to meet the service-specific demands of the user, that means lead to user satisfaction with the service. Relevant aspects of quality in this context include content quality, flexibility offered, ease of use (usability), assurance and trust, and customisation/personalisation.

**Findability:** The ease with which the target group of an online public service can locate the service after an interest or need has arisen. From a user orientation perspective, findability needs to be optimised also for persons who have only very loose knowledge about how the service they seek might be called or described, and by whom it might be offered.

**User Orientation:** The extent to which an online public service is offered (that means designed, marketed, provided, evaluated) in a way that fully addresses the needs/requirements and preferences of each member of the target population. This implies that the whole diversity of user characteristics and requirements is taken into account.

**Utility:** From the viewpoint of the individual end user, an online public service provides utility through its relevance for meeting particular needs of the user in a way which is tailored to the personal circumstances of the user. Utility here derives from, for example, the service outcomes themselves, time and cost savings, personal intrinsic gratification, social prestige and so forth.

**Visibility:** The degree to which on online public service is known to potential users, that means awareness among the target population about the service. Visibility can be influenced/managed by providers through publicity strategies.

# Using Digital Hotlines in an Anti-Corruption Campaign

**Paula F. Saddler**
*Certified Fraud Examiner, Association of Certified Fraud Examiners, USA*

## INTRODUCTION

Throughout the world, people are just as concerned about corruption as they are about unemployment, poverty, and physical security. Governments can support citizens in their fight against corruption by using digital hotlines to investigate wrongdoing and to strengthen fraud-prevention efforts. Best practices in managing digital hotlines can be packaged into a module that is rolled out to all units of government from the national to the local level.

## BACKGROUND

Every year, Transparency International (TI) prepares a barometer of global corruption, and in 2004, TI interviewed 50,000 people in 60 countries. TI reported that for 2004 and 2003, the public perceived political parties as the sector most affected by corruption, followed by parliament/legislature, the police, and the legal system/judiciary. Similarly, when asked to rate the impact of corruption on different spheres of life, people ranked 70% for politics, 60% for business, and 40% for family and personal life.

Petty administrative corruption also was mentioned by 78% of respondents as a concern. Worldwide, one in 10 persons interviewed said someone in their household had paid a bribe in the previous 12 months.

Corruption, especially in the public sector, is a worldwide epidemic that is growing rather than shrinking. TI reported that for 2004, 43% of respondents expected the level of corruption to increase in the next three years (Transparency International, 2005). With corruption on the rise, governments will need powerful and effective tools to combat fraud and abuse.

## ESTABLISHING HOTLINES

One such powerful tool is a digital fraud hotline, which should be integrated into an anti-corruption campaign. Even though some countries have passed whistle blower protection laws, their application is riddled with problems, and the whistle blower often ends up frustrated, disappointed, and unemployed (Calland & Dehn, 2004). Furthermore, the original problem that was identified by the informant often is not corrected, which discourages public servants from blowing the whistle (Devine, 2004). A conventional hotline using telephone and mail allows citizens to remain anonymous when filing a complaint, thus reducing the fear of retaliation, which may motivate them to actively fight corruption (USGAO, 1988). A digital hotline multiplies the opportunity for safe reporting to a vastly larger audience.

### How Hotlines Function

A hotline is a system that facilitates the reporting of wrongdoing or violations of the code of conduct directly to the sponsoring organization (SO). If the SO initiates an investigation, it may result in administrative sanctions according to the rules of the SO or in legal complaints filed with the national judicial system. Technology for hotlines has advanced from telephones or physical snail mail to Internet technology that now supports sophisticated features such as the following:

- Receiving and storing a large number of complaints from informants.
- Allowing informants to remain anonymous, if they so chose.
- Rapid notices to officials of an SO when a complaint is received.
- Supporting a real-time online dialogue between an informant and officials of the SO who are in different time zones.
- Classifying complaints by a variety of categories and characteristics.
- Ability to quickly adjust the classification scheme of complaints as needed.
- Ability for informant to log in (anonymously) and to track progress on his or her case.
- Maintaining a log of how a case is investigated.
- Recording the outcome of a case, such as actions taken against an employee and whether assets were recovered.
- Quickly customizing reports for detail and summary statistics.

- Preparing and distributing reports automatically on a schedule.

The sophistication of digital hotlines has been fueled by the fact that managing hotlines has become a growth business in the last 15 years. The number of vendors that provide digital hotline services has been growing because fraud and corruption are alive and thriving.

## The Global Fight Against Corruption

Many public interest organizations are fighting corruption in both the public and private spheres. Notable international efforts include the drafting of a Convention Against Corruption that is sponsored by the United Nations Office of Drug Control (UNODC). This convention was ratified by 37 national governments, and it entered into force on December 14, 2005 (UNODC, n.d.(d)).

## How Can the Digital HotLine Support Anti-Corruption Efforts?

The UN Convention Against Corruption recommends best practices for governments to foster honesty and integrity of citizens as they fulfill their obligations, whether in the public or private arena. With 71 articles organized into eight chapters, there are four main pillars of the anti-corruption model that are listed as follows (UNODC, n.d.(a)):

1. National anti-corruption policies and mechanisms
2. Strengthening judicial integrity and capacity
3. Promoting integrity in the public and private sectors
4. Denying the proceeds of corruption and recovering illicit assets

## Creating a Hotline is a Best Practice

Article 8 of the convention recommends developing a code of conduct for public officials as well as a system to facilitate the reporting of acts of corruption to appropriate authorities

*UNODC notes that critical components in enforcing a standard of conduct include ethics training, credible public complaint systems, public awareness about their rights, and appropriate disciplinary measures.* (UNODC, n.d.a, p. 6)

## Who Owns the Hotline?

Developing national policies, strategies, and action plans is critical to effectively fighting corruption. Article 5, Paragraph 1 of the convention stipulates that states shall develop and implement coordinated anti-corruption policies that are based on laws and good management principles such as integrity, transparency, and accountability and that encourage the participation of society (UNODC, n.d.(a)).

This can be accomplished by creating a special anti-corruption body, which Article 6 recommends establishing, to oversee and implement the policies outlined in Article 5 as well as to increase and disseminate knowledge about preventing corruption (UNODC, n.d.(a)).

Therefore, Article 6 supports establishing a governing body over the hotline to oversee management, which mirrors the same concept that there should be high-level governance over information technology resources (IT Governance Institute, n.d.). A key responsibility of this governing body over the hotline would be to review all complaints filed to ensure that there is follow-up on all serious cases that are reported and that this oversight would extend to protect the whistleblower, as well (USGAO, 1989). Hopefully, this governing body also would oversee the overall anti-corruption efforts of the government entity, and a hotline would be only one responsibility.

Article 6 also recommends that this governance body be independent and free from any undue influence. It should have the power to advocate for and/or resolve conflicts in laws and regulations so that there is a consistent policy that protects whistle blowers in all cases. Oversight is needed to ensure that public agencies do not bury complaints and punish the whistle blower for political reasons. One troubling trend is that national laws can negate whistle blower rights in favor of protecting national security, which denies the public's right to know about wrongdoing in this sector (Devine, 2004).

Members of this hotline governing body should not come exclusively from public service but also should include members of NGOs and community-based organizations that can bring independence to the exercise of oversight. Governments should reach out to find suitable NGOs to serve on such a body. Once again, Article 13 of the Convention confirms the importance of involving NGOs in efforts to prevent and fight against corruption and to raise public awareness about the threats that corruption poses (UNODC, n.d.(a)).

## Content of the Web Site for the Hotline

A digital hotline can harness data processing power to provide a vast amount of information to anyone. Since a hotline sits on a Web server, the site where the informant first accesses the hotline, called the landing page, can be linked to many other Web sites that are devoted to fraud prevention and education.

A recommended best practice is that a landing page for a hotline should include the following:

- Purpose of the hotline and how it relates to the anti-corruption efforts of the sponsoring organization (SO).
- Instructions on how to file complaints.
- Reports on complaints received and their status (to the extent that it can be released to the public) without jeopardizing the investigation.
- Educational materials. There should be links to other Web sites that have information on ethics. Citizen responsibility to report frauds and links to individual hotlines of the inspector generals of the various government departments.
- Links to NGOs and civil-based societies that support and counsel whistle blowers.
- Results of cases that were investigated and links to information services that track court cases.

A model Web site for anti-corruption that has these features is the Hong Kong Independent Commission Against Corruption (ICAC) (n.d.), which incorporates hotline features with fraud prevention advocacy. The ICAC has had spectacular success over the last 30 years in becoming a model for clean government (UNODC, n.d.(c)).

## Web Site Content Promoting Transparency in Government

Strengthening the integrity and capacity of judges and prosecutors is another important goal of the UN Convention that is discussed in Article 11 (UNODC, n.d.(a)). A landing page should be linked to information about the fate of prosecutions adjudicated in courts of law and internal administrative actions taken by government. Publishing the outcomes of these cases tells everyone how well investigators, prosecutors, and judges perform their jobs.

Publishing the results of cases also reinforces the credibility of the hotline and the underlying fraud prevention effort. If a person is wavering about whether to report wrongdoing, throwing light on the entire process can reassure him or her that a personal sacrifice will make a difference.

## Support for Whistle Blowers

Before an informant reports a wrongdoing, he or she should understand that such an act may adversely impact his or her personal and professional life. Support resources for informants should be included on the landing page. Some NGO advisors help to evaluate the appropriateness of the acts that whistle blowers plan to expose and whether there is a more suitable remedy for something that actually may be an administrative grievance. In planning the Web site, government units should explore whether there are local NGOs that can provide this support.

Whistle blowers should have a voice on the landing page. But when is it appropriate for the whistle blower to report about what happens as a result of filing a complaint? Citizens are naturally curious about what happens to a complaint, and reports of outcomes lend more credibility to the hotline. Thorny issues, however, revolve around how the status of the whistle blower gets reported (if they chose to identify themselves), who should report it and when, and how to verify information reported by the whistle blower.

Informants should be warned that even if they wish to conceal their identities, it may be discovered during an investigation. Dire things may happen to informants and whistle blowers who are identified—they may lose their jobs; they may suffer severe economic consequences; or, if they remain employed, they may be reassigned to meaningless tasks. They also may become burdened with expensive legal bills. In one developed country, public servants have had their security clearances revoked, which means that they not only lose their jobs but also become blacklisted from any work that requires a security clearance (Devine, 2004).

In a developing country, where one or two companies dominate a sector of the economy, being stigmatized as a whistle blower can mean never working in that particular sector again. Subsequent employment obtained in a different sector may require that the person start over on a junior level in a new profession, which results in long-term loss of income (Dimba, Stober, & Thomson, 2004).

## Required Infrastructure for Telecommunications Within the Country

Digital hotlines require an effective telecommunications infrastructure in the country. One organization that brings information and communications technology to the poor is the United Nations Development Programme (UNDP). It has an extensive Web site of information and projects in this area, and governments should explore possible services that UNDP may be able to offer in the country.

## Requirements for a Successful Digital Hotline

Adequate financial and IT resources alone will not guarantee success, especially if there is a high volume of

complaints at startup. There has to be adequate capacity in order for both investigators and the internal justice system to handle an increased workload. Investigators, prosecutors, and judges or administrative tribunals have to complete cases promptly after they are initiated through the hotline. Long delays with inadequate and incomplete reports will quickly destroy the credibility of the hotline and the related anti-corruption effort (PcaW, n.d.).

## FUTURE TRENDS

Any public entity that is establishing a digital hotline should consider the following topics:

- Is the national infrastructure for telecommunications adequate to support widespread access to the digital hotline?
- What are the objectives for the hotline, based on national, state, or local needs?
- Who owns the hotline; who is the governing body, and what is its power?
- Who manages it on a day-to-day basis?
- Structure of the hotline—What are the client agencies and how can their hotlines be coordinated?
- Telephone operators—How important is it to have telephone operators who talk with informants, and when and how should those operators be used?
- Who are the users—Are reporters restricted only to citizens, to employees, to vendors, or to any person living in the country?
- Marketing the hotline—What kind of advertising campaign will encourage citizens to use the hotline?
- Support to whistle blowers—What support and advice should be given to informants in order to warn them about the risks of filing a complaint?
- Funding—What is the budget, and how will costs be apportioned among public entities that share a hotline?
- Reports from the hotline:
- What are the annual operating reports, and who will receive them?
- When can a complaint and its investigation be disclosed to the public?
- What reports should be disclosed to the public and when?
- Feedback to the informant—When and how should the SO give feedback?
- Evaluating Effectiveness—What are the indicators of success for the hotline by quality and quantity?

## CONCLUSION

A digital hotline is a vehicle for citizens to report fraud and abuse in the public sector and, with its related Web-based technology, serves as a platform to support a culture of zero tolerance toward corruption. A digital hotline can bolster the faith and confidence of the public that its government is committed to running clean operations without corruption. If citizens believe that they can make a difference and that they will be protected from acts of retaliation, they will blow the digital whistle that they are given, and they will blow it loudly.

## KEY TERMS

**Complaint:** A statement by a person that there has been wrongdoing by one or more employees of an organization. It has to be investigated to determine if the information is true.

**Confidential Informant (CI):** Person who reports information about wrongdoing. This person does not want his or her identity revealed to the public.

**Corruption:** The misuse of entrusted power for private gain. (Downloaded from the TI Web site on December 4, 2005, from http://www.transparency.org/faqs/faq-corruption.html.)

**Hotline:** A system that facilitates the discovery of wrongdoing. It facilitates communications between an informant or a whistle blower and the sponsoring organization (SO), which investigates and prevents wrongdoing.

**Informant:** A person who discloses information about wrongdoing. This person may remain anonymous or can reveal his or her identity only to a select person within an entity, in which case this person becomes a confidential informant.

**Information Technology Governance Institute (ITGI):** Assists managers in fulfilling their responsibility to ensure that information technology is aligned with the business and delivers value efficiently and effectively (http://www.itgi.org).

**Non-Governmental Organization (NGO):** Serves the public interest. Its finances and management are independent of government.

**Public Interest Disclosure Act (PIDA):** A Part of employment law in the United Kingdom that defines what is a protected disclosure for wrongdoing. The law applies to all workers in the UK, whether they are employed in public, private, or voluntary sectors.

**Sponsoring Organization (SO):** Any entity involved in activities that has employees and volunteers and that hosts a hotline designed to receive complaints of abuse and corruption.

**Support Groups for Whistle Blowers and Confidential Informants:** Offer counseling and legal assistance to whistle blowers.

**Transparency International (TI):** An NGO that brings civil society, business, and governments together in a powerful global coalition in order to combat corruption (http://www.transparency.org/).

**United Nations Development Programme (UNDP):** The United Nations global development network. UNDP helps countries to attract and use development aid effectively (http://www.undp.org). UNDP is active in information and communication technologies for development and has a wealth of information from a network of 166 countries in which it works (http://sdnhq.undp.org/it4dev). UNDP also supports e-governance and citizen participation in government through access to information (http://www.undp.org/governance/sl-egov.htm)

**United Nations Office on Drug and Crime Control (UNODC):** A United Nations organization that supports the Global Programme against Corruption, Vienna International Centre, P.O. Box 500, Room E1272, A-1400 Vienna, Austria. Tel: +43(1) 26060-4406; Fax: +43(1) 26060-5898.

**United States General Accounting Office (GAO):** Supports the Congress of the United States to improve the performance and to ensure the accountability of the federal government for the benefit of the American people (www.gao.gov).

**Whistle Blower:** An employee who discloses an abuse of power that betrays the public trust.

**Whistle Blowing:** The act of an employee who voices concerns about wrongdoing in the workplace or through an independent entity associated with it. Whistle blowers do not conceal their identities and often communicate their concerns to supervisors, managers, executives, regulators, or the public (Calland & Dehn, 2004).

**Wrongdoing:** Any action by an employee that does not comply with the code of conduct, applicable laws, rules, regulations, or operational guidelines of the employing organization or that violates the laws of the country. Besides illegal acts, wrongdoing includes waste, mismanagement, abuse of authority, or posing a substantial and specific danger to public health and safety (Devine, 2004).

# Virtual Innovation Environment

**Nicos Komninos**
*Aristotle University, Greece*

## INTRODUCTION

Major new trends of our era emerge from the spread of information society and the increasing role of innovation as source of competitive advantage, development, and wealth. Innovation, however, is a tricky issue. We do not dispose adequate theories for predicting innovation in different sectors of industry and services, though we have plenty of tools and methods which assist and facilitate innovation in product development, process reorganization, and quality improvement. We tend to compensate the lack of theory about radical innovation (none can tell what the next big thing will be in an industry sector) with environments of innovation enabling the use of tools, instruments, and methods: financial tools, institutional tools, communication and information tools, creativity tools, and others.

The rise of the information society opened new possibilities in the creation of environments of innovation. Digital tools and virtual (digital) innovation environments may assist organizations in learning and practicing innovation. They offer new forms of government (digital this time), online or offline, for mastering the complex processes of technological development and innovation. These virtual environments are important for companies, research institutions, technology intermediary organizations, and the public administration involved in innovation and research and development (R&D) management as well.

## BACKGROUND: ENVIRONMENTS OF INNOVATION

Newer theories of innovation attribute an important role to the external environment of innovation embedded in networks and systems, communities, clusters, and regions, affecting the processes of innovation. Interactions within communities and regional or national innovation systems, combinations of roles and skills, communication channels, functional and spatial bonds bridging separate knowledge fields, are ingredients of participatory processes that result in new products and technologies (Cooke & Morgan, 1997).

Brokering theories assert that innovation derives from the synthesis of various fields of research and technology. Hargadon (2003) argues that innovation is a collaborative process in which knowledge and insights from different fields of science and technology are combined and create something new. A critical factor in achieving a new combination of unrelated knowledge is the human community in which different skills and competences are pooled together.

Nonaka and Tackeuchi (1995) describe innovation as tacit knowledge being transformed into explicit knowledge. They place great emphasis on this transformation of knowledge and explain the enormous organizational effort which is needed for this conversion of atypical and personalized knowledge into explicit, modeled know-how, and engineering. Dealing with innovation and tacit knowledge, Morgan (2001) goes one step further arguing that tacit knowledge is embedded in individuals and organizational routines which have location-specific dimensions and tend to cluster. Tacit knowledge is spatially "sticky" and despite the growth of knowledge management tools, is not easily communicated other than through personal interaction. Clustering becomes inevitable in innovative practices, not from the viewpoint of minimizing transaction costs, but in order to materialize the innovative behavior.

Evolutionary theories also assert that innovation springs from externalities, knowledge asymmetries, market imperfections, and institutions that select and manage the flow of knowledge. Learning, both as acquisition and use of existing knowledge and creation of new knowledge, is the key process. A different cognitive space is created in each organization composed of nodes and networks. The external environment has a decisive role also. Nelson and Winters (1982) explain that genetic processes to innovation are regulated by a "selection environment" which switches on-off the flow between ideas and products. Nations and regions through systems of innovation provide this selection and regulatory environment, bridging knowledge, competences, and resources from different actors, and screening of ideas and technologies through competent or funding organizations (Nelson, 1993).

A common understanding has been achieved, which attributes a major role to the environment of innovation,

pointing out at an "open innovation" paradigm (Chesbrough, 2003) in which valuable ideas, knowledge, and skills come from outside the organization. Innovation is an "environmental condition" (Komninos, 2002); it is less an individual achievement than the joint effort of communities of people working together, interacting, and sharing common goals and visions.

## THE FUTURE: VIRTUAL ENVIRONMENT OF INNOVATION

Human ingenuity recently added a new dimension to the physical and institutional environments of innovation: a digital or virtual dimension. The rise of the information society and the Internet brought into existence various fora for digital gathering, communication, and interaction, which strengthen the contribution of agglomerations and communities to innovation processes (Table 1). Henceforth innovative environments are constituted by more complex combinations among physical, institutional, and digital spaces.

A series of IT applications, systems, and digital tools are used to create virtual environments. Most are based on conventional information technologies and Internet based communication platforms. The core of solutions is on knowledge management and guidance of the innovation process rather than sophisticated telecommunications; services and knowledge management tools predominate over bandwidth. Some major categories are the following.

- **Business and Regional Intelligence:** For every organization attempting to develop a new product, it is important to know how potential customers evaluate this product, what the expected customer behaviour trends are, what similar products already exist, what their features are, which companies produce them, at which prices, for which markets, and what opportunities spring from emerging technologies. Gathering, organizing and utilizing this information can be made both easier and can be supported by using cutting-edge IT tools and employing information available on the Internet (Pawar & Sharda, 1997). Applications developed for business and regional intelligence purposes seek to facilitate information management. Their architecture combines targeted information collection, processing tools, and information dissemination to the end user (Back, 2002)
- **Virtual Communities and Clusters:** Virtual communities play a role in innovation similar to physical communities in terms of communication, socialization, and learning (Henri & Pudelko, 2003). The usual way for a virtual community to be created is with respect to a network of people sharing the same ideas or objectives. Two situations are possible. A physical-virtual situation in which the virtual extends the cooperation bonds of a physical commu-

*Table 1. Components of virtual innovation environment*

| Objective | Type of function | Type of online tool |
|---|---|---|
| Information | Learn about | Web pages; e-learning; online libraries; online databases; portals; online newsletters; blogs; digital cities |
| | Search/find | Search engines; semantic Web tools |
| | Consulting | Online technology transfer; online R&D; virtual brokering; market and technology watch; observatories |
| Communication | Communication | Electronic mail; telepresence; alerts |
| | Discussion | Discussion forum; e-communities |
| | Make a demand; give an order | Electronic exchange; e-auctions; e-commerce; virtual clusters |
| Problem-solving | Knowledge processing | Online creativity tools; online mind tools |
| | Guide a process | Digital roadmaps; online innovation management tools |
| | Turn knowledge into product | Product innovation and design tools; virtual engineering; online survey tools; virtual customer applications |

nity. In this case, most practices of the community remain in the physical space, while part of the communication and learning is transferred to the digital space. Second, a virtual-virtual situation is one in which the virtual community exists independently from the geographical gathering of people, though the members of the virtual community may meet occasionally, communicate and cooperate in physical space. In this virtual-virtual situation, the social bond is weaker, as are the emergence of intention, and the creation of identity. Virtual communities also take the form of virtual clusters. In a virtual cluster, each enterprise adds value by exchanging knowledge with other members. Internet technologies allow for increased real-time interaction, e-learning, and technology transfer, which in turn are translated into improved products and services and a reduction in transaction costs, as well (Passiante & Secundo, 2002)

- **Online Innovation Tools:** This is probably the most important component in the virtual innovation environment and includes tools and applications for solving typical knowledge management and innovation development problems. These tools can be broken down into sub-groups depending on the internal problem-solving mechanism:
  1. Roadmap tools which lead the user to problem resolution step-by-step, for instance through the stages of new product development or a spin-off company creation
  2. Dedicated tools which may assist in specific problems (i.e., drafting a business plan, benchmarking the performance of an organization, undertaking a technology audit, which rely on an input-output structure, data input and automatic result generation)
  3. Learning tools which present a problem and an overview of the methods that could be used to solve it, best practice from the past, bibliographical references and documentation
- **Web-Based Promotion Platforms:** These applications support awareness-raising on products and services, marketing, advertising, and e-commerce. They are based on a combination of Web applications, databases, and multimedia. Major categories of promotion platforms are: (1) corporate Web sites, which promote a business or organization's products or services, (2) "department stores" which group services and products from numerous suppliers together, (3) government Web sites informing citizens about the services provided by the public administration, and (4) digital cities which promote a territorial entity together with its products and services. Digital cities offer an exceptionally important promotion platform, yet underutilized. Their architecture includes numerous layers: 2-D and 3-D images of the physical space of cities and regions, infrastructure and services, products organized into databases, navigation applications, online service markets, as well as user communication interfaces where information, images and applications are synthesized (Ishida, 2000).

## CONCLUSION

The central question about the virtual innovation environment relates to how it functions. The question is what does this environment have to offer to innovation processes? What innovation functions are made easier or accelerated in the digital space?

The key to these questions lies in understanding innovation as a collective knowledge process. Knowledge is at the very epicenter of innovation. This gives the digital space a tremendous power since its exclusive ability is to manage information and knowledge. Innovation processes taking place in digital spaces complement the creative processes that occur in physical and institutional spaces. Digital spaces are primarily instrumental spaces. They facilitate the extension of networks and learning, allowing organizations to be engaged in R&D and deploy their technology capabilities, while the use of digital tools and services is improving problem-solving capabilities and know-how in individuals and institutions.

The most direct impact of the digital environment on knowledge-innovation systems relates to learning processes that are transformed and bolstered by e-learning applications. E-learning may develop on different ontological levels, at individual, team, organization, inter-organization level, and from different perspectives as well, the cognitive perspective aiming to change the structures of the learning system, the cultural perspective dealing with human behavior, and the action perspective rooted in experimental learning (Passiante & Secundo, 2002). The true power of e-learning in the field of innovation is that it enables non-conventional knowledge processes to occur either between producers and customers or between producers, suppliers, and subcontractors.

A second field of impact relates to knowledge brokering networks. Within every innovation system there is a continuous exchange and transfer of knowledge going on. By far the greater part of this network activity relates to knowledge transfer and exchange. Knowledge is the most important connective substance in knowledge brokering networks, an intangible asset

which is "traded" through partnerships and collaboration. Via multi-level virtual networks the digital environment offers new options for exchanging knowledge and communicating in real time. Virtual networking applications, such as virtual customer, virtual cluster, virtual technology exchange, virtual order placing, virtual follow-up of processes, and so forth. have greatly amplified the ability of firms to exchange knowledge, cooperate and innovate. The Internet enables the creation of multiple virtual environments and platforms for collaboration allowing firms to tap into customer and supplier knowledge through virtual knowledge brokering (Verona, Prandelli, & Sawhney, 2003).

A third field which is dramatically affected by virtual spaces relates to human resource skills. The development of digital tools and online problem solving applications is an amazing achievement. Online tools allow even the most remote worker to significantly improve his/her skills and problem solving capabilities, and within a short period of time to acquire skills disproportionate to the time he or she invested in learning them. Online tools differ from e-learning applications since they are more targeted, but primarily because they help in solving a problem without requiring detailed understanding of it. As is the case with all tools, their use does not involve understanding of how they operate. Offline/online problem solving tools are available for all types of innovation, but primarily for market and technology watch, technology transfer, new product development, and optimization of supply chains.

## KEY TERMS

**Cluster:** Network of production of interdependent companies, knowledge-producing agents, and intermediary funding and consulting organizations.

**Digital Cities:** A platform of digital community networks and information spaces using the city metaphor to exchange information and communicate.

**E-Learning:** Delivery via the Web of individualized, dynamic, and digital learning content, aiding knowledge

transfer and recombination within communities of knowledge and innovation.

**Innovation:** The act of starting something for the first time; introducing something new; the creation of a new device or process resulting from study and experimentation. A typical division is between product, process, and organization innovations. *Product innovation* is linked to the improvement or renewal of products being phased out; *process innovations* relate to the use of more advanced production technologies; *organizational innovations* introduce more efficient cost arrangement by reorganizing the entire supply chain and producer-supplier relations.

**Systems of Innovation:** Technological innovation advances through the interaction of multiple actors, between component and system producers, universities and industries, technology transfer organizations and brokers, venture capital and government funding institutions, which form national or regional networks, communities, and systems.

**Virtual Clusters:** Systems of suppliers, distributors, service providers, and clients that use internetworking technologies as the principal way of cooperating and competing.

**Virtual Communities:** A network of people assembled around a topic of common interest, or goal communicating over the Internet.

# Virtual Policy Networks

**Kathleen McNutt**
*Simon Fraser University, Canada*

## INTRODUCTION

As information cascades across the Internet and human communication patterns are transposed into computer-mediated environments, governments around the globe race to garner the benefits of ICTs and Web-based communications (Bannister & Walsh, 2002; Chadwick & May, 2002; Falch & Henten, 2000; Heeks, 2002; Ma, Chung, & Thorsona, 2005). Increasingly sophisticated user-citizens can now access numerous electronic services, collect policy-relevant information, and communicate with governments through electronic channels (Dahlberg, 2001; Lenk, 2003). Contemporary e-government, while variable across states, has evolved significantly in the last decade, pursing increasing transparency and accountability through the implementation of various e-government measures (Jaeger & Thompson, 2003; Reddick, 2005). While theoretical contentions concerning the authenticity of e-democracy have yet to abate, collections of policy actors that seek entrance and participation in the public policy process have also emerged online (Chadwick & May, 2002; Della Porta & Mosca, 2005; Klein, 2002). This article considers these online policy communities.

## BACKGROUND

### The Networked Polity

As government's increasingly look to outside sources for information, effectiveness, and legitimacy, virtual policy networks provide an ideal avenue for engaging citizens in the participation and consultation processes associated with policy decision-making (Hajer & Wagenaar, 2003; Roch, Scholz, & McGraw, 2000). Virtual policy networks are online collectives that seek to influence the policy process through the use of information and communication technologies. These networks represent the contemporary coalescence of technological and social organization, and are inscribed with key insights into human behaviour. Applying network theory to virtual policy communities provides a powerful analytical lens to study online constellations of policy actors.

Employing network analysis to understand the organization of governance, public management and policy communities is a well-established approach in the policy sciences (Carlsson, 2000; Klijn & Koppenjan, 2000; Mattila, 2003; Montpetit, 2003). The network approach is a particularly attractive conceptual option for identifying the various interactions between state and society, and for explaining variations across sectors, policy domains and states. Network theory addresses the complexities associated with new modes of governance and policy-making, recognizing the importance of categorizing actors and institutions into certain groups of policy-relevant interactions. The increasing reliance on ICTs in politics and policy-making, supports and advances the growth of network participation (Mutch, 2002). As Donald Kettl (2002) observes "networks have provided a framework for understanding the growing connection between various organizations that find themselves working together to implement public policy" (p. 112). ICTs have become crucial policy tools expanding national forums through extended online participation opportunities, altering both the policy process and the core relationship between the citizenry and governing bodies Chadwick (2003).

A network approach also provides important insights into modern governance and the complexity of contemporary policy processes. Governments today must be extremely consciousness of network dynamics and how to best manage the multitude of interests vying for particular policy outcomes. As an applied approach network analysis offers an appreciation of the challenges faced by modern government, and the variable processes conditioning the political landscape including the impact of ICTs, global policy initiatives, the burgeoning number of policy actors, and the increasingly interdependent and decentralized relations in and among states.

The state's accommodation of these interests requires overlapping networks of governance that provide policy space in which business, civic networks, and governments co-exit and collaborate to resolve policy challenges (Lowndes & Skelcher, 1998). Throughout this process network, coordination has become critical and thus one of the primary challenges for public administration and contemporary policy actors is to devise strategies that operate effectively in globalized and decentralized policy spheres. Although traditional hierarchal state's with top-down governance tendency will inevitably continue to characterize Western nations, the demands of the

networked polity oblige states to effectively adapt to the "horizontal networks that have been layered on top of the traditional vertical system" (Kettl, 2000, p. 495).

## VIRTUAL POLICY NETWORKS

### Policy Communities Online

Policy network scholars advance two primary assumptions concerning social behaviour. The first assumption contends that actors' social systems typically include a myriad of other actors, and that the interactions among these actors will significantly effect the decisions of both the group and the individuals embedded within the group (Carlsson, 2000; Hamm, 1995; Kilduff & Tsai, 2003). The second core conjecture of network theory assumes that structure matters, and that particular actors within the network will enjoy "regularities" in their patterns of interaction (Howlett, 2002). Thus, policy network analysis recognizes "that policy is made in complex interaction processes between large numbers of actors, which takes place within networks of interdependent actors ... co-operation, however, is by no means simple or spontaneous, and it requires types of game management and network constitution" (Klijn & Koppenjan, 2000, p. 139).

Online communities have also garnered extensive attention from academic researchers seeking to understand online behaviour and distill the social aspects of this technology from the more utilitarian uses (Wellman, 2001). Current research shows that online clusters tend to gravitate towards topical interest activities premised on identity, politics, social knowledge, entertainment, gaming, commerce and crime (Della Porta & Mosca, 2005; Döring, 2002; Matzat, 2002). While Internet-mediated identity and personas are malleable online, Web-based communication patterns are closely tethered to traditional social organization (Watts, 2003). Current empirical findings have already borne out the existence of online network communities that attract membership on the basis of political interest articulation and democratic engagement (Jeffery & Mayman, 2001; Mansell & Steinmueller, 2000), which is combined with significant increases in both the number of individuals using the Internet as a resource for political information, and the entry of new users engaged in online political activity (Bakardjieva, 2003; Mowbray, 2001). Combining the recently determined global properties of the Web with policy network theory allows for the discovery of virtual policy networks (Gibson, Kleinberg, & Raghavan, 1998).

### Human Shadows in the Web

The Web is a massive network with a typological structure determined by the arrangement in which the nodes of the network are connected to each other. The Web is comprised of approximately 1.5 billion pages, which are connected through hyperlink text. Hyperlinks, the glue that holds the network together, provide critical network information as connections record the direction of information flows and identify strong interconnections among particular actors. The technique used in the VPN discovery process is referred to as link-structure analysis and captures data using the latent human information embedded in Web pages and hyperlinks (Woo, 2003). For instance, hosts will publish various topical pages that provide links to alternative sources on the same subject. Among government organizations, corporations, NGOs and policy institutes, there has been a strong tendency to publish various partnership/membership lists that contain critical information concerning dominant actors of various policy communities. These processes of social organization and Web-based communication patterns leave what has been described by Farrall and Delli Carpini (2004) as "shadows in the Web graph." These technological imprints provide observable patterns of change, coalition building, and information flows, which are organized in networked environments and stamped on the sub-graph of the Web.

Using mathematics, graph theory, physics, computer science, engineering, and the new science of networks, several global properties of online communities have been identified including strong regularities among information gathering methods, hyperlink attachment, and structural traits characterized by the collective dynamics of the small world phenomena (Watts, 2003). Albert-László Barabási (2002), the first academic to map the Web, discovered that online networks are clustered, following a power law as opposed to the original assumption that they were uniform and followed a bell curve. In the case of random networks, a bell curve distribution results from the various nodes having similar probabilities of connecting with new nodes. Alternatively, in a scale free network, new nodes entering the system have a far greater probability of linking to the most connected nodes in the network, and as such, the distribution of nodes results in a concentration of links.

The application of small world networks to the structure of online communities is associated with the popular theory of six degrees of separation, which measures the structural properties of the network through path lengths (the average separation between two vertices within the network). In the case of the Web the degrees of separation, the average number of mouse clicks it take to locate

a specific document, is nineteen; however, within an online community members are typically only one or two mouse clicks away from the desired destination (Barabási, 2002). The empirical evidence garnered from the examination of these overall system laws and organizational characteristics of the Web provides us with the structural features of virtual policy networks. Using the known typological structures we may identify social networks that have emerged online and begin to focus more exclusively on the specific characteristics of individual networks (Borodin, Rosenthal, Roberts, & Tsaparas, 2001; Wu, Chen, & Sun, 2004).

## Navigating Virtual Policy Networks

The connectivity of each node (or Web site) determines both its classification and relationship to the other nodes. Using the linked structure of the Web, virtual policy networks are determined through resource lists of information documents that direct online communities towards particular information authorities (Lempel & Moran, 2000). The organizational structures of VPNs tend to mimic their real world counterparts, which suggests that the structural configuration of the network will condition policy dynamics and propensity towards change. Using two primary variables to determine network structure (symmetry and core insulation from exogenous forces) four specific ideal type virtual policy networks appear to be visible on the Web: broadcasting, regulation, circulation, and discursive.

The first type of network is protected from outside influences, controls flows of information and is resistant to the entrance of new actors. These networks simply broadcast dominate policy discourses seeking to maintain the status quo. The broadcasting VPN may be correlated with real world policy communities that are characterized as closed, with high levels of insulation from exogenous forces (Howlett, 2002). The second types of network is a circulation VPN which tends to be open to alternative policy information and competing ideas, yet impedes new membership attachment. The third ideal type of VPN is a regulation network which features limited information flow and higher levels of permeability. In these resistant networks policy leads politics with discourses characterized by core policy beliefs and porous memberships. Finally discursive virtual policy networks have more porous structures and are exposed to a constant influx of new actors and ideas. Discursive networks are by far the most democratically organized virtual policy networks, and are currently rare.

## FUTURE TRENDS

Virtual policy networks are durable patterns of online relations among a constellation of Web-based communications, with flows of information congregating around a specific policy field issue, event, institutions, or coalition. The emergence of virtual policy networks is one of the initial responses to e-government strategies. The advent and proliferation of ICTs has fundamentally altered how industrialized states are organized and the governing mechanisms employed to manage the relationship between state and society. Governments around the globe are aggressively pursuing e-government stratagems, seeking to facilitate political development through online venues. The changing relationship between state and society, and the emergence of virtual policy networks seeking to influence policy outcomes through Internet-mediated technology represents the opening up of new democratic spaces in which citizens and groups are able to organize politically.

Erik-Hans Klijn and Joop F. M. Koppenjan (2000) define policy networks as "(more or less) stable patterns of social relations between interdependent actors, which take shape around the policy problems and/or policy programmes" (p. 155). Research has established that the patterns described by Klijn and Koppenjan are occurring in an Internet-mediated environment (Bennett, 2003; Deibert, 2002). Various scholars have conducted studies on the structural features of the Web, measuring connectivity among nodes (Barabási, 2002), seeking relational context through Web pages links (Van Aelst, 2002), and undertaking in-depth analysis of particular communities' priorities using data mining techniques (Murnion & Healey, 1998). Similarly, policy scholars have determined that policy communities, and the outcomes these collectivities of policy actors are able to achieve is influenced by state involvement in networks, the social structures that characterize the networked relationships among the state and private organizations, and the network's receptiveness to new ideas and actors (Hajer & Wagenaar, 2003; Howlett, 2002; Montpetit, 2002, 2003).

## CONCLUSION

Virtual policy networks are durable patterns of online relations among a constellation of Web-based communications, with flows of information congregating around a specific policy field issue, event, institutions, or coalition. Existing policy literature suggest that various actors may participate in virtual policy networks, however such participation will be influenced by the sectoral organizational of a given policy domain, the national political system, institutional legacies, structural discourses, modes of governance, and the degree of e-government institutionalization.

## KEY TERMS

**Broadcasting VPNs:** Virtual policy networks that are closed online communities with high levels of insulation from exogenous forces

**Circulation VPNs:** Virtual policy networks that welcome competing information flows and alternative policy discourses, yet remain insulated from fluid membership.

**Discursive VPNs:** Promote democratic participation through open membership and competing flows of information.

**Hyperlink Analysis:** A methodology used to study Web-based communication

**Networks:** Dynamic systems in which membership, connectivity, and growth are fluid and complex.

**Policy Community:** Refers to groups of actors that are organized around substantive policy issues and that seeks to influence the outcomes of policy decisions.

**Regulation VPNs:** Feature limited policy discourse and dominant network norms, yet are characterized by less-limited memberships attachment.

**Virtual Policy Networks:** Durable patterns of online relations among a constellation of Web-based communications, with flows of information congregating around a specific policy field, issue, event, institutions, or coalition.

## INTRODUCTION

A key part of the appeal of interactive communications technology (ICT) has been its huge potential to facilitate citizen access to and participation in government and the political process, particularly since the advent of the World Wide Web (WWW) in the early 1990s. The ability of citizens to initiate direct contact with government individually and become civically engaged can be enhanced by telecommunications, according to e-democracy proponents (see Barber, 1984, 2003; Becker & Slaton, 2000; Cleveland, 1985; Clift, 2004; Davis, Elin, & Reeher, 2002; Nye, 1998). We refer to this use of ICT to enhance democracy as the virtual town hall (VTH). When we use the term "virtual town hall," we refer not only to specific current or prior use of ICT as a site for interactive public discourse but also to the full range of potential civic discourses that might be mediated through and enhanced by ICT (e.g., electronic town meetings, citizen juries, e-panels, and online polling, to name just a few). In short, the VTH concept encompasses all the ways in which contemporary and future interactive technologies can potentially create a "virtual public sphere," returning to "mass culture" some of the interactive and direct discourse practices of the traditional, local civic environment. We believe that such technologies have the potential, when developed and implemented properly, to enhance participatory government in any areas where broad-based access can be achieved. Likewise, this potential should encourage us to pursue the goal of increasing access to ICT for people everywhere, regarding it as a fundamental public service, like a basic utility, that constitutes a major factor in maintaining the quality of life. Governments in the United States and elsewhere have created a strong presence on the WWW since the mid- to late-1990s. However, government Web sites typically emphasize what has been called a "services first, democracy later approach," especially in the United States (Clift, 2003). The use of ICT to enhance citizen engagement with government and politics is often overlooked, downplayed, or ignored by governments in favor of the technology's capacity to help facilitate the delivery of public services.

Technology provides numerous opportunities for a more open, democratic process of governance and increased political participation. In theory, ICT makes this possible for the following reasons identified by Abramson, Atherton, and Orren (1988): the huge volume of information that can be exchanged; the ability to exchange this information without being constrained by time and space; the unprecedented control users have over what messages are received and when; the decentralization of information production and control; and the interactive nature of information exchange. Thus, the VTH can bring into being an online version of the public sphere, empowering ordinary citizens to strengthen their communities and democratic institutions (Cropf & Casaregola, 1998). The VTH uses ICT to encourage public discussion and deliberation over the proper ends of government and the means to achieve those ends. We contend the VTH can serve as a means to strengthen civil society. As noted by Putnam and others, civil society is essential to democracy. Civil society helps inculcate the core values and norms associated with democratic government. Indeed, according to Alexis de Tocqueville, civil society is what makes democratic government possible. Whether the potential of the VTH to strengthen civil society is fulfilled, however, depends on the current choices made by governments and other social institutions regarding issues of citizen access to ICT and the role of this technology in democratic governance.

## BACKGROUND: THE VIRTUAL TOWN HALL, E-DEMOCRACY, AND CIVIL SOCIETY

In general, governments' online efforts are well meaning and often effective in their own way, however, many fall short of facilitating genuine civic engagement by citizens. Fortunately, a great deal of effort has been exerted by grassroots, non-governmental organizations in creating citizen forums, which has helped fill the gap in online civic engagement. Public deliberation and decision-making is being facilitated by the use of ICT, whether the forums are

"officially" sponsored or not. The VTH is a critical element in the establishment of electronic democracy (e-democracy). According to social activist, Steven Clift (2004), "e-democracy represents the use of information and communication technologies and strategies by democratic actors (government officials, the media, political organizations, citizens/voters) within political and governance processes of local communities, nations and on the international stage" (p. 38). The advent of e-democracy has been touted since the early years of the personal computer revolution when, for example, one observer noted, "very large numbers of people empowered by knowledge … assert the right or feel the obligation to make policy" (Cleveland, 1985, p. 188). As more and more people respond to world events by participating, organizing, and deliberating online, the potential for using ICT to shape public policy is becoming more of a reality. Indeed, this is occurring on a global scale as civic groups and activists around the world seek to influence international policy-making via telecommunications (O'Brien, 2002). Fortunately, the experience in several countries (e.g., Canada, UK, and Australia) provides a source of optimism regarding technology's potential to strengthen democratic institutions and processes. Over time, however, elected leaders in all countries must use ICT to engage the public or larger numbers of people will feel alienated from government and view the political process as unresponsive to their needs.

The nexus of civil society, e-democracy, and e-government has been explored by authors such as Robert Putnam (2000) and Benjamin Barber (1984, 2003). For example, Putnam, although skeptical of the more grandiose claims of e-democracy proponents, concedes that telecommunications constitutes the most important trend toward strengthening civic engagement (p. 166). According to Barber (2003), vigorous public discussion and debate, which he refers to as "strong democratic talk," constitutes the very core of strong democratic communities. Advances in technology, Barber argues, provide the means for reducing the opportunity costs of citizen participation in democratic forums. Prior to the telecommunications revolution, participation was constrained for many citizens because of the costs incurred in taking time away from working, socializing with friends and families, or being engaged in leisure activities.

## VIRTUAL TOWN HALLS: A LITERATURE SURVEY

The scholarly literature suggests that new media technologies, particularly those found on the WWW, can be used to build civil society (Beamish, 1995; Cisler, 1993; Cropf & Casaregola, 1998; Fountain, 2001; Hale, Musso, & Weare, 1999; Levine, 2000; O'Brien, 2002; Putnam, 2000; Schuler, 1996). For example, communities using ICT can help the social integration of marginalized individuals by improving their access to other marginalized groups like themselves (Law & Keltner, 1995). Based on interviews with disabled or older users of community networks, the authors found that the marginalized users' social isolation was significantly reduced by their being able to communicate electronically with others facing similar challenges. Increasing and augmenting information sharing among people is an important foundation of social capital. By providing increased opportunities for communication among members of a community or across communities, one also increases the overall level of social trust, which can eventually be translated into collective action directed towards achieving common social goals (Kavanaugh & Patterson, 2001). This increased action can be directed toward achieving community goals and contributes significantly to an improvement in the community's overall quality of life. In a study of a community technology center, the authors found that building social capital was the critical ingredient in promoting positive change in the community (Alkalimat & Williams, 2001).

Technology can aid in creating connections between different communities, according to a study examining a series of community-based Web exhibits of the experiences of different ethnic groups in the American Southwest (Glogoff, 2001). This work reinforces the point made earlier that information sharing via ICT can help build social capital. According to the writer, the Web exhibits bring together

*[P]eople who self-identify with its content and seek out some degree of membership. Such behavior is consistent with the view that an essential element of building a climate of trust involves feeling secure in revealing vulnerable parts of ourselves to others. When people share intimate details of their lives with a* virtual *stranger, it affirms that an implicit context of trust has been established.*

The author's personal communications with exhibit visitors indicates that they believed the exhibit offered them a safe environment within which to open themselves up to others.

A recent article examines the effects on social capital of a resident-maintained "networked community" in Melbourne, Australia (Meredyth, Hopkins, Ewing, & Thomas, 2002). The Reach for the Clouds project is based in a low-income, ethnically diverse high-rise public housing development. The goal of the project, according to its sponsors, is to help residents to help themselves through

the use of network technology. The thinking behind the project was that if the tenants could learn and teach each other basic technology skills (for example, e-mail and instant messaging), they would be able to improve their community's safety by reducing the residents' sense of social isolation. Furthermore, these skills could assist tenants in increasing their employment opportunities. In this way, sponsors believed, the community network would be able to strengthen the community's social cohesion. The residents of the development, who are members of many different ethnic groups—the tenants speak at least 36 different languages—lack a sense of common identity. The sense of belonging and social connections exists within the language and ethnic groups instead of within the development. As a result of the increased access to technology there has been an augmentation of bonding capital but, at least to date, this has not had the desired effect of increasing bridging capital. The authors point out, however, that the experiment is still in its early stages. In a study of a middle-class suburban community in Toronto, Canada, the authors found that Internet usage bolsters social ties, regardless of whether they were strong or weak before (Hampton & Wellman, 1999).

Research on the effects of the WWW on social capital has identified three different approaches to computer networks and civil society (Quan-Haase & Wellman, 2002). First, the WWW can serve as a transformative agent. This comprises the literature asserting that the WWW can help bring about a dramatic increase in civic engagement. Second, the Web serves to diminish social capital. In other words, the WWW serves as a gigantic distraction drawing people away from family and community with its myriad entertainment and information opportunities. Third, the WWW serves as a supplement to social capital. Thus, instead of taking away from what people normally do, the Internet simply provides an alternative means to accomplish many of the same tasks and ends; for instance, in addition to talking on the telephone, people are sending each other e-mail and instant messages. The authors analyze data from a survey of 20,075 adult Internet users, along with results from similar surveys by other researchers. They find that, in general, the Internet adds to users' interactions via other means of communication. Thus, while face-to-face and telephone contact continue they are increasingly complemented by the ease of the Web in linking geographically dispersed individuals and groups that share common interests.

The importance of the literature cited above is that it shows the role of ICT in facilitating civic engagement and building social capital. This is accomplished through the forging of virtual connections between and within communities, as well as through the inclusion of marginalized individuals and groups in society. As a consequence of this strengthening of civil society, the political process, and other democratic institutions are also strengthened.

## EXAMPLES OF VIRTUAL TOWN HALLS

The use of ICT to enhance civic engagement has virtually exploded across the globe over the past decade. Consequently, no brief article could possibly do adequate justice to the variety of VTH experiments that exist around the world. For purpose of illustration and elucidation, we chose only five notable international examples, while recognizing that for every example chosen, literally dozens more could have been included.

1. **Almere, the Netherlands:** Citizens in Almere were invited to participate in the "co-production of interactive policy" involving the redevelopment of part of the city in 1999 (Poland, 2001). Information on the redevelopment projects was made available on the municipal Web site and a "consensus meter" was used to allow residents to select from over 200 possible projects.
2. **Houston, USA:** In 1994, thousands of Houston residents participated in an electronic town meeting to review proposals for the future of the city. Citizens gathered at five neighborhood meeting sites around the city and were linked via a satellite with a studio panel that was broadcast live on local television. The participants ranked fifty future goals for Houston that had been previously developed by citizen task forces (Teledemocracy Action News and Projects).
3. **Kalix, Sweden:** The municipal government has operated an "online town hall" (http://www.kalix.se, http://www.votia.com/kalix.demo) since September 2000. This forum provides an opportunity for citizens to chat with local political leaders and policymakers as well as to vote electronically on some issues. In September 2000, the citizens were given the opportunity to make suggestions regarding the redesign of the city center, to which the city residents responded with great enthusiasm. As a result, the city center was rebuilt taking the inhabitants' input into account.
4. **New York City, USA:** In 2002, America Speaks, Inc (http://www.americaspeaks.org/), a consulting group specializing in facilitating electronic town meetings, was asked to develop a project that would "help shape a vision for the rebuilding process" for downtown Manhattan following the Sep-

tember 11, 2001 terrorist attacks on the World Trade Center. Two town hall meetings were held, including one involving over 4,000 participants, and a two-week online dialogue that attracted another 800 participants provided valuable input to the disaster site's redevelopment process. The final report can be accessed at the America Speaks Web site (http://www.americaspeaks.org/resources/library/as/project_files/ltc/final_report_ltc2.pdf).

5. **Perth, Australia:** The Dialogue with the City project (http://www.dpi.wa.gov.au/dialogue/finalproc.pdf) was launched in 2003 by the state government to engage residents of Perth in a deliberation over the future course of the city. The stated goal of the project was to create a common vision of the city that would make it "the world's most livable city" by 2030. A Web site and an online discussion group was established as part of the project. The project culminated in a Dialogue with the City forum on September 13, 2003 involving over 1,000 participants and using computer technology to facilitate group discussion among the individuals in the assembly.

## FUTURE TRENDS

The wave of the future only a decade ago, e-democracy, is a growing reality in many parts of the globe today. A major factor in this trend is the existence of VTH as forums for online deliberation and building social capital. As technology continues to advance and costs decline, access and availability issues begin to fade in significance, allowing even the less affluent members of society to become computer users, at least in the most advanced industrial nations. As access becomes less problematic for most citizens, the number of virtual town halls can be expected to increase as well as their capacity to help shape public policy. Indeed, people's expectations regarding technology and political empowerment will continue to grow, as Cleveland (1985) predicted early in the current information age. The question is whether governments will keep pace with these growing expectations or whether they will resist popular demands for more influence in decision-making.

## CONCLUSION

The current use of ICT by governments sometimes evokes the image of a vast public sector version of Amazon.com. In other words, government Web sites provide a more efficient and cost-effective means to provide public services they have previously delivered or offered to citizens (for example, renewing a driver's license, paying a tax bill, obtaining their children's grades, etc.). While there is much to be said for this idea, scholars and civic activists believe that technology is capable of much more in the area of strengthening civic engagement and the democratic process. Utilizing technology simply to facilitate the delivery of services fails to take advantage of a key characteristic of ICT; namely, its democratizing tendencies, chief among which is the capability of bringing together large numbers of people online to deliberate and voice their opinions regarding issues. In this respect, the VTH takes advantage of ICT's potential for democratic deliberation because of the non-hierarchical, many-to-many mode of information sharing and creation.

## KEY TERMS

**Bonding Capital:** Social networks or ties that connect people to other people like themselves; tends to be exclusive of outsiders.

**Bridging Capital:** Social networks or ties that connect people to other people unlike themselves; tends to be more inclusive.

**Citizen Juries:** Groups of people, broadly representative of their communities, who are chosen to deliberate on an issue of importance to the community from which they are selected. These deliberations are usually facilitated so that each participant becomes fully engaged in the process and a consensus arrived at. At the completion of the process, the findings of the group are reported to the community for follow-up and action.

**Civic Engagement:** The process by which citizens participate in civil society and seek to influence the political process.

**Civil Society:** The domain of social life independent of the government and private markets, consisting of voluntary associations.

**E-Democracy:** The use of interactive communications technology by governments, elected representatives, civic groups, political organizations, and private citizens to

influence the political process and governmental institutions via means that can include online discussion groups, government Web sites facilitating consultation between citizens and their government, and other form of online civic participation and engagement.

**E-Government:** The use of technology to facilitate administration of government, to improve citizen access to government information and services, and to encourage civic participation in the political process.

**Electronic Town Meeting:** A process which usually involves each of the following three components: (1) the use of media technologies to present information on political issues to participants, (2) discussion and deliberation, typically via media technologies and ICT, and (3) the gathering of information and feedback, usually through a sample survey of the citizens in a given area.

**Networked Community:** Using computers to bring people together in a community setting in order to empower local residents.

**Social Capital:** Such mechanisms as networks, shared trust, norms and values that allows a society to cooperate or collaborate in order to achieve its collective goals. The sum of the institutions, relationships, and norms in a society that shape the quality and quantity of its social interactions.

# Voice Technologies in the Public Sector for E-Government Services

V

**Mark J. Headd**
*University of Delaware, USA*

## INTRODUCTION

Spurred by the development of new Extensible Markup Language (XML)-based telephony markup languages and the adoption of requirements for universal access to government Internet content (CITA, 2005), more and more governments are making use of a new family of open-standard development languages to make their visual Web applications accessible by telephones and cell phones. This article will explore the development of the factors driving this trend, and explore possible future trends as these new technologies mature.

## BACKGROUND

Early in the development of the Internet as a tool for governments to provide information and services to citizens, researchers recognized the fundamental dilemma of e-government service delivery; access to the Internet and the ability to utilize Web browsers and Web-based services is unevenly spread (Novak, 1998). In the United States (U.S.), researchers identified several key factors that help explain access to Internet technology generally and to Internet-connected computers specifically. Income and other factors unevenly spread throughout the population can influence access to the Internet (NTIA, 1999). Additionally, researchers have identified age as a key factor determining ability to access Internet resources (Fox, 2004). These factors can present significant issues for governments, which operate under a universal service delivery mandate.

At approximately the same time during the 1990s that the Internet began to be used by more and more governments, researchers at AT&T/Bell Laboratories began work on a project to develop a phone markup language to support telephone access to Internet content. Researchers at AT&T, Lucent (following the company's separation from AT&T) and Motorola continued to pursue the development of a telephony markup language and incorporated the framework of XML, which became a formal standard in 1998 (W3C, 2002). The work conducted by these organizations on phone markup languages was eventually submitted to the World Wide Web Consortium (W3C) for consideration as a formal Web standard, and the Voice Extensible Markup Language (VoiceXML) Forum was created to advance the use of voice markup languages.

These efforts resulted in the development of VoiceXML. In simplest terms, VoiceXML is a Web technology that turns any telephone, even a rotary phone, into an Internet device. VoiceXML is a non-proprietary, Web-based markup language for creating vocal dialogs between humans and computers. VoiceXML is similar to another common markup language—Hypertext Markup Language (HTML), the basic language of most visual Web pages.

## EVOLUTION OF THE VOICE WEB

Just as a Web browser renders HTML documents visually for display on a computer monitor, a VoiceXML interpreter renders VoiceXML documents for vocal representation (W3C, 2004). In this respect, one can think of a VoiceXML interpreter as a telephone-based voice browser. As with HTML documents, VoiceXML documents have

uniform resource identifiers (URIs) and can be located on any traditional Web server. However, instead of pointing a client-side Web browser at a specific URI, citizens can access a VoiceXML application by calling a telephone number from any ordinary telephone—cellular or traditional, touch-tone or rotary.

VoiceXML belongs to a family of open Web standards referred to collectively as the speech interface framework (SIF). The underlying communications protocol used by VoiceXML and the SIF is the hypertext transfer protocol (HTTP), the same basic communications format used by visual Internet applications (Rehor, 2001).

## BENEFITS OF THE VOICE WEB FOR GOVERNMENT SERVICES DELIVERY

Governments exist to provide services and information to constituents regardless of race, gender, socio-economic status or other factors. However, many governments continue to struggle with Internet access issues and ways to provide e-government services to different groups of citizens. For example, research on the ability of different groups in the U.S. to access the Internet shows clear differences between whites and other groups of citizens, with whites being more likely to have access than other groups (Novak, 1998).

There are also differences in rate of use of the Internet among older citizens as opposed to younger ones. Only about 22% of seniors in the U.S. report being able to access the Internet (Fox, 2004), and research suggests that this group faces unique barriers to traditional Internet access because of the more likely incidence of factors like poor vision and other disabilities. Research from other countries suggests a similar trend outside the U.S. (Paul, 2005). VoiceXML may be a useful technology to help address the challenges that face certain populations in accessing Internet-based government content.

VoiceXML and technologies in the SIF can help make government Internet content and applications available through any traditional or cellular telephone. In some cases, VoiceXML content and applications (when coupled with widely available speech recognition technologies) can even be made available through rotary telephones. This has the effect of dramatically widening the audience for government Web content or services.

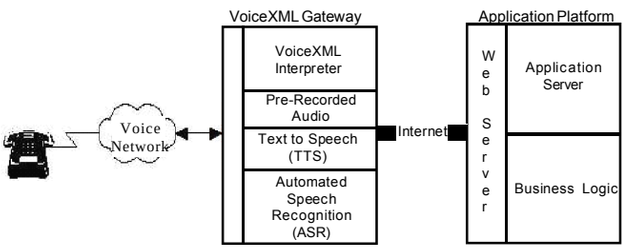
In addition, VoiceXML and the SIF can help governments address some of the most fundamental issues impacting the ability of citizens to access online government resources. Speech interfaces can be more natural than visual Web forms, particularly for those with visual disabilities or literacy issues. Additionally, the skills required to operate a telephone are more evenly spread than that of a computer or visual Web browser. In addition, while many governments still struggle to make their Internet content accessible to individuals with physical limitations, VoiceXML can enhance the accessibility of Web content and services to those with visual or other impairments.

VoiceXML can also provide a number of operational benefits for governments that make use of it as opposed to proprietary interactive voice response (IVR) technology. Because VoiceXML is a Web-based markup language, and since the vast majority of public-sector entities have infrastructures to support Web sites (West, 2004), governments can leverage existing knowledge in other markup languages like HTML to develop voice applications more quickly. Also, because the underlying

*Table 1. SIF components*

| Component | Purpose |
|---|---|
| VoiceXML | XML language for constructing dialogs with callers. |
| Speech Recognition Grammar Specification (SRGS) | XML language for specifying grammars that define allowed input to a speech application. |
| Speech Synthesis Markup Language (SSML) | XML language for specifying the rendering of synthesized (computer-generated) speech to a caller. |
| Call Control Extensible Markup Language (CCXML) | XML language for specifying call control functions, like call conferencing and session management. |

*Figure 3. Overview of a typical voice Web application*



communications protocol used by VoiceXML is the same used by visual Web applications, VoiceXML applications can use the same existing back-end business logic and legacy systems as their visual counterparts, enabling voice solutions to be efficiently introduced to government technology environments to help improve service delivery.

Distilled to its essence, the primary benefit of VoiceXML is that it extends the traditional Web development paradigm to the telephone. The same software and hardware components, the same communications protocols and the same development skill sets used to create and deploy visual Web content and applications all can be used to create voice applications.

## COMPONENTS OF A VOICEXML APPLICATION

Several key components make up a VoiceXML application (Rehor, 2001). Some of these components are identical to those found in traditional Web applications, and others fulfill the unique requirements of voice applications:

- **Application Platform:** This component typically includes a Web server and application server (it may optionally also include a database server). Business logic (i.e., the rules that govern how an application behaves) is executed by the application server and served to other components through the Web server.
- **VoiceXML Gateway:** This component includes a VoiceXML interpreter that acts as a client to the application platform. The interpreter can process VoiceXML dialogs and controls the recognition and generation of speech. It also interfaces with telephony resources.
- **Network:** This component includes a packet-based network that connects the application platform and the VoiceXML gateway. In the case of a hosted VoiceXML gateway (discussed below), the network may be the public Internet.
- **Voice Network:** Typically the Public Switched Telephone Network (PSTN), and any telephone that can connect to the telephone network.

Some of these components, most notably those making up the VoiceXML gateway, are unique to voice applications. While these components may require some specialized knowledge to manage, a large number of commercially available and open-source software components can be used (Rehor, 2005). It is possible to construct both the application platform and VoiceXML gateway entirely from open-source components if desired, obviating the need for most upfront software costs. As these software packages become more numerous, the knowledge required to manage them becomes more widely diffused.

As an alternative to managing the VoiceXML gateway component themselves, many governments are opting to outsource this function to third-party entities. A growing number of hosting providers are available to help deploy voice applications of all sizes (Jamison, 2004). This approach has the advantage of outsourcing the more esoteric portion of the application components and allowing governments to focus on those aspects with which they have the most experience.

### Challenges Facing Voice Delivery of Government Information

Despite the enormous promise that VoiceXML and related technologies show in helping governments address fundamental issues relating to access to Internet-based information and services, some challenges remain to their widespread use.

While speech may provide a more natural interface that helps overcome significant limitations in accessing written information (e.g., literacy), it is not an efficient interface for all government information or services. Voice interfaces are ideal for highly focused transactions and the exchange of succinct, highly valuable informa-

tion. Voice interfaces are not ideal for reviewing large documents, for open-ended dialogs with callers or for transactions requiring a fairly large number of multiple steps.

Additionally, VoiceXML lacks some of the more basic security mechanisms utilized in visual Web sites. For example, almost every modern Web browser will obscure password information entered into a Web-based form. This can help prevent the inadvertent disclosure of password information that may compromise users. Callers to a voice system may compromise sensitive information such as a password when it is spoken so that a VoiceXML application can recognize it. This may be mitigated somewhat by the use of touch-tone keypads, but it is generally recognized that more robust security features are needed to help foster the widespread deployment of VoiceXML applications.

Finally, there is currently poor support in the SIF for some languages (e.g., Asian languages). There are methods for developing VoiceXML applications that can mitigate this, but greater support for a wider array of languages is a critical next step in the development of VoiceXML.

In December 2005, the W3C announced plans to begin to address some of these limitations, including incorporating a technique called "speaker verification" into the next version of VoiceXML. Speaker verification provides an authentication mechanism based on a caller's voice print, or the unique characteristics of a caller's voice (W3C, 2005).

In addition, the organization has undertaken an effort to internationalize the SSML, which will allow VoiceXML applications to render different languages more naturally. An effort to incorporate native support for Mandarin Chinese is currently under way (W3C, 2005).

## FUTURE TRENDS

The VoiceXML standard has quickly matured and been widely embraced by the technology community, which has moved to deploy it on a large number of platforms. Additionally, new voice standards are being developed to bring together the visual and voice Web interfaces into a single "multi-modal" view of Web content.

Speech application language tags (SALT) is a standard for combining visual markup languages (HTML) with voice functionality (Salt Forum, 2003). Another multimodal specification (XHTML+Voice, or X+V) is being refined under the auspices of the W3C. These new standards will make it possible for a single interface, like a desktop Web browser or a personal digital assistant (PDA), to accept multiple types of input like keyboard/mouse input, voice input or stylus input (VoiceXML Forum, 2004).

These new specifications, along with the family of languages making up the SIF, will further perpetuate the trend toward device independence. In the future, governments will be able to deploy their information and applications for use in a variety of user agents and devices. This trend will result in improved access to government services and will provide a larger range of options for public-sector entities to provide services to citizens.

## CONCLUSION

VoiceXML and the technologies in the SIF hold enormous potential for improving the accessibility of government information and services. By utilizing these technologies governments can dramatically improve accessibility to a range of services not currently accessible by different groups of citizens. Governments should incorporate VoiceXML into their overall e-government structures and recognize that, while not a panacea of the problems of access, it fulfills an important role in the mission of e-government.

## KEY TERMS

**Application Server:** A hardware and/or software component that operates separately but complementarily to a Web server by processing the business logic of an application. This business logic is typically expressed using a programming language executed by an application server using input received with requests to a Web server. The application server typically sits in the middle "tier" of a multi-layered Web application. The execution of the business logic may involve querying a database and formatting data for response by the Web server. While the Web server, application server and database server components may reside on the same physical server, production performance requirements typically result in these components being placed on separate physical servers.

**Call Control Extensible Markup Language (CCXML):** An XML vocabulary that allows developers to control the nature, characteristics and duration of a phone call. Where VoiceXML allows developers to create dialogs where a caller can interact with an application or program, CCXML provides higher-level control of the interaction by allowing for the creation and termination of calls, call conferencing, sophisticated call transferring and more.

**Extensible Markup Language (XML):** A markup language specification developed under the auspices of the W3C that provides a basic framework for describing data. Unlike HTML, which is engineered for the presentation of data within a Web browser or similar device, XML can be used to provide descriptive information about data for consuming applications of many types. Additionally, while HTML tags are fixed, XML tags can be custom created by developers for different purposes provided that they adhere to the underlying specification. Most importantly, the XML specification can be used to extend (hence the name "Extensible" Markup Language) the core concept of tagging data to develop new markup vocabularies for different purposes.

**Hypertext Transfer Protocol (HTTP):** A communications protocol widely used as part of the World Wide Web. HTTP is the basic method used by Web servers to send and receive data.

**Markup Language:** In the context of the Internet, a vocabulary of tags used to describe elements of data, with each element beginning enclosed in beginning and ending tags Beginning tags are enclosed in "<" and ">" symbols, and ending tags are enclosed in "</" and ">" symbols. All modern markup languages in use today, including HTML, the underlying language of Web pages, are derived from SGML, which was used extensively in the publishing world to markup text documents prior to the widespread use of the Internet.

**Open Standard, Web Standard:** Specifications promulgated by interest groups comprised of technical experts like the World Wide Web Consortium (W3C), the Organization for the Advancement of Structured Information Standards (OASIS) and the Institute of Electrical and Electronics Engineers (IEEE).

**Speech Recognition Grammar Specification (SRGS):** An XML vocabulary for creating grammars. Grammars are a central component to voice applications that define the set of words or word combinations recognized by speech recognition technologies, and allow a user to interact with a voice application. Grammars can be thought of as the vocal counterpart to the menu items in a traditional HTML Web form. When a voice application recognizes a word or

phrase defined within a grammar file, it triggers a programmatic response based on the logic of the application.

**Speech Synthesis Markup Language (SSML):** An XML vocabulary for describing how speech should be rendered by text-to-speech engines. SSML allows voice developers to specify the characteristics of computer-generated speech, providing control over pitch, prosody, rate and other speech characteristics.

**Uniform Resource Identifiers (URI):** Names or short text strings that identify resources accessible on the Internet. www.w3.org is a URI that identifies the main Web site of the World Wide Web Consortium.

**Voice Extensible Markup Language (VoiceXML):** An XML vocabulary for creating dialogs used in voice applications. Like HTML, which is used to describe how data is displayed in a Web browser or similar device, VoiceXML describes how data should be rendered audibly to a caller using a voice browser. VoiceXML provides a mature flexible foundation on which to develop sophisticated voice applications.

**Web Server:** A hardware and/or software component that "serves" Web pages over the Internet using the HTTP protocol. Web servers respond to requests from other servers or applications (like a Web browser) and send the requested resources back using HTTP.

# Voter Information Web Sites

**Arthur Edwards**
*Erasmus University Rotterdam, The Netherlands*

## INTRODUCTION

Several election studies observe that considerations regarding issues and policies have been gaining weight in voting decisions in Western countries, at the expense of previously existing class or partisan alignments (Denver, 2003). This development may imply that voters show more information-seeking behaviour. In the 1990s, various Web sites have emerged that are designed to support the voters in this job. These voter information Web sites are nonpartisan Web sites that provide the users with information on the election promises, issue positions or past performance of political parties or individual candidates. The term *Web site* should be understood as including various Internet-based resources and facilities, such as databases, decision-support systems, and discussion forums. In this article, we address the question what these voter information Web sites may offer in terms of their potential of enhancing the quality of voting decisions. The core of this exposition will centre on the Web site design features and on how the voters make use of the Web sites.

In the next section, we will highlight the distinction between prospective and retrospective Web sites. The section titled "Voter Information Web Sites" provides an overview of the main design features of voter information Web sites. Some examples of prospective and retrospective Web sites will be discussed. In the Future Trends section, we point toward some future trends. Finally, a tentative assessment will be given of the significance of voter information Web sites for enhancing the functioning of representative democracy.

## BACKGROUND

Voters can make up their minds within different time perspectives. They can orient themselves toward a comparative assessment ex ante of the candidates' or parties' election pledges (prospective voting) or toward an ex post evaluation of the incumbents' past performance (retrospective voting).

Along these lines, two types of voter information Web sites can be distinguished:

1. Web sites that assist the voters in their prospective appraisals. One type of prospective voter information Web sites assists the voters in the job of comparing election manifestos. Election pledges and issue positions are made searchable by policy area or theme. In this article, we look at "vote matches" or "voting indication tools". These are software programmes that compare the user's answers on an issue position questionnaire with a database of candidates' or parties' electoral policy propositions, and give the users an advice about the best fitting political preference.
2. Web sites that assist the voters in their retrospective appraisals. These Web sites provide information on the past performance of elected representatives. For instance, performance data can be provided by overviews of voting records; performance evaluations can be presented in the form of ratings or in qualitative terms.

Voter information Web sites can be regarded as new nonpartisan information intermediaries in the voters' information environment (Edwards, 2005; IPDI, 2004). In this environment, a variety of information providers are active: political parties and individual politicians, actors within the media system and civil society actors (interest groups and other nonpartisan and not-for-profit organisations). The Web sites to be discussed in this article were set up by civil society actors. However, traditional media organisations are also active in this domain, as well as for-profit organisations, such as media and consultancy companies.[1]

## VOTER INFORMATION WEB SITES: DESIGN CHOICES, EXPERIENCES

### Prospective Voter Information Web Sites (Voting Indicators)

Examples of voting indicators are the *StemWijzer* in The Netherlands, the *Wahl-O-Mat* in Germany, the *PolitArena* in Switzerland and several "voting machines" in Finland.

In several countries, voting indicators were available during the European Parliament election in 2004. In this section, the main design choices will be indicated. The most successful voting indicator in The Netherlands ('most successful' in terms of number of visitors) will be discussed as an example.

## Main Design Choices

In designing voting indicators, several decisions have to be made. The main design features include:

- The basis of the parties' or candidates' profiles: Voting indicators can be based on the parties' election manifestos, on issue positions formulated by the party leaders or candidates, or on the personal answers given by individual candidates on the designers' questionnaire.
- The composition of the list of propositions: Groot (2003) formulated the following criteria for the selection of propositions: content validity (the inclusion of the most important points of contention between the parties or candidates), representational validity (the duly representation of the positions held by the different parties or candidates), avoidance of overlap and discriminatory power.
- The validation and "calibration" of the voting indicator: First, by submitting the list of propositions to party officials for authorization, and, second, by subjecting the final draft of the voting indicator to a test by politicians.
- The options for the users: the response categories and the possibilities of giving additional weights to certain themes or issues.
- The presentation of the results to the user: a single voting advice, an overview of the differences between the user's profile with the parties profiles on all propositions, the inclusion of links with relevant statements in the election manifestos, and so forth.

## The Dutch Voting Indicator StemWijzer

In a multi-party system, as in The Netherlands, comparing political parties on the basis of their election pledges is a complex task for the voters. Since the Dutch parliamentary election in 1994, the Institute for Public and Politics (IPP, an independent institute for civic education) distributes a digital voting indicator, called the *StemWijzer,* in their regular package of civic educative material.[2] This first digital voting indicator was available as a diskette. A few thousand were sold to schools and individual users. In the1998 parliamentary election, the *StemWijzer* was also made available on the Internet. About 6,500 voters made use of this Internet version (Tops, Voerman, & Boogers, 2000). In the 2002 parliamentary election, the *StemWijzer* was only available on the Internet. More than 2 million voting advices were provided.

From the beginning, the designers of the system had two aims, the first of which was educative: increasing the users' knowledge about the programmatic differences and similarities between the political parties. The second aim was to assist the users with their party choice. The educative aim is important for understanding the system's design and for the assessment of its quality.

## The Design of the List of Propositions and Party Profiles

Methodologically, the *StemWijzer* works by comparing party profiles with the profile of the user. The party profiles are based on the election platforms of the political parties. A first selection is made of about 100 propositions, considering their distribution over the themes covered in the party platforms, their saliency in the public discussion and a balance between "positive" and "negative" propositions. Then, a further selection is made of about 50 propositions, in view of saliency, clarity and formulation. This list is submitted to authoritative representatives of the political parties. They determine the party's standpoints on the propositions (agree, disagree, or neutral). They can take this opportunity to give their comments on the list. Then a final selection is made. Propositions on which there is at least not one party in agreement, and one party in disagreement, are deleted. A final control is made with regard to the distribution of the propositions over the themes, and the overall differences between the parties.[3] The final list should include between 25 and 30 propositions.

## The Method for Determining the Voting Advice

The users build their own profile by working through the list of propositions. They can choose between "agree", "neutral", "disagree", or "no opinion". When they have completed the list, they can assign some extra weight to propositions. Then the computer compares the different party profiles with the user's profile on the basis of the principle of the "smallest difference". The user gets a voting advice with a list of all parties in decreasing order of congruence, together with a comparative overview of his or her points of view on each proposition and those of all the parties included in the voting indicator.

## The Use of the Voting Indicator

How are voting indicators being used? How serious are they taken by the users, and what is their actual effect on voting decisions? In a survey among visitors of political Web sites, 60% of the visitors of the *StemWijzer* mentioned their interest in information about the positions of the political parties as a main reason for visiting the Web site (Boogers & Voerman, 2003). A survey among users of the *StemWijzer* in the 2002 parliamentary election revealed that 17% of the respondents did not attach any value to the advice, and that for 27% of the respondents the advice merely confirmed their party preference. A quarter of the users indicated that the voting advice "affected" their voting decision; another quarter indicated that the advice prompted them to reconsider their initial party preference, whereas 4% indicated that the advice actually changed their party preference (Groot, 2003).

These figures seem to indicate that the users do attach a certain value to voting indicators. However, more research is needed to ascertain which functions the voting indicators fulfil for the voters, which "styles" of using voting indicators can be distinguished, and which benefits are perceived by their users. Voting indicators may stimulate political discussions in the lifeworld of their users, discussions with family members, friends and colleagues. Users may primarily appreciate the "fun" of using a voting indicator above its information and expert functions. The experiences with the Dutch *StemWijzer* indicate that an important success factor was the cooperation with trusted media organisations, such as newspapers and broadcasting organisations.

## Assessing the Quality of Voting Indicators

The main criterion for the quality of a voting indicator would seem to be its power to generate "correct" voting advices. Ideally, this would mean that a just interpretation is made of the users' political preferences (Groot, 2003). Until now, most voting indicators are restricted to matters of policy content. However, voters can have a number of different reasons to vote for a party, such as the party's "ideology", the attractiveness of its candidates, and various strategic reasons. On the one hand, the restriction to matters of content can be seen as the main strength of voting indicators, as they hold a mirror up to the user's face. On the other hand, they may confront the users with odd advices that they would not consider in any case. The quality of voting matches has to be assessed in relation to the designers' objectives and the users' information needs, but also against the backdrop of normative ideas with regard of the act of voting. A system solely designed for yielding "correct" voting advices is not necessarily facilitating an autonomous and informed voting decision.

# Retrospective Voter Information Web Sites

Basically, these systems can take two forms. First, they can assist the voters in monitoring the parties' or candidates' enactment of their election pledges. Second, they can help the voters in evaluating the representatives' performance on the basis of voters' current preferences. In terms of models of representation, the first type of information systems supports the monitoring of 'promissory representation', which is based on the idea that candidates make promises and that, when elected in office, they have an obligation to keep these promises. The second type supports "anticipatory representation", a model of representation that is solely based upon the idea that representatives try to please the voters in the next election (Mansbridge, 2003). We will discuss an example from The Netherlands and the United States.

## Monitoring Promissory Representation

Six weeks before the Dutch parliamentary election in 2002, the Web site GeenWoorden.nl ("No Words") was launched: an initiative of the Institute for Public and Politics (IPP; the same initiator of the *StemWijzer*) and the Catholic Broadcasting Association (KRO). The project had two aims. The first aim was to provide the voters with information about the past performance of the political parties in parliament; the second aim was to promote a practice of holding politicians accountable for their deeds in office. A Web site was developed with four parts: (1) Summaries of the 1998 election programmes of the (eight) political parties represented in parliament on twelve themes; (2) An overview of their deeds on these themes; (3) Expert evaluations of the reported deeds; and (4) A discussion forum for the site visitors.

Within six policy areas (multicultural society, education, transportation, public health, moral issues, and democracy), two specific themes were chosen. Most themes were selected because of their saliency in the public discussion. The project staff made summaries of the 1998 election programmes. The parliamentary parties were asked to indicate what they had done to fulfil their promises (in 200 words on each theme). An important feature of this project was therefore that the selection of the performance data was left to the politicians themselves. Experts (staff from interest groups, academic experts and 'experience experts' from the field) were

asked to evaluate the truthfulness and effectiveness of the reported deeds (100 words on each theme). The summaries, reported deeds and evaluations were placed side by side on the Web pages, searchable by political party and theme. On the discussion forum site visitors could provide their own comments on the information and offer additional reactions. Finally, the KRO broadcasted a number of programmes on radio and TV that took up the idea of the project. For instance, on a few TV programmes politicians were invited to undergo a kind of "job evaluation interview".

### Monitoring Anticipatory Representation

In the U.S. there is a long tradition of keeping track of the voting behaviour of members of Congress. Constituents, political candidates, special interest groups and researchers have long been interested in congressional voting patterns (Manning, 1996). Project Vote Smart (PVS) is a civic organisation, founded in 1992 by a number of national leaders from various backgrounds and party affiliations. It presents itself as 'a national library of factual information about candidates and elected officials' and as a "Voter Self-Defence System" against the misinformation and the manipulative tactics propagated through the mass media by candidates and professional campaign practitioners. PVS is funded exclusively through private donations and grants from private philanthropic foundations. There is a modest number of staff, as volunteers do most of the work.

Vote Smart provides the following information about candidates for state and federal office: (1) contact and biographical information, (2) campaign finance information, (3) information on issue positions, (4) voting records (on key votes) of those candidates who have held legislative office, (5) performance evaluations (interest group ratings) and (6) public statements. For each candidate, the key votes are grouped by issue. Several criteria are used to select the votes. First, the vote should be helpful in portraying how a Member of Congress stands on a particular issue. Other criteria are comprehensibility, national media attention and a very close margin in votes. Occasionally, when a specific bill is consistently inquired about on the PVS hotline, a vote is added on the Web site. Descriptions of the votes are written by PVS staff and based on information in the *Congressional Record,* with additional background information from newspapers, magazines, and so forth. Key votes selected by PVS staff go through an approval process before Web site posting, with five political scientists of opposing viewpoints reviewing both the selection and the content. The hundreds of key votes cover a wide range of issues, divided in 30 to 40 categories. Project Vote Smart also collects performance evaluations from special interest groups who provide them. The evaluations are provided on a wide range of issues (the same categories as the key votes), and include the ratings of more than a hundred special interest groups. Most performance evaluations are displayed in a percentage format. On the Web site it is pointed out that ratings done by interest groups are biased and that some groups even select votes that tend to favour members of one political party over another. The users are advised to compare the ratings by groups on all sides of an issue.

## FUTURE TRENDS

Apart from some consolidated formats, such as VoteSmart, the development of voter information Web sites is still in the phase of trial and error. In several countries, competing versions of voting indicators are provided. One scenario is their further development in the direction of more or less reliable expert systems for the voters. Another scenario is their use in TV formats of "infotainment" drawing primarily upon their "fun" potential. Increased visibility in mainstream media can help Web sites as well. Moreover, in the future, when full-fledged digital TV becomes widespread, TV can offer interactive processing of voters' preferences. Aside from the USA, retrospective voter information Web sites are a more recent phenomenon, and less widespread. The design of retrospective Web sites poses complex informational problems. A developed official system for recording votes in legislative bodies has to be available, not to mention the problems of gathering data on other deeds of elected representatives. Another problem is how to organize the evaluation of the data. In these respects, the Dutch and American cases discussed above represent contrasting cases. Design solutions have to be found within the framework of the political system, in which the Web site has to function. Another challenge is to find a format for retrospective Web sites that makes them digestible and attractive for the users. The voting indicators seem to have a clear lead in this.

## CONCLUSION

One of the central notions underlying democratic institutions is the responsiveness of political decision making toward the citizens' wishes (Saward, 1998). In a representative democracy, periodical elections provide a dual mechanism for accomplishing this. Prospectively, they give the voters the opportunity to select political parties and candidates on the basis of their election pledges.

Retrospectively, elections are a mechanism by which incumbents can be rendered accountable. By increasing the users' political knowledge and improving the quality of their voting decisions, voter information Web sites have a potential for strengthening the quality of the electoral mechanism for responsiveness. These Web sites might be a counterbalancing force in the context of the continuing personalisation of politics and an increasing reliance on promotional campaigning styles.

However, this assessment does not imply a simple endorsement of a purely information-based model of citizenship, in which we expect the citizen "to consult each candidate's Web site during an election or the best of the Web sites that track candidate biographies, elected voting records, and even keep tabs on campaign promises delinquent" (Schudson, 2004, p. 56). Such a picture is hardly realistic. Various studies highlighted the informational shortcuts and simplifying rules that voters employ (Ferejohn & Kuklinski, 1990). Information-seeking behaviour is dependent on motivation, resources and skills. However, the opportunities and agencies in the voters' information environment can make a difference (Norris, 2001). In this environment, Web sites offer possibilities for providing information from various sources, structuring it in efficient formats, and tailoring it to individual needs. The integration of voter information Web sites in the wider voter information environment, which requires the necessary linkages with other media, should be in the focus of the designers' attention.

## KEY TERMS

**Anticipatory Representation:** A model of representation based upon the idea that representatives try to please the voters in the next election (Mansbridge, 2003).

**Promissory Representation:** A model of representation based on the idea that political parties and candidates make promises and that, when elected in office, they have an obligation to keep these promises (Mansbridge, 2003).

**Prospective Voter Information Web Sites:** Web sites that provide the user with information about the current election pledges of political parties or individual candidates.

**Prospective Voting:** An orientation in making voting decisions based on a comparative assessment of the candidates' or parties' current election pledges.

**Retrospective Voter Information Web Sites:** Web sites that provide the user with information on the past performance of individual representatives or parliamentary parties.

**Retrospective Voting:** An orientation in making voting decisions based on an evaluation of the past performance of individual representatives or parliamentary parties.

**Vote Matches:** See voting indicators.

**Voter Information Web Sites:** Nonpartisan Web sites that provide the voters with information on the election promises, issue positions or past performance of political parties or individual candidates.

**Voting Indicators:** Software programmes that compare the users' answers on an issue position questionnaire with a database of candidates' or parties' electoral policy propositions, and give the users an advice about the best fitting political preference.

## ENDNOTES

1 An example is the voting indicator provided by the media company Alma Media in Finland.

2 The word stemwijzer has a double meaning in Dutch: it can mean "voting indicator" and (the encouraging statement) "vote wiser".

3 In order to establish that the list yields enough distance between the parties the "City-block procedure" is used.

# Web Mining for Public E–Services Personalization

## INTRODUCTION

Over the last decade, we have witnessed an explosive growth in the information available on the Web. Today, Web browsers provide easy access to myriad sources of text and multimedia data. Search engines index more than a billion pages and finding the desired information is not an easy task. This profusion of resources has prompted the need for developing automatic mining techniques on Web, thereby giving rise to the term "*Web mining*" (Pal, Talwar, & Mitra, 2002).

Web mining is the application of data mining techniques on the Web for discovering useful patterns and can be divided into three basic categories: *Web content mining*, *Web structure mining,* and *Web usage mining*. Web content mining includes techniques for assisting users in locating Web documents (i.e., pages) that meet certain criteria, while Web structure mining relates to discovering information based on the Web site structure data (the data depicting the Web site map). Web usage mining focuses on analyzing Web access logs and other sources of information regarding user interactions within the Web site in order to capture, understand and model their behavioral patterns and profiles and thereby improve their experience with the Web site.

As citizens requirements and needs change continuously, traditional information searching, and fulfillment of various tasks result to the loss of valuable time spent in identifying the responsible actor (public authority) and waiting in queues. At the same time, the percentage of users who acquaint with the Internet has been remarkably increased (Internet World Stats, 2005). These two facts motivate many governmental organizations to proceed with the provision of e-services via their Web sites. The ease and speed with which business transactions can be carried out over the Web has been a key driving force in the rapid growth and popularity of e-government, e-commerce, and e-business applications.

In this framework, the Web is emerging as the appropriate environment for business transactions and user-organization interactions. However, since it is a large collection of semi-structured and structured information sources, Web users often suffer from information overload. *Personalization* is considered as a popular solution in order to alleviate this problem and to customize the Web environment to users (Eirinaki & Vazirgiannis, 2003). Web personalization can be described, as any action that makes the Web experience of a user personalized to his or her needs and wishes. Principal elements of Web personalization include modeling of Web objects (pages) and subjects (users), categorization of objects and subjects, matching between and across objects and/or subjects, and determination of the set of actions to be recommended for personalization.

In the remainder of this article, we present the way an e-government application can deploy Web mining techniques in order to support intelligent and personalized interactions with citizens. Specifically, we describe the tasks that typically comprise this process, illustrate the future trends, and discuss the open issues in the field.

## BACKGROUND

The close relation between Web mining and Web personalization has become the stimulus for significant research work in the area (Borges & Levene, 1999; Cooley, 2000; Kosala & Blockeel, 2000; Madria, Bhowmick, Ng, & Lim, 1999). Web mining is a complete process and involves specific primary data mining tasks, namely data collection, data reprocessing, pattern discovery, and knowledge post-processing. Therefore, Web mining can be viewed as consisting of the following four tasks (Etzioni, 1996):

- **Information Retrieval—IR (Resource Discovery):** It deals with automatic retrieval of all relevant documents, while at the same time ensuring that the non relevant ones are fetched as few as possible. The IR process mainly deals with document representation, indexing, and searching. The process of retrieving the data that is either online or offline from the text sources available on the Web such as electronic newsletters, newsgroups, text contents of HTML documents obtained by removing HTML tags, and also the manual selection of Web resources. Here are also included text resources that originally were not accessible from the Web but are accessible now, such as online texts made for search purposes only, text databases, and so forth.
- **Information Extraction—IE (Selection and Pre-Processing):** Once the documents have been retrieved in the IR process, the challenge is to automatically extract knowledge and other required information without human interaction. IE is the task of identifying specific fragments of a single document that constitute its core semantic content and transforming them into useful information. These transformations could be either a kind of pre-processing such as removing stop words, stemming, etc. or a pre-processing aimed at obtaining the desired representation such as finding phrases in the training corpus, transforming the presentation to relational or first-order logic form, and so forth.
- **Generalization (Pattern Recognition and Machine Learning):** Discover general patterns at individual Web sites or across multiple sites. Machine learning or data mining techniques are used for the generalization. Most of the machine learning systems, deployed on the Web, learn more about the user's interest than the Web itself.
- **Analysis (Validation and Interpretation):** A data driven problem, which presumes that there is sufficient data available, so that potentially useful information can be extracted and analyzed. Humans also play an important role in the information or knowledge discovery process on the Web, since the Web is an interactive medium. This is especially important for validation and/or interpretation but under Etzioni's view (1996) of Web mining, "manual" (interactive, query triggered) knowledge discovery is excluded and thus the focus is placed on automatic data-triggered knowledge discovery.

Web mining refers to the overall process of discovering potentially useful and previously unknown information, knowledge, and patterns from Web data. In this sense, it implicitly covers the standard process of knowledge discovery in databases (KDD) and can be considered as a KDD extension applied to the Web (Markellos, Markellou, Rigou, & Sirmakessis, 2004a). Specifically, Web mining can be categorized into three areas of interest based on which part of the Web is mined:

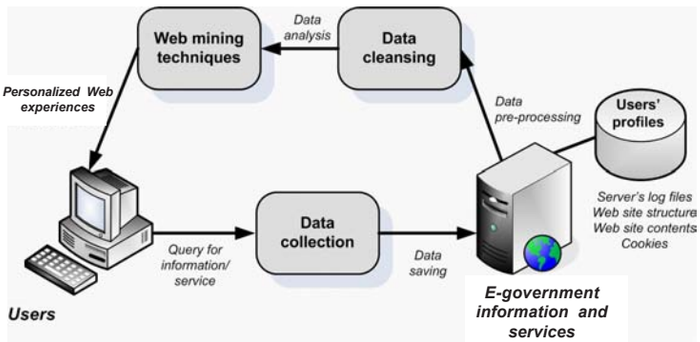
- **Web Content Mining:** Focuses on the discovery/retrieval of useful information from Web contents/data/documents. Web content data consist of unstructured data (free texts), semi-structured data (HTML documents) and more structured data (data in tables, DB generated HTML pages)
- **Web Structure Mining:** Focuses on the structure of the hyperlinks within the Web as a whole (inter-document) with the purpose of discovering its underlying link structure. Web structure data consist of the Web site structure itself
- **Web Usage Mining:** Mines the secondary data derived from Web surfers' sessions or behaviors and focuses on techniques that could predict user behavior while the user interacts with the Web (Cooley, 2000). Web usage data can be server access logs, proxy server logs, browser logs, user profiles, registration data, user sessions or transactions, cookies, user queries, bookmark data, mouse clicks and scrolls, and any other data as the result of interactions

Recently, Web usage mining (Srivastava, Cooley, Deshpande, & Tan, 2000) has been proposed as an underlying approach for Web personalization (Mobasher, Cooley, & Srivastava, 2000). The goal of Web usage mining is to capture and model the behavioral patterns and profiles of users interacting with a Web site. The discovered patterns are usually represented as collections of pages or items that are frequently accessed by groups of users with common needs or interests. Such patterns can be used to better understand behavioral characteristics of visitors or user segments, improve the organization and structure of the site, and create a personalized experience for visitors by providing dynamic recommendations. In particular, techniques such as clustering, association rule mining, and navigational pattern mining that rely on online pattern discovery from user transactions can be used to improve the scalability of collaborative filtering when dealing with clickstream and e-government data.

## WEB MINING TECHNIQUES IN E-PUBLIC SERVICES

For the implementation and successful operation of e-government, the proper design, which will be the basis in

*Figure 1. Application of Web mining techniques in e-government domain*



order to receive a series of strategic, administrative, and operational benefits, is necessary. The application of e-government in the public domain can be gradually performed in fourteen (14) levels (Markellou, Panayiotaki, & Tsakalidis, 2003). This allows the unobstructed flow of information from/to the public sector and gives the possibility not only to the citizens but also to the enterprises (private sector) to acquire better access in the services that state provides. One of these levels is the upgrade of portal with applications adjusted to every user, where Web mining techniques may be applied to improve access to information through the provided e-services (Markellou et al., 2004a; Markellou, Rigou, & Sirmakessis, 2004b).

Specifically, the deployment of Web mining in the e-government domain relates to the analysis of citizen behavior and the production of adequate adaptations. For example, given a specific citizen, the presentation of required information from an e-government portal can be tailored to meet individual needs and preferences by providing personal recommendations on topics relative to those already visited. This process is typically based on a solid user model, which holds up-to-date information on dynamically changing citizen behavior. This enables on-the-fly portal content assembly, addressing exactly what the citizen needs to know without wasting time on topics the user is already proficient or not interested in. The flowchart of this procedure is shortly illustrated in Figure 1. E-government application constructs users' profiles integrating various sources of data, pre-processes the data and applies Web mining techniques to provide the users with personalized Web experiences.

In order to personalize an e-government site, the system should be able to distinguish between different users or groups of users. This process is called *user profiling* and its objective is to create an information base that contains the preferences, characteristics, and activities of the users. In the Web domain, user profiling has been developed significantly, since Internet technologies provide easier means of collecting data about the users of a Web site, which in the case of e-government sites are citizens that must be satisfied by the provided services. A user profile can be either static, when the information it contains is never or rarely altered (e.g., demographic information), or dynamic when the user profile's data change frequently. Such information is obtained either explicitly (e.g., preferences, background, etc.) using online registration forms and questionnaires, or implicitly, by recording the navigational behavior and other users' actions from server logs, cookies, and so forth. User profiling is extremely useful to G2C (government-to-consumer) and G2B (government-to-business) applications. For example, a public authority, such as a Ministry of Finance and Economy, can customize its information/services concerning chemical and customs procedures to the relevant actors that import chemical goods. Using this aspect, the actors are facilitated in completing the necessary procedures without getting lost in the "maze" of information provided through a multi-field covering e-government Web site.

Another technique that can be used is the one of *clustering*. Page clustering identifies groups of pages that seem to be conceptually related according to the users' perception. User clustering results in groups of users that seem to behave similarly when navigating through a Web site. Such knowledge can be used in e-government in order to perform public services segmentation.

*Classification* technique can be applied after clustering in order to assign a new user to the defined groups. It uses features with high discriminative ability for defining the various profiles, for example, the profile of an active citizen may include the following values: Sex=male,

34<=Age<=40, Job=worker, Education= basic, MaritalStatus=marital, NumberOfChildren=4, and so forth. This knowledge can be used in applying personalization to e-government services and better supporting the needs of the users providing the right information, to the right people, at the right time.

For discovering relations between different types of available information in an e-government environment *association rules* can be applied. This technique may identify correlations between pages/users/services or other types of items, not directly connected and reveal previously unknown associations between groups of such items with specific similarities. The form of an association rule can be "65% of citizens that their MaritalStatus=marital search e-government portal for information about LifeEpisodes=having a baby" or "40% of the citizens who accessed help desk asked about online filling-in of tax returns and VAT." For example, the last rule may indicate that this information is not easily accessible or explanatory enough and requires redesign tasks from the portal technical group.

An extension of the previous technique comprises the *sequential pattern discovery* that can be used for revealing patterns of co-occurrence, which incorporates the notion of time. For example a pattern may be a Web page or a set of pages accessed immediately after another set of pages: "55% of new businesses who apply for a certain certificate will use the certificate within 15 days" or "Given the transactions of a citizens who has not apply for any information/services during the last 3 months, find all citizens with a similar behavior."

Finally, as search engines often appear as a helpful tool at e-government, *personalized Web search systems* may be used to enhance their functionality. In order to incorporate user preferences into search engines, three major approaches are proposed (Shahabi & Chen, 2003):

- **Personalized Page Importance:** Modern search engines employ the importance scores of pages for ranking the search results, as well as traditional text matching techniques.
- **Query Refinement:** A process composed of three steps: obtaining user profiles from user, query modification and refinement.
- **Personalized Metasearch Systems:** Metasearch systems could improve the retrieval rate by merging various ranked results from multiple search engines into one final ranked list.

## FUTURE TRENDS

On the road to enhance an e-government application and treat each user individually, personalization plays a central role. The benefits for both public authorities and citizens are significant when it really works. However, several issues still remain unclear. First of all, determining and delivering personalization is a data intensive task and requires numerous processing steps. This usually causes intolerably long response times, which in turn may lead to site abandonment. To avoid this constrain, parts of the process can be executed offline or special algorithms and structures can be used to guarantee fast online operation.

Another challenge is to ensure personalization accuracy. It is true that unsuccessful recommendations can slow down the process, confuse, and disorientate users. It is preferable not to deliver any recommendations than deliver a set of useless or harmful ones. Apart from that, personalization should be delivered in the appropriate way (avoiding user intrusion and loss of concentration) and not deprive users control over the whole process. Moreover, as e-government sites are dynamic environments, issues concerning the content or structure updating e.g. newly added topics, pages, services, etc. can be taken into consideration.

Last but not least, privacy violation during the user profiling process should be encountered (Volokh, 2000). Many users are reluctant to giving away personal information either implicitly as mentioned before, or explicitly, being hesitant to visit Web sites that use cookies (if they are aware of their existence) or avoiding to disclose personal data in registration forms. In both cases, the user loses anonymity and is aware that all of his actions will be recorded and used, often without his consent. Additionally, even if a user has agreed to supply personal information to a site, through cookie technology such information can be exchanged between sites, resulting to its disclosure without his permission. Although the new technologies and products for protecting user's privacy on computers and networks are becoming increasingly popular, none can guarantee absolutely secure communications. Electronic privacy issues in the foreseeable future will become highly crucial and intense (Markellos et al., 2004b).

## CONCLUSION

Governments enhance their attempt to offer efficient, advanced and modern services to their users (citizens and businesses) based on information and communication technologies and especially the Web. The remarkable acceptance of this powerful tool has changed the way of conducting various activities and offers citizens, businesses and public authorities limitless options and opportunities. However, the emerging problem to deal with is the way an e-government can provide its users with the right information and service according to their specific

needs and preferences. To this direction, Web mining and personalization are used for supporting tailored Web experiences.

These techniques appear as the most promising for the future, since they help to establish one-to-one relationships between users and governments, improve the performance of provided information and services, increase users' satisfaction and promote e-loyalty. On the other hand, governments take advantage of them, as long as they save costs (e.g., transactions, communication, task management, etc.), improve response times, automate various processes, provide alternative channels of cooperation and communication, and upgrade and modern their profile and image.

Many research and commercial approaches, initiatives and tools are available, based on Web site structure and contents, user's navigation, behavior and transaction history, server log files, and so forth. However, personalization requires rich data in order to provide successful output. This is not always feasible, since many users are often negative towards the idea of being stereotyped. Moreover, individuals' privacy has been put in jeopardy by the tasks of recording their activities and saving the appropriate data into their profiles. Summarizing, governments should work hard in the direction of providing the legal framework for ensuring the protection of users' privacy and also eliminating the possibility of misuse their personal information.

## KEY TERMS

**Clickstream:** It is a record of a user's activity on the Internet, including every Web site and every page of every Web site that the user visits, how long the user was on a page or site, in what order the pages were visited, any newsgroups that the user participates in and even the e-mail addresses of mail that the user sends and receives. Both ISPs and individual Web sites are capable of tracking a user's clickstream.

**Cookie:** The data sent by a Web server to a Web client, stored locally by the client and sent back to the server on subsequent requests. In other words, a cookie is simply an HTTP header that consists of a text-only string, which is inserted into the memory of a browser. It is used to uniquely identify a user during Web interactions within a site and contains data parameters that allow the remote HTML server to keep a record of the user identity, and what actions she/he takes at the remote Web site.

**Data Mining:** The application of specific algorithms for extracting patterns (models) from data.

**Knowledge Discovery in Databases (KDD):** The nontrivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data.

**Server Log:** Web servers maintain log files listing every request made to the server. With log file analysis tools, it's possible to get a good idea of where visitors are coming from, how often they return, and how they navigate through a site. Using cookies enables Webmasters to log even more detailed information about how individual users are accessing a site.

**Web Mining:** The discovery and analysis of useful information from the Web.

**Web Personalization:** It is the process of customizing a Web site to the needs of specific users, taking advantage of the knowledge acquired from the analysis of the user's navigational behavior (usage data) in correlation with other information collected in the Web context, namely structure, content and user profile data. Due to the explosive growth of the Web, the domain of Web personalization has gained great momentum both in the research and the commercial area.

**Web Usage Mining:** The application of data mining techniques to Web clickstream data in order to extract usage patterns.

# Web Sites for Senior Citizens

## INTRODUCTION

In the information era, the main source of productivity lies in the technology of knowledge generation, information processing, and symbolic communication (Castells, 1996; Van Dijk, 1999).

As Rifkin (2000) observed, it raises a service industry that substitutes the material economy, and the wealth relations are decided in the arena of the access and correct exploitation of these services.

For sociological scientists, the biggest challenge is to overcome the classical sociological concepts of knowledge gaps (Tichenor, Donohue, & Olien, 1970) and the digital divide, often technologically determined, aiming at investigating the social and cultural problems that obstacle elderly people, housewives, and many other social groups in using the Internet and making it useful for daily life. We need to make the cultural codes available for using new media through remediation work (Bolter & Grusin, 1999) linking digital languages to the main communication practices and media languages.

## BACKGROUND

The purpose of this article is to activate thoughts and valuations about cultural codes, fruition practices, usability problems, and affordances (Norman, 1988) that we have to consider when we project contents and services for elderly citizens.

Using ethnographic methods in order to understand daily practices without research bias (Silverstone, Hirsch, & Morley, 1992), we have investigated which content areas cause a real interest in the elderly and which ones should only be considered as false needs related to social pressure (Punie, 1997).

This work derives from a qualitative research developed in Turin, Italy, along with the Onlus Pari_go (www.pari-go.org), which was aimed at investigating the relationship between new technologies and the elderly in terms of access and content. The research was carried out thanks to the collaboration of 72 elderly people (44 women and 28 men) all over 60 years old living in a suburban area of the city.

The research integrated different qualitative methods:

- focus group in order to investigate everyday lives, needs, and expectations of the elderly about the Internet
- camera surveys and documental analysis of photos, diaries, and drafts about the relationship of the elderly with new technologies
- follow-up in-home interviews
- participatory observation during Web sessions in order to evaluate interaction experience

During the year, we also used participatory design tools (Laurel, 2003) in order to stimulate the direct contribution of the elderly in creating new solutions.

The recruitment was made using the snowball method (Silverman, 2000).

The object of the research aims at the following:

- to recognize key factors influencing how older people approach new technologies
- to define guidelines for enhancing the interaction, interface, and content design of Web sites aimed at this particular target group

The results of the study are not representative at the level of the whole category, but they offer the possibility of a critical analysis of the implementation of future Web platforms for elderly people, and of observing future developments.

## INTERACTION DESIGN

### Fear to be Wrong

One of the first problematic aspects that came out during the sessions was older people's fear of experiencing the new.

Contrary to new generations, which have grown up with video games, the elderly have abandoned the trial-and-error approach, the exploration of the world through unplanned manipulations of objects (Turkle, 1996). In so doing, gradually they have inhibited their skills for tack-

*Figure 1. How to come back from one window to the last one*

ling the new and dealing with it; meanwhile, children and young people use play to explore the world around them, to construct and dismantle, and to experience and to develop new skills without fears or regrets.

As we grow older, the fear of making mistakes, damaging something, or simply handling new technological devices become a frequent condition.

Often, older people fit into a rigid behaviour pattern: They are convinced that the only approach to using new technologies is through the instruction manual. That means learning the rules systematically in a standardised and impersonal way.

The proposed solution to this problem is experiencing interaction by playing with new technologies.

This approach can be introduced on two levels:

- at a teaching level, promoting personal styles, methods, and rhythms of learning
- in the production phase, designing accessible interfaces to encourage interaction and to reduce frustration, creating friendly error messages, and enabling people to reach the same goals even by different sequences

## Remediation of Other Media

During the research, we found a second problem; domesticated (Silverstone et al., 1992) to the idea of the TV screen and printed page, elderly people find it difficult to deal with the window concept: several pieces of information on the screen at once, which can be opened, closed, moved, or resized.

Older people have more difficulties with the PC (personal computer) brainframe (De Kerckhove, 1991) because they are used to monotasking, fixed, push-content windows as on the TV screen. For example, surfing on the Web site of a famous football team, users have been submerged by multiple windows, which opened at each click.

The capacity of concentration and memory are two recurrent problems among the elderly; in fact, dealing with parallel contents distributed in several windows generates stress and frustration, as well as orientation problems.

When the contents appear in a new page and the last one is reduced to an icon, many elderly people feel they have lost their place and cannot get back to previous pages using the back arrow in the browser.

Another aspect, which has proved to be difficult to acquire instinctively, is dealing with the scrolling windows. In fact, when the window is wider or longer than the screen, the elderly tend not to explore them.

Furthermore is the problem of the multitasking approach, in particular, the use of the windows icons in the status bar.

When designing interfaces, some tips include the following:

- eliminating multiple windows and pop-ups
- reducing the multitasking approach and making the interaction more linear
- designing clear graphic layouts
- reducing scrolling pages or making it clear that the visual pattern is longer than the page

## Consistency

The problem of the consistency of the interfaces, as defined by usability theories (Nielsen, 2000), is very important for older users.

In particular, dragging the mouse to move on the screen, double clicking to open a program icon, typing a Web-site address in the browser bar, or filling in a form is another hot issue.

For older people, putting the mouse in the correct position in the empty space and then using the keyword to insert the data requested was a difficult task.

Some tried to type without positioning the cursor in the blank area. Others wanted to type the name of a folder instead of looking for it with the mouse.

The action of sending data is also conflictive. Often, they feel disoriented and hesitate to decide if using the "send" arrow or clicking on the relative link.

Two-click interaction implies a strong effort for people with arthritis or hand deficiencies. Furthermore, it is not intuitive to decide when it is necessary to use one click or to double click.

During the research phase, a lot of time was spent training them to use the double click.

*Figure 2. Click responses not evident*

As Explorer 5 implemented it, experience suggests going back to one click as the unique interactive paradigm to open an application or activate a link.

Some useful tips for overcoming this situation are considering the use of one device (mouse or keyboard) and one interactive system (GUI [graphical user interface] or menu) instead of a mixed-interaction system.

It is better to adopt the following:

- graphic interfaces using icons and the mouse if no forms are to be filled in
- menu interfaces, accessible from the keyboard, if the Web site contains large spaces for writing text
- in the case of interactive digital TV, simple remote-control navigation systems
- the overcoming of the one-click-two-click dichotomy

## Evident Visual Response to Commands

One of the main problems that emerged during the research sessions regards the folder interfaces: In this case, when the user clicks one item of the menu, the content appears in a specific frame of the same page. For inexperienced users, the page seemed to remain unchanged for both menus and contents.

For example, when using the folder interface of http://www.anziani.it, by clicking on the different items of the folder, the only changing area is the center area. It is a response not sufficiently visual for older users who often do not catch the effect of the click.

From the research sessions, it emerged that it is not clear why the same action sometimes produces a different result; for example, clicking on a particular link sometimes proposes the content in the same page and sometimes opens a new one. The elderly find such inconsistency stressful. Designing for an older target implies simplifying and making the responses to commands evident in order to give immediate feedback and reassure them regarding the efficacy of the interaction.

## CONTENT DESIGN

In this phase of research, we investigated what older people imagine, and what they would like and expect to do with the Internet: what kind of information, contents, and services they feel they need. The content analysis was carried out considering two aspects:

- benchmarking and mapping existing Italian Web sites targeted at the elderly
- comparing real applications with the projection of the needs of the work group regarding the Internet

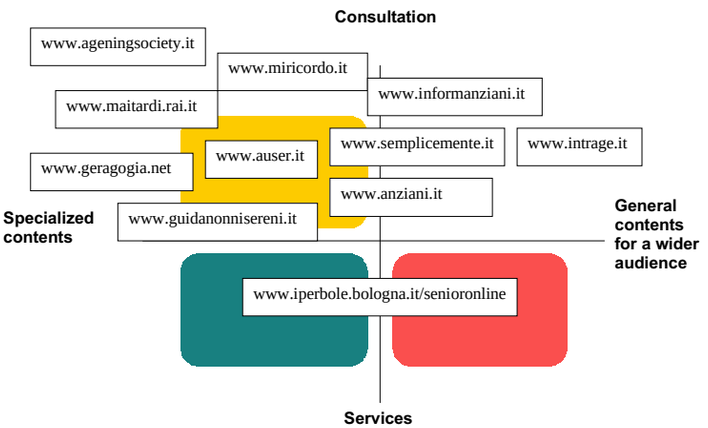
In the benchmarking phase, an evaluation grid was defined in order to identify the availability of information and services, and the availability of general or specialist content for the target.

In identifying the sample Web sites to be examined, we only considered sites targeted specifically at the elderly. The sample does not include company Web sites, which use the Internet as a promotional media offering services to older people.

As Figure 3 shows, the majority of existing sites supply information while the service sector is almost totally neglected.

Examining the area of specialist information and contents in detail, it appears that recurrent topics concern health services, assistance, and the prevention and cure of ailments of old age. After analysing the actual offer of Italian Web sites targeted at the elderly, we started investigating what contents were suitable and desirable for them.

*Figure 3. Map of Web contents for older people in Italy*



To make the task easier, we proposed this diagram (see Figure 4) with the aim of showing, describing, and discussing the different areas and functions of the Internet with the group.

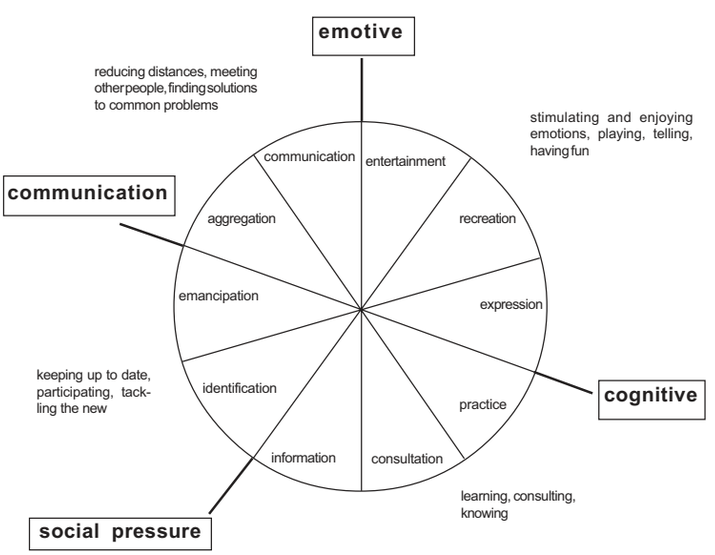
Four areas were considered:

1. **Relationship Functions:** They include activities aimed at reducing distances, meeting other people, finding solutions to common problems, and creating networks of knowledge.
2. **Emotive Functions**: That is, activities aimed at stimulating and enjoying emotions, playing, telling, and having fun
3. **Cognitive Functions:** Concern learning, consulting, and knowing
4. **Identification Functions:** Related to keeping up to date, participating, and tackling the new

The participants showed a preference for expressing their own creativity, for example, in sharing with others their experiences, poetry, pictures, tales, and so on rather than consuming prepackaged activities.

Almost everyone expressed the preference to use the Internet to enhance their access to information. They identified the time factor as the key element in accessing

*Figure 4. Textual proposal*



information, which is a discriminating factor between one citizen and another.

As well as the information services, people requested more interactive services, in particular, for dealing with bureaucracy, making health appointments, and obtaining personal advice and services. In our research, older people are less interested in the Internet from the socializing point of view. For communicating or meeting people, they think of it as the last resort, indicated only for those who have serious problems of mobility or social relations.

Physical contact and relationships are considered by elderly people to be too important to substitute with virtual experiences.

It is therefore being left aside in favour of higher priority contents.

In the same way, the sample group did not seem particularly attracted to the use of the Internet as an entertainment media.

The reason for this seems to be associated with the cost: Compared to radio, magazines, or television, the Internet connection time is thought to be expensive for what it offers.

On the information side, they would prefer more local information channels, allowing them to enjoy the rich opportunities that the territory offers and managing to bypass the traditional media, which often underline only the sensational aspects of news.

In short, they are asking for a Web site where they can easily find information and news regarding training courses, voluntary work, occasions for socializing, and so forth.

They are definitely interested in the local scene more than the broader one.

## INTERFACE DESIGN

The last step of the research was the interface design.

Using participatory design methodologies, through storyboard sketches and prototype trials, we have realized two prototypes for the graphical interface and proposed it to the participants during the focus group.

The group was invited to discuss, comment, redesign, and add images or contents to the prototypes by using mock-ups, photos, and oral and written comments, and by activating their nonspecialist competences during the exploration of the interfaces.

In the first proposal, all the menu voices are clearly expressed by textual labels: The use of images and decorations is reduced and, on the contrary, all the menu voices have a clear and unambiguous informative function.

The site is divided into four content areas according to the previous phase of the definition of contents and functions useful and desirable for the target.

The four sections are as follows:

- Information (local events, travel opportunities, local news)
- A Bit of Us (memoirs of the city, arts and crafts space)
- Easy City (health, tax, pensions, mail, public transports)
- Proposals to the local government

In this interface, the goal is to reduce the ambiguity and allow information retrieval as quick and efficiently as possible.

The contents are clearly structured by lists, and the user can search and browse them using the simple model of the data-author-title catalogue.

Also, the navigation bar is expressed by clear and extensive textual labels: Instead of the simple label "Back," we have, for instance, "Back to the previous page." Instead of the simple menu label "Insert" or "Add," we have the complete instruction "Insert a new novel."

The whole content unit is contained in the frame of the screen, without horizontal or vertical scrolling. The hypertextual complexity of the text is reduced in order to favour a linear fruition of the Web site.

*Figure 5. Visual proposal*

*Figure 6. Info visualization according to the practical experience of the town*

*Figure 7. Info visualization according to the practical experience of the town*

In the second proposal, the same typologies of contents as the first prototype are presented through metaphors (Sherson, 1999) and a visual approach (Shneiderman, 1998): The user moves the mouse on the four images in order to see the relative menus. A funny and evocative interface allows one to discover the thematic areas of the site by playing with the metaphorical meanings of the images (flowers for the artworks of the elderly, a window for travel, a bench for news and events, and the "well of desires" for proposals).

For example, in the Events section, the retrieval of the information, in spite of being presented by the data-author-title catalogue, is visualized by a map of the territory and strictly coordinated to the local knowledge of the geographical context. The information is not modelized in abstract schemes but follows an emotional design that links the abstract information to the local experience of the users.

The two proposals are supposed to give two different approaches to interaction: In the scheme, the opposite categories that the two interfaces want to suggest are summarized (see Table 1).

The last dichotomy, the present and future vs. the past, is due to the cultural brainframe of elderly people: If the first proposal represents textual and linear information retrieval, typical of the Web sites and the new-generation approach, the second proposal is based on images and on a visual approach, typical of nonalphabetical media, such as TV and popular magazines, much used by the elderly.

## FUTURE TRENDS

During the research, many interesting suggestions for future works arose.

Despite the fact that the majority of the elderly had evaluated the content proposal as being more accessible in terms of navigation and information retrieval, all the participants judged the visual interface as more attractive and desirable.

*Table 1.*

| Proposal 1: Rational | Proposal 2: Emotional |
|---|---|
| Writing | Image |
| Semantic | Analogy |
| Strictness | Metaphor |
| Awareness | Immersion |
| Functionality | Play |
| Information | Entertainment |
| Present/future | Past |

They considered the emotional proposal more original than the first one, judging the visual approach as being more innovative than the "classical" menu browsing.

After a long discussion, the elderly decided to choose Proposal 2 because of the following:

- In their opinion, the desirability value is more strategic than the usability value.
- They wanted a strong and original characterization of the Web, not to be confused with the typical generalist interfaces.
- The use of animated images is more difficult to understand than textual menus, but it allows one to overcome the fear of the interface by suggesting that the user play with it.

The use of English terms, nowadays common in media language (e.g., *news*, *mail*, *Web*, etc.), is often not understood by the elderly: Their suggestion is not to erase them, but to include the Italian translation in brackets in order to allow them to upgrade their language, favouring their inclusion in the future communication system.

This is a strong signal of their attitude to innovation: They do not want access to a simplified reality, but want to have simple and personalized tools for dealing with the complexity of the new media society.

## CONCLUSION

We have analysed up to now the main problems and proposed solutions to build accessible and appealing Web sites for elderly people.

Nevertheless, the first indication that comes out from the target group regards the approach to new technologies.

Older people confirm the absolute need of structured programs to approach new technologies in terms of the following:

- easier access to the acquisition of PCs
- Internet points close to local communities, in particular, in places where older people generally meet

- digital helpers meant as volunteers (young people or peers) to guide and assist the older people
- simple training courses just to get over the initial fear

## KEY TERMS

**Affordance:** Norman (1988) defines affordance as a property of an object, or a feature of the immediate environment, that indicates how that object or feature can be interfaced with.

**Brainframe:** According to De Kerckhove (1988), technologies and techniques of cultural transmission shape the brain functions, modifying perceptions of the world, behaviours, beliefs, and social constructs. The author has identified three types of brainframe: alphabetic, video, and cybernetic.

**Domestication:** In Silverstone et al. (1992), it is the capacity of individuals, families, households, and other institutions to bring new technologies and services into their own culture to make them their own. Domestication concerns the learning of skills, practice, and the construction of meaning.

**GUI (Graphical User Interface):** A user interface based on graphics instead of text.

**Pull Contents:** Classical approach to Web information in which the user actively reaches the contents by seeking them through search engines or by surfing the Web.

**Push Contents:** News and information are pushed from a broadcast server to a client player. Push technologies can be used to deliver personalized and updated contents to screens without the user asking for it.

**Remediation:** As Bolter and Grusin theorized (1999), the term means the formal logic by which new media refashion prior media forms. Through immediacy and hypermediacy, remediation is one of the most important traits of new media.

# Web-Based Information System at the Brazilian Ministry of Finance

**Alexandre Tabosa Trevisani**
*Ministry of Finance, Brazil*

**Ronaldo Zwicker**
*University of São Paulo, Brazil*

## INTRODUCTION

The current standard of global economic growth incorporates a disposition to undertake investments in information technology that will provide public organizations with costs reduction processes and an increase in flexibility and efficiency. The Internet technology is an outstanding case that quickly occupied a significant and increasing importance relative to the changes that are occurring at the economic and social environment. The institutional presence of the government on the Internet evolved from a simple channel to furnish information to an instrument able to aggregate, to the consolidated communication ways, new forms of relationship and supply of services to the citizen (Takahashi, 2000). This coincides with a global tendency to transform simple informative Web sites in complex transactional systems, configuring a new model to collect and distribute information (Isakowitz, Bieber, & Vitali, 1998; Marche & McNiven, 2003).

It should be considered that many times the technological infrastructure and human resources capability of the government vary widely, depending on the geographical region of the country. In function of this, the internal systems, which give support to the operation of the government machine, can be benefited through the use of Web technology, if they are inserted in the resources sharing and access distribution paradigm (McLean, 1999). Web applications development of internal scope can keep little direct relation with the universal access of citizens to public services, however, can represent the universal access to scarce resources by geographical and socially dispersed government representations.

This article reports an experience of Web technology use along the deployment of an internal Web-based information system (WIS) at a Brazilian government agency. The importance of the technology is emphasized as evidenced through development rapidity, distribution economy, and operational simplicity of the developed system. Broader reflexes that reach the citizen are also discussed.

## BACKGROUND

At the beginning of 2001, the Brazilian Ministry of Finance came across the possibility that frauds could be in course, involving civil servants who worked in its payroll administration. This fact could seriously affect the government's credibility and would certainly contribute to increase the population's disbelief in the public administration.

On that opportunity, the Human Resources Coordination of the Brazilian Ministry of Finance assigned a singular task to a group of civil servants who, at that time, worked as software developers or network supporters. The job was to develop a system to register the presence of retired civil servants so that they could demonstrate they were alive. This was necessary because some people could be taking advantage of the situation by pocketing the pensions of deceased civil servants as if they were alive. The task was a particularly challenging one because of the following reasons:

a. The system would have to work in every state of the country regardless of the available infrastructure. This was a critical point, because some states were well known for their lack of up-to-date equipment, although all states were well served in terms of a countrywide network structure.
b. The system's features should have an impact on the ever-watchful press, but above all, it should be capable of keeping people who plan to fake the process from succeeding in doing so. It was suggested that a digital picture should be obtained from the beneficiary. The system also should be able to consolidate real-time information about all records across the country in a single report, to which the coordinator ought to have access.

c. There were severe budget restrictions to buy hardware and software licenses, as well as to hire advisory services.
d. The system should be developed and implemented as quickly as possible. Initially, a 4-month deadline was set.
e. The pensioners should be summoned by mail to present themselves to the nearest Ministry of Finance office.

The Ministry of Finance has offices in every state of the country. In each state there are main offices in the capitals, as well as offices in other cities. All of these are connected by means of a single Wide Area Network furnished by a government company that provides communication and networking support. In principle this fact could enable some kind of solution based on a central system accessible from almost any place in the country via Internet protocol communication.

The work group was formed and formally designated to study, evaluate, and propose a solution. The technical knowledge of the members of the group included some expertise on client-server applications using Microsoft Access, query building via SQL, LAN management, and SSL/HTTPS secure connections. There were also some experts in human resources law to provide support for the definition of the system with regard to legal aspects and restrictions.

The secretariat of Planning, Budget and Administration of the Ministry of Finance, in the person of its General Coordinator, provided the political sponsorship for every necessary action approved by the group. The only real limitation concerned the acquisition of hardware, software licenses, and advisory services. Everything should be done with the available hardware and software resources and the group should find the solution on its own.

It was possible to use four high-performance servers with network operating system licenses (Windows Server 2000) and two Microsoft SQL Server licenses. As the group was formed by members from different states in the country, some travel expenses were assured for periodic group meetings. However, most of the work should be conducted through long-distance networking.

## ASPECTS OF DEVELOPMENT

In fact, the system requirements were very simple. There were basically two critical transactions:

a. Send the beneficiary's digital picture to a file repository; and
b. Register the beneficiary's presence in a database and print a sort of "voucher" or "receipt" with his or her picture.

Brazilian law, in some cases, allowed the beneficiary's presence to be registered by a legal representative.

The available infrastructure, the resources, and mainly the know-how of the group indicated the development of a client-server application based on Visual Basic/ Microsoft Access. This option was convenient due to the sound expertise of some of the members of the group in this area and the possibility of placing the system, on the server side, in reliable machines and in a very secure and redundant environment. But this kind of solution also suffered a major drawback: the client-side system would have to be installed in every workstation in which it would be required to run. This would bring about three problems:

1. Much money would be consumed for travel.
2. It was likely that many machines would present a performance insufficient to run the system.
3. Every system upgrade would have to be distributed to all the workstations in order to update them as well. As the system was meant to be developed very quickly, many bugs were expected and frequent update operations at every workstation seemed unfeasible.

In view of the above, it was proposed that a Web-based system should be developed and located in the same secure and redundant environment. The difficulty in adopting this solution was that no member of the group had any experience in the development of this kind of system. Nonetheless, easy access from anywhere in the country to a system of this sort, the fact that no installation and no updates would be necessary at the workstations, and the modest hardware required for running a single Internet browser meant this alternative was the most viable solution. In fact, some authors have foreseen that Web-based systems will change the way in which governments, which are widespread organizations, will come to distribute and collect information (Isakowitz, Bieber, & Vitali, 1998). There was also a certain pressure from the environment concerning the efforts undertaken by the Brazilian government to increase the importance of e-government services and digital inclusion projects, almost all of which were based on Web technologies.

Some members of the group, however, resisted the adoption of the Web technology, considering it weak, unsafe, and limited in terms of resources. Yet another issue was raised in order to persuade them: the shortage of time and money to provide adequate user training. The

argument was that a Web system would be more easily assimilated by users, in the same way as any new entertainment Web site might be. Dennis (1998) also mentions this kind of expectation, that is, the belief that users learn to use Web information systems by trial and error. However, he states that this expectation has been proven generally wrong and that formal training is a critical factor for the success of a Web-based system. Therefore, this was a risky argument.

The next step consisted of choosing a low-cost but high-efficiency software platform on which the system, based on a transactional Web site, could be built. Indeed, the most substantive and effective documentation that could be found easily on the Internet concerned the PHP (Hypertext Preprocessor) language. The language seemed to be suitable to work as a dynamic HTML page generator and as a link between that kind of interface and the MSSQL Server. Additionally, the software necessary to support it was free, which fulfilled the requirement of not purchasing any software licenses. Therefore, the platform chosen was the "PHP + MSSQL Server 2000 + IIS 4.0" triad.

The workgroup was divided into five subgroups to care for the following:

a. Interface and transactions development
b. Database modeling and administration
c. Servers and network management
d. User's manual and system documentation
e. Legislation analysis

This division showed itself almost fully coherent with the argument of the "separation of levels" proposed by Merialdo, Atzeni, and Mecca (2003), according to whom Web site design should be split into three levels: the data level, the hypertext level, and the presentation (layout) level.

Although information systems development is an issue that has been studied for the last 3 decades at least, none of the methodologies proposed in academic studies was adopted by the group. Furthermore, Web systems call for certain features that are quite different from those of traditional information systems and therefore pose new managerial and technical challenges (Isakowitz, Bieber, & Vitali, 1998). As a result, the entire system was developed in the absence of systematic approaches and rigor, relying merely on the knowledge and experience of the developers. As observe by Gellersen and Gaedke (1999), this approach to Web systems development embeds risks and indeed had unfavorable reflexes at the developed system.

The first version of the system was developed in 2 months and the state of São Paulo was chosen as the testing context. Ten centers were chosen to receive the pensioners: the state capital and nine other cities. All pensioners of the state were summoned to present themselves to the chosen center nearest to them. Some pensioners had to travel up to 100 km, but 93% of them lived in one of the cities defined as a center. Older pensioners (80 or more years) were visited in their homes, where their data and picture were collected for subsequent input into the system. A group was appointed to input the registrations into the system. Part of it stayed full time at the state capital, while the rest spent 3 to 5 days in each center.

The system showed itself to be successful in terms of ease of use for the operators and convenience for the pensioners. Some compliments were made and no claims were addressed by pensioners to the agency ombudsman. Although to date no specific study has been conducted, the entire process clearly determined an increase of people's trust in this particular segment of public administration.

The decision taken after this test was to adopt the system throughout the country in the following year (2002). The system then started with 284 users, running in Brazil's 25 capital cities on a full-time basis, and at 84 centers for 3-to-10-day periods. The final total was about 60,000 records in the system.

The latest report produced by the general coordination of human resources dates from 2003. It shows the registration of 61,638 pensioners from a universe of 65,973. The 4,335 who were not registered had their situation closely verified. From these, 915 cases were, in fact, proven to be frauds and the "pensioners" had their payments suspended. The sum of about US$6,700,000.00 per year was (and since then it continues to be) saved thanks to the Web-based process (Finance Ministry, 2003). Table 1 shows the detailed results achieved for that year.

## FUTURE TRENDS

Certain issues are still to be discussed, such as fine-tuning the information system and the process as a whole. First, a survey should be conducted in order to check on the satisfaction of users and pensioners. Afterward, the codes should be reviewed and documented from a methodological point of view, so that system continuity can be assured. Then an upgrade could be considered for improving identification, eventually using biometrical technology, and in terms of operating the system through the Internet, so that electronically certified and identified pensioners could perform the registration task in their own homes.

*Table 1. Estimated savings in 2003*

| State | Summoned | Registered | | Not Registered | | Frauds | Yearly savings |
|---|---|---|---|---|---|---|---|
| | | absolute | % | absolute | % | (1) | (2) |
| Acre | 4,734 | 4,198 | 88.7% | 536 | 11.3% | 2 | 24,000.00 |
| Alagoas | 796 | 765 | 96.1% | 31 | 3.9% | 2 | 24,000.00 |
| Amapá | 5,522 | 5,059 | 91.6% | 463 | 8.4% | 2 | 24,000.00 |
| Amazonas | 356 | 352 | 98.9% | 4 | 1.1% | 2 | 24,000.00 |
| Bahia | 1,533 | 1,431 | 93.3% | 102 | 6.7% | 20 | 240,000.00 |
| Ceará | 1,430 | 1,362 | 95.2% | 68 | 4.8% | 63 | 756,000.00 |
| Distrito Federal | 3,674 | 3,485 | 94.9% | 189 | 16.5% | 178 | 2,136,000.00 |
| Espírito Santo | 983 | 968 | 98.5% | 15 | 1.5% | 2 | 24,000.00 |
| Goiás | 752 | 698 | 92.8% | 54 | 7.2% | 2 | 24,000.00 |
| Maranhão | 541 | 515 | 95.2% | 26 | 4.8% | 2 | 24,000.00 |
| Minas Gerais | 3,214 | 3,115 | 96.9% | 99 | 3.1% | 87 | 1,044,000.00 |
| Mato Grosso | 286 | 286 | 100.0% | 0 | 0.0% | 0 | 0.00 |
| Mato Grosso do Sul | 369 | 364 | 98.6% | 5 | 1.4% | 5 | 60,000.00 |
| Pará | 734 | 705 | 96.0% | 29 | 4.0% | 5 | 60,000.00 |
| Paraíba | 689 | 657 | 95.4% | 32 | 4.6% | 5 | 60,000.00 |
| Paraná | 1,959 | 1,894 | 96.7% | 65 | 3.3% | 62 | 744,000.00 |
| Pernambuco | 2,657 | 2,562 | 96.4% | 95 | 3.6% | 77 | 924,000.00 |
| Piauí | 512 | 510 | 99.6% | 2 | 0.4% | 2 | 24,000.00 |
| Rio de Janeiro | 18,193 | 17,272 | 94.9% | 921 | 5.1% | 2 | 24,000.00 |
| Rio Grande do Norte | 582 | 497 | 85.4% | 85 | 14.6% | 7 | 84,000.00 |
| Rio Grande do Sul | 2,111 | 2,023 | 95.8% | 88 | 4.2% | 21 | 252,000.00 |
| Rondônia | 4,401 | 3,985 | 90.5% | 416 | 9.5% | 3 | 36,000.00 |
| Roraima | 2,501 | 1,797 | 71.9% | 704 | 28.1% | 2 | 24,000.00 |
| Santa Catarina | 733 | 710 | 96.9% | 23 | 3.1% | 2 | 24,000.00 |
| São Paulo | 6,155 | 5,937 | 96.5% | 218 | 3.5% | 4 | 48,000.00 |
| Sergipe | 556 | 491 | 88.3% | 65 | 11.7% | 2 | 24,000.00 |
| **TOTAL** | **65,973** | **61,638** | **93.4%** | **4,335** | **7.2%** | **561** | **6,732,000.00** |

(1) Verified among non-registered pensioners
(2) Based on average benefit of US$ 1,000.00/month

## CONCLUSION

This particular case history encompasses certain issues that can eventually be identified and compared with studies that have been carried out about public administration, e-government, and Web technology use. The case shows one small example of how one government agency is expanding its use of Web technology from simple informational Web sites toward more complex systems that configure a new paradigm for collecting and distributing information, which conforms to the perspective of Marche and McNiven (2003). Also the goal to internally develop a system adapted to the restrictions of lack of resources and local infrastructure was fully attended. The case shows how simple solutions made possible the development of the system and how the Web technology contributed decisively to the success of the project.

The good performance of the information system seems to have led the pensioners to trust much more of the entire process and it produced, above all, substantial savings in government expenditures, as a result of old frauds being discovered and new ones prevented. According to Vigoda and Yuval (2003), we can say that the system constitutes an effective causal agent for a government's improvement.

The group responsible for the definition, development, and implementation of the system consisted only of civil servants. None of the members had a formal background in Web technology and no technical support was hired due to budget restrictions. This resulted, along all system development steps, in a lack of methodology, formalism, and reliance on the group's knowledge and experience. Although the system continues to work, to this day it lacks documentation and its maintenance is performed solely by one of the members of the original group.

It is interesting to observe that the system characteristic of being spread over inner-state cities shows one way in which governments can shift their focus of governance toward a relationship with citizens. This is an example that makes clear the new role of technology in public administration (Ho, 2002). The system also seems to fit an e-government approach regarding one of the issues typified in Anttiroiko (2003), that is, to be dealt with in political communities.

Finally, the extension of the model proposed in this case can be considered to the entire Brazilian social security system, actually affected by many managerial and process problems. A huge effort should be undertaken in advance to digitally include a large mass of pensioners. This certainly would contribute a very significant step toward the consolidation of Brazilian e-government practices.

## KEY TERMS

**Beneficiary:** Pensioner, the person who receives retirement or pension wages.

**Digital Inclusion Projects:** Actions taken by governments for making information technologies available to all citizens.

**Informational Web Site:** The Web site that provides read-only information, not performing any "insert" or "update" interaction with a database.

**Internal Systems:** Systems that give support to the operation of the government machine.

**Resources Sharing:** Allocation of the same resources to multiple users.

**Traditional Information Systems:** Systems based on classic mainframe or client-server approaches, making no use of Internet browsing or Web services.

**Transactional Web Site:** The Web site that works as a true information system, that is, it provides information and performs "insert" and "update" transaction over a database.
