Dimitri Ivanovski *using* ***Chamberland****'s bacteriological filter (1884) explained the infectiousness of tobacco mosaic disease (1892) by showing it can be transmitted via cell-free filtrates from leaves of diseased plants to leaves of healthy plants. Thus the term 'filterable virus' was coined; later filterable was dropped and 'virus' took on its modern meaning.* ***F. Loeffler*** *and* ***P.Frosch****'s work on foot-and-mouth disease first demonstrated (1898) an animal disease in which a virus was the causative agent. Yellow fever was the first human disease proved (1901) to be caused by a filterable virus by* ***W. Reed****.*

During the 1890's increased knowledge of soil and water bacteria was responsible for completion of the nitrogen, sulfur and carbon cycles. Nodule-forming bacteria living in the roots of leguminous plants were found to fix atmospheric nitrogen. As a result of ***Winogradsky****'s and* ***Beijerinck****'s work on anaerobic bacteria, knowledge of a whole world of organisms able to live on elementary nitrogen, iron or sulfur has emerged.*

Evolution Theory, Darwinism and Mendelian Genetics

The first broad theory of the transmutation of organic forms was by ***Jean-Baptiste Lamarck*** *(1800–1809). He advanced the idea that the simplest forms of life had been* spontaneously *generated and that from there all other forms of life had been successively produced.*

Lamarck explained organic change as the result of two factors: the 'power of life', which was responsible for the general scale of increasing complexity formed by the different animal classes; and the influence of particular environments, accounting for the fact that species and genera could not be aligned in a single series [natural order]. Explaining how animals change in response to different environments Lamarck affiliated himself with the idea of the inheritance of acquired characters. *In his view, animals responded to environmental changes by developing new habits, leading to changes in the animals' structures which were then passed on to offspring. It took many generations for the effects of this to become appreciable.*

Lamarck had relatively little evidence for his theory beyond the structural similarities among living things. He believed the earth's age to be immeasurably greater than his predecessors had supposed, a prerequisite for any theory of the gradual change of living things over time. In Lamarck's day, however, the study of fossils, a primary impetus for enlarged views of the earth's antiquity, could not confirm the reality of evolution. Opponents such as ***Georges Cuvier*** *argued the fossil record did not reveal the translation between forms that theories such as Lamarck's demanded. Also Cuvier's system of classification, identifying four fundamentally different types of animal organization, denied a chain of being and hence the idea of linear progression central to Lamarck's thinking.*

In 1813, **William Charles Wells** *produced essays assuming that there had been evolution of humans, and recognized the principle of* natural selection. ***Charles Darwin*** *and* ***Alfred Russel Wallace*** *were unaware of this work when they jointly published the theory in 1858, but Darwin later acknowledged that Wells had recognized the principle before them.* ***Augustin de Candolle****'s natural system of classification laid emphasis on the "war" between competing species.*

By 1833 the geologist **Charles Lyell** *in the second volume of his* Principles of Geology *had set out a gradualist variation of creation beliefs in which each species had its "center of creation" and was designed for the habitat, but would go extinct when the habitat changed.*

*Lamarckism became discredited as experiments simply did not support the concept that purely "*acquired traits*" were inherited. The mechanisms of* inheritance *were not elucidated until later in the* 19^{th} *century, after Lamarck's* death. Lamarckism in toto has largely been discredited as a mechanism in evolution.

Although paleontologists and embryologists' evidence appeared to confirm the reality of evolution, its mechanism remained unresolved at the end of the century, being vigorously debated by proponents of neo-Darwinism, neo-Lamarckism, orthogenesis and other views. Darwin had not explained the causes of variation or the means by which characters are passed on from one generation to the next. Without an adequate theory of heredity it was unclear how important natural selection was in the evolutionary process. For example, inheritance of acquired characters might account for the creative side of evolution, leaving natural selection with merely the negative function of weeding out the unfit.

Though in retrospect it appears that what Darwin lacked was the theory of particulate inheritance proposed in the 1860's by **Gregor Mendel**, when Mendel's work first came to be appreciated in 1900 people saw it as an alternative rather than complementing Darwin's theory. The three Mendelians most interested in evolution, **Hugo de Vries**, **William Bateson** and **Wilhelm Johannsen**, were all highly critical of the theory of evolution by natural selection.

Thus, while the scientific community generally accepted that evolution had occurred, many disagreed that it had happened under the conditions or mechanisms provided by Darwin. In the years immediately following Darwin's death, evolutionary thought fractured into a number of interpretations, include neo-Darwinism, neo-Lamarckism, orthogenesis, Mendelism, the biometric approach, and mutation theory. Eventually this boiled down to a debate between two camps. The Mendelians, advocating discrete variation, were led by **William Bateson** (who coined the word genetics) and **Hugo de Vries** (who coined the word mutation). Their opponents were the biometricians, advocating continuous variation; their leaders **Karl Pearson** and **Walter Frank Raphael Weldon**, following in the tradition of **Francis Galton**.

An important issue in the debate between the Mendelians and the biometricians was the nature of variation in species. Darwin and Wallace believed that small variations were more important than large ones, since small variations hewed closely to an already-proven model. The biometricians agreed with this position, while the Mendelians insisted that discontinuous species were unlikely to arise from a continuous process of change. While the immediate issue of speciation was resolved in large part by the clear definition of a species as a reproductively isolated population, the rate of evolution would arise again as a point of contention in the late 20^{th} century with the proposal *of punctuated equilibrium. Most other questions resolving variation were resolved with the recognition that the size of a* genotypic *change did not always correspond with the size of the resulting* phenotypic *change.*

Another source of clashes between Mendelians and biometricians was the debate over the origins of variation. Mendelians argued for intrinsic *variations originating from* genetic *transmission; biometricians, observing primarily the* phenotype *of the organism, were not yet prepared to abandon Lamarckian views on the heritability of acquired characteristics.* ***August Weismann*** *was among those who demonstrated that acquired characteristics were not always inherited, pointing out the existence of worker ants and worker bees, and the importance of '*germ plasm*' or* gametes *in the biology of reproduction. The recognition of means of postnatal* adaptation *as inherited traits did much to explain acquired characteristics.*

Heredity

It was known from the 1840's that the organic cell reproduced asexually by fission, the nucleus dividing first. ***Mendel****'s hybridization experiments (1865) showed that independently transmitted characters separated and recombined in hybrid progeny.*

From the 1870's a number of technical advances were made in the field of experimental biology which allowed the processes occurring in the asexual reproduction of cells and in the union of sexual cells to be observed more closely: The achromatic microscope *was further improved by the introduction of the high-power immersion lens and substage illumination, while the newly discovered* aniline dyes*, together with natural dyes and some inorganic salts, were found to stain selectively certain parts of the organic cell, particularly the nucleus.*

For the next four decades, biologists succeeded to close the gap between cytology and heredity: In the 1870's it was shown by ***Hertwig****, at Berlin, and* ***Fol****, at Geneva, working on animals, and* ***Strassburger****, at Bonn, working on plants, that sexual reproduction involved the union of the nuclei of the male and female cells, from which they suggested (1884) that the nucleus of the cell was the physical basis for heredity.* ***Walter Flemming*** *(1879) coined the name* mitosis *and made first accurate accounts of chromosome numbers and figured their longitudinal splitting (1882). He then determined chromosome number (24) in man (1898).*

Edoúard van Beneden*, zoologist, first studied* meiosis *(1883) and* ***Wilhelm von Valdeyer-Hartz*** *coined the name* chromosome *(1888).* ***August Weismann****, biologist, proposed a germ-plasm theory of heredity and described the process of meiosis, whereby the number of chromosomes is halved.*

__Oscar Hertwig__ and __Theodore Bovery__ (1889–1892) showed independently that pairs of chromosome split, replicating each member before dispersing into four separate nuclei.

Finally, __Walter Sutton__ and Theodore Bovery pointed out (1902) the parallelism between chromosome behavior and Mendelism. Sutton coined the name gene *(1902) and proposed that chromosomes carry genes.*

Anatomy and physiology

Form (anatomy) and function (physiology) were traditionally conceived as a single integrated subject, but experimental techniques, particularly in the 19th century, gradually divorced the two: __Francois Magandie__ (1783–1855), __Claude Bernard__ (1813–1878), __Johannes Müller__ (1801–1858), __Carl Ludwig__ (1816–1895), __Emil Du Bois-Reymond__ (1818–1896), __William Sharpey__ (1802–1880), __Michael Foster__ (1836–1907) and __H. Bowditch__ (1840–1911) — helped create an autonomous discipline of physiology, with its research schools, professional societies and specialized journals.

Organic chemistry

Using inorganic chemistry *as its paradigm, 19th century chemists created* organic chemistry, *whence emerged the powerful ideas of* valence *and* structure. *The advent of the* periodic law *in the 1870s finally provided chemists with a comprehensive classificatory system of elements.*

By the 1880s physics and chemistry were drawing closer together in the sub-discipline of physical chemistry. Finally, the discovery of the electron *enabled the chemists to solve the fundamental problem of* chemical affinity.

The dawn of biochemistry

Chemists of the 19th century were so busy with their own science that for a long time they did not attempt to systemize the chemistry of biological processes. Most of their biochemical discoveries were incidental to their major chemical work. The most important result of the development of organic chemistry *at first, from the viewpoint of biochemistry, was the demonstration that natural organic compounds were responsive to the same laws as inorganic substances.*

The urea synthesis of __Wöhler__ (1828) and the subsequent advances in organic synthesis struck telling blows at the vitalistic hypothesis that a special force controlled living matter. Toward the middle of the century a few *chemists (chief among them was **Liebig**) really did begin to integrate their work with that of biological investigators.*

Meanwhile physiology was developing as a science in its own right, much as was chemistry. Physiologists were chiefly concerned with the mechanics of bodily organs and with studies of the nervous system. Nevertheless, it was from the physiologists that most of the advances in biochemistry came until the end of the century. The approach of these men was usually related to their studies of special systems and organs, and so an overall view of the biochemical functioning of the body was not obtained.

Many important discoveries were made in this century, but they were like isolated pieces of a jigsaw puzzle. The science was properly called physiological chemistry *at this period, since it was used mostly to help understand specific physiological problems.*

It was only at the end of the 19th century and in the 20th that the pieces began to fit together so that a unified picture of the chemical changes in the cells and their significance for the body as a whole could be obtained.

The borderline between chemistry and physiology then became a science in its own right, and to this the name biochemistry*, the chemistry of life, can more properly be applied.*

By about 1920 biochemistry possessed the basic principles upon which it is still developing. The chemical nature of the body constituents was fairly well understood, the nutritional requirements could be seen, and the enzymatic *and* hormonal *mechanisms by which metabolic processes occurred were at least known to exist.*[697]

Modern medicine

Medicine was revolutionized in the 19th century by advances in chemistry and laboratory techniques and equipment, old ideas of infectious disease epidemiology were replaced with bacteriology.

[697] *Chlorophyll* was isolated by **Pelletier** and **Caventou** in 1817, though at first its importance was not appreciated because the full significance of the photosynthetic process could not be realized until the concept of *energy* was better understood. Indeed, **J.R. Mayer**, who propounded the law of conservation of energy pointed out in 1845 that plants supplied sunlight energy as a source on which humans depended. In the meantime, the mechanism by which animals released the stored energy of plants, was clarified. By the middle of the 19th century many of the important principles of nutrition has been established, but the nature of "ferments", as *enzymes* were called during the first three quarters of the century, was the subject of much discussion.

Ignaz Semmelweis *(1818–1865) in 1847 dramatically reduced the death rate of new mothers from childbed fever by the simple expedient of requiring physicians to clean their hands before attending to women in childbirth. His discovery predated the* germ theory of disease. *However, his discoveries were not appreciated by his contemporaries and came into general use only with discoveries of British surgeon* ***Joseph Lister****, who in 1865 proved the principles of* antisepsis*; However, medical conservatism on new breakthroughs in pre-existing science prevented them from being generally well received during the* 19^{th} *century.*

After ***Charles Darwin****'s 1859 publication of The Origin of Species,* ***Gregor Mendel*** *(1822–1884) published in 1865 his books on pea plants, which would be later known as* Mendel's laws. *Re-discovered at the turn of the century, they would form the basis of classical genetics. The 1953 discovery of the structure of DNA by* ***Watson*** *and* ***Crick*** *would open the door to* ***molecular biology*** *and modern genetics. During the late* 19^{th} *century and the first part of the* 20^{th} *century, several physicians, such as Nobel prize winner* ***Alexis Carrel****, supported* eugenics*, a theory first formulated in 1865 by* ***Francis Galton****. Eugenics was discredited as a science after the Nazis' experiments in World War II became known; however, compulsory sterilization programs continued to be used in modern countries (including the US, Sweden or Peru) until much later.*

Semmelweis' work was supported by the discoveries made by ***Louis Pasteur****, who produced in 1880 the* vaccine *against* rabies. *Linking microorganisms with disease, Pasteur brought about a revolution in medicine. He also invented with* ***Claude Bernard*** *(1813–1878) the process of* pasteurization *still in use today. His experiments confirmed the germ theory. Claude Bernard aimed at establishing scientific method in medicine; he published An Introduction to the Study of Experimental Medicine in 1865. Beside this, Pasteur, along with* ***Robert Koch*** *(who was awarded the Nobel Prize in 1905), founded* bacteriology. *Koch was also famous for the discovery of the* tubercle bacillus *(1882) and the* cholera bacillus *(1883).*

For the first time actual cures were developed for certain endemic infectious diseases. However the decline in many of the most lethal diseases was more due to improvements in public health and nutrition than to medicine.

Table 4.14: NOTABLE BIOLOGISTS AND MEN OF MEDICINE (1800–1900)

Key:

A = Anatomy	E = Ecology	EN = Entomology
BI = Biochemistry	EB = Evolutionary Biology	MI = Microbiology

5. *Demise of the Dogmatic Universe*

1895 CE–1950 CE

MATURATION OF ABSTRACT ALGEBRA AND THE GRAND FUSION OF GEOMETRY, ALGEBRA, ARITHMETIC AND TOPOLOGY

LOGIC, SET THEORY, FOUNDATION OF MATHEMATICS AND THE GENESIS OF COMPUTER SCIENCE

MODERN ANALYSIS

ELECTRONS, ATOMS, NUCLEI AND QUANTA

EINSTEIN'S RELATIVITY AND THE GEOMETRIZATION OF GRAVITY; THE EXPANDING UNIVERSE

PRELIMINARY ATTEMPTS TO GEOMETRIZE NON-GRAVITATIONAL INTERACTIONS; KALUZA – KLEIN MODELS WITH COMPACTIFIED DIMENSIONS

SUBATOMIC PHYSICS: QUANTUM MECHANICS AND ELECTRODYNAMICS; NUCLEAR AND PARTICLE PHYSICS

REDUCTION OF CHEMISTRY TO PHYSICS; CONDENSED MATTER PHYSICS; THE 4^{th} STATE OF MATTER

THE CONQUEST OF DISTANCE BY AUTOMOBILE, AIRCRAFT AND WIRELESS COMMUNICATION; CINEMATOGRAPHY

THE 'FLAMING SWORD': ANTIBIOTICS AND NUCLEAR WEAPONS

UNFOLDING BASIC BIOSTRUCTURES: CHROMOSOMES, GENES, HORMONES, ENZYMES AND VIRUSES; PROTEINS AND AMINO ACIDS

ELECTROMAGNETIC TECHNOLOGY: EARLY LASER THEORY; HOLOGRAPHY; MAGNETIC RECORDING AND VACUUM TUBES; INVENTION OF THE TRANSISTOR

'BIG SCIENCE': ACCELERATORS; THE MANHATTAN PROJECT

2001	The 'Nine-Eleven' event – Muslim terror hits the USA

1895 CE **Wilhelm Conrad Röntgen** (1845–1923, Germany). Physicist. Discovered X-rays while experimenting with electric current flow in partially evacuated glass tube (cathode-ray tube). In 1912, **Max von Laue** (1879–1960, Germany) determined its wave-lengths by means of diffraction through regularly-spaced atoms in crystals.

Although Röntgen was unaware of the true nature of these 'rays', he found that they affected photographic plates, and took the first anatomical X-ray photograph [the bones of his wife's hand]. His discovery heralded the age of modern physics and revolutionized diagnostic medicine. He was the recipient of the first Noble prize for physics, in 1901.

Röntgen was educated at Zürich and was then professor of physics at the universities of Strasbourg (1876–1879), Giessen (1879–1888), Würzburg (1888–1900) and finally Münich (1900–1920).

1895 CE **Auguste** (**Marie Louis**) **Lumière** (1862–1954, France) and his brother **Louis Jean** (1864–1948) developed a satisfactory camera and projector and made the first motion-picture film-show to the general public.

Inspired by Edison's *kinematoscope* they invented the *cinematograph*: a claw mechanism to pull the film a fixed distance past the projection (and camera) lens while the light was cut off by a shutter. Their choice of 16 frames per second remained the standard filming and projection rate through all the years of silent films.

1895–1896 CE **Hendrik Antoon Lorentz** (1853–1928, Holland). A leading physicist. Established the notion that electromagnetic radiation originates due to harmonic oscillations of charged particles *inside* atoms or molecules[1]. Lorentz suggested that a strong magnetic field ought to affect these oscillations and change the wavelength of the emitted radiation. This prediction was verified in 1896 by **Pieter Zeeman** (1865–1943, Holland), a pupil of Lorentz, and in 1902 they were awarded the Nobel prize in physics for their discovery.

Since the electron theory of Lorentz could not explain the results of the Michelson-Morley experiment, he was forced to concoct the 'Lorentz transformation' equations as an ad hoc device to overcome the difficulty.

Lorentz was born in Arnhem. During 1878–1923 he was a professor of theoretical physics at Leyden University.

---

[1] According to Maxwell's theory, electromagnetic radiation is produced by oscillations of electric charges, but charges that produce *visible light* were not known at that time.

1895–1909 CE **Georg (Yuri Viktorovich) Wulff** (1863–1925, Russia). Crystallographer. Discovered that the shape of small crystals can be explained, to some extent, by a variational principle similar to that of the isoperimetric problem[2], and that their remarkable difference in structure results from the difference in the corresponding potential energies; physically, a crystal with small surface irregularities will tend to *lower its free surface energy* and this becomes the dominating factor in its shape formation.

Wulff was born in Nezhin, the Ukraine. He studied at the Universities of Warsaw (1880–1892) and Odessa (1892–1899). He then held professorial positions at Kazan and Moscow (1918–1925). Wulff showed that for every given volume, there is a unique convex body whose boundary surface has less energy than does the boundary surface of any piecewise smooth body of the same volume. In his 1895 thesis, Wulff showed that for a constant volume, the surface energy per unit area at any point on the surface depends only on the direction of the tangent plane to the surface at that point.

Moreover, the total surface energy would be minimized when the specific surface energies for each face (K_i) were proportional to the perpendicular distances (n_i or *Wulff vectors*) from a central point to each face such that $K_1 : K_2 : K_3 : \cdots = n_1 : n_2 : n_3 : \ldots$. In modern studies of crystal growth the geometric algorithm for determining the equilibrium form derived from the theorem is known as *Wulff's construction*.

1895–1901 CE **Guglielmo Marconi** (1874–1937, Italy). Inventor and electrical engineer. Became the first person to send radio communication signals through the air[3]. In 1895 he sent a wireless telegraph code signal to a distance of 2 km and in 1901 he send a code signal across the Atlantic Ocean from England to Newfoundland.

Marconi was the last in the long chain of contributors during 1884–1897: He combined **Ruhmkorff's** induction-coil, the stable *spark oscillator* of **Augusto Righi** (1850–1920, Italy), the *coherer* of **Eugene Branly** (1844–1940,

[2] In three dimensions, the perfectly smooth symmetrical sphere has the smallest free surface energy (area) when compared to all other smooth shape-sake bodies of the same volume. If however a region in space is bounded by a *finite collection of pieces of smooth surfaces* (piecewise smooth) there is an infinite number of possible surface energies; nevertheless, for each such admissible energy, the unique minimum is a convex region bounded by *planes*. The solution to this minimal problem, the optimal crystalline region, can be determined by the *Wulff construction*.

[3] The Russian claim to fame in this field is **Alexander Stepanovich Popov** (1859–1906), a physicist who devised the first *aerial* (1897), although he did not use it for radio communication. He also invented a detector for radio waves (1895).

France), **T.C. Onesti**[4] and **Oliver Lodge**, and the *antenna* of **Alexander Popov** into a workable system.

1895–1904 CE **Horace Lamb** (1849–1934, England). Applied mathematician. A student of **Stokes** and **Maxwell**; Professor at Adelaide, Australia (1875–1885) and University of Manchester (1885–1920). Author of *Hydrodynamics* (1895). Laid the foundation to modern theoretical seismology and contributed to the theory of the tides.

1895–1906 CE **Pierre Curie** (1859–1906, France). Physical chemist. Among the founders of modern physics. Discovered radium and polonium with his wife **Marie Curie** (1898), and the law that relates some magnetic properties to changes in temperature (*Curie's law*; *Curie point*). Established an analogy between paramagnetic materials and perfect gases and between ferromagnetic materials and condensed fluids.

Curie was a son of a Paris physician. Studied and taught physics at the Sorbonne, where he was appointed professor in 1904. He was run over by a dray in the rue Dauphine in Paris in 1906 and died instantly.

1895–1909 CE **Thorvald Nicolai Thiele** (1838–1910, Denmark). Mathematician with interest in astronomy. Derived a continued-fraction expansion of a given function, the convergents of which serve as *rational approximations* of the function (1909). Thiele taught in Copenhagen as well as being chief actuary of an insurance company.

1895–1915 CE **Wallace Clement Sabine** (1868–1919, U.S.A.). Physicist. Founded the science of *architectural acoustics*. Until 1895, criteria for what constituted a good acoustic hall were lacking. Sabine, a young physics instructor at Harvard University, was called on to attempt a remedy of the intolerable acoustics of the auditorium of the recently completed Fogg Art Museum[5]. He defined the parameters for good acoustical qualities before trying to translate them into practical considerations — dimensions, shapes, and building materials. He became later Hollis Professor of Mathematics and Natural Philosophy at Harvard.

---

[4] **Temistocle Calzecchi Onesti** (1853–1922).

[5] In the Fogg Art Museum it was almost impossible to understand speakers in the lecture room.

Architectural Acoustics

Before Sabine, good acoustical design consisted chiefly of imitating halls in which music sounded good. Poor acoustic design consisted of superstitious practices, such as stringing useless wires across the upper spaces of a church or auditorium. Sabine identified the persistence of sound *(i.e., the excessive reverberation) as the factor that rendered speech unintelligible. He reduced the reverberation by placing felt on particular walls.*

Sabine was the first to define reverberation time*, one important parameter of lecture halls and auditoriums. His definition was the time that it takes, after a sound is turned off, for the reverberant sound level to become barely audible. (When accurate electronic measurement of sound level became possible many years later, this turned out to be a fall in sound level of 60 db.)*

From a series of ingenious experiments Sabine deduced a mathematical model that has a relation to the full-wave model (wave equation plus boundary conditions) of classical acoustics similar to that of radiative heat transfer to electromagnetic theory or of kinetic theory to classical mechanics. His idealization that sound fills a reverberant room in such a way that the average energy per unit volume in any region is nearly the same as in any other region, applies best to large *rooms whose characteristic dimensions are substantially larger than a typical wavelength.*

It also applies to live *rooms, for which the time determined by the ratio of the total propagating energy within the room to the time rate at which energy is being lost from the room is considerably larger than the time required for a sound wave to travel across a representative dimension of the room.*

When a sound source is in a room, sound waves emanating from the source will propagate until they strike the walls. Some energy will be absorbed by it and a weaker wave will be reflected back. The reflected wave will propagate until it reaches another wall where it is again reflected with partial absorption. This process continues until all the sound energy is eventually absorbed. The overall array of randomly criss-crossing rays is called the reverberant *sound field.*

The basic assumption of geometrical acoustics *is that the room walls are irregular enough so that the acoustic energy density W is distributed uniformly through the room. For this to be true, a large number of standing waves must be involved. Since each standing waves can be considered to be made up of a number of plane traveling waves, reflecting from the walls at appropriate angles, the sound in the room at the point characterized by the position vector*

$\boldsymbol{r}$ can be represented by an assemblage of harmonic plane waves, each going in a direction (φ, θ), each with pressure amplitude $A(\boldsymbol{r}, \varphi, \theta; \omega)$, intensity $I = \frac{|A|^2}{\rho c}$ (ρ = density; c = sound velocity), and energy density $W = \frac{|A|^2}{\rho c^2}$. These entities are given by the corresponding integrals

$$p(\boldsymbol{r}, \omega) = \int_0^{2\pi} d\varphi \int_0^{\pi} A(\boldsymbol{r}, \theta, \varphi) e^{i\boldsymbol{k}\cdot\boldsymbol{r} - i\omega t} \sin\theta d\theta$$

($\boldsymbol{k}$ = wave number vector; k, θ, φ its spherical components),

$$I(\boldsymbol{r}, \omega) = \frac{1}{\rho c} \int_0^{2\pi} d\varphi \int_0^{\pi/2} |A(\boldsymbol{r}, \theta, \varphi; \omega)|^2 \cos\theta \sin\theta d\theta$$

(power per unit area normal to $\boldsymbol{k}$),

$$W(\boldsymbol{r}, \omega) = \frac{1}{\rho c^2} \int_0^{2\pi} d\varphi \int_0^{\pi} |A(\boldsymbol{r}, \theta, \varphi; \omega)|^2 \sin\theta d\theta.$$

Geometric acoustics makes here two basic assumptions:

(1) The energy flow I is homogeneous and isotropic, *i.e., the average value of $|A|^2$ over a small region in space is independent of $\boldsymbol{r}$, θ and φ.*

(2) The absorptive properties of the wall surface are represented by a single parameter, averaged over all directions of incidence and integrated over the total wall area of the room. This quantity a, called the absorption *of the room, has dimensions of area.*

The first assumption leads to the simple relation $I = \frac{1}{4}cW$ for the diffused sound field in a room, when each direction of propagation is equally likely (compared with $I = cW$ for unidirectional *plane wave). The second assumption, when coupled to the energy balance equation*

$$V\frac{dW}{dt} + Ia = 0$$

(V = volume of the room), leads to the solution

$$I = I_0 e^{-\left(\frac{ac}{4V}\right)t},$$

where I_0 is the initial value of the intensity.

The reverberation time τ is defined to be the time at which $I/I_0 = 10^{-6}$, or $\tau = \frac{V}{ac}\,55.3$ (Sabine, 1895). The reverberation time can be calculated from the room's volume and the total absorption. If τ is too long, it can easily be decreased by hanging additional curtains or sound absorbent panels.

When it is too short, electronic feedback system is used; a microphone on the ceiling picks up the incoming signal which is delayed and then re-emitted by loudspeakers.

Although τ is an important parameter related to a room's acoustic behavior, it is by no means the only one. Typical values of τ are about 0.3 sec for living rooms or up to 10 sec for large churches. Most large rooms have reverberation times between 0.7 and 2 sec. If the reverberation time is too short, sounds appear 'dead' as the lack of echo produces a very clipped sound. If τ is too long, speech becomes incoherent, and echoes drown the speaker.

Sabine appreciated both the physical *aspect of measuring and predicting the transmission and decay of sound in concert halls, and the* psychological *aspect: what makes a good hall good? He experimented to find the preferred reverberation time for musical performance.*

There are two general problems in architectural acoustics, and each has many aspects. One problem is, what do we want? *(e.g., what enables performers to play well? When they do play well, what is it that make them sound good?). The other problem is,* how can we attain what is good for the performers and what is good for the audience?

Thus, concert-hall design requires great attention both to excluding external noise and to not producing noise. Satisfactory ensemble playing depends on early reflections of sound from behind and above the performers; each player must hear all the rest by means of reflected sound that is not too much delayed.

In spite of the progress made since Sabine's time, major errors have been committed in the design of music halls. Philharmonic Hall in Lincoln Center, Manhattan, opened on September 12, 1962. There were echoes at some seat locations. The members of the orchestra couldn't hear themselves and others play. There was a lack of subjectively felt reverberation. There was inadequate diffusion of sound through the hall. Worst of all, there was an apparent absence of low frequencies: it was difficult to hear the celli and double basses. In short — it was a disaster.

It turned out that the overhead acoustic panels did not reflect low-frequency components with sufficient strength into the main audience area. This was partly the result of poor scaling *(to properly reflect musical notes of different wavelengths from an acoustic panel, the panel's geometric dimensions must be at least comparable in size with the longest wavelength present in the sound. In actual fact they were much too small).*

During 1967–1974, **Manfred Schroeder** *(Germany) and his collaborators, undertook to compare more than 20 European concert halls. They played back a certain piece of music (a multichannel tape recording of Mozart's*

Jupiter symphony played by the BBC orchestra in an anechoic room) over several loudspeakers on the stages of various concert halls. In each hall they made two channel tapes of what a dummy head heard when seated in several locations. They then put listeners in an anechoic room at Göttingen and played back to them what the dummy head heard in various concert halls. By analyzing the judgments of these listeners, Schroeder and his colleagues learned that listeners liked:

- Long reverberation times (below 2.2 seconds).
- Sound to differ at their two ears.
- Narrow halls better than wide halls. (In a wide hall the first reflected sound rays reach the listener from the ceiling. In narrow halls the first reflections reach the listener from the left and right walls, and these two reflections are different.) The less preferred halls revealed a consistent absence of strong laterally traveling sound waves.

Thus, good acoustics — given proper reverberation time, frequency balance, and absence of disturbing echoes — is mediated by the presence of strong lateral sound waves that give rise to preferred stereophonic sound. In old-style high and narrow halls, such lateral sound is naturally provided by the architecture.

By contrast, in many modern fan-shaped halls with low ceiling, a monophonic sound, arriving in the symmetry plane through the listener's head, predominates, giving rise to an undesirable sensation of detachment from the music. To increase the amount of laterally traveling sound in a modern hall, highly efficient sound scattering surfaces have been recently invented (1990).

These reflection phase gratings are based on number-theoretic principles and have the remarkable property of scattering nearly equal acoustic intensities into all directions. Such broadly scattering surfaces are now being introduced into recording studios, churches, and even individual living rooms. The sound, dispersed from the ceiling, is scattered into a broad lateral radiation pattern (horizontal plane). The far-field (Fraunhofer diffraction) of such grating is approximated by the spatial Fourier transform of the acoustic signal.

The Korteweg–de Vries Equation (1895)[6]

In 1834, *the British engineer* **John Scott Russell** *(1808–1882) was consulted as to the possibility of utilizing steam navigation on the Edinburgh-Glasgow canal. He then undertook a series of experiments, in which he observed and reported (1844) the existence of solitary gravity waves in the canal. He deduced the empirical equation* $U^2 = g(h_0 + \eta_0)$, *where* U *is the wave's speed,* h_0 *the undisturbed depth of water,* g *the acceleration of gravity and* η_0 *the amplitude of the wave.*

A theoretical study of wave motion in inviscid incompressible fluid by **J. Boussinesq**[7] *(1871) and* **Lord Rayleigh** *(1876) verified Russell's equation and showed that the wave profile* $z = \eta(x,t)$ *is given by*

$$\eta(x,t) = \frac{\eta_0}{\cos h^2\{\beta(x - Ut)\}}$$

where

$$\beta = \frac{1}{2h_0}\sqrt{3\frac{\eta_0}{h_0}},$$

$$\frac{\eta_0}{h_0} \ll 1,$$

$$U \approx \sqrt{gh_0}\left(1 + \frac{1}{2}\frac{\eta_0}{h_0}\right).$$

These authors did not, however, write down the equation for which $\eta(x,t)$ *was a solution. This final step was completed in* 1895 *by* **D.J. Korteweg**[8]

[7] **Boussinesq** (1842–1929, France).

[8] **Diederik Johannes Korteweg** (1848–1941, Holland). Applied mathematician. Educated at Delft as an engineer but later turned to mathematics. Was a professor of mathematics at the University of Amsterdam (1881–1918). Collaborated with **J.D. van der Waals** on various research topics in statistical mechanics and thermodynamics.

and **G. de Vries***. Their equation, for waves on the surface of shallow water, was*

$$\frac{\partial \eta}{\partial t} + c_0 \left(1 + \frac{3}{2h_0}\eta\right) \frac{\partial \eta}{\partial x} + \frac{1}{6} c_0 h_0^2 \frac{\partial^3 \eta}{\partial x^3} = 0$$

where $c_0 = \sqrt{gh_0}$.

This is essentially a one-dimensional wave equation in which non-linearity and dispersion occur together. It is known today as the 'KdV equation' and it has solutions known as solitons. It is characteristic of non-linear wave propagation in weakly dispersive media governed by a dispersion relation $\omega = c_0 k - \beta k^3$, *in which the relation between frequency* ω *and wave number* k, *involves the amplitude.*

Note that the soliton solution is exact *and describes a* traveling permanent profile, *which does not change its shape and propagates with constant speed. This is due to a balance between the two competing effects of non-linearity and dispersion. It is this property which gives the KdV equation its universal nature.*

Indeed, it was discovered throughout the 20^{th} *century that the equation and its modifications have many diverse applications such as: waves in a rotating atmosphere (Rossby waves), ion-acoustic waves in plasma, pressure waves in a liquid-gas bubble mixture, the non-linear Schrödinger equation and anharmonic lattice vibrations.*

1895–1915 CE **Herbert George Wells** (1866–1946, England). Novelist, sociologist, and historian. Wrote fantastic scientific romances in which he combined scientific speculations with a strain of sociological idealism: *The Time Machine* (1895), *The Island of Doctor Moreau* (1896), *The Wheels of Chance* (1896), *The Invisible Man* (1897), *The War in the Air* (1908), *The War of the Worlds* (1898), *First Men in the Moon* (1901), *The Food of the Gods* (1904), *A Modern Utopia* (1905). His novel *The World Set Free* (1914), predicted atomic bombs, atomic war and world government.

1895–1949 CE **Élie Joseph Cartan** (1869–1951, France). One of the foremost mathematician of the 20^{th} century, and one of the architects of modern mathematics. A principal founder of the modern theory of Lie groups and Lie algebras, a contributor to the theory of subalgebras and discoverer of the general mathematical form of *spinors*[9] (1913), 14 years ahead of physics. His work achieved a synthesis between continuous group, Lie algebras, differential equations and geometry.

Cartan's thesis (1894) was on the structure of continuous groups of transformations, and most of the ideas which directed all his subsequent work are to be found in it. The principal part of the thesis was devoted to the classification of simple Lie algebras over the complex field, and it completed the work of **Lie** and **Killing** on this subject.

About 1897 Cartan turned his attention to *linear associative algebras* over real and complex fields. In 1899 he began his work on Pfaffian forms, including such topics as contact transformations, invariant integrals and Hamiltonian dynamics, and his great contributions to differential geometry. Within this framework he invented the calculus of *differential forms* (1897) and introduced the concept of *wedge product*. His *exterior calculus* is anchored in the pioneering studies of **Poincaré** and **Édouard Jean Baptist Goursat** (1858–1936).

During 1904–1909 Cartan made substantial contributions to the theory of infinite *continuous groups*. In 1913 he developed systematically the theory of *spinors*, by giving a purely geometrical definition of these mathematical entities. This geometrical origin made it easy to introduce spinors into Riemannian geometry, and particularly to apply to them the idea of parallel transport.

Cartan further contributed to geometry with his theory of symmetric spaces which have their origin in papers he wrote in 1926. It developed ideas first studied by Clifford and Cayley and used topological methods developed by Weyl. This work was completed by 1932.

The discovery of the general theory of relativity in 1916 turned the attention of many mathematicians, including Cartan, to the general concept of geometry, and nearly all of Cartan's work from this time onwards is devoted to the development of a general theory of *differential geometry* (1917–1949). It forms a most vital contribution to modern mathematics.

Thus, in 1922 he proposed and developed a gravitational theory with *nonsymmetric connection* (geometry with *torsion*). The result was the *Einstein-Cartan equations* which include, in addition to Einstein's ten equations for the metric $g_{\mu\nu}$, a system of equations for the torsion tensor. The source in the torsion equation is represented by a tensor that is defined by the spin properties of matter.

It is indeed remarkable that this work was begun when he was nearly 50, and carried on until he was 80 — a most striking exception to **Hardy**'s dictum that mathematics is a young man's game.

Cartan was born in Dolomien, a village in the south of France. His father was a blacksmith. Cartan's elementary education was made possible by a state stipend for gifted children. In 1888 he entered the École Normale Superieur, where he learned higher mathematics from **Picard**, **Darboux** and **Hermite**. His research work started with his famous thesis on continuous groups, a subject suggested to him by a fellow student, recently returned from studying with **Sophus Lie** in Leipzig.

He was made a professor at the Sorbonne in 1912. The report on his work, which was the basis for this promotion, was written by **Poincaré**. He remained in the Sorbonne until his retirement in 1940.

In 1903 Cartan married Mlle Marie-Louis Bianconi. Besides a daughter, there were three sons of the marriage — **Henri Paul Cartan** (b. 1904), a distinguished mathematician in his own right who made significant advances in the theory of analytic functions, theory of sheaves, homological theory, algebraic topology and potential theory.

His other son, Jean, oriented himself toward music, and had already emerged as one of the most gifted composers of his generation, when he was cruelly taken by death. His third son, Louis Cartan, a professor of physics, was arrested by the Germans at the beginning of the Resistance and murdered by them in 1943.

Besides several books, Cartan published about 200 mathematical papers. His mathematical works can be roughly classified under three headings: group theory, systems of differential equations and geometry. These themes are constantly interwoven with each other in his work. Almost everything Cartan did is more or less connected with the theory of Lie groups.

The Calculus of Differential Forms[10]

The calculus of alternating differential forms (also known as the exterior calculus or Cartan calculus) enables one to make a systematic generalization to n-dimensional spaces of vector analysis in the plane and in three dimensional space. Thus, the theory provides a convenient and elegant way of phrasing Green's, Stokes', and Gauss' theorems. In fact, the use of differential forms shows that these theorems are all manifestations of a single underlying mathematical theory and provides the necessary language to generalize them to n dimensions.

This calculus has applications, among other things, to differential geometry and theoretical physics (e.g., relativity theory, electrodynamics, thermodynamics, analytical mechanics, particle physics). There is a very close connection between alternating differential forms and skew-symmetric tensors. The calculus of differential forms carries to manifolds (especially those that do not include a metric or a covariant derivative) such basic notions as gradient, curl and integral. Further, it enables an index-free treatment of differential geometry.

In the following, the algebraic structure of differential forms (DF) will be outlined from an axiomatic viewpoint. Then, the deep-seated reasons for the apparently arbitrary definitions will be anchored in vector analysis, and finally motivated by physical applications.

- *A real-valued twice-differentiable function* $f(x, y, z)$ *is an 0-form. It can be considered as a rule that assigns to each point in* R^3 *a real number. This generalizes to any n-dimensional manifold.*
- *Formal expressions such as*

$$\omega = A(x, y)dx + B(x, y)dy \qquad \text{and}$$
$$\omega = A(x, y, z)dx + B(x, y, z)dy + C(x, y, z)\,dz$$

are 1-forms. The first is a 1-form *in the* XY *plane (or any* 2-dimensional *manifold), while the second is a* 1-form *in* 3-dimensional *space. [A, B, C will be assumed to be real-valued infinitely differentiable functions, although this is not necessary for the derivation of some of the results.]*

[10] To dig deeper, see:
- Flanders, H., *Differential Forms with Applications to the Physical Sciences*, Dover, 1989, 205 pp.

- *The formal expression*

$$\eta = A(x, y, z)dxdy + B(x, y, z)dydz + C(x, y, z)dzdx$$

is a 2-form in a 3-space (i.e. a 3-dimensional manifold or R^3). The 2-form $\eta = A(x, y)dxdy$ *is a special case for* $B = 0,\ C = 0,\ \frac{\partial A}{\partial Z} = 0$, *and also the general case in two dimensions. The order of the differentials is essential in this product-notation;* $dxdy = -dydx$, *etc. In general* $\omega_1\omega_2 = -\omega_2\omega_1$ *for any pair of 1-forms.*

- *The formal expression* $\mu = A(x, y, z)dxdydz$ *is a 3-form. The order of the differentials is again essential, modulo cyclic permutation:* $dxdydz = dzdxdy = -dzdydx$, *etc.*

In 3-space there exist only 0-forms, 1-forms, 2-forms, and 3-forms, while in 2-space, there are only 0-forms, 1-forms, and 2-forms. In the manifold case, the above expressions hold in any given local coordinate system.

Algebraic structure: *The system of DF in 3-space, for instance, is a linear associative algebra (Grassman algebra) with a basis of 8 elements:*

$$1,\ dx,\ dy,\ dz,\ dxdy,\ dydz,\ dzdx,\ dxdydz$$

whose coefficients belong to the field of continuous functions, and whose multiplication table is specified by:

$$dxdy = -dydx, \quad dydz = -dzdy, \quad dzdx = -dxdz,$$

$$dxdx = 0, \quad dydy = 0, \quad dzdz = 0.$$

The product of a k-form and an m-form is a $(k + m)$ *form, where the integer prefix is the form's degree (dx is a 1-form, dxdy a 2-form, etc.).*

If $m + k > n$, *the number of variables, then there will be repetitions, and such a product will be zero. Since a 0-form is merely a function, multiplication by a 0-form does not affect the degree of the form. [Example:* $(xdx - zdy + y^2dz)(x^2dydz + 2dzdx - ydxdy) = (x^3 - 2z - y^3)dxdydz$.*]*

Geometrical structure: *One can naturally define the line integral of a 1-form* $\omega = Adx + Bdy + Cdz$ *along a curve* γ. *Let* γ *be a smooth simple curve, with parametric equations* $x = x(t),\ \ y = y(t),\ \ z = z(t),\ \ a \le t \le b$, *and oriented in such a way that the positive direction of* γ *is associated with* *the direction which* $x(t), y(t), z(t)$ *traverse as* t *increases from* a *to* b*; the same curve with the opposite orientation is denoted* $-\gamma$*. Then*

$$\int_\gamma \omega \equiv \int_a^b \left[A\{x(t), y(t), z(t)\} \frac{dx}{dt} + B\{x(t), y(t), z(t)\} \frac{dy}{dt} + C\{x(t), y(t), z(t)\} \frac{dz}{dt} \right] dt.$$

In this way a 1-form can be thought of as a rule that assigns a real number to each oriented curve[11]*. Note that* $\int_{-\gamma} \omega = -\int_\gamma \omega$ *since reversal of orientation of a curve changes the sign of the integral.*

A 2-form may be similarly interpreted as a surface functional, namely a function that associates with each oriented 2D *surface a real number. Again, using the local parametrization* $x = x(u, v)$, $y = y(u, v)$, $z = z(u, v)$ *with* (u, v) *belonging to a domain* D *in* R^2*, we have for a surface* S *and 2-form* η*:*

$$\int_S \eta = \int_S (Adxdy + Bdydz + Cdzdx)$$
$$= \int_D \left[A\{x(u,v), y(u,v), z(u,v)\} \frac{\partial(x,y)}{\partial(u,v)} + B\{x(u,v), y(u,v), z(u,v)\} \frac{\partial(y,z)}{\partial(u,v)} + C\{x(u,v), y(u,v), z(u,v)\} \frac{\partial(z,x)}{\partial(u,v)} \right] dudv$$

where

$$\frac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix}; \qquad \frac{\partial(y,z)}{\partial(u,v)} = \begin{vmatrix} \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} \end{vmatrix}; \qquad \frac{\partial(z,x)}{\partial(u,v)} = \begin{vmatrix} \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} \\ \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \end{vmatrix}.$$

Note that, if η *would have a* $dxdx$ *term (which formally vanishes), the determinant* $\frac{\partial(x,x)}{\partial(u,v)}$ *has equal rows, and hence vanishes. Also, if we interchange*

[11] In general, given a *1-form* and a smooth curve γ, the value of the line integral will depend on γ. However, when two curves are *parametrically equivalent*, then a *1-form* will assign the same value to both. The same is true for smoothly equivalent surfaces and *2-forms*. All these integrals can be extended to curves and surfaces embedded in any n-space ($n \geq 2$). If the space is a manifold, the integrals need to be broken up into single–coordinate–system pieces.

Parametrical equivalence: if (in any coordinate–system neighborhood through which γ passes) $x = \phi(t)$ on γ_1 with $a \leq t \leq b$ and γ_2 is given by $x = \phi[f(t)]$ over $\alpha \leq t \leq \beta$, and the function $f(t)$ maps the interval $[\alpha, \beta]$ onto $[a, b]$ in a one-to-one, differentiable manner with $f'(t) > 0$, then (and only then) are the curves γ_1 and γ_2 said to be parametrically equivalent.

x and y, the corresponding determinant changes sign; etc. This renders a geometrical motivation for the rules $dxdx = 0$, $dydx = -dxdy$, with similar results for the other Jacobian determinants.

Finally, a 3-form ν in 3-space assigns a real number to each 3D submanifold Ω of the 3-space in question. The number is $\int_\Omega \nu = \int_\Omega f(x,y,z)dxdydz$ which is just the ordinary triple integral of f over Ω.

All these integrals are true geometric entities – because they do not depend on the choice of local manifold coordinate systems, nor upon the parameterizations (coordinate systems) of the submanifolds integrated over (curves, surfaces and higher submanifolds). This concludes the description of the geometrical hierarchy.

Differentiation of forms in 3-space: *In general, if ω is a k-form, its differential $d\omega$ will be a $k+1$ form. Thus if A is a 0-form (function) then dA is (locally) the 1-form $dA = \frac{\partial A}{\partial x}dx + \frac{\partial A}{\partial y}dy + \frac{\partial A}{\partial z}dz$. If ω is a 1-form $Adx + Bdy + Cdz$ whose local coefficients are functions, then $d\omega$ is the 2-form $d\omega = (dA)dx + (dB)dy + (dC)dz$.*

If ω is a 2-form in 3-space $Adydz + Bdzdx + Cdxdy$, then $d\omega$ is the 3-form $d\omega = (dA)dydz + (dB)dzdx + (dC)dxdy$, where $d\omega$ is to be locally computed by evaluating dA, dB, and dC, and then computing the indicated products.

Since dA is a 1-form, $(dA)dx$ is indeed a 2-form and $(dA)dydz$ is a 3-form. [For example: $\omega = x^2ydydz - xzdxdy$, $d\omega = (2xy - x)dxdydz$.] The operator d is known as the exterior derivative[12]*. The derivative of a 3-form may be computed in the same fashion, but since it will be a 4-form in three variables, it will automatically be zero. Differentiation of forms in two variables is done in the same fashion*[13]*. The foregoing rules for multiplication and differentiation have in store for us a number of surprises:*

[12] There are three kinds of derivatives in differential geometry and tensor analysis:
- *The covariant derivative* in the direction of the contravariant vector $\boldsymbol{A}$ (∇_A); acts on *any* tensor; it depends only on $\boldsymbol{A}$ but not its derivatives.
- *The Lie derivative* (L_A); depends on $\boldsymbol{A}$ *and* its derivatives.
- *The exterior derivative*; acts on any totally antisymmetric, covariant tensor (= differential form) to yield a form with rank higher by one; it is also covariant.

The last two derivatives exist even in spaces without an affine connection, Γ^m_{ik}, but ∇_A exist only in an affine space (a space endowed with a connection).

[13] The rules may seem arbitrary, but in fact they "happen" to fit with the rule of the transformation of the area element through a coordinate transformation.

- *The product of two 1-forms in $\mathbb{R}^3$ yields the general formula*

$$\omega_1\omega_2 = (Adx + Bdy + Cdz)(adx + bdy + cdz)$$
$$= \begin{vmatrix} B & C \\ b & c \end{vmatrix} dydz + \begin{vmatrix} C & A \\ c & a \end{vmatrix} dzdx + \begin{vmatrix} A & B \\ a & b \end{vmatrix} dxdy \Rightarrow (\boldsymbol{\omega}_1 \times \boldsymbol{\omega}_2).$$

  In the above equation we treat (A, B, C) and (a, b, c) as the respective components of the vectors $\boldsymbol{\omega}_1 = A\boldsymbol{e}_x + B\boldsymbol{e}_y + C\boldsymbol{e}_z$, $\boldsymbol{\omega}_2 = a\boldsymbol{e}_x + b\boldsymbol{e}_y + c\boldsymbol{e}_z$, and $(\times)$ is the usual vector product operation.

- *The product of a 1-form $\omega = Adx + Bdy + Cdz$ by the 2-form $\nu = adydz + bdzdx + cdxdy$ in a 3-space yields the 3-form $(aA + bB + cC)dxdydz$. Its scalar function coefficient can be written as the scalar product of the local vectors $\boldsymbol{\omega} = A\boldsymbol{e}_x + B\boldsymbol{e}_y + C\boldsymbol{e}_z$ and $\boldsymbol{\nu} = a\boldsymbol{e}_x + b\boldsymbol{e}_y + c\boldsymbol{e}_z$, namely: $(\boldsymbol{\omega} \cdot \boldsymbol{\nu})$.*

- *If $\omega = A(x, y, z)dx + B(x, y, z)dy + C(x, y, z)dz$, then*

$$d\omega = \left(\frac{\partial C}{\partial y} - \frac{\partial B}{\partial z}\right) dydz + \left(\frac{\partial A}{\partial z} - \frac{\partial C}{\partial x}\right) dzdx + \left(\frac{\partial B}{\partial x} - \frac{\partial A}{\partial y}\right) dxdy \Rightarrow \mathrm{curl}\,\boldsymbol{\omega},$$

  where $\boldsymbol{\omega} = A\boldsymbol{e}_x + B\boldsymbol{e}_y + C\boldsymbol{e}_z$.

- *If $\nu = a(x, y, z)dydz + b(x, y, z)dzdx + c(x, y, z)dxdy$, then*

$$d\nu = \left(\frac{\partial a}{\partial x} + \frac{\partial b}{\partial y} + \frac{\partial c}{\partial z}\right) dxdydz \Rightarrow \mathrm{div}\,\boldsymbol{\nu},$$

  where $\boldsymbol{\nu} = a\boldsymbol{e}_x + b\boldsymbol{e}_y + c\boldsymbol{e}_z$.

The above examples hint to a strong link between vector analysis and differential forms. But prior to the establishment of the nature of these connections one must summarize the historical background:

Let $u = f(x, y)$, $v = g(x, y)$, then $du = \frac{\partial f}{\partial x}dx + \frac{\partial f}{\partial y}dy$, $dv = \frac{\partial g}{\partial x}dx + \frac{\partial g}{\partial y}dy$ and

$$dudv = \left(\frac{\partial f}{\partial x}\,dx + \frac{\partial f}{\partial y}\,dy\right)\left(\frac{\partial g}{\partial x}\,dx + \frac{\partial g}{\partial y}\,dy\right)$$
$$= \left(\frac{\partial f}{\partial x}\frac{\partial g}{\partial y} - \frac{\partial f}{\partial y}\frac{\partial g}{\partial x}\right) dxdy = \frac{\partial(u, v)}{\partial(x, y)}\,dxdy.$$

This ensures that a surface integral $\int_S \eta$, for any *2-form* η and 2-submanifold S in any 2-space, does not depend on local coordinate–system choices. Similar reasoning applies to forms of any degree in any dimensionality.

Early efforts to establish an algebra for points of the plane *(which has the same rules as the algebra of numbers) met with success because a suitable definition for multiplication could be found, namely, the (commutative) product of ordered–real–pair points*

$$(x_1, x_2)(y_1, y_2) = (x_1y_1 - x_2y_2, \quad x_1y_2 + x_2y_1).$$

The motivation for this rule may be seen by making the correspondence $(a, b) \leftrightarrow a + bi$ *between the plane and the field of* complex numbers. *If* $p = (x_1, x_2)$ *corresponds to* $z = x_1 + ix_2$ *and* $q = (y_1, y_2)$ *corresponds to* $w = y_1 + iy_2$, *then we see that*

$$zw = (x_1 + ix_2)(y_1 + iy_2) = (x_1y_1 - x_2y_2) + i(x_1y_2 + x_2y_1)$$

which corresponds to the point which is given as the product of p *and* q.

With this example in mind, one may attempt to find a similar definition for multiplication of points in 3-space. By algebraic methods, it can be shown that no such formula exists (if we require that the ordinary algebraic rules remain valid).

However, going to the next higher dimension, **Hamilton** *(1843) discovered that a definition for multiplication of points in* E^4 *could be given which yields a system obeying all the algebraic rules which apply to real numbers (i.e., the field axioms) except one; multiplication is no longer commutative, so that* (pq) *and* (qp) *may be different points. This system is called the algebra of* quaternions.

It was soon seen that it could be used to great advantage in analytical mechanics. By restricting points to a particular 3-space embedded in E^4, ***Gibbs*** *and others developed a modification of the algebra of quaternions which was called* vector analysis, *and which gained widespread acceptance and importance, particularly in physics.*

Let us now compare the system of vector analysis with the system of differential forms in three variables based on the four examples given above. We first notice that there is a certain formal similarity between the multiplication table for the unit vectors $\boldsymbol{e}_i \times \boldsymbol{e}_j = \sum_{k=1}^{3} \epsilon_{ijk}\boldsymbol{e}_k$ *and the corresponding table for the basic differential forms* dx, dy, *and* dz. *In the latter, however, we do not have the identification* $dxdy = dz$ *which corresponds to the relation* $\boldsymbol{e}_x \times \boldsymbol{e}_y = \boldsymbol{e}_z$. *This suggests that we link elements in pairs:*

$$\begin{matrix} dx \\ dydz \end{matrix} \leftrightarrow \boldsymbol{e}_x \quad \begin{matrix} dy \\ dzdx \end{matrix} \leftrightarrow \boldsymbol{e}_y \quad \begin{matrix} dz \\ dxdy \end{matrix} \leftrightarrow \boldsymbol{e}_z.$$

To complete these, and take into account 0-forms and 3-forms, we adjoin one more correspondence:

$$\frac{1}{dxdydz} \leftrightarrow 1.$$

We are now ready to set up a two-to-one correspondence between differential forms on one hand, and vector- and scalar-valued functions on the other. To any 1-form or 2-form will correspond a vector function, and to any 0-form or 3-form will correspond a scalar function. The rule of correspondence is indicated below:

$$\left.\begin{array}{r} A\,dx + B\,dy + C\,dz \\ A\,dy\,dz + B\,dz\,dx + C\,dx\,dy \end{array}\right\} \leftrightarrow A\boldsymbol{e}_x + B\boldsymbol{e}_y + C\boldsymbol{e}_z,$$

$$\left.\begin{array}{r} f(x,y,z) \\ f(x,y,z)\,dx\,dy\,dz \end{array}\right\} \leftrightarrow f(x,y,z).$$

In the opposite direction, we see that a vector-valued function corresponds to both a 1-form and to a 2-form, and a scalar function to a 0-form and to a 3-form. It then transpires that the single notion of multiplication among differential forms corresponds to both the scalar and vector products among vectors.

What vector operations correspond to differentiation of forms? Let us compare the differential of an 0-form $df = \frac{\partial f}{\partial x}dx + \frac{\partial f}{\partial y}dy + \frac{\partial f}{\partial z}dz$ *with the vector gradient of a scalar function* $\operatorname{grad} f = \frac{\partial f}{\partial x}\boldsymbol{e}_x + \frac{\partial f}{\partial y}\boldsymbol{e}_y + \frac{\partial f}{\partial z}\boldsymbol{e}_z$. *These are tied through the relation* $df = d\boldsymbol{r}\cdot\nabla f$.

As we proceed to 1-forms, it was shown earlier that its differential corresponds to the curl of the corresponding vector function. Finally, it was shown that the differential of a 2-form corresponds to the divergence of the corresponding vector function. Briefly, then, the single operation of differentiation in the system of differential forms corresponds in turn to the operations of taking the gradient of a scalar field and taking the curl and the divergence of a vector field. This is indicated schematically as follows:

$$\begin{array}{ccccccc} \begin{array}{c} f \\ \textit{scalar} \\ \textit{function} \end{array} & \longrightarrow & \begin{array}{c} f \\ \textit{0-form} \end{array} & \longrightarrow & \begin{array}{c} df \\ \textit{1-form} \end{array} & \longrightarrow & \begin{array}{c} \mathrm{grad}(f) \\ \textit{vector} \\ \textit{function} \end{array} \end{array}$$

$$\begin{array}{ccccccc} & & \begin{array}{c} \omega \\ \textit{1-form} \end{array} & \longrightarrow & \begin{array}{c} d\omega \\ \textit{2-form} \end{array} & \longrightarrow & \begin{array}{c} \mathrm{curl}(\boldsymbol{V}) \\ \textit{vector function} \end{array} \\ \begin{array}{c} \boldsymbol{V} \\ \textit{vector} \\ \textit{function} \end{array} & \begin{array}{c} \nearrow \\ \searrow \end{array} & & & & & \\ & & \begin{array}{c} \omega^* \\ \textit{2-form} \end{array} & \longrightarrow & \begin{array}{c} d\omega^* \\ \textit{3-form} \end{array} & \longrightarrow & \begin{array}{c} \mathrm{div}(\boldsymbol{V}) \\ \textit{scalar function} \end{array} \end{array}$$

Next, let $\omega = A(x,y,z)dx$. *Then*

$$d\omega = d(A)\,dx = \frac{\partial A}{\partial x}\,dxdx + \frac{\partial A}{\partial y}\,dydx + \frac{\partial A}{\partial z}\,dzdx = \frac{\partial A}{\partial y}\,dydx + \frac{\partial A}{\partial z}\,dzdx$$

and

$$dd\omega = d\left(\frac{\partial A}{\partial y}\right)\,dydx + d\left(\frac{\partial A}{\partial z}\right)\,dzdx = \frac{\partial^2 A}{\partial z \partial y}\,dzdydx + \frac{\partial^2 A}{\partial y \partial z}\,dydzdx = 0,$$

where we have used the symmetry of the mixed derivatives and the fact that $dydzdx = -dzdydx$. *A similar argument holds for* Bdy *and* Cdz.

Using the above results we see that the statement $ddf = 0$, *holding for a 0-form* f, *corresponds to the vector identity* $\mathrm{curl}(\mathrm{grad}\, f) = 0$ *and the statement* $dd\omega = 0$, *holding for a 1-form, corresponds to the vector identity* $\mathrm{div}(\mathrm{curl}\,\boldsymbol{V}) = 0$.

Our final connections between vector analysis and differential forms will be made by relating the integral of a form to integrals of certain scalar functions which are obtained by vector operations.

To see this we let $\boldsymbol{F} = A\boldsymbol{e}_x + B\boldsymbol{e}_y + C\boldsymbol{e}_z$ *define a continuous vector field in some region in space, and let* $\omega = Adx + Bdy + Cdz$ *be the corresponding 1-form. If* γ *is a smooth curve in the said region, and* $\boldsymbol{t}(s)$ *is a unit tangent vector to* $\gamma(s)$ *(where* s *is the arc length) then*

$$\begin{aligned} \boldsymbol{F}\cdot\boldsymbol{t} &= (A\boldsymbol{e}_x + B\boldsymbol{e}_y + C\boldsymbol{e}_z)\cdot\left(\frac{dx}{ds}\boldsymbol{e}_x + \frac{dy}{ds}\boldsymbol{e}_y + \frac{dz}{ds}\boldsymbol{e}_z\right) \\ &= A\frac{dx}{ds} + B\frac{dy}{ds} + C\frac{dz}{ds} \end{aligned}$$

and

$$\int_\gamma \boldsymbol{F}\cdot\boldsymbol{t}ds = \int_0^\ell \left(A\frac{dx}{ds} + B\frac{dy}{ds} + C\frac{dz}{ds}\right)ds = \int_\gamma \omega,$$

with ℓ *the length of the curve* γ. *The situation for integrals of 2-forms is similar.*

The theorems of Green, Stokes, and Gauss can be translated into the language of differential forms. They are all shown to be special cases of what is called the generalized Stokes' theorem, *connecting an integral of a differential form* ω *with an integral of its derivative* $d\omega$. *Symbolically*

$$\int_{\partial M} \omega = \int_M d\omega,$$

where M *is a* $k+1$ *dimensional manifold with boundary manifold* ∂M *and* ω *is a* k*-form.*

The demonstration[14] *of this statement in the case of Green's theorem is immediate since*

$$\int_\gamma \omega = \int_{\partial D}(Pdx + Qdy) = \int_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right)dxdy = \int_D d\omega,$$

where D *is a region in the* xy *plane and* ∂D *is its boundary curve* γ. *Similarly, for Stokes' theorem, if* Σ *be and oriented 2D surface embedded in* R^3 *and* $\partial\Sigma$ *its closed bounding curve (suitably oriented), we find:*

$$\begin{aligned}\int_{\partial\Sigma}\omega &= \int_{\partial\Sigma}\boldsymbol{F}\cdot d\boldsymbol{s} = \int_{\partial\Sigma}(Adx + Bdy + Cdz)\\ &= \int_\Sigma \left[\left(\frac{\partial C}{\partial y} - \frac{\partial B}{\partial z}\right)dydz + \left(\frac{\partial A}{\partial z} - \frac{\partial C}{\partial x}\right)dzdx + \left(\frac{\partial B}{\partial x} - \frac{\partial A}{\partial y}\right)dxdy\right]\\ &= \int_\Sigma d\omega.\end{aligned}$$

Finally, for a region R *in* R^3 *and its closed-surface boundary* ∂R, *with suitable orientations:*

$$\begin{aligned}\int_{\partial R}\omega &= \int_{\partial R}[Adydz + Bdzdx + Cdxdy]\\ &= \int_R \left[\frac{\partial A}{\partial x} + \frac{\partial B}{\partial y} + \frac{\partial C}{\partial z}\right]dxdydz = \int_R d\omega.\end{aligned}$$

---

[14] These are *not* in lieu of rigorous mathematical proofs.

This statement is the supercompact form of Gauss' divergence theorem, stating that the flux of a vector field out of an oriented closed surface equals the integral of the divergence of that vector field over the volume *enclosed by the surface. [In all these cases the orientations of volumes, curves and surfaces are related via the right hand rule]*

EXACT DIFFERENTIAL FORMS *constitute a special class of DF for which* $\omega = d\eta$ *[e.g.,* $\omega = 2xydx + x^2dy + 2zdz = d(x^2y + z)$*]. Clearly,* $\int_\gamma \omega = f(p_1) - f(p_0)$, *where integration extends from* p_0 *on* γ *to* p_1 *on* γ*.*

If γ *is closed and* f *single-valued, then* $p_0 = p_1$ and $\int_\gamma \omega = 0$. *In this case the line integral is* path-independent. *Furthermore, it follows directly from* $\omega = df$ *that* $d\omega = ddf = 0$ *throughout the region. This can be summarized by the flow-diagram*

$$\begin{array}{ccc} \begin{array}{c}\text{1-form } \omega \\ \text{exact in } \Omega\end{array} & \longrightarrow & \displaystyle\int_\gamma \omega \begin{array}{c}\text{independent} \\ \text{of path in } \Omega\end{array} \\ \searrow & & \nearrow \\ & \begin{array}{c} d\omega = 0 \\ \text{in } \Omega \end{array} & \end{array} ,$$

where Ω *is any sub-region in* R^n*.*

The notions of exactness and of path independence may also be given in vector form: If a vector field $\boldsymbol{F}$ *can be written as* $\boldsymbol{F} = \text{grad}\, f$, *where* f *is the* potential *of the field, then* $\int_\gamma \boldsymbol{F} \cdot d\boldsymbol{s} = f(p_1) - f(p_0)$. *For instance, if we let* $U = -f$ *be the* potential energy, *then* $\boldsymbol{F}$ *represents its force field.*

THE WEDGE PRODUCT *(WP): It is convenient to denote the multiplication of differential forms with a special symbol, the wedge* $\wedge$, *instead of just a juxtaposition that we used hitherto.*

Thus, for example, the product of the 1-forms $\omega = a_\mu dx^\mu$ and $\omega' = b_\nu dx^\nu$ *(both covariant vectors!) will be written as*

$$\omega \wedge \omega' = \frac{1}{2}(a_\mu b_\nu - a_\nu b_\mu) dx^\mu \wedge dx^\nu$$

and called the wedge product.

With $x^1 = x$, $x^2 = y$, $x^3 = z$, *we find as before*

$$\begin{aligned} \omega \wedge \omega' = (a_1b_2 - a_2b_1)dx \wedge dy + (a_2b_3 - a_3b_2)dy \wedge dz \\ + (a_3b_1 - a_1b_3)dz \wedge dx. \end{aligned}$$

With this notation, the product of differential 1-forms appear in a new light — as a totally antisymmetric form which takes in the vectors $\boldsymbol{a}(a_1, a_2, a_3)$, $\boldsymbol{b}(b_1, b_2, b_3)$ *and yields a number.*

Now, since in dyadic notation

$$\boldsymbol{ab} - \boldsymbol{ba} = (a_1b_2 - a_2b_1)(\boldsymbol{e}_x\boldsymbol{e}_y - \boldsymbol{e}_y\boldsymbol{e}_x) + (a_2b_3 - a_3b_2)(\boldsymbol{e}_y\boldsymbol{e}_z - \boldsymbol{e}_z\boldsymbol{e}_y) + (a_3b_1 - a_1b_3)(\boldsymbol{e}_z\boldsymbol{e}_x - \boldsymbol{e}_x\boldsymbol{e}_z),$$

we can set a one-to-one correspondence between the components of this totally antisymmetric tensor of the second rank and the terms of the wedge product $\omega \times \omega'$, *provided we also set the correspondence* $dx \leftrightarrow \boldsymbol{e}_x$, $dy \leftrightarrow \boldsymbol{e}_y$, $dz \leftrightarrow \boldsymbol{e}_z$, *and also* $dx \wedge dy \leftrightarrow \boldsymbol{e}_x\boldsymbol{e}_y - \boldsymbol{e}_y\boldsymbol{e}_x$, *etc. In this sense*

$$\omega \wedge \omega' \Leftrightarrow \boldsymbol{ab} - \boldsymbol{ba} \equiv \mathfrak{I} \times (\boldsymbol{b} \times \boldsymbol{a}).$$

Because of this correspondence, we may speak of the wedge product of 1-forms in the sense of DF, *and at the same time write*

$$\boldsymbol{a} \wedge \boldsymbol{b} = \boldsymbol{ab} - \boldsymbol{ba}$$

for the associated vectors. Note that $a_1b_2 - a_2b_1$ *is the signed area of the projection of the* $\boldsymbol{ab}$ parallelogram *on the* xy *plane, etc.*

The wedge product has the usual distributive and associative properties of abstract algebra over a field:

$$\begin{aligned} \boldsymbol{a} \wedge (\boldsymbol{b} + \boldsymbol{c}) &= \boldsymbol{a} \wedge \boldsymbol{b} + \boldsymbol{a} \wedge \boldsymbol{c}, \\ (\boldsymbol{a} + \boldsymbol{b}) \wedge \boldsymbol{c} &= \boldsymbol{a} \wedge \boldsymbol{b} + \boldsymbol{b} \wedge \boldsymbol{c}, \\ \alpha(\boldsymbol{a} \wedge \boldsymbol{b}) &= \boldsymbol{a} \wedge \alpha\boldsymbol{b} = \alpha\boldsymbol{a} \wedge \boldsymbol{b}, \end{aligned}$$

with $\boldsymbol{a}$, $\boldsymbol{b}$ *any forms and* α *is a scalar (0-form).*

But it is anticommutative (if $\boldsymbol{a}, \boldsymbol{b}$ *are 1-forms, or in general, if the degrees of* $\boldsymbol{a}$, $\boldsymbol{b}$ *are both odd):*

$$\boldsymbol{a} \wedge \boldsymbol{b} = -\boldsymbol{b} \wedge \boldsymbol{a}.$$

Specializing again to the case where $\boldsymbol{a}$, $\boldsymbol{b}$ *are 1-forms, the antisymmetric tensor* $\boldsymbol{a} \wedge \boldsymbol{b}$ *can be written symbolically in determinant form*

$$\begin{vmatrix} a_i & b_i \\ a_j & b_j \end{vmatrix}.$$

One can then extend $\wedge$ to triple and higher products. For example, the totally antisymmetric tensor of the third rank $\boldsymbol{a}\wedge\boldsymbol{b}\wedge\boldsymbol{c}$ *has the determinant form*

$$T_{ijk} = \begin{bmatrix} a_i & b_i & c_i \\ a_j & b_j & c_j \\ a_k & b_k & c_k \end{bmatrix}.$$

Explicitly, in triadic form,

$$T = \boldsymbol{abc} + \boldsymbol{cab} + \boldsymbol{bca} - \boldsymbol{cba} - \boldsymbol{acb} - \boldsymbol{bac}$$

is the proper definition of the triple wedge product $\boldsymbol{a}\wedge\boldsymbol{b}\wedge\boldsymbol{c}$. *This rank-3 tensor, or triadic, also known as a trivector, is antisymmetric in all its indices.*

The associated 3-form is obtained by the triple wedge product of three 1-forms corresponding to $\boldsymbol{a}$, $\boldsymbol{b}$ *and* $\boldsymbol{c}$*:*

$$\omega\wedge\omega'\wedge\omega'' = (a_1dx+a_2dy+a_3dz)\wedge(b_1dx+b_2dy+b_3dz)\wedge(c_1dx+c_2dy+c_3dz)$$
$$= \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} dx\wedge dy\wedge dz,$$

where the determinant is the 3-dimensional oriented volume of the parallelepiped spanned by the vectors $\boldsymbol{a}$, $\boldsymbol{b}$ *and* $\boldsymbol{c}$.

Science and Non-Science

The perspectives of science are, like those of philosophy and religion, thought-structures for viewing the world. Science *aims to attain objective truth, and scientific ideas ought to be ones in which we can trust as a matter of fact rather than opinion, and which are not subject to doubt and fads as are the beliefs of the religions, or even philosophies. Thus, the overall purpose of the scientific method is to make valid distinctions between the false and the true in nature, so as to render a true picture of realities and their underlying mechanisms and principles.*

Nevertheless, the average scientist *(by the very nature of his textbook-oriented education and the fact that his progress and success depend in many cases on the acceptance of given ideas) is as narrow, rigid and dogmatic as the orthodox theologician.*

In contradistinction to science and the scientific method we recognize certain related disciplines: pseudoscience *is false science, a body of 'knowledge' which is a mere belief, like astrology, alchemy, phrenology, Mesmerism, pangenesis, creationism, etc. Many of the theories of science, like the phlogiston and caloric theories, were not so much pseudoscience as* protoscience*: early first guesses that served well in their time. Indeed, the Ptolemaic geocentric astronomy, with its complex system of epicycles, would have quite adequately predicted planetary motion if only those astronomers who credited it had access to Fourier Analysis.*

Theories for which there is no concrete evidence like panspermia belong to the realm of quasi-science.

At the frontiers of science, the scientific method leads us sometimes to a multiplicity of doubts, where questions rather than answers prevail. There — we have no immutable answers, but rather hypotheses embracing the observable evidence[15].

This condition gave rise to a popular kind of imaginative literature known as science fiction (SF) *which deals principally with the impact of actual and imagined science on society and individuals.*

Unlike fantasy*, which deals with the impossible, SF describes events that* could *actually occur, according to accepted* possible *theories. While ordinary*

[15] Thomas S. Kuhn in his book "*The Structure of Scientific Revolutions*", Chicago Univ. Press, 1970) went as far as saying that scientists are 'puzzle solvers', not problem solvers.

'fiction' concerns itself more centrally with faith, psychology or history, SF is motivated by scientific knowledge.

Hence, the essential difference between SF and other forms of literature is, of course, that we are dealing with science *fiction. In some respects the very term seems to suggest a contradiction: how can the known and the make believe be part and parcel of the same creation. How can we reconcile the world of reason, manifest in technology, and the mysticism of spiritual experience?*

The basic themes of SF include space travel, time travel, and marvelous discoveries or inventions. Most modern SF stories are set in the future, but some take place in the past or even in the present day. Some are set in another universe. Some SF stories give detailed scientific explanations. Other stories simply thrust the reader into a strange time or place.

Like all fiction, SF make frequent use of myths, *those archetypal stories which provide the symbols that help us shape our world. The roots of SF, like the roots science itself are in magic and mythology.*

Science fiction is not like other writing about science; it looks forward *where other kinds usually look back, speculate — where other consolidate.*

The good SF writer is essentially a creative artist first, who knows or understands and sympathizes with one or more scientific thought. In a world where even group of scientists (e.g., physicists and geneticists) can scarcely understand each other, the SF writer sets himself as a kind of translator between different ways of seeing the world, not just todays, but tomorrow's world.

SF recognizes the germ of future development and enlarges upon it from different angles and in fanciful ways. It presupposes in its readers a willingness to consider possibility rather than fact. Prophetic accuracy is neither essential nor important ingredient of SF.

History[16]

The history of SF is also the history of humanity's changing attitude toward space and time. It is the history of our growing understanding of the universe and the position of our species in that universe. Like the history of science itself, the history of this literary form is thin and episodic until about four centuries ago, when the scientific method began to replace more authoritarian and dogmatic modes of thought, and people at last could see that the earth is not the center of the universe.

In the following survey of the history of SF we see it as a movement away from mythology toward realism; from a mythic way of seeing the world to a rational or empirical way of seeing it. As human science developed, human fiction changed with it. This movement involves a change in the world from one which lacks a clear distinction between natural and supernatural to a world in which the distinction is very clear and from which supernatural events are excluded[17].

The history of SF until 1950 *is divided into five stages:*

I. Collective prehistoric myths

Human beings felt the world to be alive with spiritual presence: divinities inhabited every bush and waterfall. People learned to fear and worship especially those gods they sensed behind the most awesome of natural phenomena — tempests, earthquakes, and the fertility of plants and animals. Our primitive ancestors knew a world that was timeless in one sense and tightly bound up by time in another.

- Bleiler, E.F., Ed. *Science-Fiction Writers*, Charles Scribner's Sons: New York, 1982.

[17] Fiction which *is* aware of this difference but deliberately presents supernatural events, is called *fantasy*.

It was a world without history, with no sense of historical change that might lead to situations different from those which people already knew; it was a world bound to the seasonal flow of time, planting and harvesting, sweating and shivering, thanking the gods for blessings and begging them to end punishments. The seasons required religious rituals, which were held to contribute to the great temporal cycle, without which humanity would surely perish. The rituals enacted episodes from the lives of the gods, explaining the creation of the world, and preserving in the memory of humanity the values of which the gods were believed to approve. These memories and values, when separated from their ritual enactment, we call myths. *Myths are the ancestors of all other fictions. They have immense inertia, persisting in time as a conservative force, teaching the old values, the old ways — resisting the new.*

Prehistoric myths abound with tales of fantastic voyages and adventures. The richest source of myths is the Bible *(the creation story etc.). Greek mythology gave us the story of the pioneer aviators Daedalos and Icaros.*

II. Ancient social utopias and fantasies *(ca 800 BCE–200 CE)*

Utopias *were the creation of an age of arbitrary authority and frequent (albeit creative) disorder, in which the security and prosperity of the majority could be imperiled at any moment by the willful behavior of a determined and powerful individual or minority. These were the wishful systems devised, by men of good will, for the constraint of the turbulent individual by means of institutions and laws. Their objective was order, their by-products were general prosperity and peace, and their foundation were a strict hierarchy in which each person not only knew and kept his proper station but enjoyed it. During this period scientific fantasy showed itself as a mingling of literature, science, and social theory.*

Hesiod *(ca 800 BCE) in his* Dreams of the Golden Age, *the Biblical visions of the* Hebrew prophets *(ca 800–300 BCE) and* ***Aeschylos*** *(ca 525–456 BCE) contain such elements.* ***Aristophanes*** *(ca 450–388 BCE) also investigated fundamental problems by distancing them through fantasy, as in* The Birds, The Frogs, *and the* Ecclesiazusae.

Social utopias rose to special importance in the prehellenist period; in the 5th century BCE up to the beginning of the 4th century BCE ***Hippodamos of Miletos*** *and* ***Phaleas of Chalcedon*** *sketched hierarchical social models, which anticipated some of the thoughts of* ***Plato*** *(427–347 BCE). In* The Republic, *Plato advocated the abolition of private wealth and the introduction of a kind of consumer communism.*

Other utopias were sketched by ***Euhemeros*** *(ca 340–260 BCE) and* ***Jambulos*** *(ca 200 BCE).*

The first true SF on record is that of the Greek writer ***Lucian of Samosata*** *(125–190 BCE). In about* 160 *CE he wrote Vera Historica (The True History) in which he described trips to the moon.*

III. The late Renaissance, reformation and the scientific revolution (1492–1752)

Science fiction's roots lie deep in the Renaissance, an epoch characterized above all by violent socio-economical changes caused by a transition from feudalism to capitalism. The explosive technological development seen during the Renaissance was intricately bound up with the progress of science in opening up the world. The new methods of research that were thereby perfected were founded upon experiment, observation, and experience.

Copernicus*' heliocentric cosmos,* ***Gutenberg****'s invention of the printing press with movable type, the voyages of discovery led by* ***Columbus****,* ***da Gama*** *and* ***Magellan*** *— each was an immense achievement in its own right; together they were the basis for a flowering of the sciences, arts, and literature on an unprecedented scale.*

The alterations in the means of production led to a transition from a theocentric to an anthropocentric world views. The emphasis was now on people and the power of the personality, the might of the individual. The revolutions of the epoch became the objective sources for the later humanist movement and for the development of a deeply humanist view of the world and mankind.

Philosophy strove for the liberation of humanity from the fetters of theological dogma. Renaissance art did away with medieval conventions and turned towards the realities of life, to the activities of humans in their changing world. From these contradictory processes new genres of literature peculiar to the new age sprang up. The modern novel began to crystallize; the epic was already loosing its importance. The Renaissance gave rise to the gradual merging of traditional imaginative fantasy with scientific ideas. Thus the Renaissance saw the birth of scientific fantasy, or, what is now called — science fiction.

The main contributors to SF during this period were:

***Thomas More** [Morus, 1478–1535 (executed)]. En English statesman and humanist*[18]*. In his Utopia (1516) he set his ideal society on an island at the very edge of the world. (The word* utopia *literally means: nowhereland).*

***Ludovico Ariosto** (Italy, 1474–1533). In his Orlando Furioso (1532) he describes a fictional voyage to the moon.*

The idea of the first robot, the legendary Golem, is attributed to the chief Rabbi of Prague, the philosopher, savant and Kabbalist, ***Yehuda Liwa*** *(1588). He was an historical figure, a friend of* ***Tycho Brahe*** *and* ***Johannes Kepler****. In real life he was a sober theologian, not a man to meddle with magic, but the legend about him was rather different.*

To protect his people against the pogroms, the tale goes, Liwa and two assistants went in the dead of the night to the River Moldau, and from the clay of the riverbank they fashioned a human figure. When Liwa inscribed the Holy Name upon its forehead, the golem opened its eyes and came to life. It was incapable of speech, but had superhuman strength. It became Liwa's servant and worked as a sanitary within the temple. Only Liwa could control it, but eventually the golem could not be controlled at all. It ran amok, attacking its creator. Its career of destruction ended only when Liwa plucked the sacred name from its forehead. Magically, the golem was once again reduced to clay.

***Thommaso Campanella** (Italy, 1568–1639) was a Dominican friar. His utopia (1602) Civitas Solis (The Sun State) describes an ideal communal society which, like More's, is located at the furthermost reaches of the known world.*

***Christopher Marlowe** (1564–1593, England) wrote (1604) The Tragical History of Dr. Faustus.*

[18] He was born in London. During his college years in Oxford, he became familiar with representatives of the "new learning" (which meant Greek learning), and he would fain have followed in their footsteps, but his father, Justice Sir Thomas, wanted him to make law his career. Toward the end of the century he became acquainted with Erasmus, who influenced him deeply in many ways. His *Epistola ad Martinum Dorpium* was a defense of Erasmus' *Moriae encomium* and of the new learning; his masterpiece, *Utopia*, revealed not only his piety and love of education and learning, but also his consciousness of social wrongs. It is a satire on English (or European) conditions, for life in Utopia is the reverse in almost every respect of English life. More gives an elaborate description of the good society, which brotherhood, universal education, and religion combined with toleration would make possible. Not only was he one of the first defenders of the education of women, but he suggested that women be admitted to the priesthood.

Francis Bacon *(1561–1626, England) wrote New Atlantis (1627). This work uses the theme of a marvelous voyage to describe a society based on experimental science and the practical wonders that science could create.*

Johannes Kepler *(1571–1630, Germany) described a trip to the moon in his Somnium (1634). This book was the first SF that tried to tell a story with scientific accuracy.*

Cyrano de Bergerac *(1619–1655, France), in his L'autre mondes (1642, 1650), combined the philosophical systems of* **Descartes** *and* **Gassendi** *in two SF stories: in the first he describes for the first time a motorized lift-off into space in a rocket propelled spaceship through which he reaches the moon. In his second he describes a flying machine which takes him into the realm of the sun.*

In 1719, after economic and social ups and downs and tireless work in a multitude of fields, **Daniel Defoe** *(1660–1731, England) at 59 published his book The Life and Strange and Surprising Adventures of Robinson Crusoe of York. This book owes its origin to the Renaissance sailor-discoveries and the picaresque fictions of many literary predecessors, and to various portrayals of island life. It follows the philosophy of John Locke, that nature and common sense are motivating forces at the source of all individual and social evolution; knowledge won from experience triumphs, and achieves success for the individual.*

The astronomical discoveries of the 17^{th} *century and* **Torricelli***'s discovery of outer space (1643) have shown how precarious was man's grip of the universe, and enhanced man's primordial fears — fears that science itself helped to create.*

Science fiction tried to deal with these fears in two ways: first, by alleviating it through rationalization (inventing myths to limit and control these fears); second, use of the scientific method to modify his environment and therefore, ultimately, his density. These two themes occur and reoccur, through the history of SF, since the scientific revolution to the present day.

As SF developed during the 1700's, it produced its first literary masterpiece; Gulliver's Travels (1726) by **Jonathan Swift** *(1667–1745, England). In his book Swift subjected to rational analysis, the economic and social aspects of the postrevolutionary age in England*[19].

[19] We find in *Gulliver's Travels* (1726) a literary reference to the two moons of Mars. But these moons were first observed by Asaph Hall in 1877. How could have Swift known? The answer is quite simple: In 1610 **Galileo** used one of the earliest astronomical telescopes to discover the 4 moons of Jupiter. When **Kepler** heard of this, he immediately assumed that Mars must have two moons.

The first story of visitors from other planets was Micromégas (1752) by ***Voltaire*** *(1694–1778, France).*

Many of the basic ingredients for science fiction had appeared in embryo form by the early 18^{th} *century. Even if SF is taken as no more than a kind of fictional humanism, it was clearly not sufficient for its growth merely to have a widespread inculcation of scientific 'facts', acceptance of the experimental method or the stimulus of apocalyptic forebodings.*

These, however tenuously, in the shape of biblical fundamentalist dogma, the beginning of experimental science in ***Roger Bacon****, the experimental laboratories of the Renaissance, and the conviction of an imminent call to final judgment – are all influences on medieval literature which yet produced no science fiction.*

It was additionally necessary for the belief to be established, amongst at least a substantial minority, that Man could, through the use of the scientific method, modify his environment and therefore, ultimately, his destiny.

IV. The industrial revolution, the Victorian period and the turn of the 20^{th} ***century*** *[1776 (first steam engine) –1913]*

The second great epoch for SF literature is closely related to the scientific and technical, political and social, military and intellectual developments in Western civilization during the 19^{th} *century.*

Indeed, the palpable progressiveness of science and technology, and the similar concreteness of political change in revolutionary Europe and America at the end of the 18^{th} *century, forced people to begin perceiving the world in new ways. Above all, humanity was finally faced with a future at once real and unknown, stimulating and terrifying.*

The industrial revolution, via the steam engine, had a profound effect on the very structure of society; on one hand, it increased mass misery, poverty and hardship. These elements influenced the Gothic novel, which featured horror, violence and the supernatural.

After all, the planets are organized according to geometrical law: Venus has no moons, the earth has one, and so Mars — between earth and Jupiter — must have two to form a geometrical progression! This conclusion has always been accepted as true, and well known to Swift.

[Jupiter, incidentally, has 14 moons (1994)]. Kepler was lucky enough to have his belief *seem* right, and hence scientific. But the scientific knowledge was still based, in part, on belief.

On the other hand, most authors were deeply impressed by the fact that the new machines were able to multiply a hundredfold the muscle power of the worker, that new secrets were being wrung from nature every day, that products were being moved to and fro on the world market quicker than ever before, and that radio created the means of immediate communication worldwide.

The belief soon surfaced that science alone would be able to bring into being a superior mode of life. Thus this second phase of SF is characterized primarily by its sense of euphoria. The leading authors of this era are:

***Ernst Theodor Amadeus Hoffmann** (1776–1822, Germany) was intensely preoccupied with the Mesmerian theory of animal magnetism (1813) and intelligent machines (1814). Other fantasy tales by Hoffmann contain ideas that play important roles throughout SF: vampirism, strange beings in animal form, non-decaying dead bodies and much more.*

***Mary Wollstonecraft Shelley** (1797–1851, England) created (1818) the monstrous figure of Frankenstein — the archetype of the restless scientist not to be deflected from his own research and experimentation. Like his famous predecessor, the single-minded quester, **Marlowe**'s Faust, Frankenstein is ready to break down the boundaries of knowledge, giving not a moment's thought to considerations of the rightness or morality of his activities. Not satisfied with half solutions or compromise, he must aim directly at the summit, become a godlike figure, a second creator. This over-reaching, of course, means his eventual fall is so much the greater.*

Mary Shelley blended the old theme of the artificial creation of life with the new contemporary genre of the Gothic novel. She thus introduced the hideous, the heinous, the cryptic, and the criminal into literature and combined them with "scientific" elements.

***Edgar Allan Poe** (1809–1849, U.S.A.) developed the SF short story. In 'The Unparalleled Adventures of One Hans Pfaall' (1835), he describes a journey to the moon. Perhaps under the influence of Cook's voyages (1773–1774) he wrote 'The Narrative of Arthur Gordon Pym at Nantucket'.*

*Under the combined influence of Mary Shelley and Poe, the Scottish poet **Robert Louis Stevenson** (1850–1894) wrote 'Dr. Jekyll and Mr. Hide (1886), where a scientist, obsessed with his pursuit of knowledge and enlightenment, is temporarily changed into a monstrous alter ego. He thus layed the foundations for an investigation into the duality of human nature by splitting it clearly into good and bad.*

***Henry Rider Haggard** (1856–1925, England) wrote 34 novels of history and adventure. His best novels are based on his experience in Africa; King Solomon's Mines (1885) became a young people's classic. It is the story of* *search for the legendary lost treasure of King Solomon. She (1887) is the story of Ayesha ('She who must be obeyed'), a white goddess of Africa who is 2000 years old but still appears young and beautiful.*

Haggard was a firm believer in the evolutionary theories of Darwin. The memorable fantasy element in the book is Ayesh's surprising death as She baths herself in a "life-giving" flame (that seems strangely prophetic of nuclear power!) and slowly reverts — in a reverse of Darwinian "ontogeny recapitulates phylogeny" — from a smashingly beautiful woman to a 2000-year-old ugly ape.

Ayesha's memorable transformation in death recurs in the mainstream utopian novel Lost Horizon (1933) by **James Hilton**[20] *(1900–1954, England) — when a beautiful "immortal" woman living well beyond her years in the salubrious atmosphere of Shangri-La (a secret Tibetian monastery) leaves her home with her new English lover only to turn wrenchingly into an ugly, aged crone during her passage out. The utopianism of Shangri-La has its ingenious combination of the careless rapture of an unpolluted "magic" atmosphere and the practice of passive Eastern mysticism. The message is clear — an utopian place of ideal perfection is an impractical scheme for social improvement.*

When Poe needed a fiction catalyzer to set off his moon voyage, he invented an atomic component of hydrogen discovered by a chemist at Nantes, France. Poe had no way of knowing that there had just been born at Nantes someone who would become the most catalytic figure in the history of SF.

Jules Verne *(1828–1905, France) was the first classic writer of SF literature, who* specialized *in science fiction. His subject is nature. The* voyages extraordinaires *explore worlds known and unknown: the interior of Africa, the interior of the earth, the deeps of the sea, the deeps of space. Characteristically, Verne's voyagers travel in vehicles that are themselves closed worlds, snug interiors from which the immensity of nature can be appreciated in upholstered comfort (e.g., the* Nautilus*). The basic activity in Verne is the construction of closed and safe spaces, the enslavement and appropriation of nature to make place for man to live in comfort. Verne's novel is built upon an unresolvable incompatibility between a fundamental materialistic ideology and a literary form that projects the world as ultimately magical in nature. He thus produced narratives that mediate between spiritualistic and materialistic world views.*

Verne draws on new discoveries, experiments in physics and chemistry, and and technological discoveries of his immediate present. He led his characters to parts of the world that at the time were largely unknown and unexplored.

[20] He went on to write his masterwork *Good Bye, Mr. Chips* (1934). In 1935 he came to live in Hollywood, where he wrote film screenplays.

These backgrounds enhanced the exotic nature of the adventurers described. For instance, Verne describes Africa (Five Weeks in a Balloon, 1863); the delta swamps of Florida (North Against South, 1873); Siberia and China (Michael Strogoff, 1871); the Arctic and the North Pole (The Adventures of Captain Hatteras, 1866); India (Around the World in 80 Days, 1873); the depths of the ocean (20,000 Leagues Under the Sea, 1869); the interior of the earth (Journey to the Center of the Earth, 1864); the deeps of space (From the Earth to the Moon, 1865)[21].

---

[21] An unknown manuscript, written by Verne in 1863, was discovered in 1989 by his great grandson Jean Verne in Toulouse. The novel *Paris in the* 20^{th} *Century* centers on the year 1963 and describes a society run by high finance and technology. In the story Verne anticipates the Daimler automobile (invented 1885), the electric chair (invented 1888) and the modern telefax machine.

The *principle* of the 4-stroke internal combustion engine was proposed in 1862 by **Alphonse Beau de Rochas**, of which Verne may have read!

Hard as it is to believe, the fax machine is older than the telephone and patents for the first prototype date back to 1843. The first commercial fax system called the *pantelegraph* was invented by the Italian priest **Giovanni Caselli** (1855). This was a relatively complicated system: an iron point crossed by a current was used to write onto a paper impregnated with a solution of potassium cyanate which is decomposed, leaving a blue mark on the paper. Despite the difficulties in synchronizing the transmitting needle and the receiving needle, the Caselli system was installed between Paris Amiens and Marseille in 1856. Verne must have known about this enterprise prior to 1863.

In 1980, modern fax machines came into being with a fax standard that allows *digital signal* to be sent over regular telephone lines in one minute or less. The pictures or text are converted to binary form and sent via standard telephone lines. On the other end, the fax machine decodes the bits and reconstructs the image.

However, Verne sometimes abused science for primarily fictional purposes: In *From the Earth to the Moon* (1865), for example, Verne has his ballistic spaceship fired from a mine 35 meters deep hole in Florida. He knew perfectly well that a hole of that depth anywhere in Florida would be under water; his straight-faced show of scientific accuracy ironically masked a satire on American ingenuity.

In *Purchase of the North Pole* (1889), some amateur scientists conspire to change the earth's axis by explosives, thus melting the polar ice cap and making accessible vast mineral wealth. Verne chose to ignore what he knew perfectly well — that the experiment would be likely to devastate all coastal cities as it would free the ice-bound land masses — not for the purpose of satire but for the simpler joy of working out the problem of axis-shifting, and the consequences be damned!

The great claim made for 20,000 *Leagues Under the Sea* is that Nemo's *Nautilus*

The era in which Verne was writing was an era of unbounded belief in science. Mankind rules the natural world and the limitless power of technology was the tool through which he ruled. This was the credo of the 19*th* *century bourgeoisie, and was the formula according to which Verne created the characters in his fictions.*

Enlightenment had paved the way to compulsory education which — according to the demands of the new forms of production — was accomplished in more and more countries and led to the growth of the reading public. The need for information in all classes of society, but especially the new middle classes, continued to increase with the growth of international trade — and as traveling became easier.

*Apart from books, there were newspapers and magazines of all kinds, and in particular, family journals, which bridged the gap between knowledge and entertainment. The now very high turnover in books helped finance research in high grade paper production and in printing itself. This led to the invention of the cylindrical paper-making machine (***John Dickinson***, 1809, England), the new steam press (***Friedrich König***, 1810–1811, Germany) and machine-aided book-sewing and book-binding methods.*

Through such developments, book production was simplified and the product made cheaper to buy. Print run multiplied and the structure of literary genres was irrevocably changed, with more and more authors working for the press.

New forms of publicity, pamphlets and early eye-witness reports had an effect on the purer forms of storytelling: the serialization of novels, stories, and travel books in magazine was tried, first of all in France, and found to be highly popular. Writers adapted their techniques to these new conditions by developing literary methods of creating and maintaining suspense. Other fundamental aspects of sale were the increasing members of new lending libraries spreading like wild fire.

---

accurately predicts the development of the submarine. In fact, Verne was creating the fictional context, fully *against* the facts of contemporary science, that would give the submarine the thrill of the fantastic — and then he used much of the book to make this fantasy plausible.

Without detracting from such inventive detail as electric lighting, chemical oxygen production, seaweed cigars, and so on, one should note that **David Bushnell**, who coined the name *submarine*, first successfully tested his *Turtle* in 1775; **Robert Fulton** demonstrated a functional steam submarine in the Seine in 1807 (this ship, incidentally, was named *Nautilus*); and the Confederate States of America, in 1864, successfully used the 9-man submarine *Huntley* — to sink the United States frigate *Housatonic*. Verne doubtless knew all this.

Only when set against this background can the far-reaching effectiveness of Jules Verne work be fully appreciated.

Since Verne was so extraordinarily successful with his basic structure, it is really not to be wondered at that many writers sought to borrow his formula. Elements of his concepts were common in adventure fiction up through the middle years of our century. Moreover, Verne's best works still rank at the forefront of SF. Versions are produced on stage, on film, or on television; famous actors do not turn down the chance to play the parts of Verne's characters. The roots of this success may be traced to Verne's skill in combining strenuous and exciting action with accurate observation of human capacity and value under most adverse conditions, in addition to immense optimism conveyed in his books.

In the 130 *years that passed since Verne embarked on his career, science and technology have made advances of which it was impossible for the author of* From the Earth to the Moon *even to dream.*

***Edward Everett Hale** (1822–1909, U.S.A.), an American Unitarian clergyman (and chaplain to the U.S. Senate), editor and humanitarian. In his SF book* The Brick Moon and Other Stories *(1869) he rendered the first serious, extended consideration of an artificial satellite launched into space. This story, however, did not have much historical influence.*

***Edward George Earle Bulwer-Lytton** (1803–1873, England). First Baron. Historical novelist and playwright in Victorian England and politician. Best known for his novel* The Last Days of Pompeii *(1834) and the SF* The Coming Race *(1871). In the last novel he describes a world inside the earth inhabited by a strange underground race with superman technology (robots, death-rays, non-conventional power sources etc.).*

***Samuel Butler** (1835–1901, England) is best known for his satirical SF novel* Erewhon *(1872) that ridicules English institutions and customs through the eyes of a traveler in a strange new world. [Erewhon — a backward rendition (almost) of the word "nowhere".] The Butler's new society is developed not from the scientific penetration of political and social problems but rather from the individual extrapolation of Darwinian ideas, to which Butler vehemently objected.*

The similarities between Butler and Bulwer-Lytton lie in the fact that both envisage a future in which the social structure they know stays largely unchanged and both have little belief in the possibility of a social flowering of mankind. They unite against the loss of individual identity, and place their hope for change principally in the use of technological and scientific discoveries.

Sir Arthur Conan Doyle *(1859–1930, England) is most known for his detective fiction hero Sherlock Holmes (1887–1915), but he wrote also a SF series based on the figure of Professor Challenger. One of these novels is The Lost World (1912), his most important contribution to the literature of SF. It is also most central in illustrating his artistic and scientific vision. The novel tells about an expedition to the upper Amazon where the group discovers an ape-man society thought to be the missing link in human evolution. The power of The Lost World lies in a consummate balance of adventure, skilled characterization, novelty of story line, and adept use of scientific themes. Doyle's use of concepts taken from paleontology and evolutionary theory gives the action verisimilitude.*

In The Poison Belt (1913) Doyle speculates that humanity may not be the culmination of evolution, but only a temporary development to be surpassed and supplanted by other higher organisms unlike it in form. The power of the story lies in Doyle's moral thesis that humanity is given a second chance to fulfill its moral destiny on earth. It must recognize its feebleness before the infinite latent power of the universe. Thus, Doyle's vision of the future of mankind is shaped, not in scientific progress, but in progressing to a higher level of moral awareness through a recognition of a world beyond this life; materialism and conventional religion only further distort our view.

Herbert George Wells *(1866–1946, England). Novelist, historian, science writer and one of the most important pioneers of modern SF.*

He was born some three years after Verne's first major success with Five Weeks in a Balloon. His fiction embodies stimulating ideas of unrivaled originality. Wells the man is as entertaining as his fiction, for he retained until the end a diabolical mixture of a sentimentalist, a moralist, a patriot, a racist, a member of a secret society and a dreamer. Out of the 120 *books that bear his name — a small but significant proportion of them are SF. Among his best known novels in this field are: The Time Machine (1895), The Invisible Man (1897), The War of the Worlds (1898) and The First Men in the Moon (1901).*

Wells made significant strides forward from the Vernian model of SF. He did not confine himself to the fictional conquest of geographical areas of the natural world known to exist though as yet still not fully explored. Wells toyed with ideas wholly new — time travel, contact with other beings, aliens, wars between worlds etc. He thus first introduced into literature those ideas and themes that for nearly a century have formed the basis of SF throughout the world and that still inspire authors now to try new variations.

The Time Machine (1895) includes references to contemporary prerelativistic interpretation of time as a 4^{th} *dimension. Wells was by no means the first writer to confront the present with either the past or the future.*

In **Mark Twain**'s humorous novel *A Connecticut Yankee in King Arthur's Court* (1899) and **Edward Bellamy**'s *Looking Backward* (1888), the heroes are sent into the past and the future respectively.

The Time Machine was however the first SF story wherein a machine is envisaged that enables travel through time at will, and in this respect it can claim to be the first example of a new branch of SF.

The War of the Worlds (1898) was certainly motivated by the "discovery" of **Schiaparelli** (1877) of canals on Mars. Wells took **Lowell**'s premise of intelligent Martians (1896), added to it the aggressive nature attributed since ancient times to the blood red planet named for the god of war, and used Lowell's scientific descriptions of Mars to extrapolate the nature and aims of the race which invades earth. This line was later extended by Edgar Rice Burroughs in his novel *A Princess of Mars* (1912).

Nowadays, people believe anything, and they exist in a world-situation of insecurity. The Victorians of the 1890's were reasonably secure, reasonably arrogant. Wells took advantage of that situation: instead of our being the imperialists, the conquerors — supposing something arrived that fully intended to conquer us? Wells' nastiness really wounds because there is the poison of moral purpose at its tip. The Martians are what *we* may become! The conquering Martians are at once the products and victims of evolution. For all their pride, they fall prey to bacteria.

The most important novel exploring technology and its future in the epoch under consideration is *The Tunnel* (1913) by **Bernhard Kellerman** (1879–1951, Germany). Kellerman's fantasy tells of a tunnel dug out under the Atlantic Ocean connecting Europe and America. It followed the spectacular sinking of the *Titanic* in the Atlantic by only two years. The impression of this catastrophe was still vivid in the minds of readers, rendering them particularly receptive to the notions of the author with his suboceanic borrowings.

Apart from the concessions to the age in which he lived (for example, anti-Semitic elements, which are incidentally also to be found in the work of Jules Verne), this novel is a model of exploiting futuristic technology. Kellerman presents on the one hand the possibilities inherent in modern industrial society, and on the other hand, explores the dangers that threaten humanity through its existing contradictions.

The name of **Edgar Rice Burroughs** (1875–1950, U.S.A.) burst onto the world scene in 1912 with two novels published one after the other in the pulp magazine *All-Story*. The first was a serial titled *Under the Moons of Mars* (republished in book form in 1917 as *A Princess of Mars*); the second was *Tarzan of the Apes*. His biggest success in terms of popularity and monetary reward came from the Tarzan stories and films. However, Burroughs was known from the start, far and wide, for his non-Tarzan science fiction as well.

Although science per se plays little part in his work (and it is safe to say that he knew and cared little about it), owing to their huge commercial success, they found countless imitators and did have a profound effect on the development of SF form in America after WWI. Tarzan became one of the most famous characters in fiction and outlived Burroughs in novels and film.

By 1975*, more than* 36 *million copies of Tarzan books, in* 56 *languages, had been sold, making Tarzan an international superman folk-hero.*

Prior to becoming a best-selling novelist, Burroughs had behind him a career as a soldier, policeman, Sears Roebuck manager, gold-miner, cowboy and storekeeper. He had two towns named after him, but never visited Africa. His stories, according to many critics, belong to the lowest stratum of literature: narrow mental world, weak plotting, paper-thin characters, cumbersome and amateurish style. Yet the readers gobbled up Burroughs, always seemingly hungry for more.

The glorification of strength and the outdoor life and simplistic solutions to the problems of a rapidly changing world were popular ideas during the time of Theodore Roosevelt. Tarzan was also a unique superman, since he reconciled elitism and democracy.

V. Dystopia *(1921–1950)*

Social and political arguments, which appeared in much early science fiction, were emphasized even more in the 1900*'s. One of the main literary currents that dominated SF during the above epoch was the newly formed* dystopia *or anti-utopia; while utopian fiction portrays ideal worlds, anti-utopian fiction sees these ideal worlds as nightmares.*

Since the 18^{th} *century, some prophetic anticipations of scientific achievements were made by physicists and SF writers alike:* ***Newton*** *(1728) in* The System of the World *(a popular version of the third book of the* Principia*) envisaged man-made satellites.* ***Jules Verne*** *(1863) anticipated rocket-launching, non-classical power source through which his* Nautilus *was propelled, incandescent lighting (1870, nine years before Edison's patent was granted) and ocean-landing of spacecraft*[22]*.* ***Mark Twain*** *(1898) forecasted television, which he named* telectroscope*.* ***Cleve Cartmill*** *(1944) correctly hypothesized, in a story called* Deadline*, how one may construct an atom bomb — as the Manhattan project was then doing in extreme secrecy. (He*

[22] **F.R. Molton** stated unequivocally in an astronomy textbook (1930) that SF stories about interplanetary travel were totally impossible and that anyone knowing the physical forces involved would know them to be so!

was interrogated by military intelligence). ***Frank Quattrochi*** *(1955) predicted the heart-lung machine.*

In the United States, magazines called pulps *have played the major role in development of SF.* ***Hugo Gernsback*** *founded the first pulp, Amazing Stories (1926). In* 1930 *he became the first person to use the term* science fiction*. The early pulp magazines concentrated on scientific marvels, but turned increasingly to major social concerns after* ***John W. Campbell*** *Jr. became editor of Astounding Science Fiction (1937). Campbell developed a group of writers who dominated the field in the mid-*1900*'s, including* ***Isaac Asimov*** *and* ***L. Sprague de Camp****.*

Science fiction gained a wider audience after WWII ended in 1945*. Its popularity grew as developments in atomic energy and space exploration showed that much SF was more realistic than many people believed.*

Karel Čapek *(1890–1938, Czechoslovakia), Czech humanist, prolific man of letters and a working journalist throughout his career. A critical observer of certain manifestations of the time. Čapek did most of his writing during the unsettled period between the first and second World Wars. In his travels in numerous countries throughout the world, and in his own country, he recognized an increase in violence, and saw the dangers inherent in manipulating people and subjecting them to faceless power. In these circumstances, it is perfectly understandable that Čapek should choose to estrange himself from individual and social trends by means of SF at the beginning of the* 1920*'s.*

In rapid succession he published a series of works that are of equal interest in terms of the history of mainstream literature and in terms of the history of SF literature. Chief among those are the play R.U.R. (Rossum's Universal Robots[23], 1920) and Krakatit[24] *(1924). In the years succeeding this burst of literary fantasy, Čapek turned his attention to the small everyday things in life. Only in* 1936 *did he revert to the metaphorical mode of SF in The War with the Newts. In all these works, Čapek shows his concern of man's destruction of himself by science; the danger to mankind arising from contradictions between the advances of technology and the stagnation in human ethical maturation.*

In R.U.R. the robots represent a complex of symbolic meanings; the threatening aspects of the industrial dehumanization of the work force as well as the pathos that surrounds the victims of the assembly line. Through this

[23] Taken from the Czech *robota*, meaning 'forced labor'. This word was invented by Čapek's brother Josef.

[24] A name of a *castle* planted in the same unstable soil as **Franz Kafka**'s (1883–1924). Both men inevitably responded to the same cultural traumas as the Austro-Hungarian Empire entered its death throes.

ambivalence, the image of the robot represents the logical outcome for the helpless masses. (In the play, the robots are not mechanical metallic creatures but androids-living organic simulacra–indistinguishable at first glance from humans.)

The title of Krakatit *gives an immediate hint of what is to come by recalling the devastating aftermath of the famous* 1883 *eruption of the volcano Krakatoa. In the novel,* Krakatit *is a superexplosive atomic substance, something like an atomic bomb, through which a dictator wants to conquer the world. Instead,* Krakatit *destroys those who try to misuse it.*

The War with the Newts *is one of the masterworks of SF. It is basically an anti-Nazi satire and a grim sense of what the future might hold in store for mankind. It is not surprising that the Gestapo tried to arrest the dead Čapek. But Čapek died before the Germans could kill him and before WWII could provide him with material that might simultaneously inspire the intensity of* Krakatit *and the complex thrust of* The War with the Newts*. Čapek's influence has been for the most part indirect, although his humane breeziness arguably infuses the work of some SF writers today.*

Aldous Huxley *(1894–1963,* England) *wrote the classic dystopia* Brave New World *(1932), a title taken from Shakespeare's* Tempest*. It describes a male-dominated world in which the population is perfectly controlled and people are genetically engineered in carefully regulated mental and physical sizes and types. The author employs characters as mouthpieces for the dialectic of his tale. They engage in Socratic dialogues. In* Brave New World*, the products of science have overwhelmed the poise of human reason.*

Huxley's great fear was not that what science could do should not be done, but that science would become the only *thing that man did — and, after all, this turns to be too little.*

The brave new world is boring. In the use of science to find safety, discipline and courage have become obsolete. A civilization ordered solely by science, sex, and drugs kills the spirit. People become mere cattle. Savagery may be preferable. The savage knows little joy and ecstasy, but by the almost limitless capacity for pain that he had learned, he can imagine, dream of, and therefore in a way attain a transcendence of the richest possible pleasure of his body. Other persons in the novel might die, but only the death of the savage can be profoundly tragic.

Virtually all that Huxley had to say in his SF centered on earth and on mankind. He tried to anatomize the confusion of human science, art, and spirit.

George Orwell *(1903–1950,* England*), novelist and political writer; can be considered as a SF writer if we define utopia as a socio-political subgenre* *of science fiction. He wrote Animal Farm (1945), a political allegory — a satire on the Russian revolution and its monstrous perversion of the vision of democratic socialism. His last novel 1984 (1949), a nightmare, is a culmination of Orwell's intellectual and artistic development: a dystopian nightmare that fuses all the themes derived from his reading, his personal history, and his involvement with some of he more significant socio-political issues of his time.*

1984 most fully dramatized Orwell's fear that a totalitarian state could legitimize its power by "altering" the past, present and future, that it could control its subjects' perception of reality by consciously manipulating language. The interpretation of language and experience, which constitutes one of the major themes of the novel, has interested thinkers from Aristotle to Karl Marx;

The specific relationship between language and political power had been discussed before, but after the Holocaust, born of the masterful evil rhetoric of the Nazi Führer, Orwell's brilliant dramatization of these themes takes on additional significance and power. (The Nazis used symbols in such a way that people did not only think about hate, but expressed hate. The Führer did not use language to teach the Germans to think; he provided them with forms through which they could act.) Orwell's socio-political legacy is therefore two-fold:

- *"Reality" and "meaning" are not identical with "fact". Meaning arises in social relationship that exist in and through the communication of significant symbols, most notably in language.*
- *History was not something to be created but rather discovered*[25]*, and intellectual freedom lay in being able to report this history. If people cannot know, cannot be certain about events, they all fall victims to the most irresponsible propaganda.*

Orwell meant, 1984 to be a warning, not a prophecy. The book's gloom is often referred to his illness and his growing conviction of the manipulability

[25] At his point Orwell's position is at par with arguments from such historians as **Benedetto Croce** (1866–1952, Italy), who insisted that all history is "present" history in the sense that it is impossible to create an objective historical narrative. History is not a mere description of the past, but an evaluation of it, with EACH GENERATION RENDERING ITS OWN VALUE JUDGMENT OF IT. The interpretation of history creates history, by constructing the mind's self-creative value judgment of events. Since the philosophical interpretation of the present generation will one day be history, philosophy and history must be considered identical.

of the human mind. The book's despair comes not just from the fact that tyranny is universal and that the individual is doomed, but from the bottomless selfishness of the human being.

Born Eric Arthur Blair in Bengal, India, son of an official in the Indian civil service. He returned with his parents to England, and after education at Eton, joined the Burmese police. Returning to Europe (1927) he chose to live among the deprived, and completed his rebirth by adopting a new name. Until 1935 *he lived with the poor, tramped over the English countryside. He participated one year (1936–1937) as a common soldier in the Spanish Civil War on the side of the Republicans, where he became disillusioned with Communism. After* Animal Farm *appeared, Orwell took a house on Jura in the Hebrides. He died of tuberculosis soon after writing his last novel, 1984.*

As scientific ways of understanding the world developed in the 17^{th} *and* 18^{th} *centuries, fiction became more and more realistic, and the realistic novel came more and more to dominate the world of fiction. Fantasy was considered a minor form, suitable for children or as light reading for adults, but not really "literature", not really serious.*

In the 19^{th} *century, realism developed new techniques for representing a whole social scene accurately and finally new ways of making individual psychology available to readers. The realistic novel presented* this *world in* this *time, competing with history and journalism as a way of recording the truth of contemporary experience. So powerful was this fictional form, that many writers and critics believed it to be the end of a long process of evolution. At last we had learned how to tell the truth in fiction! But truth is elusive and has a way of turning to dust and ashes whenever we try to stop it from growing and changing.*

All during the time of the rise of realism, a number of things had been going on which tended to counteract the realistic movement and prepared the way for a great shift in human awareness. The physical scientists, as they perfected their instruments of vision and measurement, began to explore worlds which in relation to ordinary human experience seem fantastic. Cosmic space and atomic space began to reveal their secrets, and in doing so posed problems which only "fantastic" speculation seemed able to solve.

Arthur Charles Clarke *(b. 1917, England). Science fiction novelist, scientist and prophet of space flight. Anticipated (1945) artificial communication satellites in synchronous orbits. Established in his novels futuristic technologies and scientific developments.*

Clarke joined the fledgling British Interplanetary Society at 17*, becoming its chairman while completing his B.Sc. at Kings College, London, in the late* 1940*'s. In* Interplanetary Flight (1950) *and* The Exploration of Space (1951) *he expounded his technical knowledge and enthusiasm for the 'space age' to a wide public and made him a foremost popularizer of space travel.*

At the same time he made his debut in the front rank of postwar SF writers. With Stanley Kubrick he wrote the script for 2001: a Space Odyssey (1968), perhaps the most imaginative of all SF films. In his novels he portrays man's encounter with alien intelligence as the chief turning point in a future which is cosmic and evolutionary rather than mundane and catastrophic. He conceives of man as on a continuous odyssey, facing that giant staircase as a challenge his heritage demands that he accept. Clarke has been a most influential voice in shaping SF in the epoch of the recent and continuing scientific revolution.

***Isaac Asimov** (1920–1992, U.S.A.). Influential writer of SF during the second half of the* 20^{th} *century. He wrote nearly* 500 *books on a wide gamut of scientific and non-scientific subjects. He was a pioneer in elevating the SF genre from pulp-magazine adventure to a more intellectual level that dealt with sociology, history and science.*

The special character in Asimov's work derives from the last fact that the robots stand side by side with the humans. His robot stories are consistent with his 'three rules of robotics' (1942):

(1) A robot may not injure a human being, or through inaction allow a human being come to harm.

(2) A robot must obey the orders given it by human beings except when such orders would conflict with the First Law.

(3) A robot must protect its own existence as long as such protection does not conflict with the First or Second Laws.

Asimov was born to Jewish parents in a suburb of Smolensk called Petrovich. His parents Judah and Rachel Berman Asimov moved to New York in 1923 *and settled in Brooklyn. He graduated from Columbia University (1948) with a Ph.D. in chemistry and gained the rank of associate professor in biochemistry at the Boston University (1955). In* 1958 *he reached an agreement with that University whereby he would perform no substantial duties and receive no salary, but would retain his faculty rank and status.*

Early 20^{th} *century science fiction was inspired largely by* astronomy *and to a lesser extent by physics and mathematics. These sciences, together with the preoccupation with gadgets and with a little chemistry thrown in, dominated the scene until about* 1948.

After WWII the biological sciences emerge as major elements in the genre. Having escaped at last from the unpromising side track into which this fiction *had long been diverted by the man-made bug-eyed monsters sired, or rather dammed, biology began to emerge as an SF inspiration with early* 20^{th} *century writers but it was slow to gain prominence until the WWII, when plastic surgery in particular made a considerable impact.*

By the early 1960s psychology and sociology had become a major source of science fiction stimulus and the mathematical sciences, including economics and cybernetics, were also in great evidence. The 1970s saw an even greater change, the almost total rejection of scientific reason.

Until 1945 science could be seen as the friend of mankind; modern medicine has brought about a great increase not only in longevity but in the capacity to enjoy life physically, an increase which has affected our aspirations.

However, after the explosion of the first atomic bomb its evident capacity to destroy humanity turned science into a potential enemy; the prospect of a sudden cataclysmic end to all human life has destroyed the hope slowly engendered through the 18^{th} *and* 19^{th} *centuries that science and reason would bring about an inevitable millennium. Thus we resurrected the monster of Dr. Frankenstein and the devil of Faust — forbidden, uncontrollable and therefore dangerous knowledge.*

Modern man has now come full cycle again to the more vigorous fears and uncertainties of earlier time. This is amplified by the fact that today, the sheer mass of scientific knowledge is beyond individual comprehension, despite the far higher level of general education. We have to some extent returned to the situation of the primitive man who required his myths and mysteries as protection against forces which he could neither fully understand nor control.

Because of all this, SF was firmly established as a particularly sensitive form of literature for reflecting the moods and psychoses of its host society.

1895–1932 CE **Charles Scott Sherrington** (1857–1952, England). Neurophysiologist. Formed the scientific basis of modern neurology; coined the terms *neuron* and *synapse*; demonstrated that reflexes in higher animals are integrated activities of the total organism; made lifelong study of the mammalian nervous function. Shared (with **Edgar Douglas Adrian**) the Nobel Prize for physiology or medicine (1932).

Postulated (1906) that neural reflexes must use more than one neuron; so he proposed a synapse and a neurotransmitter substance to connect the two nerve cells. Developed (1913–1930) modern techniques for recording nerve activity and outlining the nature of communication between nerves and between nerves and muscles.

Sherrington was born in London. He took his medical degree at Cambridge (1885). Taught at London University, where he became professor of pathology (1891–1895). He was then professor of physiology at Liverpool (1895–1913) and Oxford (1913–1931).

1895–1945 CE Leading Western poets and novelists from the turn of the 20^{th} century to WWII:

• Oscar Wilde	1854–1900
• Joseph Conrad	1857–1924
• Axel Munthe	1857–1949
• Arthur Conann Doyle	1859–1930
• Rudiard Kipling	1865–1941
• Ladislas Stanislas Reymont	1867–1925
• John Galsworthy	1867–1933
• Maxim Gorky	1868–1936
• Felix Salten	1869–1945
• Ivan Bunin	1870–1953
• Marcel Proust	1871–1922
• Hayim Nahman Bialik	1873–1934
• Robert Frost	1874–1963
• R.M. Rilke	1875–1926
• Thomas Mann	1875–1955
• Jack London	1876–1916
• Carl Sandburg	1878–1967
• Upton Sinclair	1878–1968
• James Joyce	1882–1941
• Jaroslav Hasek	1883–1923
• Franz Kafka	1883–1924
• Sinclair Lewis	1885–1951
• S.Y. Agnon	1887–1970
• Fernando Pessoa	1888–1935
• T.S. Eliot	1888–1965
• Karl Capek	1890–1938
• Franz Werfel	1890–1945
• Lajos Zilahy	1891–1974
• Edna St. Vincent Millay	1892–1950
• E.E. Cummings	1894–1962
• Erich Maria Remarque	1898–1970
• Bertolt Brecht	1898–1956

- Ernest Hemingway 1899–1961
- John Steinbeck 1902–1968
- William Saroyan 1908–1978
- Dylan Thomas 1914–1953

1896 CE First modern *Olympic Games* in Athens, Greece; the first known Olympic contest took place in the Stadium of *Olympia* in 776 BCE.

In 394 CE, Emperor Theodosius ordered the games ended, but they continued until 426 CE (304th Olympiad), when an earthquake destroyed the Stadium of Olympia. A second earthquake (521 CE) buried the ruins of the structure.

The Olympics were held every four years, and were used in Greece as a system of dating for literary purposes (but never adopted in every-day life); all events were dated from 776 BCE. The beginning of the year of the Olympiad was determined by the first full moon after the summer solstice, the longest day of the year. The full moon fell about the first of July. Each interval of four years was known as an *Olympiad*.

1896 CE **Arthur Schuster** (1851–1934, England). Applied Fourier analysis to determine periodicities of geophysical and astronomical time-series.

1896 CE **Max von Gruber** (1853–1927, Austria). Bacteriologist and physician. Discovered the specific *agglutination* of bacteria by the serum of an organism immune to a certain disease, such as typhoid fever and cholera. This reaction, which bears his name, is used to identify unknown bacteria and was first utilized by **Fernand Widal** in his test for diagnosis of typhoid fever. This discovery paved the road for clinical diagnosis of many contagious diseases.

Gruber studied in Vienna and Münich. He was professor at Graz (1883–1887), Vienna (1887–1902) and Münich (1902–1923).

1896 CE **Jacques Solomon Hadamard** (1865–1963, France). Outstanding mathematician. Proved the '*Prime-number theorem*'[26], which states that

[26] After proving the 'Prime-number theorem', Hadamard was fascinated by what went on in the mind of a creative mathematician. He set down his ideas in a book entitled *The Psychology of Invention in the Mathematical Field* (1945), in which he made a powerful case for the role of the subconscious. In his book he divided the act of mathematical discovery into four stages: *preparation*, *incubation*, *illumination* and *verification*.

$\pi(n)$, the number of primes less or equal to n, approaches $\left\{\frac{n}{\ln n}\right\}$ for large value of n. This conjecture was made by Gauss (1792) and Legendre (1778).

In 1852 and 1859 **Chebyshev** and **Riemann**, respectively, provided incomplete proofs to this theorem. Riemann was able to link the zeros of the Zeta function to the properties of $\pi(n)$, but he did not supply any proof for this connection. For about thirty years, other mathematicians tried to prove the main result enunciated in Riemann's paper — but to no avail. Only in 1896 was it proven independently and simultaneously by Hadamard and **Charles de la Vallée-Poussin** (1866–1962, Belgium), both using analytic methods[27]. Interestingly enough, the complex-variable methods used by Hadamard in his proof found applications in the theory of radio waves.

In 1932 **Edmund Landau** (1877–1938, Germany) and **Norbert Wiener**, using 'Tauberian theorems', simplified Hadamard's proof. Hadamard introduced the word *functional* (1903) when he studied

$$F(f) = \lim_{n\to\infty} \int_a^b f(x) g_n(x)\, dx.$$

Fréchet (1904) defined the derivative of a functional.

Hadamard also obtained important results in the theory of functions of complex variable [*multiplication theorem*, *3-circles theorem*, *gap theorem* and the *factorization theorem*], partial differential equations, theory of variations, functional analysis, geometry, hydrodynamics, theory of determinants and integral equations.

Hadamard's contributions are partly reflected in such terms as *Hadamard's inequality*, *Hadamard variational formula*, *Hadamard matrices*[28] and *Hadamard transform optics.*

---

[27] In 1892 Hadamard proved that $\xi(t) = \Gamma\left(\frac{s}{2}+1\right)(s-1)\pi^{-s/2}\zeta(s)$, is of the form $\xi(t) = C\prod_1^\infty \left(1 - \frac{t^2}{\lambda_n^2}\right)$, $\quad \sum_1^\infty \frac{1}{|\lambda_n^2|} < \infty$ where $s = \frac{1}{2} + it$.

[28] A Hadamard matrix H_n of order n is an $n \times n$ array, the elements of which are either $+1$ or -1, such that the scalar product of any two distinct rows or columns is zero. Thus H_n must satisfy $H_n H_n^T = H_n^T H_n = nI_n$. Examples are $H_1 = [1]$, $H_2 = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$. Its determinant is $\pm n^{n/2}$ (n even), its maximum eigenvalue is $\sqrt{n}$ and its inverse is $H_n^{-1} = \frac{1}{n} H_n^T$.
Hadamard matrices are realized in optical spectroscopy and image processing, with applications in chemistry, medical diagnosis, infrared astronomy, high energy physics and radar. The basic method which underlines these various applications is *multiplexing*. In conventional spectroscopy, for example, electromagnetic radiation is sorted into distinct bundles of rays corresponding to different colors. Thus each bundle is labeled by the appropriate frequency, wavelength

Hadamard was born in Versailles. He originated from a Jewish family of Lorraine. There are traces of Hadamards, printers in Metz, in the 18^{th} century, and also a remarkable great grandmother who lived during the French Revolution. Before Jacques was born the family settled in the Paris area. His father taught humanities in high school; his mother was a good pianist. He achieved the highest score ever obtained in the entrance examinations to the École Polytechnique, France's greatest school of science and, in Hadamard's youth, the foremost world institution of its type. He chose, however, École Normale Superier (1884), where he studied under **Jules Tannery**[29] and **Émile Picard**.

---

or wavenumber. The spectrum of the radiation is found by measuring the intensity of each bundle. Alternatively, the bundles can be multiplexed: instead of measuring the intensity of each bundle separately, we can measure the total intensity of *various combinations* of *bundles*. After measuring n suitably chosen combinations, the individual intensities of n different bundles can be calculated, and the spectrum obtained. Finally, by combining multiplexed radiation from different parts of the picture and from different frequency bands, it is possible to reconstruct a color picture of a scene.

The primary purpose of multiplexing is to maximize the radiant flux incident on the detector, in order to improve the signal-to-noise ratio of the final intensity display.

So where does Hadamard enter in the scheme of things? — in the design of the *mask* which splits the source beam into bundles! This mask is essentially a two-dimensional grid made of two basic elements: open and closed slots. Each element of the beam is either transmitted or absorbed. [To overcome the difficulty that there is no way of registering a negative signal with an ordinary light detector, a Hadamard matrix can always by written as difference of special matrices whose elements are 1 or 0.] Knowing the special algebra of Hadamard matrices, one can design the multiplexing spectrometer accordingly.

[29] **Jules Tannery** (1848–1910, France). Known primarily for his treatise on elliptic functions and his contributions to the history and philosophy of mathematics. Discovered the summation formula

$$\sum_{n=1}^{\infty} \frac{x^{2^{n-1}}}{x^{2^n}-1} = \begin{cases} \frac{1}{x-1}, & \text{if } |x| > 1, \\ \frac{x}{x-1}, & \text{if } |x| < 1. \end{cases}$$

The special case $x = 2$ yields the interesting result

$$\sum_{n=1}^{\infty} \frac{2^{2^{n-1}}}{2^{2^n}-1} = 1.$$

He was a professor of mathematics at Bordeaux (1893–1896), Sorbonne (1896–1909), College de France (1897–1935) and École Polytechnique (1912–1935).

As a brother-in-law of Alfred Dreyfus, Hadamard took an active interest in the *Dreyfus case*. The dangers of Hitlerism were recognized by Hadamard at an early stage and he worked to alleviate the plight of German Jewry. He escaped from France in 1941 to the United States, and moved to England to engage in *operational research* with the Royal Air Force. He had three sons and two daughters. The two elder sons were killed in action in WWI within an interval of less than two months. The third son was killed in North Africa in WWII.

Hadamard loved music and used to have a small orchestra for amateurs in his house: **Einstein** played in it whenever he was in Paris. Duhamel, the writer, was the flautist, Hadamard played the violin and Mme Hadamard played the piano, supplementing by playing the parts of the brass instruments when required.

1896 CE **Henry Ford** (1863–1947) and **Charles Brady King** drove their first gasoline cars in Detroit, MI. That same year, **Ransom Eli Olds** (1864–1950), drove his first gasoline car in Lansing, MI. Also in 1896, **Alexander Winton** successfully tested his own automobile in Cleveland. In 1903, **David Dunbar Buick** (1854–1929) built his first car in Detroit. Most of these pioneer American automakers later began the mass production of cars in the United States.

1896–1900 CE **Antoine Henri Becquerel** (1852–1908, France). Physicist. Discovered radioactivity in uranium ores and identified beta particles with Thomson's electrons.

He embarked on the subject through his interest in the relation between absorption of light and the stimulated emission of phosphorescence in some uranium compounds. Influenced by the discovery of X-rays by Röntgen, he decided to test an hypothesis that uranium salts emit X-rays when irradiated by sunlight. He found in 1896 that the uranium salts would eject penetrating radiation (as revealed by their effect on a photographic plate) even when they were not excited by the ultraviolet in sunlight. He then postulated the existence of invisible phosphorescence.

Becquerel was a member of a scientific family extending through several generations[30]. He received his formal scientific education at the École Polytechnique (1872–1874) and engineering training at the school of Bridges and

---

[30] This family of physicists includes:

- **Antoine-César** (1788–1878). Professor, Musée d'Histoire Naturelle (1837–1878); one of the creators of the science of electrochemistry.

Highways (1874–1877). In addition to his teaching and research posts he was for many years an engineer in the department of Bridges and Highways. He became a professor of physics in 1895. For his discovery of radioactivity he shared the 1903 Nobel prize for physics with the Curies.

1896–1902 CE **Walter Reed** (1851–1902, US). Surgeon and pioneer medical researcher who led to the eventual eradication of Yellow fever and typhoid fever.

Born in Belroi, Virginia and received his MD degree from the University of Virginia. He joined the Army Medical Corps (1875), served as an army surgeon in Arizona (1876–1889) and Baltimore (1890–1893), and was professor of bacteriology at the Army Medical College (1893–1902).

Much of his work was centered on epidemic diseases: malaria, diphtheria, hog cholera, typhoid fever and Yellow fever, showing them to be caused by bacilli or viruses. Discovered (1898) that the Yellow fever virus was transmitted by the mosquito *Aedes aegypti*. Walter Reed Hospital in Washington D.C. was named after him.

1896–1902 CE **Robert Hjalmar Mellin** (1854–1933, Finland). Mathematician. Introduced the *Mellin transform*[31] into linear applied mathematics

---

- **Alexandre-Edmond** (1820–1891). Son of the above. Succeeded to his professorship (1878–1891). Contributed to photochemistry. Discovered (1839) that when two pieces of metal were immersed in an electrolyte, an electric charge developed when one of the pieces was illuminated. But although he discovered the electrochemical effects of light, he did not offer any practical suggestion for its use.

- **Antoine-Henry** (1852–1908). Son of the above. Succeeded to his professorship (1892).

[31] Let $f(r)$ be a real function defined in the interval $(0,\infty)$ such that $f(r)$ is piecewise continuous and of bounded variation in every finite subinterval $[a,b]$, where $0 < a < b < \infty$. If in addition both integrals

$$\int_0^1 r^{\sigma_1-1}|f(r)|\,dr, \quad \int_0^1 r^{\sigma_2-1}|f(r)|\,dr$$

are finite for suitably chosen real numbers σ_1 and σ_2, then the Mellin transform of $f(r)$ is defined by the formula

$$F(s) = \int_0^\infty f(r)r^{s-1}\,dr,$$

where $s = \sigma + i\tau$ is any complex number in the strip $\sigma_1 < \text{Re } s < \sigma_2$. The as a powerful tool of solving problems in elasticity theory and potential theory. The Mellin transform arises from the multiplicative structure of the real line in the same way as the Fourier transform arises from its additive structure.

Mellin was pupil of **Mittag-Leffler** and then studied in Berlin (1881–1882). He was later a professor of mathematics at the University of Helsinki.

1896–1916 CE **Arnold (Johannes Wilhelm) Sommerfeld** (1868–1951, Germany). Outstanding physicist, and a prodigious producer of future Nobel prize winners. Introduced the quantization of the action integral $\int pdq$, which paved the way for modern quantum theory (1911). Defined the fine-structure constant of electromagnetic interaction, $\alpha = 2\pi e^2/hc \simeq 1/137$. In classical physics, he is known for his contributions to the theories of the gyroscope, diffraction of light (1896), and propagation of radio waves.

Sommerfeld's investigations of atomic spectra led him to suggest that, in the Bohr model of the atom, the electrons move in *elliptical orbits* as well as circular ones. From this idea he postulated the azimuthal quantum number. He later introduced the magnetic quantum number as well. Sommerfeld also did detailed work on wave mechanics, and his theory of electrons in metals proved valuable in the study of thermoelectricity and metallic conduction.

Sommerfeld was born in Königsberg, Prussia. He was educated in his native city and then became an assistant at the University of Göttingen. He served as a professor of physics at Munich (1906–1931), where he did most of his important work. Sommerfeld was a gifted teacher and educator. His 5-volume treatise '*Lectures on Theoretical Physics*' still serves today as a graduate textbook. Among his students were **W. Pauli**, **W. Heisenberg** and **H. Bethe**.

---

inversion of $F(s)$ is given by the formula

$$f(r) = \frac{1}{2\pi i}\int_\Gamma F(s)r^{-s}\,ds,$$

where Γ is a straight line parallel to the imaginary axis lying inside the strip.
The *Mellin transform* is related to the Laplace and Fourier transforms and is the appropriate tool to use for solving problems in two-dimensional elasticity theory and potential theory involving angular regions.
The *Mellin transform pair* appeared in Riemann's famous memoir on prime numbers and it was later formulated more explicitly by **E. Cahen** (1894). But the first one to put it on a rigorous basis and point some of its applications was Mellin, and that is why the transforms bears his name.

1896–1920 CE **Vilfredo Pareto** (1848–1923, Italy and Switzerland). Economist, sociologist and engineer. Developed methods of mathematical analysis in the study of economic and sociological problems.

Pareto extended Walras' theory of general economic equilibrium, and sought to extend it to the entire range of social phenomena. In his sociological theories, Pareto argued for the superiority of the *elite*, claiming that society was always composed of elites and masses.

While his sociological theories are controversial, Pareto's contributions to economics have come to be recognized as immensely important during the second half of the 20th century.

In his economic theory, Pareto rejected the treatment of utility as a *cardinally* measurable quantity whose maximization involved the comparisons of one person's happiness with another's; instead, he treated it as *ordinal* concept (i.e. one implying only a *ranking* by each individual of alternatives available to him), and defined a corresponding optimum as a condition of society from which it is impossible to make any one individual subjectively better off without simultaneously making at least one other individual worse off. This idea of '*Pareto optimum*' — according to which the economic system can, in principle, generate an optimal distribution function of welfare among its individual members — is the fundamental concept of modern welfare economics.

Pareto's work led modern economists to the finding that the conditions for such an optimum will be satisfied by a Walrasian general equilibrium, where *each consumer is maximizing utility and each producer maximizing profits*, all under conditions of perfect competition (i.e. with no single consumer or producer able to influence, on his own, any market price).

Pareto also made significant contributions to the empirical study of *income distribution*, enunciating what came to be known as *Pareto's Law*, or the *Pareto distribution of incomes.* This purported to describe the pattern of inequality of incomes which any society will tend to generate, regardless of its economic system.

Pareto was born in Paris, France, and embarked on his research after a successful career in industry. He then became a professor at Lausanne (from 1893). In his book *Mind and Society* (1916), he stressed the irrational elements in social life and emphasized the role of leading groups (elites) in society. He criticized democracy and saw history as a succession of aristocracies. Because of his antidemocratic attitudes, he is considered an intellectual forerunner of fascism. Indeed, the ideology of Italian fascism was largely based on his theory.

1896–1927 CE **Felix Édouard Justin Émil Borel** (1871–1956, France). Mathematician. Created the first effective and general theory of the measures of sets points in topological spaces, and contributed [with **H. Lebesgue**] to the development of the modern theory of functions of real variable.

Émil Borel was born in Sain-Affrique, France. His father was a Protestant village pastor and his mother came from a family of merchants. In 1889 he enrolled in the École Normale. After graduation he taught at the University of Lille, and was appointed to the faculty of the École Normale Supériere, Paris. One of the famous results of his University thesis is the so called *Heine-Borel theorem*. In 1896, Borel discovered an elementary proof of Picard's theorem. He then formulated the theory of integral functions and was first to develop (1899) a systematic theory of *divergent series*. During 1921–1927, Borel became the first to define games of strategy in *game theory*. Borel was the immediate predecessor of Lebesgue in the development of measure theory.

Borel married Marguerite Appel in 1901, but they had no children. From 1924 to 1940 he was heavily involved in politics; he served as a minister of the navy (1925–1940). In 1940 he was arrested and imprisoned by the Vichy regime. He later returned to his native village and participated in the Résistance.

In 1955, while Borel was returning from a scientific meeting in Brazil, he was injured in a fall aboard his ship and died the following year.

The 'sum' of a divergent series

In 1850, ***Stokes*** *introduced the integral formula*

$$w = \int_0^\infty \cos\frac{\pi}{2}(\omega^3 - m\omega)\, d\omega$$

representing the strength of diffracted light near a caustic (known as an Airy integral). Stokes proved that for large positive $n = (\frac{\pi}{2})^{2/3}m$*, the integral can* *be represented by a divergent series, but one still useful for calculations, if a finite number of terms are retained.*

It thus became clear to him that divergent series could be used to solve differential equations. The full recognition of the nature of those divergent series that are useful in the representation and calculation of functions, and a formal definition of these series, were achieved by ***Poincaré*** *(1886) and* ***Stieltjes*** *(1886). They defined*

$$f(x) \sim a_0 + \frac{a_1}{x} + \frac{a_2}{x^2} + \dots$$

whenever

$$\lim_{x\to\infty} x^n[f(x) - \left(a_0 + \frac{a_1}{x} + \frac{a_2}{x^2} + \dots + \frac{a_n}{x^n}\right)] = 0.$$

Such series are asymptotic expansions[32] *of functions in the neighborhood of $x = \infty$. Likewise one speaks of the series $f(x) \sim a_0 + a_1x + a_2x^2 + \dots$ as asymptotic to $f(x)$ at $x = 0$, if*

$$\lim_{x\to 0} \frac{1}{x^n}\left[f(x) - \sum_0^{n-1} a_i x^i\right] = a_n.$$

Though in the case of some asymptotic series one knows or can estimate the error incurred by stopping at a definite term, no such information about the numerical error is known for general asymptotic series. However, asymptotic series can be used to give rather accurate numerical results for large x by employing only those terms for which the magnitude of successive terms is still decreasing as one includes further terms. The order of magnitude of the error at any stage is equal to that of the first term omitted. The theory of asymptotic series, whether used for the evaluation of integrals or the approximate solution of differential equations, has been vastly extended in recent decades.

---

- Copson, E.T., *Asymptotic Expansions*, Cambridge University Press, 1965, 120 pp.

The work on divergent series described so far has dealt with finding asymptotic series to represent functions either known explicitly or existing implicitly as solutions of ODE's or PDE's.

Another problem that mathematicians tackled from about 1880 on is essentially the converse of finding asymptotic series: Given a series divergent in Cauchy's sense, can a "sum" be assigned to the series? As in so many other cases, the traces lead us back to ***Euler****, who first considered (1755) the 'sum' of a non-convergent series as the finite numerical value of the algebraic expression, from the formal expansion of which the series was derived. For instance:*

$$1-1+1-1+\cdots = \lim_{x\to 1-0}(1-x+x^2-x^3+\dots) = \lim_{x\to 1-0}\frac{1}{1+x} = \frac{1}{2}$$

$$1-2+3-4+5-\cdots = \lim_{x\to 1-0}(1-2x+3x^2-4x^3+\dots) = \lim_{x\to 1-0}\frac{1}{(1+x)^2} = \frac{1}{4}$$

In general, Euler's idea implies that[33]

$$\sum_{n=0}^{\infty} a_n = \lim_{x\to 1-0}\left(\sum_{n=0}^{\infty} a_n x^n\right),$$

for any power series with radius of convergence 1 *and for which the limit exists.*

It is clear that this convention has no general or compelling basis, since there is no reason why the same series should not result from quite different

---

[33] For example

$$\sum_{n=0}^{\infty}\frac{(-1)^n}{3n+1} = \lim_{x\to 1-}\sum_{n=0}^{\infty}\frac{(-1)^n}{3n+1}x^{3n+1} = \lim_{x\to 1-}\int_0^x \sum_{n=0}^{\infty}(-1)^n x^{3n}\,dx$$
$$= \lim_{x\to 1-}\int_0^x \frac{dx}{1+x^3} = \lim_{x\to 1-}\left\{\frac{1}{6}\ln\frac{(x+1)^2}{x^2-x+1} + \frac{1}{\sqrt{3}}\arctan\frac{2x-1}{\sqrt{3}} + \frac{\pi}{6\sqrt{3}}\right\}$$
$$= \frac{1}{3}\ln 2 + \frac{\pi}{3\sqrt{3}}.$$

In general

$$\sum_{n=0}^{\infty}\frac{(-1)^n}{\alpha n+1} = \lim_{x\to 1-}\int_0^x \frac{dx}{1+x^\alpha} = \frac{1}{\alpha}\beta\left(\frac{1}{\alpha}\right).$$

analytical expressions which leads to a different value. Take for example

$$\frac{1+x}{1+x+x^2} = 1 - x^2 + x^3 - x^5 + x^6 - x^8 + \ldots.$$

Setting $x = 1$ *renders* $1 - 1 + 1 - 1 + \cdots = \frac{2}{3}$, *different from the result given above. To eliminate such ambiguities,* ***Frobenius*** *(1880) defined summability of a series as:*

$$\lim_{x\to 1-0}\left(\sum_{n=0}^{\infty} a_n x^n\right) = \lim_{n\to\infty}\frac{S_0 + S_1 + \cdots + S_n}{n+1},$$

whenever the r.h.s. limit (of the average of the partial sums) exists. Indeed, in Euler's first example $S_n = 1, 0, 1, 0, 1, 0, \cdots = \frac{1}{2}[1 + (-1)^n]$ *so that*

$$\frac{S_0 + S_1 + \cdots + S_n}{n+1} = \frac{(n+1) + [1 + (-1)^n]}{2(n+1)} \to \frac{1}{2}.$$

Similarly, the above series $1 - x^2 + x^3 - \ldots$ *gives the partial sums of* $1, 2, 3, 4, 5, 6, \ldots$ *terms as* $1, 1, 0, 1, 1, 0, \ldots$ *so that the average sum is*

$$\frac{S_0 + S_1 + \cdots + S_n}{n+1} = \frac{(n+1) - \{\text{integer part of } \frac{1}{3}(n+1)\}}{n+1} \to 1 - \frac{1}{3} = \frac{2}{3}.$$

Considering the fact that Euler and other mathematicians made numerous valid mathematical discoveries by using series which do not converge, we conclude that these "pre–rigor" mathematicians had sufficiently good "experimental evidence" that the use of such series as if they were convergent led to correct results in the majority of cases when they presented themselves naturally.

Consider ***Fourier's*** *own example in his Theorie Analytique de la Chaleur, where he obtained the sine series for the function* $f(x) = \frac{\pi \operatorname{sh} x}{2 \operatorname{sh} \pi}$ *in the interval* $[0, \pi]$, *and found that the coefficient of* $\sin nx$ *is*

$$(-1)^{n-1}\left[\frac{1}{n} - \frac{1}{n^3} + \frac{1}{n^5} - \ldots\right] = (-1)^{n-1}\frac{n}{1+n^2}.$$

Thus, the coefficient of $\sin x$ *appears as* $1 - 1 + 1 - 1 + \ldots$, *and may therefore be expected to be* $\frac{1}{2}$, *if we adopt Euler's summation principle. And indeed, this is correct, since* $\int \operatorname{sh} x \sin x \, dx = \frac{1}{2}(\operatorname{ch} x \sin x - \operatorname{sh} x \cos x)$, *so that* $\frac{2}{\pi}\int_0^{\pi} f(x) \sin x \, dx = \frac{1}{2}$.

We see from these examples that Euler had views which do not differ greatly, at bottom, from those held by modern workers on this subject. It was his unusual instinct for what is mathematically correct which in general saved him from false conclusions.

Clearly, if $\sum a_n$ *converges, then Frobenius' procedure gives the usual sum. The Frobenius summability was generalized by* **Hölder** *(1882) and* **Cesaro** *(1890). Further progress in finding 'sums' for divergent series received its motivation from a totally different direction which, again, started with Euler.* **Euler** *(1754), in seeking a sum for the divergent series*

$$1 - 2! + 3! - 4! + 5! - \dots,$$

proved that $y(x) = x - (1!)x^2 + (2!)x^3 - (3!)x^4 + \dots$ *formally satisfies the differential equation* $x^2y' + y = x$*, for which he obtained the integral*[34]

$$y(x) = \int_0^\infty \frac{xe^{-t}}{1+xt}\,dt.$$

On the other hand, by using the rules which he had obtained for the transformation of convergent series into continued fractions, Euler found

$$y(x) = \cfrac{x}{1+\cfrac{x}{1+\cfrac{x}{1+\cfrac{2x}{1+\cfrac{2x}{1+\cfrac{3x}{1+\cfrac{3x}{1+\dots}}}}}}}$$

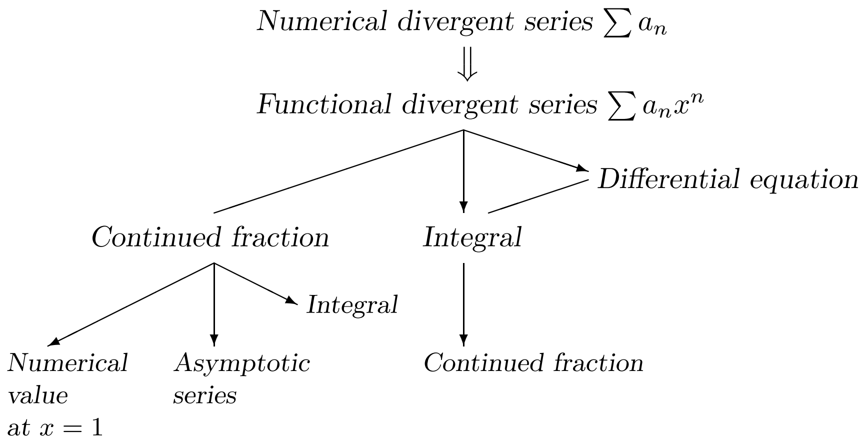
From this he subsequently calculated

$$1 - y(1) = 1 - 2! + 3! - 4! + \dots = 0.596\ 347\ 4\dots$$

This work contains two features. First, Euler obtained an integral that can be taken to be the 'sum' of the divergent series (the latter is in fact asymptotic to the integral). Then, he showed how to convert divergent series into continued fractions.

Euler's pioneering work was continued by **Laguerre** *(1879),* **Stieltjes** *(1886–95),* **Borel** *(1895–99),* **Tauber** *(1897) and* **Fejer** *(1904) along two main routes that can be summed up in the following scheme:*

[34] The substitution $1 + xt = xu$ leads to $y(x) = e^{\frac{1}{x}} \int_{\frac{1}{x}}^\infty \frac{e^{-u}}{u}\,du \equiv e^{\frac{1}{x}} E_1\left(\frac{1}{x}\right)$.



Borel *(1901) discovered a new method of summation of divergent series. First he proved the theorem that if* $f(z) = \sum_{n=0}^{\infty} a_n z^n$ *is analytic when* $|z| < r$, *then* $f(z) = \int_0^{\infty} e^{-t}\Phi(zt)\,dt$ *where* $\Phi(z) = \sum_{n=0}^{\infty} \frac{a_n}{n!} z^n$.

If the integral exists at points z *outside the circle of convergence, we define the 'Borel sum' of* $\sum_{n=0}^{\infty} a_n z^n$ *to mean the integral.*

The function $\Phi(z)$ *is called the* Borel function *associated with* $\sum_{n=0}^{\infty} a_n z^n$. *If*

$$S = \sum_{n=0}^{\infty} a_n$$

is divergent and

$$\Phi(z) = \sum_{n=0}^{\infty} \frac{a_n}{n!} z^n$$

exists and if we can establish the relation

$$S = \int_0^{\infty} e^{-t}\Phi(t)\,dt,$$

with the r.h.s integral convergent, then the series S *is said to be 'Borel summable' or 'summable (B)'.*

The above result implies that a Taylor series representing an analytic function is summable (B).

For example, the 'Borel sum' of the series $\sum_{n=0}^{\infty} z^n$ *is*

$$\int_0^{\infty} e^{-t} e^{tz}\,dt = \frac{1}{1-z}.$$

These studies in the theory of divergent series have clarified a number of hidden connections:

(*i*) *Functional divergent series have functional equivalents in the form of an integral and a continued fraction. The divergent series belongs to one or more functions, which can each be taken to be the sum of the series in a new sense of sum (summability).*

(*ii*) *A divergent series, if summable, can be manipulated precisely as a convergent series.*

(*iii*) *If a given infinite series were to arise in a physical situation, the appropriateness of any definition of its sum would depend entirely on whether the sum is physically significant.*

Cauchy's (classical) definition of a sum is the one that usually fits, because it says basically that the sum is what one gets by continually adding more and more terms in the ordinary sense. But there is no logical reason to prefer this concept to the others that have been introduced.

A general lesson here is that when a concept or technique proves to be useful even though the logic of it is confused or even nonexistent, persistent research will likely uncover a logical justification.

Thus, although concepts like summability may seem artificial, man-made, and contrived, their justification as naturally arising in mathematical solution of physical problems is now sufficient grounds for admitting them into the domain of legitimate mathematics. (This applies also to concepts such as generalized functions, non-standard analysis, and even the Newton-Leibniz non-rigorous, pre-Cauchy calculus.)

***Ramanujan**, devoid of any physical principles and completely innocent of rigor, drove Euler's concepts of divergent series 'ad absurdum'. In 1913 he presented some 'impossible' results of his own:*

$$1 + 2 + 3 + 4 + 5 + \cdots = -\frac{1}{12}$$

$$1^3 + 2^3 + 3^3 + \cdots = \frac{1}{120}$$

He obtained these results regarding the values of the Riemann zeta-function at $s = -1$ *and* $s = -3$ *respectively; they then follow from the general formula*

$$\zeta(1 - 2m) = (-1)^m \frac{B_m}{2m},$$

where B_m are the Bernoulli numbers. Ramanujan also stated (without proof) that

$$1 - 1^1 + 2^2 - 3^3 + \cdots = \int_1^\infty \frac{dx}{x^x} = 0.704\ 169\ 96\ldots,$$

where the integral can be computed by the Euler-Maclaurin formula to yield the numerical value stated on the r.h.s. We have no idea how Ramanujan reached this result, but ***G.N. Watson*** *(1929) offered the following proof: since $\int_0^\infty t^n e^{-t}\,dt = n!$, we write formally*

$$\begin{aligned} 1 - 1^1 + 2^2 - 3^3 + \ldots &= 1 + \sum_{n=1}^\infty \frac{(-1)^n n^n}{n!} \int_0^\infty t^n e^{-t}\,dt \\ &\equiv \int_0^\infty \{1 + \sum_{n=1}^\infty \frac{(-1)^n}{n!} n^n t^n\} e^{-t}\,dt. \end{aligned}$$

When u is sufficiently small, a Lagrange expansion of e^u in powers of ue^u yields

$$e^u = 1 + ue^u + \sum_{n=2}^\infty \frac{(-1)^{n-1}(n-1)^{n-1} u^n e^{nu}}{n!}$$

and hence, by differentiation,

$$e^u = (1+u)e^u[1 + \sum_{n=2}^\infty \frac{(-1)^{n-1}(n-1)^{n-1}(ue^u)^{n-1}}{(n-1)!}].$$

Thus $\frac{1}{1+u} = 1 + \sum_{n=1}^\infty \frac{(-1)^n n^n (ue^u)^n}{n!}$. Putting $ue^u = t$ in the last integral,

$$1 - 1^1 + 2^2 - 3^3 + \cdots = \int_0^\infty \frac{1}{1+u} e^{-(ue^u)} \frac{d(ue^u)}{du}\,du = \int_0^\infty e^{u - ue^u}\,du = \int_1^\infty \frac{dx}{x^x}.$$

Independently, ***John Bernoulli*** *(1696) proved that*

$$s = \int_0^1 x^x\,dx = 1 - 2^{-2} + 3^{-3} - 4^{-4} + \ldots$$

in the following way: $s = \int_0^1 e^{x \ln x}\,dx = \sum_{n=0}^\infty \frac{1}{n!} \int_0^1 x^n (\ln x)^n\,dx$. The integral is then evaluated by means of the substitution $y = \ln \frac{1}{x}$:

$$\int_0^1 x^n (\ln x)^n\,dx = (-1)^n \int_0^\infty dy\, y^n e^{-(n+1)y} = (-1)^n \frac{n!}{(n+1)^{n+1}}.$$

The Automobile (1770–1950)

The first road vehicles that could travel autonomously were powered by steam engines.

In 1770, ***N.J. Cugnot*** *of France successfully operated a three-wheeled steam-powered transportation vehicle. In* 1801, ***Richard Trevithick****, an English inventor, built a 4-wheeled steam wagon. By the mid-*1830*'s, English steam carriages were providing regular passenger service. Some of these carriages carried as many as* 20 *persons. These early cars were noisy, polluted the air with smoke and scattered hot coals. Sometimes the coals set fire to crops or wooden bridges.*

Operators of railroads and stagecoach lines opposed steam carriages because they were becoming successful rivals. The opposition resulted in an English law that put severe limits on the operation of steam carriages. This law, the locomotive act of 1865*, limited the speed of the steam vehicles to* 6 *km/h on country roads and* 3 *km/h in towns. It required that a signalman walk ahead of each steam carriage to warn of its approach. The signalman carried a red flag during the day, and a red lantern at night (Red Flag Law). This law, repealed in* 1896*, discouraged automobile development in England for* 30 *years.*

Steam cars proved impractical because they were hard to start and to operate. Their boilers generated steam too slowly for long-distance travel. Also, many people were afraid to drive a vehicle that depended for power on an open fire and hot steam.

In the late 1890*'s and early* 1900*'s, the electric car became popular in America. It was easy to operate, ran quietly, and did not give off smelly fumes. But few of the cars traveled faster than* 30 *km/h and their batteries had to be recharged about every* 80 *km. The gasoline car gradually replaced the steam and electric cars.*

In 1863, **Jean Joseph Étienne Lenoir** *(1822–1900), a French inventor, installed his one-cylinder internal-combustion engine in a clumsy vehicle that traveled* 10 *kilometers in* 2 *hours.*

In 1864, the electromechanical engineer and inventor ***Siegfried Marcus*** *(1831–1898, Germany) built in his Vienna workshops the first gasoline-driven* *carriage. His second model (1875) was already equipped with most modern technical features. It was patented in Germany (1882). He thus deserves the credit for building the first practical gasoline motorcar applicable for urban transportation. He did not, however, pursue its mass-production, and it had remained just a museum item.*

Marcus was born in Mecklenburg and worked for ***Werner von Siemens*** *during 1848–1860. In* 1885, ***Gottlieb Wilhelm Daimler*** *with* ***Wilhelm Maybach*** *and* ***Carl Benz****, in Germany, separately installed their respective engines in carriages.*

The general design of present day automobiles was developed in France, during 1890–1898 *mainly by* ***René Panhard*** *and* ***Emile Levassor*** *(1891). The cars used chains to carry the engine's power to the rear wheels. In* 1898, ***Louis Renault*** *replaced the chain with a drive shaft.*

Many American inventors experimented with gasoline-powered vehicles in the early 1890*'s. Of these, the brothers* ***Charles E. Duryea*** *(1861–1938) and* ***Frank J. Duryea*** *(1869–1967) built the first successful gasoline-powered automobile in America in* 1893–1894.

Two developments in 1901 *accelerated the growth of the automobile industry: the sharp drop in the price of gasoline and the introduction of mass production methods into the manufacture of cars. Gasoline prices were reduced after the discovery of rich oil fields in eastern Texas. Automobiles could now be operated relatively inexpensively, and they became a popular means of transportation.*

With the assembly-line method, the Olds company built 425 *cars in* 1901 *and* 5000 *in 1903.*

Henry Ford[35] *improved the assembly-line methods to cut production costs. His goal was a low-priced car that many people in all walks of life could*

[35] Ford was the foremost advocate of *anti-Semitism* in America. His weekly *The Dearborn Independence* systematically defamed American Jews for seven years (1920–1927).

afford[36]. Ford achieved this goal with his Model T.

In 1910 ***Hermann Föttinger*** *(Germany) invented the automatic gear changer. It was made using a special drive belt system mounted between the drive shaft and the propeller shaft. It enabled the suppression of the clutch.*

In 1912 General Motors introduced the electric starter. Balloon tires were introduced in 1922, and the automatic transmission in 1939. Finally, power steering was installed in cars in 1950.

During the 1890's automobiles were so new and so strange that they were shown in circuses. In 1990, about 350 million passenger cars traveled on the highways of the world.

1897 CE **Joseph John Thomson** (1856–1940, England). Physicist. Discovered the electron[37], the first known particle smaller than the atom [he called

---

Ford had a 4-volume reissue of the anti-Semitic articles of his weekly separately reprinted under the title *The International Jew*; this work was highly praised by Adolf Hitler who said to an American reporter: "*I regard Heinrich [sic] Ford as my inspiration*".

Although Ford retracted publicly [July 7, 1927] all he said about the Jews, he clung to his prejudice for the rest of his life. In any case, a considerable damage had already been done:

Anti-Semitism has come to be a particularly ugly and obscene climax in the 20^{th} century, and if any one American were to be singled out for his contribution to the evils of Nazism, it would have been Henry Ford. His republished articles and the currency which he gave to the *Protocols of the Learned Elders of Zion* had considerable impact on Germany in the early 1920's — a vulnerable and, as it proved, crucial formative time. Hitler, still an obscure figure in those days, read Ford's books, hung Henry's picture on his wall, and cited him frequently as an inspiration. He even based several sections of *Mein Kampf* upon Ford's words and accorded Henry the unhappy distinction of being the only American to be mentioned in that work.

36 Ford produced cars "in any color that the customer wanted — as long as it is black."

37 This statement is an oversimplification. The idea of an atomic unit of charge was probably formulated for the first time by **Faraday** in connection with his experiments on electrolysis. But this idea did not easily fit in with the notion of an electromagnetic field. **Hendrik Antoon Lorentz** modified and completed

them '*corpuscles*']. He came by his discovery in his attempts to explain the nature of cathode rays. By applying improved vacuum techniques, Thomson was able to demonstrate that these rays were composed of identical particles carrying negative charge. He concluded that the particles were present in all kinds of matter and could also be produced from hot metals. In 1906 he received the Nobel prize in physics for his researches into the electrical conductivity of gases.

Thomson was born in a suburb of Manchester, the son of a bookseller. In 1876 he obtained a scholarship at Trinity College, Cambridge, where he remained for the rest of his life. In 1884 he was appointed to the chair of physics at the Cavendish Laboratory.

Thomson entered physics at a critical point in its history. Following the great discoveries of the 19^{th} century in electricity, magnetism, and thermodynamics, many physicists in the 1880's were saying that their science was

---

Maxwell's theory of electromagnetism. In his theory, the electric and magnetic properties of matter are interpreted in terms of the motion of charged atomic particles. A magnetic field exerts a force on these particles, now called the "*Lorentz force*". In 1896 **Pieter Zeeman**, then an experimental physicist in Leiden, made a surprising discovery: the splitting of spectral lines by a magnetic field. Lorentz was able to explain the new phenomenon with his electron theory. He concluded that the radiation of atoms consisted of negatively charged particles with a very small mass. Also, German physicists were breathing hard on Thomson's neck throughout 1897. On Jan. 7, 1897, **Emil Wiechert** (1861–1928) issued the first statement that there may exist particles about 2000 to 4000 times lighter than the hydrogen atom. Independent of Thomson, Wiechert determined the ratio of mass to charge of the particles by deflecting them with electric and magnetic fields. Simultaneously, **Walter Kaufmann** determined the ratio of the mass to charge for cathode rays.

The Greek name '*electron*' was used for *amber* for the first time in the third century BCE by **Theophrastos**, a pupil of Aristotle. The name suggests 'lustrous metal'. Perhaps the clear lustrous yellow color of amber, so enhanced with cutting and polishing, led Theophrastos to choose such a name. The ancient Romans knew that when amber was rubbed with a piece of cloth, it picked up small particles. This was actually discovered in the 6th century BCE by the Greek philosopher **Thales of Miletos**. Later, when it was proved that this was the action of *electricity*, the energy was derived from the Greek word for amber — 'electron'. The modern name 'electron' was coined by **Stoney** (1911) for the unit of charge carried by the ion of a monovalent element in electrolysis. **Abraham Pais** coined the collective names *Lepton* (1946) and *Baryon* (1954) to classes of elementary particles, while **L.B. Okun** gave the name *Hadron* (1962) to another class.

coming to an end, much as an exhausted mine. By 1900, however, only elderly conservatives held this view, and by 1914 a new physics was in existence, which raised, indeed, more questions than it could answer. The new physics was wildly exciting to those who saw its boundless possibilities. Probably not more than a half dozen great physicists were associated with bringing about this change.

Thomson was an outstanding teacher; his importance in physics depended almost as much on the work he inspired in others as on that which he did himself. The group of men that gathered around him between 1895 and 1914 came from all over the world, and after working under him, many accepted professorships abroad. Seven Nobel prizes were awarded to those who worked under him. Thomson took his teaching duties very seriously: he lectured regularly to elementary classes in the morning and to postgraduates in the afternoon. He considered teaching to be helpful for a researcher, since it required him to reconsider basic ideas that otherwise might be taken for granted. He never advised a man entering a new research field to begin by reading the work already done. Rather, Thomson thought it wise that he first clarify his own ideas. Then he could safely read the reports of others, without having his own views influenced by assumptions that he might find difficult to throw off.

1897 CE **Alfred Tauber** (1866–1942, Slovakia & Austria). Mathematician. Discovered an important theorem through which ordinary convergence of power series is deduced from some type of summability; known as the *Tauberian theorem*[38].

---

[38] "*Abel's theorem*" states that if $\sum_{n=0}^{\infty} a_n$ is convergent with a sum S, then the series $f(z) = \sum_{n=0}^{\infty} a_n z^n$ is uniformly convergent for $|z| < 1$ and $\lim_{z\to 1} \sum_0^{\infty} a_n z^n = S$.

The direct converse of Abel's theorem is false, as is shown by the simple counter-example $f(z) = \sum_{n=0}^{\infty}(-1)^n z^n = \frac{1}{1+z}$ with $f(1) = 2$. Since $\sum_0^{\infty} a_n$ is not convergent. If, however, we impose a *restriction* on a_n as to their order of magnitude, it is possible to prove the converse theorem.

Tauber's theorem: If $a_n = o\left(\frac{1}{n}\right)$ and $f(z) \to S$ as $z \to 1$, then $\sum_0^{\infty} a_n$ converges to the sum S.

In short

$$\sum_{n=0}^{\infty} a_n = \lim_{z\to 1} \sum_{n=0}^{\infty} a_n z^n \qquad \text{(Abel)},$$

$$\lim_{z\to 1} \sum_{n=0}^{\infty} a_n z^n \;\Rightarrow\; \sum_{n=0}^{\infty} a_n, \qquad \text{if } \lim_{n\to\infty} (na_n) = 0 \qquad \text{(Tauber)}.$$

Tauber's theorem became essential to the *operational calculus* (especially for Laplace and Fourier integral transform theory) since it enables one to use the known behavior of a linear system at large times in order to deduce its behavior

Tauber was born on Pressburg (now Bratislava), Slovakia to Jewish parents. He was sent by the Nazis to Theresienstadt concentration camp on June 28, 1942 and was hauled from there to the *Auschwitz Gas Chambers* with another 53,000 Jewish inhabitants of the camp.

1897 CE, August 29 *The First Zionist Congress* opened in Basel, Switzerland, under the leadership of **Theodor Herzl** (1860–1904), the founder of the Zionist movement. It approved the programme for re-establishing a Jewish homeland in the Land of Israel.

Herzl was a product of late 19th century positivism, of the age of springtime of the nations. It was also the time of the pogroms in Russia and the Dreyfuss Affair. Herzl saw the suffering of his people as the outcome of the curse of Exile and held that political sovereignty for the Jews was the solution to the problem of *antisemitism*. After the terrible lesson of the Holocaust (1939–1945), it became the credo of the State of Israel.

Not only did antisemitism not "fall silent immediately", but the Jewish state itself became the focus of world Judeophobia. This is what actually occurred even if the hatred was transformed among the nations into "anti-Zionism". In its short history, the Jewish state has faced those who wanted to destroy her in five large-scale wars (1948, 1956, 1967, 1973, 1982) and through unrelenting terrorism within and on her frontiers (1990–2008).

Many are the praises and merits of Zionism: the renewal of a dead language, the ingathering of the exiles, and the re-establishment of a state for a persecuted, ancient people that co-founded Western Civilization and gave the world so much. The movement of revival of the Jewish nation expressed a combination of will power and the victory of man's spirit, worthy of the grave duty of the descendants of the ancient Israelites, who may take pride in about one fourth of all Nobel prizes for science since 1901[39].

---

at zero frequency (and vice versa). For example, in the case of the *Laplace transform* $f(p) = p\int_0^\infty e^{-pt}h(t)\,dt$ we have:

$$\lim_{t\to\infty} h(t) = \lim_{p\to +0} f(p) \qquad \text{(Abel)},$$

$$\lim_{p\to +0} f(p) = \lim_{t\to\infty} h(t), \qquad \text{if } \lim_{t\to\infty} t[h(t) - h(t-1)] = 0 \qquad \text{(Tauber)}.$$

[39] Jews and persons of half-Jewish ancestry have been awarded at least 161 Nobel Prizes, accounting for 22% of all such prizes awarded to individuals worldwide between 1901 and 2003, and constituting 36% of all US Nobel Prize winners during the same period. In the *scientific research* fields of Chemistry, Economics, Medicine, and Physics, the corresponding world and US percentages are 26% and 39%, respectively. (Jews currently make up approximately 0.25% of the world's

1897–1908 CE **Frederick William Lanchester** (1868–1946, England). Aeronautics pioneer who expounded, ahead of his time, the principles of heavier-than-air flight. He was a practical engineer, amateur mathematician and by trade, an automobile builder who began the construction of the first Lanchester motorcar in 1894. In 1897 he developed *the circulation theory of flight*[40]. Two books by him, containing his well-developed ideas, appeared in 1907 and 1908. He contributed to many branches of applied mathematics (e.g. operations research), and continued to produce technical inventions throughout his life.

Lanchester was born in London. After attending college he went in 1891 to work for a gas-engine works in Birmingham. In 1896 he left to set up his own automobile manufacturing firm, producing his first car the same year. He later founded the Lanchester engine company which produced cars which were relatively vibration-free and had a graceful appearance.

1897–1910 CE **Adolf Loos** (1870–1933, Austria). Modernist Viennese architect. Developed a simplified style of architecture marked by uncluttered lines and flat surfaces, setting great value on precision and economy in design. Claimed that buildings must be appropriate to their use and nothing more. His architecture was designed to show in the modern its relationship to the classic. His use of *reinforced concrete* (a new material at the time), utter lack

---

population and less than 2% of the US population.)

- *Chemistry* (25 prize winners, 18% of world total, 26% of US total)
- *Economics* (21 prize winners, 40% of world total, 54% of US total)
- *Literature* (11 prize winners, 11% of world total, 27% of US total)
- *Physiology or Medicine* (51 prize winners, 28% of world total, 42% of US total)
- *Peace* (9 prize winners, 10% of world total, 11% of US total)
- *Physics* (44 prize winners, 26% of world total, 37% of US total)

This enumeration constitutes an update and an expansion of the information on Jewish Nobel Prize winners contained in the 1997 CD ROM edition of the *Encyclopedia Judaica*.

40 He discovered that the wing can be effectively replaced by a *vortex system* consisting of a *bound vortex* which travels with the wing and *free vortices* springing from the wing tips. He was also the first to recognize the importance of *aspect-ratio* of the wing in connection with the work required for sustentation. [The slope of the *line of lift* versus the *angle of attack* depends on the aspect ratio and decreases with its decrease.]

of ornament and severe cubic form and treatment of interior space, his work become a landmark in architectural history, chiefly influencing architects in the United States.

Loos condemned *art nouveau*. In his articles in Viennese journals he structured his arguments within broad socio-political and cultural frameworks. He argued that while ornament had a place in the past, it was degenerate in modern culture. He also criticized the modern practice of architecture for lack of craftsmanship and for working in a cultural vacuum. His buildings relentlessly expressed his theories.

Loos was born in Brno (now in the Czech Republic). During his stay in the USA (1893–1896) he was strongly influenced by the Chicago School. He lived in Vienna from 1897 until his death, except for six years (1922–1928) spent in Paris.

1897–1910 CE **Ernest William Barnes** (1874–1953, England). Mathematician and bishop. Discovered a contour integral representation for the hypergeometric function[41] (1908). Made significant contributions to the theory of transcendental functions (such as the G-function[42]) and proved the so-called *Barnes lemma*.

Barnes was born in the small Oxfordshire town of Charlbury, and educated at Trinity College, Cambridge. He graduated Sc.D. in 1907. He was ordained in the Anglican Church (1902). In 1924 he was appointed by Ramsay MacDonald to the Bishopric of Birmingham.

1897–1921 CE **Vilhelm Frimann Koren Bjerkens** (1862–1951, Norway). Meteorologist and physicist. One of the founders of the science of weather forecasting.

Discovered the circulation theorems that led him to the synthesis of hydrodynamics and thermodynamics applicable to large-scale motions in the atmosphere and the ocean. This work ultimately resulted in the theory of motion of air-masses, which is essential to modern weather forecasting (1919–1921)[43].

---

41 ${}_2F_1(a,b,c;z) = \frac{\Gamma(c)}{2\pi i\Gamma(a)\Gamma(b)}\int_{-i\infty}^{i\infty}\frac{\Gamma(a+t)\Gamma(b+t)\Gamma(-t)}{\Gamma(c+t)}(-z)^t dt.$

42 $G\left(\frac{z+1}{\tau}\right) = \Gamma\left(\frac{z}{\tau}\right)G\left(\frac{z}{\tau}\right),$ where τ is a constant.

43 This work was done in collaboration with his son **Jacob Aall Bonnevie Bjerkens** (1897–1975, Norway and U.S.A.). In 1919 they coined the term *front* for an advancing discontinuity surface separating air masses of different densities, and formed when warm and cold air masses meet. They suggested that *cyclones* originate as waves along the front.

Bjerkens was born in Christiania, Norway. In 1890 he went to Germany and collaborated with **Heinrich Hertz**. In 1895 he became professor of applied mechanics and mathematical physics at the University of Stockholm. He served later as professor in Christiania (1907), Leipzig (1912), Bergen (1917) and Oslo (1926–1932).

1898 CE **Ivan Stanislavovic Bloch** (1836–1901, Poland). Banker and railway financier who devoted his private life to the study of modern industrial warfare. In his six volume master work, *La Guerre Future* (Paris, 1898) he presented a detailed analysis of modern warfare, its tactical, strategic and political implications. His main argument was that:

- New arms technology has rendered maneuvers over open ground (such as bayonet and cavalry charges) obsolete. War between Great Powers would be a war of entrenchment and that rapid attacks and decisive victories were likewise a thing of the past.

- Industrial societies would have to settle the resultant stalemate by committing armies numbering in the millions, as opposed to the tens of thousands of preceding wars. An enormous battlefront would develop. A war of this type could not be resolved quickly.

- The war would become a duel of industrial fight, a matter of total economic attrition. Severe economic and social dislocations would result in the imminent risk of famine, disease, the break-up of the whole social organization and revolutions from below.

Europe's patriots were unmoved. French cavalry and British infantry commanders only learned Bloch's lessons the hard way during WWI. The Russian and German monarchies proved equally incapable of assimilating Bloch's cautionary words concerning revolutions, paying the price with summary execution and exile, respectively.

Bloch was born into a Jewish family at Radom, Poland and died at Warsaw. In his late twenties he adopted Christianity in the form of Calvinism to ease his way up in the Russo-Polish banking system. With the banker Kronenberg of Warsaw, whose sister he married, Bloch participated in the construction of railroads in Russia.

1898 CE **John Philip Holland** (1840–1914, U.S.A.). An Irish-American inventor who built the first practical submarine. It became a model on which later submarines were developed[44].

In 1898, after 28 years of development, he privately built and launched the *Holland* (so named in 1900 by the U.S. Navy). It was a 16 m submarine, powered by a gasoline engine and electric batteries. It could reach a speed of some 15 km/h, submerged.

Holland was born in County Clare, Ireland. He began work on the idea of a submarine while a school teacher in Ireland during 1858–1872. By 1870 he had completed the first plans for his invention. In 1873, Holland came to the United States and earned his living as a school teacher in Paterson, NJ. He submitted his submarine plans to the U.S. Navy in 1875, but they were rejected. However, the *Fenian Society*, a group of Irish patriots in the United States, who hoped to destroy England's naval power, became interested. They supported Holland's experiments and gave him money to build two submarines. In 1900, the Navy bought the *Holland* and asked the inventor to build several more ships like it.

Holland died in poverty, because the company which he formed ran into difficulties.

1898 CE **Marie Sklodowska Curie** (1867–1934, France). Polish-born French physicist. Discovered the atomic origin of radioactivity and the elements radium and polonium [with **Pierre Curie** (1867–1906, France, 1898)]. She coined the word '*radioactivity*'. In 1911 she was awarded the Nobel prize for chemistry, for her isolation of pure radium from pitchblende.

Marie went to Paris in 1891. She married Pierre Curie in 1895 and gave birth to two daughters, Irène (1897) and Éve (1904). Following the sudden death of Pierre in 1906, she devoted all her energy to completing alone the

---

[44] Other pioneers also contributed to the design and development of modern naval submarines:

Gustave Zedé (1825–1891, France). A naval engineer. Built in 1888 an electricity-driven submarine (30 tons, 17 m long) that reached a range of 59 km at a speed of 15 km/h. In 1896 he invented the *periscope*.

Thorsten Nordenfeldt (1842–1920, Sweden) was first to equip submarines with torpedoes (1888).

Simon Lake (1886–1945, U.S.A.) built submarines driven with Diesel engines. His submarine *Argonaut I* was first to make long journeys in the open ocean (1898). In 1902 he developed a periscope with magnifying lenses to sight distant targets. He also built submarines with wheels, so that they could roll along the sea bottom.

scientific work that they had undertaken. In 1908 she was appointed to the professorship that had been left vacant on her husband's death. She died of leukemia caused by the exposure to radiation, a few months after the discoveries of the neutron and artificial radioactivity.

1898 CE **Martinus Willem Beijerinck** (1851–1931, Holland). Botanist. Introduced the name *Virus*[45] for the infective microorganism found in the tobacco mosaic disease. It was coined earlier (1801) by **Dominique Jean Larrey** (head surgeon of Napoleon's Egyptian campaign) as the specific external agent causing diseases.

1898–1900 CE **Joseph Larmor** (1857–1942, England). Irish mathematical physicist. Derived the *Lorentz transformation equations* before Lorentz in his prize-winning essay 'Aether and Matter' [completed 1898, published 1900]. It contains not only the exact transformations, but also the proof that one arrives at the FitzGerald-Lorentz contraction with the help of these transformations. In this work Larmor already suggested that moving clocks must run slow, and by how much.

Larmor was first to calculate the rate at which energy is radiated by an accelerated charge. He also discovered the *classical* effect of an applied magnetic field $\boldsymbol{B}$ on an electron revolving in a circular orbit [it results in the '*Larmor precession*' of the electron's orbital angular momentum about the magnetic field direction. The angular velocity of precession is equal to $\pm\frac{e|\boldsymbol{B}|}{2m}$, where e/m is the ratio of the electron's charge to its mass.] Through this model he explained the splitting of spectral lines by a magnetic field.

Larmor was born at Magheragall in Ireland and was educated at Queen's University, Belfast and St. John's College, Cambridge. He taught at Queen's College, Galway (1880–1885) and at Cambridge (1885–1932), becoming a Lucasian professor there. During 1911–1922 he was member of Parliament for Cambridge.

1898–1923 CE Repeated outbreak of *plague* in India. Death toll as high as 12 million.

1898–1907 CE **Valdemar Poulsen** (1869–1942, Denmark). Electrical engineer and inventor. Became known as the Danish Edison. Developed the

---

[45] *Virus* is the Latin word for 'poison'. The average virus is about 0.2 micron in diameter, as compared to 2 micron for the diameter of an average bacterium. It was found in 1936 that the tobacco mosaic virus was 94 percent protein and 6 percent nucleic acid. Today, we may say that just as a bacterium could be viewed as a kind of a isolated cell nucleus, a virus could be viewed as an isolated cell *chromosome*.

first *magnetic sound recorder* (1899). He later invented the arc-transmitter (1902), important for wireless telegraphy.

Poulsen's *Telegraphone* (1898) was the first practical apparatus for magnetic sound recording and reproduction. It recorded, in a magnetized steel piano wire[46], the varying magnetic fields produced by a sound. The magnetized wire could then be used to play back the sound.

The Telegraphone received considerable attention when it was exhibited at the Exposition Universelle in Paris (1900). The few words that the Austrian emperor Francis Joseph spoke into it at that exhibition are believed to be the earliest surviving magnetic recording.

Poulsen's arc-transmitter[47] was the first device for generating continuous radio waves, thus aiding the development of radio broadcasting. In 1904 he was transmitting voice over appreciable distances.

Poulsen was born in Copenhagen. He made his invention while working at the Copenhagen Telephone Company as an assistant in the technical section.

The Telegraphone was offered commercially in the US in the 1920's. Sometimes in the 1950's a workable Telegraphone was found during cleaning in the cellar at the Interior Department. It could play back a part of a radio broadcast from 1921.

In 1927, the American inventor **J.A. O'Neill** replaced the wire with a magnetically coated ribbon and since then magnetic tape recorders have dominated the recording industry.

1898–1919 CE **Jules-Jean-Baptiste-Vincent Bordet** (1870–1961, Belgium). Bacteriologist and immunologist. Discovered the role of blood serum in the human immune system response (1898) [the *complement* is the component of blood needed for antibodies[48] to react with invading bacteria]. His work made possible new techniques for the diagnosis and control of infectious

---

46 It recorded continuously for 30 minutes at a speed of 2/3 cm per second. He stretched his wire across his laboratory and put the recording apparatus on a trolley that traveled along that wire. He would run along with the moving trolley, talking into its microphone to record sound on the wire. To play back this sounds, he would roll a second trolley containing the playback equipment along the wire, and it would reproduce the sound.

47 The arc was formed between a copper cathode (positive terminal) and a carbon anode (negative terminal) in an atmosphere of a hydrocarbon gas and a transverse magnetic field. Subsequent efforts with this device by Poulsen and others made long-wave radio broadcasting possible by 1920.

48 This discovery plus the discovery of other serum factors gave rise to *humoral theory* of immunity, and the term *antigen* and *antibody* came into use. This humoral

diseases. In 1901, Bordet further showed that *complement* is used up when an antibody reacts with an antigen. He was first to isolate (1906) the whooping-cough bacillus and isolated (1909) the germs for bovine peripneumonia and Avium diphtheria.

Bordet was born in Soignies and received his MD from the University of Brussels (1892). Went to Paris (1894) to work in Metchnikoff's laboratory at the Pasteur Institute. Became Director of the Pasteur Institute in Brussels (1901), where he remained until he was succeeded by his son Paul (1940). He was awarded the Nobel Prize for Physiology or Medicine (1919) for his studies in immunology.

1899 CE The drug *aspirin* (acetyl-salicylic acid; $C_9H_8O_4$) became available as an effective remedy in relieving minor pain and in reducing fever. It was introduced by the German chemical firm of Bayer.

The Alsatian chemist **Charles-Frederic** (**Karl**) **Gerhardt** (1816–1856) discovered aspirin (1853) as a *natural* by-product of coal tar. It was first synthesized (1859) by the German organic chemist **Adolf Wilhelm Hermann Kolbe** (1818–1884) in a reaction named after him, through which salicylic acid and acetic acid are combined. The result is a colorless odorless powder with bitter taste; its structural formula consists of a benzene-ring in which one hydrogen atom is replaced by the radical $-\underset{\underset{\displaystyle \mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{OH}$, and a neighboring hydrogen atom by the radical $-\mathrm{O}-\underset{\underset{\displaystyle \mathrm{O}}{\|}}{\mathrm{C}}-\mathrm{CH_3}$.

The discovery of aspirin was motivated by the shortage of the drug *quinine*, which led chemists to search for a substitute pain reliever. The medical value of aspirin was recognized only in 1899 when **Heinrich Dreser**, a German scientist, wrote about its effectiveness as a mild sedative. Consequently, its large-scale manufacturing started at the same year by the German Firm Bayer, where **Felix Hoffman** used Kolbe's synthesizing reaction. Today, aspirin is used as a antipyretic analgesic agent in relieving the symptoms of headache, neuralgia, arthritis, rheumatism, common cold and influenza.

---

view was vigorously contested by **Elie Metchnikoff** (1845–1916) who described *phagocytosis* (the ingestion of bacteria by white blood cells) and proposed a cellular theory of immunity (inflammation). Later, **Almroth Wright** (1861–1947) combined both views by showing serum factors necessary for phagocytosis.

Aspirin

Aspirin is found naturally in certain plants and trees: e.g. the barks of the willow tree *and the* silver birch tree *as well as the leaves of* meadowsweet *and* wintergreen *plants.*

In the summer of 1758, the Rev. ***Edward Stone****, of Chipping Norton, in Oxfordshire, England, was suffering another of his bouts of fever and rheumatic twinges. By accident, he chewed on a twig of the white willow tree (*Salix alba*), and despite its "extraordinary bitterness", he was astounded to find that it relieved his "ague". He devised a method of drying and pulverizing the bark, and then experimented to discover the best dosage. Over the next five years, he gave his remedy to 50 others, and it "never failed in the cure". Enthusiastic at his discovery, on 25 April 1763 he wrote to the Earl of Macclesfield, President of the Royal Society, but was ignored.*

In the 1820s, the Swiss Pharmacist ***Johann Pagenstecher*** *began extracting a substance from the leaves of the plant* Spirea ulmaria*, commonly called* meadowsweet *and well known as a pain reliever in folk medicine. His report in a scientific journal was read in 1835 by the German chemist* ***Karl Jacob Löwig****, who, using the extract, obtained an acid, later to be known as* salicylic acid.

Earlier (1829), the French pharmacist ***H. Leroux*** *identified the active element in willow bark to be* salicin*. In 1838, the Italian* ***R. Piria*** *extracted pure salicylic acid from methyl salicylate taken from birch tree bark. The Alsatian chemist* ***Karl Friedrich Gerhardt*** *(1816–1856), a chemistry professor at France's Montpellier University, discovered (1853) the molecular structure of salicylic acid. He also tried to modify its rather severe side effect — the painful irritation of the stomach lining — but he found the procedure so time-consuming that he abandoned the drug as "of no further significance".*

But in 1860, the German organic chemist ***Hermann Kolbe*** *(1818–1884) first synthesized salicylic acid — a colorless odorless powder with bitter taste. In the following years the shortage of the drug* quinine *motivated chemists to search for a substitute fever reducing and pain reliever medicine. Salicylic acid, however, continued to be used by people whose pain was worse than that caused by the drug itself. One of these was a Herr Hoffman, who lived in the German town of Elberfeld and was crippled by arthritis. His son,* ***Felix Hoffman****, worked as a chemist at the huge Bayer drug plant nearby, and in 1895 he decided to try to change salicylic acid to end his father's suffering. He simplified Kolbe's method and came up with* acetylsalicylic acid.

Hoffman's colleague, ***Heinrich Dreser****, investigated the overall medical effects of the new drug and recognized it to be effective not only as a mild sedative, but also as a reducer of fever and inflammations. In 1899, Hoffman and Dreser coined a new name for that new drug:* aspirin *— '*a*' for 'acetyl', '*spir*' for the Spirea plant family and '*in*' to round it off.*

The following year, the Bayer drug company took out patents on aspirin, on the intermediate compounds in its manufacture, and on the design of the manufacturing equipment, and began to make huge amounts of what was to become their bestselling product all over the world.

In 1914, in anticipation to the outbreak of war and a halt in supplies from Germany, the British and Australian government offered a prize of £25,000 to anyone in Britain or the British Commonwealth who could come up with a new formulation for aspirin that could circumvent Bayer's patents. The chemist ***George Nicholas*** *took up the challenge and devised a process that yielded exceptionally pure aspirin — and won the prize. Following Germany's defeat, the victors confiscated the name 'aspirin', and the Bayer company lost its exclusive rights to both the name and the manufacture of the drug.*

Since its discovery, aspirin is used as an antipyretic analgesic agent in relieving the symptoms of headache, neuralgia, arthritis, rheumatism, common cold, influenza, inflammation, swelling and even as a blood thinner for preventing ailments — but with no known clue for its effectiveness. It was only in 1971 that researchers in Britain came up with at least one reason why aspirin works. Prostaglandins*, a group of hormone-like substances found in virtually all the tissues of the body, seem to increase the sensitivity of nerve endings at sites of inflammation — and aspirin appears to interfere with the effective action of these substances.*

Aspirin eventually became part of a group known as non-steroidal anti-inflammatory drugs (NSAIDs) which now include the more recent drug ibuprofen*. In the 1980s, aspirin was superseded by* paracetamol *(first used in 1891, but first marketed in 1953) as a popular painkiller for all ages.*

1899–1905 CE **René-Louis Baire** (1874–1932, France). Mathematician. Made significant contributions to the analysis of real functions and *functionals* and the concept of limit. Introduced the new notions of *semicontinuity*[49] of

[49] The condition of *continuity of a function* $f(x)$ at a point x states that, given ϵ, an open interval $(x-h, x+h)$ exists that for any point x' in it, $|f(x')-f(x)|<\epsilon$.

functionals and classified them into the '*Baire-functions*'. His books on analysis include: *Theorie des nombres irrationels, des limites et de la continuite* (1905) and *Lecons sur les theories generales de l'analyse* (1907–8). Baire was a student of **Volterra** and **Darboux**. Became a professor of mathematics at the Universities of Montpellier and Dijon.

The limit function of a pointwise converging sequence of continuous functions defined on a metric space is *not* necessarily continuous; a simple but profound example suffices to exhibit this property: consider an isosceles triangle with sides $AC = BC = 10$ units and base $AB = 5$ units. The sum of lengths of its sides is therefore 20 units. Mark the midpoints of AC, BC, AB at E, D, F respectively and draw the 4-segment zigzag line $AEFDB$ whose length is again 20 units. Repeat this process to each of the triangles AEF and FDB, thus producing a new 8-segment zigzag line of total length 20 units. As the process continues, the zigzag line (whose total length is always 20) will get closer and closer to the 5 unit base AB, and its vertical height will get smaller and smaller.

Clearly, the *length* of the zigzag line is a *functional* of its shape. This functional is *not continuous* at the base of the triangle, since the length of the zigzag line does *not* necessarily approximate closely the length of the base as the position of the lines gets close to the position of the base. However, the functional has the property that Baire called *lower semicontinuity*, since all the different zigzag lines we can possibly draw, as close to the base as we please, have a *lower bound*, namely 5 units, but no *upper bound*.

This can be split into two separate conditions:

(i) $f(x') < f(x) + \epsilon$,

(ii): $f(x') > f(x) - \epsilon$. It is possible that at a point x one of these conditions may be satisfied and not the other. If for every point x' in the above open interval the first condition is satisfied then the point x is said to be a point of *upper semi-continuity* of the function $f(x)$. If an open neighborhood of the point x can be determined for each ϵ, such that $f(x') > f(x) - \epsilon$, then the point x is said to be a point of *lower semi-continuity.* A function $f(x)$ is said to be *upper semi-continuous* in the interval (a, b), if every point in it is a point of upper semi-continuity.

Baire (1899) introduced the following classification: continuous functions are *functions of class* 0; a function that is a pointwise limit of a sequence of continuous functions is a *function of at most class* 1. A function is said to be of class 1 if it is of at most class 1 and not of class 0. He similarly defined the notion of *class* n for arbitrary natural number n. For example the *Dirichlet function* $f(x) = \lim_{\nu\to\infty}[\lim_{k\to\infty}(\cos\nu!\pi x)^{2k}]$ is of class 2; it takes the value 1 at rational points and 0 at irrational points.

The Magnetic Recording Story (1888–1964)

Early attempts to record sound centered about experiments to trace the vibrations of bodies emitting sound, such as tuning-forks and membranes. In 1807 ***Thomas Young*** *described a method of recording the vibration of a tuning-fork on the surface of a drum; his method was fully carried out by* ***Wilhelm Wertheim*** *in* 1842.

Recording the vibrations of a membrane was first accomplished by the French typographer and painter ***Léon Scott de Martinville*** *in* 1857 *by the invention of the phonautograph, which may be regarded as the precursor of the phonograph.*

This ingenious device consisted of a horn with a thin membrane stretched over the end, to which was attached a stiff bristle. Rotating beneath the bristle and advanced by means of a lead screw was a smoked drum. Sounds directed into the horn caused the bristle to move back and forth across the smoked paper and trace out a wave-form. For the first time in history it was possible to see sound.

The dazzling possibility that has escaped both ***Scott*** *and the acoustic experimentalist* ***Karl Rudolph König*** *(who actually constructed the first phonautograph) was the simple idea of reversing the process and retrieving the original sound which had been recorded.*

Edison's phonograph (1877) operated by indenting, or embossing, a tinfoil-covered cylinder to a varying depth corresponding to the sound pressure. The sound track was, therefore, a spiral of varying depth around a cylinder.

In 1888 ***Oberlin Smith*** *wrote an article in the magazine Electrical World in which he suggested, probably for the first time, the use of permanent magnetic impressions for sound recording. Smith visualized a cotton or silk thread in which steel dust or short clippings of fine wire were suspended, these particles to be magnetized in accordance with the undulatory current delivered from a microphone. He discussed the possibility of employing a hard steel wire, but did not believe that a wire would divide itself up properly into a number of short magnets to establish a magnetic pattern that is a replica of the microphone current. Smith never built an instrument to implement his idea.*

In 1887, ***Emile Berliner*** *(1851–1929, Germany and U.S.A.), invented the gramophone. It had a flat disc instead of a cylinder. At the turn of the century, Berliner made further commercial development of the phonograph by working out methods of mass-producing shellac records.*

It is at this very moment in the history of recorded sound that ***Poulsen*** *appeared on the scene; he came from a good family — his father was supreme court judge in Copenhagen and wanted his son to be a doctor. Valdemar accordingly enrolled in medical school, but in* 1893 *he left that school to work in the technical section of the Copenhagen Telephone Company.*

It is not known how he got the idea of recording sound by varying the magnetization of a steel wire. It is believed that he never read Smith's article. Moreover, there was no theoretical basis for believing that one could magnetize just one spot on a bar and leave the rest unaffected, and granted that, for knowing how permanent the record would actually be.

It was an amazing and counter-intuitive idea, and it was Poulsen's alone! In contradistinction to the telephone and countless other major inventions throughout the history of science, nobody else, so far as is known, even claimed to have invented the telegraphone, *as Poulsen named his invention.*

In Poulsen's machine, a large brass cylinder had spiral grooves running the length of the cylinder. Lying in the groove was a steel wire, against which rested two poles of an electromagnet, which carried the current generated by the microphone. The electromagnet was rotating, and thus magnetizing portion after portion of the spiral wire. When the recording was completed, the microphone was switched out of the circuit and a telephone receiver connected in its place. Then, by placing the recording head (which now served as a reproducing head) at the beginning of the wire spiral, the original message was heard, as the varying magnetization of the wire generated current in the windings of the electromagnet.

The low playback level (which required the use of earphone) was the besetting weakness of early magnetic recording. When it became obvious with the passage of a number of years that this obstacle was basic, magnetic recording dropped out of sight, and interest was not revived until electronic amplifiers became available.

In the late 1920*'s, engineers found a more efficient and convenient substitute for the steel wire used in Poulsen's recorder. They worked out a method for using* plastic tape *coated with magnetic material. Thus* ***J.A. O'Neil*** *(1927) replaced wire with a diamagnetic ribbon (coated with a metallic substance such as ferric oxides, chrome dioxide on a mylar tape) while* ***F. Pfleumer*** *introduced a magnetic tape made of paper coated with magnetic particles. By 1930, tape recorders based on this principle were developed in Germany. In 1935, AEG (Germany) introduced the first model of commercial tape recorder using plastic tape coated with magnetic particles; it was called the Magnetophone.*

Further improvements were made by ***Joseph Begun*** *(1905–1995, Germany and USA) who built the first tape recorder for broadcasting, later used* *in the 1936 Berlin Olympics. During WWII (1939–1945), the Germans further developed the process of recording on magnetic tape. After the war, engineers in the United States continued the German experiments.*

Begun, who was born in Danzig (now Gdansk, Poland) and graduated (1929) with a PhD from the Berlin Institute of Technology, moved to the United States in 1935 and continued to develop tape recording.

By 1950, *tape had largely replaced phonograph records for radio recording. Stereo tape recorders were introduced in the United States in* 1955. *About the same time, television stations began recording programs on videotape. In the early* 1960*'s, engineers in the Netherlands developed the cassette audio tape recorder, which was introduced in the United States in 1964.*

1899–1913 CE **Jacques Loeb** (1859–1924, Germany and USA). Biologist and pioneer of the mechanistic view of life (*The Mechanistic Conception of Life*, 1912). Found a way to remove the eggs from a female of sea-urchin and make them start their embryonic development, just as if they had been fertilized by a sperm — but without sperm[50]. He found that a dose of certain lifeless chemicals would launch the development of an organism from a single cell. This he used as a confirmation of the mechanistic view of life, i.e. that life is essentially a mechanical process which can be *entirely* explained by the laws of physics and chemistry.

Loeb was confident that the mechanics of life would prove simple enough to create life in the laboratory! He in fact prophesied *self-assembly*, i.e. that certain molecules assemble themselves into specific, predictable structures, because their shapes, their own physics and chemistry, will allow them to assemble *only* in those patterns. In the next 50 years biochemists would apply a barely reductionist approach to the study of life, and vindicate the mechanistic view with the discovery of the double helix of DNA and the cracking of the genetic code.

Loeb was born to a Jewish family in Mayen, Germany. Educated in philosophy at Berlin and in medicine at Strasbourg (MD, 1884). Assistant professor at Würzburg (1886). An interest in the philosophy of the will led to research which attempted to show, in the animal world, phenomena analogous to plant tropism. Emigrated to the USA (1891), and held various university

[50] Nowadays the procedure is quite routine and is performed even in high school biology classes to demonstrate the early stages of embryonic development.

appointments before becoming head of the general physiology division of the Rockefeller Institute for Medical Research (1910–1024). **Sinclair Lewis** made Loeb the model for Max Gottlieb, in his book "Arrowsmith". Loeb will be remembered as a champion of materialism in philosophy and the mechanical view of life in biology.

1899–1916 CE **Karl Schwarzschild** (1873–1916, Germany). A gifted astronomer whose contributions, both practical and theoretical, were of primary importance in the development of 20^{th} century astronomy and cosmology. His name is associated with a number of discoveries: Schwarzschild *radiation equilibrium*, '*distribution function*', '*velocity ellipsoid*', '*metric*', '*horizon*', '*radius*' and '*exponent*'.

Schwarzschild was first to suggest that heat and light in stellar atmospheres are transported mainly by radiation. He enunciated the principle of radiative equilibrium[51], and was first to reorganize clearly the role of radiative processes in energy transport in the stellar atmospheres.

He found, already in 1899, that the changes in luminosity of cepheids are accompanied by changes in effective temperature, suggesting that the variability is a temperature effect. In 1900, when GTR was still unknown, Schwarzschild apprehended the importance of *non-Euclidean geometry*.

He concluded that "*it is possible, without contradicting the evidence, to think of the universe as contained within a hyperbolic space with a radius of curvature larger than* 4,000,000 *radii of the earth's orbit, or within a finite, elliptical space with a radius of curvature larger than* 1,000,000 *radii of the earth's orbit, while assuming in the latter case an absorption of light equal to* 40 *magnitudes in a journey around this space*".

Although it is now known that the possible radius of curvature of the universe must be much larger than the minimum values quoted by him, his paper represents a pioneering effort in the field now referred to as *cosmology*.

In 1906 he showed that in the sun's photosphere (the layers that send out most of the radiation) the transport of energy outwards from the interior is performed by radiation. He calculated the increase of temperature with optical depth on the assumption of *radiative equilibrium* and showed that one thereby derives the correct center-to-limb darkening of the solar disc.

Schwarzschild's work on the solar eclipse of Aug. 30, 1905 is a masterpiece of insight into observation and theory.

In 1914 he investigated theoretically, and by spectrophotometric measurements, the radiative exchange and the broad *H*-and *K* lines (3933, 3968 Å)

---

[51] The idea was later followed up by **A.S. Eddington** (1916).

of the solar spectrum. He clearly saw that the further prosecution of his undertakings required an *atomistic theory of absorption* coefficients, i.e. of the *interaction of radiation and matter*. He thus turned with enthusiasm to the quantum theory of atomic structure found by **N. Bohr** in 1913. This effort resulted in his famous works on the *quantum theory of the Stark effect* and on band spectra. Independently of **A. Sommerfeld**, he developed the general rules of quantization and initiated the quantum theory of molecular spectra.

In December 1915, one month after the publication of Einstein's series of four papers outlining GTR, Schwarzschild derived (1916) the first rigorous solution of Einstein's full gravitational field equations for the static isotropic field surrounding a spherical mass. In a second paper of that year, he gave the solution for the motion of a mass point in the gravitational field of an incompressible fluid sphere. It is there that the '*Schwarzschild radius*' is introduced for the first time.

Schwarzschild sent his paper to **Einstein** to transmit to the Berlin Academy. In his reply Einstein wrote: "*I had not expected that the exact solution to the problem could be formulated. Your analytical treatment of the problem appears to be splendid*".

Neither of them, nor anybody else at that time knew that Schwarzschild's solution contained a complete description of the external field of a spherically symmetric, electrically neutral nonrotating black hole. Today we refer to it as "*Schwarzschild's black hole*".

Schwarzschild was born in Frankfurt am Main and attended a Jewish school until the age of 11. His exceptional ability in science became evident at the age of 16, when his paper on the theory of celestial orbits was published. He was then educated at the University of München. In 1901 he became professor and director of the observatory at the University of Göttingen, and in 1909 was appointed director of the Astrophysical Observatory at Potsdam. In 1909 he married a non-Jewish woman, against the objections of both families.

He participated actively in WWI as a German soldier and died on May 11, 1916, following a short illness contracted at the Russian front. His son **Martin Schwarzschild** (1912–1997) fled Nazi Germany in 1935 and emigrated to the U.S. in 1937. He became a professor of astrophysics at Princeton in 1947 and made significant contributions to our knowledge of variable stars and stellar evolution.

1899–1917 CE **Georg Alexander Pick**[52] (1859–1942, Austria and Czechoslovakia). Mathematician. Contributed to linear algebra, invariant

[52] To dig deeper, see:

- Varberg, D.E., *Pick's Theorem Revisited*, Am. Math. Monthly, 1985, *92*, 584–587 pp.

theory, potential theory, functional analysis, differential geometry and discrete (reticular) geometry. Terms like 'Pick matrices', 'Pick–Nevanlinna interpolation', and the 'Schwarz–Pick lemma' are sometimes used today. But from a lifelong work covering a wide range of topics he is best remembered, however, for 'Pick's theorem' [53] (1899).

Georg Pick was born in Vienna into a Jewish family. He entered the University of Vienna (1875) and was awarded his doctorate there in mathematics (1880). He was then appointed as an assistant to **Ernest Mach**, at the Charles–Ferdinand University of Prague and later promoted to full professorship at the German University in Prague (1892)[54]. After his retirement (1927) he returned to Vienna, only to return to Prague after the Anschluss (1938).

[53] *Pick's theorem*: The area of any simple polygon whose vertices are lattice points, is given by the formula $\frac{1}{2}b + c - 1$, where b is the number of lattice points on the boundary while c is the number of lattice points inside (by 'simple' polygon we mean one whose sides do not cross each other). There is *no* analog of Pick's theorem in 3 dimensions that expresses the volume of a polytope by counting its interior and boundary points.
This theorem was brought to wide attention in 1969 through the popular *Mathematical Snapshots* by **H. Steinhaus**. It then attracted much attention due to its simplicity and elegance. Pick's theorem is linked to several other beautiful results like the celebrated *Euler's formula* and the basic property of the *Farey Series*.

[54] There is another aspect of Pick's life which merits attention: Pick was the driving force behind the appointment of **Albert Einstein** to the chair of mathematical physics at the German University of Prague (1911–1913). In 1911 Pick introduced Einstein to the tensor calculus of **Gregorio Ricci–Curbastro** and **Tullio Levi–Civita**, which later (1915) helped Einstein formulate General Relativity.
During the years the two were close friends who also shared passionate interest in music (in fact Pick's quartet consisted of four professors from the University).

In July 1942 the Nazis moved him to Theresienstadt and he died there two weeks later aged 82.

1899–1918 CE **Kurt Hensel** (1861–1941, Germany). Mathematician. First to introduce *p-adic numbers*[55] (1899) and p-adic analysis. In recent years, p-adic arithmetic and analysis has been recognized as an important, widely generalizable field of mathematics and mathematical physics.

Hensel was born in Königsberg, a descendant of a Jewish illustrious family[56]. He studied mathematics at Bonn and Berlin and came under the influence of **R. Lipschitz**, **K. Weierstrass**, **G. Kirchhoff**, **von Helmholtz** and especially **L. Kronecker**, under whose guidance he took his Ph.D. in 1884. In 1901, Hensel became full professor at the University of Marburg, where he remained for the next 40 years.

From 1901 he was editor of the influential *Crelle's Journal*. Hensel's scientific work is based upon Kronecker's arithmetical theory of algebraic number fields and the Weierstrass method of power series development for algebraic functions. This led Hensel in 1899 to the conception of an analogue in the theory of algebraic numbers: p-adic numbers[57] which he developed into a *sys-*

[55] Though they are fore-shadowed in the work of his predecessor E. Kummer (ca 1829).

[56] The four mathematicians: **P.G. Lejeune-Dirichlet**, **E.E. Kummer**, **H.A. Schwarz** and **K. Hensel** were all members of the Mendelssohn family in the following way: Dirichlet married Rebecca (1811–1858), a sister of the composer Felix Mendelssohn. Felix's other sister, Fanny (1805–1847) was the paternal grandmother of Kurt Hensel. The second wife of Kummer, Ottilie Mendelssohn (1819–1848), was a daughter of a cousin of Fanny. Their daughter, Marie Elisabeth Kummer (1842–1921), was married to H.A. Schwarz.

[57] *The Archimedean property of the real-number system*: If $x > 0$ and if y is an arbitrary real number, there exists a positive integer n such that $nx > y$.
To prove the theorem we first show that the set of positive integers in unbounded above, from which it follows that for every real x there exists a positive integer n such that $n > x$. In this theorem we replace x by $\frac{y}{x}$, which proves the Archimedean property (AP) (also known as *The theorem of Eudoxos*).
Geometrically, AP means that any line segment, no matter how long, may be covered by a *finite number* of line segments of a given positive length, no matter how small. In other words, a small ruler used often enough can measure arbitrarily large distances. Archimedes realized that this was a fundamental property of the straight line and stated it explicitly as one of the *axioms of geometry*.
In the 19^{th} and 20^{th} centuries, *non-Archimedean* geometries have been constructed in which this axiom is rejected.

tematic theory. His pupil, **Helmut Hasse** further developed p-adic analysis (1923), and applied it to the theory of algebras over number fields.

Non-Archimedean mathematics — the strange world of p-adic numbers

The sequence of rational numbers

$$\begin{array}{l} 1.414\ 213\ 5 \\ 1.414\ 213\ 56 \\ 1.414\ 213\ 562 \\ 1.414\ 213\ 562\ 3 \\ 1.414\ 213\ 562\ 37 \\ 1.414\ 213\ 562\ 373 \\ \ldots \end{array}$$

get ever closer to $\sqrt{2}$. *The central idea here is that we have a sequence of numbers whose members get closer and closer to each other – they constitute what is called a* Cauchy sequence *[i.e. upon picking a positive distance no matter how small, there always exists some member beyond which any two members will be within that distance of each other] and therefore* ought to *converge to something.*

Normally (i.e., with distance defined in the standard way on the real axis), if we want to know whether two rational numbers are close to each other, and we have their decimal expansions, we can start from the left*, comparing digits, and the further right you can get before you run into a discrepancy, the closer together the numbers are.*

Now suppose we choose to translate decimal numbers into the binary system, e.g.

$$\begin{aligned} 519 = \quad & 1\cdot 2^9 + 0\cdot 2^8 + 0\cdot 2^7 + 0\cdot 2^6 + 0\cdot 2^5 + 0\cdot 2^4 + 0\cdot 2^3 \\ & \qquad + 1\cdot 2^2 + 1\cdot 2^1 + 1\cdot 2^0 \\ 7 = \quad & \qquad 1\cdot 2^2 + 1\cdot 2^1 + 1\cdot 2^0 \end{aligned}$$

and write these in the 2-adic form

$$\begin{array}{lr} 100\ 000\ 011\ 1. & (519) \\ 000\ 000\ 011\ 1. & (7) \end{array}$$

If we agree to read these numbers from right to left, we may think of them as being relatively close to each other, differing only in a single digit 1 *in the tenth place. On the other hand, when applying the same thinking to*

$$\begin{array}{lr} 111. & (7) \\ 101. & (5), \end{array}$$

we may think of them as being rather far apart, since they differ already in the second digit from the right. We may therefore establish the 'rule' that two 2-adic numbers are 'close' if their difference is a multiple of some large power of 2*. This rule can be made more precise, as we will see, and thus be elevated into a new (so-called 2-adic) norm for rationals – an alternative to the standard definition of norms as absolute value.*

Carrying this logic one step further we can consider sequences of 2-adically expressed integers that are Cauchy sequences in the 2-adic (though not standard) sense, and thus – one feels – "ought" to converge in the 2-adic sense, for example

$$\begin{array}{rr} 111. & (7) \\ 1\ 111. & (15) \\ 11\ 111. & (31) \\ 111\ 111. & (63) \\ 1\ 111\ 111. & (127) \\ 11\ 111\ 111. & (255) \\ \cdots & \end{array}$$

This looks as if we claim that the number $\ldots 11\ 111\ 111.$ *tends to some limit. Of course, this looks a bit silly; obviously the sequence* $\{7, 15, 31, 63, 127, 255, \ldots, 2^k - 1, \ldots\}$ *marches straight off to infinity as measured by the standard norm.* ***Hensel*** *asserted that this sequence converges (2-adically) to the rational number* -1 *with the understanding that two numbers are close if their difference is a multiple of some large power of* 2*, and they get closer and closer as the power of* 2 *increases. Indeed,*

$$\begin{array}{rl} 63 = & (-1) + 2^6 \\ 255 = & (-1) + 2^8, \qquad \textit{etc.,} \end{array}$$

so these numbers are getting closer, converging, to -1 *such that we may write*

$$\ldots 111\ 111\ 111\ 111. = -1$$

We might then ask about $\ldots 101010101,$ *with its '10' pattern repeating off to the left. Multiplying this number by 3 (multiplying by 2 and adding the original) we get*

$$\begin{array}{rl} \ldots 1\ 010\ 101\ 010. & \\ \ldots\ \ 101\ 010\ 101. & \\ \hline \ldots 1\ 111\ 111\ 111. & = -1 \end{array}$$

leading to the results:

$$\ldots 101\ 010\ 101. \quad = -\tfrac{1}{3}$$

$$\ldots 010\ 101\ 010. \quad = -\tfrac{2}{3}$$

$$\ldots 010\ 101\ 011. \quad = 1 + 2 \cdot (-\tfrac{1}{3}) = \tfrac{1}{3}$$

Now, ordinary decimal (or digital in any other base) expansions of fractions repeating off to the right converge in the standard sense to rationals with denominators that are not powers of 10 *–* e.g.[58]*:*

$$0.\overline{142\ 857} \quad = \tfrac{1}{7}$$

$$0.\overline{09} \quad = \tfrac{1}{11}$$

In similar fashion, the binary expansions repeating off to the left converge 2-adically to rationals with denominators that are not powers of 2:

$$\overline{0\ 011}01. \quad = \tfrac{1}{5}$$

$$\overline{011}1. \quad = \tfrac{1}{7}$$

$$\overline{0\ 111\ 010\ 001}1. \quad = \tfrac{1}{11}$$

$$\overline{011\ 101\ 100\ 010}1. \quad = \tfrac{1}{13}$$

It can be shown that non-periodic binary expansions going off to the left do not 2-adically converge to rational numbers. Yet such expansion are Cauchy sequences under the 2-adic norm. So, the next logical development was to define *non-periodic 2-adic expansions to be* new *2-adic numbers*[59]*, just as irrational reals are augmented to the rationals using standard norm. These new*

[58] A bar over a contiguous of digits, means the group is to repeated *ad infinitum.*

[59] Formally, this procedure is referred to as the topological completion of the set $\mathbb{Q}$ of rationals under the new, 2-adic norm.

numbers, together with the rationals $\mathbb{Q}_1$ comprise the topologically complete algebraic field (under ordinary arithmetical operations) $\mathbb{Q}_2$ of 2-adic numbers. Proceeding similarly with any other prime base p creates the $\mathbb{Q}_p$ field of p-adic numbers. $\mathbb{Q}_p$ really is a field, since within it one may add, subtract, multiply and divide (except by 0).

Following this heuristic introduction we turn to a summary of the mathematical foundations of p-adic analysis. Since ***Euclid****'s time the three-dimensional Euclidean space (and its geometry) has been described by means of real numbers and treated as the physical space. Since the time of* ***Newton*** *and* ***Leibniz****, differential equations, integrals, and other limits involving the real (and complex) algebraic fields have been used in mathematical physics.*

Important extensions of this point of view have been introduced by ***Riemann****, and later by* ***Einstein*** *using the pseudo-Riemannian geometry, but locally $\mathbb{R}^3$ is still our mathematical model for space and $\mathbb{R}^4$ for space-time. It is not customary to discuss why exactly real numbers should be used, and why this happened. The point is that physical processes take place in space and time, and space-time coordinates are usually considered as real numbers – obtained from rationals via topological completion under the standard norm.*

In computations of everyday life, in scientific experiments and in computer based representation of numbers, one is dealing with integers and fractions, that is with rational numbers; irrational numbers — infinite nonperiodic decimal expressions — are not manipulated directly (only via formal procedures or rational approximations). Results of any practical action we can express only in terms of rational numbers. There exists, however, a generally accepted expectation that if we carry out measurements and calculations more and more precisely, then in principle we can measure and compute physical quantities out to any large number of decimal digits and interpret the result as a real number. This of course is an idealization[60].

Thus, let us take as our starting point the field $\mathbb{Q}$ of rational numbers. A geometric notion of distance *corresponds to topological notion of* norm *(and thus also a* metric *– i.e. a distance – defined as the norm of a difference) on $\mathbb{Q}$. A* norm *on a field is a real-valued function $|x|$ with the following properties:*

1) $|x| \geq 0, \qquad |x| = 0 \quad \textit{iff } x = 0$

2) $|xy| = |x||y|$

3) $|x + y| \leq |x| + |y|$

[60] In the case of purely mathematical manipulations – solving equations and the like – these expectations are rooted in rigorously-proven theorems.

The last property is the well-known triangle inequality, which – for the usual absolute-value norm on the real or rational fields – is a direct consequence of the definition of the absolute value[61]*.*

---

[61] *Basic concepts:* consider a set X of elements. For each two elements (x, y) we form a real function $d(x, y)$ with the following properties:

(i) $d(x, y) \geq 0, \qquad d(x, y) = 0 \quad \text{iff } x = y;$

(ii) $d(x, y) = d(y, x);$

(iii) $d(x, y) \leq d(x, z) + d(z, y)$ for all z of X.

The function d is called a *distance* or *metric* on X. The set X, when endowed with a metric $d(\cdot, \cdot)$, is a *metric space* (X, d). The same set X can give rise to many different metric spaces (X, d). The set X will mostly be a *field* in this discussion of p-adics. [A field F is a set together with two operations $+$ and $\cdot$ such that F is a commutative group under $+$, $F - \{0\}$ is a commutative group under $\cdot$, and the distributive law holds.] The most common examples, apart from $\mathbb{Q}$, are the field of real numbers $\mathbb{R}$ and the field of complex numbers, $\mathbb{C}$. In the first case the standard distance between two points on the number line is the norm $d(x, y) = |x - y|$. In two (real) dimensions, the norm of the complex number $|a + ib| = \sqrt{a^2 + b^2}$ leads to the distance between two complex numbers $d(a + ib, c + id) = \sqrt{(a - c)^2 + (b - d)^2}$. Property (iii) is then the *actual triangular inequality* $d(x, y) \leq d(x, z) + d(z, y)$ with the geometrical interpretation that the sum of two sides of any triangle is never smaller than the third side.

The proof of 3) and thus iii) for the real line with the standard absolute-value norm is simple: adding the inequalities $-|x| \leq x \leq |x|$ and $-|y| \leq y \leq |y|$ we obtain $-[|x| + |y|] \leq x + y \leq |x| + |y|$.

But if $x + y > 0$, we have $|x + y| = x + y \leq |x| + |y|$;
whereas if $x + y \leq 0$, we have $|x + y| = -(x + y) \leq |x| + |y|$.

Hence we conclude that $|x + y| \leq |x| + |y|$ always.

Since a field possesses a unit element "1" (its identity when considered as a multiplicative group), 2) implies $|1| = |-1| = 1$ and thus also $|-x| \equiv |x|$; the latter implies (ii) for the metric $d(x, y) = |x - y|$.

Standard notation

$\mathbb{P}$ Set of prime numbers

$\mathbb{N}$ Set of natural numbers

$\mathbb{Z}$ Ring of integers

$\mathbb{Q}$ Field of rational numbers

$\mathbb{R}$ Field of real numbers

Are there any other norms on $\mathbb{Q}$ besides the standard absolute-value one? There is a remarkable theorem by **Ostrowski** *(1921) to the effect that apart from the standard norm, there is but one other nontrivial way to construct a metric (norm) on the field of rational numbers — or, more precisely, one such way per prime number. This norm is called non-Archimedean, and is based on a non-Archimedean absolute value with the properties* 1)–3) *and with the additional requirement that*

4) $|x+y| \leq \max\{|x|,|y|\}$ *for all* x, y.

This condition implies 3), *since* $\max\{|x|,|y|\}$ *is certainly smaller than the sum* $|x|+|y|$.

To understand the new, non-standard, p-adic $\mathbb{Q}$*-norms, we begin with a basic property of all rational numbers: Let* p *be any prime number* $(p = 2, 3, 5, 7, 11, \ldots)$. *Then any rational number* x *can be uniquely represented in the form*

$$x = p^{\nu} \frac{a}{b},$$

where ν *is an integer and* a, b *are integers not divisible by* p, *i.e.* ν *is the highest positive, or lowest negative power of* p *which divides* x. *We denote this number as*

$$\nu = \mathrm{ord}_p x \qquad \text{or} \qquad \nu_p(x) = p\text{-adic } \textit{valuation} \text{ on } \mathbb{Q},$$

and by definition,

$$x = p^{\nu_p(x)} \frac{a}{b}, \qquad p \not| a, b.$$

For example:

$$\begin{array}{rll}
35 = & 5 \cdot 7 \cdot 1 & \nu_5(35) = 1 \\
250 = & 5^3 \cdot 2 & \nu_5(250) = 3 \\
96 = & 2^5 \cdot 3 & \nu_2(96) = 5 \\
97 = & 2^0 \cdot 97 & \nu_2(97) = 0 \\
\frac{20}{3} = & 2^2 \cdot \frac{5}{3} & \nu_2(\frac{20}{3}) = 2 \\
1 = & 2^0 \cdot 1 & \nu_2(1) = 0 \\
0 = & p^{\infty} \cdot 0 \ (p\text{-adically}) & \nu_p(0) = +\infty \ (\text{formally!})
\end{array}$$

$\mathbb{C}$ Field of complex numbers

$\mathbb{R}^n$ n-dimensional Euclidean space

$\mathbb{Q}_p$ Field of p-adic numbers

$\mathbb{Z}_p$ Ring of p-adic integers

The basic properties of the p-adic valuation are readily proven to be:

(1) $\nu_p(xy) = \nu_p(x) + \nu_p(y)$;

(2) $\nu_p(x + y) \geq \min\{\nu_p(x), \nu_p(y)\}$

with the convention $\nu_p(0) = +\infty$. *We note that* ν_p *behaves somewhat like a logarithm would. If we compare the above two properties with the conditions 2) and 4) in the definition of the non-Archimedean norm, we see that they are very similar, except that the product in 2) has been turned into a sum (as when taking a logarithm), and that the inequality in 4) has been reversed. We can "un–reverse" the inequality by changing the sign, and then turn the sum into a product by putting it into an exponent. This suggests the following realization of the non-Archimedean norm (otherwise known as the p-adic norm):*

$$|x|_p = \begin{cases} \frac{1}{p^{\nu_p(x)}}, & \text{if } x \neq 0 \\ 0, & \text{if } x = 0 \end{cases}$$

Examples:

$6 = 3^1 \cdot 2$;	$\nu_3(6) = 1$;	$\lvert 6\rvert_3 = \frac{1}{3^1} = \frac{1}{3}$
$15 = 3^1 \cdot 5$;	$\nu_3(15) = 1$;	$\lvert 15\rvert_3 = \frac{1}{3}$
$137 = 2^0 \cdot 137$;	$\nu_2(137) = 0$;	$\lvert 137\rvert_2 = 1$

Since for $x = \frac{a}{b}$, $\nu_p(x) = \nu_p(a) - \nu_p(b)$, *we have for example:*

$$\frac{1}{4} = \frac{2^0}{2^2}; \qquad \nu_2(\frac{1}{4}) = \nu_2(1) - \nu_2(4) = 0 - 2 = -2$$

$$|\frac{1}{4}|_2 = \frac{1}{2^{-2}} = 4; \qquad |\frac{1}{2^n}|_2 = 2^n.$$

Thus, for a given prime p, two rational numbers are considered to be p-adically close if their difference is divisible by a large power of p.

The p-adic norm possesses the characteristic properties 1) through 4) above. Geometrically, the p-adic norm provides us with a notion of "size": we can use it to measure distances between numbers, i.e. to put a metric on our field. Having the metric, we can define open and closed sets and in general investigate the topology of the field $\mathbb{Q}_p$. *On other hand,* $|\cdot|_p$ *measures the degree of p-divisibility of any rational number; hence the importance of the p-adic norm concept in both number theory and topology. The p-adic metric is non-Archimedean, – meaning an interval cannot be segmented into shorter ones; and this metric also leads to rather strange topological properties of plane figures and 3-dimensional objects, in* $\mathbb{Q}_p$, *such as:*

- *all triangles are isosceles;*
- *any point in a disc is its center;*
- *any two balls are either disjoint or contained one in another (like two drops of mercury!)*

Thus the geometry of the topological space $\mathbb{Q}_p$ (the field obtained by topological completion of $\mathbb{Q}$ under the norm $|\cdot|_p$) is surprisingly unlike the geometry of the field $\mathbb{R}$ (reals) obtained by topological completion of $\mathbb{Q}$ under the standard *norm. That is a consequence of the stricter version* 4) *of the third property of the norm.*

p-ADIC NUMBERS AND ARITHMETIC

Any standard-norm real number x can be expanded in an infinite decimal representation

$$\begin{aligned} x &= \pm 10^{\nu}[x_0 + x_1\tfrac{1}{10} + x_2\tfrac{1}{10^2} + \dots] \\ &= \pm 10^{\nu}\sum_0^{\infty} x_n 10^{-n} \qquad , \qquad x_0 \neq 0, \quad x_j = 0, 1, \dots, 9 \end{aligned}$$

where ν is the highest power of 10 such that $10^{\nu} \leq |x| < 10^{\nu+1}$. In general, an infinite sequence a_n of digits $[0, \dots, p-1]$ (p prime) can represent an element of two distinct additive groups:

- *a real fractional number in the interval $[0, 1]$ expressed to base p*
- *a formal power series* $a_0 + a_1x + a_2x^2 + \dots + a_nx^n + \dots$

The latter polynomial form a ring, in which the two group operations are formal power-series addition and multiplication modulo *p.*

***Hensel** (1908) introduced a* third option *based upon the observations:*

(1) *Any ordinary integer D can be uniquely expressed as a finite sum of powers of a prime p. That is*

$$D = d_0 + d_1p + \dots + d_kp^k$$

in which d_i *is some integer from* 0 *to* $p-1$ *[e.g.* $14 = 2 \cdot 3^0 + 1 \cdot 3^1 + 1 \cdot 3^2$*;* $216 = 2 \cdot 3^3 + 2 \cdot 3^4$*].*

(2) *Any nonzero* rational number x *(not* 0*) can be written in the form*

$$x = p^{\nu} \frac{a}{b}, \qquad p \nmid a, b; \qquad\qquad \nu = \text{ integer}$$

where the integer ν *is the above defined* p*-adic valuation.*

Hensel then generalized from these two observations and introduced the Hensel series, known as p*-adic numbers*

$$x = \sum_{i=-\rho}^{\infty} c_i p^i$$

where ρ *is an integer,* $c_{-\rho} \neq 0$*,* p *is a prime and the coefficients, the* c_i*, are ordinary rational numbers reduced to their lowest form whose denominator and numerator are not divisible by* p*. Such expressions need not in general have values as ordinary rational numbers– nor are they in general real numbers (for the series is as likely as not to* diverge *in the standard norm). However, Hensel's* p*-adic numbers do converge under the* p*-adic norm. We can regard the Hensel series as analogous to the decimal (or other basis) representations of real numbers, and rewrite it as*

$$x = p^{\nu} \sum_{0 \leq n < \infty} x_n p^n$$

where x_n *are integers* $0 \leq x_n \leq p-1$*. If* $x_0 \neq 0$*, then the representation is unique and since the* p*-adic norm of each partial sum is* $p^{-\nu}$ *(again assuming* $x_0 \neq 0$*), we may extend the* p*-adic valuation (2) to all* p*-adic numbers* $x \in \mathbb{Q}_p$ *whether rational or not:*

$$\left| p^{\nu} \sum_{n=0}^{\infty} x_n p^n \right|_p = p^{-\nu}.$$

Hensel's series converges *with respect to the norm* $|x|_p$ *because one has*

$$|p^{\nu} x_n p^n|_p = p^{-\nu-n}, \quad n = 0, 1, \ldots$$

The above p*-adic number representation means that any* p*-adic number – i.e. any* x *in* $\mathbb{Q}_p$ *– is a limit (w.r.t. the* p*-adic norm) of a sequence* $\{x^{(n)}, n \to \infty\}$ *of rational numbers*

$$x^{(n)} = p^{\nu}(x_0 + x_1 p + \cdots + x_n p^n).$$

According to this scheme, any rational number, including negative numbers, can be represented in the p-adic form. For example: (subscript indicate the prime p used)

$$
\begin{aligned}
-1 \quad &= (p-1)+(p-1)p+(p-1)p^2+\dots \\
\left(\tfrac{1}{2}\right)_7 \quad &= \tfrac{8-7}{2} = 4-\tfrac{1}{2}\cdot 7 = 4+\tfrac{7\cdot 3}{1-7} \\
&= 4+3(7+7^2+\dots) = 4+3\cdot 7+3\cdot 7^2+\dots \\
\left(\tfrac{1}{24}\right)_3 \quad &= \tfrac{2}{3}+\tfrac{2+3}{1-9} = 2\cdot\tfrac{1}{3}+(2+3)[1+3^2+3^4+\dots] \\
&= 2\cdot\tfrac{1}{3}+2+3+2\cdot 3^2+3^3+\dots \\
(-5)_3 \quad &= 4-9 = 4+\tfrac{18}{1-3} = 4+2\cdot 3^2+2\cdot 3^3+\dots \\
\left(\tfrac{24}{17}\right)_3 \quad &= \tfrac{2\cdot 3+2\cdot 3^2}{2+2\cdot 3+3^2} = 3+3^3+2\cdot 3^5+3^7+3^8+2\cdot 3^9 \\
\left(-\tfrac{1}{2}\right)_3 \quad &= \tfrac{1}{1-3} = 1+3+3^2+3^3+\dots
\end{aligned}
$$

This last example can also be derived thus[62]*:*

[62] Another example serves to show that sometimes p-adics allow a more conceptual proof of a fact that seems obscure and hard to prove otherwise. Consider the usual Taylor series $\ln(1+x) = x-\frac{x^2}{2}+\frac{x^3}{3}-\frac{x^4}{4}+\dots$. Working in the field $\mathbb{Q}_2$ of 2-adic numbers, we know that powers of 2 are "small". We then put $x=-2$ to compute the natural logarithm of -1: $\ln(-1) = \ln(1-2) = -(2+\frac{2^2}{2}+\frac{2^3}{3}+\frac{2^4}{4}+\dots)$. This is of course divergent in $\mathbb{R}$, but it turns out to be convergent in $\mathbb{Q}_2$. Now, if the series converges, it must converge to zero, by the property of the logarithm:

$$2\ln(-1) = \ln(-1)^2 = \ln(1) = 0$$

This last does not hold in $\mathbb{R}$, because $ln(-1)$ (like $\sqrt{-1}$) is not in $\mathbb{R}$ but rather in $\mathbb{C}$, and is multi-valued. But under $|\cdot|_2$, $ln(-1)$ *is* in $\mathbb{Q}_p$ and is unique – and in fact it vanishes ($\sqrt{-1}$ does not exist in $\mathbb{Q}_p$, though).

We conclude that the partial sums

$$2+\frac{2^2}{2}+\frac{2^3}{3}+\frac{2^4}{4}+\dots+\frac{2^n}{n}$$

must tend (2-adically) to zero as n grows. What this means is that the terms in the 2-adic expansion "disappear to the right", – that is to say: the partial

Consider the equation $X = 1 + 3X$. This is of course easy to solve, but let us look at it as a fixed-point problem, i.e., as the problem of finding a solution for $f(x) = x$ for some function $f(x)$. Such problems are often solved by iteration, plugging in an arbitrary initial value, then computing $f(x)$ repeatedly in the hope of converging to a fixed point. To try that in our case, we take $x_0 = 1$ and iterate, so that $x_{n+1} = 1 + 3x_n$. We get:

$$\begin{aligned} x_0 &= 1 \\ x_1 &= 1 + 3x_0 = 1 + 3 \\ x_2 &= 1 + 3x_1 = 1 + 3 + 3^2 \\ &\dots \\ x_n &= 1 + 3 + 3^2 + ... + 3^n. \end{aligned}$$

The sum of the p-adic numbers

$$x = p^{\nu(x)}(x_0 + x_1 p + x_2 p^2 + \dots), \qquad 0 \le x_j \le p - 1, \qquad x_0 > 0$$

and

$$y = p^{\nu(y)}(y_0 + y_1 p + y_2 p^2 + \dots), \qquad 0 \le y_j \le p - 1, \qquad y_0 > 0$$

is again represented in the canonical form

$$x+y = p^{\nu(x+y)}(c_0+c_1 p+c_2 p^2+\dots), \qquad 0 \le c_j \le p-1, \qquad c_0 > 0,$$

where the numbers $\nu(x + y)$ and c_j are uniquely determined from the equation

$$p^{\nu(x)}[x_0 + x_1 p + \dots] + p^{\nu(y)}[y_0 + y_1 p + \dots] = p^{\nu(x+y)}[c_0 + c_1 p + \dots]$$

by the method of indefinite coefficients modulo p.

Thus, addition, subtraction, multiplication and division of p-adic numbers is carried out as for power series. In practice, the mechanics of these operations

---

sums, written in base 2, begin with longer and longer stretches of zeros. The translation of this into $\mathbb{R}$ results in the theorem:

For each integer $M > 0$ there exists an n such that the partial sum

$$2 + \frac{2^2}{2} + \frac{2^3}{3} + \frac{2^4}{4} + \dots + \frac{2^n}{n}$$

is divisible by 2^M.

What this example points to is that using p-adic methods, and in particular the methods of the calculus in the p-adic context, we can often prove facts about divisibility by powers of p which are otherwise quite hard to understand.

is therefore very much like the corresponding operations on decimals – with the exception that "carrying", "borrowing", "long multiplication", etc. go from left to right rather than from right to left. For example:

$$
\begin{array}{rrrl}
 & 3+ & 6\cdot 7+ & 2\cdot 7^2+\dots \\
\times & 4+ & 5\cdot 7+ & 1\cdot 7^2+\dots \\
\hline
 & 5+ & 4\cdot 7+ & 4\cdot 7^2+\dots \\
 & & 1\cdot 7+ & 4\cdot 7^2+\dots \\
 & & & 3\cdot 7^2+\dots \\
\hline
 & 5+ & 5\cdot 7+ & 4\cdot 7^2+\dots
\end{array}
$$

$$\frac{1+2\cdot 7+4\cdot 7^2+\dots}{3+5\cdot 7+1\cdot 7^2+\dots} = 5+1\cdot 7+6\cdot 7^2+\dots$$

Thus, in contradistinction to operations with power series *(no carrying) and* real numbers *(carrying proceeds leftward), carrying is done to the* right. *This fact explains why small perturbations can change every digit in the real case but not in power series and not in Hensel series – where one cannot disturb digits lying before those that are changed.*

Extracting roots *in p-adic arithmetic is interesting: Let us try to extract* $\sqrt{6}$ *in* $\mathbb{Q}_5$*, i.e. we want to find* $\{a_0, a_1, a_2, \dots\}, \quad 0 \le a_i \le 4$ *such that*

$$a^2 = [a_0 + a_1\cdot 5 + a_2\cdot 5^2 + \dots]^2 = 1 + 1\cdot 5.$$

Comparing coefficients of $1 = 5^0$ *on both sides gives* $a_0^2 \equiv 1 \pmod 5$*, which admits the two solutions* $a_0 = 1, 4$*. Let's select* $a_0 = 1$*. Then, comparing coefficients of 5 on both sides gives* $2a_1 \times 5 \equiv 1 \times 5 \pmod{5^2}$*, so that* $2a_1 \equiv 1 \pmod 5$*, and hence* $a_1 = 3$*. At the next step we have:*

$$1 + 1\cdot 5 \equiv (1 + 3\cdot 5 + a_2\cdot 5^2)^2 = 1 + 1\cdot 5 + 2a_2\cdot 5^2 \pmod{5^3}.$$

Hence $2a_2 \equiv 0 \pmod 5$*, and* $a_2 = 0$*. Proceeding in this way, we obtain a series*

$$a = 1 + 3\cdot 5 + 0\cdot 5^2 + 4\cdot 5^3 + a_4\cdot 5^4 + a_5\cdot 5^5 + \dots$$

where each a_i *after* a_0 *is uniquely determined. If we had chosen 4 instead of 1 for* a_0 *we would have obtained*

$$a = 4 + 1\cdot 5 + 4\cdot 5^2 + 0\cdot 5^3 + (4 - a_4)5^4 + (4 - a_5)5^5 + \dots$$

The fact that we had two choices for a_0*, and then, once we chose* a_0*, only a single possibility for* a_1*,* a_2*,* $a_3, \dots$*, merely reflects the fact that a nonzero element in any field – such as* $\mathbb{Q}$ *or* $\mathbb{R}$ *or* $\mathbb{Q}_p$ *– always has exactly two square roots in the field if it has any.*

Do all numbers in $\mathbb{Q}_5$ have square roots? We saw that 6 does; what about 7? If we had

$$(a_0 + a_1 \times 5 + \dots)^2 = 7 = 2 + 1 \cdot 5,$$

it would follow that $a_0^2 \equiv 2 \pmod 5$. But this is impossible, as we see by checking the possible values $a_0 = 0, 1, 2, 3, 4$. Thus $(\sqrt{7})_5$ does not exist (as $\sqrt{-1}$ does not exist in $\mathbb{R}$!).

The method, displayed above, of solving the equation $x^2 - 6 = 0$ in $\mathbb{Q}_5$ — by solving the congruence $a_0^2 - 6 \equiv 0 \pmod 5$ and then solving for the remaining a_i in a step-by-step algorithm — is actually quite general[63].

The next table lists some 2-adic square and cube roots that exist in $\mathbb{Q}_p$ out to 32 bits, expressed as decimals (base 10) integers.

Note that the $\mathbb{Q}_2$ square root of (-7), for instance, has nothing to do with the square root of (-7) that lives in $\mathbb{C}$, namely $0 + i2.645\ 751\ 311\ 06\dots$. Thus $\mathbb{R}$, $\mathbb{C}$ and $\mathbb{Q}_p$ are distinct topological spaces that all happen to be fields and all happen to contain $\mathbb{Q}$ (the field of rationals) as a subset. But the question remains — can one adjoin to $\mathbb{Q}_p$ roots that do not exist within it, in the same way that one adjoins $\sqrt{-1}$ to the real numbers?

In the standard norm one can adjoin a single root *of $x^2 + 1 = 0$ to the field $\mathbb{R}$ and get an entity that is both* algebraically closed *(i.e. has all roots of all polynomials with coefficients in that field) and* topologically complete *(i.e. all sequences that ought to converge – i.e. are* Cauchy sequences *– do indeed converge). For the p-adics, on the other hand, one has to adjoin an infinite number of roots and then take* another topological completion *to fill the gaps. But the resulting space is, again algebraically incomplete! The procedure can be iterated, but never actually terminates.*

---

63 *Hensel's lemma* (also known as the p-adic Newton's method of finding a real root of a polynomial):
Let $F(x) = c_0 + c_1x + \dots + c_nx^n$ be a polynomial whose coefficients are p-adic integers (that is, elements $x \in \mathbb{Q}_p$ such that $|x|_p \leq 1$, so that x is the p-adic-norm of a sequence of integers $x_n = \sum_{k=0}^{n} a_k p^k$, with a_k integers and $0 \leq a_k \leq p-1$. Any ordinary integer is also a p-adic integer). Let $F'(x) = c_1 + 2c_2x + 3c_3x^2 + \dots + nc_nx^{n-1}$ be the derivative of $F(x)$. Let a_0 be an integer $0 \leq a_0 \leq p-1$ such that $F(a_0) \equiv 0 \pmod p$ and $F'(a_0) \not\equiv 0 \pmod p$. Then there exists a unique p-adic integer a such that

$$F(a) = 0 \quad \text{and} \quad a \equiv a_0 \pmod p.$$

Conversely, if a_0 does *not* exist neither does a.
In the special case treated above, we had
$p = 5, \quad F(x) = x^2 - 6 \quad F'(x) = 2x, \quad a_0 = 1.$
The ring (not field!) of p-adic integers, is denoted $\mathbb{Z}_p$.

In general, the p-adic expansion of a in $\mathbb{Q}_p$ terminates (i.e. $a_i = 0$ for all i greater than some N) iff a is a positive rational number whose reduced–form denominator is a power p. Also, the p-adic expansion of a in $\mathbb{Q}_p$ has repeating digits from some point on iff a is rational.

Hensel defined the four basic arithmetical operations with the p-adic numbers in $\mathbb{Q}_p$ and showed that it is a field. A subset of the p-adic numbers can be put into one-to-one correspondence with the ordinary rational numbers, and in fact this subset is isomorphic to the rational numbers in the full sense of an isomorphism between two fields. In the field of p-adic numbers, Hensel defined units, integral p-adic numbers, and other notions analogous to those of the ordinary rational numbers.

By introducing polynomials whose coefficients are p-adic numbers, Hensel was able to speak of p-adic roots of polynomial equations and extend to these roots all of the concepts of algebraic number fields. Thus there are p-adic integral algebraic numbers and more general p-adic algebraic numbers, and one can form fields of p-adic algebraic numbers that are extensions of the "rational" p-adic numbers. In fact, all of the ordinary theory of algebraic numbers is carried over to p-adic numbers. Surprisingly perhaps, the theory of p-adic algebraic numbers leads to results on ordinary algebraic numbers. It has also been useful in treating quadratic forms and has led to the notion of valuation fields.

The p-adic numbers can be regarded as a completion of the rational numbers in a different way than the usual completion which leads to the real numbers. Over the last century the p-adic universe became the meeting point of algebra and analysis; p-adic numbers and p-adic analysis have come to play a central role in modern number theory. This importance results from the fact that they afford a natural and powerful language for talking about congruences between integers.

More recently, p-adic numbers have turned up in other areas of modern mathematics (algebraic geometry, representation theory) and even in physics. There is a natural scale–hierarchical and fractal-like structure in the field of p-adic numbers; and the complications of the interplay between algebraic and topological completions, and between discreteness and continuum, for those found in standard real and complex analysis.

Therefore p-adic analysis and non-Archimedean geometry might find a use the description of quantum–gravity spacetime geometry at small distances (of order of the Planck scale); indeed, there have been attempts to apply p-adics to string theories. They have also been applied to study the behavior of complicated systems such as spin-glasses, as well as chaos, in the framework of traditional theoretical and mathematical physics.

1899–1929 CE **Edmund (Georg Hermann) Landau** (1877–1938, Germany). A leading pure[64] mathematician of his time. Was educated in Berlin and was appointed professor of mathematics at Göttingen (1909–1933), following the death of Minkowski.

Apart from important work on Lambert and Dirichlet series[65] (1899–1906) and the theory of functions, his main interest was in analytic number theory, especially the distribution of prime numbers and prime ideals. In his books: "*Handbuch der Lehre von der Verteilung der Primzahlen*"[66] (1909) and "*Vorlesungen über die Zahlentheorie*" (1927), he presented for the first time a

---

64 Landau had an absolute contempt for applied mathematics.

65 Landau showed that the function

$$\xi(s) = \left(\frac{4}{\pi}\right)^{\frac{1+s}{2}} \Gamma\left(\frac{s+1}{2}\right) L(s)$$

where

$$L(s) = \frac{1}{1^s} - \frac{1}{3^s} + \frac{1}{5^s} - \cdots = \sum_{n=0}^{\infty} (-)^n \frac{1}{(2n+1)^s}$$

obeys the functional equation $\xi(s) = \xi(1-s)$. The proof hinges on the relations

$$L(1-s) = \left(\frac{2}{\pi}\right)^{s} \Gamma(s) \sin\left(\frac{\pi s}{2}\right) L(s)$$

$$\Gamma\left(\frac{s}{2}\right) \Gamma\left(1-\frac{s}{2}\right) \sin\left(\frac{\pi s}{2}\right) = \pi$$

$$\sqrt{\pi}\Gamma(s) = 2^{s-1}\Gamma\left(\frac{s}{2}\right) \Gamma\left(\frac{1+s}{2}\right)$$

66 In 1909 Landau introduced the $\{o, O\}$ notation: the notation $f(x) = O\{g(x)\}$ as $x \to \infty$ means that there is a constant K and a value x_0 of x such that $|f(x)| < Kg(x)$ whenever $x \geq x_0$, i.e. the modulus of f *grows no faster* than a constant times g as $x \to \infty$.
The notation $f(x) = o\{g(x)\}$ as $x \to \infty$, means that for every $\epsilon > 0$ there is a value x_0 of x such that $|f(x)| < \epsilon g(x)$ whenever $x \geq x_0$. In words: the modulus of f *grows more slowly* than g as $x \to \infty$.
There are various obvious extensions of this notation, such as $f(x) = O\{g(x)\}$ as $x \to 0$, which means that there exist K, x_0 such that $|f(x)| < Kg(x)$ whenever $|x| < x_0$, or $f(x) = F(x) + O\{g(x)\}$ as $x \to \infty$, which means $f(x) - F(x) = O\{g(x)\}$ as $x \to \infty$, etc. Thus the function $2x + 3x^2$ is $O(x)$ when $x \to 0$, but $O(x^2)$ when $x \to \infty$. If x is an infinitesimal quantity, then $x^2 = o(x)$, $1 - \cos x = o(x)$. If x is an infinitely large quantity, then $x = o(x^2)$.

systematic account of the analytic number theory. These books stimulated further research in the field.

During the 1920's he was the center of a fantastic flowering in the analytic theory of numbers. In lectures, as in books, his ideal was absolute rigor and completeness. The assistant was instructed to interrupt if the professor omitted anything at all. Standing before the big blackboards in the lecture halls of the new building, Landau wrote rapidly — theorem, proof, theorem, proof — while a menial with a sponge hastened after him to erase what he had written so that there would be room for him to write more. He never gave any explanation of where he was going, but he had organized his material so well that there was a quality of incredible clarity about his lectures.

Landau was a full member in most European academies. From 1927 to 1928 he was a visiting professor at the Hebrew University in Jerusalem. It was hoped that he would head the Institute of Mathematics there, but he declined and returned to Göttingen, only to be forced to resign his chair by the Nazi regime in 1933.

Landau continued to lecture, but when he announced a course in calculus, an unruly mob prevented his entering the lecture hall. Hardy arranged for him to deliver a series of lectures in England, but he returned to Germany, being tied to his native land by the fact of his wealth and possessions. He died heartbroken in 1938.

Landau was married to Maria Ehrlich, daughter of **Paul Ehrlich** (1854–1915) [discovered the "magic bullet" treatment for syphilis]. His father Leopold (1848–1920) was a known professor of gynecology at the University of Berlin, and a descendant of the famous Talmudic scholar **Ezekiel Landau** (1713–1793).

Does a Cicada 'Know' that 17 is a Fermat-Prime?

History shows us that mathematics has, to a great extent, been developed by pure mathematicians who were under the spell of the beauty of it; who were entranced by its mysterious generality and who spent their lives discovering new facts and relations in this very wide and wondrous domain. Whether *their results could be applied to astronomy, physics, chemistry, biology or technology was not, as a rule, their primary concern.*

However, the state of the art of the Natural sciences has today reached a stage where ideas, methods and results, belonging even to such an arcane branch of mathematics as advanced Number Theory can be applied with great success. The following examples are instructive:

- *In X-ray crystallography of cubic crystals it had been noted that certain reflections are absent. These correspond to the integers* $n = 7, 15, 23, 28, \ldots$, *all of the form*

$$n = 4^k(8m+7) \qquad\qquad k, m = \text{ positive integers.}$$

Number theory tells us that these are numbers which cannot be represented as the sum of three or less squares. Clearly, this fact is closely related to the 3 dimensions of our Euclidean space.

- *The theory of potentials inside a crystal lattice (e.g., the well-known Madelung constant) can best be derived with the aid of the Jacobi elliptic theta-functions which at the same time form the basis of the analytical derivation in Number Theory of the representation of an integer as a sum of squares.*

- *Several aspects of Planck's radiation formula and of the Bose-Einstein and Fermi statistics are closely related to Riemann's zeta-function* $\zeta(s)$ *defined by*

$$\zeta(s) = \frac{1}{1^s} + \frac{1}{2^s} + \frac{1}{3^s} + \cdots = \frac{1}{\Gamma(s)}\int_0^\infty \frac{x^{s-1}}{e^x - 1}\,dx \qquad (\text{Re } s > 1)$$

and which is at the base of practically all arithmetical investigations on the distribution of the prime numbers[67].

- *The partition function* $p(n)$ *enumerates the number of ways in which the integer* n *can be written as a sum of any positive integers, repetition being allowed. It is defined by the generating function*

$$\prod_{k=1}^{\infty} \frac{1}{1-x^k} = 1 + \sum p(n)x^n \qquad (|x| > 1)$$

e.g.

$$\begin{aligned} 6 \quad &= 5+1 = 4+2 = 4+1+1 = 3+3 = 3+2+1 \\ &= 3+1+1+1 = 2+2+2 = 2+2+1+1 \\ &= 2+1+1+1+1 = 1+1+1+1+1+1, \end{aligned}$$

and therefore $p(6) = 11$.

---

67 During WWII, even purely mathematical researches on the properties of the ζ-function were classified

Application of this partition function and its asymptotic behavior are now being made in different parts of physics, such as the theory of crystal growth.

- *Kelvin's expression for the capacitance* $C_{a,b}$ *of two mutually external spheres of radii* a *and* b *respectively, with their centers a distance* c *apart, can be written in the form*

$$C_{a,b} = \frac{EI}{c}\sum_{n=1}^{\infty}\left\{d(n) - d\left(\frac{n}{2}\right)\right\}\alpha^n, \qquad \alpha = \frac{E-I}{E+I}$$

where E *and* I *are the length of the external and internal tangents, respectively, to the circles obtained by cutting the spheres with a plane through their centers. The symbol* $d(n)$ *stands for the number of divisors of* n *[e.g.* $d(6) = 4$ *since the four divisors are* 1, 2, 3, 6*]. Here* $d\left(\frac{n}{2}\right) = 0$ *for any odd* n*.*

- *The "sawtooth" function* $\mathrm{Sa}(x) = [x] - x + \frac{1}{2}$ *where* $[x]$ *is the "staircase" function, equal to the integer part of* x *(i.e.* $[x] = n$ *for* $n \le x < n+1$*). This function of time is used in any television transmitter and receiver in order to scan periodically the lines and frames of the picture. As it turns out,* $\mathrm{Sa}(x)$*, used so extensively in Radio technology, is a most fundamental function in Number Theory. Some of the properties of* $\mathrm{Sa}(x)$ *are:*

(*i*) $$\frac{1}{s}\zeta(s) = \int_0^{\infty}\frac{\mathrm{Sa}(u)}{u^{s+1}}\,du \qquad -1 < \mathrm{Re}\ s < 0$$

(*ii*) $$\mathrm{Sa}(x) = \sum_{k=1}^{\infty}\frac{\sin 2\pi kx}{\pi k}$$

(*iii*) $$\sum_{k=1}^{n}\mathrm{Sa}(x - \frac{k}{n}) = \mathrm{Sa}(nx)$$

This means that a superposition of n *sawtooth functions, each one shifted over a phase difference of* $\frac{1}{n}$ *w.r.t. the preceding one, yields a further sawtooth function, but of* n *times the frequency.*

(*iv*) $$\mathrm{Sa}(x) - \mathrm{Sa}(x - \frac{1}{2}) = \frac{1}{2}\,\mathsf{S}in(2\pi x),$$

where S*in represents the 'square-sine' function which jumps from* -1 *to* $+1$ *at* $x = \ldots, -1, 0, 1, 2, 3, \ldots$ *and from* $+1$ *to* -1 *at* $x = \ldots, -\frac{1}{2}, \frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \ldots$ *whereas* *it stays constant at 1 or −1 in the intervals between the jumps. It can be also written in the forms*

$$\mathfrak{S}in(2\pi x) = \frac{\sin 2\pi x}{|\sin 2\pi x|} = (-1)^{[2x]}$$
$$= 4\mathrm{Sa}(x) - 2\mathrm{Sa}(2x)$$

It can be shown that Sa(x) *can be expanded in a series of square-sine functions of frequency* 2^n

$$(v) \qquad \mathrm{Sa}(x) = \sum_{n=1}^{\infty} \frac{1}{2^{n+1}} \mathfrak{S}in(2^{n-1} \cdot 2\pi x) = \sum_{n=1}^{\infty} \frac{1}{2^{n+1}} (-1)^{[2^n x]}$$

In contradistinction to the Fourier synthesis, the square-sine synthesis has the clear advantage that the so-called Gibbs' phenomenon is absent here! (no 'overshoot' at the discontinuities).

$$(vi) \qquad \begin{aligned} \mathrm{Sa}(\mathrm{Sa}(x)) &= -\mathrm{Sa}(x + \tfrac{1}{2}) \\ \mathrm{Sa}(\mathrm{Sa}(\mathrm{Sa}(x))) &= \mathrm{Sa}(x) \end{aligned}$$

Thus, any odd number of iteration always reproduces the original function. ***Edmund Landau*** *(1927) discovered the relation*

$$(vii) \qquad \int_0^1 \mathrm{Sa}(mx) \cdot \mathrm{Sa}(nx)\, dx = \frac{1}{12} \frac{(m,n)}{\{m,n\}}$$

In this beautiful 'orthogonality relation',

$$\begin{aligned} m, n &= \text{ positive integers} \\ (m,n) &= \text{ highest common divisor of } m, n \\ \{m,n\} &= \text{ least common multiple of } m, n \end{aligned}$$

The Sa(x) *function is connected to the first Bernoullian polynomial* $B_1(x) = x - \frac{1}{2}$ *when the latter is extended periodically outside the range* $0 < x \leq 1$*, namely*

$$(viii) \qquad \mathrm{Sa}(x) = -B_1(x - [x]).$$

The Landau 'orthogonality relation' can then be extended in the form

$$(ix) \qquad \begin{aligned} &\textstyle\int_0^1 B_k(mx - [mx]) \cdot B_k(nx - [nx])\, dx \\ &\qquad = (-)^{k+1} \tfrac{(k!)^2}{(2k)!} B_{2k}(0) \left(\tfrac{(m,n)}{\{m,n\}}\right)^k . \end{aligned}$$

These examples suffice to show that the theory of integers, properly combined with modern analysis, can link the beautiful and the applicable, and thus provide unexpected answers to real-world problems.

Number theory has been considered since time immemorial to be the very paradigm of pure (and useless) mathematics. This attitude is reflected in the name integers *— meaning the 'untouched ones'. Yet the role of integer ratios in musical scales had been widely appreciated ever since Pythagoras first pointed out their importance.*

*The occurrence of integers in biology — from plant morphology (e.g. Fibonacci Numbers) to the genetic code — is pervasive. It has been hypothesized (**Robert M. May**, 1979) that the North American* 17*-year cicada selected its life-cycle because* 17 *is a prime number, prime cycles offering better protection from predators than nonprime cycles. The suggestion that the* 17*-year cicada 'knows' that* 17 *is a **Fermat** prime has yet to be touted though.*

1900 CE, Sept. 08 A *hurricane* killed about 8000 persons in the Galveston, Texas, area. It was the worst natural disaster in United States history. The strength of the storm, coupled with the lack of adequate warning, caught the population by surprise[68].

1900 CE **Ivar Erik Fredholm** (1866–1927, Sweden). Mathematician. Among the founders of modern integral-equation theory.

He was educated at the universities of Uppsala (1886) and Stockholm (1888–1893) and became interested mainly in mathematical physics. In 1898 he received his Ph.D. from Uppsala, and turned to integral equations. He worked as an actuary until 1906, when he was appointed professor of theoretical physics at the University of Stockholm. In 1900 he developed the essential part of what is now known as the theory of Fredholm integral equations. This theory inspired the later investigations of **Hilbert**.

Previously, integral equations had received the attention of **N.H. Abel**, **J. Liouville** and **Eugène Rouché** (1832–1910) of Paris, but were quite neglected. In 1823, Abel had proposed a generalization of the *tautochrone*

[68] Since the successful launching of TIROS (Television and Infra-Red Observation Satellite) in April 1960, which inaugurated the era of weather observation by satellites, meteorologists have been able to identify and track tropical storms even before they become hurricanes.

problem, the solution of which involved an integral equation that has since been designated as being of the first kind. Liouville (1837), showed that a particular solution of a linear differential equation of the second order could be found by solving an integral equation, now designated as of the second kind. A method of solving integral equations of the second kind was given by **C.G. Neumann** (1877). Fredholm studied integral equations from the point of view of an immediate generalization of a system of linear algebraic equations.

1900 CE Yerkes Astronomical Observatory (established 1895) in Williams Bay, Wisconsin, U.S.A., was equipped with a 40-inch refractor telescope.

1900 CE **David Hilbert**[69] (1862–1943, Germany). The man who set the course for 20^{th} century mathematics. A professor of mathematics at Göttingen during 1895–1930.

His mathematical interests were wide ranging: algebraic invariant theory (until 1892); algebraic number theory (1892–1899); foundations of geometry (1898–1903); calculus of variations and the Dirichlet principle (1899–1905); integral equations (1901–1912); mathematical foundations of physics (1912–1917); logic (1917–1943); foundations of mathematics (1934–1935, with Paul Bernays[70]). Hilbert developed the theory of integral equations into a tool which enabled scientists to make breakthroughs in regions once muddy with confusion. At the International Congress of Mathematics in 1900 Hilbert presented his famous list of 23 difficult but inspiring problems, to which he believed mathematicians should address themselves. Several of these, including the Riemann conjecture, remain unsolved to this day.

Hilbert was born in Whelau, near Königsberg, East Prussia, into a Protestant family. Their Biblical names seem to indicate that they were Pietists, members of a fundamentalist sect which emphasized faith and an attitude of the heart. His father was a country judge. His mother Therese was an unusual woman — interested in philosophy and astronomy, and fascinated by prime numbers.

- Reid, C., *Hilbert*, Springer-Verlag: New York, 1970, 290 pp.
- Gustafson, K.E., *Introduction to PDE and Hilbert Space Methods*, Dover, 1999, 448 pp.

[70] **Paul Isaac Bernays** (1888–1977). Mathematician and philosopher. Of illustrious rabbinic ancestry. Collaborated with **Hilbert** in his research on the foundations of mathematics. Contributed to Axiomatic Set Theory and symbolic logic. Professor of mathematics at Göttingen and Zürich.

Hilbert grew up in Königsberg, the city of Immanuel Kant and of the famous seven great bridges through which this city entered the history of mathematics[71] [they had provided the problem, solved a century before by Euler, which lies at the foundation of the field now known as '*topology*'].

In 1880 Hilbert entered the University of Königsberg where he studied under **Heinrich Weber** (1804–1891) and **Adolf Hurwitz** (1859–1919) and met fellow-student **Hermann Minkowski** (1864–1909). In 1885 he received his Ph.D. and went to Paris, where he met the French mathematicians **Poincaré**, **Darboux**, **Picard** and **Gordan**. He then returned to his native town and stayed at the university, where he was appointed ordinary professor of mathematics in 1895. In the same year he accepted a professorship in mathematics at the University of Göttingen, where he remained for the rest of his life.

The University of Göttingen had a flourishing tradition in mathematics and physics which persisted over 150 years of uninterrupted greatness. It is associated with the names of: **Gauss**, **Weber**, **Dirichlet**, **Riemann**, **F. Klein**, **Hurwitz**, **Hilbert**, **Minkowski**, **Nernst**, **Landau**, **Noether**, **Born**, **Debye**, **Weyl**, **Courant**[72], **Heisenberg**, **Franck**, **Runge**, **Carathéodory**, **Voigt**, **Prandtl**, **Wiechert**, **Schwarzschild**, **Zermelo**, **Landé**, **von Neumann**, **Wiener**, **Jordan**, **Pauli**, **Wigner**, **Birkhoff**, **von Laue**, **von Kármán**, **Siegel**, **Veblen** and many others.

The last decade of Hilbert's life was darkened by the tragedy brought upon himself, Göttingen and many of his students and colleagues by the Nazi regime. In 1935, Hilbert's antecedents were examined. There was a joke that there was only one Aryan mathematician in Göttingen and in his veins Jewish blood was flowing. The joke was based upon the fact that during Hilbert's illness, he had received a blood transfusion from Courant. Now the question was seriously raised if it was not suspicious for an Aryan mathematician to have the name David. It finally became necessary for Hilbert to produce the autobiography of his great grandfather Christian David Hilbert to show that David was a family name.

---

[71] There was at that time a rare concentration of youthful scientific talent in Königsberg: at one point, **Wilhelm Wien**, **Arnold Sommerfeld** and **Hermann Minkowski** were all simultaneously in attendance at the Altstadt Gymnasium (1882–1884). David Hilbert attended another school and did not have the opportunity to become acquainted with any of these boys during his school days.

[72] For further reading, see:
Courant, R. and D. Hilbert, *Methods of Mathematical Physics*, Interscience Publishers, 1953, Vols I-II.

Hilbert died of complications arising from the physical inactivity that resulted from an accident. Not more than a dozen people attended the morning funeral service in the living room of the house on Wilhelm Weber Strasse in Göttingen. Arnold Sommerfeld spoke of Hilbert's work.

At the time of his death, there was scarcely a mathematician in the world whose work did not derive in some way from that of Hilbert. There are *Hilbert spaces*, *Hilbert inequality*, *Hilbert transform*[73], *Hilbert invariant integral*, *Hilbert irreducibility theorem*, *Hilbert base theorem*, *Hilbert axiom*, *Hilbert subgroups*, *Hilbert class-field*.

A *Hilbert space* (H) is a linear vector space of infinite dimensionality. By a vector $\boldsymbol{x}$ in such an infinite-dimensional space, we mean an infinite sequence of complex numbers $\boldsymbol{x} = (x_1, x_2, \ldots)$, where we always assume that these numbers obey the condition that the series $\sum_1^\infty |x_k|^2$ converges.

The basic operations on vectors are defined for the vectors of H in just the same way as for ordinary vectors, since the convergence of the above sum guarantees the meaningfulness of the sum of vectors and their product by a finite scalar, as well as of the *scalar product*

$$(\boldsymbol{x}, \boldsymbol{y}) = \sum_{k=1}^{\infty} x_k \bar{y}_k$$

of two vectors in H (the bar denoting complex conjugate).

[73] The *infinite Hilbert transform* of a function $f(x)$ is defined as

$$g(u) = \frac{1}{\pi} P \int_{-\infty}^{\infty} \frac{f(x)dx}{x-u}.$$

When viewed as an integral equation for the unknown $f(x)$ in terms of the known $g(x)$, it has the explicit solution: $f(x) = \frac{1}{\pi} P \int_{-\infty}^{\infty} \frac{g(u)du}{x-u}$. The transform is thus its own inverse.

The *finite Hilbert transform* is defined as $g(u) = \frac{1}{\pi} P \int_{-1}^{+1} \frac{f(x)dx}{x-u}$, $-1 \leq u \leq 1$. Its solution (inverse) takes the form $f(x) = \frac{1}{\sqrt{1-x^2}} \left\{ C + \frac{1}{\pi} P \int_{-1}^{+1} \sqrt{1-u^2} \frac{g(u)du}{u-x} \right\}$, where $-1 < x < 1$, and C is an arbitrary constant. Note that $\frac{C}{\sqrt{1-x^2}}$ is a solution of the homogeneous equation $\frac{1}{\pi} P \int_{-1}^{1} \frac{f(x)dx}{x-u} = 0$.

Finite Hilbert transforms are encountered in the *theory of dislocations* and in the aerodynamic theory of a thin airfoil. In this context it is known as the *airfoil equation* (**Prandtl**, 1918).

The sum

$$(\boldsymbol{x},\boldsymbol{x}) = \sum_{k=1}^{\infty} |x_k|^2 \equiv \|\boldsymbol{x}\|^2 \geq 0$$

defines the square of the *norm* (*length*) of the vector $\boldsymbol{x}$. The scalar product obeys the same basic rules as in finite dimensional spaces. In particular, the inequality

$$|(\boldsymbol{x},\boldsymbol{y})| \leq \|\boldsymbol{x}\|\|\boldsymbol{y}\|$$

holds, and so does the triangle inequality

$$\|\boldsymbol{x}+\boldsymbol{y}\| \leq \|\boldsymbol{x}\| + \|\boldsymbol{y}\|.$$

Also, the square of the norm of a sum of orthogonal vectors equals the sum of the squares of the norms of the summands (*Pythagorean theorem*).

The fundamental *basis vectors* in the Hilbert space H described above are the unit orthogonal (orthonormal) vectors $\boldsymbol{a}^{(1)} = (1,0,0,\ldots)$, $\boldsymbol{a}^2 = (0,1,0,\ldots)$, etc. The *components* x_k of a vector $\boldsymbol{x}$ can be expressed as the scalar products $x_k = (\boldsymbol{x},\boldsymbol{a}^{(k)})$. Another Hilbert space, denoted by F, is the *function space*, where continuously varying functions of one or several variables play the role of vectors.

Let $f(x)$ be a function defined on the interval $a \leq x \leq b$. We can regard $f(x)$ as a vector, where the value of $f(x_0)$ is associated with the point x_0 in the interval and gives the "component of $f(x)$ with index x_0".

Thus in this case the independent variable x, which varies continuously through all values in the interval, plays the role of an index for the components, i.e., $f(x)$ has a continuous set of components. In general H is complex: $f(x) = f_1(x) + if_2(x)$, with $f_1(x)$, $f_2(x)$ real functions defined on the finite interval $a \leq x \leq b$ of the real axis.

To define the norm and the scalar product in F, we need only replace summation by integration everywhere in the previous formulas. We define the *scalar product* by

$$\{\varphi(x),\psi(x)\} = \int_a^b \varphi(x)\overline{\psi(x)}dx$$

and the square of the *norm* by

$$\|f(x)\|^2 = \{f(x),f(x)\} = \int_a^b |f(x)|^2 dx.$$

Let $\varphi_k(x)$ (k – a discrete index) be an orthonormal system, i.e.,

$$\int_a^b \varphi_p(x)\varphi_q(x)dx = \delta_{pq},$$

and let $f(x)$ be any function (vector) in F. We introduce the (generalized) *Fourier coefficients*

$$a_k = \{f(x), \varphi_k(x)\} = \int_a^b f(x)\overline{\varphi_k(x)}dx$$

of the function $f(x)$, which are the magnitudes of the projections of $f(x)$ onto the vectors $\varphi_k(x)$ in F. It can be shown that if

$$\sum_{k=1}^{\infty} |a_k|^2 = \int_a^b |f(x)|^2 dx,$$

then the infinite sum $\sum_{k=1}^{\infty} a_k \varphi_k(x)$ is the generalized Fourier series of the function $f(x)$.

In direct analogy with the definition of the distance between points in an n-dimensional space as the length of the vector $\boldsymbol{x} - \boldsymbol{y}$ [namely, $\sqrt{\sum_1^n |x_k - y_k|^2}$], one defines the "distance" between two functions $f(x)$ and $g(x)$ in a functional space as $\sqrt{\int_a^b |f(x) - g(x)|^2 dx}$. The expression $\int_a^b |f(x) - g(x)|^2 dx$ is (up to a normalization constant) the *mean-square deviation* between the functions $f(x)$ and $g(x)$.

Now, in an n-dimensional space, the angle between the vectors $\boldsymbol{x}$ and $\boldsymbol{y}$ is defined as

$$\cos\phi = \frac{\sum_1^n x_k y_k}{\sqrt{\sum_1^n x_k^2 \sum_1^n y_k^2}}.$$

The function-space analog is (for real-valued functions)

$$\cos\phi = \frac{\int_a^b f(x)g(x)dx}{\sqrt{\int_a^b f^2(x)dx \int_a^b g^2(x)dx}}, \quad |\cos\phi| \le 1 \,,$$

the latter following from the *Cauchy inequality*.

Much of modern quantum theory employs infinite-dimensional vector spaces (Hilbert spaces) in which the unit vectors are quantum *state vectors*[74].

Hilbert was a small, quiet, unpretentious man, but with such an alert mind and air of deep concentration that in a little while one was under his spell. He

[74] These are often describable as complex *wave functions* of particle positions or velocities, or (in quantum field theories) as complex *functionals* of a field distribution (e.g. electric or magnetic) in $\mathbb{R}^3$ space at a fixed time-slice of an $\mathbb{R}^4$ spacetime.

quickly saw relationships which illuminated dark areas and led to solutions of problems on which other mathematicians had worked without success for years.

Hilbert's interests were purely scientific. He cared only for basic theory. He was not too interested in undergraduate students, but could be easily upset if a promising graduate student decided to leave mathematics for marriage or such similar frivolity. He cared little for broad educational questions and less for practical applications of science, but he was a great teacher, one who puts his finger on the heart of a problem and lights up the mind with a flash of understanding.

Students flocked to him as to no one else on the continent. Many of the 20^{th} century's most influential mathematicians and physicists, including **von Kármán**, **Toeplitz**, **Zermelo**, **Courant**[75], **Born**, **Heisenberg** and **Oppenheimer**, were his devoted disciples. Hilbert held the view that nature is inherently mathematical, and therefore urged his students to search for mathematical solutions in areas where practical men saw only insurmountable chaos.

Hilbert's greatest heritage is the notion that there is no gap between pure and applied mathematics and that between mathematics and science as a whole, a fruitful community can be established. This optimism echoes in an epitaph of his own words (1930) that has been placed over his grave in Göttingen:

"Wir müssen wissen. Wir werden wissen".

"The infinite! No other question has ever moved so profoundly the spirit of man."

1900–1906 CE **Reginald Aubrey Fessenden** (1866–1932, U.S.A.). Pioneer radio engineer and inventor. Made first radio broadcast of human voice and music over the air (Dec. 24, 1906). The first to experiment with modulation of radio waves (1902).

Fessenden was born in East Bolton, Quebec, Canada, of American parentage. He was chief chemist of Edison Laboratory (1887–1890); professor at the University of Pittsburgh (1893–1900); headed National Signaling Co. (1902–1910). Invented the electrolytic detector (1900), and the heterodyne receiver.

Patented some 300 inventions, including a radio compass, sonic depth finder, submarine signaling devices and turbo-electric drive for battleships.

In his 1906 radio broadcast, he spoke from Brant Rock, Mass. to ships offshore in the Atlantic Ocean on a carrier frequency of 50 kHz with a transmitter of power 1 kilowatt. He put two musical tunes, a poem and a talk on the air, and they were heard by radio operators several hundred kilometers away.

1900–1907 CE **Hugo Marie de Vries** (1848–1935, Holland). Botanist and geneticist. Rediscovered and verified Mendel's principle[76], marking the beginning of modern genetics (1900–1903). His studies of osmosis in plant cells brought to light the crucial role of osmosis in animal and plant physiology.

After a lengthy series of experiments in plant breeding (1890–1900), de Vries deduced the laws of heredity. He then began to reexamine Darwin's concept of evolution in the context of Mendel's results, and asserted that *mutations*[77] account for the key evolutionary steps in the creation of new species.

de Vries was highly critical of the theory of evolution by natural selection and stressed the importance of mutations in plant evolution, believing that the *genes* provide a mechanism through which natural selection can operate.

He was born in Haarlem, Holland and was a professor at Amsterdam (1878–1918).

1900–1908 CE **Ernst Friedrich Ferdinand Zermelo** (1871–1953, Germany). Mathematician. Made important contributions to the development of set theory, particularly in developing the *axiomatic set theory* that now bears his name. Following the pioneering work of Georg Cantor he provided (1900)

---

[76] *Mendelism*: The study of heredity stemming from the ideas of **Gregor Mendel** whose key assertion was that the reproductive cells of living organism contain 'factors' transmitting discrete characters. A hybrid pea-plant, for example, formed by crossing tall and dwarf varieties, would receive a factor for tallness from one parent, and one for dwarfness from the other. Half of its reproductive cells would contain one factor, and half the other, with no blending. Such suppositions explained observable distributions of types found in the offspring of hybrids. Mendel's work was neglected until rediscovered by **de Vries** (1900). Modern Mendelism, however, stems from **T.H. Morgan** and his colleagues who successfully identified 'factors' as *genes* (parts of chromosomes) present in the nucleus of every cell. At first, genes were thought to control *visible* characters of the organism on a one-for-one basis. Later it was realized that the genotype-phenotype relation is more complex.

[77] *Mutation*: Sudden discontinuous changes in an organism which are transmitted to offsprings, as opposed to the very slight variations described by Darwin (1859).

an ingenious proof to the '*well-ordering theorem*'[78] which led him to identify (1904) a crucial, but hitherto unrecognized, set-theoretic axiom: the *axiom of choice.*

Before Zermelo's work, this axiom was implicitly assumed in mathematical logical reasoning, and it is, in fact, a necessary hypothesis in his well-ordering theorem, as well. It states that if A is a set of non-null disjoint sets a, there exists a set C containing precisely one element of each $a \in A$.

In 1908 he gave the first axiomatic description of set theory including seven axioms: Axiom of *extensionability*, Axiom of *elementary sets*, Axiom of *separation*, *Power set* axiom, *Union* axiom, Axiom of *choice* and Axiom of *infinity.* Though later modified to avoid the paradoxes discovered by Bertrand Russell and others, it remains one of the standard methods of axiomatizing set theory. In particular, the axiom of choice remained a key result in many mathematical applications of set theory. Zermelo also contributed to the calculus of variations and to statistical mechanics.

Zermelo was born n Berlin and studied at Halle and Freiburg. Became a professor at Göttingen (1905), eventually moving to Freiburg, where he resigned his post (1935) in protest against the Nazi regime, but was reinstated in 1946.

1900–1912 CE **Max (Karl Ernst Ludwig) Planck** (1858–1947, Germany). Distinguished theoretical physicist. Originated quantum theory. Asserted that radiated energy is emitted in discrete, finite, irreducible units, or *quanta*.The amount of energy E contained in each quantum is proportional to the radiation's frequency ν, the proportionality factor being a universal constant, h. It is termed "the elementary quantum of action", and became known later as *Planck's constant*[79] [$h = 6.626\ 075\ 5 \times 10^{-27}$ erg-second]. In

[78] The '*well-ordering theorem*': Every set can in principle be arranged in a series (endowed with a total ordering) for which each subset has a least term. A *total ordering* is a relation $a \leq b$ (a comes before b) so that for any two statements a and b, either $a \leq b$ or $b \leq a$, and $a = b$ iff $a \leq b$ *and* $b \leq a$. If there are three elements a, b and c such that $a \leq b$ and $b \leq c$, then $a \leq c$ (*transitivity* property of the relation).

[79] Max Planck first pointed out that a new fundamental length scale could be constructed from the constants $\hbar$, c, and G ($\hbar = h/(2\pi)$).
According to the Heisenberg uncertainty principle, the measured energy of a system is subject to a minimal uncertainty ΔE if measured over a time period Δt, where ΔE and Δt are related by $\Delta E \Delta t \sim \hbar$. If this principle is applied to the gravitational field, one can expect sudden and unpredictable changes in the measured energy, momentum and stress distributions, which in turn cause fluctuations in spacetime curvature by GTR. To estimate the scale of these fluc-

1900 Planck formulated the correct mathematical description of thermal electromagnetic radiation from a perfect absorber (black body) in which energy is emitted and absorbed in *discrete energy packets*, or '*quanta*', each of energy $E = h\nu$.

Einstein later showed (1905) that the radiation is also *propagated* in such discrete quanta (named '*photons*') and that these photons carry momentum (and angular momentum) as well as energy.

A hypothetical body (assumed for simplicity to be surrounded by vacuum) that completely absorbs all radiant electromagnetic energy falling on it, reaches some steady-state temperature, and then re-emits that energy as quickly as it absorbs it. Since this scenario, although realistic enough in many actual cases, is thermodynamically out-of-equilibrium, it is usually recast as the following thought experiment: one considers a box (shape unimportant), with thick walls composed of the perfect absorber. The *equilibrium* radiation spectrum inside this box ('blackbody radiation') is then measured outside by drilling a small hole in the blackbody wall.

Planck assumed that the sources of radiation are oscillating atoms, capable of jumping from one discrete energy level E_2 to another discrete lower level E_1, such that the *frequency* of the ensuing radiation is $\nu = \frac{E_2 - E_1}{h}$. The *amount* of radiant energy in the box per unit volume and per unit wavelength is given by a distribution law that depends both on the wavelength $\left(\frac{c}{\nu}\right)$ *and*

---

tuations we may assume that the ripples of geometry produced by the quantum effects propagate like gravitational waves at the speed of light.

If the uncertainty in spatial position is represented by a sphere of radius r, the corresponding uncertainty in time is $\Delta t = \frac{r}{c}$. The corresponding energy fluctuations are then of order $\Delta E \sim \frac{\hbar c}{r}$. The *gravitational self-energy* of these fluctuations, i.e., the negative of the energy required to pull the energy ΔE (mass $\frac{\Delta E}{c^2}$) apart against its own gravity is of order $-\frac{GM^2}{r} = -\frac{G}{r}\left(\frac{\Delta E}{c^2}\right)^2 \sim -\frac{G\hbar^2}{r^3 c^2}$. If we choose the length scale r small enough, a point is reached where the quantum energy will occasionally fluctuate into existence (zero-point motion) without any external work. This happens when the gravitational binding self-energy reaches a value comparable to the energy ΔE itself, so that the net "energy penalty" incurred by the quantum fluctuation may vanish (which is also the regime where black holes, baby-universes and spacetime wormholes may arise). This disruptive regime is approached when $\frac{G(\Delta E)^2}{rc^4} \sim \Delta E \sim \frac{\hbar c}{r}$, or when $\Delta E \sim \sqrt{\frac{\hbar c^5}{G}} \sim 2 \times 10^9$ Joule $\sim 10^{17}$ GeV. This corresponds to a mass of $\sqrt{\frac{\hbar c}{G}} \sim 2 \times 10^{-8}$ kg, a characteristic fluctuation time $\sqrt{\frac{\hbar G}{c^5}} \sim 10^{-44}$ sec, and a length scale $\frac{\hbar c}{\Delta E} \sim \sqrt{\frac{\hbar G}{c^3}} \sim 10^{-35}$ m, known as the *Planck length*. At Planck scales, it is expected that quantum gravity effects would be of great importance.

the equilibrium absolute temperature T, according to the universal law of '*blackbody radiation*':

$$E_\lambda(\lambda;T) = \frac{8\pi hc}{\lambda^5}\left[e^{\frac{hc}{k\lambda T}} - 1\right]^{-1},$$

where c, h, k are three universal constants: the speed of light in vacuum, Planck's constant and Boltzmann's constant, respectively.

For blackbody temperatures up to several hundred degrees Kelvin, most of the radiation is in the infrared region of the electromagnetic spectrum. At increasingly higher temperatures, the total radiated energy increases and its peak shifts to shorter wavelengths, so that a significant portion of the blackbody spectrum is radiated as visible light (beginning with *red* and progressing to cover more of the visible colors of the rainbow as T increases).

The total energy density (per unit volume) is $E = \int_0^\infty E_\lambda d\lambda$. The introduction of a new variable $\xi = \frac{1}{\lambda}\left(\frac{hc}{kT}\right)$ yields the "*Stefan-Boltzmann law*" (1884):

$$E = 8\pi\frac{(kT)^4}{h^3c^3}\int_0^\infty \frac{\xi^3 d\xi}{e^\xi - 1} = \sigma T^4,$$

where

$$\sigma = \frac{8\pi^4 k^4}{15c^3h^3} = 7.56\times 10^{-15}\text{erg}\cdot\text{cm}^{-3}\cdot\text{deg}^{-4}$$

is the "Stefan-Boltzmann constant".

The peak of the curve $E_\lambda(\lambda,T)$ is at $\lambda=\lambda_m$, where $\left(\frac{\partial E}{\partial\lambda}\right)_{\max} = 0$. It yields "*Wien's displacement law*" (1896):

$$\lambda_m T = \frac{hc}{(4.965)k} = (0.2898)\ cm\cdot{}^\circ K.$$

This law relates a star's color to its surface temperature: the intensity of light from a cool star peaks at long wavelengths, and thus the star appears *red*.

A hot star's intensity curve is skewed toward short wavelengths, and thus the star appears *blue*. The maximum intensity of a star of intermediate temperature (such as the sun) occurs near the middle of the visible spectrum, giving the star a yellow-white color.

Planck was born in Kiel. He studied at the universities of Münich[80] and Berlin and was appointed a professor in Kiel (1885) and in Berlin (1889),

[80] Planck's teacher, **Philipp Johann Gustav von Jolly** (1809–1884, Germany), advised him (1876) against the study of physics, since after all it was essentially *finished* (!), so that for anyone who wanted to do active scientific research, it would scarcely be worthwhile to go into this field.

where he resided for the rest of his life. In 1918 he was awarded the Nobel prize in physics. **Albert Einstein** and **Niels Bohr** applied Planck's quantum theory to problems of photoelectric emission and atomic structure, respectively. The new theory succeeded in explaining the structure of the outer part of the atom.

1900–1918 CE **Georg Simmel** (1858–1918, Germany). Philosopher and sociologist. Insisted that the *natural sciences* as well as history offer only an image of reality that is transformed by the theoretical or historical *a priori*; Philosophy and sociology offer two different aspects of the situation of man in the world; They are two autonomous interpretations of mental life. He admitted the influence of economic facts on intellectual attitudes but insisted that the effects of intellectual patterns on economics act likewise.

He maintained that the decisive factor of *human attitude* is antecedent to changes of social and economic institutions. *Sociology* is conceived by Simmel as the doctrine of the forms of the relations between individuals, independent of spiritual contents which are subject to historical change. It is the "geometry of social life".

Religion and the *arts* represent to Simmel autonomous worlds which are independent of *science* but accessible to the philosopher, provided he does not disregard their autonomous foundations; the poet and the artist while forming their own image of life, (although determined by the historical situation of his lifetime), transcends historical conditions and testifies that life always hints beyond itself. The principal problem of *influence* is formulated by Simmel as the difficulty to seize life without violating it.

Simmel was born in Berlin to Jewish parents who converted to Christianity. Taught at the University of Berlin (1885–1914) and the University of Strasbourg. He did not form a school; many of his former pupils died on the battlefields of WWI. His works have been influential in the United States.

1900–1921 CE **Louis Bachelier** (1870–1946, France). Mathematician. In his dissertation (1900) he described the mathematical theory of *Brownian motion*, namely — the one-dimensional diffusion of probability. (5 years before **Einstein**!). Prior to **Wiener** he obtained (1913) some important properties of the so-called Wiener-Lévy process (1923). Bachelier applied the theory to economy and claimed that successive price-changes are statistically independent and follow a one-dimensional Brownian motion.

Bachelier was a professor at the University of Besancon.

1900–1922 CE **Max Wilhelm Dehn** (1878–1952, Germany and USA). Mathematician. Contributed to the foundation of geometry (1900–1906), theory of groups, and topology (1906–1922). Solved the third of Hilbert's 23 Paris problems on the *congruence of polyhedra*.

He showed, as Hilbert conjectured, that a regular tetrahedron cannot be cut up and reassembled into a cube of equal volume (1900–1901). Dehn wrote one of the first systematic expositions on *topology* (1907) and later formulated important problems on *group presentations*, namely the *word problem*[81] and the *isomorphism problem*.

Dehn was born in Hamburg to Jewish parents. He studied at Göttingen under Hilbert's supervision, obtaining his doctorate in 1900. Converted to Christianity (1900) under Hilbert's influence. Held academic positions at the Universities of Münster, Kiel and Breslau (1900–1915). Served in the German army during WWI (1915–1918). Held the chair of Mathematics at the University of Frankfurt on M. (1921–1935). Dismissed (1935) by the Nazis and lived as a refugee in various European countries (1935–1939). Immigrated to the US (1940) in the wake of the brain-drain[82] and held minor academic positions at the Universities of Idaho, Chicago and Maryland. Finally he became a professor of Mathematics in Black Mountain College, North Carolina (1945–1952), where he died at the age of 74.

Two areas, or two volumes, P and Q, are said to be *congruent by addition* if they can be dissected into corresponding pairs of congruent pieces (e.g. familiar proofs of the Pythagorean theorem). Any two equal polygon areas are congruent by addition, and the dissection can always be carried out with a straightedge and compasses. Likewise, *congruence* by *subtraction* refers to a case where corresponding pairs of congruent pieces can be added to P and Q to give two new figures which are congruent by addition. Max Dehn showed that two equal *polyhedral volumes* are not necessarily congruent by either addition or subtraction.

1900–1936 CE **Edmund Husserl** (1859–1938, Germany). Philosopher and mathematician. The father of modern *existentialism*. Developed the

---

[81] The *word problem* asks the fundamental question of whether there is an algorithm to determine if a word in a group given by a presentation is trivial. It has since been shown that no such algorithm exists in general.

[82] The United States found itself immeasurably enriched, for almost all the members of the Hilbert school and many other European scientists emigrated to that country. This exodus included: **Artin**, **Courant**, **Debye**, **Einstein**, **Ewald**, **Feller**, **Franck**, **Friedrichs**, **Gödel**, **Hellinger**, **von Karman**, **Landé**, **Lewy**, **Neugebauer**, **von Neumann**, **Emmy Noether**, **Nordheim**, **Ore**, **Polya**, **Szegö**, **Szilard**, **Tarski**, **Olga Taussky**, **Teller**, **Weyl**, **Wigner**.

philosophy of *phenomenology* (the study of relationship of the conscious mind to objects, stressing the existence of an inner reality in the mind). Claimed that the correct procedure for any philosophy must be the understanding of things as they are presented in the form of empirical evidence to experience, and that such understanding must be *intuitive*.

Concluded that the proper objects of all exact disciplines, philosophy as well as *logic and mathematics*, are *essences* (abstract entities present to the mind but not themselves states of mind). Where Husserl mainly concerned himself with the mind's intellectual activities and their objects, Heidegger applied the phenomenological method to the emotions.

Husserl was born to Jewish parents in Prossnitz, Moravia and was baptized as a Christian (1887). Studied in Leipzig and Berlin (where he worked with **Karl Weierstrass**) before coming under the influence of the philosopher **Franz Brentano** in Vienna (1883). He held posts at Halle (1887–1901), Göttingen (1901–1916), where he was a colleague of **David Hilbert**. He finally settled as professor at Freiburg (1916–1928).

Husserl fell victim to the Nazi academic purge, while his successor and former pupil, Martin Heidegger, became a Nazi sympathizer. His most influential books: *Logische Untersuchungen* (Investigation in Logic, 1900), *Ideen zu einer reinen phänomenologie* (Ideas concerning pure phenomenology, 1913), *Die Krisis der europäischen Wissenschaften* (The crisis of European Science, 1936).

1900–1938 CE **Franz Boas** (1858–1942, Germany and USA). Founder of the science of cultural anthropology. Contributed to ethnology, linguistics and physical anthropology, especially to the understanding of the mentality, art, religion, and folklore of primitive societies.

Boas was born to Jewish parents in Minden, Rhine-Westphalia, Germany and received his doctorate at Kiel (1881). Trained initially as a geographer, he shifted his interests to ethnology as a result of contacts with Eskimos in the course of an Arctic expedition. Work in British Columbia, among the Kwakiutl, led him to devote himself entirely to anthropology and also to emigrate to the USA (1886).

Between 1900–1905 he provided the first specific proof of cultural relationship between Siberians, Eskimos and American Indians. He demonstrated that races of man are mixed to some extent and objected to *evolutionary assumptions*, *geographical determinism* and *racial determinism*.

Boas maintained that culture was a more or less autonomous realm which could not be explained in terms of other factors and that the complexity of cultural phenomena was inevitably overwhelmed by detail.[83] His writings include *The mind of Primitive Man* (1911) and *Anthropology and Modern Life* (1928).

1900–1942 CE **Marc Aurel Stein** (1862–1943, Hungary and England). Archaeological surveyor, scholar and explorer. Provided the basis of modern knowledge of the geography, history and cultures of Central Asia.

As a result of more than 15 journeys on foot and horseback (two of which alone totaled 40,000 km) through some of the highest and most isolated mountains and deserts in the world, he established for the first time the extent of the intercourse between Indian, Iranian, Hellenistic and Chinese civilizations, and the overland lines of communication between China and the West during the many centuries before these were finally replaced by the sea route.

In his first three journeys (1900–1916) he crossed the Hindukush and Pamirs, and explored Chinese Turkestan. His most famous discovery was the *Cave of the Thousand Buddhas* at Ch'ien-fo-tung, from which he brought back a great cache of documents in several languages and works of art, dating from the 5^{th}–10^{th} centuries and which had been walled up in the 11^{th} century. It was the greatest archaeological discovery ever made in Asia.

Stein undertook a series of jurneys to trace the vestiges of the prehistoric Indus civilization westward to the Tigris. Other expeditions established the line of Alexander's route and of Marco Polo's journeys. At the age of 80 he was exploring the gorges of the Indus climbing a succession of passes 4600 meters high.

Stein was born to Jewish parents in Budapest, and educated in his native city, and at Vienna, Tübingen, Oxford and London, where he took up oriental studies. In 1888 he was appointed registrar of the Punjab University at Lahore, India, and principal of the Oriental College in the same university. In 1900–1901 Stein directed archaeological expeditions in Chinese Turkestan for the Indian government. He lived most of his life in India and died at Kabul, Afghanistan.

---

[83] Boas' critique of evolutionary and racial assumptions sprang from his Germanic heritage and a disillusionment with Victorian civilization. This led him to insist that 'laws' of cultural development must be derived from the comparison of reconstructed histories of particular cultures rather than of characteristics of various racial groups assumed to be at different stages of development (cultural relativism).

After WWII, there was a reaction against cultural relativism and a reassertion of evolutionary themes. After more than a century of serious study, the concept of *culture* still evidences the unresolved tension between an evolutionary perspective and a humanistic orientation toward distinctive species characteristic of man.

1901 CE On the invitation of **Felix Klein** (1849–1925, Germany), **Ricci-Curbastro** and **Levi-Civita** published a joint expository memoir illustrating the application of the tensor methods to geometry and physics, and offering abundant evidence of the utility of tensor analysis in applied mathematics.

They showed that tensor calculus comes near to being a universal language in mathematical physics. It allows for compact expression of equations and provides a guide to the selection of physical laws. In particular, if a system of equations is expressible as the vanishing of a tensor, then the system will be invariant under a wide class of transformations of all variables in the system. But this is precisely the *covariance* condition imposed by one of the postulates of *General Relativity* on a system of equations, if the system is to be an admissible mathematical formulation of an observable sequence of events in physics.

Indeed, the theory of tensors was presented essentially in the form used by Einstein fifteen years later. **Marcel Grossmann** (1878–1936, Zürich), a Swiss geometer, mastered the new calculus and taught it to **Einstein**. This was timely, since tensor calculus was the particular kind of generalized vector analysis appropriate for expressing the differential equations of the gravitational field, and the effects of gravity on the flat four-dimensional space of STR.

1901–1902 CE **Martin Wilhelm Kutta** (1867–1944, Germany). Applied mathematician. Known for the *Runge-Kutta* method (1901) for numerically solving ordinary differential equations and for his important pioneering work on the aerodynamic theory of aerofoils (1902). His particular aim was to understand the effect of curvature — why a horizontally placed curved surface produced a positive lift.

Kutta studied at Breslau (1885–1890), Munich (1891–1894) and Cambridge (1898–1899). He became a professor at Stuttgart (1914) and remained there until his retirement (1939).

On the Wing[84]

The circulation theory of lift for two-dimensional wings of infinite span (1902–1909) is anchored in the studies of ***Lord Rayleigh*** *(1878) on the flow around a circular cylinder and the discovery by* ***Helmholtz*** *(1858) concerning the creation of vorticity by sharp edges.*

In general, a fluid element in a flow can experience translation, rotation and distortion. If rotation is absent, the result is a potential flow *or a* vortex-free flow; *whereas, if the element also rotates, we have a* rotation flow *or a* vortex flow. *Parallel flow with uniform velocity is the simplest example of vortex-free flow, because the fluid elements just travel parallel with no rotation nor distortion. In a* parallel shear-flow *in two dimensions, the velocity is uniform in the stream direction but non-uniform in a perpendicular direction; consequently the element is both rotated and distorted. This is the simplest example of vortex-flow (every element rotates, but the fluid* as a whole *does not necessarily rotate).*

In a circulatory flow *(circular streamline) with constant angular velocity, there is a vortex flow with no distortion. In this case the tangential velocity u of each element, though constant in magnitude along a given streamline, increases linearly from the center outwards.*

It is easy to show that if one chooses a velocity distribution along a radial ray of radius r such that the product $ru =$constant, the flow is vortex-free. The expression $2\pi ru$ is known as circulation; *so constant circulation guarantees a potential flow.*

To avoid a singularity at $r = 0$, let us assume a circulatory flow around a ball or cylinder. Then we already know through the Magnus effect *that when the body is given an additional translatory motion, the combined flows produce (by Bernoulli's theorem) a pressure difference, and hence a 'lift' force, perpendicular to the trajectory of the body.*

The cylinder, however, has an unsuitable shape *for a wing, because the air's viscosity creates around it a boundary layer that greatly increases the body's resistance to motion. To minimize this effect, the cylinder must be*

[84] For further reading, see:

- von Karman, T., *Aerodynamics*, McGraw-Hill, 1963, 203 pp.
- Ashley, H. and M. Landahl, *Aerodynamics of Wings and Bodies*, Dover, 1965, 279 pp.

'streamlined' in order to make it a good aerofoil. Observations of anatomy of birds and fishes, together with numerous experiments, have taught man that the boundary of the leading edge *of the moving object should curve as gradually as possible (large radius of curvature) while the* trailing edge *be made as sharp as possible.*

All this was known before 1902. But then ***Kutta*** *(1902) and independently* ***Joukowski*** *(1906) discovered that when a cylindrical body of* arbitrary cross-section *moves with velocity U in a fluid*[85] *of density ρ and there is a circulation of magnitude Γ around it, a force is produced equal to the product $\rho U\Gamma$ per unit length of the cylinder. The direction of the force is normal to both the velocity U and the axis of the cylinder.*

For a cylindrical body with arbitrary cross-section the circulation is understood as the product of the mean value of the component of the velocity along an arbitrary closed curve encircling the body, multiplied by the length of arc of that curve.

If the flow is vortex-free, this product has the same value independent of the choice of curve. The calculation of the lift thus reduces to the mathematical problem of the determination of the magnitude of the circulation as a function of the velocity and as a function of the shape of the wing section.

Now, apart from being able to calculate the circulation, there is the physical problem of how to generate *circulation in the first place. The answer to this last question was, however, known already to* ***Helmholtz****; he showed that if there is no initial vorticity in the fluid (e.g., if the fluid is originally at rest), vorticity can only be created by* friction *or by a presence of sharp edges on a body.*

This means that if the process of putting a wing section in motion creates a vortex (i.e. a rotation of a part of the fluid), a rotation in the opposite sense is created in the rest of the fluid, simply by Newton's principle of action and reaction. This rotary motion of the fluid appears as the circulation around the wing section.

So Kutta and Joukowski set forth (1902–1909) to calculate the circulation generated by a 2-D wing-section with infinite span and having a sharp trailing edge. In earlier times, the instinctive impression was that air hits the inclined wing surface and that the airplane is therefore carried by the air below. It is now clear that the airplane wing is at least partially hung up or sucked up *by the air passing along the upper surface. In fact, the contribution to the total lift from the negative pressure or suction developed at the upper surface is larger than the contribution from the positive pressure at the lower surface.*

[85] U is also equivalently equal to the wind (fluid) speed past a *stationary* object.

What happens to the vortex created near the trailing edge? Kutta and Joukowski showed that this starting vortex *is swept away and that conditions of smooth flow prevail at the trailing edge as the motion develops ('Kutta-Joukowski condition'). This allows one to calculate the circulation as if the vortex did not exist, turning the whole problem of lift into a purely mathematical exercise*[86]*. The assumption was indeed borne out by visual observations, and the fit of circulation theory with experimental results.*

A comparison between Newton's theory of lift and circulation theory shows that Newton's result is in error by an order of magnitude.

If the span of the wing is infinite, no work is required to obtain lift. Moreover, if we neglect friction and assume that the fluid closes around the wing, the motion can be described by the mathematical solution for nonviscous *fluids ('d'Alembert's Paradox'). In real fluids, however, because of frictional effects, the streamlines do not follow the surface of the body back to the rear end, but separate from the surface somewhere, thus leaving downstream an eddying part called the* wake*.*

Consequently, the pressure over the rear part of the body cannot reach such high values as are calculated for the nonviscous fluid. Because the pressures at the front and the rear are no longer balanced, a pressure drag *occurs, known as the* wake drag*. In addition, work must be expanded to obtain lift, known as* induced drag*.*

To sum up: When the streamlines passing around an obstacle in their path are not symmetric, the velocity of the flow on one side of an object may be different from the velocity on the other side. If the flow satisfies Bernoulli's law, then there will be lower pressure on the side with higher velocity. The resulting force on the object will have a major component perpendicular to the flow. There is a way to create asymmetry of streamlines with a symmetrical obstacle by imparting it with a rotational motion relative to the surrounding fluid.

When the body, however, has an intrinsic geometrical asymmetry, like an aerofoil for example, it is the fluid that is 'rotated' around the body, thus creating the lift. The 'lift' on an aircraft's wing or aerofoil enables it to rise from the ground. The shape of the wing is designed to produce the circulation.

---

[86] In order to avoid the mathematical difficulty of calculating the circulation integral for the aerofoil, Kutta and Joukowski found an ingenious method that automatically reduces the problem to that of a flow past a circular cylinder; because of the two-dimensional nature of the problem, the *conformal transformation* $z = \zeta + \frac{\ell}{\zeta^2}$ (with ℓ constant) maps the aerofoil's ζ-plane onto the circular cylinder z-plane, for which an exact solution was known for an incompressible inviscid fluid (Rayleigh 1878).

The circulation adjusts itself so that the velocity at the trailing edge (where a singularity can occur) is finite. Thus a definite value of the lift is obtained for any given wing speed when steady motion is reached.

1901–1906 CE **Henri Léon Lebesgue** (1875–1941, France). A leading mathematician of his day. Revolutionized the field of integration with his generalization of the Riemann integral. Introduced the 'Lebesgue measure', which deals with the determination of the content of geometrical configurations, or more generally, of point sets.

He began his career at the universities of Rennes and Poitiers. In 1912 he became a professor at Collège de France. Also contributed to the fields of topology ('pavement theorem'), Fourier series and potential theory.

Towards the end of the 19^{th} century, mathematical analysis was effectively limited to continuous functions, and artificial restrictions were necessary to cope with discontinuities that cropped up with greater frequency as more exotic functions were encountered. The Riemann method of integration was applicable only to continuous (and a few discontinuous) functions.

Influenced by the work of **E. Borel**, **C. Jordan** and other theories of measure and content, Lebesgue formulated his theory of measure in 1901. In 1902 he framed a new definition of the definite integral. With the Lebesgue integration, any bounded summable function is the derivative of its indefinite integral, except possibly at an ensemble of points with zero measure.

Lebesgue integration was also instrumental in greatly expanding the scope of Fourier analysis.

Measure and modern integration (1894–1906)

(A) The Riemann-Stieltjes Integral

Fourier (1822) discovered that the Fourier series expansion depends on integrals. Assuming that

$$f(x) = \frac{1}{2}a_0 + \sum_{n=1}^{\infty}(a_n \cos n\pi x + b_n \sin n\pi x),$$

Fourier derived the formulas

$$a_n = \int_{-1}^{1} f(x)\cos n\pi x\,dx, \qquad b_n = \int_{-1}^{1} f(x)\sin n\pi x\,dx$$

Thus the existence of the series depends on the existence of the integrals for a_n and b_n, and this in turn depends on how discontinuous f is. It was known (though not rigorously proved) that every continuous function had an integral, so the next question was how the integral should, or could, be defined for discontinuous functions. The first precise answer was the Riemann [1854] integral concept, based on approximating the integral by step functions.

We recall the definition of the Riemann integral of a bounded function in the closed interval $[a, b]$. Suppose that $f(x)$ is bounded over (a, b); we subdivide this interval by means of the points $x_0, x_1, \dots, x_n$ so that $a = x_0 < x_1 < x_2 \cdots < x_{n-1} < x_n = b$. Let m_ν, M_ν be the lower and upper bounds of $f(x)$ in the interval $x_{\nu-1} < x \le x_\nu$, and let

$$s = \sum_{\nu=1}^{n} m_\nu(x_\nu - x_{\nu-1}), \qquad S = \sum_{\nu=1}^{n} M_\nu(x_\nu - x_{\nu-1}).$$

When the number of division points is increased indefinitely so that the greatest interval $x_\nu - x_{\nu-1}$ tends to zero, each of the sums s and S tends to a limit. If the limits are the same *for* every *sequence of partitions*

$$a = x_0 < \xi_1 < x_1 < \xi_2 < x_2 \cdots < \xi_n < x_n = b$$

as $\max|x_\nu - x_{\nu-1}| \to 0$, then their common value is the Riemann Integral

$$I = \lim_{\substack{\max|x_\nu - x_{\nu-1}|\to 0\\ n\to\infty}} \sum_{\nu=1}^{n} f(\xi_\nu)(x_\nu - x_{\nu-1}) \equiv \int_a^b f(x)\,dx.$$

Stieltjes *(1894) showed that it is also possible to integrate $f(x)$ w.r.t. a function $g(x)$ over the bounded interval $[a, b]$. He defined*

$$\lim_{\substack{\max|x_\nu - x_{\nu-1}|\to 0 \\ n\to\infty}} \sum_{\nu=1}^{n} f(\xi_\nu)(g(x_\nu) - g(x_{\nu-1})) = \int_{x=a}^{b} f(x)\,dg(x)$$

for an arbitrary sequence of partitions

$$a = x_0 < \xi_1 < x_1 < \xi_2 < x_2 \cdots < \xi_n < x_n = b$$

This generalization is known as the Riemann-Stieltjes integral. One must not write here the limits of integration as $g(a)$ to $g(b)$ because $g(x)$ may not be monotonic. It is x, not $g(x)$, that is required to increase steadily throughout the integration domain.

Stieltjes integrals often have an "intuitive" meaning (line integrals, surface integrals, volume integrals; integrals over distributions of mass, charge, and probability). Note that Stieltjes integrals include ordinary integrals and sums as special cases:

$$\int_a^b f(x)\,dg(x) = \int_a^b f(x)g'(x)\,dx$$

whenever $g(x)$ is continuously differentiable on (a, b), and

$$\sum_k f(k) = \int_{-\infty}^{\infty} f(x)\,d\sum_k U_-(x-k) \qquad \left[U_-(x) = \begin{cases} 0 & \text{if } x < 0 \\ 1 & \text{if } x \geq 0 \end{cases}\right]$$

The Riemann-Stieltjes integral $\int f\,dg$ exists when f is continuous and g is of bounded variation. It is then shown that

$$\int_{x=a}^{b} g\,df = [fg]_a^b - \int_{x=a}^{b} f\,dg,$$

which is of much wider validity than the Riemann integration by parts result

$$\int_a^b f(x)g'(x)\,dx = [f(x)g(x)]_a^b - \int_a^b f'(x)g(x)\,dx,$$

valid when both f and g are differentiable for all $a \leq x \leq b$.

(B) Countable sets; measure

The Riemann integral is valid for a wide class of functions. Any function with a finite number of discontinuities belongs to this class, and indeed so do all functions bounded over a finite interval and having a countable *infinity of discontinuities*[87]*. Yet, the Riemann integral suffers from several difficulties; Consider, for example, the classic function of Dirichlet (1829):*

$$f(x) = \begin{cases} 1 & \text{if } x \text{ is rational} \\ 0 & \text{if } x \text{ is irrational} \end{cases}$$

Now, since there are "very few" rationals, only a countable number in fact, we strongly suspect that the integral of this function is zero. However, if we form the upper and lower Riemann integrals by partitioning $[0, 1]$ *into small segments* Δx_i *and write*

$$\overline{\int} f(x)\,dx = \sum_i \Delta x_i \max[f(x)], \qquad x_i \le x \le x_i + \Delta x_i$$

$$\underline{\int} f(x)\,dx = \sum_i \Delta x_i \min[f(x)], \qquad x_i \le x \le x_i + \Delta x_i$$

in the usual way, we see that no matter how small the subinterval, Δx_i*, the maximum of* $f(x)$ *on this interval is always* 1 *and the minimum is always zero. Thus*

$$\overline{\int} f(x)\,dx = 1 \quad \text{and} \quad \underline{\int} f(x)\,dx = 0$$

so the Riemann integral does not exist.

To cope with such functions, a more general integral, the Lebesgue integral*, was introduced. To this end, mathematicians have invented a new concept — measure.*

Measure *generalizes the concept of length (on a line), area (in a plane), and so on, to quite general set of points. It has its roots in metric geometry, where a number is assigned to a length, an area or a volume.*

In antiquity, measurement was at first considered just a case of comparison with a standard unit. Then the problem of incommensurables revealed that

---

[87] A necessary and sufficient condition that a bounded function $f(x)$ on (a, b) be Riemann-integrable is that the *points of discontinuity* of $f(x)$ form a set of *measure zero.*

the question was not as simple as intuition suggests, and that it requires a consideration of infinite processes. When calculus was fully developed, there came the more sophisticated point of view that, for most figures, measures do not *exist a priori but are contingent on the existence of associated limits. The evaluation of such limits became the task of integral calculus, a tool that also gives measures for many physical entities such as mass, work, force, charge, etc.*

As scientific history advanced, both physical and abstract geometrical concepts became more complicated, and there arose an ever greater need for precise mathematical formulation.

In Cantor's theory of the infinite, one-to-one correspondence is the criterion for determining whether two sets have the same cardinal number or whether one aggregate "has more elements" than the other. But this does not give the "length" (or area or volume) of a point set. In fact, the interval $[0,3]$ *has the same cardinal number of points,* C*, as* $[0,1]$*, although Euclidean geometry says the former is three times the latter in length. (We have used the bracket* [ ] *symbolism to indicate that the intervals in question include the end-points:* 0 *and* 3 *in the first case,* 0 *and* 1 *in the second.)*

What sort of rule can we apply to infinite sets to obtain a suitable measure for such abstractions as 'length', 'area' or 'volume', so that there may be applications to their counterparts in the physical world? In dealing with the set of all real numbers, the Cartesian picture is the number axis. Here one uses a standard length for the unit interval $[0,1]$ *and marks it off repeatedly to obtain the intervals* $[1,2]$, $[2,3]$, *etc.*

If measure *is to be just a generalization of length, it would seem a good idea to say that the* measure *of the set of real numbers in each of these intervals is also one unit. Thus one can readily measure point sets that are either simple intervals or finite unions of nonoverlapping intervals.*

But certain other questions naturally present themselves: If from the set of all real numbers between 0 *and* 1 *we remove the end-points* 0 *and* 1*, what is the length or measure of the remaining set, that is, the open interval* $(0,1)$*? Or suppose that we remove all the rational fractions that have* 1 *as numerator:* $1/1$, $1/2$, $1/3$, $1/4$, $1/5, \ldots$*; what is the measure of the residue? Or suppose that we go further and remove all the rational points in* $[0,1]$*; what length remains?*

In the last years of the nineteenth century, ***Émil Borel*** *gave much creative thought to these and many more difficult questions of the same kind. Then, in 1902, with Borel's ideas as background,* ***Henri Lebesgue*** *(1875–1941) established a* general *theory of measure. He abstracted its structure from all the particular "measure theories" of the past — empirical, abstract geometrical, Borelian, etc.*

In geometrical measurements, perimeters of polygons are obtained by totaling the lengths of individual sides, and area is sometimes found by subdividing a polygon into triangles, measuring these, then adding up. Such procedures assume: The whole is equal to the sum of its parts. In Lebesgue's generalization this becomes: The measure of the logical sum, or union, of a finite or countably infinite number of nonoverlapping sets is equal to the sum of their measures. (Where the number of sets is countably infinite, the existence of a measure will involve the question of convergence of a series.)

On the other hand, generalizations of measures do not illustrate the classic postulate which asserts that the whole is greater than one of its parts. That axiom applies to finite sets only. The essence of infinity is that the whole of an infinite collection does equal a part. Then, in general measure theory, a statement which combines finite and infinite attributes is: The measure of a set is either equal to or greater than the measure of a proper subset.

Again, abstraction from particular measures leads to the assumption: The measure of a set is zero or some positive real number. Also, it is postulated that the measure of the empty set $\emptyset$ *is zero.*

That "nothing" and zero are not identical is indicated by the fact that the converse of the axiom just stated is false. If the Lebesgue measure of a set is zero, this aggregate is not necessarily empty. In general measure theory, a set consisting of a single point like the origin, or the point $x = 1$ *on the* X*-axis, or the point* $x = 3$*, etc. measures zero. (The reason for this is that the interval is the basis of linear measure, and a single point can be covered by an arbitrarily small interval.)*

If we accept a postulate stating that for finite and countably infinite sets the whole is equal to the sum of its parts, then the measure of a set containing two isolated points is zero, as is the measure of any finite or countably infinite collection of isolated points.

Now, referring to a question raised earlier, the aggregate of all fractions with numerator 1 can be shown to measure zero, and the same is true of the class of all rational numbers between 0 and 1. For this reason, when such sets are removed from the interval $[0, 1]$*, the residual set still measures 1 unit. Thus the aggregate of irrational numbers in* $[0, 1]$ *measures 1 unit. More formally, if we symbolize the class removed by* E *and the residue by* E'*, the logical sum or union of* E *and* E' *is the unit interval. Therefore*

$$\begin{aligned}\text{(measure of } E\text{)} + \quad \text{(measure of } E'\text{)} &= \text{measure of } [0,1] \\ 0 + \quad \text{measure of } E' &= 1 \\ \text{measure of } E' &= 1\end{aligned}$$

Here the measure of the whole interval is equal to the measure of the part E', but is greater than the measure of the part E.

Let us agree that the measure of the interval $[0,1]$ is its length, 1. The measure of an arbitrary interval $[a,b]$ is obviously its length, $b-a$. Similarly, if we have two disjoint intervals $[a_1,b_1]$ and $[a_2,b_2]$, it is natural to interpret the length of the set E consisting of these two intervals as the number $(b_1-a_1)+(b_2-a_2)$.

However, the concept of length (measure) of a set in the line requires a rigorous mathematical definition. The problem of defining the length of sets or, as we may now say, of measuring sets is very important, because it is of vital significance in generalizing the concept of an integral[88]*. The concept of measure of a set also has applications to other problems in the theory of functions, in probability, topology, functional analysis, etc.*

Harnack *(1885) discovered that any countable subset $\{x_0, x_1, x_2, \dots\}$ of the line continuum $\mathbb{R}$ could be covered by a collection of intervals of arbitrarily small total length: For one can cover x_0 by an interval of length $\frac{\epsilon}{2}$, x_1 by an interval of length $\frac{\epsilon}{2^2}$, x_2 by an interval of length $\frac{\epsilon}{2^3}, \dots$, so that the total length of the intervals used is $\leq \epsilon$.*

This seemed to show that countable sets were of measure zero. Yet, mathematicians were reluctant to say this of dense countable sets, like the rationals. **Jordan** *(1892) demonstrated that dense countable sets like the rationals also have measure zero.*

It can be shown that a set may have the cardinality of the continuum and yet have measure zero! Indeed, construct the set P (known as Cantor's perfect set) as follows: delete from the closed interval $[0,1]$ the open interval $\left(\frac{1}{3},\frac{2}{3}\right)$, which forms the middle third. From each of the remaining intervals $\left[0,\frac{1}{3}\right]$ and $\left[\frac{2}{3},1\right]$ we delete its middle third. This process of deleting the middle third of the remaining intervals can be continued infinitely and generally, at the nth step we have thrown out 2^{n-1} adjacent intervals of length $\frac{1}{3^n}$. The sum of all removed intervals is then equal to

$$S = \frac{1}{3} + \frac{2}{9} + \frac{4}{27} + \dots \frac{2^{n-1}}{3^n} + \dots = \frac{1/3}{1-2/3} = 1$$

Thus, the sum of the lengths removed to form the Cantor set is 1; Therefore, the set itself has the measure zero[89].

[88] Since an integral can be viewed as the *area* under a graph, its dependence on the concept of measure is clear.

[89] *Alternative proof*: Consider all numbers of the form $0.a_1a_2a_3\dots$ (in base 3) with $a_i = 0$ or 2. Evidently, this set covers *part* of the real numbers in $[0,1]$. Now, the

Armed with this preliminary background, we may next proceed to a more rigorous treatment of the Lebesgue integral.

(C) The measure of a set of points

We shall now define a new generalization of 'length', starting from an open set, which may contain an infinity of intervals.

The measure of an open subset of the interval (a, b) is defined to be the sum of the lengths of its constituent intervals. It is always convergent, since the sum of any finite number of terms is the sum of the lengths of a finite number of non-overlapping intervals, all contained in an interval (a, b), and so is not greater than $b - a$. Hence, the measure of any open set contained in (a, b) does not exceed $b - a$.

The exterior measure $m_e(S)$ of any bounded linear point-set S is the highest lower bound of the combined length of any set of intervals covering S. Clearly,

$$0 \leq m_e(S) \leq b - a$$

The interior measure $m_i(S)$ of S is defined as the difference between the length $b - a$ of any bounded interval (a, b) containing S and the exterior measure of the complement of S w.r.t. (a, b):

$$m_i(S) = b - a - m_e\{(a, b) - S\}$$

The set S is a measurable set with the Lebesgue measure $m(S)$ if and only if

$$m_e(S) = m_i(S) = m(S)$$

---

set is *non-denumerable* since each a_i can take two values such that the cardinality is $2^{\aleph_0} = C$. Yet it can be shown that the *measure* of this set is zero.

(D) The measure of a function

A bounded function $f(s)$ defined on (a,b) is measurable on (a,b) if and only if the set of points x in (a,b), such that $f(x) \le c$, is measurable for every real value of c.

A continuous function is measurable. All the ordinary functions of analysis may be obtained by limiting processes from continuous functions, and so are measurable. An extreme example is

$$f(x) = \lim_{m\to\infty} \left[\lim_{n\to\infty} \{\cos m!\pi x\}^{2n} \right]$$

If x is rational, $m!x$ is an integer if m is large enough. Hence

$$f(x) = \begin{cases} 1, & x \text{ rational} \\ 0, & \text{otherwise} \end{cases}$$

This function presented by Dirichlet — which, as we saw earlier, has no Riemann integral — is therefore measurable.

(E) The Lebesgue integral

Let there be given a real function $y = f(x)$, measurable and bounded on the bounded interval (a,b). Let c and d be the highest lower bound and the lowest upper bound of $f(x)$, respectively. As in the Riemann integration, the integral is obtained by dividing the interval of variation of $f(x)$

$$c = y_0 < \eta_1 < y_1 < \eta_2 < \cdots < \eta_n < y_n = d.$$

Let e_ν be the set of points x in (a,b) such that $y_{\nu-1} < f(x) \le y_\nu$ $(\nu = 1,2,\ldots,n)$. Since $f(x)$ is measurable, the sum $\sum_{\nu=1}^{n} \eta_\nu m(e_\nu)$ can be shown to tend to a unique finite limit I for every sequence of partitions as $\max|y_\nu - y_{\nu-1}| \to 0$. *The quantity*

$$I = \lim_{\max|y_\nu - y_{\nu-1}|\to 0} \sum_{\nu=1}^{n} \eta_\nu m(e_\nu) \equiv \int_a^b f(x)\,dx$$

is the definite integral of $f(x)$ over (a,b) in the sense of Lebesgue. The Lebesgue integral can also be defined for an unbounded function, as well *as for an unbounded interval. If a function has a Riemann integral, then it also has a Lebesgue integral, and the two are equal.*

We have demonstrated above that the Dirichlet function does not have a Riemann integral. Since it is measurable it has a Lebesgue integral, the value of which is readily seen to equal zero. Thus, a function can be discontinuous almost everywhere (except on a set of measure zero) and yet have a Lebesgue integral.

During the first quarter of the 20th century, the notion of the integral was further extended. **Radon** *(1913) invented an integral transform that bears his name. His transform embraces both the Stieltjes and Lebesgue's integral and is in fact known as the Lebesgue-Stieltjes integral. The generalizations cover not only broader or different notions of integrals on point sets of n-dimensional Euclidean spaces but even domains in more general spaces such as spaces of functions. The applications of these more general concepts are now found in the theory of probability and stochastic processes, statistical mechanics, quantum mechanics and quantum field theory, ergodic theory, spectral theory, and harmonic analysis (generalized Fourier analysis).*

Genetics and Evolution (1901–1909)

The theory of evolution did not arise fully formed in 1859. *Of course neither Wallace nor Darwin knew exactly how isolation and heredity could create new species, because they did not know genetics*[90]. *Modern evolutionists con-*

[90] Only in the 1940s, as the nature of the gene was becoming clear could Harvard biologist **Ernst Mayr** offer an explanation: a new species is a result of some change in the environment that splits the population. The sudden rise of a mountain, a prolonged climatic change, the shift of a river — any of these will suffice. If the two groups are kept apart for a sufficiently long time, unable to breed with each other, natural selection and random mutations will force their gene pools to diverge. If the old barrier to the two populations then drops and the organisms mingle again, they might no longer be able to interbreed because their genes are no longer compatible (or their interbreeding might result in sterile individuals). They have become two species.

tinue to improve on **Darwin** *and* **Wallace***:* **Hugo Marie de Vries** *(1848–1935, Holland), a Dutch botanist, discovered mutations and pointed out the importance of mutations in the process of evolution (1900). Shortly thereafter (1903) it was recognized that chromosomes, minute threadlike structures in the cell nucleus, are the carriers of hereditary characteristics. This discovery, which also showed a linkage of characteristics that* **Mendel** *had not suspected, was made independently by* **Walter Stanborough Sutton** *(1877–1916, U.S.A.),* **Theodor Boveri** *(1862–1905, Germany), and* **Thomas Hunt Morgan** *(1866–1945, U.S.A.).*

Finally, in 1909, **Wilhelm Ludvig Johannsen** *(1857–1927, Holland), a plant physiologist, discovered the unit of heredity — the gene — and coined the terms genotype and phenotype. The particular combination of genes that an organism has – is called its genotype (genos = race, kind). An organism's genotype represents the actual genes that are present in the cells. The effect caused in the organism by these genes is called its phenotype (pheno = to show).*

The word phenotype refers to what you can see [e.g. the genotype of a pure tall plant is TT; its phenotype is tall. The genotype of a pure short plant is tt; its phenotype is short. The genotype of an F_1 pea plant is Tt; its phenotype is tall. In such a plant the dominant trait appears, or is expressed. The recessive trait is hidden. Thus the phenotype tall can result from two different genotypes, TT or Tt. Plants pure for tallness have two T genes. When both genes of the pair are the same, the organism is said to be homozygous for that trait. An organism may be homozygous dominant or homozygous recessive.

If the paired genes are not the same, the organism is heterozygous for that trait. Heterozygous organisms are also called hybrid. Plants that have the mixed genotype Tt are heterozygous (or hybrid) tall.

Genes that have contrasting effects on a characteristic are called alleles. Tallness (T) and shortness (t) are alleles. Genes that have more than two alleles are said to have multiple alleles (e.g. genes for blood type in humans have 3 alleles). However, an individual can have only 2 alleles for a particular characteristic, even when the gene has more than 2 alleles. An individual inherits just 2 alleles, one from each parent, for each paired gene location on its chromosomes.

Over the generations, the gene pool of a population (i.e. the total genetic material) changes. A gene pool changes when the frequency of the alleles in the gene pool change. Allele frequency is the term used to describe how often a particular allele occur in a population.

Evolution by natural selection depends on the genetic makeup of an organism. If a trait is determined by genes, then when a trait is selected, the genes *for it are also selected. The frequency of traits in a population is determined simply by observing the members of the population.*

In 1908, **G.H. Hardy** *(1877–1947) and* **W. Weinberg** *(1862–1937) discovered independently the mathematical result that in a sexually-reproducing population the frequency of the allele does not change if:*

- *mating is random*
- *mutations do not occur*
- *there is no immigration or emigration*
- *the population is large and the allele frequencies are high (to prevent genetic drift, i.e. random changes in gene pool).*

Under these ideal conditions, the allele frequencies are related to trait frequencies through an algebraic equation. The conclusion is known as the Hardy-Weinberg principle and implies that under the above conditions evolution does not occur.

Random mating means that there is no preference shown for any particular phenotype when mating [e.g. an individual that is Aa is not preferred over an aa individual].

Mutations are changes in the genetic material. When mutations occur in reproductive cells, they can be inherited. Gene mutations introduce new alleles into a population and are the main source of genetic variation. The rate is generally very low in any population, but its effects may be amplified by natural selection.

Migration, the movement of organisms from one location to another, allows for evolutionary change in two ways. First, it causes gene flow in or out of a population and consequently the appearance of new traits. Since some traits may be beneficial for survival in the new environment, gene combinations that cause these traits would persist or even be preferentially enhanced in succeeding generations, thus changing their frequency in the gene pool. In small populations, random events may drastically affect gene frequencies even in the absence of migration or mutations and cause genetic drift.

The Hardy-Weinberg principle is important in understanding evolution because it implies that reproduction by itself does not lead to evolutionary change in large populations. However, changes in the conditions listed above will result in changes in the gene pool and thus cause evolution. Since the rigid conditions required for the operation of the Hardy-Weinberg principle are probably never met in the real world, one mathematically expects evolution to occur.

Natural selection is probably the most important factor in changing gene pools. When environmental conditions favor a particular trait, the frequency of the alleles that produce that trait will tend to increase in the next generation. If the environment does not favor a particular trait, the frequency of its alleles will tend to decrease. Thus, natural selection can lead to the formation of new species and the extinction of old ones.

1901–1912 CE **Wilhelm Weinberg** (1862–1937, Germany). Physician and founder of *population genetics*. Discovered in 1908 (independently of G.H. Hardy and slightly ahead of him) the equilibrium law of monohybrid populations[91] and the varied processes of attainment of equilibria in polyhybrid population. In his studies of population genetics, Weinberg's derivations of the correlation between relatives expected under Mendelian heredity took into account both genetic and environmental factors: he was the first to partition the total variance of phenotypes into genetic and environmental components. He was also first to construct morbidity tables modeled after the long-known mortality tables.

Weinberg was born to a Jewish father and a Protestant mother. He studied medicine at the Universities of Tübingen and Münich and obtained his Ph.D. in 1886. After clinical experience in Berlin, Vienna and Frankfurt he established himself in Stuttgart as a general practitioner and obstetrician (1889).

[91] *Hardy-Weinberg principle*. In the absence of mutation and selection, the frequencies of genés allele in any large, randomly mating population will reach an equilibrium distribution in one generation and remain in equilibrium thereafter regardless of whether the alleles are dominant or recessive. Let A and a be two different alleles that are passed down in the population from one generation to the next in a given gene (in standard Mendelian notation, 'A' is dominant and 'a' is recessive). A given individual could then have one of the three combinations AA, Aa or aa. Let mating be random and let all three combinations have an equal likelihood of surviving to produce offsprings. If p and $q = 1 - p$ be the relative frequencies of A and a respectively in the population, the three genotypes AA, Aa and aa, occur with relative frequencies p^2, $2pq$, q^2, respectively. The proportions $p^2 : 2pq : q^2$ are reached already in a single generation of random mating, and are kept stable for all successive generations as long as the basic assumptions underlying the process do not change.

When there is no alternative way to ascertain whether mating is random, the Hardy-Weinberg ratio becomes a useful criterion for random mating.

For 42 years he had a large private practice and also acted in public capacities as physician to the poor. He attended more than 3500 births, including more than 120 twin births. He thus came to be interested in the incidence of monozygotic and dizygotic twin births in his statistical data (1901). He proceeded to discover differences between mono- and dizygotic twins in a variety of traits, including the inheritance of a twinning tendency for dizygotic but not for monozygotic twins.

When Weinberg became aware of Mendelism he asked himself "how would different laws of inheritance influence the composition of the relatives of given individuals". This eventually led him to the Hardy-Weinberg law. Weinberg had no personal collaborators or students. Only in his later years did a new generation begin to explore his field of research.

1901–1928 CE **Roald Amundsen** (1872–1928, Norway). Polar explorer. First to navigate and chart the *Northwest passage* and to fix the position of the *North Magnetic Pole* (1903–1905); First to reach the *South Pole* (Dec 14, 1911). Flew across the North Pole with **Lincoln Ellsworth** and **Umberto Nobile** (1926); Disappeared on flight to rescue Nobile who was lost returning from the North Pole.

Author of *North West Passage* (1908); *The South Pole* (1912); *The North East Passage* (1918–1920); *Our Polar Flight* (1925); *First Crossing of the Polar Sea* (1927); *My Life as an Explorer* (1927).

Amundsen was born at Borge, a village near Oslo to a family of Viking ancestry. From boyhood days his life was singularly purposeful — he wished to be a polar explorer. Like Fridjof Nansen before him he devoted a great deal of time to training and strengthening his physique to be ready for the hazardous adventures he was determined to undertake. He bowed however to his mother's wish that he study medicine. But at the age of 21, when both his parents died, Roald Amundsen sold his medical textbooks, packed away the cranium he had studied and announced his intention of becoming a polar explorer.

From his painstaking study of polar expedition literature, Amundsen had learned their inability to captain a vessel. Consequently he went to sea (1894) aboard a sealing vessel, gaining his master's ticket commanding the "*Belgica*" expedition to Antarctica (1897–1899). His next project was to head an arctic expedition, in search of the sea route north of the North American Continent (so-called *Northwest Passage*). His scientific goal was to reach the *magnetic north pole*. He therefore left for Hamburg, where he studied earth magnetism, and at the same time laid meticulous plans for his expedition.

He set out from Christiana (now Oslo) in June 1903 on board the *Gjoa*. For two years the expedition stayed on King William Island, studying the polar magnetic field and learning the Eskimos' way of life (clothing, food, customs, dog-team transportation, etc.). In October 1905 he traveled 800 km with dog-teams across the ice to Eagle City in Alaska to tell the world of the expedition's achievement. While making plans to drift with Nansen's *Fram* with the ice from Siberia toward the North Pole, he changed his plans (1910) and won the race to the South Pole, beating **Robert Falcon Scott** to it.

Amundsen's victory in the race for the South Pole by no means satisfied his desire to reach new goals. On his return from Antarctica, he immediately set preparations in motion for a new expedition. The Arctic was still Amundsen's first love, and he aimed to explore its remaining unknown areas and to repeat Nansen's attempt to drift over the Pole. WWI delayed the execution of the plan, but in June 1918 the expedition left Norway. The "Fram" was no longer seaworthy, so Amundsen designed his own ship, the "Maud", christening it — characteristically enough — not with champagne, but with a block of ice.

The "Maud" expedition, loaded with apparata for oceanographic, meteorological and earth-magnetism measurements, was the biggest and best equipped geophysical expedition ever to have embarked on a polar exploration. But the project was to bring one disappointment after another.

Sailing into the Arctic, the ship froze into the coastal ice and lay helpless for the two first winters. It soon needed extensive repairs. These were carried out in Seattle where the "Maud" was equipped for more years in the ice. In June of 1922 the ship again moved north, only to freeze fast by Wrangel Island, on the far northeast of the USSR.

The ship moved with the ice onto the continental shelf off northeastern Siberia, where it remained for three years.

The ambitious expedition had failed to attain its geographical goals, but the geophysical data which was compiled, largely by meteorologist/oceanographer **Harald Ulrik Sverdrup**, earned the "Maud" expedition the reputation of being one of the most important research projects ever carried out in the Arctic.

In May 1926 Amundsen left Spitsbergen aboard the airship *Norge*. With him were Lincoln Ellsworth, the Italian Umberto Nobile — who had constructed the vessel and flew it — and the pilot Hjalmar Riiser-Larsen, who served as navigator. In addition there was a crew of 12.

After a flight of only 16 hours, the men were able to drop the Norwegian, American and Italian flags over the North Pole. On 14 May the "Norge" landed at Teller in Alaska. The crew had covered 5,456 kilometers in 72 hours, and were the first men to have flown from Europe to America. The route of the "Norge" had been plotted right across unknown polar territory, and Amundsen was able to state that there were no land areas there. The last remaining blank on the world map had been filled in.

The acclaim of the world reached new heights. In the USA and Japan in particular, his name was especially revered. But the period was saddened by an unfortunate enmity that had arisen between Amundsen and Umberto Nobile, who tried to detract from Amundsen's part in the "Norge" flight, while Amundsen criticized the airship.

Nevertheless, he showed his magnanimity to the full when the news came in May, 1928 that Nobile's new airship, the "Italia" had crashed in the Arctic.

Without hesitation Amundsen volunteered to take part in a rescue attempt, and in June he was one of the six men who took off from the town of Tromsø in a French aircraft, the Latham. Nobile and his crew were rescued on 22 June. But three hours after Amundsen's plane took off it transmitted what were to be its final signals. The aircraft never returned.

In a letter, describing his reactions at the time he reached the South Pole on Dec 14, 1911, Amundsen openly confessed that "*no man has ever stood at the spot so diametrically opposed to the object of his real desires*". For Amundsen, the man who went where none have gone before, a new goal always beckoned. He himself described his life as a "*contest journey towards the final destination.*"

1901–1935 CE **Issai Schur** (1875–1941, Germany and Israel). Mathematician. Contributed to number theory and algebra. Laid the foundations to the theory of linear representations of groups. Extended finite group theory to compact groups. Named after him are: *Schur's canonical form* (triangular matrices), *Schur index*, '*S-functions*', *Schur's inequality*, *Schur's lemma* (irreducible matrices) and *Schur-Toeplitz theorem*[92].

Schur was born in Mohilev, the Ukraine, and was educated at the University of Berlin (1894–1901). He was a pupil of **Frobenius**. In 1920 he was appointed a professor of mathematics in Berlin, but was forced to relinquish his position in 1935 because of the Nazi race laws. Schur came to Israel in 1939, and died in Tel-Aviv.

1901–1940 CE **Karl Landsteiner** (1868–1943, Austria-Hungary and U.S.A.). Immunologist and pathologist. Elucidated the fundamental basis of immunological processes. One of the founders of *immunochemistry* and the discoverer of the basic blood types. Defined the relationships between *antibody* and *antigen* with chemical precision. Awarded (1930) the Nobel prize for physiology or medicine for the discovery of the blood groups.

---

[92] A matrix is unitarily similar to a diagonal matrix iff it is normal.

Discovered (1901) the A, B, O human blood types, the ABO classification, and showed that there are also many subsidiary groupings (1927), one of which, Rh (Rhesus) is important in the aetiology of hemolytic disease of the newborn (1940). This discovery made possible the development of safe blood transfusions. It also provided useful techniques for establishing paternity and for genetic studies on the origins of human populations. Discovered (1908) that a virus causes poliomyelitis.

Landsteiner explored and defined the various types of immune response and was the first to realize that allergies have an immunological basis. In 1927 he reported (with **Philip Levine**) the discovery of the M and N *agglutinogens*.

Landsteiner was born in Vienna to Jewish parents[93]. After graduating in medicine (1891) he studied chemistry under **Emil Hermann Fischer**. In 1898 he returned to Vienna to begin the lifelong studies which were to transform the science of immunology and greatly increase our understanding of the body's mechanism for protection against disease. From 1909 he was a professor of pathological anatomy, but in 1922 he fled the chaos of postwar Vienna and eventually reached the U.S.A. to join the Rockefeller Institute in New York (1922–1929).

1902 CE, May 08, 07:52 LT Eruption of *Mont Pelée* on the Island of Martinique destroyed the Caribbean coastal town of St. Pierre, and all but two of its 28,000 inhabitants perished within minutes by a *nuée ardente*[94]. The hot-gas hurricane avalanche plunged down the slopes at a speed of about 100 km/h and engulfed the town with a searing 800 °C emulsion of gas, glass and dust. The gas was mostly CO_2. The city was burned to ashes by a *fire storm*, similar to that which occurred in several German cities during WWII and the atomic destruction of Hiroshima (and perhaps the *fire and brimstone* of Sodom and Gomorrah!).

---

[93] **Landsteiner** filed an injunction to prevent his inclusion in *Who's Who in American Jewry*. He explained:
"It will be detrimental to me to emphasize publicly the religion of my ancestors, first as a matter of convenience, and, secondly, I want nothing in the slightest degree to cause any mental anguish, pain, or suffering to any members of my family. My son is now nineteen years old and he has no suspicion that any of his ancestors were Jewish."

[94] Hot ash and dust fragments and gases are ejected in a glowing cloud that runs downhill with amazing speed. The solid particles are actually buoyed up by the hot gases, so that there is little frictional resistance to this incandescent, fluidized avalanche. It is a silent and swift killer. **Frank Alvord Perret** (1867–1943, U.S.A.) made extensive observations of hundreds of *nuées ardentes* at close quartes since 1902, and provided the basis for much of the later work in this field.

It is sobering to scientists who render advice to others to recall the statement of Professor Landes of St. Pierre College, issued a day before the cataclysm: "*The Montagne Pelée presents no more danger to the inhabitants of Saint Pierre than does Vesuvius to those of Naples*". Professor Landes perished with the others.

1902–1903 CE **Walter Stanborough Sutton** (1877–1916, USA). Physician and geneticist. Provided first conclusive evidence that chromosomes carry units of inheritance and occur in distinct pairs. His work formed the basis for the chromosomal theory of *heredity*.

He suggested that Mendel's "factors" are located on chromosomes. After observing chromosomal movements during meiosis, Sutton developed the chromosomal theory of heredity. He noticed that chromosomes occur as pairs, and that gametes (egg and sperm cells) receive only one chromosomes from each pair when they form during meiosis. This corroborated Mendel's theory that the genetic "factors" were segregated. Sutton gave Mendel's "factors" the name we use today: "genes".

In 1903 Sutton [and independently **Theodor Boveri** (1862–1915, Germany) proposed that each egg or sperm cell contains only one of each chromosomes pair. This connected two phenomena: the patterns by which pairs of Mendel's factors assort themselves and the precisely similar sorting and recombination of the chromosomes in the formation of the germ cells and the fertilization of the egg.

Sutton was born in Utica, NY. Had private surgical practice in Kansas city.

1902 CE **Luigi Bianchi** (1856–1928, Italy). Mathematician. Obtained cyclic relations between the covariant derivatives of Riemann's symbols. These identities have proven to be of the greatest importance for subsequent researches, both in differential geometry and relativity. In any space with an affine connection, not necessarily Riemannian, one can define the Riemann curvature tensor. The Bianchi identity is then a differential relation satisfied by the Riemann tensor components, their first derivatives and the connection.

These identities can be extended to the curvature on an arbitrary *fiber bundle*, where they take on the simple form[95] $D\Omega = 0$, in the powerful

[95] Starting from the Riemann-Christoffel curvature tensor

$$R^i_{jk\ell} = \Gamma^i_{rk}\Gamma^r_{j\ell} - \Gamma^i_{r\ell}\Gamma^r_{jk} + \frac{\partial \Gamma^i_{j\ell}}{\partial x^k} - \frac{\partial \Gamma^i_{jk}}{\partial x^\ell},$$

we assume that the affine connection Γ^i_{jk} is symmetric in its lower indices and employ geodetic coordinates (in which locally $\Gamma = 0$) at the point being consid-

Cartan notation. The deep significance of the Bianchi identity is its pivotal role in proving the relation between analytical integrals over a manifold and topological indices.

Bianchi was born in Parma and died at Pisa. He studied under **Betti** and **Dini** at the University of Pisa and then continued his studies at Münich and Göttingen under **Klein**. From 1881 onwards he was a professor at Pisa.

In the context of general relativity, the *contracted form* of these identities ensure automatic local energy-momentum conservation in the **Einstein** field equations.

1902–1908 CE **William Maddock Bayliss** (1860–1924, England). Physiologist. With **Ernest Henry Starling** (1866–1927, England), physiologist, found (1902) the first evidence of the existence of *hormones* through their discovery of the digestion hormone *secretin* (secreted by the intestine and activating the pancreas to liberate digestive fluids). Starling used the word *hormone*[96] (1905) to describe secretin and other substances produced in one

---

ered. The covariant derivative of the above expression is then simply

$$R^i_{jk\ell;m} = \frac{\partial R^i_{jk\ell}}{\partial x^m} = \frac{\partial^2 \Gamma^i_{j\ell}}{\partial x^m \partial x^k} - \frac{\partial^2 \Gamma^i_{jk}}{\partial x^m \partial x^\ell},$$

since the Γ^i_{jk} (but not their derivatives necessarily) all vanish at this point. Cyclically permuting the indices k, ℓ, m in the above equation and adding the three resulting equations yields the identity

$$R^i_{jk\ell;m} + R^i_{j\ell m;k} + R^i_{jmk;\ell} = 0.$$

But this is a tensor equation and, having been proved true in the geodetic frame, must be true in all frames. Also, since the chosen point can be any point, it is valid at all points in space (i.e. on the manifold). It is the *Bianchi identity*, and applies not only to affine manifolds but to *fiber bundles*, constructed on a spacetime "base manifold" with a particular symmetry Lie group as the "fiber". In modern *Gauge Theories*, thought to describe all known particle and field interactions, the *vector potentials* constitute the bundle connection, the *field strengths* make up the curvature tensor, and the *Bianchi identity* $D\Omega = 0$ is simply a generalization of the two source-free Maxwell equations in electromagnetism. For an n-dimensional base manifold, the fiber-bundle version of Bianchi's identity reduces to the Riemann-curvature version if the *fiber* is chosen to be the Lie group $GL(n, R)$ of local tangent-space base changes; the resulting fiber bundle is known as the *frame bundle* of the given base manifold.

96 From the Greek *Horman* = to set in motion, to arouse. Name chosen because of the marked stimulating effect of the endocrine secretions on various organs of the body.

part of the body but active elsewhere. Their joint work helped to establish *endocrinology* as a special area of scientific knowledge. Bayliss was the first to describe (1908) the action of hormones and put forward the theory of hormonal control.

Starling was a professor at University College, London (1899–1923). Bayliss taught physiology at the same university (1888–1924).

Hormones

Endocrinology is concerned with the study of the biosynthesis, storage, chemistry, and physiological function of hormones and with the cells of the endocrine glands and tissues that secrete them. In medicine, endocrinology deals with disorders of the endocrine system and its specific secretions, hormones. Most hormones reach their targets via the blood. Although every organ system secretes and responds to hormones (including the brain, lungs, heart, intestine, skin, and the kidney), the clinical specialty of endocrinology focuses primarily on the endocrine organs, meaning the organs whose primary function is hormone secretion. These organs include the pituitary, thyroid, adrenals, ovaries and testes, and pancreas.

All multicellular organisms need coordinating systems to regulate and integrate the function of differentiating cells. Two mechanisms perform this function in higher animals: the nervous system and the endocrine system. The endocrine system acts through the release (generally into the blood) of chemical agents and is vital to the proper development and function of organisms. The integration of developmental events such as proliferation, growth, and differentiation (including histogenesis and organogenesis) and the coordination of metabolism, respiration, excretion, movement, reproduction, and sensory perception depend on chemical cues, substances synthesized and secreted by the specialized cells within the animal.

Hormones serve as a means of communication among various parts of an organism. They act as 'chemical messengers' that help these parts function together in a coordinated way. In plants, hormones regulate many aspects of growth. In man and other animals, hormones control and regulate such important body activities as growth, development, metabolism and reproduction.

Since 1902, more than 30 hormones produced by the human body have been identified, e.g.: insulin, thyroxine, cortisone, testosterone ($C_{19}H_{28}O_2$), estrogen, adrenalin ($C_9H_{13}O_3N$), relaxin. Ways were found of removing hormones from living tissues. The first hormone to ever be synthesized was oxytocin (1954).

Most human hormones are either steroids (sex hormones and the hormones of the adrenal cortex) or contain some form of amino acids. The chemical structure of hormones enable it to combine with a receptor in the cells of its target. The union of the hormone with the receptor triggers a change in the chemical processes of the cell. This change, in turn, modifies many of the hundreds of chemical activities of the cell and cause the target to behave in a certain way.

Hormones are biologically effective in small amounts and are produced by endocrine glands within the body that empty their secretions directly into the lymph and the bloodstream. They can be divided into three classes of compounds: proteins, amino-acid derivatives, and steroids.

Protein type of hormones are produced by the pituitary glands, parathyroid glands, islets of Langerhans and cells of the gastrointensinal tract.

Amino-acid based types are produced by the thyroid glands and the adrenal glands. These hormones unite with receptors on the outer membrane of the target cell and this union may change the structure of the cell membrane, allowing certain substances to enter or leave the cell. These substances alter the chemical activities of the cell. In other cases, the union seems to influence the activities of enzymes located on the membrane.

Steroid types of hormones are produced by the testes, ovaries, placenta, corpus luteum, and adrenal cortex. These hormones become attached to receptors and then enter the nucleus of the target cell. In the nucleus, the hormone affects the activity of the genes.[97]

---

[97] An estimated 1 million people in the United States, half of them adolescents, abuse anabolic steroids, a group of synthetic hormones. Anabolic steroids are synthetic androgens (male reproductive hormones) that were developed in the 1930s to prevent muscle atrophy in patients with diseases that prevented them from moving about. In the 1950s, anabolic steroids became popular with professional athletes, who used them to increase muscle mass, physical strength, endurance, and aggressiveness. In truth, their athletic performance was probably enhanced, at least in part, by drug-induced euphoria and increased enthusiasm for training.

As with other hormones, the concentration of steroids circulating in the body is precisely regulated, so use of anabolic steroids interferes with normal physiological processes. Even during short-term use and at relatively low doses, anabolic

If an organism fails to produce the proper kind or amount of hormones, serious disturbances may result[98].

steroids have a significant effect on mood and behavior. At higher doses, users experience disturbed thought processes, forgetfulness, and confusion, and often find themselves easily distracted. The term “steroid rage” refers to the mood swings, unpredictable anger, increased aggressiveness, and irrational behavior exhibited by many users.

Anabolic steroids elevate blood pressure, damage the liver, and increase low-density lipoprotein (LDL) concentration, raising the risk of cardiovascular disease. In adolescents, these steroids cause severe acne and stunt growth by premature closing the growth plates in bones. Abuse of these hormones reduces sexual function and can shrink the testes, leading to sterility. These drugs remain in the body for a long time. Their metabolites (breakdown products) can be detected in the urine for up to six months.

When their serious side effects became known in the 1960s, anabolic steroid use became controversial, and in 1973 the Olympic Committee banned their use. They are now prohibited worldwide by amateur and professional sports organizations. However, according to the U.S. Drug Enforcement Administration, a multimillion-dollar black market exists for these synthetic hormones. They are both injected and taken in pill form. Steroid abusers who share needles or use nonsterile techniques when they inject steroids are at risk for contracting hepatitis, HIV, and other serious infections.

The typical anabolic steroid user is a male (95%) athlete (65%), most often a football player, weight lifter, or wrestler. Surprisingly, though, about 10% of male high school students have used anabolic steroids and about one third of these students are not even on a high school team. These adolescents use the hormone only to change their physical appearance — to pump up their muscles (“bulk up”) — and increase endurance. Many anabolic steroid users have difficulty realistically perceiving their body images. They remain unhappy even after dramatic increases in muscle mass.

People also abuse other hormones, including human growth hormone (GH) and erythropoietin. Human growth hormone, like anabolic steroids, helps build muscle mass but also causes acromegaly. Erythropoietin increases the concentration of red blood cells. Although increased oxygen transport enhances the performance of an endurance athlete up to 10%, abnormally high concentrations of red blood cells can cause serious cardiovascular problems. Erythropoietin abuse has caused the deaths of several athletes.

[98] In primitive men, dysfunction of their hormones resulted in disturbed behavior that was sometimes interpreted by their tribesmen as a manifestation of supernatural powers; perhaps such primitive man merely had a severe hyperthyroid condition, causing his eyeballs to bulge so strangely. His sometimes rapid, excitable speech may have given the impression that he was ‘communicating’ with

The hormone concept consolidated earlier anatomical, physiological and clinical observations: 17^{th} century anatomists [e.g., **Marcello Malpighi** *(1628–1694, Italy);* **Thomas Wharton** *(1614–1673, England)] had been fascinated by the 'glands' (pancreas, thyroid, parotid, ovaries, etc.), postulating various physiological roles.*

The study of endocrinology began when ***A.A. Berthold*** *(1812–1886) noted (1849) that castrated cockerels did not develop combs and wattles or exhibit overtly male behavior. He found that replacement of testes back into the abdominal cavity of the same bird or another castrated bird resulted in normal behavioral and morphological development, and he concluded (erroneously) that the testes secreted a substance that "conditioned" the blood that, in turn, acted on the body of the cockerel. In fact, one of two other things could have been true: that the testes modified or activated a constituent of the blood or that the testes removed an inhibitory factor from the blood. It was not proven that the testes released a substance that engenders male characteristics until it was shown that the extract of testes could replace their function in castrated animals.*

The concept of internal secretion developed in the 19^{th} century; ***Claude Bernard*** *described it in 1855, but did not specifically address the possibility of secretions of one organ acting as messengers to others. Still, various endocrine conditions were recognized and even treated adequately (e.g., hypothyroidism with extract of thyroid glands).*

Hermann Boerhaave *(1668–1739, Holland) elaborated mechanical models of secretion. Glands' secretions were firmly implicated in disease by 19^{th} century clinicians.*

In 1894, **Edward Albert Sharpey-Schäfer** *(1850–1935, England) and* **George Oliver** *(1841–1915, England) identified a physiologically active substance called* adrenaline*, secreted by the adrenal medulla.*

Many of the hormones' metabolic effects have been elucidated. Some have been synthesized and replacement therapy is frequently possible in cases of insufficiency.

---

unseen spirits, and he would consequently be allowed to take over the role of the witch doctor. Sometimes a disturbance of the pituitary glands would result in either giantism or dwarfism, through which an individual could convince others of his special 'powers'.

The Insulin Story – or, the Nobel Committee goofs again

In 1869 ***Paul Langerhans****, a medical student in Berlin, was studying the structure of the pancreas under a microscope when he noticed some previously unidentified cells scattered in the exocrine tissue. The function of the "little heaps of cells," later known as the* Islets of Langerhans*, was unknown, but* ***Edouard Laguesse*** *later suggested that they may produce a secretion that plays a regulatory role in digestion.*

In 1889, the physician ***Oscar Minkowski*** *in collaboration with Joseph von Mehring removed the pancreas from a healthy dog to demonstrate this assumed role in digestion. Several days after the dog's pancreas was removed, Minkowski's animal keeper noticed a swarm of flies feeding on the dog's urine. On testing the urine they found that there was sugar in the dog's urine, demonstrating for the first time a relationship between the pancreas and diabetes. In 1901, another major step was taken by* ***Eugene Opie****, when he clearly established the link between the Islets of Langerhans and diabetes: Diabetes mellitus is caused by destruction of the islets of Langerhans and occurs only when these bodies are in part or wholly destroyed. Before this demonstration, the link between the pancreas and diabetes was clear, but not the specific role of the Islets.*

Over the next two decades, several attempts were made to isolate the secretion of the Islets as a potential treatment. In 1906 ***George Ludwig Zuelzer*** *was partially successful treating dogs with pancreatic extract, but was unable to continue his work. Between 1911 and 1912,* ***E.L. Scott*** *at the University of Chicago used aqueous pancreatic extracts and noted a slight diminution of glycosuria, but was unable to convince his director and the research was shut down.* ***Israel Kleiner*** *demonstrated similar effects at Rockefeller University in 1919, but his work was interrupted by World War I and he was unable to return to it.* ***Nicolae Paulescu****, a professor of physiology at the Romanian School of Medicine, published similar work in 1921 that was carried out in France and patented in Romania, and it has been argued ever since that he is the rightful discoverer.*

However, the Nobel Prize committee in 1923 credited the practical extraction of insulin to a team at the University of Toronto. In October 1920, ***Frederick Banting*** *was reading one of Minkowski's papers and concluded that it is the very digestive secretions that Minkowski had originally studied that were breaking down the Islet secretion(s), thereby making it impossible to extract successfully. He jotted a note to himself: Ligate pancreatic ducts* *of the dog. Keep dogs alive till acini degenerate leaving Islets. Try to isolate internal secretion of these and relieve glycosurea.*

*He traveled to Toronto to meet with **J.J.R. Macleod**, who was not entirely impressed with his idea. Nevertheless, he supplied Banting with a lab at the University, an assistant (medical student **Charles Best**), and ten dogs, while he left on vacation during the summer of 1921. Their method was tying a ligature (string) around the pancreatic duct, and, when examined several weeks later, the pancreatic digestive cells had died and been absorbed by the immune system, leaving thousands of Islets. They then isolated the protein from these Islets to produce what they called* isletin. *Banting and Best were then able to keep a pancreatectomized dog alive all summer.*

*Macleod saw the value of the research on his return from Europe, but demanded a re-run to prove the method actually worked. Several weeks later it was clear the second run was also a success, and he helped publish their results privately in Toronto that November. However, they needed six weeks to extract the isletin, dramatically slowing testing. Banting suggested that they try to use fetal calf pancreas, which had not yet developed digestive glands; he was relieved to find that this method worked well. With the supply problem solved, the next major effort was to purify the extract. In December 1921, Macleod invited the biochemist **James Collip** to help with this task, and, within a month, the team felt ready for a clinical test.*

On January 11, 1922, Leonard Thompson, a fourteen-year-old diabetic, was given the first injection of insulin. However, the extract was so impure that he suffered a severe allergic reaction, and further injections were canceled. Over the next 12 days, Collip worked day and night to improve the extract, and a second dose injected on the 23rd. This was completely successful, not only in not having obvious side-effects, but in completely eliminating the symptoms of diabetes. However, Banting and Best never worked well with Collip, regarding him as something of an interloper, and Collip left the project soon after.

*Over the spring of 1922, Best managed to improve his techniques to the point where large quantities of insulin could be extracted on demand, but the extract remained impure. However, they had been approached by **Eli Lilly** with an offer of help shortly after their first publications in 1921, and they took Lilly up on the offer in April. In November, Lilly made a major breakthrough, and they were able to produce large quantities of purer insulin. Insulin was offered for sale shortly thereafter.*

Macleod and Banting were awarded the Nobel Prize in Physiology or Medicine in 1923 for the discovery of insulin. Banting, insulted that Best was not mentioned, shared his prize with Best, and Macleod immediately shared his with Collip. The patent for insulin was sold to the University of Toronto *for one dollar. The exact sequence of amino acids comprising the insulin molecule, the so-called primary structure, was determined by British molecular biologist* ***Frederick Sanger****. It was the first protein to have its structure be completely determined. He was awarded the Nobel Prize in Chemistry in 1958. In 1967, after decades of work,* ***Dorothy Crowfoot Hodgkin*** *determined the spatial configuration of the molecule, by means of X-ray diffraction studies. She had been awarded a Nobel Prize in Chemistry in 1964 for the development of crystallography.* ***Rosalyn Sussman Yalow*** *received the 1977 Nobel Prize in Medicine for the development of the* radioimmunoassay *for insulin.*

1902–1909 CE **Archibald Edward Garrod** (1857–1936, England). Physician and biochemical geneticist. Pioneered the study of inherited human metabolic diseases and first to link it to genetic causes (1908). Recognized that gene products are proteins and that a gene is a recipe for a single chemical. Proposed the mode of action of the hereditary substance known as '*one gene-one enzyme*'[99] (1902). By this it is meant that every gene acts by initiating the synthesis of an enzyme which catalyzes a specific reaction.

Professor at Oxford (1920–1928).

1902–1911 CE **Willis Haviland Carrier** (1876–1950, USA). Engineer and inventor. Designed the first scientific system to clean, circulate, and control the temperature and humidity of air (1902). He developed the first safe, low pressure centrifugal refrigeration machine using nontoxic, nonflammable refrigerant.

Born near Angola in western New York, Carrier attended Cornell University, graduating in 1901. He formed (1915) the Carrier Engineering Corporation. By controlling humidity as well as temperature, he invented *air conditioning*[100] as we know it today.

---

99 The idea was not developed, however, until the introduction of the genetic analysis of the lower organisms and of techniques of mutagenesis. When in the 1960's the relation between *gene and enzyme* was analyzed at the molecular level, it became clear that the *one gene-one enzyme* hypothesis needed to be replaced by *one gene-one polypeptide chain*. At any rate, Garrod was far ahead of his time.

100 The term "*air conditioning*" was used for the first time by **Stuart W. Cramer**, a textile engineer from Charlotte, N.C. It became a recognized branch of engineering in 1911.

1903 CE **Hantaro Nagaoka** (1865–1950, Japan). Theoretical physicist. Postulated an atomic model in which electrons revolve around a positive charged nucleus, ahead of Rutherford[101] (1871–1937).

Nagaoka adopted his idea from Maxwell's paper (1859) on the stability of motion of *Saturnian rings*. His atomic model consists of a central attracting mass surrounded by rings of revolving electrons. The model was soon rejected because of its mechanical instability[102]. By 1911, however, quantum effects had brought physicists to believe that ordinary mechanics and electrodynamics could not describe the behavior of atoms. In 1913, **Niels Bohr** (1885–1962) quantized the Nagaoka-Rutherford atom, restricting the electrons to paths in which the ratio of their kinetic energy to their orbital frequency equals a multiple of Planck's constant.

1903–1913 CE **Willem Einthoven** (1860–1927, Holland). Dutch physiologist. Discoverer of the electrical properties of the heart and the founder of electrocardiography[103]. In 1903 he invented his famous string galvanometer, with which he was able to measure changes of electrical potential caused by contractions of the heart's muscle. On this basis he developed, during 1908–1913, the graphical diagnostics of cardiopathology. He received the 1924 Nobel prize for his investigations of the electrical currents of the heart.

Einthoven was born in Semarang, Java. His family moved to the Netherlands in 1870. He studied at the University of Utrecht and became a professor of physiology at the University of Leyden, in 1885.

1903–1964 CE **Waclaw Sierpinski** (1882–1969, Poland). Mathematician. Made important contributions to set theory and number theory. His

---

[101] Rutherford's biographers agree that Rutherford was unaware of Nagaoka's paper until March 11, 1911. But Nagaoka *did* visit him at Manchester sometime prior to July 1910.

[102] The rings of Saturn are stable because the force operating between the particles of debris that make them up is *attractive*. In Nagaoka's model, the force operating between the electrons is *repulsive*.

[103] The first *electrocardiogram*, however, was obtained earlier by the physiologist **Augustus D. Waller** (1856–1922) in 1887. He reported: "I dipped my right hand and my left foot into a couple of basins, ... which were connected with the two poles of the electrometer, and at once had the pleasure of seeing the mercury column pulsate." This pulsating mercury recorded the heart's electrical tracings via a light beam that then created an image on photographic plates being carried by a toy train and thus provided the first noninvasive procedure to examine the heart.

contributions to number theory (e.g. in the theory of equipartitions) were continued and developed by **G.H. Hardy**, **E. Landau** and **H. Weyl**. His many papers (ca 700) contain new and important theorems (some of which bear his name), geometrical constructions (*Sierpinski curves*[104]), and original and improved proofs of earlier theorems. His findings stimulated further research by mathematicians throughout the world.

Sierpinski was educated at the University of Warsaw during 1900–1904 under the guidance of **G. Voronoi**. He lectured at the University of Lvov until 1914 and then, after WWI, at the University of Warsaw, where he established with others the Polish School of Mathematics.

Birth of Cinematography (1883–1903)

The idea of portraying things in motion has interested man since earliest times. In painting in Altamira Cave in Spain, prehistoric artists tried to show animals running by painting them with many legs. Ancient Egyptian and Greek bas-reliefs portray figures in the act of moving.

*About 65 BCE, the Roman poet **Lucretius** discovered the principle of persistence of vision*[105]*. About 200 years later, the astronomer **Ptolemy of Alexandria** experimentally proved the principle.*

---

104 In todays terminology these are the *triadic Sierpinski carpet* (with fractal dimension $D = 1.8928$), *Sierpinski gasket* and *Sierpinski arrowhead*.

105 When light falls on the retina, a chemical change takes place in its tissues, which is manifested by a change in color in the retinal pigment or *visual purple*. How this chemical change gives rise to the sensation of light is not known. Immediately after being affected by light, the retina loses its power of vision at the region excited, owing to the chemical change in the visual purple. The brain does not see a light until about $\frac{1}{10}$ sec after the light is turned *on*. The image *persists* (lasts) about $\frac{1}{10}$ sec after the light is turned *off*. This persistence of the visual image explains why a glowing matchstick seems to leave a trail behind it when thrown away in the dark. A motion-picture projector throws about 24 still pictures on the screen in a second, but we see a continuous movement. Each picture on the screen is presented to the eye before the previous image in the brain fades out.

In 1798, the Belgian physicist **Etienne Gaspard Roberts** *developed a sophisticated version of the* Magic Lantern *which he called* phantascope, *presenting shows to the public.*

During the 1800's many men experimented with devices that would make pictures appear to move. However, a scientific study of the optical appearances of moving objects had began in 1824 with the rediscovery of the persistence of vision by the physician **Peter Mark Roget**[106] *(1779–1869, England). Roget's paper, presented before the Royal Society, inspired several scientists to engage in experimental research, among them the Belgian physicist* **J.A.F. Plateau**.

In 1832, Plateau discovered a method for viewing a series of pictures, representing phases of motion. The pictures were mounted in chronological sequence on the rim of a disc and were observed through slots in a similar disc mounted on the same rotating shaft. The pictures, antedating photography, were necessarily drawings of assumed phases of motion. **Franz von Uchatius** *(1811–1881), an Austrian artillery officer, in 1853, combined the disc device with the magic lantern and projected the pictures upon a screen.*

In 1860 **Coleman Sellers**, *a mechanical engineer, in Philadelphia, made the first known endeavor to harness photography to the recording of motion. He posed his sons in a series of photographs showing them, in successive phases of a cycle of action, driving a nail into a box. The photographs were mounted on the blades of a paddle wheel, which when revolved from a given point of view produced the illusion of motion. The Machine was patented as the* kinematoscope *in 1861. However, photography at that time required exposures so long that a true record of motion was not possible.*

The first successful photography of motion *was made in 1872 by the San Francisco photographer* **Eadweard Muybridge** *(1830–1904), who recorded the progressive motion of race-horses through the use of a series of coordinated cameras [he set 24 cameras in a row, with strings stretched across the race track to the shutter of each camera. When the horse ran by, it broke each string in succession, tripping the shutters]. His experiments were carried out at the ranch of* **Leland Stanford** *— the future site of the campus of Stanford University.*

---

106 **Roget** was a physician and philologist, remembered for his *Thesaurus of English Words and Phrases* (1852) — a comprehensive classification of synonyms or verbal equivalents that is still popular in modern editions. He studied medicine at the University of Edinburgh and later helped found the medical school at Manchester. From 1808 to 1840 he practiced in London.

During the late 1800*'s, inventors in France, Great Britain, and the United States tried to find ways to make and project motion pictures. These experimenters included* ***Thomas Armat*** *(1866–1948),* ***Charles F. Jenkins****, and* ***Woodville Latham*** *of the United States;* ***William Friese-Greene*** *and* ***Robert W. Paul*** *(1869–1943) of Great Britain,* ***Charles-Émile Reynaud***[107] *(1844–1918), the brothers* ***Lumière***[108] *of France and* ***Max Skladnowsky*** *(1863–1939) of Germany. After many failures, success came to several pioneers at about the same time.*

The first motion-picture camera was invented in 1887 *by* ***Augustin Le Prince*** *in Leeds, England, after ten years of laborious efforts. However, in lack of a suitable material for projection (a coated celluloid film of sufficient strength), he could not perfect his machine for commercial uses.*

At about the same time, the French physiologist ***Étienne Jules Marey*** *(1830–1904), who was in communication with Muybridge, demonstrated (1888) to the French Academy of Sciences his* chambre chronophotographic*, embodying the essential principles of the cine-camera. His camera, however, was inferior to that of Le Prince and non of his films were projected until ten years later. [Marey is known for his work on the physiology of the heart and circulation, human and animal locomotion and the flight of birds and insects.]*

In 1887 *Thomas A. Edison began work on a device to make pictures appear to move. Influenced by the technological achievements of* ***Le Prince*** *and* ***Marey****, he made some progress in* 1889*, after* ***Hannibal W. Goodwin*** *had developed the transparent nitro-celluloid film base that was tough but flexible such that it could hold a coating, or film, of chemicals sensitive to light (celluloid film first introduced in* 1883 *by* ***John Carbutt*** *of Philadelphia);*

Thus, a series of pictures could be photographed on the film and moved rapidly through a camera. Previously, most photographs were taken on glass

---

[107] This inventor presented (1892) in Paris moving cartoons of animated drawings. One cartoon involved more than 600 painstakingly drawn images on a 45 meter ribbon projected on a permanent background scene. To this end he used two projectors: the animated drawing passed in front of a lens and were then projected off a mirror into the screen. The Lumières saw it and promptly made use of his ideas.

[108] The pioneer motion-picture tycoon **Charles Pathé** (1863–1957, France) acquired the Lumière patents (1902) and by 1912 had established one of the largest film production organizations in the world. He introduced the *newsreel* in France (1909) and shortly after in the USA and Britain. He dominated the world film market during the first years of the 20th century. Before 1918, 60 percent of all films were shot with Pathé.

plates that had to be changed after each exposure. ***George Eastman****, a pioneer in making photographic equipment, manufactured the film.*

Using the Eastman film, Edison's assistant ***William Kennedy Laurie Dickson*** *invented the kinetoscope, a cabinet in which 15 meters of film revolved on spools. A peephole in the cabinet enabled a person to watch the pictures move.*

In 1892, ***Ottomar Anschutz*** *(1846–1907, Prussia) was first to show in public (Europe and USA) moving photographs. In 1894 he projected moving sequences of animals and human figures on large screens. His viewing machines were developed from 1886. The first had a wooden disc with 24 glass positives fixed onto it; a Gessler tube fashioned into a spiral form and powered by a Ruhmkorff induction coil fed from batteries, was the light source. This flashed briefly as each picture passed the viewing aperture.*

Birt Acres *(1854–1918, USA and England) was an inventor who developed (1895) a modified version of Edison's kinetoscope. This was the first amateur Cine Camera. On March 30, 1895 Acres filmed the Oxford-Cambridge boat race and on May 29, 1895 he filmed the Derby.*

Projected on a screen picture at a rate of 40 frames per second, he showed short films of men boxing, a review of the German Emperor, Epsom Downs Derby race, serpentine dancing and the sea breaking against the embankment.

In 1894, the Kinetoscope Parlor was opened in New York City and later that year in London and Paris, including coin-operated kinetoscopes. In spite of its success, ***Edison*** *believed that moving pictures were only of passing interest. However, other inventors disagreed. On Dec. 28, 1895, motion pictures were projected for the first time on a screen in a Paris café by* ***the Lumière brothers****. Some simple scenes, including that of a train arriving at a station, were shown.*

Within few months, 'movies' were being shown in all the major cities of Europe. Edison was quick to adapt to the new situation and using a projector invented by ***Armat****, he presented the first public exhibition of motion pictures projected on a screen in New York City on April 23, 1896. The program included a few scenes from a prize fight, a performance by a dancer, and scenes of waves rolling onto a beach. By 1900, motion pictures had become a popular attraction in music halls, fairs, museums and theaters in many countries.*

Soon, however, spectators became bored, attendance declined, and the motion picture faced extinction. One development saved the movies — they began to tell stories. As early as 1899, the movies received their next impetus *from* ***George Méliès*** *(1861–1938), French magician and theater owner. He saw the movie as a mechanical extension of magical illusion, with which he could achieve effects never before conceived. Within a few years Méliès invented or stumbled upon double exposure, stop motion, fast and slow motion, animation, fades, dissolves, almost the entire repertory of the optical tricks used in film making from that time until the nascence of computer-generated special effects.*

In 1900 *he filmed the old fairy tale Cinderella. Though the film, less than* 350 *meters long, was little more than picture-book illustration, it had a beginning, middle, and end — it told a story. Méliès' imaginative films astonished and delighted movie-goers the world over. He flung himself into the work of writing scenarios, designing and painting scenery, and appearing in his own films. But this versatile and ingenious pioneer was no businessman. In* 1914 *the war ended his career as a producer; in* 1925 *he lost his theater, destroyed all the films in his possession and vanished.*

Edwin S. Porter *— filming for the Edison company in America — was influenced by Méliès and, in* 1903, *made the first motion picture using modern film techniques to tell a story; "The Great Train Robbery", an* 11*-minute Western describing a train robbery and the pursuit and capture of the robbers.*

Porter was perhaps the first director to recognize that a motion picture need not be filmed in the strict sequence of the action. The story switched back and forth between a number of settings, and so Porter realized that it was impractical to shoot the story in sequence. His pioneer work in filming and editing set the standard for directors throughout the world for several years.

In 1904, *Edison made the first attempt to produce a sound moving picture by synchronizing the projector with the phonograph. In 1906,* ***Eugen Augustin Lauste*** *(France) invented the production of sound from photographed vibrations on a film, projected upon a selenium cell. This was a crucial step in the development of the sound motion picture.*

In the mid 1920*'s, Bell Telephone Laboratories finally developed a system that successfully coordinated sound on records with the projector: The era of the silent movie ended in* 1928 *when sound was directly photographed on the film.*

1903 CE, Dec. 17 The brothers **Wilbur** (1867–1912) and **Orville** (1871–1948) **Wright** (U.S.A.). Made the world's first successful flight in a power-driven, heavier-then-air machine which they invented and built.[109]

The flight was made at Kitty Hawk, NC. The plane flew about 40 meters and remained airborne for 12 seconds.

The brothers became interested in aviation after reading about the death of pioneer glider **Otto Lilienthal** in 1896. They experimented with model wings in a small wind tunnel, which they built in their shop, in order to obtain reliable data of air pressure on curved surfaces. Then, in the summer of 1902, they built a glider based on their new figures. This glider had aerodynamic qualities far in advance of any tried before. With it they solved most of the problems of balance in flight. They then made some 1000 glides in this model, before equipping it with an engine. They were so sure of the accuracy of their calculations that they were not surprised when the machine flew.

1903–1911 CE **Carl Neuberg** (1877–1956, Germany, Israel and U.S.A.). Physician, engineer, jurist, chemist, biologist and biochemist. First used the term *Biochemistry* (1903) and founded the first biochemistry journal: *Biochemische Zeitschrift* (1906). Discovered (1911) *carboxylase* in yeast which was the first indication that the energy on the cellular level is essentially supplied by burning *hydrogen* rather then carbon. Made other contributions to the understanding of fermentation.

Neuberg was born in Hanover to a Jewish family. Studied in Berlin and Breslau. Professor at Berlin (1919–1938), Jerusalem (1939–1941), New York (1941–1950), Brooklyn Polytechnic (1951 ff.).

[109] In 1906, *Scientific American* magazine sneered at the "alleged" flights of the Wright brothers. One hundred years later (in connection with another matter) the magazine apologized, saying scientists had "dazzled us with their fancy fossils, their radiocarbon dating, and their tens of thousands of peer-reviewed journal articles. As editors, we had no business being persuaded by mountains of evidence."

Development of Aeronautical Science

Part I: Aviation, from Aristotle to the Wright Brothers (1903)

"There are three things which are too wonderful for me, yea, four which I know not: The way of an eagle in the air..."

Proverbs **30**, 18

Aeronautics is the art of 'navigating the air'. It is divisible into the main branches — aerostation, dealing properly with machines which, like balloons, are lighter than air, and aviation, dealing with the problem of artificial dynamic flight by means of flying machines (aircraft) which, like birds, are heavier than air.

*Historically, aviation is the older of the two. In the legends and myths of men or animals which are supposed to have traveled through the air, such as: Pegasus, Medea's dragons, Daedalus and Ezekiel's flying creatures [**Ezekiel** I, 5–26] as well as in Egyptian bas-reliefs — wings appear as the means by which aerial locomotion is effected.*

The above quotation serves to show that as early as the 4^{th} *century BCE, man admitted his ignorance of aerodynamics.* ***Aristotle*** *(384–322 BCE) is no exception: although he mentioned the problem of solid bodies moving in the air, he believed there is always a force necessary to sustain a uniform or even decelerated motion. He thus looked for a force which pushes forward a flying ball, instead of looking for a force which resists the motion. With such a "negative" approach to dynamical processes, no understanding of flight was possible.*

Many great men with artistic imagination studied the fundamentals of bird flight and speculated on the possibilities of human flight. The drawings and notes of ***Leonardo da Vinci*** *(1452–1519) represent an excellent example of such studies. He considered two methods of flight. One method is an imitation of bird flight (a man equipped with a pair of wings, beating them like a bird. An aircraft of this type is called today an ornithopter).*

The other method was based on a screw, called now the screw of ***Archimedes*** *— which would penetrate the air. This is the predecessor of the* *present day helicopter. The characteristic feature underlying both proposed systems, was the general belief that lift and propulsion should be accomplished by the same mechanism. This is true for the bird, whose propulsion and sustentation are produced by the motion of the same wings. It is also correct in the case of the helicopter.*

The idea of imitating bird flight was predominant for centuries in the minds of inventors. Some, however, recognized the limitations of mere imitation of nature, as one pioneer in aeronautics once remarked: "The successful locomotive was not based upon an imitation of an elephant". It is thus clear that the concept of sustentation by flapping wings or by a screw preceded that of a rigid *(fixed-wing)* airplane.

A step forward in the latter direction was taken by the father of modern dynamics: ***Galileo Galilei*** *(1564–1642) recognized the law of inertia and had a correct notion of* air resistance. *He observed that the movement of a pendulum was slowly amortized by air resistance, and actually tried to determine the dependence of air resistance on velocity. This task was however left to* ***Isaac Newton*** *(1642–1727). From the fundamental laws of mechanics he derived the formula, known generally as* Newton's sine-square law of air resistance, *for the force acting on an inclined flat plate exposed to a uniform air-stream*[110].

Newton stated clearly that the forces acting between the solid and the fluid depend on their relative *motion. [This was already understood by* ***da Vinci****, who said: "The resistance of an object against air at rest is equal to the resistance of the air moving against the object at rest".]*

In the 216 *years that elapsed between the publication of Newton's* Principia *(1687) and the date of the first mechanical flight (1903), a great number of observations were made to determine the resistance experienced by a body, in water as well as in air.*

In the long list of experimenters, engineers, and physicists we find the names of many generally known scientists: ***Edme Mariotte*** *(1620–1684),*

---

110 $F = \rho S V^2 \sin^2\alpha$, where F is the change of momentum of the fluid mass hitting the plane in unit time at inclination α. Here V is the *relative* velocity of fluid and plate, S is the plate's area and ρ is the fluid's density. The force F is directed normal to the plate. The quantity $(\rho S V \sin\alpha)$ is evidently the mass flow in unit time through a cross-section $(S\sin\alpha)$, equal to the projection of the plate area perpendicular to the original flow direction; and this must be multiplied by the velocity component $(V\sin\alpha)$ created by the impact. The dependence of the force on $\sin^2\alpha$ is *not* found in Newton's work and was deduced by other investigators, based on a method of calculation which Newton used for comparison of the air-resistance of bodies of different geometrical shapes.

***Benjamin Robins** (1707–1751), **Jean le Rond d'Alembert** (1717–1783), **Charles Bossut** (1730–1814), **Jean Charles de Borda** (1733–1799), and **Antoine Condorcet** (1743–1794).*

Remarkable experiments were carried out at the end of the 19^{th} *century and the beginning of the* 20^{th} *century by **Alexandre Gustave Eiffel** (1832–1923, France) and his collaborators, who used the tower named after Eiffel in Paris. The best method for measuring air resistance is to put a model in an artificial stream of air, i.e. the method of the* wind tunnel. *The first man to make such an installation was **Francis Herbert Wenham** (1824–1908, England), who in* 1871 *designed it for the Aeronautical Society of Great Britain.*

*In 1891 **Nikolai E. Joukowski** (1847–1921), at the University of Moscow, built a tunnel two feet in diameter. No wind tunnel built before* 1910 *had more than* 100 *horsepower [today, wind tunnels may employ* $250,000$ *horsepower for driving the air-stream].*

The experimental evidence has shown that the dependence of the resistance on the sine of the inclination angle is nearly linear, and not square as Newton had stated. It is believed that Newton's law contributed to pessimistic forecasts on the possibilities of powered flight and thus delayed its development[111].

*The idea that lift can be accomplished by moving inclined surfaces in the flight direction, provided we have mechanical power to compensate for the air resistance that hinders this motion, was clearly enunciated for the first time by **George Cayley** (1773–1857, England) in* 1809–1810. *He was first to announce the* principle of the airplane *as we know it today. It can be said*

[111] According to Newton, the *lift* (vertical component of F) is proportional to $\sin^2\alpha\cos\alpha$ while the *drag* is proportional to $\sin^3\alpha$. Being very small for small values of α, the airplane designer needs tremendous wing area to obtain a sufficient amount of lift. On the other hand the ratio between lift and drag (horizontal component of force) is equal to $\cot\alpha$, which is large only if α is small. If Newton's law is correct, the poor designer has only the choice of either making a huge contraption having a very large wing area, and therefore a heavy structural weight, or building a machine with reasonable wing area but low lift-drag ratio, which means a heavy engine for propulsion.

that Cayley was the man who founded the science of aerodynamics[112]*, and was probably the first man to describe fixed-wing, powered airplane moved by propellers.*

In 1842, ***William Samuel Henson*** *(1805–1888), a British inventor, patented plans for the first plane with a steam engine, two propellers, fixed wings and a passenger cabin. But Henson's "airliner" was never built. In* 1848 *a friend of Henson,* ***John Stringfellow****, built a small model plane using Henson's design. The model was successfully launched but was able to stay in the air for only a short time.*

Throughout the 19^{th} *century, two practically unrelated developments took place side by side. On one hand, flight enthusiasts developed their own rather primitive theories of bird flight, and tried to apply their results to the requirements of human flight. On the other hand, a mathematical theory of fluid dynamics was developed by scientists, who did not provide much useful advice to those who wanted to fly.*

In the experimental vein, interdisciplinary efforts by physicists, aeronauticists, and physiologists, during 1868–1910*, were directed towards the determination of the power required for flight. The fact that birds actually fly through the air furnished a certain solid support for the speculations.*

It was shown by ***Herman von Helmholtz*** *(1868–1873),* ***Charles Renard*** *(1847–1905, France, 1889–1903),* ***Étienne Jules Marey*** *(1830–1904, France, 1873–1890) and* ***R. Henry*** *(1891) that the ratio* W/S *[*$W =$ weight, $S =$ wing area, $\rho =$ *density of the air], known as wing loading, is related to the ratio* W/P *[*$P =$ expended power*], known as power loading, through the equation*

$$P/W = constant \times \sqrt{\frac{W}{\rho S}}.$$

For soaring birds it was found that wing-loading increases like the cube of the weight, which means that flying becomes more of a problem for a large bird than for a small one and that there is a certain size beyond which a living creature is unable to fly.

A second problem that bothered the experimentalists was to find the most efficient shapes for wings. ***Helmholtz*** *(1858) showed that if there is no initial*

vorticity in the fluid, e.g., if the fluid is originally at rest, vorticity can only be created by friction or by the presence of sharp edges on the body. Following this lead, experiments began either in wind tunnels or by means of actual flying in gliders.

*It was found by **H. Phillips** (1885), **Octave Chanute** (1832–1910, U.S.A., 1894–1897), **Alphonse Pénaud** (1850–1880, France), **Samuel P. Langley** (1834–1906, U.S.A.), **Otto Lilienthal** (1848–1896, Germany, 1889) and **Charles M. Manly** (1876–1927, U.S.A.) that curved wing surfaces are superior to flat surfaces in their lift-drag ratio, and also because they show positive lift in the case of zero angle of attack.*

***Wilbur** (1867–1912) and **Orville** (1871–1948) **Wright** were familiar with all practical aerodynamical ideas developed before them by various researchers. In addition to a remarkable talent for construction, they had the ability to utilize model experiments for their full-scale design*[113].

However, at the time of the first human flight (1903), no theory existed that would explain the support obtained by means of a curved surface. It seems that the mathematical theory of fluid motion was unable to explain the fundamental facts revealed by experimental aerodynamics.

On the theoretical front, it became clear to the scientists of the 18^{th} *and* 19^{th} *centuries that the problem is not as simple as Newton thought, and that one cannot replace the flow by parallel motion. In 1878, **Lord Rayleigh** (1842–1919) found that the superposition of a circulatory flow around a circular cylinder, upon a uniform flow perpendicular to it, produces a force perpendicular to the direction of the original flow (or to the direction of motion of the cylinder through stationary air). This result was used to explain the so-called Magnus effect, which had been known to artillerists since the beginning of the* 19^{th} *century. Rayleigh himself undertook his study to elucidate the swerving flight of a "cut" tennis ball*[114].

***Anton Flettner** (1885–1961, Germany), an engineer from the University of Göttingen, harnessed the Magnus effect to drive a boat by wind power (1924). In lieu of the usual sail (which is nothing but an airfoil), a circular cylinder was erected vertically on the boat and made to spin around its axis some 2 revolutions per second. This spin created the circulation, that when added to the laminar wind flow invoked the 'Magnus-force', that drove the*

---

113 Their airplane had the following parameters: $W = 340$ kg, $S = 46.45$ m^2, $W/S = 7.32$ kg/m^2 (a little larger than that of a vulture), $P = 595$kg·m/sec, $P/W = 1.75$ m/sec. According to Renard's formula, the value of the power required per unit weight would be 1.35 m/sec.

114 Lord Rayleigh, "*On the Irregular Flight of a Tennis-Ball*", Messenger of Mathematics **7**, 14–16 (1878).

ship in a direction that is normal both to the cylinder-axis and the wind flow. By rotating two tandem cylinders in opposite directions, the boat could be made to turn around. In 1925 *a Flettner 'rotorship', 680 tons, crossed the Atlantic Ocean. The ultimate failure of the invention, however, was due to economic reasons*[115]*.*

The connection between the lift of airplane wings and the circulatory motion of the air around them was recognized and developed by 3 *persons of very different mentality and training:* ***Frederick W. Lanchester*** *(1878–1946),* ***Wilhelm Martin Kutta*** *(1867–1944)* and ***Nikolai Egorovich Joukowski*** *(1847–1921, Russia).*

Kutta, a pure mathematician, became interested in Otto Lilienthal's gliding experiments and therefore in aerodynamic theory. His particular aim was to understand the effect of curvature — why a horizontally placed curved surface produces a positive lift (1902). Joukowski had extensive training in mathematics and physics, obtained originally in Russia and Paris. In 1872 *he became professor of mechanics at the Polytechnical Institute, and in* 1886 *at the University of Moscow. During* 1902–1909*, independently of Kutta and Lanchester, he developed the mathematical foundations of the theory of lift, at least for two-dimensional flow, i.e. for wings of infinite span and constant cross section.*

Although ***Cayley*** *described the propeller*[116] *already in* 1809 *and* ***Henson***

[115] In 1926 Flettner established in Berlin an aircraft company that produced helicopters much used in WWII. After the war he emigrated to the U.S.A., and became president of the Flettner Aircraft Co., Queens, NY.

[116] A propeller is a device which converts the engine torque into a thrust, which must be enough to overcome the drag of the entire aircraft and also provide additional power to enable the aircraft to climb. It does this by making use of the resistance of the air, whole *reaction* on the blades produces two forces: one of which is the desired *thrust* along the axis of rotation, while the other acts as a brake on the engine shaft. In steady flight, the torque developed by the engine exactly balances the breaking action due to air resistance.

The thrust of the propeller is obtained by giving a backward momentum to the air with which it comes in contact, and to do this effectively, the propeller blades are given first an *aerofoil* shape and then a twist. The actual thrust is caused by the difference in pressure in front and behind the propeller disc. From the viewpoint of general principles of mechanics, the propeller, like the rocket, is a device for propulsion by reaction.

There is an economic upper limit to the speed at which the blades can rotate and still work efficiently. This limit is reached when the tip speed approaches that of sound. A forward speed of 950 km/hour may represent the limit which a propeller-driven aircraft can attain in still air at altitude. Apart from these *designed it as an integral part of powered flight in* 1842*, the physics of the propeller began to be understood during* 1865–1909 *due to the* momentum theory *of* ***W.J.M. Rankine*** *(1865) and the* blade-element theory *of* ***William Froude*** *(1878, England) and* ***Stefan Drzewiecki*** *(1844–1938, Poland and France, 1892–1909).*

Part II: Balloons and Airships (1783–1937)

The dove of ***Archytas of Tarentum*** *(c. 428–347 BCE) is the earliest suggestion of true aerostation. It may conceivably represent an anticipation of the hot-air balloon.*

In the middle ages, vague ideas appear of some ethereal substance so light that vessels containing it would remain suspended in the air. ***Roger Bacon*** *(1214–1294) wrote that man might fly if he were attached to a large hollow globe made of very thin metal and filled with ethereal air or liquid fire, which would float on the atmosphere like a ship on water. But Bacon never tried to put this idea into practice.*

This state of affairs persisted for the next 500 *years. It was generally believed that if a substance lighter than air were found, human flying would be possible. Thus, when* ***Henry Cavendish*** *discovered hydrogen in* 1766 *and* ***Joseph Priestley*** *elaborated in* 1774 *on the lighter density of hot air, these discoveries were immediately put to use;*

In 1766*, it occurred to* ***Joseph Black*** *of Edinburgh, that a thin bag filled with hydrogen gas would rise to the ceiling of a room. But for some reason the experiment failed and Black did not repeat it, thus allowing a great discovery, almost within his reach, to escape him.*

In 1782, ***Tiberius Cavallo*** *(1749–1809), an Italian experimental physicist living in England, was first to show that* soap bubbles *filled with hydrogen*

considerations, however, the propeller shows serious faults of an aerodynamic nature even at moderate speeds: the vortex system developed by the blades represent so much wasted power, for the rotational motion adds nothing to the thrust, and the disturbances thus created can interfere seriously with the otherwise smooth flow over the wings.

would float upward when they were released. A year later, the French brothers ***Joseph Michel Montgolfier*** *(1740–1810) and* ***Jacque Étienne Montgolfier*** *(1745–1799) made a hot-air balloon*[117] *that successfully carried a man [Jean Francois Pilâtre de Rozier, historian to King Louis XVI of France; Oct.* 15, 1783*. He was killed in* 1785 *in the explosion of a combination hydrogen and hot-air balloon].*

The Montgolfier brothers arrived at their idea of hot air in their balloon after a careful study of ***Priestley****'s book on gases. In this balloon, no source of heat was taken up, so that the air inside rapidly cooled and the balloon soon descended.*

In the same year (1783), another group launched a hydrogen-filled balloon. The group consisted of two brothers of the Robert family under the supervision of the French physicist ***J.A.C. Charles*** *(who discovered one of the gas laws, which bears his name). The balloon,* 4 *m in diameter, was made of thin silk varnished with a solution of elastic gum. The hydrogen gas was obtained by the action of dilute sulphuric acid upon iron filings, and was introduced through leaden pipes.*

Since 1784 *the balloon has been applied to the study of the atmosphere, via barometric, thermometric, hygrometric, gravimetric and magnetic observations. Thus, for example,* ***J.L. Gay-Lussac*** *and* ***J.B. Biot*** *ascended up to the height of* 7 *km in* 1804 *to measure the variation of the earth's magnetic and gravity fields with elevation.*

No sooner was the balloon discovered than it received a military status. It was used in the French Revolutionary was (1794), the French campaign in Italy (1859), the American Civil War (1861) and the Franco-Prussian War (1870–1871) for reconnaissance, transportation (e.g. carrying pigeons), communication and even bomb-throwing. The first air-raid in history took place in 1849*, when the Austrians sent balloons over the city of Venice during the Italian uprising. Each balloon carried some* 14 *kg bomb with a time fuse [the first bombs dropped from airplanes in warfare were released over Lybia in* 1911 *by Italian aviators during a war between Italy and Turkey].*

In 1914*, the balloonist* ***Hans Berliner*** *traveled some* 3053 *km from Germany to the U.S.S.R. In* 1961 ***Victor G. Prather*** *and* ***Malcolm Ross*** *of the United States ascended to the height of* 34.6 *km.*

---

[117] An airtight bag that is able to rise in the air because it is filled with light gases. Early balloons were usually made of silk or cotton cloth that was coated with rubber to make the balloon airtight. Today, balloons are made of plastic. The earliest balloons were filled only with heated air, since it is about half as dense as cold air.

From the very first invention of balloons, the problem has been how to navigate them by propulsion. Experiments with airships[118] *started with the French engineer* ***Henri Giffard*** *(1825–1882), who in* 1852 *ascended in a cigar-shaped balloon (length = 44 m; diameter = 12 m; total weight = 1475 kg) driven by a* 3 *horsepower (2.2 kilowatt) steam engine linked to a propeller. It drove the craft about* 8 *km/hour for* 27 *km, from Paris to the city's outskirts. Giffard's engine lacked the power to turn the balloon completely around and return to the starting point.*

Many men continued to work on airships through the 19^{th} *century. The first rigid ship was built by the Austrian engineer* ***David Schwarz*** *in Berlin. It crashed on its first flight on Nov.* 3, 1897. *The work of Schwarz influenced* ***Ferdinand von Zeppelin*** *(1838–1917), a retired German army officer, to begin work on airships. Throughout* 1900–1937, *rigid airships built by Zeppelin and other Germans regularly plied the world skies.*

During 1910–1914, *the German Airship Transportation Company carried about* 35,000 *passengers without a single death, though there were several accidents. The fastest airship built by Zeppelin could fly about* 80 *km/hour. During WWI, the German used airships for scouting, observation and supply work. They made over* 50 *bombing raids on England.*

In 1928, *the Germans completed the* Graf Zeppelin, *a giant airship [length = 240 m, diameter = 30 m] that carried* 50 *passengers and their baggage at a speed of* 110 *km/hour. It was used for regular commercial service between Germany and South America. The largest airships ever built was the* Hindenburg *[length = 247 m, diameter = 41 m, 1936]. It burst into flames on May* 6, 1937, *while approaching Lakehurst, NJ. This marked the end of the use of airships for regular passenger service.*

In World war II, small airships called blimps *played a vital part in protecting ships against submarine attacks: Blimps located submarines and attacked them with depth charges and other weapons. Today, blimps are used mainly for advertisement over the skies of major cities.*

[118] Lighter-than-air aircraft that have their own motive power and can be steered in any direction by their crews. Airships were once called *dirigibles*, which comes from the Latin word *dirigere*, meaning to *steer*.

Part III: Rocket and Jet Propulsion (1232–1945)

When air is allowed to escape from an inflated balloon, the balloon moves in a direction opposite to the escaping air. This principle, in its varied forms, is so obvious that it could not have escaped the observant eyes and the inquisitive minds of erudite men of antiquity. Granted the invention of the wheel, it must have occurred to some of them to watch the recoil of a cart, say, when an object was being thrown from it in the opposite direction.

Indeed, ca 100 *BCE,* ***Heron of Alexandria*** *built a steam jet engine, called an aeolipile: a spherical cauldron was supported by a vertical axis. Escaping from the cauldron through elbow-shaped pipes, the steam pushed these pipes in opposite directions, and the sphere rotated.*

Nature, of course, preceded man in the field of rocket propulsion: it is used for locomotion by jellyfish and mollusks like the octopus and squid. The large brown jellyfish swims by pulsations of its bell, which expands and contracts like an umbrella being opened and closed. Cephalopods, on the other hand, contract their mantle, forcing a narrow stream of high pressure water out through a flexible siphon.

The rocket probably evolved in a simple way from the incendiary arrow. It is known that the Greeks used flying incendiary objects to burn enemy cities in their wars. Thus it is even possible that they already knew how to prepare explosive mixtures. As early as 1044*, the Chinese learned that salpeter added to charcoal and sulfur made it fizz alarmingly.*

Somebody in China, between 1044 *and* 1232*, discovered that if charcoal, sulfur and salpeter are grounded very finely, mixed thoroughly in the proportion of* 1: 4: 4 *and the mixture packed into a close container it will, when ignited, explode with a delightful bang. The mixture was applied both to fireworks and to primitive military devices in the war of* 1232 *against the Mongols. There we encounter the earliest version of a 'rocket-arrow': The powder was packed in a long thin tube to keep it from going off all at once. The tube was open at the rear end such that the reactive thrust made the use of the bow redundant.*

The new weapon spread quickly, and by 1300 *it was well established in Europe, the realms of Islam and the Far East. As with printing and the clock escapement, we do not know just how this knowledge traveled from China westward: whether over the northern route through Russia (then under the Mongol yoke), or south through Muslim lands.*

The next step was taken by ***William Congreve*** *(1805), the father of military rocketry. Although Newton's laws had by then been known for more than* *a century, it was the practical needs of warfare which brought about the development of the rocket and* not *the indulgence of savants in the consequences and uses of Newtonian theory.*

The Congreve rockets were about 100 *cm in length,* 9 *cm in diameter, weighted as much as* 30 *kg and were equipped with a stabilizing wooden tail rod, some* 5 *m in length. It could travel* 2.4 *km with rather poor accuracy, and chiefly effective for its noise, glare and incandescent power. It was thus used against masses of troops within easy range, or to set fire to buildings. The rocket consisted of two parts: a head projectile made of hollow metal that could be filled either with explosives (acting as a bursting anti-personnel shell) or incandescent material. Screwed to the head was an iron casing in the rear, containing the propellant gun-powder.*

An English inventor, ***William Hale****, improved the accuracy of military rockets by substituting three fins for the long wooden tail that had been used to guide the rocket.*

The modern era of rocketry begins with the pioneering work of ***Konstantin E. Tsiolkovsky****, who first stated the correct theory of rocket propulsion in* 1903. *But the indifference of the Russian government to his new ideas, and the political events that overwhelmed Russia during* 1914–1932*, prevented the penetration of his revolutionary ideas into Europe and the United States.*

Consequently, his notions were rediscovered by ***Robert H. Goddard*** *(1918) in the United States and* ***Hermann Oberth*** *in Germany (1923). Of these three pioneer thinkers, Goddard was the first to undertake specific translation of his theories into shootable rockets and patentable devices. But even so, Goddard's development of a successful solid-fuel ballistic rocket by* 1918*, lay unused for* 25 *years.*

Oberth began his study of the space flight problem about the time of WWI, and presented his first treatment in his book Die Rakete zu den Planetenraum *(The rocket into interplanetary space), published in* 1923*. It is the first book to contain the notion of* escape velocity *(although the concept was recognized by Goddard already in 1912). This book stimulated the foundation in Germany of* The Society for Space Travel *(1927).*

In 1926*, Goddard conducted the first successful launch of a liquid propellant rocket. It climbed* 56 *meters into the air at a speed of about* 100 *km/hour.*

The three pioneers had one thing in common — their funds were extremely limited. None had a financially strong sponsor (eccentric inventors with new ideas, do not usually get such sponsors). They all had excellent ideas imagination, and even skill, but they failed to perceive the development costs and the amount of hard work required before attaining convincing results.

The history of technology proves that when the time is ripe, people are to be found thinking about or working on the same problems in almost all civilized countries. Indeed, since the early 1920's, with the development of inexpensive, mass-produced light metals, highly efficient oxidizers which could be handled, and reliable, accurate electronic equipment — three basic elements became available for the revival of the ancient art of rocketry.

Thus we see, since 1928, private groups, inventors and engineers in many countries working on rocket propulsion. Particularly in Germany, serious study had begun on rocket-propulsion as a means of aircraft locomotion. In 1928, ***Max Valier*** *became one of the first individuals to experiment with a liquid-propellant rocket motor, which he used to drive a small racing car. In 1928, rocket powered winged flight was demonstrated in its first primitive form with glider flights in Germany. In 1929, a seaplane made a solid-propellant rocket-assisted takeoff at Dessau, Germany. Later,* **Fritz von Opel** *(1899–1971) flew a glider almost 3 km from Frankfurt-am-Main, Germany, with 16 rockets of 25 kg thrust each.*

Above all, however, it was the military potential*, an art lost to artillery in the* 19^{th} *century, which created missilery as a strategic weapons system, and brought forth the technology that made possible the birth of practical astronautics.*

The treaty of Versailles prohibited military aviation, and thus prompted the German Army in 1931 to initiate a serious, albeit modest and secret, investment in the possible military potential of the rocket as a carrier of explosives. Now, for the first time, rocketry had a sponsor: private industry or government would not have spent hundreds of millions of dollars for a new technical idea which, in the foreseeable future, would not produce any profit. The Germans were looking for a new superior weapon system which has not prohibited to them by the Treaty of Versailles. This called for strict secrecy, and hence no involvement of private industry.

In 1935, **Werner von Braun** *worked on liquid propellant rocket engines for aircraft application, and in 1936 he mounted a 300 kg thrust engine onto small aircraft in the first airplane ground test, using a propulsion system of this type.*

Hardly anyone in the world knew before 1943 that such a development was underway. Yet by 1945 the Peenemuende team (1936–1945) had a rocket lead of approximately ten years. The product of this effort, namely, the V-2 guided ballistic missile, was used by von Braun and his colleagues to bombard London. Some 1100 such flying bombs fell in England between Sept. 1944 and March 1945. American forces captures many of these V-2 missiles and sent them (together with some 200 German rocketeers) to the United States for use and research. The history of rocketry is summarized in table 5.2.

Table 5.2: Rockets (1232–1981 CE)

- *c. 25,000 BCE* *The* bow *and* arrow *are invented; The idea of the* rocket *probably followed the sight of* flaming arrows *flying through the air — a military technique of ancient times (c. 3500 BCE).*

- *c. 360 BCE* **Archytas of Tarentum** *built the first known device that operated on* reaction principle: *thrusts from jets of stream moved pigeon-shaped device.*

- *c. 210 BCE* *Earliest recorded mention of gunpowder from* China. *Bamboo tubes filled with salpeter, sulphur and charcoal used as primitive bombs tossed into ceremonial fires.*

- *1045 CE* *Use of gunpowder and rockets formed an integral aspect of Chinese military tactics.*

- *1232 CE* *Rocket fire-arrows used by the Chinese Sung Dynasty to repel Mongol invaders at the battle of Kai-fung-fu (capital of the Chinese kingdom of Honan). The huge rockets could be heard for about 24 km away and at the point of impact, devastated an area with radius of 700 m. Apparently these large military rockets carried incendiary material and iron shrapnel.*

- *1248 CE* *Mongols brought the Chinese rockets to Europe, and used them against Magyar forces at the battle of Sejo which preceded their capture of Buda (Dec 25), and at the battle of Legnica in Silesia. [Accounts also describe Mongols use of a noxious smoke screen — possibly the first instance of chemical warfare.]*

- *1258 CE* *Mongols use rockets to capture the city of Baghdad (Feb 15).*

- *1268–1288 CE* *Arabs adopted the rocket into their own arm inventory and used them against the French army of King Louis IX during the 7th Crusade (1268). The Arabs used them again during their attack on Valencia, Spain.*

- *1300–1750 CE* *Rockets found their way into European arsenals, and thenceforth many armies adopted and improved the technology of these 'flying bombs'. The French used rockets at the Siege of Orleans during the Hundred Years War against the English (1429). Rockets reached Italy (1500), England (1647), The Netherlands (1650) and Germany (1668). By 1730 the Germans were manufacturing rockets weighing 24–54 kilograms.*

It is known that the construction of these bombs was rudimentary, and their use undoubtedly hazardous, for they were made of paper *which was lacquered or pasted with starch, thus forming a tube which was narrow at one end, the mouth, and was sealed at the front. The tube, loaded with charcoal, salpetre and sulphur, was the ancestor of solid fuel rockets, in which the combustion forced the ejection of a mass of warm air which propelled the whole rocket.*

- *1379 CE* The word rocket was first used (in Italian, rocketta).
- *1650 CE* Writer **Cyrano de Bergerac** suggested rockets as means of traveling from earth to moon.

  Rockets reached a remarkable degree of perfection:

  - Rockets have fins.
  - Multi-stage accelerating rockets were invented: this consisted of a main rocket to which back-up rockets were connected.
- *1687 CE* **Isaac Newton** published his laws of motion. His third law — for every action there is an equal and opposite reaction — explains the basic motive force of rocket engines.
- *1715 CE* The first military rocket factory in the world was built near St. Petersburg by Peter the Great.
- *1792–1798 CE* In the Battle of Seringapatam, India between the English and the army of Tippu Sultan, the English ranks are overwhelmed by a barrage of thousands of rockets. These rockets were metal-made with a range of about 1 km; improvements were made in their manufacture and firing method.
- *1804–1865 CE* **William Congreve** (England), the true pioneer of modern rockets, improved their ballistic stability, range and destructive power, turning rockets into a powerful military weapon. He was first to think of igniting the explosive charge separately from the propellant charge, which were placed in different compartments. His 27 kg models were launched from inclined ramps for aerial bombing and horizontal ramps for field bombing. His rockets played a major role in the bombing of Boulogne (1806), Copenhagen (1807), Leipzig (1813), Baltimore (1814), Mexico (1847), and in the North American Civil War (1861–1865).
- *1850 CE* Further improvement of rockets by **William Hale** (England).

- *1883 CE* ***Konstantin Tsiolkovsky*** *(Russia) pioneered in application of rocketry to space travel. He laid the theoretical groundwork for space flight such as calculating the* escape velocity *and use of* liquid fuel rocket.

- *1909–1941 CE* ***Robert H. Goddard*** *(USA) built and tested for the first time* liquid-propellant rockets*, thus making many basic advances in rocketry. Speculated (1919) on sending rockets to the moon. First launched rocket carrying instruments (camera, barometer, thermometer, 1926).*

- *1923 CE* ***Hermann Oberth*** *(Germany) promoted development of rocketry and space travel.*

- *1933 CE Soviet liquid-propellant sounding rocket reached 5 km altitude.*

- *1942 CE First successful test of German V-2 rocket at Peenemünde. Powered by* liquid oxygen and alcohol. *It traveled 200 km, reached an altitude of over 80 km and landed* $3\frac{1}{2}$ *km from target.*

- *1957 CE US* Jupiter C, *three-stage ICBM (Inter Continental Ballistic Missile) was launched. Recoverable nose cone traveled 460 km up into space.*

- *1958 CE US* Atlas *ICBM missile fired; had maximum range up to 14,400 km.*

- *1959 CE US two-stage ICBM,* Titan 1, *was tested successfully. It had a maximum range of 9600 km.*

- *1969 CE* Saturn 5 *rocket launched 43.2 ton Apollo 11 command module and lunar lander on successful manned voyage to the moon. The 110 m tall, three-stage liquid-fuel rocket developed about 3.5 million kg of lift-off thrust from five first-stage engines. Four smaller second-stage engines produced about 0.45 million kg of thrust, while a single third-stage engine produced enough thrust to orbit the earth and later to break away for the moon.*

- *1981 CE First flight of the first* reusable *rocket, the US space shuttle* Columbia. *Shuttle was powered by three variable-thrust liquid-fuel engines (burning liquid oxygen and liquid hydrogen). Shuttle's two solid-fuel rocket boosters (for lift-off) developed 0.8 million kg of thrust. The* Columbia *exploded during its return voyage on Feb 01, '03, killing all seven astronauts on board at height of 65 km over Texas.*

Aircraft Jet Propulsion (1909–1960)

The theory of the propeller came to completion during the period 1918–1929 *in Germany, England and Italy. It thus took over half a century for a progressive clarification of ideas on the functioning of the propeller: from the analogy with a screw jack to a complete theory based on the principles of scientific fluid mechanics, and using all the mathematical methods of this science.*

From a practical point of view, great progress had also been made in the construction of propellers. However, the difficulties that arose in relation to the supersonic propeller *caused both theoreticians and engineers to look elsewhere for different solutions. In fact, the quest for jet propulsion goes back to* 1909, *the year in which the French engineer* ***René Lorin*** *first proposed the idea of the* ramjet *engine*[119], *the simplest of all jet engines.*

If we imagine that an airplane is flying very fast, *say over* 650 *km/h (e.g. if the plane is first being set into motion by an auxiliary rocket), then the air that enters the engine through a front inlet is being compressed (rammed) without any auxiliary device, since the air cannot move through the engine fast enough to make room for new air coming in. The compressed air becomes very hot. The hot air then flows past the fuel inlets and ignites the fuel. The mixture of air and fuel burns* continuously *in a combustion chamber. The pressure generated by the burning fuel and air sends a flaming exhaust out the jet nozzle and drives the engine forward.*

Thus, using the ram effect, *one can simplify the turbojet engine by virtually discarding the compressor and the turbine. The resulting device is called a* ramjet. *It possesses extreme mechanical simplicity but is penalized in comparison with other jet engines by higher fuel consumption — at least up to the flight-speed range of high supersonic Mach-numbers; and by the fact that without a specific starting drive it functions only above a certain threshold flight velocity.*

The ramjet was displayed for the first time in Paris by the French engineer ***René Leduc*** *in* 1938. *It has since been used for the propulsion of guided missiles such as the U.S. Bomarc.*

An ingenious device that functions right from zero flight speed *is the* pulse-jet. *Like the ramjet, it works without compression, and therefore does not need a turbine for compressor drive. It differs from the ramjet in that the*

119 Lorin, R., "La propulsion à grande vitesse des véhicules aériens: Étude d'un propulseur à réaction directe", *L'Aérophile* **17** (1909) 463–465. "Propulsion par réaction directe et son application à l'aviation", *ibid* **18** (1910) 322–325.

process is not continuous, but periodic. This device has intake valves which open and close somewhat as in a reciprocating engine, but the valves are controlled automatically, principally by resonance with the periodic process of successive compression, combustion, and outflow.

*The first practical application of this idea was made by the Germans in the design of their V-*1 *flying bomb (1944). These were automatically controlled unmanned aeroplanes, airborne by wings.The V-*1 *carried an explosive charge of* 300 *kg to a distance of the order of* 240 *km, at a speed of* 650 *km/h. The propulsive unit of this device, which was carried above the fuselage and aft of the short and extremely simple wings, consisted mainly of a slightly tapered sheet steel tube, the forward portion of which formed the combustion chamber.*

As the aircraft moved forward (usually launched by a catapult), the dynamic pressure of the air on the forward end of the steel tube forced open an assembly of spring-leaf flap valves; a quantity of fuel was then injected into the chamber and the mixture fired by an electric spark. The resultant gas pressure was large enough to close the spring-leaf valves on the forward end, so that a high-speed jet of gas rushed out at the rear end — giving the machine a forward impulse. As the gas emerged, the pressure in the combustion chamber fell, the valves opened and the whole process started again, giving the characteristic 'motor-cycle' sound (frequency of about 40 *per second) which Londoners soon learned to recognize. This primitive engine developed* 600 *h.p.*

It is hard to conceive of anything simpler and more suitable for rapid production in time of war[120]*, but as a weapon it failed completely once the initial surprise was over. An aircraft which flies straight and level and at constant speed is a choice target for anti-aircraft gunners, who with the aid of radar, reaped a rich harvest.*

Certainly, the ramjet and the pulsejet were not the answer for all the needs of commercial and military aviation. Already in the early 1920*'s engineers began to realize that jet propulsion, and propellers driven by gas turbines, showed promise.*

Indeed, aircraft designers had long lamented the fact that the task of propelling a plane by pushing air from fore to aft (propeller) was achieved inefficiently; obviously dissipating energy by additional friction, and requiring an extra amount of engine weight. The blast of the exploding air-petrol mixture is first used to push a piston, whose reciprocating movement is transformed by means of a connecting rod and crank into rotation of the main shaft, which finally produces by means of a propeller, the necessary thrust to

[120] With the exception of the Japanese "suicide planes".

push the plane forward. Quite a number of links, gliding parts, and bearings are required for each of the many cylinders of the 2, 4 or 6 engines of a plane, each item incurring frictional losses.

Was there no shortcut for transforming the blast of the burnt gases into the final forward thrust on the plane?

***A.A. Griffith**, one of the pioneers in aircraft gas-turbine research expounded his early theories in England (1926). In 1930 **Frank Whittle** (England) patented a design for a jet-aircraft engine. In the early 1930's, engineers in the United States and several European countries worked to develop a practical jet engine. Whittle had tested some of his designs by 1938. Finally, in 1939, the Heinkel Company in Germany built and flew the first jet-engine airplane designed by **Hans Joachim Pabst von Ohain**. Its compressor was of the centrifugal type and the turbine had radial inflow.*

The first successful turbojet airplane (with an engine designed by Whittle) was flown in Great Britain in 1941. The first successful jet-propelled combat airplane was flown in Germany in 1942. In 1944, jet airplanes began to be used by the German fighter squadrons, eliciting the astonishment of allied aviators.

In the turbojet engine, air is compressed mechanically instead of ramming it by the aircrafts motion through the air. A compressor takes air from the outside and brings it to a certain pressure in order to make the combustion and the transformation of heat into mechanical energy more economical. The air stream mixed with the injected fuel is burned in a combustion chamber. The exhaust of this chamber drives the turbine and then escapes from the rear. The shaft-output of the turbine drives the compressor. Ordinarily the gas leaves the turbine at high velocity, and forms the jet that furnishes the thrust. Thus, the turbine-compressor combination ultimately serves as a gas generator for producing the jet.

Turbojets produce thrusts ranging from 10,000 to 150,000 Newton. A turbojet of moderate size uses about 250,000 kg of air per hour. It also requires about 4500 liters of fuel per hour. If a 4-engine turbojet airplane flies at 1000 km/h, it travels only about 50 meters per liter. The turbine wheel must be made of materials which can withstand temperatures as high as 870°C, caused by the hot gases (such materials were not available in the pre WWII years).

Two kinds of compressors may be used in turbojets:

(1) A centrifugal-flow compressor squeezes the air by bringing it into the center of a rapidly spinning wheel, which throws the air towards the rim. There it enters a nearly circular expanding passage, where its speed decreases and its pressure increases.

(2) An axial-flow compressor which raises the pressure of the air up to 12 times that at the inlet.

Turbojet engines power most military aircraft. An afterburner gives the turbojet extra power by spraying additional fuel into the burning mixtures of air and fuel.

A turboprop engine is similar to the turbojet, except that most of its thrust comes from a propeller driven by the gas turbine. The jet exhaust adds only a slight extra thrust. It usually contains two turbines; one drives the propeller and the other drives the compressor. The turboprop is most efficient for short flights at relatively low speeds, and is well suited for business aircraft.

A turbofan is another modification of the turbojet, and is employed by many commercial airliners, including the Boeing 727. Turbofan engines have fans at their front end that act like ordinary propellers. These fans take in large amounts of air through the engine, making it more powerful at low speeds than a turbojet. As a result, the airplane can take off in a shorter distance. Also, the fanjet burns less fuel for the thrust it produces, increasing the distance the airplane can fly without having to refuel.

The fans (propeller-like wheels) at the front end push air back into the engine. This air divides into two streams: one stream goes through the compressor, combustion chambers and turbines of an enclosed turbojet engine. The other stream flows around the engine. The two air streams finally combine at the jet nozzle to produce the thrust. A low speeds, turbofan engines are more powerful than turbojets because the huge fans suck greater amounts of air through the engine.

The first scheduled airline flights by jet transports were launched in 1952 by Great Britain. In 1958, commercial jet passenger service began between New York and London. The turbofan engine was introduced into commercial use in 1960.

A rocket engine ejects a stream of rapidly moving gas particles through nozzles located at its rear. There hot gases are the result of burning fuel in a combustion chamber of the rocket as the fuel and oxidizer are consumed and ejected.

Let $m(t)$ *be the mass of the burnt fuel and oxidizer that is ejected up until time* t *through the rocket nozzle, and* $M(t)$ *the mass of the rocket (including the remaining fuel and oxidizer).*

Let $\boldsymbol{u}$ *and* $\boldsymbol{v}$ *be the respective center of mass velocities of* m *and* M *at time* t*, relative to some suitable inertial frame (the same for both) and let* $\boldsymbol{F}^e$ *represent the total external force acting on the craft in the same frame.*

During a time interval Δt, a mass Δm is ejected and the rocket's velocity changes by $\Delta \boldsymbol{v}$. Clearly $\Delta M = -\Delta m$. Consider the system of all particles of which the rocket is composed at time t. Its momentum is $M\boldsymbol{v}$. At time $t + \Delta t$ the momentum is $(M - \Delta m)(\boldsymbol{v} + \Delta \boldsymbol{v}) + (\Delta m)\boldsymbol{u}$. The total rate of change of momentum (of ejecta plus craft) is then $\left\{M \frac{d\boldsymbol{v}}{dt} + \frac{dm}{dt}(\boldsymbol{u} - \boldsymbol{v})\right\}$, and this must be equal to $\boldsymbol{F}^e$, according to Newton's second law.

Denoting by $\boldsymbol{w} = \boldsymbol{u} - \boldsymbol{v}$ the relative instantaneous velocity of the center of mass of the ejected mass w.r.t. the center of mass of the rocket, one arrives at the rocket equation

$$M \frac{d\boldsymbol{v}}{dt} = \boldsymbol{F}^e + \boldsymbol{w}\frac{dM}{dt} = \boldsymbol{F}^e - \boldsymbol{w}\frac{dm}{dt}.$$

The term $\left\{\boldsymbol{w}\frac{dM}{dt}\right\}$ is referred to as the thrust (or reactive force) of the rocket engine.

The rocket equation can be written in the alternative form

$$\frac{d(M\boldsymbol{v})}{dt} = \boldsymbol{F}^e + \boldsymbol{F}^R,$$

where $\boldsymbol{F}^R = \boldsymbol{u}\frac{dM}{dt} = -\boldsymbol{u}\frac{dm}{dt}$ is the reactive force relative to the inertial frame. In this form, Newton's second law is applied to the rocket proper, and the thrust appears as an additional external force on the system of the instantaneous mass $M(t)$.

Since $\frac{dM}{dt} < 0$ and the direction of $\boldsymbol{w}$ is opposite the rocket's motion, the thrust gives a contribution to $M\frac{d\boldsymbol{v}}{dt}$ that produces a positive acceleration. To achieve large accelerations design engineers must deal with ejection speeds $\boldsymbol{w}$ that are very high, with combustion chambers and nozzles that are capable of large through-put.

For one-dimensional motion with $\boldsymbol{F}^e = 0$, fixed $|\boldsymbol{w}| = w_0$, initial velocity v_0 and initial rocket mass M_0, the rocket equation reduces to $-\frac{dM}{M} = \frac{dv}{w_0}$, yielding the Tsiolkovsky formula (1914) applicable to spaceflight,

$$v = v_0 + w_0 \ln \frac{M_0}{M}.$$

In order for v to exceed the rocket-frame exhaust speed w_0 by a factor N, we must have $\{M_{\text{initial}}/M_{\text{final}}\} = e^N$ (assuming $v_0 = 0$); thus, to exceed the exhaust velocity by any substantial factor, the payload M_{final} must be a small fraction of the entire rocket mass.

Consequently, a rocket is a jet-propelled missile which carries along with it the source of its propulsion energy, and its basic functioning is independent of the presence of the atmosphere.

Rocket propulsion is the only autonomous active propulsion system that can function in vacuum. It is in this respect that a rocket differs from an aircraft jet engine*. The latter uses air to burn its fuel, and can therefore operate only in the atmosphere.*

The equation of the jet engine *is therefore somewhat more involved: air enters at the* front *intake of the engine and, after compression, supports the combustion of the fuel; the exhaust gases are ejected with high velocities at the* rear *of the engine. The above rocket equation is then modified to read (ignoring air drag)*

$$M\frac{d\boldsymbol{v}}{dt} = \left\{-\boldsymbol{w}\frac{dm}{dt} - \boldsymbol{u}\frac{d\mu}{dt}\right\} \equiv thrust,$$

where $\mu(t)$ *is the mass of air processed by the engine up to time* t*,* $m(t)$ *is the mass of fuel ejected up to time* t*,* $\boldsymbol{w}$ *is the relative velocity of the exhaust gases w.r.t. the* engine *and* $\boldsymbol{u}$ *is the ejection velocity relative to the inertial frame.*

Since both $\frac{dm}{dt}$ *and* $\frac{d\mu}{dt}$ *are positive and* $\boldsymbol{u}$ *is in the same direction as* $\boldsymbol{w}$*, both terms of the thrust represent positive acceleration. In fact, even though* $|\boldsymbol{w}| > |\boldsymbol{u}|$*, the term* $\boldsymbol{u}\frac{d\mu}{dt}$ *contributes the major part of the thrust because* $\frac{d\mu}{dt}$ *is usually* 20 *or so times greater than* $\frac{dm}{dt}$ *(that is, the air-to-fuel mass ratio is* 20 *or more). The relative exhaust speed,* w*, is usually at least several times greater than the forward speed of the engine w.r.t. the still air.*

The propulsive efficiency *of engines that furnish a reactive thrust is estimated as follows: let the craft (ship or aircraft) propel itself by taking in a mass* M *of fluid per second, of velocity* u_1 *relative to itself, and eject it behind it at higher velocity* $u_2 > u_1$*. The thrust of the craft is* $M(u_2 - u_1)$*, and the power employed in the propulsion is* $Mu_1(u_2 - u_1)$*, since the craft is moving* forward *with velocity* u_1*.*

Now, the engine must supply the power $\left\{\frac{1}{2}Mu_2^2 - \frac{1}{2}Mu_1^2\right\}$ *per second in order to sustain the motion. This is equal to* $\frac{1}{2}M(u_2 + u_1)(u_2 - u_1)$*. The power efficiency is then:*

$$\eta = \frac{\text{power useful in propulsion}}{\text{power expended}} = \frac{Mu_1(u_2 - u_1)}{\frac{1}{2}M(u_2 + u_1)(u_2 - u_1)} = \frac{2u_1}{u_2 + u_1} < 1.$$

This ratio may be made close to unity by making u_2 *tend to* u_1 *and by making* M *greater in order to keep the thrust* $M(u_2 - u_1)$ *invariant. If* $u_2 = 2u_1$*, i.e., if the acceleration is* 100 *percent, the efficiency is only* 67 *percent.*

The above calculation ignores the fuel mass relative to that of the air; it also does not include all *the losses — such as, for example, the loss due to* *the rotational motion imparted to the fluid or the friction on the propeller blades.*

The principle that an efficient propulsion requires as small a value as possible for the velocity increment of fluid passing through it, applies to other propulsive devices based on the reaction principle. We often have to tolerate jet velocities that are high compared to the flight velocity, although we know that the propulsive efficiency will be poor.

For example, with rockets the outflow velocity of gas may be equal to 2 *km/sec whereas the flight velocity may be only around* 300 *m/sec. One can easily calculate how poor a rocket airplane would be for commercial purposes.*

1904 CE Mount Wilson Astronomical Observatory founded by **George Ellery Hale** (1868–1938, U.S.A.) on Mount Wilson, California (1740 m above sea level). Equipped with a 100-inch reflector telescope in 1917.

1904 CE **John Ambrose Fleming** (1849–1945, England). Engineer. Inventor of the diode vacuum tube that acts as a rectifier for the detection of "wireless" radio signals. The Fleming *valve* was the first practical radio tube, and the first practical application of the *Edison effect*. Fleming made numerous contributions to electronics, photometry, electric measurements and wireless telegraphy.

Fleming was born in Lancaster, Lancashire. He was educated at University College, London and Cambridge University under **James Clerk Maxwell**. He was first to hold the title of professor of electrical engineering at University College.

1904–1907 CE **Bertram Borden Boltwood** (1870–1927, U.S.A.). Scientist. First proposed to use radioactivity data to date minerals. Determined *radium* to be a decay product of uranium (1904) and developed a radioactive dating method for uranium bearing rocks (1907). Discoverer of *ionium*, isotope of thorium (atomic mass 230), which naturally transforms into radium (1907).

Boldwood was born at Amherst, MA. Professor at Yale (1897–1927).

1904–1930 CE **Ludwig Prandtl** (1875–1953, Germany). Pioneer in modern fluid mechanics. Made fundamental contributions in the theory of *boundary layers* (1904) and the field of *wing theory* (1918). An engineer by training, he was endowed with an unusual ability of putting physical phenomena into relatively simple mathematical form and establishing systems of simplified equation which expressed the essential physical relations.

Through his far-reaching concept of the *boundary layer*, he showed the way to treat satisfactorily the flow past a streamlined body at high Reynolds numbers[121]. This discovery led to an understanding of skin friction drag, and the way in which streamlining reduces the drag of airplane wings and other moving bodies. In 1918, Prandtl formulated the flow past a finite wing for straight wings with large aspect ratio. This was done independent of a similar work published in 1897 by **F.W. Lanchester**[122], and is known today as the *Lanchester-Prandtl wing theory.*

Prandtl made important advances in the theories of heat transfer in incompressible fluid (Prandtl number[123]), subsonic and supersonic flows and turbulence (*mixing length*). He also made notable innovations in the design of wind tunnels and other aerodynamic equipment. His advocacy of monoplanes greatly advanced heavier-than-air aviation.

Prandtl was born in Freising. In 1901 he became professor of mechanics at the University of Hanover, where he continued his earlier efforts to provide a sound theoretical basis for fluid mechanics. He served as professor of applied mechanics at the University of Göttingen from 1904 to 1953, and established there a school of aerodynamics and hydrodynamics that achieved world renown. In 1925 he became director of the Kaiser Wilhelm (later the Max Planck) Institute for Fluid Mechanics.

---

121 When a fluid flows past a fixed body, because of the effect of viscosity, no matter how small, the layer of the fluid immediately adjacent to the body's surface is at rest. The viscosity is then virtually confined to a very thin layer close to the body and a thin wake extending from the body. In this region, the spatial velocity gradient normal to the body is large, and consequently the viscous forces would not be negligible even if the viscosity were small. In the boundary layer the flow may be laminar, turbulent or a combination of both. Under certain circumstances a *reverse flow* can develop close to the wall.

122 Both established a conceptual model for lift and drag based on *vorticity.* It is hard for an active and creative mind to remember from which readings or conversations the first inspiration arose. Some feel however, that Prandtl did not fully acknowledge his debt to Lanchester in his publications.

123 *Prandtl's number* $\sigma = \frac{\mu/\rho}{\kappa/\rho c_p} = \frac{\mu c_p}{\kappa} = \frac{\text{kinematic viscosity}}{\text{thermal diffusivity}}$, is an index of a fluid's capacity to diffuse momentum as compared with its capacity to diffuse heat. It is a material property that depends on its pressure and temperature [air = 0.733; water = 6.75; mercury = 0.044; glycerin = 7250, at standard temperature and pressure].

1904–1930 CE **Frigyes (Friedrich) Riesz** (1880–1956, Hungary). Mathematician. Foremost among the founders of functional analysis, which has found important applications to mathematical physics [*Riesz-Fischer theorem*, *Riesz representation theorem*]. Discovered general L^p spaces for $p > 1$, $p \neq 2$ and their adjoints. Was first to introduce the concepts of the abstract operator, the *adjoint operator* and the sufficient conditions for the existence of the *inverse operator*. During 1924–1930 Riesz created the theory of subharmonic functions.

Riesz was born to Jewish parents in Györ. He studied at the polytechnic in Zürich and then at Budapest and Göttingen before taking his doctorate at Budapest. He then taught mathematics at the University of Cluj (1911–1922) and was appointed professor of mathematics at the University of Budapest in 1946.

1905 CE The first *geothermal power* station was built at Larderello, Italy.

Energy: Availability, Consumption, and Conversion

Prior to the Industrial Revolution, the sun *was the only source of energy widely available to humankind.* Wood-burning *has been used, where available, since prehistory.* Sails *to harness sun-created wind power were first hoisted* 5000 *years ago,* windmills *were erected* 2000 *years later, and* water-wheels, *which use water raised by the sun, were used* 2000 *years after that.* Coal *came into general use just* 300 *years ago, and* oil *and* gas *only in the last* 100 *years. Not until the* 20^{th} *century did non-solar derived energy arrive, in the forms of* geothermal *and* nuclear power.

The natural flows of energy that have been used for millennia are known as renewable *sources. The amount of energy fossil fuels can supply is ultimately limited by geology. These are known as* non-renewable *sources. As global energy demand grows and non-renewable sources are depleted, attention is turning back to the renewables [*biomass *(plant or animal matter that can be* *converted into fuel), hydropower, solar, power from the sea, geothermal, wind, and nuclear power]*[124].

The standard of living of a population seems to be, in first approximation, a function of the amount of power available per capita. Judging by the present energy consumption in countries such as the United States or Canada, a supply of about 10 *KW per capita would appear to satisfy the energy requirement in an industrial society. This number includes all forms of energy put to work in the service of man, such as the fuel powering our cars, the food we ingest, and the power needed to operate machine tools and household appliances, heat and light habitats, etc.*

Supposing one can stabilize the world population at about 9×10^9 *people, one arrives at a figure of* 9×10^{10} *KW as the power requirement of humanity. The power accessible at present is still far short of this goal. Large areas of the world are still underdeveloped, as indicated by the estimated total present power of* 3×10^9 *KW, corresponding to a world average of only about* 1 *KW per capita.There is a need, then, to increase the world power supply about thirtyfold*[125].

---

124 Nearly half of the world's population rely on *biomass*, mostly in the form of wood. *Falling water* generates 25% of the world's electricity, yet this technology is still underexploited. The *sun* already contributes significantly to the energy needs of buildings through walls and windows, and there is a massive increase in investment in technologies to make efficient use of the sun's energy.

Ocean power comes in four main forms: wave power, tidal power, current power and ocean thermal energy conversion — which exploits temperature differences between the surface and depths. The ultimate energy potential is massive but only a small fraction is likely to be harnessed.

The earth's temperature rises 1 °C every 30 m down: more in geologically active areas. *Geothermal power* makes use of this heat, either directly as hot water or to produce electricity.

Winds are caused by uneven heating of the earth's surface. The power of winds is proportional to the cube of wind speed. Windmills can be used either to generate electricity or to do mechanical work.

Oil is the world's largest energy source, but the time when this will no longer be so is already in sight. *Coal* is the most plentiful fossil fuel. Its use is growing at a rate (3% per year) that will intensify problems of acid rain and carbon dioxide. *Natural gas* accounts for 18% of the world's current annual energy budget.

125 If one wants to make 9×10^{10} KW available entirely through conversion of nuclear energy into useful work, one gram of rest mass must be converted into other forms of energy each second!

A possible source of nuclear energy is the heavy hydrogen or "deuterium", D,

***Volta**'s battery (1795) that converts chemical energy (without moving mechanical parts) into electrical energy, gave **Ampère**, **Oersted**, and **Faraday** their first experimental supplies of electricity. The lessons they learned about electrical energy and its intimate relation with magnetism spawned the mighty turboelectric energy converters — steam and hydroelectric turbines — which power modern civilization.*

Forms of energy are interchangeable. When gasoline is burned in an automobile engine, potential chemical energy is first turned into heat. A portion of this heat, say 25%, is then converted into mechanical motion. The remainder of the heat is wasted and must be removed from the engine. A multitude of processes and devices have been found which facilitate these transformations from one form of energy to another. To date we recognize seven forms of macroscopic interconvertible energy: Electromagnetic, chemical, nuclear, thermal, kinetic, electrical and gravitational.

Some examples are: Gravitational to kinetic to electric via watermills and hydroelectric plants; chemical to thermal to kinetic to electric via turbines and electric power stations; electromagnetic to chemical via photosynthesis (in plants) and photochemistry (in photographic films); Electromagnetic to electrical via photoelectricity, radio antenna and solar cells; chemical to electromagnetic via chemiluminescence (fireflies); chemical to kinetic in muscles, rockets and firearms; electrical to electromagnetic via electromagnetic radiation (radio, TV etc.) and electroluminescence; thermal to chemical via boiling and dissociation; electrical to chemical through electrolysis and battery charging; chemical to electrical through batteries and fuel cells; thermal to electromagnetic via thermal radiation; nuclear to thermal via radioactivity fission and fusion. (From the 42 combinatorial conversion possibilities, 13 are as yet unknown.)

The general laws governing energy conversion are the laws of thermodynamics, which can be paraphrased thus:

- *You can't win (conservation of mass-energy and other quantities).*
- *You can't break even (some energy will unavoidably be lost in all heat engines — the 'Second Law of Thermodynamics'). This law is less restrictive for some processes, such as those where kinetic or chemical energy are converted into or produced from electricity without turning into heat first. We can then escape the Carnot efficiency straitjacket. Chemical*

present in seawater. In certain fusion reactions about 1/200 of the rest mass of D is converted into useful energy. The total amount of D in the sea is about 6×10^{16} kg. If this supply is used at a rate of 9×10^{10} KW, it will last for 10^{10} years.

> *batteries perform this trick. So do fuel cells, solar cells, and many other direct conversion devices (energy transformation without moving parts, such as shafts and pistons).*

Direct conversion is desirable in places where energy conversion equipment must run for years without maintenance or breakdown. Also, direct conversion is required where the ultimate in reliability is required, such as on scientific satellites and manned space flights. Under these circumstances, direct conversion will be more reliable and trustworthy than dynamic conversion.

Some methods of direct energy conversion include nuclear-heated thermoelectric generators, thermionic converters and magnetohydrodynamic converters, hydrogen-oxygen fuel cells and nuclear batteries[126].

An example of man's effort to harness natural energy sources is the tapping of geothermal energy.

For years man has viewed with awe the spectacular bursts of natural steam from volcanoes, geysers, and boiling springs. Although the use of hot springs for baths dates to ancient times, the use of natural steam for the manufacture of electric power did not begin until the turn of the 20^{th} *century. For the next several decades, there was no other major development in the field. During* 1950–1972, *production of power from geothermal sources began in the United States, Japan, New Zealand, Iceland, and the Soviet Union.*

Most of the promising areas for geothermal power development are within belts of volcanic activity. A major belt, called "the ring of fire", surrounds the Pacific Ocean. The "hot spots" favorable for geothermal energy are related to volcanic activity in the present and the past 10 *million years.*

Volcanoes produce the most dramatic displays of natural steam. Water that comes into contact with molten lava (temperatures of $2000\,^\circ C$ *and higher) near the earth's surface can exist only as steam. Rapid expansion of steam and other gases below the surface cause some of nature's most violent and explosive eruptions. That of Mt. Vesuvius in* 79 *CE, for example, destroyed the city of Pompeii.*

---

[126] In a *nuclear battery*, a central rod is coated with an electron-emitting *radioisotope* (a beta-emitter; say strontium-90). The high-velocity electrons emitted by the radioisotope cross the gap between the cylinders and are collected by a simple metallic sleeve and sent to the load. Space charge effects do *not* prevent the electrons from crossing the gap as they do in the thermionic converter because the nuclear electrons have a million times more kinetic energy than those boiled off the thermionic emitter surface: Consequently, they are too powerful to be stopped by any space charge in the narrow gap.

Almost all active volcanoes have fumaroles, or vents, that discharge steam and other hot gases. But, despite the large quantities of steam discharged during active volcanism, the energy cannot be harnessed as a dependable source of power. In some areas the emission of steam cannot be controlled, and in other areas the costs of controlling the steam would exceed the value of the power obtained.

More promising sources of commercial steam *are certain in other subsurface hot spots or geothermal reservoirs that are generally found in areas of volcanism. These reservoirs contain larger and more dependable volumes of steam or hot water. Wells are drilled into the reservoirs to tap the naturally hot fluids that may drive power generators.*

Most known geothermal reservoirs contain hot water rather than steam. Water at depth and under high pressure remains liquid at temperatures far above $100\,^{\circ}C$ *(the boiling point of water at sea level). When this water is tapped by drilled wells and rises to the surface, the pressure falls. As the pressure decreases, the water boils, perhaps violently, and the resulting steam is separated from the remaining liquid water. Because the well itself acts as a continuously erupting geyser, the expanding steam propels the liquid water to the surface and pumping costs are obviated.*

Generally speaking, geothermal fields are either hot-spring systems or deep insulated reservoirs that have little leakage of heated fluids to the surface. Yellowstone National Park and Weirakei, New Zealand are examples of large hot spring systems. Larderello in Italy and the Salton Sea area of California are examples of insulated reservoirs.

Hot springs *have a plumbing system of interconnected channels within rocks. Water from rain or snow seeps underground. If the water reaches a local region of greater heat it expands and rises, pushed onward by the pressure from new cold and heavy water that is just entering the system. The hot water is discharged as hot springs and geysers.*

1905 CE **Emanuel Lasker** (1868–1941, Germany). World chess champion[127] (1894–1921) and mathematician. He proved (1905) that every polyno-

[127] Unlike many chess geniuses, Lasker's interests were far from narrow, and his concern with philosophical matters led to a deep consideration of what he called the "philosophy of struggle". For Lasker, the chessboard was a stage reflecting the struggle of life in its purest form, a view encapsulated in his well-known

mial ideal is a finite intersection of primary ideals. In 1921, **Emmy Noether** generalized this result in the framework of her foundation of abstract algebra.

Lasker, a mathematician by training, gave up mathematics for chess because, as a Jew, his chances of obtaining a professorship in a German university were practically nill. Later, fleeing the Nazi Holocaust, he had to leave all his possessions in Germany. Neither experience made him bitter. As he explained to a friend: "*In mathematics, if I find a new approach to a problem, another mathematician might claim that he has a better, more elegant solution. In chess, if anybody claims he is better than I, I can checkmate him*".

Lasker was born in Poland. He studied mathematics and philosophy at several German universities and was a student of **Hilbert**, receiving his Ph.D. in 1902. When the Nazis came to power (1933), he was forced to leave Germany and had to come out of retirement in chess to earn his living. He first stayed in Russia during 1934–1938 as a professor of mathematics. Emigrated in 1938 to the United States, where he taught mathematics in several universities. Died in New-York.

1905–1917 CE Years of revolution and terror in Russia which had great impact on World history throughout the 20^{th} century. The traits of the revolutionary situation was engineered by industrial revolution and unwittingly sponsored by a doomed regime. One result of this transformation was the attempt made by the new technicians of espionage, provocation and counter-revolution to dominate the new proletarian masses by creating government rather than police-sponsored worker's unions which were managed and directed by police agents. All this paved the way for chaos, intrigue, hypocrisy and betrayal and heralded upcoming social upheavals.

The 1905 revolution was the melting pot from which emerged one of the greatest revolutionary transformations in modern Jewish history. It proved to be a renaissance for political, spiritual, literary and ideological factors.

The trends which were born from this great upheaval encompassed a new Jewish revival from which a new Zionist revolution sprang. Side by side, an enormous mass emigration to the New World laid the foundation for the flourishing Jewish centers in America. The sons, grandchildren and great

---

remark, "On the chessboard lies and hypocrisy do not long survive." He went on to note that "there are 64 squares on the chessboard, if you control 33 of them you must have an advantage." While this is a vast oversimplification of the situation it points out the importance of positional play in the thinking of chess masters.

grandsons of these immigrant would later contribute most significantly to the cultural and scientific milieu of the United States of America.

1905–1925 CE **Richard Martin Willstätter** (1872–1942, Germany). One of the leading organic chemists and biochemists of the early 20^{th} century. Discovered the structure of many natural substances of biological significance. Laid the foundations for the later elucidation of the structure of *alkaloids*, *chlorophyll* and *photosynthesis*. His chemical researches on *enzymes*, ferments and *cholesterol* (in relation to longevity) led to further important developments in this field. The preeminence of the German dye industry was to a great extent due to his discoveries. His overall research on complex organic substances, especially on the coloring matter (anthocyanins and chlorophyll) in plants and on enzymes earned him the Nobel prize for chemistry (1915).

Willstätter was born in Karlsruhe to Jewish parents of rabbinic ancestry. In 1890 he entered the University of Münich, and later served as a professor of organic chemistry in Zürich (1905–1912). He then became the director of the Kaiser Wilhelm Institute in Berlin (1912–1916) and eventually a professor at Münich University. Willstätter retired prematurely (1924) in protest of the increasing anti-Semitism among his colleagues. His property was confiscated and he fled to Switzerland (1939) to escape the Gestapo[128].

[128] Of all the prominent Jewish scientists in Germany, Willstätter presents the most complex, most puzzling, and probably the most tragic picture in his imperviousness toward the Jewish problem in Germany. In 1933 Willstätter visited England and the United States. He was received enthusiastically everywhere, honored in many ways and offered several excellent positions. He turned them down and stayed in Germany, even when the situation became threatening and humiliating for the Jews. It seems difficult to understand the psychology of a man, conscious of his illustrious Jewish ancestry, who had suffered all his life from anti-Semitism and witnessed the horrible persecution of the Jews prevailing in Germany. When **Chaim Weizmann** asked him, “Professor Willstätter, why do you not leave Germany?”, he replied that “one does not leave his mother even when she behaves badly.” He thus continued to stay in Germany until the end of 1938 and decided to leave only when conditions became unbearable and his life was threatened.

The Chemistry of Plant Metabolism

The overall process by which plants absorb, use, and store radiant energy is called photosynthesis. Through this process the chlorophyll of green plants catalyzes the formation of carbohydrates from atmospheric carbon dioxide and water through the action of sunlight. Schematically

$$sunlight \; + \; CO_2 \; + \; H_2O \xrightarrow{\text{chlorophyll}} O_2 \; + \; carbohydrates.$$

In the reverse process (arrow points in the opposite direction) known as animal respiration, cellular oxidation of food (carbohydrates proteins, fats) releases carbon dioxide, water and liberate thermal energy at a rate of 683 kcal per mole.

The concepts involved in these metabolic processes developed slowly alongside the fundamental mainstream ideas of physics and chemistry in the past three centuries:

***Van Helmont** (1620) had been the first to discover the existence of different gases; in particular, he described the properties of carbon dioxide. After conducting many experiments, he concluded that plants were nourished not from the soil but exclusively from water. Through the next century, research on various gases continued at an intensifying pace and in 1723 **Stephen Hales** (1677–1761, England) found that plant growth depended on the very carbon dioxide[129] that Van Helmont had discovered.*

***Joseph Priestley** concluded (1772) that plants not only consumed CO_2 but gave off oxygen, while animals consumed oxygen and gave off CO_2.*

***Jan Ingenhousz** (1779) showed that plants absorbed CO_2 from the atmosphere and water in the presence of sunlight, while their green portion gave off oxygen. In the absence of light the roots, flowers and fruits gave off CO_2. He was the first to recognize (1796) clearly two distinct respiratory cycles in*

129 Although CO_2 makes up only 0.03 percent of the volume of the atmosphere, the total amount of *carbon* in the CO_2 of the atmosphere is 4×10^{14} kilograms. Fifty times as much as this is dissolved in the ocean, either as CO_2 or CO_3^-, so that the total mass of carbon available for life, in the air and sea together is 2×10^{16} kilograms. This amounts to 80 times the carbon existing in all living things. If the carbon of CO_2 is considered the general food supply of all life, there is enough of it to spare to support all the individual organisms our planet now carries.

plants, and that sunlight was essential for the production of oxygen by the leaves.

At about the same time (1782), ***Jean Senebier*** *(1742–1809, Switzerland), botanist, demonstrated that green plants convert CO_2 to oxygen under the influence of light and suggested that CO_2 nourishes the plant.*

With the growing appreciation of catalysis that came about in the early 19^{th} century, it was suspected that some catalyst is associated with the "greenness" of plants.

Consequently, the chemists ***Pierre Joseph Pelletier*** *(1778–1842, France) and* ***Joseph Bienaimé Caventou*** *(1795–1877, France), extracted (1817) the green substance of plants and named it chlorophyll (from the Greek green leaf). Caventou also discovered strychnine (1818), quinine (1820) and caffeine (1821).*

Nicholas de Saussure *(1767–1845, Switzerland) showed (1804) that green plants absorb water and require CO_2 from the air and nitrogen from the soil. It was asserted in 1840 by the agricultural chemist* ***Jean Baptiste Joseph Dieudonné Boussingault*** *(1802–1887, France) that higher plants cannot utilize atmospheric nitrogen but only nitrogen from nitrates in the soil.*

It was later found that other elements, too, are engaged in cyclic processes: sulfur, phosphorus, iron, chlorine, magnesium, potassium, sodium and calcium are absorbed from the soil by the plants and incorporated into their tissue. All these elements must be in a water-soluble salt or ionic form in the soil solution, being taken up with the water that all living cells require[130].

---

[130] These minerals originate in the soil as it is formed from rock, and they are normally replaced in the soil as plants and animals die and decay. Small amounts arrive as rain washes down particulate matter suspended in the air. Thus, there are *mineral cycles* in which a molecule of, say, potassium phosphate moves from the soil to plant to animal to bacterium or fungus and then back to soil. If the cycle is broken when a plant is harvested, a need to replenish the soil is established. Of the required minerals, *nitrogen* is frequently in limited supply. Although 78 percent of air is nitrogen gas (N_2), elemental nitrogen must be transformed into an *ionic form* [ammonium ion $-NH_4^+$ or nitrate ion $-NO_3^-$] before plants can absorb and use it. Since most chemical constituents of life are either nitrogen-containing (e.g., 16 percent of protein is nitrogen) or have their synthesis and degradation controlled by proteinaceous enzymes, cellular growth and development is directly limited by the supply of nitrogen.

Phosphorous, as the phosphate ion ($-PO_4^{+3}$) is built into nucleic acid and the phosphate-phosphate bond in ATP, bears the chemical-physical energy needed for every energy-requiring process in cells.

Potassium plays many different roles: It is the primary regulator of the move-

Henri Dutrochet *(1776–1847, France) showed (1837) that CO_2 is absorbed only by those plant cells that contain chlorophyll and only in the presence of light.*

Julius von Sachs *(1832–1897, Germany) discovered (1865) that chlorophyll in plants is found only in small bodies (later termed chloroplasts), and that chlorophyll is the key compound that turns CO_2 + water into starch while releasing oxygen.*

The concept of photosynthesis was introduced in 1893 *to signify the new biochemical approach. It stood for the chemical activity of plants and their ability to synthesize carbohydrates. It was coined by the German-born* ***George Engelmann*** *(1809–1884, U.S.A.). He was a meteorologist, physician and botanist, who practiced medicine in St. Louis (from 1835) and made meteorological and botanical observations during the rest of his life.*

A century after the isolation of chlorophyll, its structure was finally worked out (1910) by ***Richard Willstätter*** *(1872–1942, Germany) and*

---

ment of water into and out of plant cells; it is part of many enzymes, and it forms complexes with organic acids within the cells. *Sodium* acts much like potassium.

Calcium and magnesium are enzyme activators, serve as carriers for other ions through *plant cell membranes*, and reduce the toxicity of other ions which may be in excess.

Magnesium, as part of the chlorophyll molecule, has a vital role in *photosynthesis.*

Sulfur's main roles are as constituents of certain amino acids, cysteine and methionine, that determine the 3-dimensional shape of proteins and as parts of compounds that regulate the oxidation-reduction state of cells.

Chlorine is needed in the form of a chloride ion as part of the enzyme complex that breaks water in photosynthesis, releasing molecular oxygen into the atmosphere.

Iron ions are involved in cellular energy transmission in both respiration and photosynthesis. It is also required for the synthesis of chlorophyll.

In addition to these minerals, at least five other are required in very small or trace amounts:

Zinc and *copper* are required as parts of certain enzymes.

Manganese, is part of the enzyme complex that releases oxygen in photosynthesis.

Plant cells will not divide without *boron*, and growing tissues of the root and shoot meristem will die without continuous supplies of borate ions.

All plants require *molybdenum* in order to carry on normal nitrogen metabolism, and many plants also require *silicon*, *germanium*, *vanadium*, or *gallium* for reasons which are completely obscure.

Hans Fischer[131] *(1881–1945, Germany). They took the molecule of chlorophyll apart and deduced its composition from the nature of the fragments ($C_{55}H_{72}MgN_4O_5$).*

As it turned out, chlorophyll closely resembles, in its basic structural pattern, the molecule of heme, which is found in hemoglobin, catalase, *and the* cytochromes. *Its chief points of difference are, first, that it contains an atom of* magnesium *in the center of the molecule, where heme contains an atom of iron. Secondly, attached to it is a long hydrocarbon molecule of the type known as* carotenoid.

The chlorophyll molecule absorbs both violet and red light, hence vegetation is green. It thus acts as a selective antenna that plants use to harvest the sun and open the way to the processes of life.

Carotene ($C_{40}H_{56}$) accompanies chlorophyll in photosynthetic organisms. Its role is partly to harvest some sunlight that is not absorbed by chlorophyll, as well as to react with energetic oxygen molecules so as to protect the cell from degradation. The yellow-orange of carotene remains masked by the chlorophyll until the fall, when the chlorophyll molecule decays and is not replaced; that leaves sturdier carotene molecule to exhibit its powers of light absorption, and the leaves turn yellow.

The light-activated chlorophyll is raised to a high-energy state. It can then expend its energy and return to "ground state" by bringing about some energy-consuming reaction *that is central to the process of photosynthesis. The discovery of this key chemical reaction had to await the days of isotope* tagging.

1905 CE **Arthur Harden** (1865–1940, England). First to detect and identify inorganic phosphate in *metabolic intermediates*[132]. It marked the birth of the systematic study of intermediary metabolism. Discovered (1904) the

[131] Won the Nobel prize (1930) for chemistry for studying the coloring matter of *blood* and *leaves* and synthesizing *hemin*.

[132] Compounds required for the reaction to take place but are not involved as the original compound or as the final ones.

first coenzyme[133] *zymase* (with **W.J. Young**) which they have obtained from yeast.

Harden was professor of biochemistry (from 1912) in London. Awarded the Nobel prize for chemistry (1929).

He found (1905) that when the rate at which yeast cells produce CO_2 begins to fall off, it can be restored by the addition of an inorganic phosphate (e.g. KH_2PO_4); as the evolution of CO_2 proceeded, the quantity of the phosphate remaining in solution decreased. The organic compound found to combine with the phosphate group was later identified as *fructose diphosphate*, the first known metabolic intermediate.

1905 CE **Albert Einstein**[134] (1879–1955, Switzerland, U.S.A.). One of the greatest scientists of all times. Revolutionized scientific thought with new conceptions of time, space, mass, energy and gravitation. He treated matter and energy as interchangeable, rather than distinct categories, and showed that energy and momentum on the one hand, and time and space on the other, are "rotated" into each other when the observer changes his state of motion. He also deduced, on purely theoretical grounds, the relativity of measured time durations and of simultaneity, as well as the dynamical nature of space-time and the effects of gravitation upon geometry and the flow of time. His deductions concerning the inter-convertibility of mass and energy revealed the theoretical possibility of releasing vast amounts of energy bound up in atomic nuclei. Thus, Einstein was one of the harbingers of the atomic age.

In his two theories of relativity, as in his bold contributions to statistical physics and to early quantum theory, he established new paradigms for how hypotheses and theories of modern physics should be enunciated, thus playing a central role in the *demise of the dogmatic universe*. His most astonishing

---

133 A compound that is not a protein but which is required for the protein to act as an enzyme. Beginning with the 1920's and continuing to the present day, the chemical nature of various coenzymes was worked out. Most coenzymes proved to contain phosphorus atoms as part of their molecules.

achievement, the General Theory of Relativity (GTR), finally made *cosmology* a full-fledged branch of physics. GTR has also initiated a far-reaching geometrization and algebraization of our conception of physical reality, that is still in full swing at the dawn of the 21^{th} century.

He was the first to grasp that Planck's discovery had far-reaching implications for the nature of light, and he introduced the revolutionary concept of the wave-particle duality of light, in the process explaining the photo-electric effect and developing the theoretical underpinnings of *laser* theory and *photonics*.

In 1905 Einstein contributed 4 papers to **Annalen der Physik**, each of which became the basis of a new branch of physics[135]:

(1) The paper: "*Die von der molekularkinetischen Theorie der Wärme gefordete Bewegung von in ruhenden Flüssigkeiten suspendierten Teilchen*" (On the movement of small particles suspended in a stationary liquid governed by the molecular kinetic theory of heat)[136]. Between 1905 and 1908, Einstein published 5 papers on this subject. The 1905 paper developed the mathematical theory of the irregular motion of microscopic particles suspended in a liquid or gas[137]. Einstein used this phenomenon to support both the atomic hypothesis and the molecular kinetic theory of heat. This work, along with later experimental confirmation by Jean

---

[135] The year 1905 is known in science as the "*miraculous year*" with its Latin counterpart "*annus mirabilis*", long used to describe the year 1686, during which Isaac Newton laid the foundations for much of physics and mathematics and revolutionized 17th-century science. It seems entirely fitting to apply the same phrase to the year 1905, during which Albert Einstein not only brought to fruition parts of that Newtonian legacy, but laid the foundation for the break with it that has revolutionized 20th-century science.
Incidentally, the phrase was coined without reference to Newton. In a long poem entitled *Annus Mirabilis*: The Year of Wonders, 1666, **John Dryden**, the famed Restoration poet, celebrated the victory of the English fleet over the Dutch as well as the city of London's survival of the Great Fire.

[136] For further reading, see:
Einstein, Albert, *Investigations on the Theory of the Brownian Movement*, Dover, 1956, 119 pp.

[137] *Einstein's equation* for the mean square displacement $\overline{r^2}$ of spherical particles of radius r_0, moving in a gas of viscosity η at an absolute temperature T after an observation time t, is $\overline{r^2} = \left[\frac{kT}{3\pi\eta r_0}\right] t$.

Perrin (1909), provided the most convincing evidence available up to that time for the existence of molecules and atoms.

In this paper Einstein did *not* set out to explain old 19^{th} century observations, as he stated very clearly at the beginning of his paper: "*In this paper, it will be shown that according to the molecular-kinetic theory of heat, bodies of microscopically visible size suspended in a liquid, will perform movements of such magnitude that they can be easily observed in a microscope, on account of the molecular motions of heat. It is possible that the movements to be discussed here are identical with the so-called* "*Brownian molecular motion*"; *however, the information available to me regarding the latter is so lacking in precision, that I can form no judgment in the matter*".

It took a long time for *Brownian motion* to work itself into the main stream of physics. But when it was finally recognized as a phenomenon worthy of serious study, the consequences were striking[138]. Eventually, the theories of Brownian motion made contact with the quantum theories of the 20^{th} century.

(2) The paper: "*Über einen die Erzeugung und Verwandlung des Lichtes betreffenden heuristischen Gesichtspunkt*" (On the heuristic viewpoint concerning the production and transformation of light). Scientists before Einstein had discovered that certain metals eject electrons when struck by light[139], but scientists could not explain this phenomenon on the basis of the classical electromagnetic theory. Einstein boldly adopted Planck's hypothesis of 1900 (that radiant energy is emitted and absorbed not in continuously divisible amounts, but rather in discrete units (*quanta*) depending on the frequency of light. Einstein, however, took it more seriously than Planck ever did — by positing that light also *exists* and *propagates* in these discrete quanta (later called *photons*), and that these light-particles carry momentum as well as energy — both determined

---

[138] The physical phenomenon described by **Robert Brown** (1827) was the complex and erratic motion of grains of pollen suspended in a liquid. In the many years which have passed since this description, *Brownian motion* has become an object of study in pure as well as applied mathematics. Even now many of its important properties are being discovered.

[139] *The photoelectric effect* (1902). The number of electrons emitted per second is proportional to the *intensity* of the incident light. The maximum energy of the electrons, however, does not depend on the intensity but on the *frequency* of the incident radiation. No photoelectric emission occurs at all below a certain threshold frequency, whatever the light intensity. Note that Planck's discovery remained isolated until Einstein presented the first general interpretation of h.

from its frequency via Planck's constant, h. In so doing, Einstein introduced into physics the revolutionary concept of *particle-wave duality*. Later (1920's) **de Broglie** and **Schrödinger** extended these concepts to *matter* and enshrined it in Quantum Mechanics. Einstein supposed that in the photoelectric effect, each ejected electron received its energy and momentum from one quantum of the incident light.

Einstein's photoelectric equation $\left[\frac{1}{2}mv^2 = h(\nu - \nu_0)\right]$ was tested experimentally by **Hughes** and **Millikan**, who established its accuracy over a wide range of frequencies, and measured the value of h. It was thus made clear that the new quantum theory of radiation gave a correct account of the photoelectric effect in metals, and that the classical wave theory was inadequate to deal with the interactions between atoms and radiation.

(3) In a paper: "*Zur Elektrodynamik bewegter Körpen*" (On the electrodynamics of moving bodies)[140], Albert Einstein introduced his special theory of relativity (STR). It replaced Newtonian concepts of space and of separate absolute time, with a single geometrical framework of space-time. It is the greatest contribution, since the 17^{th} century, to our understanding of time and of classical (non-quantum) dynamics.

In formulating the STR, Einstein was motivated by two basic facts:

- The equations of the electromagnetic field are *not* covariant w.r.t. the Galilean transformation.
- Experimentally, the velocity of light is the same for all unaccelerated observers, independent of the apparatus employed for its measurement.

His idea was then to look for *another* linear transformation between inertial frames [it must be linear, because only for a linear transformation is the unaccelerated motion of a particle in one frame, seen as unaccelerated motion in the other]. Maxwell's equations then are covariant with respect to that new transformation. Simple algebra leads one to the so-called *Lorentz transformation*[141].

Thus, STR is based on two fundamental principles:

(1) A principle of covariance under change of inertial frame (generalization of the Newton-Galilei *relativity principle* to encompass *all* laws of physics).

(2) The constancy of the velocity of light[142].

When these principles are translated into mathematics, the results yield the Lorentz transformation law between the coordinates (x, y, z, t) and (x', y', z', t') of a physical event as seen in any two inertial systems moving relative to each other with uniform velocity[143].

---

141 $x' = \frac{x-vt}{\sqrt{1-\left(\frac{v}{c}\right)^2}}$; $y' = y$; $z' = z$; $t' = \frac{t-\frac{v}{c^2}x}{\sqrt{1-\left(\frac{v}{c}\right)^2}}$. These formulae connect the coordinates (x, y, z, t) and (x', y', z', t') of two reference systems K' and K, such that K' moves relative to K with uniform velocity v in the positive x-direction.

142 This second principle is really an amalgam of two sub-hypotheses: the independence of the speed of light upon (a) source motion, and (b) observer (inertial) motion. If we assume, as Einstein did, that light propagation obeys Maxwell's equation in any inertial frame, this makes (a) obvious; (b) then follows as special case of the *first* principle.
Furthermore, since Maxwell's equations are assumed to hold in all inertial frames, the raison d'etre for the ether hypothesis 'softly and suddenly vanishes away', as Lewis Carroll might have put it!

143 The famous "*Twin paradox*"; one of a pair of twins stays at home, remaining at rest in an inertial frame of reference at all times, while the other goes on a space flight, traveling with, say, speed $v = \frac{3}{5}c$ for two years of his own time, then switching to *another inertial frame* for the return journey at the same speed $\frac{3}{5}c$. The total time ticked off by the traveler's clock will be four years, while an identical clock carried by the homebody twin will have ticked off five years

If one accepts that the equations of the electromagnetic field are true for all observers in inertial frames (they are *Lorentz covariant*), then one must discard the principle of *Galilean covariance*, and the equations of particle mechanics must be rendered *Lorentz covariant* instead.

Although the mathematical results are expressed in simple algebra that can be understood by high-school students, its physical implications are revolutionary and profound. For example: the rate of flow of time depend on the state of motion of the observer. Also, two events at two different locations, can be seen to be simultaneous by one observer, and yet will *not* appear so to a second observer moving w.r.t. the first.

Since the Lorentz transformation depends only on the relative velocity and *not* on acceleration, STR holds for an accelerated observer, provided the rules for synchronizing clocks at different locations are suitably modified to include acceleration effects — similar to the way in which Newton's second law must be modified by non-inertial forces in an accelerated frame. However, it is much easier to work out the physics of an accelerated laboratory in a continuous succession of instantaneous comoving inertial frames, performing a succession of infinitesimal Lorentz transformations between such frames.

A physicist in an accelerated laboratory knows he is being accelerated, because his accelerometers do not read zero and he cannot play three dimensional billiards. But his instantaneous inertial frame is *continuously changing* according to a specific, known rule, and the Lorentz transformation can be adjusted for him each instant anew.

The Lorentz-covariantization of the laws of dynamics, necessitated by STR, caused a fundamental change in our notions of the properties of space, time, velocity, acceleration, force, mass, momentum, energy, power and field.

(4) In a paper: "*Ist Die Trägheit eines körpers von seinem Energiegehalt abhänging*?" (Does the inertia of a body depend on its energy content?) Einstein expounded the revolutionary idea that the conservation of total energy is equivalent to the conservation of mass. That is, the invariance of total energy implies the invariance of total relativistic mass. The ensuing

---

between departure and arrival of the traveling twin. There is no contradiction with the principle of equivalence of inertial observers because the traveling twin switches Newtonian frames at one point in the journey. The twins are therefore *not* equivalent observers, because one can tell from inertial effects which of the twins changed rest frames and which did not.

relation $E = mc^2$ expresses the fact that mass-energy can be expressed in energy units as E, or equivalently in mass units, as[144] $m = E/c^2$.

---

[144] Around the year 1850 physicists began to realize that one can extend the law of conservation of energy from the realm of mechanics into other branches of physics, by conceiving, for example, of heat and electricity as other forms of energy. The heat content of an object was soon recognized as the *disordered* kinetic energy of its atoms or molecules, moving randomly in all directions so that the net momentum vanishes. (In contrast, the ordinary kinetic energy $\frac{1}{2}mv^2$ is always accompanied by a net momentum mv of the object.) Other forms of energy were noticed soon afterward that truly deserve the name of "internal" energies because they are not associated with any (classical) motion of any objects. Such a form of internal energy is represented by the various chemical bonds of molecules, which are of essentially electromagnetic and quantum-mechanical nature (although they *do* involve motions of electrons and nuclei). By convention, one talks about a binding energy of a molecule if one has to do work to break the bond between its constituents. Accordingly, during the formation of such a bond, positive energy must be given up to the environment, for example, as heat in most oxidation processes.

Nevertheless, matter and energy were considered two separate and distinct entities existing in an all-pervading ether.

This was justified because the speed of light c is so large, that for any *non-nuclear process* observed before the advent of STR, the mass changes $\frac{\Delta E}{c^2}$ are negligible. Thus, for all energy-conversion processes then known, rest-mass and energy may be assumed to be separately conserved to a high degree of accuracy.

The relation $E = mc^2$ can be derived theoretically in STR, in many different ways. For example, if a point-mass' momentum is to be $\boldsymbol{p} = m\boldsymbol{v}$ as in Newtonian mechanics, and if momentum is to be conserved in billiard-ball collisions, the conservation law $\Delta\left(\sum \boldsymbol{p}_i\right) = 0$ must be Lorentz covariant, and thus is mathematically possible if the inertia of a mass m depends upon its velocity in any given frame in accordance with the expression $m = m(v) = \frac{m_0}{\sqrt{1-\frac{v^2}{c^2}}}$; m_0 is called the *rest mass*.

Applying Newton's second law in one dimension,

$$\boldsymbol{F} = \frac{d}{dt}m(\boldsymbol{v})\boldsymbol{v} = \frac{d}{dt}\left[\frac{m_0\boldsymbol{v}}{\sqrt{1-\frac{v^2}{c^2}}}\right],$$

the work done by accelerating the body from $v = 0$ to $|\boldsymbol{v}| = V$ is

$$W = \int_{v=0}^{V}(\boldsymbol{F}\cdot\boldsymbol{v})\,dt == m_0\int_0^V \boldsymbol{v}\,d\left[\frac{\boldsymbol{v}}{\sqrt{1-\frac{v^2}{c^2}}}\right] = [m(\boldsymbol{v}) - m_0]c^2 = E - E_0.$$

Classical electromagnetism is consistent, ab initio, with STR: Maxwell's

---

Hence $E = mc^2 = \frac{m_0c^2}{\sqrt{1-\frac{v^2}{c^2}}}$, with the accompanying momentum

$$\boldsymbol{p} = m(\boldsymbol{v})\boldsymbol{v} = \frac{m_0\boldsymbol{v}}{\sqrt{1-\frac{v^2}{c^2}}}.$$

Furthermore, E and $\boldsymbol{p}$ are tied up by the algebraic relation $E^2 - p^2c^2 = m_0^2c^4$. For particle of zero rest mass (e.g., a photon), $m_0 = 0$ and therefore $E = |\boldsymbol{p}|c$ or $p = \frac{E}{c}$. Clearly, $\frac{E^2}{c^2} - p^2 = m_0^2c^2$ is invariant under the Lorentz transformation.

At rest, or low (non-relativistic) speeds $|\boldsymbol{v}| \ll c$, the relation $E = mc^2$ yields the "rest energy" of an object of mass m — some of which is transferred into other forms of energy whenever the object takes part in some exothermic transmutation, such as in a nuclear reaction, in which this mass is not conserved. (This is true for chemical reactions too, but the conversion of energy into rest-mass is negligible in this case.)

The great technological impact made by the discovery of methods for converting rest energy into useful work stems from the fact that light's speed c happens to be so large in everyday units. The work that can in principle be extracted from the conversion of 1 kg of mass is, in mks units ($c = 3 \times 10^8$ m/sec; $1\ J = \frac{5}{18} \times 10^{-6}$ kilowatt-hour): $W = 1 \times (3 \times 10^8)^2 = 9 \times 10^{16}\ J = 2.5 \times 10^{10}$ KWh. Otherwise stated: one gram of matter is equivalent to 3000 tons of coal!

The relation $E = mc^2$ also states the mass equivalence of the binding gravitational energy between masses. For example, when two spherical masses m_1 and m_2 form a two-body system, part of their combined mass is eaten up by the gravitational binding energy: $G\frac{m_1m_2}{2Rc^2}$. Here R is the separation between the mass-centers of the co-orbiting masses and the factor $\frac{1}{2}$ indicates that the *gravitational mass-defect* arising from the mutual potential energy is partially offset by the masses orbital kinetic energy. The mass-equivalent of the binding energy of the earth-moon system is about 4×10^{14} grams. It is the mass of a small mountain, ca 400 meters high, which constitutes about $5 \cdot 10^{-12}$ of the moon's mass.

Similarly, the mass defect of a self-gravitating non-rotating earth of mass M and radius a is $\Delta M = \frac{2}{5}\frac{GM^2}{ac^2}$. If a deranged accountant could tally the total mass defect ΔM from the knowledge of the exact distribution and composition of its constituent materials, he would discover a shortfall of 1.6×10^{18} grams, which is of the order of $3 \cdot 10^{-10}$ of the earth's mass. GTR introduces some extremely small correction to the STR expression for mass defects we have used here.

equations are invariant under the Lorentz transformation and do not need to be modified. However, STR gives us a new point of view, enhances our understanding of electromagnetism and introduces relativistic corrections to the interactions of charged masses with electromagnetic fields.

Other realms of physics are also affected, including the microscopic world of elementary particles that abide by the rules of quantum mechanics, special relativity and quantum electrodynamics. All laws are written so as to be covariant under the Lorentz transformation. This encompasses also the theories of weak interactions, responsible for β-decay, and the strong nuclear interactions which hold the nucleus together. Nowhere yet is there evidence for the breakdown of STR over the many scale decades in energy, time, distance and mass accessible to modern particle accelerators.

The metric of the new, "**Minkowski**" 4-dimensional space-time introduced into physics with STR is pseudo-Euclidean[145]. Laws of Euclidean geometry are still valid for the spatial part of space-time, but only in inertial frames; they are *violated* in a non-inertial frame. [To see this, consider a rigidly rotating disc in a Minkowski space-time. An inertial observer, who is *not* participating in the rotation, attaches a non-rotating circle under the rotating disc, measures the circumference L and diameter D of the disc, and finds $L/D = \pi$. But in a frame set up by an observer on the rotating disc, one finds that $L'/D' > \pi$, as a careful use of the Lorentz transformation shows.]

The year 1905 was ripe for the discovery of relativity. In 1900, **Larmor** (1857–1942) had already suggested that moving clocks must run slow, and by how much. Lorentz had published the final version of his transformation in 1903. In 1904 Poincaré attached the name of Lorentz to the transformation, and stated that there must be a new dynamics in which no velocity can exceed the velocity of light.

The sun loses a mass-equivalent of radiation at the rate of 4.5 million tons per second. At this rate it loses a moon-mass once every 500,000 years, and an earth-mass every 40 million years. The sun's radiation incident each second on the earth's surface has a mass equivalent of order 2 kilograms.

145 The distance (interval, ds) between two closely neighboring points is given by $ds^2 = -c^2dt^2 + dx_1^2 + dx_2^2 + dx_3^2$. Writing $-c^2dt^2 = -dx_0^2$, we have $ds^2 = -dx_0^2 + dx_1^2 + dx_2^2 + dx_3^2$, which is the analog of the Pythagorean theorem in *Minkowski geometry*. For two events having a time-like separation — i.e. there exists an inertial frame in which they occur at the same spatial point — $ds^2 < 0$, so technically ds is imaginary in this case.

Lorentz himself, in spite of his early involvement, was not happy with relativity and felt, to his last day, that time and space are completely distinct and a universal *true* time must exist.

Einstein was born in Ulm, Württemberg, Germany, the son of Hermann and Paulina (neé Koch) Einstein. After public school in Münich and in Aarau, Switzerland, Einstein studied mathematics and physics at the Swiss Polytechnic Institute in Zürich. He graduated in 1900.

From 1902 to 1909 he worked as an examiner at the Swiss Patent Office, in Bern. This job allowed him much free time, which he spent in scientific investigations. In 1903 Einstein married a fellow member of his class at Zürich — Mileva Maric (1875–1948) from Serbia. They had two sons: Hans Albert (1904–1973) and Edward (1910–1964). He became a Swiss citizen in 1905. The year 1905 was Einstein's '*annus mirabilis*' — a year to rank alongside 1543 (when Copernicus published '*De Revolutionibus Orbium Coalestium*') and 1686 (when Newton completed his '*Principia*').

One of the great ironies in the history of physics, is that Einstein submitted his 1905 paper on special relativity to the University of Bern in support of his candidacy for an affiliation giving him the right to practice as a *Privatdocent* (entitled to offer instruction under the auspices of the university) — and it was rejected! However, his work attracted the interest of greater men, in particular **Max Planck** in Germany and **H.A. Lorentz** in Holland. It is amazing how a junior civil servant with only the formal training of a schoolteacher could rearrange the structure of physics created by such giants as **Maxwell**, **Boltzmann**, **Lorentz** and **Planck**.

Einstein once remarked that he had never met a real physicist until he was 30. The only person he was able to discuss his ideas with was an engineer, **Michelangelo Besso** (1873–1955), then also an employee at the patent office, whom Einstein had known since his student days in Zürich, and whom he has immortalized in the last sentence of his 1905 paper: "*In conclusion I wish to say that in working at the problem here dealt with, I have had the loyal assistance of my friend and colleague M. Besso, and that I am indebted to him for several valuable suggestions*".

Immediately after the publication of that paper, Einstein was offered an associate professorship at the University of Zürich, which he held for three semesters[146]. In 1911 he joined the German University in Prague, where he held the position of professor ordinarius in physics, the highest academic rank.

[146] His boss at the Patent Office had no idea what a great scientist he was harboring within his walls, and when Einstein announced his resignation from his post he was greatly surprised and asked him for his reasons. Einstein told him that he had been offered the post of Professor at the University of Zürich. 'Now

Despite his absorption in his scholarly pursuits, he could not fail to notice the political strife and quarrels between the rival nationalists, and felt great sympathy for the Czechs and their aspirations. In 1912 Einstein returned to Switzerland, where he taught at the Polytechnic, the same place to which he had come as a poor student in 1896. His friend and colleague, Max Planck, succeeded in obtaining for him a professorship at the Prussian Academy of Science in Berlin, a research institute where Einstein could devote all his time to research.

Einstein took up his new position in April 1914. Very soon after making the move to Berlin with her husband, Mileva Einstein returned to Zürich with their two boys. As the war raged on unabated, Einstein remained separated from his family in the German capital, where he was putting the finishing touches to the general theory of relativity.

The stress of the war[147], many years of overwork and a catalogue of personal catastrophes were to take their toll on Einstein with unexpected ferocity. In the early part of 1917, he fell into a period of a severe sickness from which he did not fully recover until 1920 and which severely hampered his work. With the help of his cousin, Elsa Löwenthal, Einstein dragged himself out of his depression which had accompanied the physical symptoms. He divorced Mileva in 1919, giving her and the children the entire proceeds from the Nobel prize which he was certain to receive within a few years (1922). He later married Elsa who became his lifelong companion.

International fame came to Einstein in 1919, with the announcements that a prediction of his general theory of relativity was verified. In 1921 he was awarded the Nobel prize in Physics for his work on the photoelectric effect. In 1932 Einstein accepted an invitation to spend the winter term at the California Institute of Technology. By January 1933, Einstein resigned from his position at the Royal Prussian Academy of Sciences, and never returned to Germany. Many positions were offered him, but he finally accepted a professorship at the new Institute for Advanced Study in Princeton[148], New Jersey, and later became an American citizen.

Einstein', he answered, 'don't make any foolish jokes. Nobody would believe such an absurdity.'

147 One of his friends, a physician, described Einstein's lifestyle during the first half of the war thus: "... *he sleeps until he is wakened; he stays awake until he is told to go to bed; he will go hungry until he is given something to eat; and then he eats until he is stopped*". During the first three months of his illness, diagnosed as a stomach ulcer, Einstein lost some 25 kg.

148 His first impressions of Princeton were: "*A quaint ceremonious village of puny demigods on stilts*".

During WWII secret news reached U.S. physicists that the German uranium project was progressing. Einstein, when approached by his friend **Leo Szilard** (1898–1964), signed a letter to President Roosevelt pointing out the feasibility of atomic energy. It was that letter which sparked the Manhattan Project and future developments of atomic energy. In 1945 Einstein retired from his position at the institute, but continued to work there. Despite his advancing age he continued to work on the "Unified Field Theory", which attempted as a first step to unify gravitation and electromagnetism into one theory.

Einstein was not only one of the greatest scientists of all time, but also a generous person, who took out time and effort to help others and spoke out openly for his beliefs and principles. He never forgot that he had been a refugee himself, and lent a helping hand to the many who asked for his intervention. The man who refused to write popular articles for his own profit, devoted hours to raising money for refugees and other worthwhile causes.

Einstein was a Jew, not only by birth but also by belief and action. He was in full harmony with the two fountain heads of Judaism: Justice and Charity. The democratic and humanitarian character of the Mosaic Law was deeply embedded in his conscience, and the magnificent poetry of the Old Testament prophets filled him with awe. He took an active part in Jewish affairs, wrote extensively, and attended many functions in order to raise money for Jewish causes. He was first introduced to Zionism during his stay in Prague, where Jewish intellectuals gathered in each other's homes talking about their dream of a Jewish homeland.

In 1921, **Chaim Weizmann** (1874–1952), then president of the World Zionist movement, asked Einstein to join him on a fund-raising tour of America to seek aid for the nascent Hebrew University. Einstein readily agreed, since his interest in the university had been growing. The tour was highly successful. He visited the land of Israel and was greatly impressed by what he saw. Einstein appeared before the Anglo-American Committee of Inquiry in 1946, and entered a strong plea for a Jewish homeland.

When the State of Israel was established, he hailed the event as the fulfillment of an ancient dream, providing conditions in which the spiritual and cultural life of a Hebrew society could find free expression. After Weizmann's death he was asked by **David Ben-Gurion** (1886–1973), then the Prime Minister of Israel, to stand as a candidate for the presidency of the young state, which he declined "being deeply touched by the offer but not suited for the position". When he was hospitalized for the illness which proved to be his last, he took with him the notes he had made for the television address he was to give on Israel's seventh Independence Day.

Some of the theoretical physicists who collaborated with Einstein in Princeton were: **Boris Podolsky** (1896–1966; coll.: 1931–1935), **Leopold Infeld** (1898–1968; coll.: 1936–1939), **Nathan N. Rosen** (1909–1992; coll.: 1932–1937). Rosen worked with Einstein on the foundations of Quantum Mechanics, gravitational lenses, and on two-sheeted spaces ('*Einstein-Rosen bridge*'). Infeld also collaborated with Max Born on non-linear corrections to Maxwell's equations under conditions of strong fields.

As Einstein's own mathematical skills were not exceptional, he had employed the assistance of an outstanding mathematician in his work on GTR. He was **Jakob Grommer** (ca 1883–1933), with whom he coauthored a number of papers and was acknowledged in others, during 1917–1929. It means that Grommer collaborated with Einstein for twelve years — longer than anyone else. Grommer was born in Brest-Litovsk. He was a studious disciple in the local Yeshiva, intending to become a Rabbi. A burning interest in mathematics brought him to Göttingen. In an incredibly short time, he not only acquired a deep knowledge of mathematics but produced an essay which so impressed **David Hilbert** that the faculty decided to grant him a doctorate in spite of the fact that he had never graduated from high school. If one considers that he was disfigured as the result of a malignant disease, and that he was, moreover, physically weak, then one can appreciate how uncommon the talents were which this man brought into the world. In 1929 Grommer returned to his homeland. He became a professor in Minsk and a member of the Academy of the Belorussian Soviet Republic.

Worldview XXIX: Einstein

God, Nature and Quantum Mechanics

* * *

"The eternal mystery of the world is its comprehensibility."

* * *

"How insidious Nature is when one is trying to get at it experimentally."

(1915)

* * *

"Coincidence is God's way of remaining anonymous."

* * *

"Nature conceals her secret by exaltedness, but not by cunning."

(1930)

* * *

"Nature is showing us only the tail of the lion. But I have no doubt that the lion belongs to it, even though, because of its Colossal dimensions, it cannot directly reveal itself to the beholder."

(1914)

* * *

"I want to know how God created this world. I am not interested in this or that phenomenon, in the spectrum of this or that element. I want to know His thoughts, the rest are details."

* * *

"Raffiniert ist der Herr Gott, aber boshaft ist er icht. ("God is subtle, but he is not malicious.")

* * *

"What really interests me is whether God could have made the world differently; in other words, whether the demand for logical simplicity leaves any freedom at all."

* * *

"When I am judging a theory, I ask myself whether, if I were God, I would have arranged the world in such a way."

* * *

"The more success the quantum theory has, the sillier it looks."

* * *

"...undoubtedly a piece of definite truth – but not the whole truth, let alone the definite truth."

(1931, on quantum mechanics)

* * *

"It is hard to sneak a look at God's cards. But that he would choose to play dice with the world is something that I cannot believe for a single moment."

(1942)

* * *

"I can, if the worse comes to the worst, still realize that God may have created a world in which there are no natural laws. In short, a chaos. But that there should be statistical laws with definite solutions, i.e., laws that compel God to throw dice in each individual case, I find highly disagreeable."

* * *

"Quantum mechanics is very worthy of regard. But an inner voice tells me that this is not the true Jacob. The theory yields much, but it hardly brings us close to the secrets of the Ancient One. In any case, I am convinced that He does not play dice."

(1926)

* * *

"I admire to the highest degree the achievement of the younger generation of physicists which goes by the name of quantum mechanics and believe in the deep level of truth of that theory; but I believe that the restriction to statistical laws will be a passing one."

(1929)

* * *

"You believe in a God who plays dice, and I in complete law and order in a world which objectively exists, and which I, in a wildly speculative way, am trying to capture... Even the great initial success of the quantum theory does not make me believe in the fundamental dice game."

Albert Einstein, in a letter to Max Born, December 4, 1926

Mathematics

* * *

"As far as the laws of mathematics refer to reality, they are not certain; and as far as they are certain, they do not refer to reality."

* * *

"How can it be that mathematics, being after all a product of human thought independent of experience, is so admirably adapted to the objects of reality?"

* * *

"Since the mathematicians have invaded the theory of relativity, I do not understand it myself anymore."

*
*
*

“Do not worry about your difficulties in mathematics, I assure you that mine are greater.” (replying to a letter from a little school-girl)

*
*
*

“I don’t believe in mathematics.”

*
*
*

“God does not care about our mathematical difficulties. He integrates empirically.

Music

*
*
*

“Music does not influence *research work, but both are nourished by the same sort of longing, and they complement each other in the release they offer.”*

(1928)

*
*
*

“First I improvise and if that doesn’t help, then I seek solace in ***Mozart****; but when I’m improvising and it appears that something may come of it, I require the clear constructions of* ***Bach*** *in order to follow through.”*

*
*
*

*“***Bach*** *and* ***Mozart*** *are my favorites; also* ***Schubert****, because of the composer’s ability to express emotions. I am considerably less fond of* ***Beethoven****, since his music is too dramatic and personal.*
Handel *is technically good but displays shallowness.* ***Schumann****’s shorter works are attractive because they are original and rich in feelings.*

Mendelssohn *had considerable talent but lacked depth. I like some lieder and chamber music by* ***Brahms****.*
I find ***Wagner****'s musical personality indescribably offensive so that for the most part I can listen to him with disgust. I consider* ***Richard Strauss*** *gifted but without inner truth and concerned too much with outside effects."*

(1939)

Science and mankind

* * *

"Why does this magnificent applied science which saves work and makes life easier bring us so little happiness? The simple answer: because we have not yet learned to make sensible use of it. Concern for man himself and his fate must always be the chief interest of all technical endeavors... in order that the creations of our mind shall be a blessing and not a curse to mankind. Never forget this in the midst of your diagrams and equations."

From an address at the California Institute of Technology,

Pasadena, February 1931

* * *

"One thing I have learned in a long life: that all our science, measured against reality is primitive and childlike – and yet it is the most precious thing we have."

* * *

"Science without religion is lame; religion without science is blind."

* * *

" Science will stagnate if it is made to serve practical goals."

* * *

" Physical concepts are free creation of the human mind and are not, however it may seem, uniquely determined by the external world."

(1937)

* * *

"The most beautiful thing we can experience is the mysterious. It is the source of all true art and science."

* * *

"The whole of science is nothing more than the refined thinking... Most of the fundamental ideas of science are essentially simple, and as a rule, can be expressed in a language comprehensible to everyone."

(1936)

* * *

"A theory, in order to deserve confidence, has to be based on generalizable facts... Never has a truly useful and profound theory been discovered by pure speculation."

(1918)

* * *

"Only the theory decides what can and what cannot be observed."

(1926)

* * *

"No amount of experimentation can ever prove me right; a single experiment can prove me wrong."

* * *

"Development of Western Science is based on two great achievements: the invention of the formal logical system (in Euclidean geometry) by the Greek Philosophers, and the discovery of the possibility to find out causal relationships by systematic experiment (Renaissance)."

(1953)

Judaism

* * *

"The Jewish religion is... a way of sublimating everyday existence... It demands no act of faith – in the popular sense of the term – on the part of its members. And for that reason there has never been a conflict between our religious outlook and the world outlook of science."

(1930)

* * *

"The support for cultural life is of primary concern to the Jewish people. We would not be in existence today as people without this activity in learning."

(1950)

* * *

"The pursuit of knowledge for its own sake, and almost fanatical love of justice and the desire for personal independence – these are the features of the Jewish tradition which makes me thank my stars that I belong to it."

(1934)

* * *

"Were I wrong, one professor would have been quite enough."

In response to a manifesto in which 100 Nazi professors charged him with scientific error

On the Human Condition

* * *

"Comfort and happiness have never appeared to me as a goal... The trite objects of human efforts – possessions, outward success, luxury – have always seemed to me contemptible, since early youth.

I live in that solitude which is painful in youth, but delicious in the years of maturity."

* * *

"Of what is significant in one's own existence, one is hardly aware, and it certainly should not bother the other fellow. What does a fish know about the water in which he swims all his life?

The bitter and the sweet come from the outside, the hard from within, from one's own efforts. For the most part I do the thing which my own nature drives me to do. It is embarrassing to earn so much respect and love for it. Arrows of hate have been shot at me too, but they never hit me, because somehow they belonged to another world, with which I have no connection whatsoever."

* * *

"The years of anxious searching in the dark, with their intense longing, their alternations of confidence and exhaustion and final emergence into light – only those who have experienced it can understand it."

* * *

"Personalities are not formed by what is heard or said, but by labor and activity. The most important method of education accordingly always has consisted of that in which the pupil was urged to actual performance."

* * *

"I believe with Schopenhauer that one of the strongest motives that leads men to art and science is escape from everyday life with its painful crudity and hopeless dreariness from the fetters of one's own ever-shifting desires. A finely tempered nature longs to escape from personal life into the world of objective perception and thought."

* * *

"I cannot imagine a God who rewards and punishes the objects of his creation, whose purposes are modeled after our own – a God, in short, who is but a reflection of human frailty... It is enough for me to contemplate the mystery of conscious life perpetuating itself through all eternity, to reflect upon the marvelous structure of the universe which we can dimly perceive and try humbly to comprehend even an infinitesimal part of the intelligence manifested in Nature.

(1932)

* * *

"The most precious things in life are not those one gets for money."

(1946)

* * *

"Morality is of the highest importance – but for us, not for God."

(1927)

* * *

"Try not to become a man of success, but rather try to become a man of value."

(1955)

* * *

"I soon learned to ferret out that which might lead to the bottom of things, to disregard everything else, to disregard the multitude of things that the mind but detract from the essential."

(1948)

* * *

"To us believing physicists the distinction between past, present, and future has only the significance of a stubborn illusion."

(1955)

* * *

"I believe that the terrible decline in man's ethical behavior is due primarily to the mechanization and depersonalization of our lives – a disastrous by-product of the development of the technological-scientific intellect."

(1946)

* * *

"Politics is for the present, while an equation is for eternity."

* * *

"Death is an old debt that one eventually pays. Yet instinctively one does everything possible to postpone this final settlement. Such is the game that nature plays with us."

(1955)

* * *

"If all efforts are in vain and mankind ends in self-destruction, the universe will not shed a single tear over it."

(1946)

* * *

"I do not know how the Third World War will be fought, but I do know how the Fourth will: with sticks and stones."

* * *

"If you want to live a happy life, tie it to a goal, not to people or things."

* * *

"A life directed chiefly toward the fulfillment of personal desires sooner or later always leads to bitter disappointment."

(1954)

* * *

"What is the meaning of human life, or for that matter, of the life of any creature? To know an answer to this question means to be religious."

* * *

"Mankind remains as idiotic as it always was, and it's no great pity; but that no one would then play Bach or Mozart any more – that is a pity."

(1950)

* * *

"The rarest and most valuable of all intellectual traits is the capacity to doubt the obvious."

* * *

"Everything is determined, the beginning as well as the end, by forces over which we have no control. It is determined for the insect as well as for the star. Human beings, vegetables, or cosmic dust, we all dance to a mysterious tune, intoned in the distance by an invisible player."

* * *

"Academia places a young person under a kind of compulsion to produce impressive quantities of scientific publications – a temptation to superficiality, which only strong characters can resist."

* * *

"Great spirits have always encountered violent opposition from mediocre minds."

* * *

"Imagination is more important than knowledge."

* * *

"Everything should be made as simple as possible, but not simpler."

* * *

"The search for truth is more precious than its possession.

* * *

"I never worry about the future. It comes soon enough."

(1945)

Others on Einstein

* * *

"Einstein is a typical Old Testament figure, with the Jehovah-type attitude that there is a law and one must find it."

Abraham Pais

* * *

"Einstein's struggle is our struggle today; It is the search for a final theory."

Steven Weinberg, 1993

* * *

"Few scientists have ever poised their ambitions as poetically or as nakedly as Einstein who spoke sometimes as if God were someone he met for coffee every day... To Einstein, God was a code word for the mystery and grandeur of the universe, the wellspring of awe, a reminder that there was something at the core of existence that all his equations could only graze, as he said once, "something we cannot penetrate"."

(Dennis Overbye, 1998)

* * *

"When I read a book on Einstein's physics of which I understood nothing, it doesn't matter: that will make me understand something else.*"*

(Pablo Picasso, 1956)

* * *

"I was able to appreciate the clarity of his mind, the breadth of his documentation, and the profundity of his knowledge... One has every right to build the greatest hopes on him and to see in him one of the leading theoreticians of the future."

Marie Curie, 1911

* * *

"Einstein would be one of the greatest theoretical physicists of all time even if he had not written a single line on Relativity."

Max Born

* * *

"What we must particularly admire in him is the facility with which he adapts himself to new concepts and knows how to draw from them every conclusion."

Henri Poincaré, 1911

* * *

"Even though without writing each other, we are in mental communication for we respond to our dreadful times in the same way and tremble together for the future of mankind... I like it that we have the same given name."

Albert Schweitzer, 1955

* * *

"The revolutionary proletariat salutes the great revolutionary of the natural sciences as a fellow fighter against the dark forces of ignorance, barbarism and reaction."

(Soviet 'Pravda' on Einstein 50^{th} birthday, March 14, 1929)

* * *

"An Englishman would scarcely have produced this theory; perhaps it reflects the abstract-conceptual character of the Semite..."

(Sommerfeld to Wien (1907) on the Theory of Relativity)

* * *

"Unconfined by conventional restrictions, he confronted the world spirit as a laughing philosopher, and his witty sarcasm mercilessly castigated all vanity and artificiality".

Hans Byland (Einstein's classmate), 1928

* * *

"As befits a genius, Einstein ideas on gravitation had been irrational – a mixture of philosophical requirements with a powerful physical insight and a progressive penetration into the preparatory studies of the mathematicians."

(Felix Klein, 1921)

* * *

"Ptolemy made a universe, which lasted 1400 years. Newton, also, made a universe, which lasted 300 years. Einstein has made a universe, and I can't tell you how long that will last."

George Bernard Shaw

* * *

"One of the greatest – perhaps the greatest – of achievements in the history of human thought."

Joseph John Thomson, discoverer of the electron,

referring to Einstein's work on General Relativity, 1919

* * *

"Einstein was a physicist and not a philosopher. But the naive directness of his questions was philosophical."

C.F. von Weiszaecker

* * *

"Einstein explained his theory to me every day, and soon I was fully convinced that he understood it."

Chaim Weizmann, 1929

* * *

"Einstein was indisputably one of the greatest men of our time. He had, in a high degree, the simplicity characteristic of the best men of science – a simplicity which comes of a single-minded desire to know and understand things that are completely impersonal."

* * *

"He removed the mystery from gravitation, which everybody since Newton had accepted with a reluctant feeling that it was unintelligible."

* * *

"Of all the public figures that I have known, Einstein was the one who commanded my most wholehearted admiration... Einstein was not only a great scientist, he was a great man. He stood for peace in a world drifting towards war. He remained sane in a mad world, and liberal in a world of fanatics."

Bertrand Russell, 1955

* * *

"A generation or more ahead of his time, he gave physicists the theoretical tools to describe the big bang, quasars, pulsars and black holes. We live in Einstein's universe, and the only way to end our account of his scientific achievements is by looking at his description of the universe in which we live."

* * *

"At the end of the 1980s, a satellite known as COBE (from Cosmic Background Explorer) was launched by NASA to study the background radiation with more precision than ever before. In 1992, the NASA team announced that they had discovered exactly the kind of ripples in time that the theory

had predicted. It was headline news around the world – the combination of Einstein's general theory, the big-bang model, and the added ingredient of dark matter, had been vindicated. This was, and is, the most compelling evidence ever that the universe we live in is described by the equations of the General Theory of Relativity – that it is, indeed, Einstein's universe."

M. White and J. Gribbin, 1993

1905–1911 CE **Ejnar Hertzsprung** (1873–1967, Denmark). Astronomer. Discovered the most important graph ever plotted by astrophysicists. It relates the total energy output of each group of stars to the corresponding stellar temperature (known as "*Hertzsprung-Russell diagram*" (or 'R-H diagram'). His discovery, although just a method of two-dimensional spectral classification[149] of stars, led astronomers to extremely important discoveries concerning the relations between the luminosities and surface temperatures of stars which eventually resulted in the understanding of processes of stellar evolution.

Hertzsprung specialized in the study of binary stars and star clusters, and in 1905–1907 announced the discovery of *giant stars* (more voluminous than the mean; brightness and spectral class increase together). He was the first to recognize the distinction between giant and *dwarf* stars.

In 1908 Hertzsprung plotted a scatter diagram of stellar absolute magnitude against spectral class and in 1911 he compared colors and luminosities of stars within several clusters by plotting their magnitudes against their colors. In 1913 he calculated the distance of the *Small Magellanic Cloud* from the solar system.

Hertzsprung was born in Fredericksberg, Denmark. In 1898 he graduated from the Polytechnical Institute in Copenhagen in chemical engineering and then spent the next several years as a chemist in St. Petersburg, Russia. In

[149] "*Classification is one method, probably the simplest method, of discovering order in the world. By noting similarities between numerous distinct individuals as forming one class or kind, the many are in a sense reduced to one, and to that extent simplicity and order are introduced into the bewildering multiplicity of nature*". (A. Wolf, "Classification", *Encyclopedia Britannica* **5** (1954), 778.)

1901 he went to Leipzig to study photochemistry and returned to Denmark in 1902 to begin his study of astronomy. In 1909 he was invited by **Karl Schwarzschild** to Göttingen and later followed him to the Potsdam Observatory. From 1919 to 1944 he was a professor at the University of Leyden, Holland.

1905–1933 CE **Otto Toeplitz** (1881–1940, Germany and Israel). Mathematician. Toeplitz was born in Breslau (now Wroclaw, Poland). His father, Emil, and his grandfather, Julius, were both Gymnasium teachers of mathematics; and they themselves published several mathematical papers. In Breslau, Toeplitz completed his classical Gymnasium and then studied at the university, where he specialized in algebraic geometry and received his Ph.D. in 1905.

He began his academic career in Göttingen as a disciple of **David Hilbert**. Toeplitz was later a professor at Kiel (1913–1927) and Bonn (1927–1933). His scientific work centered around the theory of integral equations, theory of matrices[150], theory of quadratic forms and the theory of functions of infinitely many variables, fields to which he has made lasting contributions. The Nazis expelled him from Germany in 1938, whereupon he became a professor of mathematics at the Hebrew University in Jerusalem.

The Harvard Women (1882–1924)

There is some irony to the fact that Harvard University, long a stronghold of the all-male tradition in American colleges, was the institution that nurtured some of America's first leading women astronomers.

Edward Charles Pickering *(1846–1919, U.S.A.) was a pioneer astronomer in the study of stellar spectroscopy, and especially in the study of the spectra of binary stars. In* 1877 *he became director of the Harvard College Observatory. The work of* ***Pietro Angelo Secchi*** *(1818–1878, Italy), based*

[150] Introduced the $n \times n$ *Toeplitz matrices* having equal elements along diagonals parallel to the *principal* diagonal; *circulant matrices* are special cases of Toeplitz matrices.

on visual inspection of stellar spectra through a spectroscope, was the only attempt to classify stars according to the appearance of their spectra.

***Henry Draper** (1837–1882, U.S.A.), an amateur astronomer, had in* 1872 *became the first to photograph the spectrum of a star. Upon Draper's death, his widow endowed a new department of stellar spectroscopy at Harvard. As director, Pickering hired among his assistants a number of women, several of whom went to work on the problem of classifying spectra of stars:*

***Williamina P. Fleming** (1857–1911) published in* 1890 *the first Draper Catalog of Stellar Spectra. This catalog assigned some* 10,350 *stars in the Northern Hemisphere to spectral classes A through N, in a simple elaboration of a rudimentary classification scheme adopted earlier by Secchi.*

***Antonia C. Maury** (1866–1952), a niece of Henry Draper, classified during* 1889–1905 *the brighter stars from the north pole to declination* 30° *south of the equator. One of her classes, denoted by the letter C, was later recognized as* giant stars. *Maury's discovery helped* **Hertzsprung** *confirm the distinction he had found between giant and main-sequence stars, and he thought her work to be of fundamental importance. Another of her discoveries was a periodic doubling of lines in the case of Mizar, one of the stars in the handle of the Big Dipper. This was the first star to be recognized as a "spectroscopic binary".*

The most important of the Harvard workers in spectral classification arrived on the scene in 1896. *Her name was* ***Annie Jump Cannon** (1863–1941), and she gradually modified the classification system to the present sequence, finding that the arrangement O, B, A, F, G, K, M*[151] *was a logical ordering, with smooth transitions from one type to the next*[152]. *Cannon was able to distinguish the gradation so finely that she established the ten subclasses for each major division that are in use today. During her career at Harvard she personally classified* 500,000 *stars whose spectra appeared on survey plates covering both hemispheres. Cannon layed the groundwork for modern stellar spectroscopy, so fundamental to our understanding of the stars.*

***Henrietta Swan Leavitt** (1868–1921) joined the group as a volunteer in* 1894 *and subsequently played a leading role in the study of variable stars.*

---

[151] **H.N. Russell** proposed a scheme by which every student can remember the order of classes in the spectral sequence: The class letters are the first letters in the words, "*Oh, Be A Fine Girl, Kiss Me*!"

[152] At this time, there was still no inkling of the fact that this was a temperature sequence.

The Harvard women, including those mentioned here and several whose names are now obscure, were a remarkable group. They were responsible for a number of major advances in the science of astronomy at a time when its basis in physics was just becoming clear.

Conquest of the Polar Regions (1906–1912)

The explorers who followed Columbus soon found that North America was not a part of Asia, as they believed at first. At this time, British, French, and Dutch adventurers were more interested in finding the easy route to Asia than they were in exploring and settling North America. So they began to look for the Northwest passage, or waterway, that would take them through the continent.

Man had long known that the North Pole lay in the midst of the Arctic Ocean, 640 *kilometers from Cape Columbia, Canada. The Arctic is a frozen sea; tides and currents keep the ice pack in motion, making surface travel hazardous. During the brief Arctic summer, when the sun never sets, the surface of the ice pack melts. Great stretches of water open between the ice floes. Many men braved these waters in search of the Northwest passage and their quest is a tale of adventure and heroism. No country tried harder than England to find the passage.* ***Martin Forbisher*** *(1535–1594) began a series of English expeditions in* 1576*. Other Englishmen continued these explorations for* 300 *years.*

After the defeat of Napoleon at Waterloo in 1815*, Britain pledged herself to maintain the freedom of the seas, and the new Hydrographic Department of the Royal Navy, which has been established in* 1811*, began to carry intensive scientific surveys to make navigation safer for merchant shipping. Thus the Navy returned to the quest for the Northwest passage. It was interested in the passage for scientific reasons, but there was also alarm at the rapid extension* *of Russian influence on the shores of the Arctic Ocean, the Bering Sea and the Pacific seaboard.*

It seemed possible that the British and Americans might have to contend with a third power on the American continent and it was only a matter of time before the Russians began to search for the passage between the Pacific and the Atlantic. In 1847, **John Franklin** *(1786–1847, England) perished with his* 129 *men, and were only recently found. Finally, in 1906,* ***Roald Amundsen***[153] *(1872–1928, Norway) completed the first trip through the Northwest passage with his ship Gjöa, traveling from east to west, bringing to an end a* 400 *year long saga.*

At the turn of the 20th century it was realized that the best time for polar exploration was not during the summer, but during the long, dark winter. Temperatures plunge and savage winds rage across the Arctic in winter, yet the sea is frozen solid, providing a route to the pole for men with dog sleds.

In 1891*, the Philadelphia Academy of Natural Sciences put* ***Robert Edwin Peary*** *(1856–1920, U.S.A.) in charge of an expedition to northern Greenland. The knowledge gained from his experiments on this trip was proof that Greenland is an island. Other expeditions between* 1893 *and* 1897 *resulted in important scientific discoveries about the nature of the polar regions. Peary tried to reach the pole in* 1898 *and* 1905 *but failed. The final assault began in July* 1908*; with four Eskimos and his chief assistant,* ***Matthew Henson****, he reached the North Pole on April* 6*,* 1909[154]*.*

The South Pole lies in a high, mountain-rimmed plateau in the midst of the frozen Antarctic continent. It is the coldest and most desolate region

---

[153] During the International Geophysical Year (1957–1958), the U.S. Navy discovered a deep-channel route close to Amundsen's path. Through this channel, the U.S. atomic submarine *Seadragon* made in 1960 the first *underwater* crossing of the Northwest passage. It traveled 1368 km from Lancaster Sound, through the Canadian Arctic Islands, and into the McClure Strait. In 1969, the U.S. icebreaker-tanker *Manhattan* became the first commercial ship to complete the passage.

[154] Nearly 50 years after Peary's expedition reached the North Pole, the U.S. Navy atomic-powered submarine *Nautilus* slipped under the polar icecap off Point Barrow, Alaska, on Aug. 1, 1958. Guided by inertial navigation devices, Commander **William R. Anderson** pointed the submarine toward the North Pole. It was cruising as fast as 40 km/hr, with closed-circuit television plotting the outline of the icecap overhead. At 11:45 PM on Aug. 3, the *Nautilus* reached the North Pole, some 120 meters beneath the ice. Two days later the submarine surfaced in the Greenland Sea. The 5069-kilometer voyage extended through the back door of the *Northwest passage*, from the Pacific to the Atlantic.

on earth, larger in area than Europe and the United States together. In complete contrast to the Arctic — an ocean hemmed in by land — Antarctica is a landmass, hemmed in by sea and, for most of the year, by a rampart of pack-ice. Two great indentations, the Ross and Weddell seas, on the coastline of the continent closest to the South Pole itself, offered explorers the most promising entrances to the heart of the continent.

Roald Amundsen left Norway in 1910 *aboard his ship, the Fram. He hoped at first to reach the North Pole by drifting with the ice floes in the Arctic seas. But just as he was about to sail, he learned that Admiral R.E. Peary had arrived at the North Pole. Amundsen changed his plans and headed south to the Antarctic. In January* 1911 *he pitched camp on the Ross Ice Shelf and in October, when spring came to the Antarctic, Amundsen and four companions started inland across the ice. They had four sledges drawn by dogs. They traveled much of the time across the lofty plateau (3350 meters high and crisscrossed by dangerous cracks in the ice). On Dec.* 14, 1911, *the little group reached the South Pole.*

A month later, on Jan. 18, 1912, **Robert Falcon Scott** *(1868–1912, England), leading a rival expedition, found Amundsen's tent and flag still standing. Broken in spirit and body they began the long march to their base. It ended in a tragedy: Scott and his two remaining companions died on March* 29, 1912, *of hunger an cold, only* 18 *km from a supply depot. The three bodies, as well as Scott's own* Journal *were found by a search party on November* 12, 1912. *The epitaph on Scott's tomb reads: "To strive, to find, and not to yield".*

This race for the South Pole was one of the most dramatic events of the 20^{th} *century; the protagonists — Scott and Amundsen — were both highly capable, dedicated professionals. Their backgrounds, however, were very different, as were their characters. Scott was, by nature and training, a man in whom the desire for discovery for its own sake overlaid by the realization of the importance of scientific discovery, which had perhaps to some extent been forced upon him by the nature of the sponsored, semi-official expeditions that he had commanded.*

Amundsen was a free lance who had been inspired by his spirit of adventure to make the almost impossible Northwest passage in a puny vessel. In the Arctic he had learned that survival could best be ensured by copying the way of life of its inhabitants, the Eskimos, and this he did with conspicuous success. Like Peary, he employed dog teams to draw his sledges, sacrificing them in what to dog lovers seems a ruthless way, and he used Eskimo clothing.

Scott seems to have had no intention of taking dogs. He was a believer in woolen clothing, worn with waterproof gabardine smocks, although these tended to freeze solid.

In May 1926 Amundsen and Lincoln Ellsworth, an American explorer, crossed the North Pole in a dirigible, The Norge. The pilot of the Norge was Umberto Nobile, an Italian explorer. He organized a North Pole expedition in 1928, but it met with disaster. For six weeks, Nobile was believed dead. Amundsen led a party to find him. It was Amundsen's last expedition. He was lost in the Arctic while flying in an airplane with five other men. No one knows how the men died. Soon after their disappearance, Nobile was rescued.

1905–1907 CE **Joseph Henry Maclagen Wedderburn** (1882–1948, USA). Mathematician. Made advances in algebra, especially in the theory of rings, algebras and matrix theory. Discovered two fundamental theorems known by his name, one on the classification of semi-simple algebras, and the other on finite division rings: He showed (1907) that every semisimple algebra is a direct sum of simple algebras and that a simple algebra was a matrix algebra over a division ring. He showed (1905) that non-commutative finite field could not exist. This had as a corollary the complete structure of all finite projective geometries, showing that in all these geometries *Pascal's theorem* is a consequence of *Desargues' theorem*.

Wedderburn was born in Forlar, Angus, Scotland. He entered Edinburgh University (1898), obtaining a degree in mathematics (1903). He then pursued postgraduate studies in Leipzig, Berlin and Chicago, and returned to Edinburgh as lecturer (1905–1909). In 1909 he moved to Princeton, New Jersey, but returned to fight in the British army during WWI. After the war he settled at Princeton University until his retirement in 1945.

1905–1936 CE **Alexis Carrel** (1873–1944, France and U.S.A.). Surgeon and biologist. Developed techniques for rejoining severed blood vessels (1905) and transplantation of organs. Performed the first successful heart surgery on a dog (1914). Developed a form of artificial heart that was used during cardiac surgery (1936). Successful in cultivating chicken heart tissue outside the body for many years. Constructed a perfusion pump, for keeping organs alive outside the body.

Carrel was born in Lion, France and educated there. Professor at the University of Lion (1900–1902); to U.S.A. (1904). On the staff of the Rockefeller Institute for Medical Research (1906–1938). Awarded the Nobel prize for physiology or medicine (1912) for vascular grafting of blood vessels.

1905–1945 CE **Henry Joseph Round** (1881–1966, England). Electronic engineer. Discoverer of the phenomenon of electroluminescence[155] (the emission of light from a semiconductor diode). After the application of a potential of ten volts between two points on a crystal of carborundum, the crystal gave out a yellowish bright light (1907).[156,157]

Round is also known for numerous inventions that contributed to the development of radio communications. He worked with Marconi's Wireless Telegraph Company, both in the United States and England (1902–1914), where he build early radio direction finders and radio telephones. During WWI he installed networks of radio direction finders for military intelligence purposes.[158]

Rejoining the Marconi company after the war, Round designed and installed several important transmitters: from one, the first radio telephone messages were sent from Europe across the Atlantic. As a consultant to the Admiralty during WWII, Round worked on submarine-detection through echo sounding.

1906 CE **Lord Kelvin** disputed the developing theory of radioactive disintegration of atoms, suggesting that radium (discovered 1898) is not an element but a molecular compound of lead and helium. In 1911, **Marie Curie** proved him wrong.

1906 CE, April 18, 05:12 PST A major earthquake hit the city of San Francisco, causing 700 casualties, massive destruction, and marking the end of the Golden West[159].

---

[155] See: Loebner, E.E., *Subhistories of the light-emitting diode*, IEEE Transactions on Electron Devices, pp. 675–699 (1976).

[156] Round, H.J., *A Note on Carborundum*, Electrical World, 49, p. 308 (1907).

[157] In 1962, four research groups in the U.S. simultaneously reported a functioning LED semiconductor laser based on gallium arsenide crystals, thus opening the field of solid-state optoelectronics.

[158] One of these alerted the British Admiralty to the departure of the German fleet from Wilhelmshaven on May 30, 1916; the fleet's interception on the following day by the British occasioned the Battle of Jutland.

[159] Without California's mountain-building and faulting it would be hard to imagine the Central Valley, San-Francisco Bay, and the Peninsula. The same features that make California earthquake-prone make it resource-rich as well as visually beautiful!

1906–1913 CE **Eugen Augustin Lauste** (1857–1935, France). Inventor. The Father of Sound-on-Film. Invented the production of sound from photographed vibrations *on a film*, projected upon a selenium cell. This was a crucial step in the development of the sound motion picture.

Although he achieved synchronization by photographing the sound *and* picture on the same strip of film, his invention was hindered by problems of amplification.

In 1913, Lauste took his equipment to the USA in search of support and funds, but he was met with lack of enthusiasm from the film industry.

In the mid 1920's, Bell Telephone Laboratories finally developed a system that successfully coordinated sound on records with the projector: The era of the silent movie ended in 1928 when sound was directly photographed on the film.

1906 CE **August Paul von Wassermann** (1866–1925, Germany). Physicist, bacteriologist and immunologist. One of the founders of immunology. Discovered and gave his name to a blood-serum test for syphilis (1906): an infected person will produce syphilis antibodies in the blood and in the *Wassermann test* these will react with known antigens to form a chemical complex.

Wassermann was born in Bamberg, Germany to Jewish parents and remained in close contact with Judaism throughout his life. Worked in Koch Institute for Infectious Diseases, Berlin (1890–1913) and in the Kaiser Wilhelm Institute in Berlin-Dahlem (1913–1925). Professor at the University of Berlin (1906–1911); Appointed full professor there in 1911. Worked under **Robert Koch** (1901).

1906 CE **Hermann Walther Nernst** (1864–1941, Germany). Physicist and chemist. Made extensive contributions to thermodynamics and electrochemistry. A founder of modern physical chemistry.

Formulated the third law of thermodynamics. It states that the entropy of any body vanishes at absolute zero. This theorem is deduced from quantum statistics and depends on the concept of discrete quantum states. It cannot be derived from purely classical statistics, in which entropy is only defined to within an arbitrary additive constant.

He also contributed to the theory of galvanic cells, thermodynamics of chemical equilibrium, theories of ions[160], properties of vapors at high temperatures and of solids at low temperature, and the mechanism of photochemistry.

---

[160] Nernst's application of the *Boltzmann factor* (by which the number of microstates in a reservoir decrease when the reservoir gives up energy) is widely used in physiology. Suppose that certain ions can pass easily through a semipermeable membrane of a neuron cell. An electrical potential is then established

His work had important applications in industry and science. He received the Nobel prize for chemistry on his researches in thermochemistry (1920).

Nernst was born in Briesen, Prussia and was educated at the universities of Zürich, Graz and Würzburg. In 1887 he became assistant to **Wilhelm Ostwald**, who with **Jacobus van't Hoff** and **Svante Arrhenius** established the independence of physical chemistry. He was a professor of physical chemistry at Göttingen (1890–1905) and Berlin (1905–1933).

Nernst was an exception to all the formality of Göttingen. He frightened everyone with his automobile. It was the first car in Göttingen, and Nernst was proud of it. One day he tried to show his students that it was safer than a fiacre (a coach and two horses). While several of them watched, he waved, started the motor, over-optimistically turned a corner with a roar, and promptly crashed into a shop window. There were no injuries, except for Nernst's dignity, but the incident helped to humanize life in Göttingen.

Nernst had two sons and three daughters. The two sons were killed in WWI. Two of his daughters were married to Jews and forced to leave Germany under the Nazis. Nernst retired in 1933. Thanks to the generosity of Lindemann he was invited to Oxford (1937). As for countless other German scientists, the Nazi period was for him a personal disaster in many respects.

Nernst was one of the first scientists to recognize Einstein, following the latter's publication in the Miraculous Year (1905). By 1909, Nernst had verified experimentally Einstein's conclusions concerning the law of Dulong and Petit that followed from the quantum-theoretical interpretation of the specific heat of solids.

Thus, Nernst came to believe that Einstein quantum theory of solids best fitted both the measured values and his theorem, and was ready to follow, pragmatically, Einstein's quantum ideas in his own specialized field.

In 1922 Nernst and Einstein issued together a new refrigerating patent.

---

across the cell. If the concentrations of the ions are C_1 and C_2, inside and outside respectively, then the resulting potential is $V = \frac{kT}{q} \log_e \left(\frac{C_1}{C_2}\right)$, where q is the charge on each ion, T is the absolute temperature, and k is Boltzmann's constant (*Nernst equation*).

The ions most important to the cell membrane potential are sodium (Na^+) and potassium (K^+). Each ionic species has associated with it a membrane potential that is maintained by a 'pump' in the membrane that forces Na^+ out and K^+ into the cell. At equilibrium, the Nernst equation shows that $V_{\text{Na}} = \frac{kT}{q} \log_e(C_0^{\text{Na}}/C_i^{\text{Na}}) = 55$ millivolt, $V_{\text{K}} = \frac{kT}{q} \log_e(C_0^{\text{K}}/C_i^{\text{K}}) = -70$ millivolt. These are referred to as the sodium and potassium resting potentials.

In an obituary in 1942, Einstein paid tribute to Walther Nernst, who died in 1941; Just as if there were no war, he gave homage to the liberal-mindedness of his sometime patron and colleague.

1906 CE **Greenleaf Whittier Pickard** (1877–1956, USA). Electrical engineer and inventor. Discovered the *crystal detector* — the point-contact rectifier that was the forerunner of the *transistor* (1948).

He found that the contact between a fine metallic wire ("cat whisker") and the surface of a certain crystalline materials (notably silicon) rectifies and demodulates high-frequency alternating currents, such as those produced in a receiving antenna of radio waves. This device, called a crystal detector (patented by Pickard in 1906) was an essential component of the crystal set, a form of radio receiver that was popular until it was replaced by the triode vacuum tube.

Pickard was one of the first to demonstrate the wireless electromagnetic transmission of speech. In 1899, at the Blue Hills Observatory at Milton MA, he transmitted spoken messages by radio over a distance of 15 km, using a carbon-steel detector to recover the audible signal that had been impressed on the *radio-frequency carrier waves.*

Pickard (a grandnephew of the poet John Greenleaf Whittier, 1807–1892) was educated at Harvard University and M.I.T., Cambridge. He worked as an engineer at the American Telephone and Telegraph Company (1902–1906) and after 1945 headed the electronics engineering firm of Pickard and Burns.

Crystal radio receivers were inconvenient, however, because the signal received was very weak and in order to hear it, it had to be connected to a loudspeaker, which itself was connected to a headset. The completion of the first *diaphragm and trumpet loudspeakers* encouraged **David Sarnoff** to undertake the industrial manufacture of diode and triode radio sets, which were enclosed in wooden boxes so that it was possible to listen in as a group without any special equipment. This was an enormous success and it prepared the arrival of radiotransmission to a large audience. Most of these receivers appeared in 1921.

1906 CE **Henry Harrison Chase Dunwoody** (1842–1906, USA). Army General and inventor. Patented *silicon carbide* (carborundum) crystal radio detector. It allows current to flow in one direction, so that only the upper half of the modulated wave is allowed to pass. It lead to the advent of 'crystal set' (1910), making it possible for amateurs to build their own wireless receivers and listen to early radio transmissions.

1906 CE **Bernard Brunhes** (1867–1910, France). Physicist. Discovered the phenomenon of *geomagnetic reversal* in ancient lava flows from the Massif Central mountain range in France.

Many rock samples (containing iron-rich minerals particles) of different ages and from different localities have shown a magnetic polarization opposite to that of the present field. Brunhes found evidence of the latest of such reversals, occurring some 700,000 years ago, in iron-rich particles in an ancient lava flow in France.

Since then, examples have been found in almost every part of the world. It is believed that the earth's field reversed its polarity several times during the past 20 million years — the duration of the reversal process being of the order of 10,000 years.

1906–1907 CE **Andrei Andreyevich Markov** (1856–1922, Russia). Mathematician. Developed the theory of linked probabilities where the occurrence of one event determines the probability distribution of the following event, so that the future distribution of a variable depends only upon the present value and not on the sequence of past events. These sequences are named for him since he was first to study them systematically. Usually the term *Markov process* is restricted to sequences of events in which the random variables can assume continuous values. The analogous sequences of discrete-valued variables are called *Markov chains*.[161]

Markov was born in Ryazan, Russia. From 1886 he taught at the University of St. Petersburg. His early work was devoted to number theory, analysis and continued fractions, but after 1900 he was chiefly occupied with probability theory. He derived his results *without* using the notion of measurable functions and modern theories of integration. His theory is widely applied in many natural phenomena, especially in the biological and social sciences.

1906–1908 CE **William Sealy Gossett**[162] (1876–1937, England). Mathematician. Made notable contributions to statistical theory, especially to *small-*

sample theory. Discovered the "*Student's*" *t-distribution*[163] (1907). His work with the t-ratio was destined to become a cornerstone of modern statistical methodology due to its fundamentality for inference. In particular it paved the way for the analysis of variance, which was to occupy an important place in the next generation of statistical research.

Gossett was born in Canterbury. After earning an Oxford degree in mathematics and chemistry under **Airy**, he began working in 1899 for Messrs. Guinness, a Dublin brewery.

Fluctuations in materials and temperature and the necessity for more accurate statistical analysis of a variety of processes, from barley production to yeast fermentation, urged him to seek mathematical advice. In 1906 he was therefore sent to work under **Karl Pearson** at University College, London. In the next few years Gossett made his most important contributions to statistics. He worked for the Guinness Company throughout his entire life.

1906–1914 CE **Boris Borisovich Golitzin** (1862–1916, Russia). Physicist and seismologist. Invented and built the *electromagnetic seismograph*[164]

[163] Because of his company's policy, which forbade publication by employees, it was necessary for Gossett to publish his scientific papers under a pen name. The pseudonym he chose was "*Student*". The *Student*'s distribution with ν degrees of freedom is specified by the probability density function $f(x) = \frac{1}{\sqrt{\pi\nu}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \left(1 + \frac{x^2}{\nu}\right)^{-(\nu+1)/2}$. For $\nu = 1$ it coincides with the Cauchy probability law. The n^{th} moment $E[x^n]$ exists only for $n < \nu$. If $n = \nu$ and n is odd then $E[x^n] = 0$, but if $n < \nu$ and n is even, then $E[x^n] = \nu^{n/2} \frac{\Gamma(\frac{\nu+1}{2})\Gamma(\frac{\nu-n}{2})}{\Gamma(\frac{1}{2})\Gamma(\frac{\nu}{2})}$. If $X_0, X_1, \ldots, X_n$ are $(n+1)$ independent random variables, each normally distributed with parameters $\mu = 0$ and $\sigma > 0$, then the random variable $\frac{X_0}{\sqrt{\frac{1}{n}\sum_{k=1}^{n} X_k^2}}$ has as its probability law the Student's distribution with parameter n, which is *independent* of σ.
Gosset discovered the t-distribution by a combination of mathematical and empirical work with *random numbers*, an early application of the *Monte-Carlo method*.

[164] In older seismographs (of the *mechanical* type), the motion is transferred from the pendulum to the recording pens in a purely mechanical way, and simultaneously magnified. In addition, the recording is mechanical (stylus on smoked paper). These requirements imply that the seismograph becomes rather bulky, and that friction is introduced both in the mechanical transmission and recording. To overcome friction it is necessary to use large pendulum masses, and indeed, pendulum masses of as much as 20 tons were used. In the Golitzin

with photographic recording (1906). This invention was a cardinal development in the science of seismology, since it enabled seismologists to obtain higher-quality data, with greater magnification over a wider spectral window.

Golitzin was born and educated in St. Petersburg. He studied first at the Naval Academy and then at the University. He completed his studies at the University of Strasbourg (1887–1891), and became in 1893 a professor of physics at Dorpat. In 1912 he received a D.Sc. degree from the University of Manchester. He died of pneumonia, contracted while traveling across Russia to establish a network of seismic stations equipped with his seismographs.

1906–1915 CE **Paul Langevin** (1872–1946, France). Physicist and inventor. Known for his fundamental work on the theory of *paramagnetic* substances (1906), the *Kerr effect* (1907), the *Bohr magneton* (1911) and the invention of *sonar* (1918). In 1908, Langevin derived a stochastic ordinary differential equation modeling *Brownian motion*.

Langevin's approach to the Brownian motion was different than those of **Einstein** and **Smoluchovski**: A Brownian particle of radius a, moving under the action of a random force, will obey the equation

$$m\frac{d^2x}{dt^2} + \gamma\frac{dx}{dt} = F(t),$$

where $x(t)$ is the position of the particle, m its mass, $\gamma \approx 6\pi\eta a$ is the frictional resistance coefficient and $F(t)$ represents the random force which fluctuates both in direction and magnitude, transferring momentum via collisions to m.

The force $F(t)$ is microscopically complicated, since each Brownian particle is typically subjected to some 10^{16} consecutive random impacts per second. However, on a macroscopic scale it can be considered as a stochastic process with independent, stationary distribution at each instance. One notes that the averages

$$\bar{x}(t) = \frac{1}{\Delta t}\int_t^{t+\Delta t} x(\tau)d\tau;$$

electromagnetic seismograph one or several coils are attached to the pendulum such that they are moving in the field of a permanent magnet. The magnet is attached to the frame and the coils are connected to a galvanometer. On the arrival of seismic waves, the coil is set in motion relative to the magnet, and induced current is used to deflect a galvanometer mirror. In this construction, friction is avoided.

$$\bar{F}(t) = \frac{1}{\Delta t}\int_t^{t+\Delta t} F(\tau)d\tau$$

satisfy the above equation of motion, when $x(t)$ and $F(t)$ are the *actual* position and force.

Our eye, or whatever measuring instrument is used, observes not $x(t)$ but rather the average $\bar{x}$. A solution of the Langevin's equation leads directly to Einstein's equation

$$\langle x(t)^2\rangle = kTt/3\pi\eta a,$$

where the absolute temperature of the ambient fluid enters via equipartition.

Einstein's own treatment of Brownian motion is formulated as follows. Denote the average density of particles at point x and time t as $n(x,t)$, and the fraction of particles which shift from point x to within $(x+\Delta, x+\Delta+d\Delta)$ in a *short time* τ as $\varphi(\Delta)$.

It is assumed that $\int_{-\infty}^{\infty}\varphi d\Delta = 1$ (particle conservation), $\int_{-\infty}^{\infty}\varphi\Delta d\Delta = 0$ [symmetry: $\varphi(-\Delta) = \varphi(\Delta)$], and that the probability of large shifts is small, i.e. $\varphi(\Delta)$ is concentrated at small values of Δ.

Clearly,

$$n(x, t+\tau) = \int_{-\infty}^{\infty} n(x-\Delta, t)\varphi(\Delta)d\Delta.$$

Expanding the density in Taylor series

$$n(x-\Delta, t) = n(x,t) - \frac{\partial n}{\partial x}\Delta + \frac{\partial^2 n}{\partial x^2}\frac{\Delta^2}{2} - \cdots;$$

substituting this expansion into the integral and performing the integration, one obtains, in the limit $\tau \to 0$, for $n > 1$:

$$\frac{\partial n(x,t)}{\partial t} = D\frac{\partial^2 n}{\partial x^2},$$

$$D = \frac{1}{2\tau}\int_{-\infty}^{\infty}\varphi\Delta^2 d\Delta \qquad (diffusivity).$$

It follows from this equation, that if initially the particles were concentrated at the point x_0, then at moment t later we have

$$n(x,t) = \frac{1}{\sqrt{2\pi Dt}}e^{-\frac{(x-x_0)^2}{2Dt}}.$$

This implies that the root mean square of the deviation of the Brownian path is $\langle (x-x_0)^2\rangle^{1/2} = \sqrt{2Dt}$.

To derive an explicit expression for D, Einstein assumed that the particles suspended in the fluid fall under gravity and rise again by diffusion; the two competing tendencies balance on average to yield a Boltzmann distribution in the heights of the suspended particles, on account of the concentration gradient that gravity tends to set up.

The *steady-state* velocity of a particle subject to force F is given by Stokes' law $v = \frac{F}{6\pi\eta a}$, where a is the particle's radius and η the viscosity of the medium. Now, the statistical equilibrium condition is $nv = (-)D\frac{\partial n}{\partial x}$ where the $+x$ direction is *up*, since the r.h.s. is the average number of particles crossing a unit surface area downwards per unit time (due to gravity) and the l.h.s. is the number of particles which cross by diffusion in the *opposite* direction (by definition of D). Also

$$n = n_0 \exp\left((-)\frac{\chi}{kT}\right),$$

where χ is the potential of the force F, i.e. $F = \frac{\partial \chi}{\partial x}$. Hence:

$$(-)D\frac{\partial n}{\partial x} = Dn\frac{1}{kT}\frac{\partial \chi}{\partial x} = \frac{D}{kT}(nF) = nv = \frac{Fn}{6\pi\eta a},$$

namely

$$D = \frac{kT}{6\pi\eta a}$$

(*Einstein-Smoluchovski* relation). This relation, when combined with the above root mean square derivation, yields the Langevin expression for $\langle x(t)^2\rangle$.

1906–1916 CE **Marian Ritter von Smolan-Smoluchovski** (1872–1917, Poland). Outstanding theoretical physicist and a fine experimentalist as well. Developed the theory of the Brownian motion on the basis of the molecular kinetic theory, independently of Einstein, using a somewhat different method[165].

Smoluchovski, born to a Polish family, spent his early years in Vienna, where he also received his university education. After finishing his studies

[165] Smoluchowski showed that in the presence of a force-field, Einstein's equation $\frac{\partial P(t,x)}{\partial t} = D\frac{\partial^2}{\partial x^2}P(x,t)$ for the probability density $P(x,t)$ that a particle is at x at time t, should be replaced by $\frac{\partial P}{\partial t} = -\frac{1}{f}\frac{\partial}{\partial x}(PF) + D\frac{\partial^2 P}{\partial x^2}$. Here f is a frictional coefficient which can be expressed in terms of the viscosity of the ambient fluid and the size of the particles. The symbol F stands for either a constant force $(F = -a)$ or an elastic restoring force $(F = -bx)$.

in 1894, he worked in several laboratories abroad, then returned to Vienna, where he became Privatdocent. In 1900 he became a professor of theoretical physics in Lemberg (now Lviv), where he stayed until 1913. In that period he did his major work. In 1913 he took over the directorship of the Institute for Experimental Physics at the Jagiellonian University in Cracow. There he died, the victim of a dysentery epidemic. Einstein called him an ingenious man of research and a noble and subtle human being.

Functional Analysis (1900–1928)

Functional analysis (FA) seeks to discover deep-seated abstract relations that are common to certain branches of analysis, such as integral equations, the calculus of variations, differential equations, operator calculus, the theory of functions of a real variable, the theory of approximation of functions, linear algebra, and topology.

The rise and spread of functional analysis in the 20^{th} *century had two main causes. On the one hand it became desirable to interpret from a uniform point of view the copious factual material accumulated in the course of the* 19^{th} *century in various, often hardly connected, branches of mathematics.*

The beginnings of FA lies in the recognition that widely different kinds of mathematical operations*, from the basic operations of arithmetic to differentiation and integration, have strikingly many features in common; and that the* mathematical objects *subjected to these operations exhibit the same or similar properties in relation to the operations, although they originate from quite different fields of mathematics.*

Moreover, FA permitted an understanding of many results in the above domains from a single point of view and often promoted the derivation of new ones. In recent decades the preparatory concepts and apparatus were then used in a new branch of mathematical physics — quantum mechanics.

On the other hand, the investigation of mathematical problems connected with quantum mechanics became a crucial feature in the further development of FA itself; It created, and still creates fundamental branches of this development: numerous new concepts, which have become the basis of FA, are frequently used in modern mathematics.

Thus, FA has not yet reached its completion by far. On the contrary, undoubtedly in its further development the questions and requirements of contemporary physics will have the same significance for it as classical mechanics had for the rise and development of the infinitesimal calculus in the 18^{th} *century. Some of the main topics of FA are: Abstract spaces (metric spaces, normed spaces); functionals, approximation theory, operators (quantum mechanics makes extensive use of the mathematical apparatus of the theory of self-adjoint-operators).*

A brief history

FA was born in the early years of the 20th century as a part of a larger trend toward abstraction. This same trend contributed to the foundations of abstract linear algebra, modern geometry *and* topology. *Historically, the roots of FA must be sought in the period 1822–1837 in connection with early attempts to solve integral equations:* ***Fourier*** *(1822) offered the solution* $g(x) = \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-itx} f(t)\,dt$ *to the equation*

$$f(x) = \int_{-\infty}^{\infty} e^{itx} g(t)\,dt.$$

Abel *(1823) followed with the solution* $g(x) = \frac{1}{\pi}\int_a^x \frac{f'(y)}{\sqrt{x-y}}\,dy$ *to the equation*

$$f(x) = \int_a^x \frac{g(y)}{\sqrt{x-y}}\,dy$$

where $a \le x \le b,\ \ f(a) = 0.$

Liouville *(1837) discovered that the ODE* $f''(x) + f'(x) = g(x)$ *with the initial conditions* $f(a) = 1,\ f'(a) = 0$ *can be converted into the integral equation*

$$f(x) = \cos(x-a) + \int_a^x \sin(x-y) g(y)\,dy.$$

By the middle of the 19th century, interest in integral equations centered around the solution of certain boundary-value problems involving the Laplace equation $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0,$ *which were known to be equivalent to integral equations. It was then discovered that the study of integral equations is closely related to the study of systems of linear equations of infinitely many unknowns.*

The first rigorous treatment of the general theory of integral equations was given by the Swedish astronomer and mathematician ***Ivar Fredholm*** *in a series of papers from 1900 to 1903. His work was quite influential and attracted a great deal of attention although, curiously, his techniques were largely ignored for years.*

David Hilbert *continued Fredholm's work in a series of seminal papers (1904–1910). The importance of Hilbert's contribution is that he completely abandoned the integral equations, showing it to be a special case of the theory of systems of linear equations, thus beginning the* algebraization of analysis.

In another vein, ***Fréchet****, building on* ***Voltera's*** *concept of* functionals, *advanced a new '*Functional Calculus*' which was based on two very general principles:*

- *Basic notions from set theory,*
- *A notion of* limit, *which was assumed to be available in the particular class of spaces he considered.*

*In modern terms, Fréchet's 'Functional Analysis' was an early example of what we would now call '*point set topology*'. In particular, it was Fréchet who formalized the notion of a* metric space. *The main results in his 1906 thesis were generalizations of the work of*

▷ ***Cantor*** *(by generalizing the notions of the* interior of a set, a derived set, compactness, perfect set*)*

▷ ***Baire*** *(by generalizing the notion of* semi-continuous functions*)*

▷ ***Cesare Arzelà*** *(by extending the notion of* compactness *to set of functions)*

All these developments did not *stem from Hilbert's work. Fréchet's approach was so revolutionary, that he felt the need to justify it even as late as 1950.*

Hilbert's successors were ***Erhard Schmidt*** *(1907),* ***Friedrich Riesz*** *(1907) and* ***Ernst Fischer*** *(1908) who considered the notion of* convergence in the mean *for square-summable functions. Other important players in the story of FA were* ***Eduard Helly*** *(1922) and* ***Hans Hahn*** *(1922), but it was* ***Stefan Banach*** *(1922) who gave the first complete treatment of* abstract normed vector spaces.

As an example we consider the generalization of the classical concept of differentiation such that it can meet the needs of wider applications:

Traditionally, differentiation enables us to find the tangent to a curve at a given point. Very often, in a diagram showing a curve with a tangent, there is a considerable stretch where the eye cannot distinguish the curve from the tangent. In other words, over a single interval the tangent gives an excellent approximation to the curve. If (x, y) *is a point on the tangent to the graph* $y = f(x)$ *at the point* (x_0, y_0), *then the equation of the tangent is* $y - y_0 = f'(x_0)(x - x_0)$, *which is a* linear relation. *So, the problem of differentiation is equivalent to the problem of finding a linear function, relating the change in input to the approximate change in output, the approximation being good for small changes.*

In order to clarify what we mean by 'a good approximation' we turn to the traditional calculus. For instance, when $f(x) = x^3$ *we find that* $f(x_0 + h) - f(x_0) = 3hx_0^2 + (3h^2x_0 + h^3)$. *If* x_0 *is of order 1 and* h *is of the order, say, of* 10^{-6}, *then* h^2 *and* h^3 *are of the orders* 10^{-12} *and* 10^{-18} *respectively, and we may well write* $f(x_0 + h) - f(x_0) = 3hx_0^2 + \cdots$, *where the dots represent nonlinear terms in* h *that are small compared with* h. *If we use* $e(h)$ *to represent the terms omitted — "e" for error — a formal statement is that if* $f(x_0 + h) - f(x_0) = mh + e(h)$, *where* $e(h)/h \to 0$ *as* $h \to 0$, *then* $f'(x_0)$ *exists and has the value* m.

We now take a very small step in the direction of generalization, and consider a function f *that maps the vector* $u = (x, y)$ *to* $w = (q, p)$, *where* $p = xy$, $q = x^2 + y^2$. *Let* $h = (a, b)$. *When* (x, y) *change to* $(x + a, y + b)$, *the corresponding changes in the mapping are* $\Delta p = ya + xb + \cdots$ *and* $\Delta q = 2xa + 2yb + \cdots$, *where the omitted terms involve* a^2, ab *and* b^2. *Thus we may write* $\begin{pmatrix} \Delta q \\ \Delta p \end{pmatrix} = \begin{pmatrix} 2x & 2y \\ y & x \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix}$. *The vector* (a, b) *in this equation represents* h *(the change in input) and the approximate change in output is given by* Mh, *where* M *is the* 2×2 *matrix in the above equation. The error in our approximation is given by* $e(h) = (ab, a^2 + b^2)$.

We cannot keep our earlier condition, $e(h)/h \to 0$, *since in general it is not possible to divide one vector by another. However, we are not really interested in the* direction *of the vector* $e(h)$, *since we propose to neglect this vector. All we want to be sure of, is that its size is negligible compared with that of* h. *Sizes are measured by norms*[166]. *So the condition,* $\|e(h)\|/\|h\| \to 0$, *as* $\|h\| \to 0$, *is meaningful and is all we need demand. We are thus led to reformulate our definition of differentiation in a way that suits the above example and works equally well for a function* f *in any* Banach space:

If

$$f(u_0 + h) - f(u_0) = Mh + e(h),$$

[166] $\|v\|$, the norm, is the *length* of the vector v in a Euclidean space.

*where M is a bounded linear operator and $\|e(h)\|/\|h\| \to 0$ as $\|h\| \to 0$, the function f is called Fréchet-differentiable at the point u_0, and we define $f'(u_0) = M$ as the Fréchet derivative at a point u_0. (**Maurice Fréchet**, 1925).*

Requiring M to be bounded is much like requiring the number $m = f'(x_0)$ in traditional calculus to be finite. Note that the Fréchet derivative in our example is a matrix, and not a single number, since it transforms a vector into another nonparallel vector (in general). Multiplication by a number cannot do this, for it leaves the direction of the vector invariant. Multiplication by a matrix can change both length and direction, and $f'(u)$ turns out to be such a transformation.

The availability of a generalized derivative does not mean that all theorems of the traditional calculus have counterpart in functional analysis. Roll's theorem, for one, does not have such counterpart[167]. This means that the mean value theorem can only be generalized as an inequality.

1906 CE **Albert Einstein** completed a paper on the *specific heat of solids*, the first paper ever written on the quantum theory of the solid state (published, 1907) and the first attempt to deal with the problem of specific heats in the context of the quantum theory. Until 1906, Planck's quantum had played a role only in the rather isolated problem of blackbody radiation and in Einstein's explanation for the photoelectric effect in terms of the light quantum (photon). Einstein's work on specific heats made it clear for the first time that quantum concepts have a far more general applicability.

In the classical model of a monatomic solid, each atom vibrates about an equilibrium position; these vibrations constitute the thermal agitation of the crystal. The specific heat at constant volume is then defined as $C_v = \left(\frac{\partial E}{\partial T}\right)_v$,

[167] *A counter-example*: let ϕ map $t \to (x, y)$ with $x = t - t^2$, $y = t - t^5$. Then $\phi'(t) = (1 - 2t, 1 - 5t^4)$. Now $\phi(0) = (0, 0)$ and $\phi(1) = (0, 0)$, but there need be no T with $0 < T < 1$ such that $\phi'(T) = 0$. When we are dealing with a single number that starts at 0 and returns to 0, there will be a moment when its stops growing and begins to decrease, or vice versa. But when the output involves two numbers, x and y, there need be no such special moment (the number x ceases growing when $t = 0.5$, but y continues to grow until $t = 0.67$ approximately).

where E is the energy of vibration of the atoms and T is the absolute temperature. To within an additive constant, this energy E is the internal energy U of the solid.

Invoking the principle of equipartition of energy, adumbrated by **Clausius** and stated clearly by **Maxwell** (1860), each atom has $\frac{1}{2}kT$ of energy per degree of freedom (on average), with 6 degrees of freedom. Therefore N atoms have a total of $E = 6N\left(\frac{1}{2}kT\right) = 3NkT$. The heat capacity associated with these atoms is $C_v = \frac{dE}{dT} = 3Nk$ in this classical model.

The value $3Nk$ agrees with experimental results fairly well for most elemental solids at *high temperatures*; at low temperatures C_v is much lower than the constant $3Nk$ value. Experimentally, C_v for non-metals is found to be approximately proportional to T^3 at low temperatures, approaching zero as $T \to 0$.

Einstein set forth to explain the discrepancy and his work, like his innovative articles of 1905, proceeded directly and succinctly to the heart of the matter: He realized that the gradual disappearance of the atomic heat in approaching absolute zero is a *typical quantum effect*.

It is due to the fact that, in contrast to the fundamental assumptions of the classical law of *equipartition*, the oscillating lattice constituents cannot take up arbitrarily small amounts of thermal energy but (according to quantum mechanics) only integral energy quanta[168] $h\nu$ true for every oscillator of eigenfrequency ν. With decreasing temperature, the mean thermal energy kT finally becomes smaller than one vibrational quantum $h\nu$ for any given oscillation mode of frequency ν. Below that temperature, less and less energy quanta are available to the crystal — more and more modes of vibration are "frozen out".

Consequently, with decreasing number of the degrees of freedom which are able to absorb thermal energy, the specific heat decreases toward zero. The lighter the atoms of a specific crystal are, the higher is the temperature at which this "starving" of degrees of freedom occurs. This is due to the fact that the vibrational energy quanta are the larger the smaller the oscillating masses are.

The statistical computation is very similar to that of the cavity oscillations which lead to Planck's radiation formula and the result reflects this similarity. If we assume *a single eigenfrequency* ν_0 of the crystal atoms, Einstein's

[168] These mechanical vibrational quanta are known today as *phonons*, rhyming with *photons*. A phonon is the quantum of *sound* or *elastic* waves in a crystal lattice.

theory[169] leads to the atomic heat

$$C_v = 3Nk\xi^2 \frac{e^\xi}{(e^\xi - 1)^2},$$

where $\xi = \frac{h\nu_0}{kT}$, instead of the classical result $C_v = 3Nk$. At sufficiently high temperature $(\xi \to 0)$, this expression approaches $3Nk$ in agreement with the law of **Dulong** and **Petit**. The characteristic eigenfrequency ν_0 was determined by Einstein from a comparison of his formula with the empirical temperature dependence of the specific heats. (For alkali halide crystals, he obtained values of ν_0 that agreed within 20 percent with the frequencies of the optical fundamental vibrations.)

---

169 Einstein wrote the energy per each of the $3N$ one-dimensional oscillators as

$$U(\nu, T) = \frac{\int \epsilon e^{-\epsilon/kT}\omega(\nu,\epsilon)d\epsilon}{\int e^{-\epsilon/kT}\omega(\nu,\epsilon)d\epsilon}.$$

The exponential factor denotes the statistical Boltzmann factor for the energy ϵ. The weight factor ω contains the dynamic information about the density of states between ϵ and $\epsilon + d\epsilon$. For the case at hand (linear oscillators), the classical theory requires $\omega \equiv 1$, which leads to the *equipartition* result $U = kT$. Einstein's assumption, written in modern notation, is $\omega = \sum_n \delta\left[\epsilon - \left(n + \frac{1}{2}\right)h\nu\right]$.

A straightforward integration then yields $E = 3NU = \frac{3N}{2}h\nu + 3N\frac{h\nu}{e^{h\nu/kT}-1}$. Taking the derivative w.r.t. T, Einstein's final expression for C_v is obtained.
Debye's analysis (1912) begins with the results for the characteristic vibrations of an enclosure of volume V in which two kinds of elastic waves can propagate with the respective velocities v_ℓ (longitudinal) and v_t (transverse). The number of characteristic frequencies and of corresponding lattice models (coupled-atom modes) between ν and $\nu + d\nu$, counting all types of waves, is $dn = 4\pi V\left(\frac{1}{v_\ell^3} + \frac{1}{v_t^3}\right)\nu^2 d\nu$. Altogether, $3N$ of them are found, going up to ν_0 such that $3N = \frac{4\pi V}{3}\left(\frac{1}{v_\ell^3} + \frac{2}{v_t^3}\right)\nu_0^3$. Hence $dn \equiv g(\nu)d\nu = \frac{9N}{\nu_0^3}\nu^2 d\nu$. To each degree of freedom (mode) having frequency ν, Debye assigned the average energy found in Einstein's single-mode analysis. Hence $dn' = \left[\frac{9N}{\nu_0^3}\nu^2 d\nu\right]\frac{1}{e^{\frac{h\nu}{kT}}-1}$. The total vibrational energy of the solid is $E - E_0 = \int_0^{\nu_0} h\nu dn' = \frac{9Nh}{\nu_0^3}\int_0^{\nu_0}\frac{\nu^3 d\nu}{e^{h\nu/kT}-1}$ where E_0 is the energy at absolute zero, corresponding to atoms executing zero-point motion. The expression for $C_v = \left(\frac{\partial E}{\partial T}\right)_v$ then leads to the Debye integral.

In spite of this success, it was clear that the basic assumption of Einstein's theory, the existence of only one eigenfrequency of the crystal, is too much of a simplification. Thus it was not surprising that this model failed to yield the observed relation $C_v \propto T^3$ at low temperatures, since the higher frequency did not "freeze" at the same temperature values for lower frequencies.

Debye (1912) first carried out the quantization of the eigenfrequencies of the entire lattice (coupled-atoms eigenmodes of vibration). The crystal in his theory is treated as *one* atomic system the states of which are characterized by different eigenfrequencies, with a limiting maximal cut-off vibration frequency.

His final formula is

$$C_v = 9Nk\left(\frac{T}{\Theta_{_D}}\right)^3 \int_0^{\Theta_D/T} \frac{x^4 e^x}{(e^x-1)^2}dx,$$

where $\Theta_{_D} = \frac{h\nu_c}{k}$ is the *Debye temperature*, and the cut-off frequency ν_c is determined from $3N = \frac{4\pi}{3}V\left(\frac{1}{v_\ell^3} + \frac{2}{v_t^3}\right)\nu_c^3$. Here V is the volume of the sample, and $\{v_\ell, v_t\}$ are the respective longitudinal and transverse propagation velocities of elastic waves in the crystal.

Certain deviations from the Debye theory are still to be observed at low temperatures as well as very high temperatures, due to the still insufficient treatment of *details of the vibrational spectrum*. These include the anharmonicity of the vibrations, which causes a decrease of the higher vibrational quanta and may be though of as due to collisions among phonon pairs. For metals, a small contribution of free electrons to the observed specific heat has also to be taken into account at low temperatures.

1906–1916 CE **Pierre Maurice Duhem** (1861–1916, France). Historian of science. Uncovered unsuspected aspects of medieval science and contradicted the myth of medieval scientific backwardness. He brought to light the Parisian school, in particular the work of **Jean Buridan** (1295–1358), **Nicole Oresme** (1323–1382) and **Albert of Saxony**[170] (1316–1390, Germany) and showed how their work on mechanics was known to **Leonardo da Vinci** and subsequently led in the 17^{th} century to the development of such basic notions of Galilean and Newtonian physics as *impetus* (momentum) and *inertia*.

---

[170] Also known as Albert von Helmstädt. German scholastic philosopher. Rector of University of Paris (1353–1362) and of University of Vienna (1365–1366). Bishop of Halberstadt (1366). Wrote on mathematics, physics, logic. Helped spread the logic of William of Ockham.

Duhem taught at Lille (1887–1893), Rennes (1893–1894), and Bordeaux (1894–1916). In his early work (1903) he made pioneering attempts to establish a theory of irreversible thermodynamic processes, but these ideas were in advance of their time and did not receive recognition in his lifetime. This was partly because he disproved a favorite theorem of **Berthelot**, an influential chemist and minister of education who saw to it that Duhem was never elected to a chair at Paris.

1906–1925 CE **Maurice Rene Fréchet** (1878–1973, France). Distinguished mathematician. Created a geometry of abstract metric spaces. Developed further the functional calculus of **Volterra** and introduced the concept of the '*Fréchet derivative*'.

Fréchet was born in Maligny, France. He was a professor of mechanics at the University of Poitiers (1910–1919), a professor of higher calculus at the University of Strasbourg (1920–1927) and a professor of mathematics at the University of Paris (1928–1948).

The *Fréchet derivative* of a nonlinear operator is a generalization of the derivative of a real-valued function based on the idea of *local linearization*; it enables us to find a linear approximation to a nonlinear operator in a neighborhood of some given point. Regarding this as a point in the appropriate function space, we can find a local linearization of the original nonlinear operator equation in a neighborhood of this point. We can iterate this process, and it is a generalization of *Newton's method* for solving an equation in a single real variable.

Let $P\colon S \to B_2,\ S \subseteq B_1$ be an operator mapping of a subset S of Banach space B_1 into a Banach space B_2. Let x_0 be an element of B_1 such that S contains a neighborhood of x_0.

Then P is said to be *Fréchet differentiable* at x_0 if there is a continuous *linear* operator $L\colon B_1 \to B_2$ such that $P(x) = P(x_0) + L(x - x_0) + G(x, x_0)$, with $G\colon B_1 \to B_2$ defined by $G(x, x_0) = P(x) - P(x_0) - L(x, x_0)$, satisfying

$$\lim_{\|x-x_0\|\to 0} \left\{ \frac{\|G(x,x_0)\|_{B_2}}{\|x - x_0\|_{B_1}} \right\} = 0.$$

If such a continuous (bound) *linear operator* L exists for a particular x_0 in B_1 we denote it $P'(x_0)$, the Fréchet derivative P at x_0, and write

$$P(x) = P(x_0) + P'(x_0)(x - x_0) + G(x, x_0)$$

where $G(x, x_0)$ satisfies the condition given above.

Consider the following examples:

- Denote the real line by $\mathbb{R}$ and let $[a,b]$ be an interval in $\mathbb{R}$. Now $\mathbb{R}$ is a *Banach space* with norm $\|x\| = |x|$ for x in $\mathbb{R}$. Let $f\colon [a,b] \to \mathbb{R}$ be a real valued function, and let x_0 be in $[a,b]$; then the Fréchet derivative of $f(x)$ at x_0 is the ordinary derivative $f'(x_0)$. Since $f'(x_0) = \lim_{|x-x_0|\to 0} \frac{f(x)-f(x_0)}{x-x_0}$, it follows that $f(x) = f(x_0) + f'(x_0)(x-x_0) + G(x,x_0)$ with $\lim \frac{|G(x,x_0)|}{|x-x_0|} = 0$.
- The n-dimensional Euclidean space, E^n, with norm $\|x\| = \left(\sum_{i=1}^n x_i^2\right)^{1/2}$ is also a Banach space.

Let $P\colon S \to E^n$, $S \subseteq E^n$ be a mapping defined on a subset S of E^n which contains a neighborhood of a point x_0. It is not hard to show that $P'(x_0)$, if it exists, is the *Jacobian* matrix with elements $\left.\frac{\partial P_i}{\partial x_j}\right|_{x_0}$, $i,j = 1,2,\ldots,n$.

A sufficient condition for the existence of $P'(x_0)$ is the continuity, at x_0, of the partial derivatives. In this case, we have $P_i(x) = P_i(x_0) + \sum_{j=1}^n \left.\frac{\partial P_i}{\partial x_j}\right|_{x_0} (x-x_0)_j + G_i(x,x_0)$, $\quad i = 1,2,\ldots,n$. The limit $DP(x_0)(y) = \lim_{\eta\to 0} \frac{P(x_0+\eta y)-P(x_0)}{\eta}$, if it exists, is called the *Gâteau derivative* (1919) of P at x_0 in the direction y, where $y \in E^n$.

As a special application of the foregoing theory consider the mapping of the complex number $x+iy$ in E^2 to $f(x,y) = u(x,y) + iv(x,y)$. This function corresponds to $f(x,y) = \begin{pmatrix} u \\ v \end{pmatrix}$ in column vector notation for the mapping f.

The Fréchet derivative $f'(z_0)$ exists at $z_0 = x_0 + iy_0$ and is expressible as the Jacobian matrix $f'(z_0) = J(z_0)$ given by $J(z_0) = \begin{pmatrix} u_x & u_y \\ v_x & v_y \end{pmatrix}$ where $u_x = \left.\frac{\partial u}{\partial x}\right|_{z_0}$, etc., provided that for every w in E^2 the limit $Df(z_0)(w) = \lim_{a\to 0} \frac{f(z_0+aw)-f(z_0)}{a}$ exists and $Df(z_0)w = J_0(z)w$.

Now suppose that the limit does exist for *every* w in E^2 and that $Df(z_0)w = J_0(z)w$. Then, regarding w and $f'(z_0)w$ as complex numbers, we have (with $w = w_1 + iw_2$),

$$f'(z_0)w = J_0(z)w = \begin{pmatrix} u_x & u_y \\ v_x & v_y \end{pmatrix} \begin{pmatrix} w_1 \\ w_2 \end{pmatrix} = \begin{pmatrix} u_x w_1 + u_y w_2 \\ v_x w_1 + v_y w_2 \end{pmatrix}.$$

Applying the rules of complex multiplication, we find

$$f'(z_0) = \frac{u_x w_1^2 + v_y w_2^2 + (u_y + v_x)w_1 w_2 + i\{v_x w_1^2 - u_y w_2^2 + (v_y - u_x)w_1 w_2\}}{w_1^2 + w_2^2}.$$

Since $f'(z_0)$ is independent of w we must have $u_x = v_y$ and $u_y = -v_x$ (the *Cauchy-Riemann relations*!), leading to $f'(z_0) = u_x + iv_x = v_y - iu_y$. Thus

$$f'(z_0) = \begin{pmatrix} u_x & -v_x \\ v_x & u_x \end{pmatrix} = u_x I + v_x J$$

where

$$I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

This matrix representation can be seen to be algebraically equivalent to the complex number $f'(z_0) = u_x + iv_y$ by means of an isomorphism between the complex number field and 2×2 matrices of the form $aI + bJ$. (In fact, we have $I^2 = 1$, $J^2 = -1$ so that, putting $I \sim 1$ and $J \sim i$ we have $aI + bJ \sim a + bi$ for any real numbers a and b.)

1906–1931 CE **Paul Ehrenfest** (1880–1933, Austria). Theoretical physicist. Clarified many of the basis assumptions of statistical mechanics[171], and contributed a variety of particular results[172]. He tackled the basic problem of reconciling the reversibility of classical mechanics with the irreversibility of the events of ordinary experience, showing that this is due to the extreme improbability of processes in which order spontaneously increases.

Ehrenfest was born in Vienna to Jewish parents who moved to the capital in 1860 from their home in Loschwitz, a little village in Moravia. He was educated in the University of Vienna and was a student of **Ludwig Boltzmann**. In 1912 he succeeded **H.A. Lorentz** to the chair of theoretical physics in Leyden.

During his entire academic life he was fully committed to maintaining clarity and intelligibility in the flood of new development, and in doing so extended himself up to and beyond the limits of his resources. Despite his

---

171 Collaborated in part of his work with his wife **Tatyana Alexeyevna Ehrenfest-Affanasyeva** (1876–1964).

172 For example, in 1913 Ehrenfest was first to suggest the correct quantization of the energy levels of the rigid molecular rotor with moment of inertia I: starting from the classical expression $E = \frac{1}{8\pi^2 I}$ (action)^2, he derived $E_n = \frac{n^2 h^2}{8\pi^2 I}$, $n = 1, 2, \ldots$.

achievements in science he was dissatisfied with his own development. Thus, the problems of his own life, exacerbated by the persecution of the Jews by the Nazis, led him to take his own life.

Albert Einstein, a dear friend of Ehrenfest, sought the origin of the tragedy in that "*he suffered incessantly from the fact that his critical faculties transcended his constructive capacities*".

1906–1932 CE **Oswald Veblen** (1880–1960, U.S.A.). Distinguished mathematician. Made major contributions to projective geometry, and differential geometry; laid the foundation to modern topology.

Was among the few American scholars who came forth publicly against the Nazi persecution of Jewish mathematicians.

He was the nephew of **Thorstein Bunde Veblen** (1857–1929, U.S.A.), the known economist and social critic. Weblen taught mathematics at Princeton University (1905–1932). In 1932 he helped organize the Institute of Advanced Study in Princeton and became a professor there.

1906–1936 CE **Harry Bateman** (1882–1946, U.S.A.). Applied mathematician. Made important contributions to the theory of partial differential equations of mathematical physics, especially in hydrodynamics and electrodynamics. He also wrote much on integral equations and special functions. One of the first to apply Laplace transforms to integral equations (1906).

Bateman was born in Manchester, England to Jewish parents and studied at Cambridge (1900–1904), Göttingen (1905) and Paris (1906). In 1910 he removed to the United States, and in 1917 became a professor of mathematics, theoretical physics and aeronautics at the California Institute of Technology in Pasadena, CA. He accumulated a vast store of information on all the familiar special functions of mathematical physics and on his death the publication of his manuscript was undertaken by **Arthur Erdélyi** and his associates in the form of the series *Higher Transcendental Functions* and *Tables of Integral Transforms.*

1906–1955 CE **Ernst Frederik Werner Alexanderson** (1878–1975, U.S.A.). Electrical engineer and inventor. Pioneer in electrical power engineering and broadcasting.

Born in Uppsala, Sweden and studied at Lund University (1896), Royal Institute of Technology, Stockholm (1897–1900), and received a Ph.D. from the Technical University of Berlin (1901). He came to the US (1901) and designed for Fessenden the high-frequency generator (1906). Associated with General Electric Co. (1902–1948), and with RCA from 1952.

Invented a high-frequency (2 kW, 100 kHz) *alternator*[173] that greatly improved transoceanic radio (1906), multiple-tuned antenna, and selective radio tunning circuit (1916). Improved transoceanic communication and firmly established the wireless as an important tool in shipping and warfare. Made the first transmission (1924) of a fax message across the Atlantic. Among his other inventions: vacuum-tube telephone transmitter; electric ship propulsion, railroad electrification, and power transmission. Also made significant contributions to television (1927) and color television (1955). Issued 322 patents in radio, television and computer technologies.

1907 CE **Pierre Weiss** (1865–1949, France). Physicist. Contributed to modern theory of *magnetism*, especially *ferromagnetism*.

Suggested the theoretical existence of small *magnetic domains*[174] and developed a domain theory of ferromagnetic materials: when the dipoles of the domain are aligned, a strong and stable magnetic field results. Weiss treated phenomenologically spontaneous magnetization of metals like iron by his theory[175] — a prototype of many attempts to describe cooperative condensed–matter effects like melting of solids, order-disorder transition in alloys etc.

The Curie-Weiss Law of ferromagnetism describes the behavior of the magnetic *susceptibility* of many solids. Weiss also determined a unit of magnetic moment known as *Weiss magneton*. He was first to introduce the useful concept of *mean-field approximation*, called *Weiss field*.

Weiss was born in Mulhouse, France, and was a professor at Zürich (1902) and Strasbourg (1919).

---

173 *Alternator*: a device that converts direct current into alternating current capable of producing continuous radio-frequency waves and thereby revolutionizing radio communication.

174 He suggested that each piece of a paramagnetic material consists of regions (domains) already magnetized and that the direction of their magnetization differs from one region to another so as to cancel out in the whole piece. When the piece is subjected to a uniform magnetic field from outside, the direction of magnetization within each domain turns toward alignment with that field, and a net magnetization appears in the material. It turns out that a domain cannot choose the direction of its magnetization at random; it must choose that direction from among a very few easy directions of magnetization in the crystalline structure of the material.

175 According to this scheme, each magnetic atom experiences a field proportional to the magnetization $\boldsymbol{B}_{\text{effective}} = \lambda \boldsymbol{M}$ where λ is a constant independent of temperature. This means that each spin sees the average magnetization of all other spins (in truth, it can only "see" its nearby neighbors).

History of Magnetism III[176] *(1895–1928)*

*Matter is essentially electrical in nature, and magnetic effects arise from the distribution of currents of the electrical charges in matter and from the quantum-mechanical spin of charged electrons and nuclei. According to the view now accepted by physicists, the magnetic properties of matter are explained in terms of the quantum states and orbitals of electrons within atoms and molecules and (macroscopically) in multi-atom condensed matter. As early as 1820, **Ampere** suggested that magnetism was due to electric current circulating within matter. However, the identification of these "Amperian currents" with orbital motion of electrons is a later achievement due principally to **J.J. Thomson** (1897), **Lord Rutherford** (1911), and **Niels Bohr** (1913). In fact, **Maxwell** himself endeavored (1861) to detect such gyroscopic effects, but without success. The Stern-Gerlach experiment (1920-1) showed that the electron's intrinsic quantum angular momentum (spin) makes it a permanent magnet, and in fact it is spin rather than orbital electron motion that came to be understood as the main source of macroscopic magnetic effects. Spin is not directly associated with actual spatial motion, but is interconvertible with orbital angular momentum and, like it, exhibits gyroscopic inertia.*

*In 1915, **Albert Einstein** and **Johannes de Haas** (1878–1960) conducted an experiment that gave the first proof of the existence of mechanical rotation induced by magnetization: An iron cylinder hung vertically by means of a wire. A fixed solenoid was placed coaxially around the cylinder. The iron was magnetized by an alternating current run through the solenoid. If the magnetic moment* $\boldsymbol{M}$ *of the magnetized body (at rest) is due to circulating hidden (molecular, atomic and/or macroscopic) electric currents, the current due to the flow of electrons in their closed orbits with orbital angular momentum* $\boldsymbol{J}$ *will induce the magnetization* $\boldsymbol{M} = -\frac{e}{2m} g\boldsymbol{J}$ *per electron, where* (e, m)

are the charge and mass of the electron respectively and the dimensionless factor $g > 0$ is now called the Lande factor or gyromagnetic ratio.

Einstein argued that $g = 1$ per classical theory. To see this consider one electron moving with uniform velocity $v = 2\pi r\nu$ in a circular orbit with radius r and frequency ν. The angular momentum has the magnitude $mvr = 2\pi r^2 m\nu$. An amount of electric charge $(-e\nu)$ passes per second through a point of the orbit. The magnetic moment is therefore equal to $(-e\nu)(\pi r^2)$. Hence $g = 1$.

Einstein and de Haas obtained the mean experimental value $g = 1.02$, apparently confirming the classical value. By the 1920's however, their measurements were considered to have been in error, because the new experimental value of g was found to lie close to 2. Ampere's molecular currents were then abandoned in favor of the spin theory of electron magnetism. However, in the pre-spin days of 1915, any dynamical theory of ferromagnetism had necessarily to be incorrect. Einstein could not know that his theoretical prediction for iron was wrong by a factor of 2.

Electrons may give rise to a magnetic field in two ways:

(1) An electron revolving in an orbit about the nucleus of an atom *(or the nuclei of a molecule) is equivalent to a tiny current which gives rise to a magnetic field; this classical phenomenon extends to quantum–mechanical orbitals, as well as to conduction electrons in meso- or macroscopic matter (e.g. in metallic conduction – band orbitals).*

(2) It has also been found necessary to make the hypothesis that electrons always spin *about any given axis in a manner loosely analogous to the spin of the earth about its axis. This quantum-mechanical spin also gives rise to a magnetic field quite independently of any orbital motion the electron may possess. The observed Cartesian components of both spin an orbital angular momenta take discrete values: $\{-\frac{\hbar}{2}, \frac{\hbar}{2}\}$ for the former, $\{-l\hbar,\ -(l-1)\hbar,\ \dots\ l\hbar\}$ for the latter, $\hbar = h/2\pi$ being the reduced Planck's constant. The pure-spin Lande factor* twice *the classical value, while the purely orbital value equals the classical result.*

In an atom containing many electrons, it is possible that the orbits of the electrons and their spins may be so oriented that the atom as a whole possesses a resultant magnetic moment, i.e., acts like a tiny magnet. We say that the atom then possesses a permanent magnetic moment. *(The same holds for an ion or molecule.) If such an atom is placed in an external magnetic field, two things occur. First, the external field tends to turn the tiny magnet parallel to the field, thus adding the field due to the Amperian current to the external field. This phenomenon is called* paramagnetism.

Second, the atom, because of its intrinsic electrical character, will have induced currents set up due to asymmetric response of oppositely-orbiting electrons to the applied field. The net magnetic field due to these currents is opposite *to the external field, resulting in the phenomenon of* diamagnetism. *In general, the diamagnetism effects are masked by the larger paramagnetic effects if the latter are present, though their relative strengths depend on the temperature.*

If an atom or molecule does not possess a permanent magnetic moment — that is to say, its orbits and spins are so oriented that their individual fields cancel in the absence of an external field[177] *— such an atom or molecule exhibits diamagnetism only.*

In the case of ferromagnetic *materials such as iron, not only is the underlying atom or molecule paramagnetic, but a new and unusual phenomenon is present that accounts for the very conspicuous magnetic properties of such (usually solid) materials. It was found from the experimental work of* ***Weiss*** *(1907) that iron in the bulk, even when not magnetized as a whole, consists of a large number of grains or* domains *that act as permanent magnets. These domains are small compared to ordinary macroscopic dimensions but large compared with atomic sizes.*

There are typically some 10^{17} *to* 10^{21} *atoms in each domain. At sufficiently low temperatures the magnetic moments of the atoms, ions or molecules within a domain are forced by quantum nearest-neighbor couplings (such as covalent bonds and Pauli exchange forces) to be parallel, rise to a large magnetic moment per domain. The process of magnetization of macroscopic samples of iron consists in bringing the magnetic moments of the domains into parallelism with the external field.* Magnetic saturation *is present when*

---

[177] One reason for that cancellation is that electrons usually occupy their permitted state in *pairs*; in each pair one electron's spin is oriented 'up' and the other's 'down' (along any given axis of measurement). In some molecules or atoms, however, the elementary magnets are odd in number and/or they do not cancel one another's effect which thus *add up* to yield a net atomic or molecular magnetic–dipole moment. The material may then be *paramagnetic* or *ferromagnetic*. The former involves only independent responses of each molecule to an external field, and so can occur in any phase (gaseous, liquid, solid). *Ferromagnetism* involves collective behavior of nearby molecular magnets, so does not arise in gases and disappears above the material's *Curie temperature*.

Iron, Cobalt, Nickel and the loadstone of the ancients are among the ferromagnetic materials that had long been known, and more are constantly being discovered. *Antiferromagnetism* and *ferrimagnetism* are allied, similar phenomena.

all the domains have their moments parallel. is explained by the fact that the domains offer resistance to orientation.

Experimental evidence for this grain-like structure is found in the Barkhausen effect (1919), observed when a sample of iron is being magnetized. If a B-H curve is determined very accurately, it is found that the increase in magnetization of iron occurs in jumps rather than continuously. These jumps correspond to reorientation of the magnetic moments. By suitable amplification of the induced currents it is possible to actually observe (or rather, listen to) the orientation of a simple domain.

A domain cannot select the direction of its magnetization at random; it must choose that direction from among a very few easy directions of magnetization in the crystalline structure of the material. More recently, it has become clear that the magnetization within a domain does not "flop" in so abrupt a fashion. Instead, the magnetizing force makes the favorably disposed domains grow at the expense of those less favorably disposed. The wall between two adjacent domains moves more or less smoothly, providing a gradually increasing region of favorable magnetization.

Even on the atomic scale the wall itself is not abrupt; the elementary magnets in the wall also change their directions smoothly. The wall moves by a smooth and orderly change in the directions of the elementary magnets, subject to the "fuzziness" of quantum mechanics (there is an uncertainty relation *between different Cartesian components of spin magnetization). The approximate, semiclassical picture is as follows: induced by a magnetizing force applied from outside, the directions of magnetization of the elementary magnets* rotates *about a line perpendicular to the wall, and thus the wall moves, overcoming various obstacles: pinning, inertia, eddy-current losses, etc.*

The Critical Temperature

With the aid of this picture of moving domain walls, the process of magnetizing a ferromagnet can be traced:

As the external magnetizing field Hext increases, the magnetization increases because more domain walls are enabled to move. But the magnetization cannot increase indefinitely; when there are no walls left to be moved, the torque due to the field (Hext plus that due to the already–aligned domains) can do little to increase the magnetization further. That final saturation magnetization *represents the magnetization that each domain had already, which* *did not appear macroscopically because the many domains were magnetized in random directions.*

When the magnetizing external field is removed, the piece still exhibit a net magnetization (Fig. 5.1.1b) because the domains cannot easily return to randomized orientations. This remanence *magnetization can be made to disappear only by exerting a magnetizing field in the opposite direction (Fig. 5.1.1c). Increasing that reverse field still further (Fig. 5.1.1d) can magnetize the piece in the other direction until it is again saturated. If this process is continued by cycling the direction of the magnetizing field, the plot of magnetization against field (Fig. 5.1.1e) traces a closed curve called a* hysteresis loop.

In the technological uses of magnets, the form of that loop is extremely important. The magnetization that remains when the magnetizing field is removed, for example, is a measure of how strong a permanent magnet can be made of the material. The area of the loop is a measure of how much power will be lost to heat, sound etc. if the material is used to make cores in transformers.

Of more fundamental concern, however, is the saturation magnetization of the material. Since that represents the spontaneous magnetization within each domain, it is a property of the substance that is independent of how it is fabricated into pieces. Again, as with electrical conduction, the clearest insights come from examining how the property varies with temperature.

The form of that variation in nickel is shown in Fig. 5.1.2. As the metal is heated, the saturation magnetization declines, and at a critical temperature *(631 degrees absolute, or 358 degrees centigrade), it falls precipitously to zero. Above that temperature, the substance is no longer a ferromagnet; it behaves like many other metals and non-metals, and is* paramagnetic.

When it is cooled again, the magnetization within the domains reappears and traverses the same curve in the opposite direction. In other words, the spontaneous magnetization of the material varies simply and reversibly with the temperature and vanishes above a critical temperature. Iron behaves similarly but with a different critical temperature (1043 degrees absolute, or 770 degrees centigrade).

The Internal Field

This phase–transition behavior is somewhat reminiscent of melting. When a solid material melts, the orderliness characteristic of crystallinity abruptly *disappears and the crystals fall apart into a disorderly liquid. The vigor of the atomic vibrations becomes sufficient to overcome the forces tending to hold the atoms in their orderly arrays.*

The analogy between the critical temperature at which a crystal melts and the critical temperature at which ferromagnetism disappears suggests examining the heat capacity of a ferromagnet. Heating an ordinary solid will raise its temperature progressively up to its melting point. Then, as the solid begins to melt, enough heat must be supplied to melt it completely before the temperature of the liquid will rise further. In other words, at that melting temperature the heat capacity of the material is infinitely large; supplying heat makes no change in its temperature.

The heat capacity of a ferromagnet behaves somewhat similarly (Fig. 5.1.3); it shows a sharp spike at the critical temperature. To be sure, the heat capacity is not infinite; the temperature of the material will not stay constant while heat is supplied. Nevertheless, the behavior of the heat capacity is anomalous — a conspicuous departure from the smooth behavior observed in other metals.

It was Weiss again who suggested in 1907 a way to account for the variation of the spontaneous magnetization in the domains with varying temperature. He imagined a force originating in the material itself and tending to align all the elementary magnets in a domain in the same direction — a force directly proportional to the magnetization already present in the domain.

Notice how neatly that idea can explain the behavior diagrammed in Figs. 5.1.2 and 5.1.3. The heat vibrations tend to disturb the alignment of the elementary magnets, increasingly so as the temperature rises. The more that alignment is disturbed, the lower is the spontaneous magnetization. But, according to Weiss, the force (actually torque) tending to align the elementary magnets is itself proportional to the extent of alignment that it achieves. Hence, as the temperature increases, the magnetization decreases calamitously; as the temperature decreases, the magnetization again lifts itself "by its own bootstraps."

At the critical temperature, the heat capacity displays a peak because a small increase of temperature induces a large increase of disorder in the arrangement of the elementary magnets. For disordering that arrangement, heat is required, just as heat is required to disorder the atomic arrangement in a melting solid.

In order to explain the origin of the internal forces that Weiss imagined, it seemed natural at first to turn to the magnetic forces between the elementary magnets; the van der Waals forces between molecules suggested ways in which those magnets might tend to align one another. If the magnets were arranged *in strings, for example, they would adopt a head-to-tail arrangement (Fig. 5.1.4a) of the sort required rather than an arrangement (Fig. 5.1.4b) that has no net magnetization.*

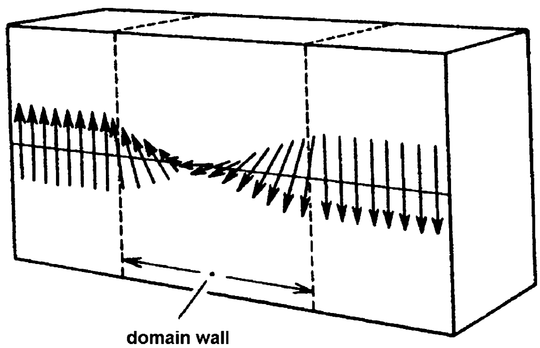
Unfortunately, when numbers were put into Weiss' theory, it turned out that magnetic forces between the elementary magnets are 10^3 *times too small to account for the measured behavior of ferromagnets. The Weiss internal field, so necessary to the picture of ferromagnetic behavior, had to be accepted for many years without explanation of its origin.*

It was clear that the needed factor of 10^3 *could not be found in the magnetic forces between the elementary magnets. And it was also clear that electrostatic forces operating on the electronic constituents of atoms might have the needed magnitude. Is there a way for electrostatic forces to align the spinning electrons?* ***Werner Heisenberg*** *was the first to recognize that quantum mechanics offers a positive answer to this question.*

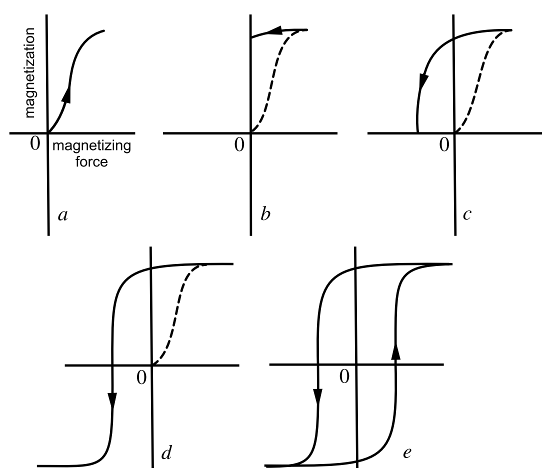
Until now we have spoken of quantum states, orbitals and spins for each electron separately, as if we could lay hands on it and label it. But when many electrons are crowded into a solid, there is no way to distinguish one from another. The Pauli exclusion principle (Fermi-Dirac statistics) comes into play in atoms, molecules and conduction bands, dictating that no two electrons with their spins aligned may occupy the same orbital. This result in "exclusion" or "exchange" forces among electrons, a key effect in chemical bonds and all aspects of condensed matter and atomic physics. In particular, a conjunction of exclusion and electrostatic forces between electrons in molecular orbitals often causes their spins to align.

The principles of quantum mechanics have been brought to bear in order to treat the entire assembly of electrons (and nuclei) as a single physical system. But as so often happens in physical science, the application of those principles to special cases is difficult – and the quantum many-body models we have for describing ferromagnetism, ferrimagnetism and antiferromagnetism, while promising, are greatly oversimplified. Much of the present research in the physical theory of solids and other phases of condensed matter is devoted to perfecting methods for applying quantum-mechanical principles to elucidate the collective behavior of electrons, atoms, ions, molecules, and then mesoscopic and macroscopic structures.

1907 CE **Lee de Forest** (1873–1961, U.S.A.). Inventor. Pioneered in wireless telegraphy and radio broadcasting. Invented the *triode vacuum tube*



Smooth change in direction of magnetization within a domain wall.



The magnetization of a ferromagnet with changing magnetizing force.

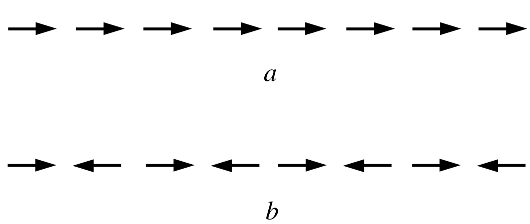

Fig. 5.1.4: The arrangement of magnets *a* has a lower energy than the arrangement *b*

and with it the radio amplifier, as a direct application of the *Edison effect* (1883). He obtained patents on more than 300 inventions. Forest staged the first musical radio broadcast in history, from the Metropolitan Opera House in New York City (1910).

Forest was born in Council Bluffs, Iowa. He graduated from Yale University in 1896 and moved to the Pacific coast in 1911. He worked on methods for photographing sound waves on motion picture films.

How the Triode was Invented[178] (1907–1914)

The triode vacuum tube was the first electronic device capable of amplification. Unfortunately, de Forest did not understand how his invention actually worked, having stumbled upon it by way of circuitous (and occasionally unethical) routes:

The vacuum tube actually traces its ancestry to the lowly incandescent light bulb of **Thomas Edison**. *Edison's bulbs had a problem with progressive darkening caused by the accumulation of soot (given off by the carbon filaments) on the inner surface of the bulb. In an attempt to cure the problem, he inserted a metal electrode, hoping somehow to attract the soot to this plate rather than to the glass. Ever the experimentalist, he applied both positive and negative voltages (relative to one of the filament connections) to this plate, and noted in 1883 that a current mysteriously flowed when the plate was positive, but none flowed when the plate was negative. Furthermore, the current that flowed depended on how hot he made the filament. He had no theory to explain these observations (remember, the word electron wasn't even coined until 1891, and the particle itself wasn't unambiguously identified until J.J. Thomson's experiments of 1897), but Edison went ahead and patented in 1884 the first electronic (as opposed to electrical) device, one that exploited the dependence of plate current on filament temperature to measure line voltage indirectly. This instrument never made it into production since it was inferior to a standard voltmeter; Edison just wanted another patent, that's all (that's one way he ended up with over 1000 of them).*

---

178 Adapted from: Lee, Thomas H., *The Design of CMOS Radio-Frequency Integrated Circuits*, Cambridge University Press, 2003.

The funny thing about this episode is that Edison arguably had never invented anything in the fundamental sense of the term, and here he had stumbled across an electronic rectifier but nevertheless failed to recognize the implications of what he had found. Part of this blindness was no doubt related to his emotional (and financial) fixation on the DC transmission of power, where a rectifier had no role.

At about this time a consultant to the British Edison Company named ***John Ambrose Fleming*** *happened to attend a conference in Canada. He dropped down to the U.S. to visit his brother in New Jersey and also stopped by Edison's lab. He was greatly intrigued by the "Edison effect" (much more so than Edison, who found it difficult to understand Fleming's excitement over something that had no obvious promise of practical application), and eventually published papers on the Edison effect from 1890 to 1896. Although his experiments created an initial stir, Röntgen's announcement in January 1896 of the discovery of X-rays as well as the discovery of natural radioactivity later that same year soon dominated the interest of the physics community, and the Edison effect quickly lapsed into obscurity.*

Several years later, though, Fleming became a consultant to British Marconi and joined in the search for improved detectors. Recalling the Edison effect, he tested some bulbs, found out that they worked all right as RF rectifiers, and patented the Fleming valve (vacuum tubes are thus still known as valves in the U.K.) in 1905. The nearly-deaf Fleming used a mirror galvanometer to provide a visual indication of the received signal, and included this feature as part of his patent.

While not particularly sensitive, the Fleming valve was at least continually responsive, and required no mechanical adjustments. Various Marconi installations used them (largely out of contractual obligations), but the Fleming valve never was popular (contrary to the assertions of some poorly researched histories) — it needed too much power, filament life was poor, the thing was expensive, and it was remarkably insensitive detector compared with, say, Fessenden's barretter, and well-made crystal detectors.

De Forest*, meanwhile, was busy in America setting up shady wireless companies whose sole purpose was to earn money via the sale of stock. "Soon, we believe, the suckers will begin to bite," he wrote in his journal in early 1902. As soon as the stock in one wireless installation was sold, he and his cronies picked up stakes (whether or not the station was actually completed), and moved on to the next town. In another demonstration of his sterling character, he just outright stole Fessenden's barretter (simply reforming the Wollaston wire into the shape of a spade) after visiting Fessenden's laboratory, and even had the audacity to claim a prize for his invention. In this case, however, justice did prevail and Fessenden won an infringement suit against de Forest.*

Fortunately for de Forest, **Dunwoody** *invented the carborundum detector just in time to save him from bankruptcy. Not content to develop this legitimate invention, though, de Forest proceeded to steal Fleming's vacuum tube diode, and actually received a patent for it in 1905. He simply replaced the mirror galvanometer with a headphone, and added a huge forward bias (thus reducing sensitivity of an already insensitive detector). De Forest repeatedly and unconvincingly denied throughout his life that he was aware of Fleming's prior work (even though Fleming published in professional journals that de Forest habitually and assiduously scanned) and to bolster his claims, de Forest pointed to his use of bias, where Fleming used none. Conclusive evidence that de Forest had lied outright finally came to light when historian Gerald Tyne obtained the business records of* ***W. McCandless****, the man who made all of de Forest's vacuum tubes (de Forest called them audions). The records clearly show that de Forest had asked McCandless to duplicate some Fleming valves months before he filed his patent. There is thus no room for a charitable interpretation that de Forest independently invented the vacuum tube diode.*

His crowning achievement came soon after, however. He added a zigzag wire electrode, which he called the grid, between the filament and wing electrode (later known as the plate), and thus the triode was born. This three-element audion was capable of amplification, but de Forest did not realize this fact until years later. In fact, his patent application only mentioned the triode audion as a detector, not as an amplifier. Motivation for the addition of the grid is thus still curiously unclear. He certainly did not add the grid as the consequence of careful reasoning, as some histories claim. The fact is that he added electrodes all over the place. He even tried "control electrodes" outside of the plate! We must therefore regard his addition of the grid as merely the result of haphazard but persistent tinkering in his search for a detector to call his own. It would not be inaccurate to say that he stumbled onto the triode, and it is certainly true that others had to explain its operation to him.

From the available evidence, neither de Forest nor anyone else thought much of the audion for a number of years (1906–1909 saw essentially no activity on the audion). In fact, when de Forest barely escaped conviction and a jail sentence for stock fraud after the collapse of one of his companies, he had to relinquish interest in all of his inventions as a condition of the subsequent reorganization of his companies, with just one exception: the lawyers let him keep the patent for the audion, thinking it worthless.

He intermittently puttered around with the audion and eventually discovered its amplifying potential, as did others almost simultaneously (including rocket pioneer **Robert Goddard***). He managed to sell the device to AT&T in 1912 as a telephone repeater amplifier, but initially had a tough time because of the erratic behavior of the audion. Reproducibility of device characteristics* *was rather poor and the tube had a limited dynamic range. It functioned well for small signals, but behaved badly upon overload (the residual gas in the tube would ionize, resulting in a blue glow and a frying noise in the output signal). To top things off, the audion filaments (made of tantalum) had a life of only about 100–200 hours. It would be a while before the vacuum tube could take over the world.*

Fortunately, some gifted people finally became interested in the audion. ***Irving Langmuir*** *at GE Lab in Schenectady worked to achieve high vacua, thus eliminating the erratic behavior caused by the presence of (easily ionized) residual gases. De Forest never thought to do this (in fact, warned against it, believing that it would reduce the sensitivity) because he never really believed in thermionic emission of electrons (indeed, it isn't clear he even believed in electrons at the time), asserting instead that the audion depended fundamentally on ionized gas for its operation.*

After Langmuir's achievement, the way was paved for a bright engineer to devise useful circuits to exploit the audion's potential. That bright engineer was ***Edwin Howard Armstrong*** *who invented the regenerative amplifier/detector in 1912 at the tender age of 21. This circuit employed positive feedback (via a "tickler coil" that coupled some of the output energy back to the input with the right phase) to boost the gain and Q of the system simultaneously. Thus high gain (for good sensitivity) and narrow bandwidth (for good selectivity) could be obtained rather simply from one tube. Additionally, the nonlinearity of the tube demodulated the signal. Furthermore, over-coupling the output to the input turned the thing into a wonderfully compact RF oscillator.*

In a 1914 paper titled "Operating Features of the Audion," Armstrong published the first correct explanation for how the triode worked, and provided experimental evidence to support his claims. He followed this paper with another ("Some Recent Developments in the Audion Receiver") in which he additionally explained the operation of the regenerative amplifier/detector, and showed how to make an oscillator out of it. The paper is a model of clarity and quite readable even to modern audiences. De Forest, however, was quite upset at Armstrong's presumptuousness. In a published discussion section following the paper, de Forest repeatedly attacked Armstrong. It is clear from the published exchange that, in sharp contrast with Armstrong, de Forest had difficulty with certain basic concepts (e.g., that the average value of a sine-wave is zero), and didn't even understand how the triode, his own invention (more of a discovery, really) actually worked.

The bitter lifelong enmity that arose between these two men never waned.

1907–1908 CE **Hermann Minkowski** (1864–1909, Germany). Outstanding mathematician and theoretical physicist. Developed the geometrical theory of numbers and used geometrical methods to solve difficult problems in number theory, mathematical physics and the Theory of Relativity. His concept of 'space-time' has proved to be one of the most valuable contributions ever made to theoretical physics by a mathematician, and made it possible for **Einstein** to formulate the theory of General Relativity.

Minkowski's early work was in number theory and n-dimensional geometry. In 1883, while only 18 years old, he shared with **Henry Smith** the Grand Prix des Sciences Mathematiques of the Paris Academy, for his work on the problem of representation of a number as a sum of 5 squares. In his book *Geometrie der Zahlen* (1896), the connection between geometry and number theory was forged into a strong link. In this book he proved many beautiful relationships at the interface of geometry and number theory.

His most famous result, known as *Minkowski's theorem*, states that any convex planar region symmetrical about $(0, 0)$ and having an area greater than 4 contains integer lattice points apart from $(0, 0)$. This theorem, and its generalization to higher dimensional spaces, is particularly useful in proofs concerning the representation of numbers by quadratic forms, such as the decomposition of certain primes into sums of squares.

In an address before the Göttingen Mathematical Society in 1905, Minkowski hypothesized that someday soon, number theory would triumph in physics and that, for example, the decomposition of primes into the sum of 2 squares would be seen to be related to important properties of matter.

Another intriguing geometrical concept due to Minkowski is that of a '*ray body*' (strahlkörper), defined as a region in n-dimensional Euclidean space containing the origin and whose surface, as seen from the origin, exhibits only one point in any direction. In other words, if the inner region were made of transparent glass and only the surface were opaque, then the origin would be visible from each surface point of the 'ray body' with no intervening surface points (any convex region is a ray body, but the converse does not hold). Minkowski proved the bizarre theorem that if the volume of such a body does not exceed $\zeta(n)$ [Riemann zeta function], a volume-preserving linear transformation exists such that the transformed body has no points in common with the integer lattice, other than the origin.

Around 1902, Minkowski became increasingly fascinated by the riddles of electromagnetism, as had recently been formulated in the works of **H.A. Lorentz**. His earlier friendship with **H. Hertz** may have also contributed to these interests. In 1907 he was able to show that the electromagnetic scalar and vector potentials as well as the charge-current densities are 4-vectors w.r.t. the Lorentz symmetry group of Special Relativity, while the electromagnetic field-strengths form a second rank skew-symmetric 4-tensor. On Nov. 5, 1907 he gave in Göttingen a colloquium about relativity, in which he identified the Lorentz transformation with pseudorotations[179].

Then, in 1908, he presented the Maxwell-Lorentz equations in four-dimension tensor form[180].

At a scientific gathering in Cologne in 1908, Minkowski introduced the concept of *space-time*. A point in space at an instant in time (an *event*) he called a 'world point', and the totality of all conceivable world-points is a

[179] In 1905 **Hilbert** and **Minkowski** conducted a joint seminar on the 'electrodynamics of moving bodies', with **Max Born** as one of the students. The FitzGerald contraction, Lorentz time dilation and the Michelson-Morley experiments were discussed. However, the name of Einstein was never mentioned. When the work of the Bern patent clerk finally reached Göttingen, Minkowski recalled his former student in Zürich and remarked: "*Oh, that Einstein, always missing lectures — I really would not have believed him capable of it*!" (translated).

[180] The Lorentz covariant tensor formulation of the Maxwell theory was a natural consequence of Einstein's postulate of equivalence of inertial systems, since it implies that all the equations of physics must be form-invariant under Lorentz transformations. Consequently, it should be possible to express them as absolute or covariant relations between four-tensors, and the transformation laws of the tensors become the transformation laws of the fields, current-charge distribution, positions, times, etc.

Consider first the inhomogeneous pair of Maxwell equations in empty space with sources: $\operatorname{curl}\boldsymbol{B} - \frac{1}{c^2}\frac{\partial \boldsymbol{E}}{\partial t} = \frac{1}{c^2}\boldsymbol{J}$, $\operatorname{div}\boldsymbol{E} = \rho$ and introduce $x_4 = ict$, $J_4 = ic\rho$, where $i = \sqrt{-1}$ and boldface quantities are spatial vectors (3-vectors). These equations become,

$$\begin{array}{lllll}
0 & +\dfrac{\partial(cB_3)}{\partial x_2} & -\dfrac{\partial(cB_2)}{\partial x_3} & -\dfrac{\partial(iE_1)}{\partial x_4} & = \dfrac{1}{c}J_1, \\
-\dfrac{\partial(cB_3)}{\partial x_1} & +0 & +\dfrac{\partial(cB_1)}{\partial x_3} & -\dfrac{\partial(iE_2)}{\partial x_4} & = \dfrac{1}{c}J_2, \\
\dfrac{\partial(cB_2)}{\partial x_1} & -\dfrac{\partial(cB_1)}{\partial x_2} & +0 & -\dfrac{\partial(iE_3)}{\partial x_4} & = \dfrac{1}{c}J_3, \\
\dfrac{\partial(iE_1)}{\partial x_1} & +\dfrac{\partial(iE_2)}{\partial x_2} & +\dfrac{\partial(iE_3)}{\partial x_3} & +0 & = \dfrac{1}{c}J_4.
\end{array}$$

Here, the left-hand sides of the four equations can be recast in terms of a 4×4 antisymmetric matrix, which hints at the possibility of defining a four-tensor of second rank, known as *the field-strength tensor*, according to the scheme

$$F = \begin{bmatrix} 0 & B_3 & -B_2 & -iE_1/c \\ -B_3 & 0 & B_1 & -iE_2/c \\ B_2 & -B_1 & 0 & -iE_3/c \\ iE_1/c & iE_2/c & iE_3/c & 0 \end{bmatrix}.$$

We can then write the above pair of Maxwell equations in the form

$$\sum_{\nu=1}^{4} \frac{\partial F_{\mu\nu}}{\partial x_\nu} = \frac{1}{c^2} J_\mu \qquad (\mu = 1, 2, 3, 4),$$

or simply

$$\operatorname{div} F = -\frac{1}{c^2}\mathrm{J}.$$

The remaining (homogeneous) Maxwell equations $\operatorname{curl} \boldsymbol{E} + \frac{\partial \boldsymbol{B}}{\partial t} = 0$, $\operatorname{div} \boldsymbol{B} = 0$, can be similarly expressed in tensor form if we introduce a second antisymmetric tensor $G_{\mu\nu}$ defined as follows:

$$G = \begin{bmatrix} 0 & -E_3/c & E_2/c & -iB_1 \\ E_3/c & 0 & -E_1/c & -iB_2 \\ -E_2/c & E_1/c & 0 & -iB_3 \\ iB_1 & iB_2 & iB_3 & 0 \end{bmatrix}.$$

We then write the homogeneous Maxwell equation pair as

$$\sum_{\nu=1}^{4} \frac{\partial G_{\mu\nu}}{\partial x_\nu} = 0 \qquad (\mu = 1, 2, 3, 4),$$

or $\operatorname{div} G = 0$.

The tensor $G_{\mu\nu}$ is known as the *dual* to $F_{\mu\nu}$ and is related to it via the equation $G_{\alpha\lambda} = -iF_{\mu\nu}$, where α, λ, μ, ν is an even permutation of 1, 2, 3, 4. It can be shown that G is a 4-tensor (transforms as a tensor under Lorentz-transformations) F is. It is readily seen that $\operatorname{div} G = 0$ is equivalent to

$$\frac{\partial F_{\alpha\lambda}}{\partial x_\mu} + \frac{\partial F_{\lambda\mu}}{\partial x_\alpha} + \frac{\partial F_{\mu\alpha}}{\partial x_\lambda} = 0.$$

In the absence of sources, $\operatorname{div} F = 0$, $\operatorname{div} G = 0$ express the full set of Maxwell's equations in covariant form in terms of a single tensor and its dual. The covariance of Maxwell's equations w.r.t. Lorentz transformations is thus made manifest.

'world'. A particle of matter or light enduring for a finite time interval will correspond to a curve which he called 'world line', the points of which can be labeled by successive readings of the time that would be exhibited by a clock carried by the particle.

In the language of Cartan's exterior-form calculus,

$$F = \sum_{\mu,\nu} F_{\mu\nu} dx_\mu \wedge dx_\nu$$

and

$$^*F = G = \sum_{\mu,\nu} G_{\mu\nu} dx_\mu \wedge dx_\nu$$

are a pair of dual *2-forms* which are both closed in the no-source case: $dF = dG = 0$. With a source J_μ present, $dF = 0$ still, but the inhomogeneous Maxwell equations become $d^*F = \frac{1}{c}{}^*J$, the 3-form $^*J$ being the dual of the 4-current 1-form, $J = \sum_\mu J_\mu dx_\mu$. Viewing the *2-form* F as the curvature of a *fiber bundle*, with Minkowski spacetime as its base manifold and the abelian $U(1)$ group of complex phases as its fiber, the homogeneous half of Maxwell's equations, $dF = 0$, is seen to be the Bianchi identity for the connection A_μ (= 4-vector potential $(\boldsymbol{A}, \frac{i}{c}\Phi)$). This is valid because $F = dA$ is an *exact*, and therefore also *closed*, 2-form in Minkowski 4-space, where the 1-form A is defined as $A = \sum_\mu A_\mu dx_\mu$. For non-abelian fiber groups, this Bianchi identity and the corresponding inhomogeneous field equations generalize to

$$dF_a + \sum_{b,c} g f_{abc} A_b \wedge F_c = 0$$

and

$$d^*F_a + \sum_{b,c} g f_{abc} A_b \wedge {}^*F_c = \frac{1}{c^2}\,{}^*J_a\ ,$$

where: a, b, c are indices in the adjoint representation of the (Lie) group, $A_a = \sum_{\mu=1}^{4} A_{\mu a} dx_\mu$ is the connection 1-form, f_{abc} are group structure constants, and g is a coupling constant (generalization of electric charge). These are the field equations of the Yang-Milles (YM) gauge theory for the given (Lie) group. In the 1970s and 1980s it was discovered that all known subnuclear forces are described by Yang-Milles gauge field theories. Unlike Maxwell's equations the YM eqs. are nonlinear and the abelian relation between fields (curvature) and potentials (connection) is likewise modified:

$$F_\alpha = dA_\alpha + \sum_{b,c} g f_{abc} A_b \wedge A_c$$

The Newtonian absolute time and space, discarded by Einstein, are supplanted by the absolute 'world' of fused *space-time*. The distance between points in this space-time is a *space-time interval* that is invariant, as measured by all observers (via their respective reference frames) in inertial motion. This invariant space-time interval can be real, zero or imaginary, and is defined by the rule that its square is equal to the difference between the squares of the temporal interval and spatial distance between the two world points concerned, where c, the speed of light in *vacuum*, is used to inter-convert units of space and time. One of the peculiarities of the geometry of Minkowski space (space-time) is that on the world-lines of light, the space-time intervals are of zero length.

Following Minkowski, Einstein came to the conclusion that the objective world of physics is essentially a 4-dimensional structure. Its resolution into three-dimensional space and one-dimensional time is not the same for all observers.

Minkowski was born in Alexotas, near Kovno, to a family that left their native Russia [because of the persecution to which Jews were subjected by the Czar's government] and moved to Königsberg, Prussia (1872). He studied in the local high school, and completed his higher education at the universities of Königsberg and Berlin.

Among his teachers were **Kronecker**, **Weierstrass** and **Kirchhoff**. He received his Ph.D. at the University of Königsberg and served as a professor at Zürich (1896–1902) and Göttingen (1902–1909).

On Jan. 10, 1909 he was suddenly stricken with acute appendicitis. He died two days later, not having yet attained his 45^{th} year, at the height of his scientific creativity. On Wednesday, Jan. 11, 1909, the announcement was made to the students. One of the students recalled: "*Because of the great position of a professor in those days and the distance between him and the students, it was almost more of a shock for us to see Hilbert weep than to hear that Minkowski was dead*".

The Special Theory of Relativity[181] *(1905–1908)*

(I) Historical background and fundamental principles

At the end of the 19th century an optimistic view was taken of the achievements of theoretical physics. Few problems, so it seemed, remained to be solved. There were, however, some details which marred this general picture. For example, the rate of advance of the perihelion of Mercury's orbit exceeded the predicted amount by nearly 10 percent. Attempts to describe the interaction of radiation and matter led to a formula which disagreed with experiment. Certain problems in the optics of moving media were still unresolved, and atomic spectra as well as the dynamical stability of atoms were not yet understood. The billions–of–years age of the solar system required that the sun shine steadily for a duration exceeding by far that accounted for by its gravitational collapse upon formation from cold gases. But few physicists would have thought at the time that these particular features of nature would require for their explanation a complete revolution in physical ideas. To see why this was unavoidable, a reexamination of the fundamentals of Newtonian mechanics and the wave theory of light is called for.

In Newton's hand mechanics was formulated based on the notions of absolute space and time. *The time variable occupied a unique position as the independent variable in terms of which the position of a particle is described. Its measure and flow is unrelated to the choice of the particular* reference system *used for the description of mechanical problems.*

By a system (or frame) of reference we mean a system of coordinates used to measure and indicate the position of a particle in space, as well as mutually synchronized clocks fixed in this system, serving to indicate time. Reference systems which move with uniform velocity relative to the idealized "fixed

stars" (in which Newton's first law is valid) are known as inertial frames. Consider a reference frame S and another reference frame $\bar{S}$ moving uniformly relative to S with finite velocity $\boldsymbol{v}$.

A physical event occurs at a point in space and at an instance of time and is specified by the entities $(\boldsymbol{r}, t)$ in S and $(\boldsymbol{r}', t')$ in $\bar{S}$. According to classical mechanics these entities are related by the Galilean transformation equations

$$t' = t, \qquad \boldsymbol{r}' = \boldsymbol{r} - \boldsymbol{v}t \tag{1}$$

Clearly, if the first law is valid in S, then it is also valid in $\bar{S}$, and in all other inertial frames as well. In fact, all three Newton's laws are the same in all inertial frames, and no frame has any preference over another.

The laws of mechanics are thus independent of the uniform rectilinear velocity of the system, and one cannot determine it by means of any internal mechanical experiment. This last statement is known as Newton's principle of relativity.

It can thus be said that the idea of an absolute coordinate-system can be replaced by that of the whole set of inertial frames, no one of which is preeminent. The situation in Newtonian dynamics at the end of the 19th century was therefore that the need for an absolute space had been replaced by that of a set of inertial frames. The problem of specifying the frames was still unresolved. Likewise, the concept of absolute time has been left untouched.

How fared (then relatively new) the Maxwell equations w.r.t. the Galilean transformation and the ensuing Newtonian principle of relativity?

In empty space the fields $\boldsymbol{H}$ (and $\boldsymbol{E}$) satisfy the wave equation $\nabla^2 \boldsymbol{H} = \frac{1}{c^2}\frac{\partial^2 \boldsymbol{H}}{\partial t^2}$, etc. where c, with dimensions of velocity is the ratio of electromagnetic and electrostatic units of charge. Already in 1856 ***Weber*** *and* ***Kohlrauch*** *compared the capacity of a Leyden jar as measured by an electrostatic method, with that calculated from the effects of current produced by discharging the jar. These experiments gave a value of c equal to $3.1 \times 10^{10} \frac{\text{cm}}{\text{sec}}$, close to the speed of light in vacuo. This suggested the identification of light and electromagnetic radiation, and such an identification gave a very satisfactory explanation to optical phenomena.*

The wave equation, however, contains no reference to the velocity of the source of the light and this naturally suggests that the velocity of light must be independent of the velocity of its source. This is in agreement with observations. For example, there exist certain 'double stars' consisting of two stars moving in orbits about their common center of gravity. At one point in the orbit one star will be traveling towards the earth, and the other away from it.

If their center of gravity is at a distance h from the earth, the light will reach the earth at a time of order h/c after it has been emitted, where c is the speed of light. For any small change Δc in c, we have a change $\delta t = -(h/c^2)\Delta c$ in the time of arrival. This change would produce apparent irregularities in the motion of such stars. No such irregularities have ever been observed and we are forced to conclude that the velocity of light is independent of the velocity of the source.

However, this independence of the velocity of light on the velocity of its source poses the problem of the coordinate-system with respect to which c is to be measured. In the theory of sound a similar problem arises, but there it is easily resolved since the speed is to be measured relative to the still air.

In the nineteenth century, it seemed reasonable to give a similar answer in the case of light. This required the postulation of an unobserved, all-pervasive medium — the luminiferous aether or ether *— in which the wave motion took place (first introduced by Hooke in 1667). This ether could have the great advantage of linking the hitherto separated theories of mechanics and electromagnetism.*

But alas, Maxwell's equations are not invariant in form w.r.t. the Galilean transformation! In other words: the speed of light is not invariant under this transformation. Indeed, since

$$\frac{\partial}{\partial t} = \frac{\partial}{\partial t'} - \boldsymbol{v}\cdot\nabla'; \qquad \nabla = \nabla',$$

the wave equation for $\boldsymbol{H}$, say, in $\bar{S}$, becomes

$$\nabla'^2\boldsymbol{H} - \frac{1}{c^2}\frac{\partial^2\boldsymbol{H}}{\partial t'^2} = \left(\frac{\boldsymbol{v}}{c}\cdot\nabla'\right)\left(\frac{\boldsymbol{v}}{c}\cdot\nabla'\boldsymbol{H} - \frac{2}{c}\frac{\partial\boldsymbol{H}}{\partial t'}\right).$$

There are therefore three logical possibilities:

(a) *In electrodynamics there* is *a preferred inertial frame, the so-called ether rest-frame S, in which Maxwell's equations are valid and in which light is propagated at exactly the speed c. In a frame $\bar{S}$ moving at a constant velocity v with respect to this ether frame an observer would measure a different light velocity, ranging in magnitude from $c-v$ to $c+v$. By an optical experiment in $\bar{S}$ one could determine the value of v. Galilean transformations apply to all physical laws.*

(b) *A relativity principle exists for both mechanics and electrodynamics but the laws of electrodynamics are not correct. Experiment should be able to detect deviations from Maxwell's laws, which should then be reformulated. The Galilean transformation would apply to the corrected laws.*

(c) *A relativity principle exists for both mechanics and electrodynamics but Newton's laws are not correct. Experiments should show deviations from Newtonian mechanics and those laws must be reformulated. The Galilean transformation does not apply and a new transformation must be found which leaves Maxwell's equations and the new mechanical laws invariant.*

The critical experiment of Michelson and Morley (1887) failed to detect a motion of the earth relative to a preferred reference frame. This led Einstein to assume that (1) must be replaced by new equations such that consistency with experiment is attained without having to discard either Maxwell's equations or Newton's principle of relativity. Einstein's theory of relativity accepts (c) and is based on two fundamental postulates:

(A) *The principle of relativity*[182]

[182] Note that *accelerated* motion of a reference frame relative to an inertial frame of reference can, of course be detected. A *mechanical* experiment of this kind was designed (1851) by **Foucault**, *optical* variants of the experiment were carried out by **Francis Harress** (1911) and the French physicist **George Sagnac** (1869–1926) in 1913 (Published in Comptes Rendus de l'Academie des Sciences, **157**, 708–710, 1410–1413, 1915).
According to the *Sagnac-Harress experiment*, two pulses of light are sent (by means of reflections) from a split source in opposite directions around a stationary circular loop of radius R. Clearly, since they will travel the same distance at the same speed, they will each travel full-circle and arrive at the light detector, near the light source, simultaneously.
If the loop itself is rotating during this procedure, however, the pulse traveling in the same direction as the rotation of the loop must traverse a slightly greater distance than the pulse traveling in the opposite direction. As a result, the counter-rotating pulse arrives at the end point slightly earlier than the co-rotating pulse. Quantitatively, if we let ω denote the angular speed of the loop, then the circumferential tangent speed of the end point is $v = \omega R$, and the relative speed of the wave front and the receiver at the end point is $c - v$ in the co-rotating direction and $c + v$ in the counter- rotating direction. Both pulses begin with an initial separation of $2\pi R$ from the end point, so the difference between the travel times is

$$\Delta t = 2\pi R \left(\frac{1}{c - v} - \frac{1}{c + v} \right) = \frac{4\pi R v}{c^2 - v^2} = \frac{4A\omega}{c^2 - v^2} \approx \frac{4A\omega}{c^2}$$

where $A = \pi R^2$ is the area enclosed by the loop. This analysis is perfectly valid in both the classical and the relativistic contexts. The *interference* of the two coherent beams will result in a *fringe shift* $\Delta\varphi = \Delta t \frac{c}{\lambda} = \frac{4A\omega}{c\lambda}$. Indeed Sagnac, using an area of $863 cm^2$, a mercury lamp with wavelength $\lambda = 0.436$ micron as light source and an angular velocity of about 14 rad/sec, predicted a fringe shift of $\Delta\varphi = 0.037$ – which agreed nicely with the observations.

One cannot determine the uniform rectilinear motion of a reference system by means of any *internal experiment (non existence of absolute motion).*

(B) *The principle of the constancy of the velocity of light*[183]
The velocity of light is one and the same in all inertial systems, independent of the observer's velocity with respect to the frame in which the light source is at rest.

(A) has an equivalent form known as the principle of covariance*. It states that if a physical event or process is observed from any inertial frame, then the physical entities such as time, spatial coordinates, velocities etc., will change in such a way that the laws of nature remain invariant with respect to transformation of these entities from one inertial frame to another. When these laws are written in terms of the coordinates, times and other physical attributes in different inertial frames they will have one and the same form. If it were otherwise, the experimental laws deduced by means of internal measurements would depend on the frame's uniform rectilinear motion.*

(A) has two important consequences. The first states that there is no preferred coordinate system *in which the laws of nature are simpler than in*

The shift can be used to determine the angular velocity ω.

If the Earth is used as the turntable its angular velocity can likewise be determined. This experiment was carried out in 1925 by **Michelson** and **Gale**. The angular velocity corresponded to the component of the angular velocity of rotation of the Earth along a plumb line at the point of observation. For the experiment two kilometers of pipes were laid and a second circuit was built to determine the zero point of displacement of the fringes.

Michelson and Gale used a circuit of area $0.2km^2$. The formula becomes $\Delta\varphi = \frac{4A\omega}{c\lambda} sin\phi$, where ϕ is the latitude. Michelson was at latitude 41.8° and looked for a fringe shift of $\Delta\varphi = 0.236 \pm 0.002$. The observed fringe shift was 0.230 ± 0.005. Excellent agreement! Thus, unlike uniform translational motion of the earth, its rotation can be determined by various physical experiments.

The fringe shift is known as the *Sagnac effect* and the modern fiber-optic experimental set-up is known as *Sagnac interferometer*.

Sagnac belonged to a group of friends that notably included **Pierre** and **Marie Curie**, **Paul Langevin**, **Jean Perrin** and the mathematician **Emil Borel**. The Sagnac effect is at the basis of interferometers and *laser gyroscopes* developed since the 1970s.

183 In recent years [see e.g Amelino–Camelia, G., *Doubly – Special Relativity*, Int. J. Mod. Phys., 2002, D11, 1643 pp] there arose a modified theory of Special Relativity in which there is not only an observer-independent maximum velocity (the speed of light), but an observer-independent minimum length (the Planck length). Doubly–Special Relativity is also called *Deformed Special Relativity*.

other inertial frames, since the existence of such a system is ruled out by the principle of covariance. The second consequence of (A) is that a light ray emitted from a source at rest in S will appear to an observer at rest with respect to S, to move in one and the same velocity c irrespective of the constant rectilinear motion of S relative to the fixed stars. This is in fact an application of the principle of relativity to electromagnetic phenomena.

This consequence is not *trivial. It does not hold in acoustics. For if a sound source is placed on a uniformly moving platform the velocity of sound with respect to the stationary air is always c, say, irrespective of the source motion. But it is $c - v$ relative to the source observed in the line of motion ahead of the source and $c + v$ in the other direction.*

Note that (B) follows from the principle of covariance provided that the validity of Maxwell's electrodynamics is assumed, for both Maxwell's equations and the velocity c are laws of nature, and as such must be the same for all inertial frames.

***Einstein** (1905) then set forth to deduce a new transformation law in accord with his two postulates. Based on a few simple optical thought-experiments, it was found to be*

$$\boldsymbol{r}' = \gamma(\boldsymbol{r}_1 - \boldsymbol{v}t), \qquad t' = \gamma(t - \frac{\boldsymbol{v}\cdot\boldsymbol{r}}{c^2}) \tag{2}$$

where

$$\boldsymbol{r}_1 = \frac{1}{\gamma}\boldsymbol{r} + \frac{\gamma - 1}{\gamma v^2}(\boldsymbol{v}\cdot\boldsymbol{r})\boldsymbol{v}, \qquad \gamma = \frac{1}{\sqrt{1 - \frac{v^2}{c^2}}}.$$

This is known as the Lorentz transformation.

Defining the dyadic

$$\Phi = I + \frac{\gamma - 1}{v^2}\boldsymbol{v}\boldsymbol{v}, \qquad \Phi^{-1} = I - \frac{\gamma - 1}{v^2}\boldsymbol{v}\boldsymbol{v}, \tag{3}$$

the transformation law and its inverse are

$$\begin{aligned} \boldsymbol{r}' &= \Phi\cdot\boldsymbol{r} - \gamma t\boldsymbol{v}; & \boldsymbol{r} &= \Phi\cdot\boldsymbol{r}' + \gamma t'\boldsymbol{v}; \\ t' &= \gamma\left(t - \frac{\boldsymbol{r}\cdot\boldsymbol{v}}{c^2}\right); & t &= \gamma\left(t' + \frac{\boldsymbol{r}'\cdot\boldsymbol{v}}{c^2}\right) \end{aligned} \tag{4}$$

Also

$$\begin{aligned} \frac{\partial}{\partial t} &= \frac{\partial t'}{\partial t}\frac{\partial}{\partial t'} + \frac{\partial \boldsymbol{r}'}{\partial t}\cdot\frac{\partial}{\partial \boldsymbol{r}'} = \gamma\left(\frac{\partial}{\partial t'} - \boldsymbol{v}\cdot\nabla'\right) \\ \nabla = \frac{\partial}{\partial \boldsymbol{r}} &= \frac{\partial \boldsymbol{r}'}{\partial \boldsymbol{r}}\cdot\frac{\partial}{\partial \boldsymbol{r}'} + \frac{\partial t'}{\partial \boldsymbol{r}}\frac{\partial}{\partial t'} = \nabla' + \boldsymbol{v}\left[\frac{\gamma - 1}{v^2}\boldsymbol{v}\cdot\nabla' - \frac{\gamma}{c^2}\frac{\partial}{\partial t'}\right]. \end{aligned} \tag{5}$$

Some algebra is needed to show from this that indeed

$$\nabla^2 - \frac{1}{c^2}\frac{\partial^2}{\partial t^2} = \nabla'^2 - \frac{1}{c^2}\frac{\partial^2}{\partial t'^2} \tag{6}$$

This result was expected since it just reflects the postulate of the constancy of the velocity of light, upon which the Lorentz transformation is based.

(II) The 4-dimensional 'space-time' world (Minkowski 1908) and relativistic electrodynamics

It follows directly from (2, *I*) *that*

$$r'^2 - c^2 t'^2 = r^2 - c^2 t^2. \tag{1}$$

This can be rewritten as

$$x_1'^2 + x_2'^2 + x_3'^2 + x_4'^2 = x_1^2 + x_2^2 + x_3^2 + x_4^2, \tag{2}$$

provided we introduce the coordinates $(x_1, x_2, x_3, x_4 = ict)$, *or simply* $(\boldsymbol{r}, ict)$. *In other words: the* pseudonorm *of the spacetime positional 4-vector, is invariant under both ordinary 3-rotation and Lorentz transformations. (It is called a* pseudonorm *because it lacks the positive–definiteness of an actual norm.) Eq.* (6, *I*) *can be recast in terms of a 4-dimensional* gradient operator,

$$\nabla_\mu = (\nabla, \frac{1}{ic}\frac{\partial}{\partial t}) \qquad (\mu = 1, 2, 3, 4) \tag{3}$$

to read

$$\sum_{\mu=1}^{4} \nabla_\mu'^2 = \sum_{\mu=1}^{4} \nabla_\mu^2. \tag{4}$$

These considerations prompted ***Minkowski*** *to define a general 4-vector (real 3-vector and a imaginary scalar) as an ordered pair* $(\boldsymbol{A}, i\theta)$ *which transforms like* $(\boldsymbol{r}, ict)$ *under a general Lorentz transformation; namely*

$$\left.\begin{aligned} \boldsymbol{A} \to \boldsymbol{A}' &= \boldsymbol{A} + \frac{\gamma-1}{v^2}(\boldsymbol{v}\cdot\boldsymbol{A})\boldsymbol{v} - \frac{1}{c}\gamma\boldsymbol{v}\theta \\ \theta \to \theta' &= \gamma\big(\theta - \frac{\boldsymbol{v}\cdot\boldsymbol{A}}{c}\big) \end{aligned}\right\} \tag{5}$$

For example $(\boldsymbol{J}, ic\rho)$ *is a 4-vector. To see this we recall the* continuity equation $\nabla\cdot\boldsymbol{J} + \frac{\partial\rho}{\partial t} = 0$ *(expressing local charge conservation) Upon substitution of the operators* ∇ *and* $\frac{\partial}{\partial t}$ *from* (4, *I*), *we obtain*

$$\frac{\partial}{\partial t'}\big(\gamma\rho - \frac{\gamma}{c^2}\boldsymbol{v}\cdot\boldsymbol{J}\big) + \nabla'\cdot\big[\boldsymbol{J} + \frac{\gamma-1}{v^2}\boldsymbol{v}(\boldsymbol{v}\cdot\boldsymbol{J}) - \gamma\rho\boldsymbol{v}\big] = 0.$$

This will yield $\nabla' \cdot \boldsymbol{J}' + \frac{\partial \rho'}{\partial t'} = 0$ *guaranteeing the covariance of charge conservation – if and only if:*

$$\rho' = \gamma\big(\rho - \frac{1}{c^2}\boldsymbol{v}\cdot\boldsymbol{J}\big); \qquad \boldsymbol{J}' = \boldsymbol{J} + \frac{\gamma-1}{v^2}\boldsymbol{v}(\boldsymbol{v}\cdot\boldsymbol{J}) - \gamma\rho\boldsymbol{v} \tag{6}$$

which complies with the definition $(5, II)$*. In a similar way, it is shown that* $(\boldsymbol{A}, i\frac{\phi}{c})$ *is a four-vector on the strength of the invariance of the Lorentz-gauge condition* $\boldsymbol{\nabla}\cdot\boldsymbol{A} + \frac{1}{c}\frac{\partial\phi}{\partial t} = 0$.

The covariance of 4-vectors suggests that for any two 4-vectors, their scalar product is invariant under the Lorentz transformation. Indeed, using $(5, II)$*, it is easily shown that*

$$(\boldsymbol{A}, i\theta)\cdot(\boldsymbol{B}, i\phi) = (\boldsymbol{A}\cdot\boldsymbol{B}) - \theta\phi \tag{7}$$

is invariant. In particular, the square of the pseudonorm of a 4-vector is a 4-scalar or Lorentz invariant:

$$(\boldsymbol{A}, i\theta)\cdot(\boldsymbol{A}, i\theta) = |\boldsymbol{A}|^2 - \theta^2 = |\boldsymbol{A}'|^2 - \theta'^2 \tag{8}$$

4-vectors thereby divide into 3 categories: space-like $|\boldsymbol{A}|^2 - \theta^2 > 0$, *time-like* $|\boldsymbol{A}|^2 - \theta^2 < 0$ *and light-like* $|\boldsymbol{A}|^2 = \theta^2$.

We saw earlier (cf. Minkowski) that the electromagnetic fields, $\boldsymbol{E}$ *and* $\boldsymbol{B}$ *can be arranged into* $F_{\mu\nu}$*, the skew-symmetric rank 2 field-strength 4-tensor. This transforms as* $a_\mu b_\nu - a_\nu b_\mu$ *where* a, b *are any two 4-vectors. From this and Eq.* $(5, II)$*, the Lorentz transformation law for* $\boldsymbol{E}$ *and* $\boldsymbol{B}$ *is readily found:*

$$[c\boldsymbol{B}, -i\boldsymbol{E}] \Rightarrow \begin{cases} \boldsymbol{E}' = \gamma\boldsymbol{E} - \dfrac{\gamma-1}{v^2}(\boldsymbol{v}\cdot\boldsymbol{E})\boldsymbol{v} + \gamma(\boldsymbol{v}\times\boldsymbol{B}) \\ \boldsymbol{B}' = \gamma\boldsymbol{B} - \dfrac{\gamma-1}{v^2}(\boldsymbol{v}\cdot\boldsymbol{B})\boldsymbol{v} - \dfrac{\gamma}{c^2}(\boldsymbol{v}\times\boldsymbol{E}) \end{cases} \tag{9}$$

These equations were first obtained by ***Minkowski*** *in 1908.*

As we saw, the field–strength (or electromagnetic field) 4-tensor is

$$F_{\alpha\beta} = [\boldsymbol{B}, -i\boldsymbol{E}/c] = \left[\begin{array}{ccc|c} & & & -iE_x/c \\ & -(I\times\boldsymbol{B})_{ij} & & -iE_y/c \\ & & & -iE_z/c \\ \hline iE_x/c & iE_y/c & iE_z/c & 0 \end{array}\right] \tag{10}$$

The tensor $F_{\alpha\beta}$ is called the electromagnetic field tensor and $F_{\alpha\beta} = \nabla_\alpha A_\beta - \nabla_\beta A_\alpha$ in terms of the 4-vector potential. The sourceless Maxwell equations, $dF = 0$, is then satisfied automatically; while the source Maxwell equations,

$$\sum_{\alpha=1}^{4} \nabla_\alpha F_{\alpha\beta} = -\frac{1}{c^2} J_\beta$$

become (in the Lorentz gauge the 4-vector wave equation)

$$\Box A_\mu = -\frac{1}{c^2} J_\mu \tag{11}$$

where $\Box \equiv \boldsymbol{\nabla}^2 - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}$ is the D'Alembertian operator.

- *Since $\nabla_\mu J_\mu = 0$ is a 4-scalar while ∇_μ is a vector, J_μ must transform like a 4-vector (Eq. (6, II)). The charge in a volume element is $q = \rho\, dx_1\, dx_2\, dx_3$. It can be shown that q integrated over a volume τ outside of which $\rho = 0$, is a Lorentz invariant. This is the law of invariance of electric charge. Moreover*

$$\begin{aligned} \frac{d}{dt}\int_\tau \rho\, dx_1\, dx_2\, dx_3 &= \int_\tau \frac{d\rho}{dt}\, dx_1\, dx_2\, dx_3 \\ &= \int_\tau (\frac{\partial\rho}{\partial t} + \text{ div } \boldsymbol{J})\, dx_1\, dx_2\, dx_3 \equiv 0, \end{aligned} \tag{12}$$

meaning that the total charge present in all space is time-independent.

(III) Matrix representation

The Lorentz transformation in (2, I) can be put in a convenient matrix form. Introducing a unit vector $\boldsymbol{n}$ in the direction of the velocity $\boldsymbol{v}$, $\boldsymbol{n} = \frac{1}{|\boldsymbol{v}|}\boldsymbol{v} = n_1\boldsymbol{e}_1 + n_2\boldsymbol{e}_2 + n_3\boldsymbol{e}_3$, the transformation equations are recast as

$$\begin{aligned} \boldsymbol{r}' &= \Phi\cdot\boldsymbol{r} - \gamma\beta\boldsymbol{n}(ct), & \Phi &= I + (\gamma-1)\boldsymbol{n}\boldsymbol{n} \\ ct' &= -\gamma\beta(\boldsymbol{n}\cdot\boldsymbol{r}) + \gamma(ct), & \beta &= \frac{v}{c}\ ,\ \gamma = \frac{1}{\sqrt{1-\beta^2}} \end{aligned} \tag{1}$$

or

$$\begin{bmatrix} y' \\ z' \\ x' \\ ct' \end{bmatrix} = \begin{bmatrix} 1+(\gamma-1)n_2^2 & (\gamma-1)n_2n_3 & (\gamma-1)n_1n_2 & -\gamma\beta n_2 \\ (\gamma-1)n_2n_3 & 1+(\gamma-1)n_3^2 & (\gamma-1)n_1n_3 & -\gamma\beta n_3 \\ (\gamma-1)n_1n_2 & (\gamma-1)n_1n_3 & 1+(\gamma-1)n_1^2 & -\gamma\beta n_1 \\ -\gamma\beta n_2 & -\gamma\beta n_3 & -\gamma\beta n_1 & \gamma \end{bmatrix} \begin{bmatrix} y \\ z \\ x \\ ct \end{bmatrix} \tag{2}$$

The case in which the direction of $\boldsymbol{v}$ *is chosen in the* $\boldsymbol{e}_1$ *direction* $(n_2 = n_3 = 0)$ *degenerates into*

$$\begin{bmatrix} y' \\ z' \\ x' \\ ct' \end{bmatrix} = \begin{bmatrix} 1 & \cdot & \cdot & \cdot \\ \cdot & 1 & \cdot & \cdot \\ \cdot & \cdot & \gamma & -\beta\gamma \\ \cdot & \cdot & -\beta\gamma & \gamma \end{bmatrix} \begin{bmatrix} y \\ z \\ x \\ ct \end{bmatrix} \tag{3}$$

Eq. $(1,\ III)$ *can be written in the compact form*

$$x^{\nu\prime} = \Lambda^{\nu}_{\mu} x^{\mu} \qquad (\nu, \mu = 1, 2, 3, 4) \tag{4}$$

or in index-free form

$$\boldsymbol{x}' = L(\boldsymbol{n},\ \beta) \cdot \boldsymbol{x}, \qquad \boldsymbol{x} = L^{-1} \cdot \boldsymbol{x}' = L(-\boldsymbol{n},\ \beta) \cdot \boldsymbol{x}' \tag{5}$$

We recall next the Lorentz invariant

$$ds^2 = c^2\, d\tau^2 = c^2\, dt^2 - dx^2 - dy^2 - dz^2 = -\sum_{\mu,\nu} g_{\mu\nu}\, dx_\mu\, dx_\nu \qquad \mu, \nu = 1, 2, 3, 4$$

The tensor

$$G = g_{\mu\nu} = \begin{bmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ & & & -1 \end{bmatrix} \tag{6}$$

is called the metric tensor *corresponding to the line element. It is a metric of a pseudo-Euclidean 4-dimensional space-time world known as* Minkowski space*. It is immediately noticed that*

$$LG\widetilde{L} = G, \qquad (\sim \text{ is transpose}), \tag{7}$$

There is an alternative way to represent the Lorentz transformation as an imaginary rotation *in 4-dimensional Euclidean space. To see this we choose*

$$x_4 = ict, \quad \gamma = \cos\eta, \quad i\beta\gamma = \sin\eta \qquad n_2 = n_3 = 0 \tag{8}$$

The Lorentz transformation equations in the new variable, can be exhibited as

$$\begin{bmatrix} x_2' \\ x_3' \\ x_1' \\ x_4' \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \cos\eta & \sin\eta \\ 0 & 0 & -\sin\eta & \cos\eta \end{bmatrix} \begin{bmatrix} x_2 \\ x_3 \\ x_1 \\ x_4 \end{bmatrix} \tag{9}$$

The orthogonal matrix in (9, III) represents a rotation in the x_1x_4 plane by an imaginary angle $\eta = i\mathrm{th}^{-1}\left(\frac{v}{c}\right)$. The corresponding metric is $g_{\mu\nu} = \delta_{\mu\nu}$. The transformation in (9, III) is then written as

$$x_\mu' = q_{\mu\nu} x_\nu \tag{10}$$

where

$$q_{\mu\nu} = \begin{bmatrix} 1 & & & \\ & 1 & & \\ & & \gamma & i\beta\gamma \\ & & -i\beta\gamma & \gamma \end{bmatrix} \tag{11}$$

(IV) The Lorentz Group; Wigner's rotation

In (9, III) we put $\eta = i\theta$. Then $\gamma = \mathrm{ch}\ \theta$, $\gamma\beta = \mathrm{sh}\ \theta$ and the transformed coordinates (x_1, x_4) undergo the 2×2 orthogonal matrix rotation

$$\begin{bmatrix} x_1' \\ x_4' \end{bmatrix} = \begin{bmatrix} \mathrm{ch}\ \theta & i\mathrm{sh}\ \theta \\ -i\mathrm{sh}\ \theta & \mathrm{ch}\ \theta \end{bmatrix} \begin{bmatrix} x_1 \\ x_4 \end{bmatrix} \quad \text{or} \quad [\boldsymbol{x}'] = A(v)[\boldsymbol{x}] \tag{1}$$

The set of all such matrices $A(v)$ forms a Lie group. $A(v)$ depends continuously on the velocity parameter v such that

$$A(v_1)A(v_2) = A(v_3), \qquad v_3 = \frac{v_1 + v_2}{1 + \frac{v_1 v_2}{c^2}} \tag{2}$$

(law of relativistic collinear velocity addition) and the matrices $A(v)$ have a determinant of $+1$ for $\gamma > 0$.

Since

$$A(v) = \text{ch}\ \theta \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + \text{sh}\ \theta \begin{bmatrix} 0 & i \\ -i & 0 \end{bmatrix} = \exp\left\{\theta \begin{bmatrix} 0 & i \\ -i & 0 \end{bmatrix}\right\}, \tag{3}$$

we say that the matrix $\begin{bmatrix} 0 & i \\ -i & 0 \end{bmatrix}$ *is the generator of this representation.*

Returning to the general case, when the relative velocity $\boldsymbol{v}$ *between frames is not parallel to any space axis, it can be shown that the generator is the* 4×4 *matrix*

$$\sigma = \begin{bmatrix} 0 & 0 & 0 & i\lambda \\ 0 & 0 & 0 & i\mu \\ 0 & 0 & 0 & i\nu \\ -i\lambda & -i\mu & -i\nu & 0 \end{bmatrix} \tag{14}$$

where (λ, μ, ν) *are the direction cosines of* $\boldsymbol{v}$. *The transformation itself is given by the* 4×4 *matrix*

$$L(\boldsymbol{v}) = e^{\theta\sigma} = I + \sigma \text{sh}\ \theta + \sigma^2(\text{ch}\ \theta - 1) \tag{5}$$

In this general case, however, the product of two Lorentz transformations matrices $L(\boldsymbol{v}_1)$ *and* $L(\boldsymbol{v}_2)$, *yield a third Lorentz transformation* $L(\boldsymbol{v}_3)$ *only if the two velocities* $\boldsymbol{v}_1$ *and* $\boldsymbol{v}_2$ *are parallel. If not, we find that*

$$L(\boldsymbol{v}_3) = RL(\boldsymbol{v}_2)L(\boldsymbol{v}_1), \tag{6}$$

where R *is a* 3×3 *real space rotation matrix, representing the so-called Wigner's rotation (***Wigner** *1939). The parameters of the rotation are*

$$R = R(\boldsymbol{e}, \psi); \quad \boldsymbol{e} = \frac{\boldsymbol{v}_2 \times \boldsymbol{v}_1}{|\boldsymbol{v}_2 \times \boldsymbol{v}_1|}; \quad \psi = 2\tan^{-1}\left\{\frac{\sin\varphi}{\tau + \cos\varphi}\right\}, \tag{7}$$

where $\boldsymbol{e}$ *is a unit vector in the direction of the axis of rotation,* φ *is the angle between the vectors* $\boldsymbol{v}_1$ *and* $\boldsymbol{v}_2$, $\tau = \sqrt{\frac{(\gamma_1+1)(\gamma_2+1)}{(\gamma_1-1)(\gamma_2-1)}}$ *and* ψ *is the Wigner rotation angle. Wigner's rotation is a purely kinematic relativistic phenomenon, with the following dynamical consequence: a rigidly accelerated body (for which the instantaneous acceleration is not parallel to the instantaneous velocity exhibits an instantaneous rigid rotation relative to an external inertial frame, even in the absence of torques as measured in an instantaneous inertial rest frame. A comoving observer will observe no centrifugal or Coriolis effects, yet an external observer would find that the body at rest in it, is rotating.*

*Because of the presence of the Wigner rotation, the $L(\boldsymbol{v})$ matrices themselves do not form a group. This rotation is also the origin of the Thomas precession (**Thomas** 1926). The latter is the phenomenon according to which a spinning mass like an electron in an atom, say, or the earth orbiting the sun, exhibits a precession of its axis of spin about the orbital axis as it follows its orbit (or orbital) in a central potential field, such that the ratio of the precessional period to the orbital period is* $2\frac{c^2}{v^2}$.

The Thomas precession is manifested as a factor 2 reduction in the torque related spin-orbit coupling effect in atomic physics. It is encountered in the fine structure of atomic levels, where it causes the magnetic field, as seen by the electron, to be half as effective as one would naively expect. This field itself results by Lorentz–transforming the nuclear electric *field to the electron's comoving frame; all possible Lorentz* and *3-rotation transformations do, however, form one – the Lorentz Lie group $SO(3,\ 1)$ – of which 3-rotations comprise the $SO(3)$ subgroup.*

*When this result became known, it surprised many, including **Pauli** and even **Einstein** himself. The gravitational (classical) version of the Thomas precession, called* geodetic precession *in GTR, is one of several effects being tested by the relativistic spinning–gyro experiment which was put into orbit in 2004.*

As stated previously, the matrix L has the property

$$LG\widetilde{L} = G, \qquad (\sim \text{ is transpose})$$

where G is the metric matrix 4-tensor of Minkowski space.

The real contravariant space time position 4-vector $x^\mu,\ 0 \le \mu \le 3\ ;\ x^0 = ct_1$ $\boldsymbol{x} = \boldsymbol{r} = (x^1, x^2, x^3)$ *can be represented by the hermitian* matrix

$$X = \begin{bmatrix} ct+z & x-iy \\ x+iy & ct-z \end{bmatrix}, \tag{8}$$

whose determinant $|X| = c^2t^2 - x^2 - y^2 - z^2$ is the Lorentz invariant pseudonorm. We note that

$$\begin{aligned} X &= ct\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + x\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} + y\begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix} + z\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \\ &= ctI + x\sigma_x + y\sigma_y + z\sigma_z = x^\mu\sigma_\mu, \end{aligned} \tag{9}$$

where $\sigma_\mu = (I, \boldsymbol{\sigma})$, I being the 2×2 unit matrix and σ_j $(j = 1, 2, 3)$ are the Pauli spin matrices and the Einstein summation convention (for repeating indices) is used. Note that in this representation of 4-vectors, imaginary 4^{th} coordinates are replaced with real 0^{th} coordinates, and a covariant 4-vector is related to its contravariant counterpart via $a_\mu = \eta_{\mu\nu} a^\nu$, where

$$\eta = \begin{pmatrix} 1 & & & \\ & -1 & & \\ & & -1 & \\ & & & -1 \end{pmatrix}$$

is the pseudo–Euclidean Minkowski metric tensor. It can easily be shown that if we represent the Lorentz transformation by the 2×2 matrix

$$L = \begin{bmatrix} \text{ch}\,\frac{\theta}{2} - n_3 \text{sh}\,\frac{\theta}{2} & -(n_1 - in_2)\text{sh}\,\frac{\theta}{2} \\ -(n_1 + in_2)\text{sh}\,\frac{\theta}{2} & \text{ch}\,\frac{\theta}{2} + n_3 \text{sh}\,\frac{\theta}{2} \end{bmatrix} \equiv \exp\left[-\frac{1}{2}\theta(\boldsymbol{n} \cdot \boldsymbol{\sigma})\right] \tag{10}$$

then

$$\begin{bmatrix} ct' + z' & x' - iy' \\ x' + iy' & ct' - z' \end{bmatrix} = L \begin{bmatrix} ct + z & x - iy \\ x + iy & ct - z \end{bmatrix} L^* \tag{11}$$

Note that L in this representation is not unitary, but its determinant is unity. All 4-vectors $\boldsymbol{A}$ will transform like X,

$$A' = LAL^*; \quad \textit{with } A = a^\mu \sigma_\mu,\ A' = a'^\mu \sigma_\mu. \tag{12}$$

(V) Relativistic mechanics

Consider a point moving with velocity $\boldsymbol{u}(t)$ relative to S. In $\bar{S}$, connected to S by the Lorentz transformation $(2,\ I)$, the transformed velocity is $\boldsymbol{u}'(t')$, where

$$\boldsymbol{u} = \frac{d\boldsymbol{r}}{dt}, \qquad \boldsymbol{u}' = \frac{d\boldsymbol{r}'}{dt'}$$

But since $d\boldsymbol{r} = \Phi \cdot d\boldsymbol{r}' + \gamma \boldsymbol{v}\, dt'$ *and* $dt = \gamma\,(dt' + \frac{1}{c^2}\boldsymbol{v} \cdot d\boldsymbol{r}')$

$$\boldsymbol{u} = \frac{\boldsymbol{v} + \frac{1}{\gamma}\Phi \cdot \boldsymbol{u}'}{1 + \frac{1}{c^2}(\boldsymbol{v} \cdot \boldsymbol{u}')} \tag{1}$$

We observe that $\boldsymbol{u}$ *in* $(1,\ V)$ *does not transform like a part of a* 4*-vector. Instead, it has much more complicated transformation properties. The reason for this complexity is that although* $\boldsymbol{r}$ *is a part of a* 4*-vector* $(\boldsymbol{r}, ict)$, dt *is not invariant as it is in the Newtonian theory, and consequently* $\frac{d\boldsymbol{r}}{dt}$ *is not a part of a* 4*-vector. In place of* $\frac{d\boldsymbol{r}}{dt}$ *we thus consider* $\frac{d\boldsymbol{r}}{d\tau}$, *where*

$$d\tau^2 = dt^2 - \frac{(d\boldsymbol{r})^2}{c^2} \tag{2}$$

is a Lorentz invariant. In fact, $d\tau = dt$ *when* $d\boldsymbol{r} \equiv 0$, *i.e. in an inertial frame where the particle is momentarily at rest; in other words, in a frame co-moving with the particle – one of its instantaneous rest frames.* $d\tau$ *is an infinitesimal increment of the particle's proper time. The entity* $\frac{d\boldsymbol{r}}{dt}$ *is the spatial part of a 4-vector and thus transforms simply. We have*

$$d\tau = dt\sqrt{1 - \frac{1}{c^2}(\frac{d\boldsymbol{r}}{dt})^2} = dt\sqrt{1 - \frac{\boldsymbol{u}^2}{c^2}} \tag{3}$$

Since $(\boldsymbol{r}, ict)$ *is a* 4*-vector, we are led to consider the* 4*-vector*

$$u_\mu = \left(\frac{d\boldsymbol{r}}{d\tau}, ic\frac{dt}{d\tau}\right) = (\gamma\boldsymbol{u}, i\gamma c), \qquad \sum_{\mu=1}^{4} u_\mu^2 = -c^2,$$

where $\gamma = \left(1 - \frac{\boldsymbol{u}^2}{c^2}\right)^{-1/2}$, *and* $\boldsymbol{u} = \frac{d\boldsymbol{r}}{dt}$ *is the Newtonian velocity.*

Next, we define a 4-scalar m_0 *to be the mass of the particle at rest (i.e. in its instantaneous rest frame* $\bar{S}$*). Then* p_μ *is also a* 4*-vector – known as the* 4*-momentum:* $p_\mu = (\gamma m_0 \boldsymbol{u},\quad i\gamma m_0 c)$*. Furthermore, the entity* $\frac{dp_\mu}{d\tau}$ *is also a* 4*-vector, known as the Minkowski force 4-vector or 4-force*

$$K_\nu = \frac{dp_\mu}{d\tau} = m_0\frac{du_\nu}{d\tau} = m_0\frac{d^2x_\nu(s)}{d\tau^2} = m_0\gamma\frac{d}{dt}[\gamma\boldsymbol{u},\quad i\gamma c] = [\gamma\boldsymbol{F}, K_4], \tag{4}$$

where $\boldsymbol{F}$ *is the* 3*-dimensional vector* $\frac{d}{dt}(m_0\gamma\boldsymbol{u})$ *equal to the ordinary time derivative of the momentum (because the instantaneous inertia of the particle in a general inertial frame is* $m(\boldsymbol{u}) = m_0\gamma(\boldsymbol{u}) \geq m_0$*). Differentiating the identity* $\sum u_\mu^2 = -c^2$ *w.r.t. particle proper time* τ *we obtain the identity* $\sum K_\mu u_\mu = 0$, *from which we derive*

$$K_4 = \frac{i}{c}\gamma(\boldsymbol{F}\cdot\boldsymbol{u}). \tag{5}$$

Eq. $(4,\ V)$ *is the covariant equation of motion for a massive particle. It relates the Minkowski force, which is determined by the environment (fields* *and other particles) to the rate of change of the 4-velocity w.r.t. the proper time τ of the particle. The spatial components of $(4,\ V)$ generalize Newton's 2^{nd} law of motion, whilst its 4^{th} (time) component is a statement of relativistic energy conservation.*

We next apply the above to a "particle" defined as a spatially–infinitesimal volume element of a charged medium subject to electromagnetic fields. The force $\boldsymbol{F}$ per unit volume (in any frame) is then the Lorentz force per unit volume $\boldsymbol{f} = \rho\,[\boldsymbol{E} + (\boldsymbol{u} \times \boldsymbol{B})]$ and

$$\frac{i}{c}\boldsymbol{E} = (F_{41}, F_{42}, F_{43}); \quad \boldsymbol{B} = (F_{23}, F_{31}, F_{12}); \quad \left(\frac{\rho\boldsymbol{u}}{c}, i\rho\right) = \frac{1}{c}(J_1, J_2, J_3, J_4)$$

and $\boldsymbol{f} = (f_1, f_2, f_3, f_4)$, we thus find the covariant form: (summation convention employed)

$$f_\nu = F_{\nu\mu}J_\mu = F_{\nu\mu}c^2\frac{\partial F_{\mu\lambda}}{\partial x_\lambda} = \boldsymbol{F} \cdot \mathrm{div}\ \boldsymbol{F}$$

The 4th component of f_ν in this equation is simply

$$f_4 = \frac{i}{c}(\boldsymbol{E} \cdot \boldsymbol{J}) = i\frac{\rho}{c}(\boldsymbol{E} \cdot \boldsymbol{u}) = \frac{i}{c}(\boldsymbol{f} \cdot \boldsymbol{u}).$$

Apart from the Minkowski–geometric conversion factor $\frac{i}{c}$, this has the meaning of the rate at which the field does work on the sources per unit volume. The spatial part of f_μ is the rate of change of mechanical momentum (i.e. 3-force) per unit volume. Altogether, the force density is the 4-vector density (i.e., its volume integral transforms as a 4-vector)

$$f_\mu = \rho\left[(\boldsymbol{E} + \boldsymbol{u} \times \boldsymbol{B}), \quad \frac{i}{c}\boldsymbol{E} \cdot \boldsymbol{u}\right]. \tag{6}$$

From $(4,\ V)$ and $(5,\ V)$ we have

$$\frac{d}{dt}\left[\frac{m_0c^2}{\sqrt{1 - \frac{\boldsymbol{u}^2}{c^2}}}\right] = \boldsymbol{F} \cdot \boldsymbol{u} \tag{7}$$

Since $\boldsymbol{F} \cdot \boldsymbol{u}$ is the total rate of work done by the force or the particle; the expression in square brackets on the left is the total motion energy (rest plus kinetic) of the particle. If we write

$$\frac{m_0c^2}{\sqrt{1 - \frac{\boldsymbol{u}^2}{c^2}}} = m_0c^2 + m_0c^2\left[\frac{1}{\sqrt{1 - \frac{\boldsymbol{u}^2}{c^2}}} - 1\right], \tag{8}$$

the part m_0c^2 *is the rest energy, or intrinsic energy, whereas the remaining part is the relativistic kinetic energy which is approximated by* $\frac{1}{2}mu^2$ *for* $\frac{|\boldsymbol{u}|}{c} \ll 1$.

It is easily seen that the spatial part of $(4,\ V)$, *namely*

$$\frac{d}{dt}\left[\frac{m_0\boldsymbol{u}}{\sqrt{1-\frac{\boldsymbol{u}^2}{c^2}}}\right] = \boldsymbol{F}, \tag{9}$$

approximates Newton's second law in an inertial coordinate system when $\frac{|\boldsymbol{u}|}{c} \ll 1$, *in which regime* $m(\boldsymbol{u}) \approx m_0$ *is approximately motion-independent.*

If we define

$$E = \frac{m_0c^2}{\sqrt{1-\frac{\boldsymbol{u}^2}{c^2}}},$$

Then, since the spatial part of p_μ *is* $\boldsymbol{p} = \gamma m_0\boldsymbol{u}$, *it follows that*

$$E^2 = c^2\boldsymbol{p}^2 + m_0^2c^4, \tag{10}$$

a generalization of the classical nonrelativistic relation $E = \frac{\boldsymbol{P}^2}{2m}$.

Note that

$$p_\mu = (m\boldsymbol{u}, \quad i\frac{E}{c}) = (\boldsymbol{p}, i\frac{E}{c}), \quad m = m(\boldsymbol{u}) = \frac{m_0}{\sqrt{1-\frac{\boldsymbol{u}^2}{c^2}}} \quad (motion - mass) \tag{11}$$

where

$$p_\mu^2 = -m_0^2c^2.$$

(VI) The 'Twin Paradox' — a one-way time machine

Einstein's STR brought with it some remarkable implications. There were consequences that seemed opposed to our intuition and common sense, in a way that classical theories were not; e.g., the increase of inertia with speed and the so-called 'twin paradox'. It was aspects such as these which conferred on it a glamor and popular interest probably never equaled in the whole history of physics.

Of all the supposed paradoxes engendered by relativity theory, the 'twin paradox' (or 'clock paradox') is most famous, and has been the most controversial (although it is extremely well supported by experiments). It asserts that if one clock remains at rest in an inertial frame, and another, initially synchronized with it, is taken off on any sort of path and finally brought back to its starting point, the second clock will have lost time as compared with the first. It is not that the traveling clock is somehow damaged by the excursion; indeed a co-traveling astronaut will end up by becoming younger than his twin brother who stayed with the stationary clock.

This result, which was stated by Einstein in his very first relativity paper (1905), became the subject of raging controversy in the physical literature during the years 1939–1959. The matter was finally settled by experimental tests in nuclear physics during 1960–1963, and later tests – involving the hauling of atomic clocks aboard aircraft – established the effect for macroscopic objects[184].

*The experiments thus far accessible to us are not those of spaceships traveling at near-light speeds; rather, they involve high-precision nuclear and atomic processes, and atomic clocks moving at aircraft and satellite speeds. Thus, in the early 60's, several measurements utilizing the Mössbauer effect — recoilless, extremely narrow-linewidth gamma ray emission from radioisotopes embedded in crystal lattices — were carried out to verify the special-relativistic time dilatations. In one such experiment (**Hay** et al. 1960), a rotating cylinder carried a gamma-ray source* (^{57}Co) *wrapped in a band around it. A larger, concentric band, containing the isotope* ^{57}Fe, *was supported via a pair of perpendicular discs.*

---

[184] In both types of experiments, a *gravitation* part of the twin–paradox effect, predicted by Einstein's GTR, must sometimes be added to the *motional* (STR) effect, to obtain agreement with experiment. Both effects must be (and are) accounted for in GPS technology, since it depends on satellite–borne atomic clocks.

When the apparatus was at rest, the ^{57}Fe *nuclei could optimally absorb photons emitted by the inner* ^{57}Co *band. But when the apparatus was spun about the cylinder axis (at 500 revolutions per second) the different linear velocities of emitter and absorber resulted in a degraded absorption efficiency — by an amount found to agree with the prediction of STR. In effect, the inner-radius emitter atoms constitute the stay-at-home twin, while the absorber atoms represent the traveling twin. The central frequencies of the emission and absorption bands represent the rate of "ticking" of the respective twins' gamma-ray "clocks".*

In this language, the outer clock ticks slower *than the inner one — the "traveling twin" ages less, as predicted by STR. Actually,* both *clocks in the experiment execute (literally) round trips; but the emitter is accelerated to lower speeds in the (approximately inertial) laboratory frame. For that reason, its "clock ticks" will be more closely spaced in time — as reckoned by a non-rotating observer – than the "ticks" of the absorber "clock".*

The Mössbauer effect also figured in the celebrated Pound-Rebka experiment (1959)*, which verified that clocks tick faster the higher their altitudes in the Earth's gravitational field — as predicted by GTR. Later, in the 70's,* both *types of time dilatation were also verified using pairs of atomic (MASER) clocks – one of which went on a round-trip aboard a plane.*

Consider a flat pseudo-Euclidean 4-space (a.k.a. Minkowski space); a point is labeled $(t, \boldsymbol{x})$*, where* $\boldsymbol{x}$ *belongs to ordinary Euclidean 3-space. (Such a point is called an "event".) The difference between two events,* $(t_2, \boldsymbol{x}_2) - (t_1, \boldsymbol{x}_1) = (t_2 - t_1, \boldsymbol{x}_2 - \boldsymbol{x}_1)$*, is a 4-vector, and is labeled "timelike", "lightlike" or "spacelike" according as the value of* $c^2(t_2 - t_1)^2 - (\boldsymbol{x}_2 - \boldsymbol{x}_1)^2$ *is positive, zero or negative. Each point* $(t, \boldsymbol{x})$ *is the apex of a local* future light-cone*, consisting of all future points* $(t', \boldsymbol{x}')$ *so that the interval* $(t', \boldsymbol{x}') - (t, \boldsymbol{x})$ *is lightlike; the* interior *of this cone consists of all future points for which the interval is* timelike*.*

For any vector $a = (\alpha, \boldsymbol{\beta})$*, we define its "square" or "pseudo-norm" to be:* $a^2 = \alpha^2 - \boldsymbol{\beta}^2$ *where* $\boldsymbol{\beta}^2$ *is the usual norm in 3-dimensional Euclidean space. Accordingly, a* scalar product *in Minkowski space is defined: if*

$$a^{(i)} = (a_0^{(i)}, \boldsymbol{a}^{(i)}), \quad i = 1, 2,$$

then

$$a^{(1)} \cdot a^{(2)} \equiv \frac{1}{2}\{(a^{(1)} + a^{(2)})^2 - (a^{(1)})^2 - (a^{(2)})^2\}.$$

The above-defined square is clearly not a norm*, since* $a^2 = 0$ *for all lightlike vectors; nor is it even a* seminorm*, as* $a^2 < 0$ *for all spacelike vectors. That is why we refer to it as a "pseudo-norm".*

We next investigate how the triangle inequality *of Euclidean norms fares for this pseudo-norm of Minkowski space, & how this relates to the STR Twin Paradox.*

Consider three points (events) A, B, C in Minkowski space; let C and B be inside the future light cone of A. We also assume C to be in the future light cone of B (Fig. 5.2). We denote the timelike vectors AB, BC, AC by c, a, b, respectively; in some inertial frame, let

$$\begin{aligned} c &= (c_0, \boldsymbol{c}) \\ b &= (b_0, \boldsymbol{b}) \\ a &= (a_0, \boldsymbol{a}), \end{aligned}$$

where the 0-components are the (real) time coordinates of the three events in this frame, and we select units in which the speed of light equals 1.

Since $b = a + c$ *we have*

$$b^2 = (a_0 + c_0)^2 - (\boldsymbol{a} + \boldsymbol{c})^2 = a^2 + c^2 + 2a \cdot c = a^2 + c^2 + 2(a_0 c_0 - \boldsymbol{a} \cdot \boldsymbol{c}). \quad (1)$$

Now, the "length" of these three intervals by their pseudo-norms, are:

$$\tau_1 = \sqrt{c^2} = \sqrt{(c_0)^2 - \boldsymbol{c}^2}; \quad \tau_2 = \sqrt{a^2}; \quad \tau_3 = \sqrt{b^2}.$$

Physically, these are the proper times of the respective intervals; e.g. τ_1 *is the time interval between events A and B as reckoned aboard a spaceship of uniform velocity whose worldline intersects events A and B.*

We rewrite the above equation $(1,\ VI)$ *as*

$$(\tau_3)^2 = (\tau_2)^2 + (\tau_1)^2 + 2(\sqrt{(\tau_2)^2 + \boldsymbol{a}^2}\sqrt{(\tau_1)^2 + \boldsymbol{c}^2} - \boldsymbol{a} \cdot \boldsymbol{c}) \quad (2)$$

But on the strength of the identity

$$(\alpha^2 + \beta^2)(\gamma^2 + \delta^2) \equiv (\alpha\gamma + \beta\delta)^2 + (\alpha\delta - \beta\gamma)^2,$$

we have:

$$\begin{aligned} [(\tau_2)^2 + \boldsymbol{a}^2][(\tau_1)^2 + \boldsymbol{c}^2] &\equiv [|\boldsymbol{a}||\boldsymbol{c}| + \tau_1\tau_2]^2 + [\tau_2|\boldsymbol{c}| - \tau_1|\boldsymbol{a}|]^2 \\ &\geq (|\boldsymbol{a}||\boldsymbol{c}| + \tau_1\tau_2)^2 \geq (\boldsymbol{a} \cdot \boldsymbol{c} + \tau_1\tau_2)^2, \end{aligned}$$

so

$$\sqrt{(\tau_2)^2 + \boldsymbol{a}^2}\sqrt{(\tau_1)^2 + \boldsymbol{c}^2} \geq \boldsymbol{a} \cdot \boldsymbol{c} + \tau_1\tau_2,$$

hence (2) implies

$$(\tau_3)^2 \geq (\tau_1 + \tau_2)^2 \Rightarrow \tau_3 \geq \tau_1 + \tau_2.$$

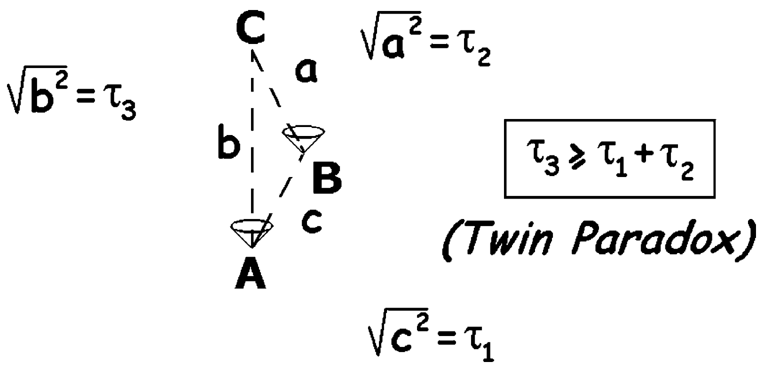

Fig. 5.2: A triangle of timelike vectors (=intervals) in Minkowski space. Local future light-cones are shown; the vertical direction is time (in some reference frame), while the horizontal directions are spatial in the same frame

By the above interpretation of τ_i as proper times, it follows that the journey $A \to B \to C$ (which is accelerated in the immediate vicinity of B) takes less proper time than the unaccelerated worldline $A \to C$. Hence the Twin Paradox!

In this way a variant of the Euclidean triangle inequality, which holds for Minkowski space is used to furnish a 4-geometrical proof of the twin paradox of STR (Note that in a Euclidean space one would instead have $\tau_3 \leq \tau_1 + \tau_2$).

(VII) Relativistic wave phenomena

Acoustic Doppler shifts are derived on the assumption that the radiation propagation speed is constant relative to the medium, whereas the wave's frequency is affected by the motion of both source and observer. Electromagnetic theory, however, requires a modification of these assumptions for two reasons:

- *Non-existence of 'medium' for vacuum propagation;*
- *The replacement of the Galilean transformation by the Lorentz transformation*

Consider a source of electromagnetic waves moving with uniform velocity $\boldsymbol{v}$ *relative to an observer in* S. *If the source is at rest in* S', *then an observer at* $0'$ *(the origin of* S'*) describes a monochromatic plane-wave emitted from the source as being proportional to* $e^{i(\boldsymbol{k}'\cdot\boldsymbol{r}'-\omega' t')}$. *Similarly, an observer at* 0 *in* S *describes the same wave as being proportional to* $e^{i(\boldsymbol{k}\cdot\boldsymbol{r}-\omega t)}$.

Due to the form-invariance of the basic wave equation

$$\nabla^2\Phi - \frac{1}{c^2}\frac{\partial^2\Phi}{\partial t^2} = \nabla'^2\Phi - \frac{1}{c^2}\frac{\partial^2\Phi}{\partial t'^2},$$

the phase of the plane-wave solution of this equation is itself a 4-scalar

$$\boldsymbol{k}'\boldsymbol{r}' - \omega' t' = \boldsymbol{k}\boldsymbol{r} - \omega t. \tag{1}$$

Working in the imaginary–4^{th}*–component representation of Minkowski space, this scalar can be written as a dot product of the position 4-vector* $(\boldsymbol{r},\ ict)$ *and the 4-vector*

$$k_\mu = (k_1, k_2, k_3, \frac{i\omega}{c}) = (\boldsymbol{k},\quad i\frac{\omega}{c}), \tag{2}$$

namely

$$(\boldsymbol{r},\quad ict)\cdot(\boldsymbol{k},\quad \frac{i\omega}{c}) = k_1x_1 + k_2x_2 + k_3x_3 + k_4x_4 = \boldsymbol{k}\cdot\boldsymbol{r} - \omega t \tag{3}$$

The entity k_μ *is therefore a covariant 4-vector of zero magnitude*

$$k_\mu k_\mu = k_1^2 + k_2^2 + k_3^2 + k_4^2 = |\boldsymbol{k}|^2 - \frac{\omega^2}{c^2} = 0 \tag{4}$$

It transforms according to the equations

$$\boldsymbol{k}' = \boldsymbol{k} + \left[\frac{\gamma-1}{v^2}(\boldsymbol{v}\cdot\boldsymbol{k}) - \gamma\frac{\omega}{c^2}\right]\boldsymbol{v}; \qquad \omega' = \gamma(\omega - \boldsymbol{v}\cdot\boldsymbol{k}) \tag{5}$$

Putting $\boldsymbol{v}\cdot\boldsymbol{k} = \omega\frac{v}{c}\cos\theta$, *we obtain*

$$\omega' = \omega\frac{1-\frac{v}{c}\cos\theta}{\sqrt{1-\frac{v^2}{c^2}}} \tag{6}$$

and by symmetry

$$\omega = \omega'\frac{1+\frac{v}{c}\cos\theta'}{\sqrt{1-\frac{v^2}{c^2}}} \tag{7}$$

where θ' *is the angle between* $\boldsymbol{v}$ *and* $\boldsymbol{k}'$.

Eliminating both ω *and* ω' *between these equations we derive the relation:*

$$\cos\theta' = \frac{\cos\theta - \frac{v}{c}}{1 - \frac{v}{c}\cos\theta}; \qquad \cos\theta = \frac{\cos\theta' + \frac{v}{c}}{1 + \frac{v}{c}\cos\theta'} \tag{8}$$

Finally, from (5, VII), $\boldsymbol{k}\times\boldsymbol{v} = \boldsymbol{k}'\times\boldsymbol{v}$, *which implies*

$$\left.\begin{aligned} \sin\theta' = \frac{k}{k'}\sin\theta = \frac{\omega}{\omega'}\sin\theta = \sin\theta\frac{\sqrt{1-\frac{v^2}{c^2}}}{1-\frac{v}{c}\cos\theta} \\ \sin\theta = \sin\theta'\frac{\sqrt{1-\frac{v^2}{c^2}}}{1+\frac{v}{c}\cos\theta'} \end{aligned}\right\} \tag{9}$$

Combining (8, VII) *and* (9, VII), *we have*

$$\tan\theta = \sin\theta'\frac{\sqrt{1-\frac{v^2}{c^2}}}{\cos\theta' + \frac{v}{c}}; \qquad \tan\frac{\theta'}{2} = \tan\frac{\theta}{2}\sqrt{\frac{1+\frac{v}{c}}{1-\frac{v}{c}}} \tag{10}$$

Equations (6, VII)–(10, VII) *give the apparent frequency and direction of an electromagnetic radiation source which is moving uniformly relative to the observer* S. *For* $\frac{v}{c} \ll 1$, *the relativistic formulae reduce to the well-known classical ones:*

$$\omega \approx \omega'(1 + \frac{v\cos\theta'}{c}); \qquad \omega' \approx \omega(1 - \frac{v\cos\theta}{c}); \tag{11}$$

For light in vacuo, as contrasted with sound, it has been proved impossible to identify a medium of transmission relative to which the source and observer are moving. Hence, the statements 'source receding from observer' and 'observer receding from source' are physically identical situations and must exhibit the same Doppler shift. The familiar observed effects of 'red-shift', 'blue-shift', and the aberration of star light, are all direct consequences of (6, VII)–(10, VII). *Note however that at* $\theta = \frac{\pi}{2}$, $\omega = \omega'\sqrt{1-\frac{v^2}{c^2}} = \omega'(1 - \frac{1}{2}\frac{v^2}{c^2} + \dots)$ *predicts the purely relativistic transverse Doppler shift.*

(VIII) Lagrangian and Hamiltonian of Electrodynamics

*Consider first the noncovariant Lagrangian formulation of electrodynamics (**Schwarzschild** 1903). In the presence of charged bodies or a charged medium, and in the Lorentz gauge, Maxwell's equations mean that the potentials comply with the equations*

$$\left.\begin{aligned} \nabla^2\boldsymbol{A} - \frac{1}{c^2}\frac{\partial^2\boldsymbol{A}}{\partial t^2} = -\frac{1}{c^2}\boldsymbol{J}, \qquad \nabla^2\phi - \frac{1}{c^2}\frac{\partial^2\phi}{\partial t^2} = -\rho \\ \text{div }\boldsymbol{A} + \frac{1}{c^2}\frac{\partial\phi}{\partial t} = 0 \end{aligned}\right\} \tag{1}$$

For a charge distribution with local density ρ *and velocity* $\boldsymbol{v}$, $\boldsymbol{J} = \rho\boldsymbol{v}$. *The Lagrangian density of sourceless electromagnetic fields is* $\mathcal{L} = \frac{1}{2}(\boldsymbol{E}^2 - c^2\boldsymbol{B}^2)$ *where* $\boldsymbol{E} = -\nabla\phi - \frac{\partial\boldsymbol{A}}{\partial t}$, $\boldsymbol{B} = \text{curl }\boldsymbol{A}$. *In the presence of sources, we must add to it the term* $(\boldsymbol{A}\cdot\boldsymbol{J} - \rho\phi)$, *resulting in*

$$\mathcal{L} = \frac{1}{2}\left[\left(-\nabla\phi - \frac{\partial\boldsymbol{A}}{\partial t}\right)^2 - c^2(\text{curl }\boldsymbol{A})^2\right] + (\boldsymbol{A}\cdot\boldsymbol{J} - \rho\phi) \tag{2}$$

Then the Euler-Lagrange equations – resulting from the condition that the action $\int d^4x\mathcal{L}$ *be extremal at the actual field configuration in Minkowski space – are:*

$$\frac{\partial\mathcal{L}}{\partial\phi} - \text{div }\left[\frac{\partial\mathcal{L}}{\partial(\nabla\phi)}\right] - \frac{\partial}{\partial t}\left(\frac{\partial\mathcal{L}}{\partial\dot{\phi}}\right) = 0 \tag{3}$$

$$\frac{\partial\mathcal{L}}{\partial\boldsymbol{A}} - \text{div }\left[\frac{\partial\mathcal{L}}{\partial(\nabla\boldsymbol{A})}\right] - \frac{\partial}{\partial t}\left(\frac{\partial\mathcal{L}}{\partial\dot{\boldsymbol{A}}}\right) = 0 \tag{4}$$

To establish that Maxwell's equations (1, $VIII$) *indeed follow from* (2, $VIII$)–(4, $VIII$) *we verify that*

$$\frac{\partial\mathcal{L}}{\partial\phi} = -\rho; \qquad \frac{\partial\mathcal{L}}{\partial\dot{\phi}} = 0; \qquad \frac{\partial\mathcal{L}}{\partial(\nabla\phi)} = \left(\nabla\phi + \frac{\partial\boldsymbol{A}}{\partial t}\right);$$

$$\text{div }\frac{\partial\mathcal{L}}{\partial(\nabla\phi)} = \left(\nabla^2\phi + \frac{\partial\text{div }\boldsymbol{A}}{\partial t}\right) = \left(\nabla^2\phi - \frac{1}{c^2}\frac{\partial^2\phi}{\partial t^2}\right);$$

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{A}} = \boldsymbol{J}; \qquad \frac{\partial \mathcal{L}}{\partial \dot{\boldsymbol{A}}} = \left(\nabla\phi + \frac{\partial \boldsymbol{A}}{\partial t}\right); \qquad \frac{\partial}{\partial t}\frac{\partial \mathcal{L}}{\partial \dot{\boldsymbol{A}}} = \left[\frac{\partial^2 \boldsymbol{A}}{\partial t^2} - c^2 \text{ grad div } \boldsymbol{A}\right] \tag{5}$$

$$\begin{aligned}\frac{\partial \mathcal{L}}{\partial(\nabla \boldsymbol{A})} &= -\frac{c^2}{2}\frac{\partial}{\partial \nabla \boldsymbol{A}}(\text{curl } \boldsymbol{A})^2 \\ &= \frac{c^2}{4}\frac{\partial}{\partial \nabla \boldsymbol{A}}[(\nabla \boldsymbol{A} - \boldsymbol{A}\nabla) : (\nabla \boldsymbol{A} - \boldsymbol{A}\nabla)] = (I \times \text{curl } \boldsymbol{A});\end{aligned}$$

$$\text{div } \frac{\partial \mathcal{L}}{\partial(\nabla \boldsymbol{A})} = c^2 \text{curl curl } \boldsymbol{A}$$

*In order to build the Lorentz-invariant Lagrangian density (**Born** 1909), we start from the expression (equation(2, $VIII$))*

$$\boxed{\mathcal{L} = \frac{1}{2}(\boldsymbol{E}^2 - c^2\boldsymbol{B}^2) + (\boldsymbol{A}\cdot\boldsymbol{J} - \rho\phi)} \tag{6}$$

where $\{\boldsymbol{E}, \boldsymbol{B}, \boldsymbol{A}, \boldsymbol{J}\}$ are ordinary 3-vectors, and express it in terms of 4-vectors and 4-tensors. We have already shown that (summation convention)

$$(\boldsymbol{A}, \frac{i}{c}\phi)\cdot(\frac{1}{c}\boldsymbol{J}, i\rho) = \frac{1}{c}(\boldsymbol{A}\cdot\boldsymbol{J} - \rho\phi) = \frac{1}{c}J_\alpha A_\alpha \qquad \alpha = 1,2,3,4 \tag{7}$$

We also know that

$$\boxed{F_{\mu\nu} = \frac{\partial A_\mu}{\partial x_\nu} - \frac{\partial A_\nu}{\partial x_\mu}} \tag{8}$$

It then follows that

$$-\frac{c^2}{2}(F_{\mu\nu}F_{\mu\nu}) = \boldsymbol{E}^2 - c^2\boldsymbol{B}^2. \tag{9}$$

Hence manifestly covariant (relativistic) form of the Lagrangian density is:

$$\boxed{\mathcal{L} = -\frac{c^2}{4}(F_{\alpha\beta}F_{\alpha\beta}) + J_\alpha A_\alpha} \tag{10}$$

From the principle of least (or more precisely extremal) action one derives the covariant form of the Euler-Lagrange equation

$$\frac{\partial \mathcal{L}}{\partial A_\alpha} - \frac{\partial}{\partial x_\beta}\left(\frac{\partial \mathcal{L}}{\partial(\partial A_\alpha/\partial x_\beta)}\right) = 0 \tag{11}$$

where

$$\frac{\partial \mathcal{L}}{\partial A_\alpha} = J_\alpha, \qquad \frac{\partial \mathcal{L}}{\partial(\partial A_\alpha/\partial x_\beta)} = c^2 F_{\alpha\beta}, \qquad \frac{\partial}{\partial x_\beta} F_{\alpha\beta} = \frac{1}{c^2}\, J_\alpha \tag{12}$$

We must still add to the Lagrangian density the matter kinetic energy. Thus, in the case of a charged point-particle of mass m, charge e and trajectory $\boldsymbol{r}(t)$ and velocity $\boldsymbol{v}(t) = \frac{d\boldsymbol{r}}{dt}$, *the particle–dependent term in the Lagrangian* $L = \int d^3\boldsymbol{x}\, \mathcal{L}$ *is:*

$$L_p\{\boldsymbol{r}(t), \boldsymbol{v}(t); t\} = \frac{1}{2} m\boldsymbol{v}^2(t) + \frac{1}{c} e\boldsymbol{v}(t)\cdot \boldsymbol{A}\{\boldsymbol{r}(t), t\} - e\phi\{\boldsymbol{r}(t), t\} \tag{13}$$

(the particle is assumed to move much slower then light, $|\boldsymbol{v}| \ll c$, so the Newtonian kinetic energy can be used).

In this representation, the principle of least action renders the particle equation of motion

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \boldsymbol{v}}\right) - \frac{\partial L}{\partial \boldsymbol{r}} = 0 \tag{14}$$

Carrying out the differentiation with

$$\frac{\partial L}{\partial \boldsymbol{v}} = m\boldsymbol{v} + \boldsymbol{A}, \qquad m\boldsymbol{v} = \boldsymbol{p} = \text{ mechanical momentum}$$

$$\frac{\partial L}{\partial \boldsymbol{r}} = e \text{ grad } (\boldsymbol{A}\cdot\boldsymbol{v}) - e\nabla\phi = e\ (\boldsymbol{v}\cdot\nabla\boldsymbol{A}) + e\ \boldsymbol{v}\times \text{curl } \boldsymbol{A} - e\nabla\phi,$$

the particle equation of motion becomes

$$\frac{d}{dt}(\boldsymbol{p} + e\boldsymbol{A}) = e\ (\boldsymbol{v}\cdot\nabla\boldsymbol{A}) + e\boldsymbol{v}\times \text{curl } \boldsymbol{A} - e\nabla\phi, \tag{15}$$

But the total time-derivative $\frac{d\boldsymbol{A}}{dt}$ consists of two parts: the change $\frac{\partial \boldsymbol{A}}{\partial t}$ of the vector potential with time at a fixed point in space, and the change due to motion of the charged particle:

$$\frac{d\boldsymbol{A}}{dt} = \frac{\partial \boldsymbol{A}}{\partial t} + \boldsymbol{v}\cdot\nabla A \tag{16}$$

Therefore

$$m\frac{d^2\boldsymbol{r}}{dt^2} = m\frac{d\boldsymbol{v}}{dt} = \frac{d\boldsymbol{p}}{dt} \quad = -e\left[\frac{\partial \boldsymbol{A}}{\partial t} + \nabla\phi\right] + \boldsymbol{v}\times \text{curl } \boldsymbol{A} \\ = e\boldsymbol{E} + e\left(\boldsymbol{v}\times\boldsymbol{B}\right) = \text{ the Lorentz force} \tag{17}$$

($\boldsymbol{A}$, ϕ, $\boldsymbol{E}$ and $\boldsymbol{B}$ are evaluated at the particle's trajectory).

The foregoing results can be made Lorentz invariant upon the introduction of the relativistic particle Lagrangian

$$L_p = -m_0c^2\sqrt{1-\frac{v^2}{c^2}} + e\,\boldsymbol{A}\cdot\boldsymbol{v} - e\phi \tag{18}$$

The corresponding particle Hamiltonian is

$$\mathcal{H}_p = \boldsymbol{v}\cdot\frac{\partial L}{\partial \boldsymbol{v}} - L = \frac{m_0c^2}{\sqrt{1-\frac{v^2}{c^2}}} + e\phi \tag{19}$$

with the 3-vector *mechanical* momentum

$$\boldsymbol{p} = \frac{m_0\boldsymbol{v}}{\sqrt{1-\frac{v^2}{c^2}}} \quad , \tag{20}$$

and the corresponding canonical 3-vector *momentum*

$$\boldsymbol{\pi} = \frac{\partial L}{\partial \boldsymbol{v}} = \boldsymbol{p} + e\,\boldsymbol{A} \tag{21}$$

Note that the potential $\boldsymbol{A}$ does not appear explicitly in $\mathcal{H}$ because the magnetic field is perpendicular to the Lorentz force and thus does not exert work upon the charged particle. The first term on the r.h.s. of (18, $VIII$) *arises from the Lorentz-invariant of the action integral of a particle*

$$-m_0c^2\int_{t_1}^{t_2} d\tau = -\int_{t_1}^{t_2} m_0c^2\sqrt{1-\frac{v^2}{c^2}}\,dt$$

where τ is the proper time (time elapsed in the particle's rest-frame).

We express the Hamiltonian in terms of the canonical momentum defined above:

$$(\mathcal{H}_p - e\phi)^2 = c^2(\boldsymbol{\pi} - e\boldsymbol{A})^2 + m_0^2c^4. \tag{22}$$

The canonical (Hamilton) equations are then equivalent to the relativistic equation of motion of the charged particle acted upon by the Lorentz force law.

(IX) The equations of electrodynamics in the presence of a gravitational field

The Lorentz-covariant electromagnetic field equations can easily be generalized so that they are applicable in an arbitrary 4-dimensional curved pseudo-Riemannian (i.e. locally Minkowskian) manifold, i.e., in the presence of an external gravitational field.

As seen above the Lorentz–covariant equations of the electromagnetic field in STR (no gravity) are

$$\text{div } F = -\frac{1}{c^2}\, J, \qquad \text{div } J = 0, \qquad J_\mu = (\boldsymbol{J}, ic\rho)$$

$$F = F_{\mu\nu} = \frac{\partial A_\nu}{\partial x_\mu} - \frac{\partial A_\mu}{\partial x_\nu} = (\boldsymbol{B}, -\frac{i\boldsymbol{E}}{c})\ ,$$

where, as usual, Greek letters are used for 4-space indices. Switching from flat Minkowski space to locally Minkowski, 4-dimensional manifold of metric $g_{\mu\nu}$ and curvilinear coordinates x^μ –also switching from imaginary–4^{th}–coordinate notation to the more modern real–0^{th}–coordinate representation for the local Minkowski space – these equations take on the form:

$$\frac{1}{\sqrt{-g}}\frac{\partial}{\partial x^\nu}(\sqrt{-g}F^{\mu\nu}) = \frac{1}{c^2}\, J^\mu \qquad \text{(Maxwell's source equations)}$$

$$\frac{1}{\sqrt{-g}}\frac{\partial}{\partial x^\mu}(\sqrt{-g}J^\mu) = 0 \qquad \text{(Continuity equation)}$$

where $g = -det|g_{\mu\nu}|$ and

$$\mathbf{g}_{\mu\nu} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}$$

In a locally free-falling coordinate system (frame).

The equations of motion of a charged particle in the presence of both gravitational and electromagnetic fields is then a generalization of $m_0 \frac{du^\mu}{d\tau} = e\, u_\nu\, F^{\nu\mu}$ ($u^\mu =$ components of the 4-velocity vector), namely

$$\frac{e}{c}\, u_\nu F^{\nu\mu} = m_0 c\left(\frac{du^\mu}{d\tau} + \Gamma^\mu_{\nu\lambda} u^\nu u^\lambda\right),$$

where Γ is the manifold's affine connection (expressible in terms of $g_{\alpha\beta}$ and their derivatives) and

$$g^{\mu\lambda} g_{\lambda\alpha} = \delta^\mu_\alpha (Kronecker\ delta), \qquad F^{\alpha\beta} = g^{\alpha\mu} F_{\mu\nu} g^{\nu\beta}$$

(X) Stress-energy-momentum tensor

***Minkowski** (1908) recast the electromagnetic field equations via a continuum–mechanics covariant representation by means of a single entity — the symmetric zero-traced 2-indexed 4-dimensional, covariant electromagnetic stress-energy-momentum tensor in free space*

$$S_{\mu\nu} = \left[\begin{array}{ccc|c} -T_{11} & -T_{12} & -T_{13} & -icQ_1 \\ -T_{21} & -T_{22} & -T_{23} & -icQ_2 \\ -T_{31} & -T_{32} & -T_{33} & -icQ_3 \\ \hline -icQ_1 & -icQ_2 & -icQ_3 & W \end{array}\right]; \quad S_{\mu\nu} = S_{\nu\mu}; \quad S_{\mu\mu} = 0 \quad (1)$$

with

$$\begin{aligned} T_{ij} &= \boldsymbol{EE} + \boldsymbol{c}^2\, B\boldsymbol{B} - \frac{1}{2} I(E^2 + c^2\, B^2), \qquad i,j = 1,2,3 \\ \boldsymbol{Q} &= [\boldsymbol{E} \times \boldsymbol{B}] \\ W &= \frac{1}{2}(E^2 + c^2\, B^2) \end{aligned} \quad (2)$$

Where $\boldsymbol{Q}$ is the Poynting vector, W is the electromagnetic field energy density and τ_{ij} is the electromagnetic field stress 3-tensor, and where the imaginary–4^{th}–component representation of Minkowski 4-space is used. In terms of the skew – symmetric electromagnetic field 4-tensor, this symmetric stress–energy–momentum tensor can be elegantly represented as follows:

$$S_{\mu\nu} = c^2(F_{\mu\alpha}F_{\alpha\nu} + \frac{1}{4}F_{\alpha\beta}F_{\alpha\beta}\delta_{\mu\nu}) = c^2(F{\cdot}F + \frac{1}{4}(F : F)I)$$

where $\delta_{\mu\nu}$ is the Kronecker delta and $I = I_4$ is the 4×4 unit matrix. Taking the 4-divergence and using the covariant form of Maxwell's equations, we readily obtain

$$\frac{\partial S_{\mu\nu}}{\partial x_\mu} = -J_\alpha F_{\alpha\nu} = f_\nu, \quad (3)$$

where J_μ is the 4-current density and f_μ is the Lorentz 4-force density; that is $J_\mu = (\boldsymbol{J}, ics)$ and $f_\mu = (\boldsymbol{f},\ f_4 = \frac{i}{c}P)$ with $\boldsymbol{f} = \rho\boldsymbol{E} + \boldsymbol{J} \times \boldsymbol{B}$ the Lorentz 3-force per unit volume exerted by the fields on the sources, and $P = \boldsymbol{J}{\cdot}\boldsymbol{E}$ the power (work per unit time) exerted by the fields upon a unit volume of sources.

In terms of the Newtonian (3D space, 1D time) block–decomposition of the 4-matrix S (given by Eqs. (1, X) *and* (2, X) *above)* (1, X) *becomes:*

$$\begin{cases} \boldsymbol{\nabla}(c^2\boldsymbol{Q}) + \frac{\partial W}{\partial t} = -P & \nu = 4 : \text{ local energy conservation} \\ \boldsymbol{\nabla}\cdot\boldsymbol{T} + \frac{\partial \boldsymbol{Q}}{\partial t} = -\boldsymbol{f} & \nu = 1,2,3 : \text{ local momentum conservation} \end{cases} \tag{4}$$

From Eqs. (4, X) we see that the Poynting vector has a dual interpretation: it is both the local 3-momentum density and the local energy – current density of the electromagnetic fields in empty space (i.e. without a medium).

(XI) Quantum correction to the Maxwell equations

An electromagnetic field (classical or quantum) may produce charged electron-positron pairs (as well as heavier pairs such as proton-antiproton) as a consequence of quantum effects and these charged particles – whether real or virtual *– have a real effect upon the fields themselves (back–reaction). This means that the dynamics of a classical field contain nonlinear quantum corrections to the Maxwell equations, even in empty space.*

A way to think of these corrections is to realize that the vacuum is not empty, but rather it is a complicated nonlinear *medium — especially when probed with high fields and/or at high frequencies. It is, however, an* isotropic, homogeneous *and* Lorentz invariant *medium — not an "ether" in the 19th century sense.*

One may define an effective Lagrangian density $\mathcal{L}_{\text{eff}} = \mathcal{L}_0 + \delta\mathcal{L}$, *where* $\mathcal{L}_0$ *is the classical term while* $\delta\mathcal{L}$ *includes the quantum corrections and can be expanded perturbatively as a joint Taylor expansion in* $\alpha = \frac{e^2}{4\pi\hbar c}$ *(fine-structure constant),* eE *and* eB.

W. Heisenberg *and* ***H. Euler*** *have derived (1936) an analytical approximation to the nonlinear correction term, valid in the* low frequency limit *(*$f \ll \frac{m_e c^2}{h} \sim 10^{20}$ *Hz,* $m_e =$ *the electron mass) and to all orders in* eE, eB *but zeroth order in* α *(at fixed* eE, eB*). To lowest (4th order) in the fields, their transcendental–function expression for* $\delta\mathcal{L}$ *reduces to the quartic form*

$$\delta\mathcal{L}^{(4)} = \left(\frac{\alpha}{4\pi}\right)^2 \frac{2\hbar^3}{45 m_e^4 c^5} \left[(\boldsymbol{E}^2 - c^2\boldsymbol{B}^2)^2 + 7(\boldsymbol{E}\cdot\boldsymbol{B})^2 c^2\right].$$

This expression is Lorentz covariant, *since*

$$\boldsymbol{E}^2 - c^2\boldsymbol{B}^2 = -\frac{c^2}{2} F : F \quad \text{and} \quad \boldsymbol{E}\cdot\boldsymbol{B} = -\frac{c}{4} F : G\,.$$

in terms of the (imaginary–4^{th}–component representation) Minkowski skew–symmetric electromagnetic field 4-tensor, $F_\mu\nu$, and its dual, $G_{\mu\nu} = {}^*F_{\mu\nu}$.

Their approximation applies at wavelengths which are much longer than the electron's Compton wavelength. The correction becomes non-negligible only at field strengths of the order $\frac{m_e^2 c^3}{e\hbar} \sim 10^{16}\ \frac{\text{Volt}}{\text{cm}}$. The latter quantity has been known as the Schwinger critical field *ever since* ***Julian Schwinger*** *(1951) reanalyzed the problem using his elegant functional methods. The non-quadratic correction $\delta\mathcal{L}$ to the classical Lagrangian, results from the virtual production of an* electron-positron pair *in the external EM field. Two examples of observable physical effects which result from the Euler-Heisenberg correction are: 'light by light' scattering (the collision of two γ rays), and the Delbrück effect (1933; scattering of a photon by the Coulomb field of the nucleus).*

The fundamental reason that quantum theory engenders nonlinear corrections to the Maxwell empty-space equations is this: the coupled Maxwell-Dirac operator field equations are themselves nonlinear[185]. Even in the absence of physical ('on shell', i.e. non-virtual) electrons or positrons, the vacuum itself has a finite quantum amplitude to occasionally-produced virtual $\{e^+, e^-\}$ pairs for short periods of time (of order 10^{-21} sec). Upon integrating out these electronic vacuum fluctuations, the nonlinearity of the original Maxwell-Dirac equations is manifested as nonlinear corrections to the purely EM sector of the theory. At the classical level Maxwell's equations in vacuum receive nonlinear corrections. At the level of quantized EM fields, the nonlinearities result in effects such as photon splitting *in a strong magnetic field, as well as the above-mentioned light-by-light and light-by-field scattering processes.*

We note in passing that the nonlinear modifications to classical EM theory in vacuo are not all quantum in origin; the minimal framework needed to encompass both Maxwell's theory and Einstein's GTR is the Einstein–Maxwell coupled field equations, which are nonlinear and yet completely classical (i.e. non-quantum) in origin.

Further work on nonlinear corrections to Maxwell's equations under conditions of strong fields was done by ***Infeld*** *and* ***Born****.*

[185] As are even the coupled *classical* Maxwell-Lorentz equations of motion for a charged electron interacting with dynamical electromagnetic fields.

1907–1909 CE **Leo Hendrik Baekeland** (1863–1944, U.S.A.). Chemist and inventor. Invented the first synthetic plastic material, *Bakelite*[186], that had no counterpart in nature. Bakelite is the prototype of a phenomenally comprehensive family of synthetic polymers called plastics and resins.

Baekeland was born in Ghent, Belgium. He received his Ph.D. from the University of Ghent (1884) and emigrated to the U.S. (1889). Before he was 30 he sold a new type of photographic paper of his own invention to Eastman Kodak for a million dollars (which in those days was really worth a million – no income tax either). Baekeland, an extraordinary gifted young chemist and entrepreneur, began his search for a synthetic substitute for *shellac*[187].

Earlier work by **Adolf von Baeyer** (1835–1917, Germany), who had mixed phenol with formaldehyde, pointed Baekeland down the right road to his discovery. What was a nuisance material for Baeyer, became a cornerstone for Baekeland. Bakelite was unusually strong in spite of its relatively light weight and it was inert to acids and bases, unaffected by heat and effective as an electrical insulator. It could be colored or dyed to suit customer taste.

1907–1923 CE **Luitzen Egbertus Jan Brouwer** (1881–1966, Holland). Dutch mathematician. The founder of topology[188] and mathematical neo-intuitionism. Some of his well known results are the *plane translation theorem* (1907) and the *fixed-point theorems*[189] (1907) that are of special importance in game theory and differential geometry.

---

[186] Made from phenol and formaldehyde. The result of the polymerizing reaction is *polyphenolformaldehyde*. Upon heating, cross-links are formed between the chains of the polymer and a thermosetic material is obtained.

[187] *Shellac* is a natural product made from the resinous secretions of the tiny *lac* bugs common to India and Southeast Asia. It is found in lacquers, varnishes, waxes, and other protective agents for coating a variety of surface materials.
Lac bugs pierce the bark of a tree and feed on the sap, discharging a quantity of *lac* as a protective agent. This sticky resin accumulates about the bug until it is all but completely encapsulated, leaving only an opening or two for breathing and for the worm-like larvae of the next generation to exit. The female dies after feeding, leaving colonies of bodies to be collected and processed to make shellac. A few hundred thousands of these little bugs are needed to each pound of shellac produced. At the turn of the 20^{th} century, more than 3000 ton of shellac were imported to the United States each year.

[188] The study of the most basic properties of geometrical surfaces and configurations, that remain unchanged upon continuous transformations.

[189] A *Fixed-Point property* is illustrated in the following simple example: consider the square $0 \leq x \leq 1$, $0 \leq y \leq 1$ in the first quadrant of a Cartesian coordinate system. We place one dot anywhere on each of the two vertical sides of the square (the lines $x = 0$ and $x = 1$). We then draw a continuous curve connecting

In 1911 he discovered his *theorems of topological invariance*. In addition he merged the ideas of **Cantor** with the early topological concepts that existed before his time. In his doctoral thesis "*On the Foundations of Mathematics*" he shaped the beginnings of the neo-intuitionist school. In 1908 he rejected as invalid the use in mathematical proofs of the *principle of the excluded middle*, according to which every mathematical statement is either true or false, no other possibility allowed. During 1918–1923 he reformulated set theory, theory of measure and a theory of functions, without using the above principle.

In 1907 Brouwer also took up Kronecker's program of the "*arithmetization*" of mathematics through the elimination from it of all "*non-constructive concepts*"[190], but his "*intuitionism*" made little headway among practicing math-

---

the two dots. This curve must necessarily cut the diagonal ($x = y$) in at least one point. Here is why: Any continuous curve $C(x)$ can be regarded as a *mapping* of the unit interval $0 \leq x \leq 1$ *into itself*, since it associates every point x on this interval with another such point $C(x)$ that also lies in the range between 0 and 1. The *diagonal line*, however, corresponds to points that map to themselves under this transformation; they *remain fixed*. Consequently, any point x that maps to a point on the diagonal is a fixed point of the transformation. In other words, it is a point for which $C(x) = x$. It is then argued that every such curve mapping the unit interval to itself must possess at least one such point. Since the fixed points are given by $C(x) = x$, it follows that determining fixed points is the same as *solving equations*.

Brower's "fixed-point" theorem': If X is a closed disc, then every *continuous* map into itself $X \to X$ has a fixed point. In general, we say that a subset X of 3-dimensional space has a *fixed point property* iff every continuous transformation of X into itself has a fixed point. It is easy to see that a closed disc with the center point removed does not have this property (e.g. rotation).

Every vector field on an even-dimensional sphere must have at least one singular point. In applications of topology to other branches of mathematics, "fixed point" theorems play an important role. In particular, these theorems provide a powerful method for the proof of many mathematical 'existence theorems' which at first sight may not seem to be of geometrical character (e.g. the fundamental theorem of Algebra). A famous example is a fixed point theorem conjectured by **Poincare** (1912) and proved by **G.D. Birkhoff** (1916). This theorem has as an immediate consequence the existence of an infinite number of periodic orbits in the restricted problem of 3 bodies. Since then topological methods have been applied with great success to the study of the qualitative behavior of dynamical systems.

[190] In Kronecker's view transcendental numbers do not exist, since they require an infinite number of fractions or operations for their representation. According

ematicians, who feared Brouwer's views would unnaturally and unnecessarily limit the development of mathematics.

Hermann Weyl (1951) summarized this state of affairs: "*At the end of the* 19^{th} *century it became clear that the unrestricted formation of sets, subsets, sets of sets, etc., together with an unimpeded application as to the original elements of the logical quantifiers* '*there exists*' *and* '*all*" ... *inexorably leads to antinomies.*

The 3 *most characteristic contributions of the* 20^{th} *century to the solution of this Gordian knot are associated with the names of L.E.J. Brouwer, David Hilbert and Kurt Gödel. Brouwer's critique of* '*mathematical existentialism*' *not only dissolved the antimonies completely but also destroyed a good part of classical mathematics that had heretofore been universally accepted...*

Brouwer served as a professor of mathematics at the University of Amsterdam during 1909–1951, with the exclusion of 1945–1946 since he was suspected of collaborating with the Nazis in WWII.

to him nothing could be said to have a mathematical existence unless it could actually be constructed in terms of *finite* number of positive integers. Kronecker is thus a mathematician in whom a computer can believe.

"Have You Seen a Molecule?" (1803–1908)

"This conclusion, that heat consists in mechanical processes, in motion, has spread over the whole cultivated world like wildfire. There is a huge mass of literature on this subject, and now people are everywhere eagerly bent on explaining heat by means of motions. They determine the velocities, the average distances, and the paths of the molecules, and there is hardly a single problem which could not, people say, be completely solved in this way by means of sufficiently long calculations. If, then, we are astonished at the discovery that heat is motion, we are astonished at something which has never been discovered. It is quite irrelevant for scientific purposes whether we think of heat as a substance or not".

Ernst Mach, 1909 (1838–1916)

"Atoms are only hypothetical things".

Friedrich Wilhelm Ostwald, 1906 (1853–1932)

"... merely statistical validity of the Second Law is not good enough; irreversibility is a fundamental property of natural processes, and any molecular hypothesis — or perhaps all conceivable molecular hypotheses based on Newtonian mechanics — that permits any exception, must be wrong".

Ernst Zermelo, 1906 (1871–1956)

The success of Newton's planetary laws of motion led to attempts at more theories similarly based on the laws of motion. Could not some theory of gases be constructed, to account for Boyle's law (1660) by "predicting it", and to make other predictions and increase our general understanding? Gases move easily, diffuse among each other and seep through porous walls. Could these properties be "explained" in terms of some mechanical picture? Newton's contemporaries revived the Greek philosopher's idea of matter being made of "fiery atoms" in constant motion.

Indeed, in 1738, ***Daniel Bernoulli*** *published a 'bombardment' theory in which he pointed out that* moving *particles would produce pressure by bombarding the container, and he suggested that heating it, must make its* *particles move faster. However, his outline was incomplete. This idea stayed dormant for more than a century, when* ***Joule*** *(1847),* ***Clausius*** *(1850),* ***Maxwell*** *(1860) and* ***Boltzmann*** *(1860) set forth the kinetic theory of gases based on the assumption that a gas consists of small elastic particles in rapid motion, and the pressure on the walls is simply the accumulated effect of bombardment.*

*In the field of chemistry, molecules seemed useful: a helpful concept that made the regularities of chemical combinations easy to understand and provided a good start for a simple theory of gases (**Dalton**, 1803; **Avogadro**, 1811). But did they really exist? There was only circumstantial evidence that made the idea plausible. Many scientists were skeptical, and at least one great chemist maintained his right to disbelieve in molecules and atoms even until the beginning of the* 20^{th} *century[191]. Yet one piece of experimental evidence appeared as early as 1827: the Brownian motion.*

*The Scottish botanist **Robert Brown** (1773–1858) made an amazing discovery — he practically saw molecular motion: Looking through his microscope at small specks of solid suspended in water, he saw them dancing with an incessant jiggling motion. The microscopic dance made the specks look alive. Brown was in fact watching the effects of water molecules jostling the solid specks. If the molecules were infinitely small and infinitely numerous, they would bombard a big speck symmetrically from all sides and there would be no Brownian motion to see. At the other extreme, if there were only a few, very big molecules of surrounding water, the speck would execute infrequent, violent jumps when it did get hit. From what we see, we infer something between these extremes: there must be many molecules in the container, hitting the speck from all sides, many times a second.*

In a short time, many hundreds of molecules hit the speck from every direction, and occasionally a few hundreds more hit one side than the other and drive it noticeably in one direction. A big jump is rare, but several tiny random motions in the same general direction may pile up into a visible shift. Detailed observations and calculations from later knowledge tell us that what we see under the microscope are those gross resultant shifts; but, although the individual movements are too small to see, we can still estimate their speed by cataloging the gross staggers and analyzing them statistically.

The kinetic theory was successful not only in providing a theoretical interpretation to the ideal gas equation and the Avogadro hypothesis, but also in yielding a gamut of molecular properties such as speed, number, mass and

---

[191] It is a matter of record that as late as 1908, distinguished scientists such as **Ernst Zermelo**, **Wilhelm Ostwald** and **Ernst Mach**, doubted the atomic theory of matter. Mach died unconvinced.

size. Already in 1865, ***Loschmidt*** *obtained estimates of molecular diameters from measurements of liquid density and gaseous viscosity, a method which is now of historical interest only.*

A number of independent methods were devised to measure ***Avogadro's number*** N_0*: Since* $N_0 = R/k$ *[where* k *is the Boltzmann constant and* R *the universal gas constant],* k *was determined from physical laws in which it appeared [e.g. Stefan-Boltzmann law, Planck's law, Einstein's mean-square displacement law of Brownian motion, and Boltzmann's energy partition formula as applied by* ***Perrin****]. In addition,* N_0 *could be directly obtained from Faraday's law of electrolysis and the calculation of a voluminal element of a crystal lattice* $[N_0 = (6.0225 \pm 0.0003) \times 10^{23}$ *molecules/mole].*

So, by 1908, molecules have graduated from speculative tiny ad-hoc entities into full-fledged 'citizens' of the real physical world, except for one attribute — visibility. Could we actually see a molecule? That would indeed be convincing. Scientists of the 19^{th} *century agreed that seeing is hopeless — not just unlikely but impossible, for a sound physical reason.*

Seeing uses light, which consists of waves, ranging in wave-length from 7000 Å for red to 4000 Å for violet: with the naked eye we can see the shape of a pin's head, a millimeter across (10^7 Å $= 10^3$ *microns). With a magnifying glass we examine a fine hair, 0.1 millimeter thick* (10^6 Å $= 10^2$ *microns). A smoke speck is 0.01 millimeter in size* (10^5 Å $= 10$ *microns). With a high-power microscope we see the smallest bacteria* (10^3 Å $= 0.1$ *microns) or a typical particle in Brownian motion. But beyond that scale, vision using ordinary light stops, as the light's wave-length becomes comparable to the object's size. So, viruses (ca 100 Å) and molecules (ca 1–10 Å) cannot be seen with light waves.*

However, early in this century, X-rays offered indirect information: X-ray diffraction patterns revealed both the arrangements of atoms in crystals and the spacing of their layers. Such measurements confirmed estimates on molecule's size and even the general shape of some big molecules.

With the advent of the electron microscope, virus particles and big molecules are "seen", and recently the tunneling microscope has allowed us to see, under favorable conditions, individual atoms. These glimpses of molecular structure agree well with the speculative pictures drawn by chemists, arguing from chemical behavior.

The vicissitudes of scientific atomism is clearly reflected in the quotations at the head of this article. It took almost the whole of the nineteenth century to establish atomism on a sound experimental basis and this required an immense amount of chemical investigation. When success was finally in sight, a number of men of science and philosophers rejected atomism as a kind *of illusion. Antiatomic views were published by such men as* ***Ernst Mach*** *(1838–1916),* ***Pierre Duhem***[192] *(1861–1916), even by a practical chemist like* ***Wilhelm Ostwald*** *(1853–1932); these men were fighting a rearguard action at the very time when atomism had ceased to be a hypothesis, when atoms could be counted and weighed, yet ceased to be atoms in the literal sense, for they were reduced to other elements incredibly smaller than themselves.*

Our Material Culture — Metals, Ceramics and Plastics[193]

Metals have been known since ancient times [Au, Ag, Cu, Fe, Pb]. The basic characteristic of metals is that they loose their electrons rather easily. A sample of a pure metal may be regarded as a framework or lattice of positive metal ions suspended in a sea of electrons. The "free electrons" composing the sea have been liberated by the metallic atoms. Unlike covalent compounds and many nonmetals, the electrons are not localized between pairs of atoms but move freely about through the whole system. These freely moving electrons account for the high electrical conductivity of metals. Electrons carry kinetic energy as well as negative charge; hence metals tend to be good conductors of

---

[192] Duhem also erroneously pictured the mechanism of an explosive reaction as the breakdown of a "false-equilibrium", failing to see that it is a question of *activation energy*, or energy necessary to break some bonds in the molecule of the explosive substance [see "Thermodynamique" by **Y. Rocard**, Masson et Cie 1952].

[193] For further reading, see:

- Dobbs, F.W., *The Age of the Molecule*, Harper and Row, 1976, 336 pp.
- Atkins, P.W., *Molecules*, W.H. Freeman, 1987, 197 pp.

heat as well as electricity. Because metals have no specifically directed bonds, layers of metal ions can glide over each other with relative ease. For this reason metals can be deformed readily without breaking, and they possess such properties as high malleability and ductility.

Metallurgy is concerned with obtaining pure metals from naturally occurring materials. First it is necessary to separate the ore (chemical compound containing the metal) from the various other substances with which it is found. Then, it is necessary to carry out a chemical reaction or reactions to liberate the metal from its compound. Metals almost always occur naturally in ionic compounds in which they have lost their electrons and become positive ions.

Obtaining the pure metal means, in chemical terms, restoring the electrons to the metal ion so that it becomes a neutral atom. This process of gaining electrons is called reduction. The most easily reduced metals, those lowest in the activity series, were discovered first. The most active metals, such as sodium (1807) and aluminum (1825), were discovered more recently. The most active metals are reduced by electrolysis; less active ones are produced by reduction with carbon. Aluminum is an example of the former, iron of the latter.

The earth's crust is made of about 8 *percent (by weight) of aluminum,* 5 *percent of iron and* 4 *percent of calcium. Potassium, sodium, and magnesium (extracted from sea water and dolomite) also occur in large amounts. The core of the earth is believed to be made up mainly of nickel and iron.*

Gold was used for ornaments, plates, and utensils as early as 3500 *BCE. Silver was used as early as* 2400 *BCE, and many ancients considered it to be more valuable than gold, because it was rarer in the native state. Native copper also was used at an early date in tools and utensils, because it was found near the surface of the ground, and could easily worked and shaped. Since about* 1000 *BCE, iron and steel have been the chief materials for construction.*

There are 81 *metals in the periodic table of the elements.*

Ceramics (from the Greek Keramos = potters, clay) are generally complex silicates that have been heated so that they are hard and fire resistant. The chief feature of ceramics is their great resistance to chemicals and high temperatures. China, pottery, porcelain, brick, tile, sewer pipe and refractories are all typical ceramics. The three principal raw materials used in making ceramics are clay, feldspar, and sand.

Pottery, the oldest form of ceramic products, dates back to prehistoric times. Examples of pottery more than 6000 *years old have been found in several parts of the world. Industrial uses of ceramics began during the* 1900*'s. Military requirements of WWII (1939–1945) created a need for high performance materials and helped speed the development of ceramic science and* *engineering. During the* 1960*'s and early* 1970*'s, advances in atomic energy, communications, and space travel required new kinds of ceramics.*

Within the last 200 *years, man's knowledge of the nature and structure of matter has had an impact on his ability to create or alter materials for particular purposes. According to a recent estimate there are some* 6 *million known chemical compounds. Man's ability to synthesize many of them and construct such a variety of new materials from them has had an enormous impact on his material culture. A great many of the substances that are directly involved in our daily lives have been developed in their present-form through a knowledge of chemistry.*

The manufacture of chemical compounds and materials is so complex and varied that it defies any effective categorization. Some of the different types of materials in whose manufacture or processing chemistry plays some role are: drugs, agrichemicals *(fertilizers, pesticides),* coloring materials *(paints, dyes, inks),* explosives, photographic materials, industrial chemicals *(H_2SO_4, HCl, HNO_3, petrochemicals),* modified naturally occurring substances *(sugar, starch, gelatin, leather, soap, paper),* materials used for building, constructing and manufacturing *(ceramics, metals, polymeric materials), and a* miscellany of other materials *(adhesives, oils, waxes, detergents, flavors, fragrances, cosmetics).*

A polymer[194] *(from the Greek* polis *= many, and* meros *= part, together "something of many parts") is a giant molecule composed of recurring identical units called* monomers*. The number of monomers in a polymer may reach hundreds of thousands and its molecular weight varies between* 5000 *and* 20 *million. [Water has a molecular weight of* 18*, polyisoprene (natural rubber) has a molecular weight of about one million; that means that a mole of water weights about an ounce, while that of rubber weights a ton!]*

Polymers are created by a process of polymerization*, in which many identical molecules are combined together, sometimes to form a long chain, sometimes to form a more complex network with cross-linkages.*

Recognition of the special properties of the natural polymers *began already in the middle of the* 19^{th} *century, long before their structure became known.* ***Berthelot*** *discussed (1863) the polymerization of olefins and effected the polymerization of ethylene in 1869.* ***Eugen Bamberger*** *(1857–1932, Switzerland) synthesized polyethylene in* 1900*.*

The most important kind of non-living materials that are polymeric in their structure are: plastics, synthetic fibers and synthetic rubber.

---

[194] The name was coined by **Berzelius** (1833) for a member of a subclass of *isomers*.

Plastics (from the Greek plastikos = able to be molded) are synthetic polymers. Polymers used in plastics may be classified into two types based on the type of linkage of the monomers — addition polymers, and condensation polymers.

Another classification divides polymers into two groups based on their behavior when subjected to heat. A polymer that is readily softened by heat is referred to as being thermoplastic. Each polymer can be repeatedly heated and softened (e.g., polyethylene, rubber, synthetic fibers, polypropylene, teflon, polyvinyl chloride (PVC), acrylic, cellulose, acetate).

In contrast, some polymers are composed of chain of polymers which are cross-linked. These polymers do not soften upon heating and remain rigid. They are called thermoset plastics (e.g., a Melamine dinner ware, Epoxy, Polyester, Silicone).

The product formed by the polymerization of different monomers is called a copolymer. An example of this type of reaction is the production of S rubber. The addition of one part styrene to three parts butadiene polymerizes in the presence of the catalyst sodium and results in an excellent rubber substitute.

The properties of plastics can also be affected by the use of various additives. Some types used include foamers, fillers, solvents, plasticizers, dyes, lubricants, and stabilizers.

Manufacturers make plastics from raw materials such as coal, limestone, petroleum, salt, and water. Solid plastics can be made to look and act like glass, wood, metal, and other materials. But they can usually be manufactured more cheaply than these materials. Liquid plastics may be used as adhesives and paints. Scientists and engineers have developed hundreds of plastics. These made materials have a wide variety of characteristics such as hardness, softness and transparency.

Fabrics woven from plastic fibers feel soft, but the fibers are made from hard plastics. Nylon is hard enough to be used to make gears for machinery, yet when drawn into fine threads, nylon can be used to weave delicate stockings and lingerie.

Some plastics are foamed to make soft sponge-like materials used in cushions for furniture and automobiles.

Transparent plastics such as vinyls, polystyrenes and polyethylenes are used as envelops to package food, medicines, toys, and many other products. Contact lenses made of acrylic are more transparent and less fragile than lenses made of glass. Decorative plastics often look like gold, silver, marble, wood or leather.

Plastics are used in industry, home building, medicine and science. In medicine, certain plastics have important uses because they do not harm the body and are not affected by its chemicals. Doctors use plastics rivets, screws and plates to join broken bones. They sew up wounds and surgical incisions with plastic threads. In science polyethylene plastics made good shields for nuclear reactors; they absorb neutrons better than an equally thick shield of concrete or water, yet are much lighter. Other plastics, called scintillation plastics, can detect radioactivity or passage of charged particles.

Polymer science and the plastic industry, both of which continue to exert an incredibly large impact on Western culture, trace their beginning to natural rubber.

On his second voyage (1494), Columbus found the natives of Haiti playing with rubber balls. Earlier, in the 13^{th} *century, articles of rubber (including balls for games), were in common use among the Mayas and Aztecs. The explorers learned that the Indians made "water proof" rubber shoes by dipping their feet in latex, the milky white ooze of the rubber tree. The Indians also made waterproof bottles by smoothing latex on a bottle-shaped clay mold. They dried the latex over a fire, and then washed out the clay. The South American Indians called the rubber tree cahuchu, which means weeping wood.*

Since 1615, *the Spaniards conquerers were themselves using rubber to weatherproof soldiers' cloaks, but no one in Europe was aware of the existence of rubber. It was left for the French, more than a century later, to carry the study and the use of rubber to Europe;* ***Charles de la Condamine*** *(1701–1774), who had been sent by the French Academy of Sciences on an expedition to Peru, brought back (1736) caoutchouc, as the substance was then called. But only in* 1751, *fifteen years after the expedition, he gave an account of it to the Academy. Rubber received its name when (1770)* ***Joseph Priestley*** *found it would rub off pencil marks.*

By the late 1700*'s, chemists had found that hardened latex dissolved in turpentine made a waterproofing liquid for cloth. In* 1823, *the Scottish chemist* ***Charles Macintosh*** *(1766–1843) began manufacturing the "mackintosh" raincoats that became world-famous. Early rubber products became sticky in hot weather, and stiff and brittle in cold weather.*

In 1826, ***Michael Faraday***, *discovered that rubber is a hydrocarbon.*

In 1839, ***Charles Goodyear*** *(1800–1860, U.S.A.) made a serendipitous discovery of the process of vulcanization through which rubber could be made stronger and resistant to heat and cold, by heating it together with sulfur [Vulcan, the Roman god of fire]. With vulcanization, the rubber industry grew rapidly: vulcanized rubber was elastic, airtight and watertight.*

In 1860, ***Greville Williams*** *(1829–1910, England) discovered that natural rubber yields, upon heating, a colorless liquid that he called isoprene. His was, in fact, a process of depolymerization.*

At first, manufacturers used only wild rubber which came mostly from the Amazon Valley of Brazil. At the request of the British government, an amateur botanist ***Henry A. Wickham*** *(1846–1928) took about 70,000 seeds of the Hevea brasiliensis tree from Brazil to England (1876). Seedling from the sprouted seeds in a Kew Gardens greenhouse were then taken to Ceylon and Malaya for replanting on plantations.*

The invention of the automobile in the late 1800's created a tremendous demand for rubber. By 1914, the yearly production of plantation rubber had exceeded that of wild rubber.

The importance of rubber in wartime became obvious during WWI. Armies needed rubber-tired vehicles to carry troops and supplies. The German were cut off from their natural-rubber supplies by the Allied blockade, and began to make synthetic rubber. But it did not work well. Experiments in producing synthetic rubber continued in the 1920's chiefly by scientists in Germany and the United States.

In 1942, the Japanese invaded Southeast Asia and cut off over $\frac{3}{4}$ of the West's supply of natural rubber. As early as 1939, perceptive governments and rubber corporations realized the dangers inherent in fighting wars that would involve reduction of rubber supplies. Germany, the Soviet Union, Britain, and the United States began stepping up their efforts to produce synthetic rubbers.

The first synthetic was based on the discovery of the priest ***Julius Arthur Nieuwland*** *(1878–1936, Belgium and U.S.A.) at Notre Dame University. He worked on (1904–1924) the synthesis of rubber from acetylene and sold his patents to the DuPont Company in 1925. At DuPont,* ***Wallace Carothers*** *(1896–1936, U.S.A.) further developed Nieuwland's ideas into neoprene (1932), and made important contributions to the understanding of polymers in general. Isoprene, the monomer of natural rubber, is difficult to synthesize, and the attention of the German I.G. Farben group and the Standard Oil was directed toward rubber synthesis from butadiene.*

Alongside with the development of synthetic rubber, chemists had the good fortune to discover other plastic materials, based also on natural polymers.

Natural cellulose $(C_6H_{10}O_5)_n$, like starch and glycogen, is a polymer of glucose ($C_6H_{12}O_6$), but neighboring glucose units are linked differently. This one difference — a simple twist of a link — makes cellulose indigestible by *humans (termites and herbivorous animals* can *digest cellulose if certain enzymes are present). The major part of the rigid portion of many plants is cellulose. Cotton and linen are about* 98 *percent cellulose. The explosive cellulose nitrate [$C_6H_7O_2(O{\cdot}NO_2)_3$] was discovered (1846) by* ***Schönbein*** *by treating cotton fibers with certain acids.*

Alexander Parkes *(1813–1890, England) tried to create a moldable material from it by treating it with a variety of solvents. The plastic material that he created, called Parksine (1862), was used to produce a variety of objects, such as combs. His associate* ***Daniel Spill*** *(1832–1887, England), invented Xylonite (1867). However, Parksine had an unfortunate habit of shriveling and wrinkling.* ***John Wesley Hyatt*** *(1837–1920, U.S.A.), a printer in Albany, N.Y., who sought to win a $10,000 prize for developing the best substitute for ivory in billiard balls remedied the deficiencies of Parksine. Although he did not win the prize, the material, Celluloid (1869), which he prepared by mixing camphor with cellulose nitrate and a solvent, was a superior product. Celluloid could be sawed, carved and made into sheets. As a result, new plastic products appeared on the market. Common Celluloid articles included combs, collars, dentures, carriage curtains, clock cases and the first photographic roll film. But Celluloid was hard to mold and it caught fire easily.*

Soon after the invention of Celluloid, chemists developed other products made from plant fibers. In 1884 *the French chemist* ***Hilaire Chardonnet*** *(1839–1924) invented viscose rayon, the first man-made fiber. The chemist* ***Jacques Edwin Brandenberger*** *(1872–1954, Switzerland) invented cellophane (1908) [when one presses on a cellophane sheet or tries to tear it, one is experiencing the strength of the hydrogen bonds!]*

During the 1800*'s English and German chemists experimented with combinations of carbolic acid (phenol, C_6H_5OH) and formaldehyde (CH_2O). This combination produced a resin, but the chemists could not control the violent reaction.* ***Leo Hendrik Baekeland*** *(1863–1944, U.S.A.) succeeded (1909) in controlling the reaction and invented the first completely synthetic resin, Bakelite.*

Baekeland produced his resin while trying to make a better kind of varnish. At first, he did not recognize the value of Bakelite as a plastic material. ***Richard W. Seabury*** *(1883–1970, U.S.A.), a rubber manufacturer, showed that the new resin could be molded. He mixed Bakelite with asbestos fibers, and molded a part for an electrical instrument.*

Bakelite became widely used to make telephones and handles for pots and irons. The electrical and automative industries used Bakelite for many products. Unlike celluloid, Bakelite was not flammable.

Synthetic fibers, like plastics, had their origin in experiments with cellulose. At the end of the 19^{th} *century, two different processes for preparing a cellulose* *thread called rayon were developed. In 1931,* **Wallace Carothers** *(1896–1937, U.S.A.) synthesized a material stronger than silk, which is now called nylon.*

Other plastic materials were synthesized all through the 20^{th} *century, each with its own specific use: Cellulose Acetate (1927); Urea-formaldehyde (1928); Perspex (1936); Polyurethane (1939); Polyester resins (1942); Silicone (1943); Teflon (1943); Epoxy resins (1947); Polypropylene (1957); Polycarbonate (1958).*

Polymers[195]

Unsaturated monomers under high pressure and temperature and in the presence of a catalyst, link to each other to form long chains. For example, with the aid of a catalyst, one molecule of ethene combines with a second molecule of ethene to form a dimer:

$$
\begin{array}{ccccc}
 & H & & H \\
 & | & & | \\
H - & C & = & C \\
 & & & | \\
 & & & H
\end{array}
\quad + \quad
\begin{array}{ccccc}
 & H & & H \\
 & | & & | \\
H - & C & = & C \\
 & & & | \\
 & & & H
\end{array}
\longrightarrow
\begin{array}{cccccccc}
 & H & & H & & H & & H \\
 & | & & | & & | & & | \\
H - & C & - & C & - & C & = & C \\
 & | & & | & & & & | \\
 & H & & H & & & & H
\end{array}
$$

This molecule in turn links to a third molecule, and a fourth, and continuous on to form a giant molecule consisting of up to several thousands units of ethene, called polyethylene

$$
\begin{array}{cccccccccccccccccc}
 & H & & H & & H & & H & & H & & H & & H & & H & & H \\
 & | & & | & & | & & | & & | & & | & & | & & | & & | \\
H - & C & - & C & - & C & - & C & - & C & - & C & - & C & \ldots \text{etc.}, \ldots - & C & = & C \\
 & | & & | & & | & & | & & | & & | & & | & & & & | \\
 & H & & H & & H & & H & & H & & H & & H & & & & H
\end{array}
$$

[195] To dig deeper, see:

- Perepechko I.I., *An Introduction to Polymer Physics*, Mir Publishers: Moscow, 1981, 266 pp.

We thus write that the monomer $CH_2 = CH_2$ *was transformed into the polymer* $(\text{—}CH_2\text{—}CH_2\text{—})_n$. *The brand name of this plastic is Handi-Wrap and it is used for food wrappings, tubing, molding objects, and electrical insulation.*

If the hydrogens of the monomer ethylene are replaced by fluorines, the monomer tetrafluoroethylene $(CF_2 = CF_2)$ *becomes upon polymerization polytetrafluoroethylene (teflon) used for lining in cooking utensils.*

A number of additional polymers are made from hydrocarbon compounds with a carbon-carbon double bond (alkenes); propylene is similar to ethylene, but one of the ethene hydrogens is replaced by a methyl group

$$\begin{array}{ccccc} & & & & H \\ & & & & | \\ CH_3 & \text{—} & C & = & C. \\ & & | & & | \\ & & H & & H \end{array}$$

When polymerization occurs, polypropylene is obtained $[CH(CH_3)CH_2]_n$.

Special catalysts are used in synthesis to ensure that there is little chain branching and that $\{\text{—}CH_3\}$ *groups all point in the same direction. This yields an extremely orderly solid (crystalline-like) with many useful properties, namely — stiffness, resistance to abrasion and high enough melting point for objects made from it to be sterilized. However, because the* CH_3 *groups are liable to oxidation, polypropylene articles usually have antioxidants incorporated into them to divert attack by oxygen. Polypropylene is used for ropes, fishing-nets, toys, housewares, baby bottles, wire insulation, pipe and fittings.*

Vinyl chloride (C_2H_3Cl), *is derived from an ethylene molecule by replacing a hydrogen atom with a chlorine atom. It can be polymerized to form polyvinyl chloride* $(CHClCH_2)_n$ *or PVC, one of the most versatile and adaptable of all plastics. The addition to it of certain synthetic resins (plasticizers), makes PVC softer and more flexible. Moreover, PVC can be mixed with a very wide range of additives chosen to tailor its properties to many different applications. When properly protected by additives, it is chemically resistant to attack and degradation.*

PVC is used for imitation leather, phonograph records, packaging, pipes, credit cards, baby pants, rain coats. About 3 million tons are used annually in the United States alone, of which 10,000 tons are used for making credit cards.

Vinylidene chloride $(C_2H_2Cl_2)$ *may be polymerized on its own or copolymerized with vinyl chloride to give the polymers known collectively as saran* $(CCl_2CH_2)_n$, *used for upholstery covers and as a protective film (saran wrap).*

If the monomer is styrene (a benzene ring in which one hydrogen atom was replaced by $CH = CH_2$*; discovered in 1839 by a Berlin pharmacist by the name of* **Simon***), the polymer is polystyrene used for styrofoam, insulation, combs, toys, models, and household articles. Likewise, the monomer acrylonitrile*

$$\begin{array}{c} H - CH{=}CH \\ \qquad\quad | \\ \qquad\quad CN \end{array}$$

yields upon polymerization the polymer polyacrylonitrile

$$\begin{array}{c} (-CH_2 - CH-)_n \\ \quad | \\ \quad CN \end{array}$$

known commercially as Acrilan (or Orlon). It is used for fibers in the production of carpeting, clothing, etc.

Rubber is a polymer of a five-carbon compound called isoprene

$$\begin{array}{c} CH_2{=}CH - C = CH_2 \\ \quad | \\ \quad CH_3 \end{array}$$

The polymer may be linear, cross-linked, or it can exist in more complex configurations. Polymer molecules of unstretched rubber fold back on themselves somewhat like irregular coils. Stretching the rubber straightens the chain of folded molecules. Releasing the rubber lets the chain return to its coiled position. The sulfur that combines with the rubber during vulcanization sets up "cross links" between the rubber chains so that the chains are bound together and cannot slip past one another. This gives elasticity and strength to the vulcanized product.

The number of cross links increases with the amount of sulfur, such that the rubber becomes stiffer, tougher, and less stretchable (chemists use the word elastomer for any substance, including rubber, that stretches easily to several times its length, and returns to its original shape).

The molecule that has proved most useful in synthetic rubber is butadiene: $CH_2{=}CH{-}CH{=}CH_2$*, easily obtained from coal tar, coal gas or from ethyl alcohol (obtained from grain fermentation). It was later found that addition of styrene stabilizes synthetic rubber. These styrene butadiene rubbers (SBR) are the most common general purpose rubbers. Another synthetic product, polymerized chloroprene* ($CH_2{=}CCl{-}CH{=}CH_2$)*, known as neoprene is particularly heat and weather resistant.*

Methyl methacrylate ($C_5H_8O_2$) *is the monomer from which the polymer known as lucite, plexiglass, or perspex is derived. Bulky, irregular side groups* *attached to the basic ethylene fragment cause the polymer chains to lie together in a very irregular way, so that the solid is internally very chaotic. Since the solid is amorphous on a molecular scale, it does not scatter light that passes through. Consequently, blocks of the polymer are brilliantly transparent, like clean water.*

If one of the side groups ($—CH_3$) *of the monomer, that is responsible for its rigidity, is removed, the resulting substance serves as a base for* acrylic paints.

The polymerization of adipic acid *($C_6H_{10}O_4$) with* hexamethylene diamine *($C_6H_{16}N_2$) by condensation, yields the polymer* polyhexamethylene adipamide *$[CO(CH_2)_4CONH(CH_2)_6NH]_n$, known as* nylon, *the first completely synthetic fiber. It is strong, springy, resists abrasion, and has good electrical qualities. Used for fabrics, gears, bearings, hardware, brush bristles, electrical appliances.*

Artificial (as well as natural) fibers should consist of long molecules that can be made to lie parallel *to each other as they are drawn out into a thread. This can be achieved by linking together an acid and an alcohol molecule as in the process of ester formation, but in such a way that the ester molecule can go on growing at each end. This results in indefinitely long molecules of repeating units called* polyesters. *Thus, if* terephthalic acid *($C_8H_6O_4$) is allowed to react with* ethylene glycol *($C_2H_6O_2$), the result is the polymer* polyethylene terephthalate *$[O_2CC_6H_4CO_2C_2H_4]_n$. It can be made into either a fiber (Dacron) or a film (Mylar).*

The first synthetic heart *was made of Dacron. Mylar is used in* cassette tapes.

1907–1920 CE **Ernest Rutherford** (1871–1937, England). Physicist. Proposed the concept of a nuclear atom in which a smaller center is surrounded by electrons (1911). Discovered the *proton* (1919) and suggested the existence of the *neutron*. Rutherford inspired two generations of physicists, and his discoveries had a major influence on the scientific thought of his era[196].

Rutherford was born in Spring Grove, New Zealand. He was educated at Canterbury College, Christchurch, and went to the Cavendish Laboratory at Cambridge to work under **J.J. Thomson**. In 1902 he discovered Thorium X with **Frederick Soddy** (1877–1956) and during 1906–1909 he showed alpha-particles to be nuclei of helium atoms. For these discoveries he won the Nobel prize for chemistry in 1908. In 1919 he succeeded J.J. Thomson to the Cavendish chair at Cambridge.

1907–1945 CE **Ellsworth Huntington** (1876–1947, U.S.A.). Geographer and explorer. Was concerned with the complex origins and causes of the world's major civilizations and why they had emerged in particular locations. He laid particular emphasis on *climatic* factors and contended that certain types of climate were favorable to a high level of civilization. This climate is characterized by a moderate temperature, and by the passage of frequent barometric depressions which give a sufficient rainfall and changeable stimulating weather. He argued that the location of the hearths of particular civilizations could be matched with critical environmental limits, and saw in *climatic changes* the clues to unexplained shifts in these centers[197].

---

[196] Yet, four years before his death (1933), Rutherford said, firmly and explicitly, that he did not believe the energy of the nucleus would ever be released. Nine years later (1942), in Chicago, the first fission pile began to run.

[197] Huntington gives three interesting examples:

- The level of civilization in ancient Greece was critically affected by the average *rainfall*: Up to about 400 BCE Greece had been well watered and forested, with perennial streams unsuited to the development of mosquitoes, but after that date the rainfall diminishes greatly. The streams were reduced in summer to stagnant pools and swamps, with the result that malaria became endemic and undermined the vitality of the population.

- The level of civilization in *Rome* fluctuated with the average *rainfall*: The rigorous Roman life of the early Republic (450–420 BCE) was based on intensive agriculture. This was a period of very high civilization *and* very heavy rainfall. Towards 250 BCE the spirit of discipline and rural simplicity began to decay. The period from 225 to 200 BCE was one of economic stress — marked by decreasing rainfall. The second century BCE with its low fain-fall witnessed great decline in agriculture. During this period malaria became endemic because of formation of stagnant pools and marshes. From 100–50 BCE heavy rains again brought an increase in general luxury and comfort. From 80 CE onwards, as rain fall decreases there was a gradual decline and 180–190 CE were years of famine and pestilence. 193–210 CE saw a slight increase in prosperity, but then began in full force the long "decline and fall of the Roman Empire".

Huntington was born in New England into a congregational family, studied at Harvard and later held a post at Yale. Took part in expeditions to Mesopotamia, Turkestan and later to all the continents. Authored many books and papers, among them: *The Pulse of Asia* (1907), *Civilization and Climate* (1915), *Mainsprings of Civilization* (1945).

Huntington advanced (1923) an hypothesis that solar activity has an ongoing effects on terrestrial climates. He went further to suggest a correlation of *sunspot activity* with terrestrial weathers and especially linked high sunspot with intensified terrestrial atmospheric circulation. He pointed out that in the northern hemisphere, *cyclonic storm*-belt centers more nearly on the magnetic pole rather than on the geographic pole, just as do auroral displays which are more obviously related to sunspots.

Moreover, he found correlation between sunspot extremes and severe droughts and indicated that hurricane activity increased at times of high sunspots. On the other hand he pointed out that during the Little Ice Age in Europe (1430–1850 *CE*) the sun seems to have gone through a calm period, in which sunspots were practically absent[198].

Due to the great complexity of the problem, work on climatic changes must be restricted more to *correlation* than to *mechanism*. Yet, Huntington suggested a crude model for the interaction of the sun's photosphere with the earth's atmosphere: Increasing sunspot indicate increased emission of charged particles. Many of these become trapped in the earth's magnetosphere from which they filter down to the lower atmosphere, mainly near the magnetic poles. From there they exert pressure over air-mass formations, as in northern Canada. These rapid pressure changes may occur simultaneously in several widely separated areas and intensify cyclonic activity in the mid latitudes; under favorable conditions, comparatively small causes may have disproportionately large effects.

- There were four great waves of emigration from *Arabia*; the first during the 4^{th} millennium BCE, the second (Amorite) about 2000 BCE, the third (Aramean) mainly around 1350 BCE, and the fourth (Arabian) culminated in the Islamic expansion of the 7^{th} century CE. All of them are attributed to dry periods preceding the actual outbursts.

[198] Sunspot-free periods, known as *Maunder-minimum* occurred at irregular intervals in earlier times.

A recent study of tree-rings has revealed an apparent correspondence between periods of drought in the high plains of the Western U.S. and the minimum of the 22-year sunspot cycle.

1908–1911 CE **Jean Baptiste Perrin** (1870–1942, France). Physicist. Designed experiments that established the reality of atoms and gave a macroscopic confirmation to the **Einstein-Smoluchovski** theory of Brownian motion. Determined the '*Avogadro number*' and molecular size through an ingenious experiment in which he used colloidal suspensions of gum resins of uniform size in water, and registered via microscope[199] the dependence of the concentration of these grains on height.

Since the suspended particles obtained kinetic energy from their collision with the water molecules (Brownian motion), they attain a stationary suspension at constant temperature in a uniform gravitational field.

The application of Boltzmann's *energy partition function* for the number of molecules at energy level ϵ $[N = N_0 e^{-\epsilon/kT}]$ where ϵ is the gravitational potential energy mgH, [m, mass of a colloidal particle and H, height above a reference level], yields the density of gum particles (concentration) at any level, through the Laplace 'isothermal atmosphere' formula $\rho = \rho_0 e^{-mgH/kT}$. When m is corrected for buoyancy of the liquid and ρ/ρ_0 is measured, k can be calculated, and through it the Avogadro number.

In 1895 Perrin found evidence that cathode rays are negatively charged particles. In 1901 he presciently proposed a "nucleo-planetary" model of atomic structure, with a positively-charged "sun" surrounded by many smaller negatively charged "planets". The periods of rotation of these planets might correspond to different wavelengths in the emission spectrum.

Perrin emphasized an analogy of Brownian movement paths with non-differentiable functions (previously studied by **Riemann** and **Weierstrass**[200]). This analogy seems to have stimulated some of the later research on functional integrals, notably by **Wiener**.

1908–1928 CE **Wilhelm Geiger** (1882–1945, Germany). Physicist. Developed the *Geiger counter* [used for the detection of radioactivity]. His work

---

[199] The introduction of the *ultramicroscope* in 1903 rendered visible small colloidal particles whose greater activity could be measured more easily.

[200] **Weierstrass** (1872) constructed a function, defined by the Fourier-series: $f(x) = \sum_{n=0}^{\infty} a^n \cos(\pi b^n x)$ where a, b are real, $b > 1$, $0 < a < 1$, $ab \geq 1$. The series is uniformly convergent in any interval, so that $f(x)$ is everywhere continuous. However, the series obtained via term by term differentiation is divergent. This property is maintained if we choose $a = b^{D-2}$, $1 < D < 2$, where D has the modern meaning of *fractal dimension*. One can consider the above function to be the real part of the *complex Weierstrass function* $W(t) = \sum_{n=0}^{\infty} a^n e^{\pi i b^n t}$. It yields a 3-dimensional *Brownian surface* that renders a visual realization of the stochastic Brownian process (**Mandelbrot**, 1982).

on the deflection of α-particles by thin metal foils led **E. Rutherford** to discover his model of atomic structure in 1911. Geiger and **Walther Müller** improved the 1908 counter and made it more sensitive and durable (1928).

The counter is usually in the form of a thin metal cylinder enclosed in a glass tube. The metal will serve as one electrode. A straight wire projected into the cylinder is the other electrode. The electrodes are maintained at a voltage which is just short of breakdown potential of the air or other gas in the cylinder. If ionizing radiation enters the cylinder, the gas will ionize, setting up a weak current, which is revealed by light signals, by clicks picked up by earthphones or by readings on a meter.

Geiger was born in Neustadt, Germany. He was Rutherford's assistant from 1906 to 1912. He later became a professor of experimental physics at Tübingen University. When **Hans Bethe** was dismissed (1933) from his position as theoretical physicist at that university, Geiger turned his back on him. With **Heisenberg**, **Hahn** and other notable physicists, Geiger joined the Nazi nuclear war-effort.

1908 CE, June 30, 00:14:28 GMT A mysterious object exploded in the sky at altitude ca 8 km over the basin of the River Podkamennaya Tunguska in central Siberia ($60°55'$N, $101°57'$E).

The explosion itself took the form of a vertical column of fire, and spewed up incandescent matter to a height of 20 km. *Heat* radiation was felt at 70 km from the epicenter. The event was *seen* in the sunlight at distance of 500 km and *heard* over a distance of 1270 km.

Near the epicenter, trees of a coniferous forest were uprooted within a radius of 25 km and burnt inside a radius of 15 km, their tops charcoaled. The total energy of the object was calculated to be equivalent to 12 megaton of TNT[201]. There was lack of evidence for either an impact crater or sizable debris. Had the object arrived 4^h27^m later, it would have landed on the city of Petrograd, then capital of the Russian empire. No other event of its kind has ever been recorded.

Punctuated Evolution — the Evils and Blessings of Planetesimal Bombardment

The surfaces of Mercury, Venus, Mars and moon are dotted with many thousands of craters, most of which were made within a few hundred million years after the solar system formed. During this epoch, meteoroids by the millions must have rained down on all the planets of the inner solar system as the last chunks of matter to reach the planets encountered the new planetary surfaces. This earlier bombardment included comets *as well as* asteroids. *The earlier bombardment essentially ended* 3.5×10^9 *years ago. Our own planet shows only a few large meteorite craters, representing relatively recent impact.*

Although the earth surely did not escape this rain of terror, the first few hundred million years of our geological record have vanished because of erosion and the movement of crustal plates. Comets (which spend most of their lives in the frozen depths of space at the boundaries of the solar system) represent the best preserved primitive material, that is relatively accessible to us, because they orbit the sun in highly elongated trajectories that carry them much further from the sun than any of the planets.

At this huge distance from their central star, no heating has disturbed the original state of the condensed material. Individual comet nuclei are generally only a few kilometers in diameter and consist of frozen "snowballs" of water, carbon dioxide and other gases, silicate dust plus more complex molecules including organic compounds.

Upon approaching the sun, some of the cometary ice vaporize, producing a gauzy cone around the nucleus and a long, rarefied tail that streams away from the sun for millions of kilometers. Another source of somewhat primitive matter resides in the lumps of debris called asteroids and meteoroids, which, like short period comets, orbit the sun in rather elongated trajectories, but which always remain fairly close to the sun.

Although the delivery of life seeds to earth via comets *seems unlikely, comets may have provided earth with the basic materials necessary for life to form. Scientists have suggested that collisions of comets and the accretion of cometary matter to the earth provided a plausible mechanism for supplying part of the* earth's early atmosphere. *The same collisions might form local concentrations of organic molecules and liquid water on the earth's surface, where, in the presence of solar ultraviolet radiation, amino acids and other biochemical compounds could form spontaneously.*

Comets may have provided much of the earth's water, volatiles, *and* organic molecules, *thus depositing some of the biogenic material from which primitive* *life ultimately formed. Subsequent impacts, however, could easily have erased many of the earth's life forms, leaving only the most adaptable to develop further.*

This duality of comets, as both life giving and life threatening, is a theme that began with ***Isaac Newton*** *and* ***Edmund Halley*** *(1688), the latter suggesting (1694) that cometary collisions might well cause a major extinction of species, but the fine debris would then settle onto the earth's surface and render the soil more suitable for vegetable production and animal life. In 1750* ***De Maupertuis*** *wrote that comets could crash into the planets, and the resultant heat and contamination of atmosphere and water would lead to mass extinction.*

It has been concluded recently from the fossil record (1992) that throughout the history of multicellular life — from 600 *million years ago — some* 60 *percent of all species extinctions may have been caused by impacts of asteroids, comets or other extraterrestrial bodies. Some of these impacts would have eliminated* $\frac{2}{3}$ *or more of species living at the time. The mass extinction at the end of the Cretaceous period,* 65 *million years ago, that accounted for the demise of the dinosaurs, is widely thought to be an example of such a calamity*[202].

Other collisions would have destroyed between 5 *and 60% of the standing population of species. Extinction levels up to 5% fall into the range of "background" extinction, the result of biotic effects including the overwhelming success of one species over another, or local disasters such as a hurricane that destroys animals and plants unique to one island.*

Throughout history, background extinction has cumulatively accounted for the loss of 40% of species, a much lower figure than most biologists have guessed. The above conclusions were reached by dating asteroid collisions from their impact craters and checking them against known mass extinctions. If it is true that throughout earth history, 60% of all species have gone extinct through asteroid impact, then the odds are better than even that Homo sapiens *will end its tenure in the same way.*

It might then turn out that those planets where mass extinction periodically "clear the undergrowth" for new species to dominate, will allow evolution to proceed more rapidly than it can on planets where no mass extinction occur. In other words, a precondition for a planet to evolve intelligent life

[202] It has been estimated that the said extinction could have been precipitated by an asteroid measuring about 10 kilometers across that slammed into the Yucatan with a yield equivalent of 100 million megatons of TNT. This event is just one of a dozen or more such mass extinctions found at intervals of about 26 million years through the fossil record of life.

sooner rather then later could be that at long intervals, large impacts did occur, eliminating most species of life, which were then replaced with new species.

In 1978, *an explosion equivalent to* 100 *kilotons of TNT was detected in the South Pacific. Once suspected of being a clandestine nuclear test, the event is now considered to have been an asteroid strike. In Jan.* 1991 *an asteroid* 10 *meters in diameter passed between the earth and the moon, scoring a near miss.*

Countless millions of asteroids hug an orbit between Mars and Jupiter, forming a belt that normally poses no threat to life on earth. Occasionally, however, some are jostled out of the belt to assume earth-crossing orbits. Some 150 *such asteroids with a diameter of at least* 1 *km have been detected, with* 2 *or* 3 *new ones discovered every month.*

It is estimated that between 1000 *and* 4000 *earth-crossing asteroids exist with diameters equal to or larger than* 1 *km. An equal number of comets may pose a similar threat. Most asteroids with diameters ranging from* 10 *to* 100 *meters explode on hitting the earth's atmosphere, usually with no harmful effects. The larger and denser ones in this range penetrate further.*

The Siberian bolide, is thought to have been 90–190 *meters across*[203]*. It is estimated that impacts of this magnitude occur once every* 2000 *years. The impact of a* 1*-km or larger object occur once every* 300, 000 *years, and carries the potential to severely disrupt or even terminate our civilization; huge quantities of ash, dust and vapor would penetrate into the atmosphere, shrouding the sun and triggering the equivalent of a "nuclear winter". Objects up to* 5 *kilometers in diameter arrive once every million years and cause mass extinction; agriculture and civilization would certainly collapse and the future existence of the human species would be in doubt.*

1908 CE, Dec. 28 A major earthquake destroyed the cities of Messina and Reggio, killing some 80,000 people in Calabria and Sicily[204].

---

[203] Z. Sekanina, The Tunguska event: No cometary signature in evidence, *Astrophys. Jour.* **88**, 1382–1414, 1983.

[204] Global statistics confirm that earthquakes in the 20th century still take an average toll of 10,000 lives and cost $400 million a year worldwide. Earthquakes are still difficult to forecast: seismology, soil mechanics, and engineering cannot prevent vast damage. But most engineers believe that improved education,

1908 CE **Hermann Anschütz-Kaempfe** (1872–1931, Germany). Engineer. Invented the gyrocompass.

1908–1909 CE **Fritz Haber** (1868–1934, Germany). Chemist. One of the first chemists to bridge the gap between pure and theoretical chemistry on one hand and its industrial applications on the other. His most important work was on high-pressure synthesis of *ammonia* from its elements nitrogen and hydrogen[205]. This process known as the *Haber process of ammonia synthesis* (1909) (for which he was awarded the Nobel prize in 1919), *laid the foundation of the fertilizer and explosive industries*.

Haber was born in Breslau, Silesia, Germany (now Wročlav, Poland), the son of a Jewish dye-stuffs merchant. His early training was in organic chemistry with a view to his entering the family firm. At Karlsruhe, however, he took up the study of physical chemistry, and started to apply it to chemical problems of practical importance. He became a professor at Karlsruhe (1898), and director of the Kaiser Wilhelm Institute for Physical Chemistry, Berlin (1911–1933). During WWI he put all his energies into the German war effort, working on explosives, petrol, and the poison-gas chlorine[206].

Haber believed that his development of the use of *chlorine gas* for the German general staff would help bring a swift victory and thus limit overall suffering. On the eve of the first use of the gas against Allied troops in 1915, Haber's wife committed suicide, tormented by her husband's horrific contribution to the war.

Haber[207] then came up with a far more potent poison, the *mustard gas* ($C_4H_8SCl_2$) which was used with devastating results by Germans at Ypres in 1917. It is a volatile liquid, odorless and therefore is not immediately detectable by smell. Where it touches the skin and is inhaled, it forms blisters.

---

warning systems, maps of fault lines and expected hazards, better building design, careful zoning, and stricter building codes can reduce risk to life.

205 The process operates at a high temperature (ca 450°C) and pressure (up to 1000 atmospheres) with *iron* as a catalyst: $N_2+3H_2 \leftrightharpoons 2NH_3$. The gases are cooled and the ammonia is separated. Only about 15% of the mixture is converted to ammonia. The unreacted substances are recycled.

206 Consequently, the award to him of the Nobel prize for chemistry led to some criticism from scientists in the allied countries. His work is said to have prolonged the first World War by two years, as it enabled Germany to manufacture explosives long after natural supplies of ammonia-yielding compounds had been exhausted.

207 His colleague **Gerhard Schroeder** produced the *nerve gas* ($C_6H_{14}O_3PF$) but it was never used by the Germans in WWII.

Those who do not die at once, or from infections that follow the blistering, suffer a generalized poisoning that renders them ill for the rest of their lives.

About 100,000 allied soldiers in WWI died due to gas poisoning. After the Armistice, the Allied considered Haber a war criminal. Haber was demoralized, but he continued to conduct research and provided the Nazis with *Cyclone B*, used in their *Gas Chambers* to murder six million of his own people during WWII. In 1920 he became involved in the futile effort to pay off the German war debts by means of gold extracted from seawater(!)

Upon the rise of the Nazis to power in Germany (1933), Haber was forced to resign his directorship of the Kaiser Wilhelm Institute[208]. He removed to Switzerland and died there, heartbroken, a year later.

1908–1922 CE **Carl Vilhelm Ludvig Charlier** (1862–1934, Sweden). Astronomer. Developed a cosmological theory of an "hierarchical" fractal universe along the lines of **Lambert** (1761), in which galaxies form clusters, clusters form superclusters and so on ad infinitum. By arranging the dimensions suitably, it is possible in this way to construct a universe with *zero average density*. [Example: A cluster of order n contains p^n stars of mass m in a volume kq^n; its average density $\rho = \left(\frac{m}{k}\right)\left(\frac{p}{q}\right)^n \to 0$ as $n \to \infty$ if $p < q$.] Thus, one avoids the infinities inherent in the Newtonian treatment of an homogeneous universe with a finite average density.

Charlier universes are inhomogeneous, and no volume V is large enough to be typical. This model eliminates *Olbers' paradox* if the average density of matter in a cluster is less for higher order clusters than for lower order clusters,

---

[208] Haber's conversion to Christianity and all the services rendered by him to Germany's war-effort, industry and science did not make him less of a Jew in the eyes of the Nazis.

In May 1933, **Max Planck** went to congratulate the newly elected Führer. He seized upon the opportunity to plead on behalf of his friend Haber, who was already blacklisted. Planck spoke of Haber's major contributions to Germany's war-effort and postwar chemical industry. "*There are*", he said, "*nevertheless, Jews of various kinds, and distinction should be made in favor of those among them who are of great value to humanity and of distinguished German families of high culture...*". The Führer stopped him there and remarked: "*It is not true, a Jew is a Jew, ... I have to act against all of them in the same way*".

Planck then went on to say that Germany needs its Jewish scientists and their dismissal will cause many of them to leave Germany, which will have a grave consequences for German science. But the Führer went into a frenzy and Planck had to leave.

and is probably the only explanation which does not invoke a systematic motion of all stars[209].

Charlier was educated at the University of Uppsala and the Stockholm Observatory. He then became the observatory director at the University of Lund (1897–1927). After working in celestial mechanics, the calibration of photographic photometry, and the theory of lenses, he turned to statistics where he made extensive statistical studies of the distribution and motion of stars in the solar neighborhood. Named after him are: *Gram-Charlier series*, *Lunar crater Charlier*, *Martian crater Charlier* and Minor Planet #8677 Charlier. He was a *1933 Bruce Medalist*.

1908–1928 CE **Godfrey Harold Hardy**[210] (1877–1947, England). One of the greatest pure mathematicians of the 20^{th} century. Helped foster, more

---

[209] Carl Charlier's first publication on hierarchy "*Wie eine unendliche Welt aufebauen sein kann*" (1908), contains mathematical errors. The correct result was first derived in 1909 by **Hugo von Seeliger** in a letter to Charlier, who acknowledged and used this result in a second article (1922).
John Herschel (1848), in his review of the first volume of Alexander von Humboldt's *Kosmos*, hinted at the possibility of hierarchical structure as a solution to Olbers' paradox. **Richard A. Proctor** (1837–1888, England), an astronomer and popularizer of science, presented in *Other Worlds than Ours* (1871) a semiquantitative treatment of a hierarchical solution. But neither Herschel nor Proctor derived the conditions with any generality and precision.
Edward Fournier d'Albe (England), in his book *Two New Worlds* (1907), dismissed absorption as a possible rescue mechanism for the Olbers' paradox and revived a long-forgotten idea of **Lord Kelvin** (1901): if the universe began in the finite past, then only a finite part is visible. The rest — the part beyond a certain distance — cannot be seen because the light from this part has not had time to reach us. Moreover, Fournier d'Albe championed the notion of hierarchy and elaborated on the idea that our visible universe is just one in a multiuniverse. All universes have similar structure, he suggested, and differ only in scale.
Fournier d'Albe's fractal theory of the universe, greatly influenced Charlier and stimulated him to derive the mathematical conditions for a hierarchical solution to the riddle of darkness.

than anyone else, analytic methods for the resolution of discrete problems of higher arithmetic.

Hardy contributed fundamentally to many realms in mathematics, including analytic number theory, Diophantine analysis, Fourier series[211], divergent series, integral equations, inequalities, distribution of primes and the Riemann zeta function[212]. His books and articles had a decisive influence on the development of the above topics.

Hardy collaborated with **J.E. Littlewood** (1885–1977), **S. Ramanujan** (1887–1920) and **E. Landau** (1877–1938).

Although Hardy boasted that he had never done anything useful in the sense of practical applications, he discovered [concurrently with the German physician **Wilhelm Weinberg**] an important and useful law in population genetics. It became centrally important in the study of many genetic problems, including Rh blood group distribution and hemolytic diseases.

He showed that in large enough populations obeying Mendelian laws of heredity, and in the absence of outside influences and of mutations, random mating will produce within *one generation*, a *stationary* genotype distribution with unchanged gene frequency.

Hardy was born in Cranleigh, Surrey. Both his parents were extremely able people and mathematically minded, but want of funds had prevented them from acquiring a university training.

- Hardy, G.H., *A Course of Pure Mathematics*, Cambridge University Press, 1967, 509 pp.

[211] **Riemann** conjectured that the function $\sum_{n=1}^{\infty} \frac{\sin(\pi n^2 t)}{n^2}$ is continuous but nowhere differentiable. However, neither he nor **Weierstrass** succeeded in proving this. **Hardy** (1916) showed that the function is not differentiable at any irrational point and at some specific rationals. Finally (1971), mathematicians were able to show that it is differentiable at any rational point $\frac{P}{Q}$ with $P \equiv Q \equiv 1 \pmod 2$. Weierstrass (1872) introduced his famous function $\sigma(t) = \sum_{n=1}^{\infty} \alpha^n \cos(\beta^n t), \quad 0 < \alpha < 1$. He showed that this function is continuous but nowhere differentiable whenever $\alpha\beta$ exceeds a certain value. Hardy (1916) showed that $\alpha\beta > 1$ is all that is needed.

[212] He proved that there are an infinity of roots of $\zeta(x + iy) = 0$ on the line $\frac{1}{2} + iy$ $(y \neq 0)$. The *Riemann hypothesis* claims that *all* zeros of $\zeta(x + iy)$ are of that form.

He was a child prodigy[213]. He went to Trinity College, Cambridge, in 1896, was first wrangler in 1900 and was awarded (with **Jeans**) the Smith's prize in 1901. He taught mathematics at Cambridge during 1900–1919. In 1919 he was appointed to the Savilian chair of geometry at Oxford University. He returned to Cambridge in 1931 as Sadleirian professor of pure mathematics, and remained there until his death.

Hardy is credited with the following toast in a meeting of the London Mathematical Society: "*Here is to pure mathematics, let it be of no use to anybody*". Hardy described himself as a *problem-solver*, and did not claim to have introduced any new system of ideas. Yet he had a profound influence on the mathematics of his time.

[213] May this explain his interest in Ramanujan and also his preoccupation with population genetics?

Worldview XXX: Hardy

* * *

"The function of a mathematician is to do something, to prove new theorems, to add to mathematics, and not to talk about what he or other mathematicians have done. Painters despise art-critics, and physicists, or mathematicians have usually similar feelings. Exposition, criticism, appreciation, is the work for second rate minds."

* * *

"Most people can do nothing at all well; perhaps five or even ten percent of men can do something rather well.It is a tiny minority who can do anything really *well, and the number of people who can do two things well is negligible."*

* * *

"Mathematics, more than any other art or science, is a young man's game. Newton, who was one of the world's three greatest mathematicians, gave up mathematics at fifty ... His greatest ideas of all, fluxions and the law of gravitation, came to him when he was twenty-four(1666). He made big discoveries until he was nearly forty, but after that he did little but polish and perfect. Galois died at twenty-one, Abel at twenty seven, Ramanujan at thirty-three, Riemann at forty. There have been men who have done great work a good deal later; Gauss' great memoir on differential geometry was published when he was fifty (thought he had the fundamental ideas ten years before), I do not know an instance of a major mathematical advance initiated by a man past fifty."

* * *

"If intellectual curiosity, professional pride, and ambition are the dominant incentives to research, then assuredly no one has a finer chance of gratifying them than a mathematician. His subject is the most curious of all – there is none in which truth plays such odd pranks. It has the most elaborate and the

most fascinating technique, and gives unrivaled openings for the display of sheer professional skills. Finally, as history proves abundantly, mathematical achievement, whatever its intrinsic worth, is the most enduring of all. We can see this even in semi-historic civilization. The Babylonian and Assyrian civilizations have perished; Hammurabi, Sargon, and Nebuchadnezzar are empty names; yet Babylonian mathematics is still interesting, and the Babylonian scale of 60 is still used in astronomy. But of course the crucial case is that of the Greeks.

The Greeks were the first mathematicians who are still 'real' to us today. Oriental mathematics may be an interesting curiosity, but Greek mathematics is the real thing. The Greeks first spoke a language which modern mathematicians can understand; as Littlewood said to me once, they are not clever schoolboys or 'scholarship candidates', 'but fellows of another college'. Immortality may be a silly word, but probably a mathematician has the best chance of whatever it may mean... Mathematical game, if you have the cash to pay for it, is one of the soundest and steadiest of investments."

* * *

"Immortality is often ridiculous or cruel: few of us would have chosen to be Og or Ananias or Gallio. Even in mathematics, history sometimes plays strange tricks; Rolle figures in the text-books of elementary mathematics like Newton; Farey is immortal because he failed to understand a theorem which Haros have proved perfectly fourteen years before; the names of five worthy Norwegians still stand in Abel's Life*, just for one act of conscientious imbecility, dutifully performed at the expense of their country's greatest man. But on the whole the history of science is fair, and this is particularly true in mathematics. No other subject has such clearcut of unanimously accepted standards, and the men who are remembered are almost always the men who merit it."*

* * *

"A mathematician like a painter or a poet, is a maker of patterns... The mathematicians' patterns, like painters' or the poet's, must be beautiful*; the ideas, like the colors or the words, must fit together in a harmonious way. It may be very hard to* define *mathematical beauty, but that is just as true of beauty of any kind – we may not know quite what we mean by a beautiful poem, but that does not prevent us from recognizing one when we read it. Every chess-player can recognize and appreciate a 'beautiful' game or a problem. Yet a chess problem is* simply *an exercise in pure mathematics."*

* * *

A chess problem is genuine mathematics, but it is in some way 'trivial' mathematics. However ingenious and intricate, however original and surprising the moves, there is something essential lacking. Chess problems are unimportant. *The best of mathematics is* serious *as well as beautiful... The 'seriousness' of a mathematical theorem lie, not in its practical consequences, which are usually negligible, but in the* significance *of the mathematical ideas which it connects. We may say, roughly, that a mathematical idea is 'significant' if it can be connected, in natural and illuminating way, with a large complex of other mathematical ideas. Thus a serious mathematical theorem, a theorem which connects significant ideas, is likely to lead to important advances in mathematics itself and even in other sciences. No chess problem has ever affected the general development of scientific thought. The chess problem is the product of an ingenious but very limited complex of ideas, which do not differ from one another very fundamentally and had no external repercussions. We should think in the same way if chess had never been invented, whereas the theorems of Euclid and Pythagoras have influenced thought profoundly even outside mathematics."*

* * *

Euclid's theorem *(existence of the infinity of prime numbers) is vital for the whole structure of arithmetics. The primes are the raw material out of which arithmetics is built, and Euclid's theorem assures us that we have plenty of material for the task. But the* theorem of Pythagoras *(irrationality of* $\sqrt{2}$*) and its extensions (to very wide class of 'irrationals') has wider applications: Euclid's theorem tells us that we have a good supply of material for the construction of a coherent arithmetics of the integers. Pythagoras' theorem and it's extensions tell us that, when we have constructed this arithmetic, it will not prove sufficient for our needs, since there will be many magnitudes which obtrude themselves upon our attention and which it will be unable to measure. Pythagoras discovery led to the construction of the much more profound theory of Eudoxos , the finest achievements of Greek mathematics. This theory is astonishingly modern in spirit, and may be regarded as the beginning of the modern theory of irrational numbers, which has revolutionized mathematical analysis and had much influence on recent philosophy... It is obvious that irrationals are uninteresting to an engineer, since he is concerned only with approximations, and all approximations are rational."*

* * *

“A serious theorem is a theorem which contains ‘significant’ ideas. There are two things which seem essential, a certain generality *and a certain* depth*:*

The idea should be one which is a consistent in many mathematical constructions, even if stated originally in a fully special form, is capable of considerable extension and is typical of a whole class of theorems of its kind. The relation revealed by the proof should be such as connect many different mathematical ideas.

Depth is difficult to define. It has something to do with difficulty*. It seems that mathematical ideas are arranged somehow in strata, the ideas in each stratum being linked by a complex of relations both among themselves and above and below. The lower the stratum, the deeper (and is general the more difficult) the idea. Thus the idea of an ‘irrational’ is deeper than that of an integer, but there are many theorems about integers which we cannot appreciate properly, and still less prove, without digging deeper considering what happens below”.*

* * *

“A physicist is trying to correlate the incoherent body of crude fact confronting him with some definite orderly scheme of abstract relations, the kind of schema which he can borrow only from mathematics.

A mathematician, on the other hand, is working with his own reality. Of this reality, I take a ‘realistic’ and not an idealistic view.

This realistic view is much more plausible of mathematical than of physical reality, because mathematical objects are so much more what they seem. A chair or a star is not in the least like what it seems to be; the more we think of it, the fuzzier its outline become in the haze of sensation which surrounds it; but 2 or 317 has nothing to do with sensations, and its properties stand out the more clearly the more we scrutinize it. Pure mathematics seems to me a rock on which all idealism founders: 317 is a prime, not because we think so, or because our minds are shaped in one way rather than another, but because it is so*, because mathematical reality is built that way.”*

* * *

“A science or an art may be said to be ‘useful’ if its development increases, even indirectly, the material well-being and comfort of men, if it promotes happiness. It is undeniable that a good deal of elementary mathematics (including calculus) has considerable practical utility; the engineers could not

do their job without a fair working of mathematics, and mathematics is beginning to find applications in medicine and biology and the social sciences. These parts of mathematics are, on the whole, rather dull; they are just the parts which have least aesthetic value. The 'real' mathematics of the 'real' mathematicians, the mathematics of Fermat and Euler and Gauss and Abel and Jacobi and Riemann and Ramanujan, is almost wholly 'useless'. It is the dull and elementary parts of applied mathematics, as the dull and elementary parts of pure mathematics, that work for good and ill[214]. It is the commonplace and dull that counts for practical life."

* * *

"In great mathematics there is a very high degree of unexpectedness, combined with inevitability and economy."

* * *

"Young Men should prove theorems, old-men should write books"

* * *

"The mathematician's patterns, like the painter's or the poet's must be beautiful; the ideas, like the colors or the words must fit together in a harmonious way. Beauty is the first test: there is no permanent place in this world for ugly mathematics."

* * *

"I believe that mathematical reality lies outside us, that our function is to discover or observe it and that the theorems which we prove, and which we describe grandiloquently as our "creations," are simply the notes of our observations."

* * *

214 During WWI Hardy took this to extreme, saying that: "a science is said to be useful if its development tends to accentuate the existing inequalities in the distribution of wealth, or more directly promotes the destruction of human life."

“Archimedes will be remembered when Aeschylos is forgotten, because languages die and mathematical ideas do not. “Immortality” may be a silly word, but probably a mathematician has the best chance of whatever it may mean.”

* * *

“The fact is that there are few more “popular” subjects than mathematics. Most people have some appreciation of mathematics, just as most people can enjoy a pleasant tune; and there are probably more people really interested in mathematics than in music. Appearances may suggest the contrary, but there are easy explanations. Music can be used to stimulate mass emotion, while mathematics cannot; and musical incapacity is recognized (no doubt rightly) as mildly discreditable, whereas most people are so frightened of the name of mathematics that they are ready, quite unaffectedly, to exaggerate their own mathematical stupidity.”

* * *

“I had better say at once that by ‘mathematics I mean real mathematics, the mathematics of ***Fermat*** *and* ***Euler*** *and* ***Gauss*** *and* ***Abel****; and not the stuff that passes for mathematics in an engineering laboratory. I am not thinking of “‘pure mathematics” (though naturally that is my first concern), I count* ***Maxwell*** *and* ***Einstein*** *and* ***Eddington*** *and* ***Dirac*** *among real mathematicians.”*

* * *

“It seems to me that no philosophy can possibly be sympathetic to a mathematician which does not admit, in one manner of other, the immutability and unconditional validity of mathematical truth. Mathematical theorems are true or false; their truth or falsity is absolutely independent of our knowledge of them. In some sense, mathematical truth is part of objective reality.”

Hardy-Littlewood conjecture — the clustering of Prime Numbers (1919–1922)

The prime number theorem tells us that the average density of primes around x is approximately[215] $\frac{x/\ln x}{x} = \frac{1}{\ln x}$*. This means that if we consider an interval of length Δx about x and choose any integer t in this interval, then the probability of t being a prime will approach* $\frac{1}{\ln x}\Delta x$ *as* $x \to \infty$, *if* Δx *is small compared to* x.

This implies that the primes tend to thin out as x grows larger. The law that governs the distribution of primes as we go higher up in the number series has boggled the minds of number-theorists since the time of Euler. We know, for example that the so-called "twin primes" (i.e., pairs of primes of the form x, $x + 2$), occur very high up in the number series. The largest pair discovered up to 1995 is

$$242,206,083 \cdot 2^{38,880} \pm 1,$$

and has 11,713 *decimal digits. Statistics indicate that twins tend to thin out as we move higher up in the number series since, if p is a prime, it becomes less and less likely that $p + 2$ is also a prime on account of the thinning out of the primes themselves. Indeed,* **Viggo Brun** *(1885–1978) proved that the sum of* $\frac{1}{p}$ *taken over all twin primes converges:*

$$B = \left(\frac{1}{3} + \frac{1}{5}\right) + \left(\frac{1}{5} + \frac{1}{7}\right) + \left(\frac{1}{11} + \frac{1}{13}\right) + \left(\frac{1}{17} + \frac{1}{19}\right) + \dots$$
$$= 1.902\ 160\ 54\dots$$

where B is known as the Brun constant. This theorem (1919) tells us that there are not very many twin primes compared with the total number of primes, since $\sum \frac{1}{p}$ taken over only the twin converges, while $\sum \frac{1}{p}$ extended over all primes diverges.

A study of prime tables has shown that constellations of primes other than twins reoccur in the number series. Of special interest are prime triplets $(p, p+2, p+6)$ *and* $(p, p+4, p+6)$, *and prime quadruplets* $(p, p+2, p+6, p+8)$. *These constellations are exemplified in* $(41, 43, 47)$, $(37, 41, 43)$ *and* $(11, 13, 17, 19)$, $(101, 103, 107, 109)$ *respectively.*

---

[215] The nth prime has therefore the approximate value $p_n \sim n \ln n$.

***Hardy** and **Littlewood** (1922) made the following conjecture: P_x, the number of prime constellations $p \le x$, as $x \to \infty$ is asymptotic to*

$$\pi_2(x) = P_x(p, p+2) \sim 2C_2 \int_2^x \frac{du}{(\ln u)^2} \le 2C_2 \frac{x}{(\ln x)^2}$$

$$C_2 = \prod_{p \ge 3} \left\{1 - \frac{1}{(p-1)^2}\right\} = \prod_{p \ge 3} \frac{p(p-2)}{(p-1)^2} = 0.660\ 16\ldots$$

The 'twin-prime constant' C_2 was calculated in 1961. Numerical evidence shows (1976) that $\pi_2(10^{11}) = 224,376,048$. For other prime constellations, the Hardy-Littlewood formulae are:

$$\pi_3(x) = P_x(p, p+2, p+6) \sim P_x(p, p+4, p+6) \sim \frac{9}{2}C_3 \int_2^x \frac{du}{(\ln u)^3}$$

$$\frac{9}{2}C_3 = \frac{9}{2} \prod_{p \ge 5} \frac{p^2(p-3)}{(p-1)^3} = 2.858\ 248\ 596\ldots$$

$$\pi_4(x) = P_x(p, p{+}2, p{+}6, p{+}8) \sim \frac{1}{2}P_x(p, p{+}4, p{+}6, p{+}10) \sim \frac{27}{2}C_4 \int_2^x \frac{du}{(\ln u)^4}$$

$$\frac{27}{2}C_4 = \frac{27}{2} \prod_{p \ge 5} \frac{p^3(p-4)}{(p-1)^4} = 4.151\ 180\ 863\ 237\ 4\ldots$$

Some of the largest known prime quadruplets $(p, p+2, p+6, p+8)$ are:

$$p = 10^{99} + 349,781,731 \qquad (1995)$$

$$p = 10^{499} + 883,750,143,961 \qquad (1996)$$

$$p = 10^{599} + 1,394,283,756,151 \qquad (1997)$$

The table below compares the computer-count against calculation made by means of the Hardy-Littlewood formulas for $x \le 10^8$:

Constellation	*Count*	*Approximation*
$(p, p+2)$	$440,312$	$440,368$
$(p, p+2, p+6)$	$55,600$	$55,490$
$(p, p+4, p+6)$	$55,556$	$55,490$
$(p, p+2, p+6, p+8)$	$4,768$	$4,734$

The Hardy-Littlewood conjecture can be extended to longer finite constellations, for example it can be shown that

$$P_x(p+11, p+13, p+17, \ldots, p+59, p+61, p+67) \sim 187{,}823 \cdot 7 \int_2^x \frac{du}{(\ln u)^{15}}$$

where the numerical constant is equal to

$$\frac{2^{14}}{1^{15}} \cdot \frac{3^{14}}{2^{15}} \cdot \frac{5^{14}}{4^{15}} \cdot \frac{7^{14}}{6^{15}} \cdot \frac{11^{14}}{10^{15}} \cdot \frac{13^{14}}{12^{15}} \cdot \frac{4 \cdot 17^{14}}{16^{15}} \cdot \frac{6 \cdot 19^{14}}{18^{15}} \cdot \frac{9 \cdot 23^{14}}{22^{15}} \cdot \prod_{p \geq 29} \frac{p^{14}(p-15)}{(p-1)^{15}}.$$

Despite the fact that the primes are not all individually known, these constants can be computed to any desired accuracy*! This astonishing result is due to the fact that the constants are expressible in terms of the* prime zeta-function.[216]

An Unbelievable Identity (1917)

The classical theory of numbers was based, up to the 18th century, on the unique representation of an integer as a product of prime numbers*; these* multiplicative *building blocks, and the concept of* divisibility *— are central to the theory.* ***Euler*** *(1748) laid the foundations to a new branch of number theory centered on the representation of integers as* sums of other integers *–*

216 *e.g.:*

$$\begin{aligned}
\ln C_2 &= \sum_{p\geq 3} \ln \frac{p(p-2)}{(p-1)^2} = \sum_{p \geq 3} \left\{ \ln\left(1 - \frac{2}{p}\right) - 2\ln\left(1 - \frac{1}{p}\right) \right\} \\
&= \sum_{p\geq 3} \left\{ -\frac{2}{p} - \frac{1}{2} \cdot \frac{4}{p^2} - \frac{1}{3} \cdot \frac{8}{p^3} - \cdots + \frac{2}{p} + \frac{1}{2} \cdot \frac{2}{p^2} + \frac{1}{3} \cdot \frac{2}{p^3} + \ldots \right\} \\
&= \sum_{p\geq 3} \sum_{j=2}^{\infty} \frac{2 - 2^j}{j} \cdot \frac{1}{p^j} = -\sum_{j=2}^{\infty} \frac{2^j - 2}{j} \sum_{p \geq 3} \frac{1}{p^j}
\end{aligned}$$

an additive theory, based on the concept of partition[217]*. The word "partition" has numerous meanings in mathematics. Any time a division of some object into subobjects is undertaken, the word partition is likely to pop up. In the present context, the partitions of a number are the ways of writing that number as a sum of positive integers*[218]*. For example, the five partitions of* 4 *are*

$$4, \quad 3+1, \quad 2+2, \quad 2+1+1, \quad 1+1+1+1$$

and we write $p(4) = 5$*. Surprisingly, such a simple matter requires some deep mathematics for its study.*

The theory of partitions has an interesting history. Certain special problems in partition date back to the Middle Ages; however, the first discoveries of any depth were made when **Euler** *proved many beautiful and significant partition theorems. Other great mathematicians —* **Lagrange** *(ca 1775),* **Legendre** *(1801),* **Gauss** *(1808),* **Jacobi** *(1829),* **Sylvester** *(1855),* **Cayley** *(1876),* **Ramanujan** *(1917) and* **Hardy** *(1917) have contributed to the development of the theory. The various theoretical aspects of this subject have recently found applications to statistical mechanics, combinatorics, analysis and number theory. In these diverse applications, one is struck by the interplay of combinatorial and asymptotic methods.*

Returning to the concept of partition of a positive integer n*, we define it as a finite nonincreasing sequence of positive integers* $\lambda_1, \lambda_2, \ldots, \lambda_r$*, such that* $\sum_{i=1}^{r} \lambda_i = n$*. The partition function* $p(n)$ *is the number of partitions of* n*.*

For example

$p(0) = 1$ *[an empty sequence forms the only partition of zero]*

$p(1) = 1$

$p(2) = 2$;2, $1+1$

---

[217] To dig deeper, see:

- Andrews, G.E., *The Theory of Partitions*, Cambridge University Press, 1998, 255 pp.

[218] In the *general problem of additive arithmetic* we are given a system A of integers $a_1, a_2, a_3, \ldots$, where A might contain all the positive integers, or the squares, or the primes. We then consider all possible representations of an arbitrary positive integer in the form $n = a_{i_1} + a_{i_2} + \cdots + a_{i_s}$, where s may be fixed or unrestricted, the a's may or may not be necessarily different, and order may or may not be relevant, according to the particular problem considered. We denote by $p(n)$ the number of such representations. We then ask, what can be said about $p(n)$? e.g., is there always one representation for every n?

$p(3) = 3$;3, 2 + 1, 1 + 1 + 1

$p(4) = 5$;4, 3 + 1, 2 + 1 + 1, 1 + 1 + 1 + 1

$p(5) = 7$;5, 4 + 1, 3 + 2, 3 + 1 + 1, 2 + 2 + 1, 2 + 1 + 1 + 1, 1 + 1 + 1 + 1 + 1

$p(6) = 11$

$p(7) = 15$

$p(8) = 22$

$p(9) = 30$

$p(10) = 42$

$p(20) = 627$

$p(50) = 204,226$

$p(100) = 190,569,292$

$p(200) = 3,972,999,029,388$

$p(721) = 161,061,755,750,279,477,635,534,762$

To evaluate $p(n)$, ***Euler*** *invented a powerful weapon provided by the theory of generating functions; namely, he was seeking a function* $F(x)$, *whose power-series expansion has* $p(n)$ *for its general coefficient. Indeed, he discovered that*

$$F(x) = \prod_{n=1}^{\infty}(1-x^n)^{-1} = \frac{1}{(1-x)(1-x^2)(1-x^3)\dots} = 1 + \sum_{n=1}^{\infty} p(n)x^n = \sum_{n=0}^{\infty} p(n)x^n. \tag{1}$$

To see this, one writes the infinite product as

$$(1 + x + x^2 + \dots)(1 + x^2 + x^4 + \dots)(1 + x^3 + x^6 + \dots)\dots$$

and multiplies the series together: Every partition of n *contributes just* 1 *to the coefficient of* x^n. *It is obvious that the finite product* $\left[(1-x)(1-x^2)\dots(1-x^m)\right]^{-1}$ *enumerates the partitions of* n *into parts which do not exceed* m *or (what is the same thing) into at most* m *distinct parts.*

Hardy *and* ***Ramanujan*** *(1917) set forth to invert (1), namely solve for* $p(n)$ *in terms of* $F(x)$. *Clearly, Cauchy's integral theorem implies that*

$$p(n) = \frac{1}{2\pi i}\int_C \frac{F(x)}{x^{n+1}}\,dx, \tag{2}$$

where, say, C is a circle centered in the origin and inside *the unit circle $|x| = 1$. The evaluation of this integral leads eventually to the* exact *result (as completed by* **Rademacher** *in 1937):*

$$p(n) = \frac{1}{\pi\sqrt{2}} \sum_{k=1}^{\infty} A_k(n)\sqrt{k}\Big[\frac{d}{dx}\frac{\operatorname{sh}\left\{\frac{\pi}{k}\sqrt{\frac{2}{3}(x-\frac{1}{24})}\right\}}{\sqrt{x-\frac{1}{24}}}\Big]_{x=n}, \tag{3}$$

where

$$A_k(n) = \sum_h \omega_{h,k} e^{-\frac{2\pi i n h}{k}},$$

the sum being over h values prime to k and less then it, $\omega_{h,k}$ being a certain 24^{qth} *root of unity*[219].

As one may discern, $p(n)$ grows astronomically. Actual enumeration of the $3,972,999,029,388$ *partitions of* 200 *by hand would certainly take more than a lifetime. However, the first* 5 *terms of the remarkable Hardy-Ramanujan formula give the correct value of* $p(200)$.

This unbelievable identity wherein the left-hand side is the humble arithmetic function $p(n)$ and the right-hand side is an infinite series involving π, square roots, complex roots of unity, and derivatives of hyperbolic functions provided not only a theoretical formula for $p(n)$ but also a formula which admits relatively rapid computation.

For example, comparing the first 8 *terms of the series for $n = 200$, we find that the result is*

---

219 Hardy and Ramanujan actually proved that $p(n)$ is the *integer nearest* to $\sum_{k=1}^{\nu}$, where ν is of the order $\sqrt{n}$. One thus obtains the *exact* value of $p(n)$ with a *finite* number of terms. **Ramanujan** (1913), in his famous letter to Hardy (problem 14), actually suggested that the first term of the series may suffice. "Ramanujan's false statement" Hardy later said, "was one of the most fruitful he ever made."

1st	*term*	$+3,972,988,993,185.896$
2nd	*term*	$+36,282.978$
3rd	*term*	-87.555
4th	*term*	$+5.147$
5th	*term*	$+1.424$
6th	*term*	$+0.071$
7th	*term*	$+0.000$
8th	*term*	$+0.043$
		$3,972,999,029,388.004$

which is the correct value of $p(n)$ *within* 0.004.

The Hardy-Ramanujan formula is connected also to the theory of modular functions. To see this we put $x = q^2 = e^{2\pi i\tau}$ $(\mathrm{Im}\ \tau > 0)$ *into Euler's formula. It then follows that* $q^{\frac{1}{12}} \prod_1^\infty (1 - q^{2n}) = x^{\frac{1}{24}}/F(x)$.

Prior to 1917, $p(n)$ *were calculated either directly from Euler's formula* (1) *or from the known recursion formula*[220]

$$p(n) = \frac{1}{n} \sum_{k=1}^{n} \sigma(k) p(n-k), \tag{4}$$

where $\sigma(k)$ *is the sum of divisors of* k. *Thus* $p(n)$ *was calculated for* $n \leq 200$ *by* ***Percy Alexander MacMahon***[221] *(1916). Ramanujan used his data to discover, with the aid of the theory of modular functions, that:*

$$p(5m + 4) \equiv 0 \pmod{5}$$
$$p(7m + 5) \equiv 0 \pmod{7}$$
$$p(11m + 6) \equiv 0 \pmod{11}$$
$$p(25m + 24) \equiv 0 \pmod{5^2}$$
$$p(49m + 47) \equiv 0 \pmod{7^2}$$

---

220 Proved with the aid of Euler's formula

$$(1 - x)(1 - x^2)(1 - x^3) \cdots = \sum_{n=-\infty}^{\infty} (-1)^n x^{\frac{1}{2}n(3n+1)}.$$

221 Soldier and mathematician (1854–1928, England). Served as a major in the Artillery before seriously taking up mathematics. He then became a professor of mathematics at the Woolrich army school. Since 1904 had been associated with St. John's college in Cambridge. Contributed to combinatorics.

For large values of n, one obtains from (3) the asymptotic law (with $k = 1$, $A_k(n) = 1$):

$$p(n) \approx \frac{1}{4n\sqrt{3}} e^{\pi\sqrt{\frac{2n}{3}}} \qquad (5)$$

For example, with $n = 243$, *(5) yields* $p(n) \approx 1.38 \times 10^{14}$ *while the exact result is*

$$p(243) = 133,978,259,344,888.$$

In deriving the analytic expression for $p(n)$, Ramanujan supplied the central idea in the form of a conjecture and Hardy furnished the technical skill. ***Hans Adolph Rademacher*** *(1892–1969, Germany) made the formula exact in 1937.*

Hardy and Ramanujan were a formidable pair; as a mathematical team, they would remind us of the story of the two men, one blind and the other lame, who together could do what no normal man could. Whatever the proper assignment of credit, "we owe the theorem" Littlewood would write, "to a singularly happy collaboration of two men, of quite unlike gifts, in which each contributed the best, most characteristic, and most fortunate work that was in him. Ramanujan's genius did have this one opportunity worthy of it."

1909 CE **William Bateson** (1861–1926, England). Geneticist. Coined the term *genetics*. One of the founders of the science of genetics. Experimentally confirmed Mendel's reports and demonstrated *genetic linkage*.

1909 CE **Axel Thue** (1863–1922, Norway). Mathematician. Proved[222] that for all integers $m \neq 0$ and $n \geq 3$, the Diophantine equation with integer coefficients

$$g(x, y) = a_0x^n + a_1x^{n-1}y + \cdots + a_{n-1}xy^{n-1} + a_ny^n = m$$

has at most a finite number of integer solutions x, y.

Thue was born in Tönsberg. He enrolled at Oslo University in 1883. He was a professor of applied mathematics at Oslo from 1903 to 1922. During

[222] Thue's theorem was characterized by **Edmund Landau** (1922) as "*the most important discovery in elementary number theory that I know*". In 1967, **Alan Baker** (England) proved that for any solution, both $|x|$ and $|y|$ cannot exceed a certain constant C whose value can be calculated explicitly in terms of m, n and the coefficients $a_0, a_1, \ldots, a_n$.

1890–1891 he studied at Leipzig under **Sophus Lie**, but his works do not reveal Lie's influence, probably because of Thue's unwillingness to follow anyone else's line of thought.

1909 CE **A. Wieferich** (Germany). Mathematician. Proved that if p is a prime and if xyz is not a multiple of p, the equation $x^p + y^p = z^p$ cannot be solved in integers unless p^2 divides $(2^{p-1} - 1)$. This criterion is sufficient to preclude solutions for all $p < 100,000$, except 1093 and 3511. (No one has proven that there are infinitely many p values which satisfy $p^2 \nmid 2^{p-1} - 1$). In 1910, **D. Mirimanoff** showed that $p^2 \nmid 3^{p-1} - 1$ is an equally valid criterion.

In 1914, **H.S. Vandiver** proved that $p^2 \nmid (5^{p-1} - 1)$ is also a necessary condition for $x^p + y^p = z^p$ to be soluble. Then **Frobenius** arrived with 11 and 17, and it has also been shown that if p is a prime of the form $6x - 1$, then $7^{p-1} - 1$, $13^{p-1} - 1$ and $19^{p-1} - 1$ must each be divisible by p^2 if Fermat's conjecture is to be violated for power p. Under such restrictions, the minimal prime exponent p required was continually raised, and in 1941 it was shown that if $x^p + y^p + z^p = 0$ and no member of the triple x, y, and z is a multiple of p, then p must be not less than $253,747,889$.

Prime Numbers[223] *— The Inexplicable Secret*

* * *

"And Joseph gathered corn as the sand of the sea, very much, until he stopped numbering; for it was without number."

(*Genesis 41*, 49; ca 1750 BCE)

"The sequence of Prime numbers is a mystery that the human mind will never penetrate."

(**Leonhard Euler**)

"There are two facts about the distribution of prime numbers which I hope to convince you so overwhelmingly that they will be permanently engraved in your hearts. The first is that despite their simple definition and role as the building blocks of the natural numbers, the prime numbers belong to the most arbitrary and ornery objects studied by mathematicians: they grow like weeds among the natural numbers, seeming to obey no other law than that of chance, and nobody can predict where the next one will sprout.

The second fact is even more astonishing, for it states just the opposite: that the prime numbers exhibit stunning regularity, that there are laws governing their behavior, and that they obey these laws with almost military precision."

(**Don Zagier**, Inaugural lecture, Bonn University; May 05, 1975 CE)

- Landau, E., *Hendbuch Der Lehre Von Der Veteilung Der Primzahlen*, Chelsea, 1953, vol I–II.

An integer greater than one is called a prime number if its only positive divisors (factors) are one and itself. For example, the prime divisors of 10 *are* 2 *and* 5*; and the first six primes are* 2*,* 3*,* 5*,* 7*,* 11 *and* 13*. The Fundamental Theorem of Arithmetic states that the primes are the building blocks of the positive integers: every positive integer is a product of prime numbers in one and only one way, except for the order of the factors. (This is the key to their importance: the prime factors of an integer determine its properties.)*

The ancient Greeks proved (ca 300 BC) that there were infinitely many primes and that they were irregularly spaced (there can be arbitrarily large gaps between successive primes). On the other hand, in the nineteenth century it was shown that the number of primes less than or equal to n *approaches a constant times* $n/(\ln n)$ *(as* n *becomes very large); so a rough estimate for the* n*th prime is* $n \ln n$*.*

The Sieve of Eratosthenes is still the most efficient way of finding all very small primes (e.g., those less than $1,000,000$*). However, most of the largest primes are found using special cases of Lagrange's Theorem from group theory.*

In 1984 Samuel Yates defined a titanic prime to be any prime with at least $1,000$ *decimal digits. When he introduced this term there were only* 110 *such primes known; now there are over* 1000 *times that many! And as computers and cryptology continually provide new impetus to search for ever larger primes, this number will continue to grow. Before long we expect to see the first ten-million digit prime.*

The factorization of a number into two large prime numbers, found in 1997 by Samuel Wagstaff and colleagues at the University of Indiana.

Up to 1800, the theory of numbers consisted of a collection of isolated results. ***Gauss****' work (1801) heralded the modern theory of numbers and determined the directions of work in the subject up to the present time. Subsequent innovations were made by* ***Dirichlet*** *(1837–41) and* ***Riemann*** *(1859) in analytic number theory, which uses analysis in addition to algebra to treat problems involving the integers.*

Positive integers can be partitioned into three classes: the unit, 1*; the* primes, 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, . . .; *and the* composite numbers, 4, 6, 8, 9, 10, ... *A number greater than* 1 *is* prime *if its only positive divisors are* 1 *and itself; otherwise it is* composite.

Primes have interested mathematicians at least since Euclid, who proved they were infinitely many. The general problem of determining whether a large number is prime or composite, and in the latter case determining its factors, has fascinated number theorists down the ages. With the advent of high speed computers in the second half of the 20th century, considerable advances have been made, although most fundamental problems in number theory still remain unsolved[224]*, awaiting the mathematicians of genius in fu-*

224 For example:

- To find a prime number greater than a given prime.
- To find the prime number which follows a given prime.

ture centuries[225].

Prime numbers do not distinguish themselves from composite numbers in any obvious way. If we look, for example, at the list of all prime and some odd composite numbers up to 100*,*

prime:	2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97
composite:	9, 15, 21, 25, 27, 33, 35, 39, 45, 49, 51, 55, 57, 63, 65, 69, 75, 77, 81, 85, 87, 91, 93, 95, 99,

and list the primes among the 100 *numbers immediately preceding and the same number immediately following* 10 *million:*

9,999,901	10,000,019
9,999,907	10,000,079,
9,999,929	
9,999,931	
9,999,937	
9,999,943	
9,999,971	
9,999,973	
9,999,991,	

we see no apparent reason why one number is prime and another is composite. To the contrary, upon looking at these numbers one has the feeling of being in the presence of one of the inexplicable secrets of creation. That mathematicians have not penetrated this secret is perhaps most convincingly shown by

- To compute directly the nth prime number, when n is given.
- To find the number of primes not greater than a given prime (exact formula).

[225] The twelve greatest number theorists during the past 25 centuries are: **Pythagoras** (ca 580–500 BCE, Greece); **Euclid** (330–260 BCE, Greece); **Diophantos** (206–290 CE, Greece); **Fermat** (1601–1665, France); **Euler** (1707–1783, Switzerland); **Lagrange** (1736–1813, France); **Legendre** (1752–1833, France); **Gauss** (1777–1855, Germany); **Jacobi** (1804–1851, Germany); **Riemann** (1826–1866, Germany); **Hardy** (1877–1947, England); **Ramanujan** (1887–1920, India).

the ardor with which they search for bigger and bigger primes. With numbers which grow regularly, like squares or powers of two, nobody would ever bother writing down examples larger than the previously known ones, but for prime numbers, people have gone to a great deal of trouble to do just that.

Moreover, it was found that the inquiry into composite numbers is not easier than investigations about prime numbers! Thus, for example, we are not yet able to answer the question whether or not, among the Fermat numbers $F_n = 2^{2^n} + 1 \quad (n = 1, 2, 3, \dots)$, *there are infinitely many composite numbers. So far we only know about* 100 *such composites, of which the greatest is* F_{23471} *(year 1999).*

A composite number C *can always be written as a product in at least two ways (since* $1 \cdot C$ *and* $C \cdot 1$ *are always possible). Call these two products*

$$C = ab = cd,$$

then it is obviously the case that c *divides* ab. *Set*

$$c = mn,$$

where m *is the part which divides* a, *and* n *the part which divides* b. *Then there are integers* p *and* q *such that*

$$a = mp$$
$$b = nq.$$

Solving $ab = cd$ *for* d *gives*

$$d = \frac{ab}{c} = \frac{(mp)(nq)}{mn} = pq.$$

It then follows that

$$\begin{aligned} S &\equiv a^2 + b^2 + c^2 + d^2 \\ &= m^2p^2 + n^2q^2 + m^2n^2 + p^2q^2 \\ &= (m^2 + q^2)(n^2 + p^2). \end{aligned}$$

Consequently, $a^2 + b^2 + c^2 + d^2$ *is never prime! In fact, the more general result that*

$$S \equiv a^k + b^k + c^k + d^k$$

is never prime for k *an integer* ≥ 0, *also holds.*

Divisors, sums of divisors and aliquot parts

Let n be any natural number greater than 1 and let the distinct primes in its factorization be $p_1, p_2, p_3, \ldots, p_k$. Suppose that the prime p_1 occurs α_1 times in the factorization of n, the prime p_2 occurs α_2 times, and so on. Then, the fundamental theorem of arithmetic[226] *states that the unique prime factorization of n is:*

$$n = p_1^{\alpha_1} p_2^{\alpha_2} \ldots p_k^{\alpha_k}. \tag{1}$$

The divisors of n are all possible products of prime powers where the power of p_j can assume the values $0, 1, 2, \ldots, \alpha_j$. We can then count $d(n)$, the number of different divisors of a number n (including 1 and n)

$$d(n) = (\alpha_1 + 1)(\alpha_2 + 1) \ldots (\alpha_k + 1). \tag{2}$$

One may also consider the sum of all divisors (again, including 1 and n)

$$\begin{aligned} \sigma(n) &= (1 + p_1 + p_1^2 + \cdots + p_1^{\alpha_1})(1 + p_2 + p_2^2 + \cdots + p_2^{\alpha_2}) \\ &\quad \times \ldots (1 + p_k + p_k^2 + \cdots + p_k^{\alpha_k}) \\ &= \frac{p_1^{\alpha_1+1} - 1}{p_1 - 1} \cdot \frac{p_2^{\alpha_2+1} - 1}{p_2 - 1} \cdot \ldots \cdot \frac{p_k^{\alpha_k+1} - 1}{p_k - 1}. \end{aligned} \tag{3}$$

Thus e.g.

$$d(p^\alpha) = \alpha + 1; \qquad \sigma(p^\alpha) = \frac{p^{\alpha+1} - 1}{p - 1}.$$

The function $\sigma(n) - n$ yields the sum of divisors of n other than n itself. This is known as aliquot parts of a number.

Examples of theorems:

- *Prove that $\log n \geq k \cdot \log 2$, where n is any natural number and k is the number of distinct primes that divide n.*

  This obviously holds for $n = 1$ $(k = 0)$ Let $n = p_1^{\alpha_1} p_2^{\alpha_2} \ldots p_k^{\alpha_k}$, where n is a natural number greater than 1 and $p_1, p_2, \ldots, p_k$ its prime divisors. Since none of the p_i is less than 2 and each $\alpha_i \geq 1$, then $n \geq 2^{\alpha_1 + \alpha_2 + \cdots + \alpha_k} \geq 2^k$. Taking the natural logarithm of this yields the desired result: $\log n \geq k \cdot \log 2$.

---

[226] This theorem does not seem to have been stated explicitly before **Gauss**. It was, of course, familiar to earlier mathematicians, but Gauss was the first to develop arithmetic as a systematic science.

- *Every composite number n has at least one prime divisor less than or equal to $\sqrt{n}$. Indeed, if n is a composite number, then $n = ab$, where a and b are natural numbers $< n$. Without loss of generality, we may assume that $a \leq b$. Hence $n = ab \geq a^2$ so that $a \leq \sqrt{n}$. But the number a is > 1, because if $a = 1$, then we should have $n = b$ while at the same time $b < n$. However, the number a has a prime divisor p which is obviously $\leq a$ and so $\leq \sqrt{n}$. But p, being a divisor of a divisor a of the number n, is also a divisor of n. The number n has therefore a prime divisor $p \leq \sqrt{n}$.*

- *For any number, the least divisor greater than 1 must be a prime number.*

  If the number is a prime, its least divisor greater than 1 is the number itself, which is a prime. If it is not a prime, and it has a composite least divisor, this number has lesser divisors (> 1) of its own so it cannot be the least.

Degree of compositeness

There are two ways in which it is natural to "measure", or quantify, the degree of compositeness of a number[227] n:

- *By its number of divisors, $d(n)$.*
- *By its number of prime factors: Let $f(n)$ denote the number of different prime factors and $F(n)$ denote the number of total prime factors. For example,*

  $$f(2^3 \cdot 3^2 \cdot 5) = 3; \qquad F(2^3 \cdot 3^2 \cdot 5) = 6; \qquad F(2^k) = k.$$

  [For a prime number n: $f(n) = F(n) = 1$.]

Dirichlet *(1838) showed that*

$$\lim_{n\to\infty} \left\{ \frac{1}{n}[d(1) + d(2) + \cdots + d(n)] \right\} \Rightarrow \ln n.$$

[227] In this section, "number" means "natural number" unless stated otherwise.

Ramanujan *(1917) proved that*

$$\lim_{n\to\infty} \frac{1}{n}[f(1) + f(2) + \cdots + f(n)] \Rightarrow \log\log n,$$

$$\lim_{n\to\infty} \frac{1}{n}[F(1) + F(2) + \cdots + F(n)] \Rightarrow \log\log n.$$

Twin primes

Clearly, there are no successive primes except 2 *and* 3*, since all primes* > 2 *are odd. However, there are many pairs of successive odd primes, known as twin primes, such as* $(3,5)$, $(5,7)$, $(11,13)$, $(17,19)$, $(29,31)$, $(41,43)$*. There are* $152,892$ *such pairs of numbers less than* 30 *million. We do not know whether the number of such primes is infinite. In other words, we do not know whether the number* 2 *can be written as a difference of two primes in an infinity of ways.*

The probability that two random numbers near x *are both prime is of order* $\left(\frac{1}{\log x}\right)^2$*; i.e. in an interval from* x *to* $x+a$ *one may expect of order* $\frac{a}{(\log x)^2}$ *such numbers. Actually, we should expect a bit more, since the fact that* n *is already a prime slightly changes the chance that* $n+2$ *is prime (e.g.* $n+2$ *is certainly odd). An easy heuristic argument gives* $c\frac{a}{(\log x)^2}$ *where* $c = 1.320\ 323\ 631\ 6\ldots$*. Thus, for example, in the interval between* $10^{15} \to 10^{15} + 150,000$*, the expected number of twin primes is* 166 *against* 161 *actually found. This extremely good agreement is especially surprising, since it has not yet even been proved that there are infinitely many such pairs, let alone that they are distributed according to the conjectured law.*

According to ***Hardy*** *and* ***Littlewood*** *(1922), the number of prime quadruplets (4-tuples of successive odd primes) with* $p < x$ *is asymptotic to*[228]

$$Q(x) = c\int_2^x \frac{dt}{(\log t)^4}, \qquad c = 4.151\ 180\ 863\ 237\ 4\ldots,$$

[228] In this chapter and elsewhere in this book we sometimes use the British notation $\log x$ for $\ln x$.

where c is known as the Hardy-Littlewood constant. In the vicinity of a large x*, the average density of prime quadruplets* $\sim \frac{dQ}{dx} = \frac{c}{(\log x)^4}$.

It is easy to prove that there exist arbitrarily long sequences of natural numbers which contain no prime numbers. A sequence of m *such successive numbers is, for example, the sequence* $(m+1)!+2,\ (m+1)!+3,\ (m+1)!+4, \dots, (m+1)!+(m+1),$ *because the first number of this sequence is divisible by* 2*, the second by* 3*, etc., and the last by* $m+1$*; thus they are all composite. For* $m = 100$ *the numbers would be gigantic, but between the prime numbers* 370,261 *and* 370,373 *there lie* 111 *successive composite numbers. Among the hundred and one successive numbers from* 1,671,800 *to* 1,671,900 *there is no prime number.*

It is difficult to prove that there exist prime numbers on both sides of which there are arbitrarily many composite numbers, i.e. that for every natural m *there exist prime numbers* p *such that each of the numbers* $p-k$ *and* $p+k$*, where* $k = 1, 2, \dots, m$*, is composite.*

In 1975, the largest known twin primes were

$$76 \cdot 3^{139} \pm 1 = \begin{array}{l} 158,733,282,881,841,916,274,491,012,923,328,901,749, \\ 236,259,319,203,520,296,443,150,620,292 \pm 1. \end{array}$$

By 1995, the record grew to numbers with 11,713 *digits!*

Fermat's Last Theorem[229] *(250–1980 CE)*

The history of FLT starts in ca 250 CE with **Diophantos**, *whose Arithmetica considered many problems in elementary number theory. A typical problem, taken from Book II, Problem 8, would be to divide a given square into the sum of two squares. His solution, in modern notation, is as follows: let a^2 be the given square for which one wants to find x and y such that $a^2 = x^2 + y^2$. As usual, Diophantos asks for rational solutions. For a suitably chosen number m, one can write $y = mx - a$. When this is substituted into the former equation, one finds $x = \frac{2am}{m^2+1}$. Here m may be any rational number. Diophantos must have proceeded only by illustrating the method on a sample. He chooses $a = 4$ and takes a solution that corresponds to $m = 2$ in our formula, giving $x = \frac{16}{5}$, $y = \frac{12}{5}$. One verifies that indeed $\left(\frac{16}{5}\right)^2 + \left(\frac{12}{5}\right)^2 = 4^2$.*

To us this problem is quite straightforward, but it was not always so. In the oldest preserved Diophantos manuscript, copied in the 13^{th} century, we find at this point the following heartfelt remark by the scribe: "Thy soul, Diophantos, to Satanos, for the difficulty of thy problems and this one in particular".

The Arithmetica was one of the last Greek mathematical works translated into Latin (1575). **Fermat** *(1601–1665) had a copy of Bachet's translation of 1621 and made a series of intriguing annotations in its margins. Sometime in the late 1630's, while reading the section which solves the problem given above, he added in the margin: "On the other hand, it is impossible to separate a cube into two cubes, or a biquadrate into two biquadrates, or generally any power except a square into two powers with the same exponent. I have discovered a truly marvelous proof of this, which however the margin is not large enough to contain".*

Thus, the basic claim of Fermat's Last Theorem is that the equation $x^n + y^n = z^n$ has no solutions when x, y, z are nonzero integers and $n > 2$.

---

229 To dig deeper, see:

- Stewart, I. and D. Tall, *Algebraic Number Theory and Fermat's Last Theorem*, A K Peters, 2002, 218 pp.
- Van der Poorten, A., *Notes on Fermat's Last Theorem*, Wiley, 1996, 222 pp.
- Ribenboim, P., *13 Lectures on Fermat's Last Theorem*, Springer-Verlag, 1979, 302 pp.

Generations of mathematical historians have debated whether Fermat really did have a proof, through many experts doubt that he did. For one thing, the equation $x^n + y^n = z^n$ *was atypical for Fermat — the vast majority of the other equations he studied dealt with exponents* ≤ 4. *Also, in his correspondence, he only stated FLT for the exponent* $n = 3$. *As for Fermat's "marvelous proof", it probably used his technique of infinite descent.*

His 'descent proof' for $n = 4$ *is actually known: it follows from a theorem of Fermat's on the area of a right triangle with integral sides not being able to be a square. This proof is given in one of his marginal notes — this time the margin was big enough. It seems likely that Fermat thought that his proofs for* $n = 3$ *and 4 can be generalized, but that they actually did not*[230].

After Fermat's death, in 1670, *his marginal notes were published by his son.*

In 1729, ***Goldbach*** *wrote Euler and mentioned the conjectures of Fermat presented in the published notes. This got* ***Euler***, *only* 22 *at the time, thinking about number theory. Three years later, Euler wrote his first paper on number theory, disproving a conjecture of Fermat on primes of the form* $2^{2^n} + 1$. *For the next forty years, Euler proved many of Fermat's conjectures and in so doing, transformed number theory from a collection of miscellaneous facts and results into an organized body of knowledge at the very center of mathematics.*

Consider an example of what Euler did: In Book VI of the Arithmetica, *Fermat had claimed in a marginal note that the only integer solutions to* $x^3 = y^2 + 2$ *are given by* $(x, y) = (3, \pm 5)$. *To prove this, Euler uses numbers of the form* $a + b\sqrt{-2}$, *with* a, b *integers.*

Here is his proof: $x^3 = y^2 + 2 = (y + \sqrt{-2})(y - \sqrt{-2})$. *One can show that* $y + \sqrt{-2}$ *and* $y - \sqrt{-2}$ *are relatively prime*[231], *and since their product*

230 Fermat claimed to have found a proof of the theorem at an early stage in his career (1637). Much later (1659) he spent his time and effort proving the cases $n = 4$ and $n = 5$. Had he had a proof to his theorem earlier, there would have been no need for him to study specific cases.

Furthermore, if he really thought he had a proof, he would have announced the result publicly, or challenge some English mathematician to prove it. It is likely that he found a flaw in his own proof, and never bothered to erase the marginal comment because it never occurred to him that anyone would see it there. All the facts indicate that Fermat quickly became aware of the incompleteness of the (allegedly general) "proof" of 1637. Of course, there was no reason for a public retraction of his privately made conjecture.

231 No common factor $p + q\sqrt{-2}$ for any integer p, q. These complex numbers $p + i\sqrt{2}q$, form a *ring*.

is a cube of $(x+0\sqrt{-2},)$ *each of them must also be a cube of a number of the form: integer + integer*$\sqrt{-2}$*, so*

$$y+\sqrt{-2}=(p+q\sqrt{-2}\,)^3=p^3-6pq^2+(3p^2q-2q^3)\sqrt{-2}$$
$$\Rightarrow 1=3p^2q-2q^3=q(3p^2-2q^2).$$

The last equation implies $p=\pm1$ *and* $q=1$*. Substituting this in, we get* $y=p^3-6pq^2=\pm5$ *and* $x=3$*, as claimed.*

This proof, while elegant, is incomplete, for we have not shown that numbers of the form $a+b\sqrt{-2}$ *have unique factorizations into primes, or even for that matter, that there are primes in this ring, or that any ring element factorizes into them (although it is relatively easy to prove that the numbers* $a+b\sqrt{-2}$ *do have these properties). There are three reasons why the above example is important:*

- ▷ *It reminds us that there are many Diophantine equations besides just FLT, and that what we really want is a method for dealing with as many of them as possible.*
- ▷ *It generalizes the integers to a set of numbers which has much of the same arithmetic structure (addition, multiplication, etc.). This sort of generalization occurs frequently in mathematics.*
- ▷ *Finally, the equation* $y^2=x^3-2$ *is an example of an elliptic curve. Elliptic curves play a crucial role in the eventual 1990s proof by A. Wiles of FLT, which uses analytical number theory.*

Clearly it is sufficient to prove FLT for $n=4$ *(done by Fermat) and for* n *an odd prime, since we can factor the exponent. It can also be assumed that* x*,* y*,* z *are nonzero relatively prime integers, because we can cancel common factors. By the early 1800's, all of Fermat's problems were solved except for FLT (thus engendering the name, Fermat's Last Theorem). That being said, the highlights of the* 19^{th} *century work on the FLT is given by the following chronological list:*

- *1816 — The French Academy announces a prize for resolutions of FLT (either proof of the conjecture or of its falsehood).*
- *In the 1820's,* ***Sophie Germain*** *showed that if* p *and* $2p+1$ *are prime, then* $x^p+y^p=z^p$ *has no solution with* $p\nmid xyz$*. This latter condition defines the so-called Case I of FLT. [Case II is where* $p\mid xyz$ *and is usually regarded as being much harder.]*
- *1825 —* ***Dirichlet*** *and Legendre prove FLT for* $n=5$*.*

- *1832* — ***Dirichlet***, *after trying to prove it for* $n = 7$, *proved it for* $n = 14$.
- *1839* — ***Lamé*** *proved FLT for* $n = 7$.
- *1847* — *Lamé and Cauchy presented false proofs of FLT.*
- *1844–1857* — ***Kummer****'s work on FLT.*

Kummer (and Cauchy and Lamé) started, á la Euler, by factoring the right hand side of the FLT equation as

$$x^p = z^p - y^p = (z - y)(z - \zeta y)(z - \zeta^2 y \cdots (z - \zeta^{p-1} y)$$

where $\zeta = e^{2\pi i/p} = \cos(2\pi/p) + i\sin(2\pi/p)$ *is a* p^{th} *root of unity* *and satisfies* $\zeta^p = 1$. *In general, working with roots of unity will require us to use number rings of the form* $a_0 + a_1\zeta + \cdots + a_{p-1}\zeta^{p-1}$, $a_1 \cdots a_{p-1} \in \mathbb{Z}$ *which are called cyclotomic integers* *(*$\mathbb{Z}$ *is the ring of integers:* $0,\ \pm 1,\ \pm 2,\ \ldots$*). But a problem arises when unique factorization, one of our main tools, fails for the cyclotomic integers. As Kummer discovered in* 1844, *this first occurs for* $p = 23$ *(and now we know that unique factorization fails for all larger primes as well).*

Kummer's solution to this was twofold. First, he introduced a generalization of cyclotomic integers, called ideal numbers, *which make up for the lack of unique factorization. Second, he defined the* class number h, *which measures how badly unique factorization is violated.*

Here is a summary of Kummer's results:

- *1847* — *Theorem: FLT holds for* p *if* $p \nmid h$ *(such* p *are called* regular primes*).*
- *1847* — *Theorem:* p *is regular iff* p *does not divide the numerator of the Bernoulli numbers* $B_2, B_4, \ldots, B_{p-3}$.

  We can define the Bernoulli numbers by the Taylor expansion $\frac{x}{e^x - 1} = \sum_{n=1}^{\infty} \frac{B_n}{n!} x^n$. *A corollary of this result is that for* $p < 100$, *only* 37, 59, *and* 67 *are irregular.*
- *1850* — *The French Academy offers a second prize for a solution to FLT, withdraws it, and then awards a medal to Kummer.*
- *1857* — *Kummer develops complicated criteria for proving FLT for certain irregular primes. There are some gaps in his proofs which are later filled by* ***H.S. Vandiver*** *in the* 1920*'s. These results establish FLT for* $p < 100$.

Further developments occurred as follows:

- *1908 — The Wolfskehl prize for a solution to FLT is announced. Later inflation of the Deutschmark reduced the value of this prize considerably, but did not reduce the flow of crank solutions submitted.*
- *1909 —* ***Wieferich*** *proved that if* $x^p + y^p = z^p$ and $p \nmid xyz$ *(Case I of FLT), then* $2^{p-1} \equiv 1 \bmod p^2$*. This is a strong congruence which is particularly easy to check on a computer.*
- *1953 —* ***Kustaa Adolf Inkeri*** *(1908–1997, Finland) proved that if* $x^p + y^p = z^p$ and $x < y < z$, *then* $x > p^{3p-4}$.
- *1971 —* ***Brillhart***, ***Tonascia*** and ***Weinberger*** *showed that Case I of FLT is true for all primes less than* $3 \cdot 10^9$.
- *1976 —* ***Wagstaff*** *showed that FLT is true for all primes less than* 125, 000.

The conclusion of all this work is that any counter-example to FLT must involve $p > 125,003$ *and* $z > y > x > (125,003)^{375,005} \approx 4.5 \cdot 10^{1,911,370}$.

Missing from the present account of FLT is the work of the many mathematicians who created the theories of reciprocity theorems, class field theory, elliptic curves, modular forms and Galois representations, and searched out the amazing connections between them[232]; and also the work in the 1980s and 1990s, including the first valid proof of FLT by A. Wiles in the 1990s.

1909–1913 CE **William David Coolidge** (1873–1975, USA). Physicist and inventor. Developed a method of producing fine tungsten wires for use as filaments of light bulbs (1909). Invented the '*Coolidge tube*', a device for emitting X-rays (1913). This invention completely revolutionized the generation of X-rays and remains to this day the model upon which all X-ray tubes for medical applications are patterned.

232 For example, it was discovered only in 1984 by **R.C. Mason** that the proof of Fermat's theorem for *polynomials* is rather trivial!
Let $x(t)$, $y(t)$, $z(t)$ be relatively prime polynomials in one variable over the field of complex numbers. Then $[x(t)]^n + [y(t)]^n = [z(t)]^n$ is valid only for $n \le 2$. The proof follows as a corollary of *Mason's theorem* (1984): If $a(t)$, $b(t)$, $c(t) = a(t) + b(t)$ be relatively prime polynomials, then $\max\ \deg\{a, b, c\} = n_0(abc) - 1$, where $n_0(f) =$ number of *distinct* roots of f.

Coolidge was born in Hudson, MA and graduated from M.I.T. (1896), majoring in electrical engineering. He received his Ph.D. from the University of Leipzig. During WWII he contributed to the development of radar.

1909–1917 CE **Sören Peter Lauritz Sörensen** (1868–1939, Denmark). Chemist. Introduced the symbol pH to denote the negative logarithm of the concentration of the hydrogen-ion in a *Sörensen scale* that serves as a measure of acidity or alkalinity of a solution. Pointed out the effect of pH on enzyme activity.

Sörensen was director of Chemical Department, Carlsberg Laboratory, Copenhagen (1901–1939).

Acidic solutions contain hydrogen-ions, H^+ (actually *hydroniom-ions*, H_3O^+). A basic solution contains hydroxide-ions, OH^-. *Pure water* at 25°C contain hydrogen-ions in concentration 1×10^{-7} mole/liter, and hydroxide-ions in the same concentration. These ions are formed by the dissociation of water[233]: $H_2O \rightleftharpoons H^+ + OH^-$. *Acidic solutions* contain hydrogen-ion in large concentration and hydroxide-ion in a very small concentration. The range of acidities and basicities for aqueous solutions fall between 1 mole/liter solutions of strong acids and 1 mole/liter of strong bases. It includes practically all the solutions associated with the *metabolism of living organisms* as well as most of the aqueous solutions taking part in *geological processes*. The corresponding hydrogen-ion concentrations lie between 1 and 10^{-14} mole/liter.

Sörensen expressed the acidities of aqueous solutions on a logarithmic scale, defined as: $\mathrm{pH} = -\log_{10}[H_3O^+]$. The symbol pH was intended originally as an abbreviation for the phrase "potential of hydrogen-ion". Electric potential difference between the electrodes for certain types of galvanic cells vary linearly with this particular property of the electrolyte. So called "pH meters" operate on this principle.

Sörensen reported in 1917 that *egg albumin* has a molecular weight of 34,000 (determined through osmotic pressure measurements).

---

233 The reaction $H^+ + OH^- \rightleftharpoons H_2O$ has an *ion-product*

$$K_W = [H] \times [OH^-] = 1.0 \times 10^{-14} \mathrm{mole}^2/\mathrm{l}^2$$

at room temperature (25°C). The quantity pH is defined as the *negative logarithm of the hydrogen ion-concentration*. At the *neutral point* where $[H^+] = [OH^-]$, the pH is 7. If $pH < 7$, the solution is *acid*; if $pH > 7$, the solution is *alkaline*.

1909–1925 CE **Karl Bosch** (1874–1940, Germany). Chemist. Developed the nitrogen fixation process for the synthesis of ammonia (invented by **Fritz Haber**) to an industrial scale (1914), enabling the Germans to manufacture explosives without relying on foreign imports of nitrogen bearing materials, capable of being blocked by the allies in WWI. In peacetime, the process allowed the cheap manufacture of fertilizers, equally vital to the survival of a country. Invented a process for manufacture of hydrogen (1925).

Bosch was born in Cologne and studied chemistry at the University of Leipzig, taking his doctorate in 1898. He became chairman of the vast industrial conglomerate IG Farbenindustrie AG (1925). In 1931 he received the Nobel Prize for Chemistry (jointly with **Friedrich Bergius**) for their work on high-pressure synthesis reactions.

1909–1926 CE **Peter** (**Joseph William**) **Debye** (1884–1966, Netherlands and U.S.A.). Physicist. Contributed widely to physical chemistry and particularly to our understanding of solids. His theory on the thermal vibration of a solid (1911) is among his best known works. Studied molecular structure through investigations on *dipole moments* and on diffraction of X-rays and electrons in crystals and gases (1916). Proposed (with **Giauque**, 1926) that paramagnetic salts could be used for achieving very low temperatures.

Revised **Pierre Dulong** and **Alexis Petit**'s value of 6 cal/mole/°C for the molar heat capacity of most substances (1819) by correcting at low temperatures for quantum freeze-out of vibrational modes of the atoms (1912). The resulting theoretical curve, which descends to 0 cal/mole/°C at 0°K, is found to agree with experiment and was seen as an early success for quantum physics.

Discovered (1909) a useful asymptotic expansion of Bessel functions for large real argument x and index ν (ν/x fixed). Awarded the 1936 Nobel prize in chemistry.

Debye was born in Maastricht, Holland. Director of Kaiser Wilhelm Institute for Physics, Berlin (1935–1940). Professor at Cornell University (1940–1950). Debye was a Nazi sympathizer and intensely supported the German Nazi Party and Hitler from May 1933 together with his friends **Werner Heisenberg** and **George Braque**.

However, being a Dutch citizen, he was forced to leave Germany after the German occupation of the Netherlands.

1909–1929 CE **Phoebus Aaron Theodor Levene** (**Fishel Aaronovich Levin**, 1869–1940, U.S.A.). Biochemist. Discoverer of RNA and DNA.

First to identify *sugar ribose* (1909) and *deoxyribose* (1929) in nucleic acids[234]. Levene maintained that, in the nucleic acid molecule, each ribose (or deoxyribose) portion has a phosphorous group attached to one side and a *purine* or *pyrimidine* to the other. This combination of groups is called a *nucleotide*. In his pioneering work Levene determined the formation of nucleotides and how they combine in *chains*.

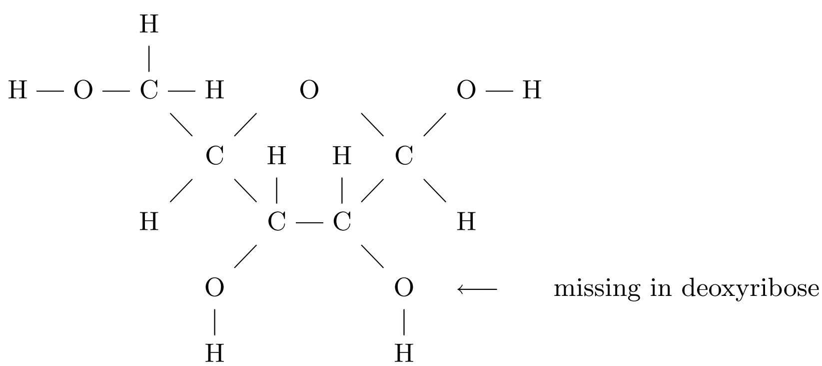
Levene was born in Sagor, Russia to Jewish parents and immigrated to the U.S. in 1892. He was a member of the Rockefeller Institute (now Rockefeller University) during 1905–1939.

1909–1930 CE **Otto Selz** (1881–1943; Germany). Father of modern cognitive psychology. Had decisive influence on the key ideas of Popper's philosophy of science with its emphasis on the method of trial and error. His theory of problem solving and scientific discovery laid the foundation for much of contemporary cognitive psychology. Expounded his views in his books: "*Über die Gesetze des geordneten Denkverlaufs*" (1913) and "*Zur Psychologie des produktiven Denkens und des Irrtums*" (1922).

Otto Selz was born in Munich to Jewish parents. Studied law and philosophy in Munich and Berlin (Ph.D. 1909; Habilitation at the University of Bonn 1912).

---

[234] *Ribose* differs from glucose, fructose, and galactose in that it has 5 carbons instead of 6. This five-carbon chain tends to form a ring with an oxygen atom connecting the first and 4-th carbon atoms



Later, Levene discovered that not all nucleic acid molecules contain ribose; some contain a closely related sugar, which differs only in the absence of one of the oxygen atoms of ribose. Its name is, therefore, *deoxyribose*.
It is on the basis of these two sugars that nucleic acid came to be divided into two groups: *ribonucleic acid* (RNA), which contained ribose; and *deoxyribonucleic acid* (DNA), which contained deoxyribose.

After serving on the Western front in WWI (1915–1918) he occupied positions in psychology and philosophy at the Universities of Bonn and Mannheim (1920–1932).

In 1933 he was dismissed from his academic positions because of his Jewish descent and he went into exile in the Netherlands. In 1942 the Nazis confined him to the Amsterdam Ghetto. He was arrested (1943) and soon thereafter perished with his entire family in the gas chambers of Auschwitz.

1909–1933 **Alfred Haar** (1885–1933, Hungary). Mathematician. Worked in analysis, studying orthogonal systems of functions, partial differential equations, Chebyshev approximations, linear inequalities and compact continuous groups.

In his doctoral thesis (under Hilbert, 1909) he discovered the first *wavelet*[235] *basis* (system of compactly supported orthonormal functions generated from a single function by translation and dilation) known as *Haar-basis*. Introduced (1932) a measure on groups, now called the *Haar measure*, which allows an analogue of Lebesgue integrals to be defined on locally compact topological groups [it was used by **von Neumann**, by **Pontryagin** (1934) and **Weil** (1940) to set up an abstract theory of commutative harmonic analysis].

Haar was born in Budapest and died in Szeged. He traveled to Germany (1904) to study at Göttingen. He taught there until 1912, when he returned to Hungary and held chairs at Budapest and Szeged universities.

1909–1937 CE **Constantin Carathéodory** (1873–1950, Greece and Germany). Pure and applied mathematician. Made significant contributions to the calculus of variations, theory of real and complex functions, conformal mapping and the theory of point-set measure. An *outer measure* and a *pseudomeasure* in complex analytic space are named after him. His interests also extended beyond pure mathematics into applications to mechanics, thermodynamics, relativity theory and geometrical optics.

---

[235] *Wavelet theory* is based upon a multiresolution spectral decomposition that allows information in both time and frequency domains (or space and wavenumber domains) to be retained. Earlier pioneers (except **Alfred Haar**) include **Paul Levy**; **Eugene Wigner** (*Wigner distribution*, 1932); **Dennis Gabor** (*Gabor expansion*, 1946). **Jean Morlet** and **Alex Grossman** (1975–1981) initiated modern wavelet theory while developing the previous idea of *Windowed Fourier Transform* (D. Gabor). It has since found extensive applications in digital signal processing, image processing and music. Important later contributions were made by **Y. Mayer** and **Stephane Mallot** (1986), **I. Daubechies** (1988) and **L. Cohen** (*Cohen classes*, 1989).

Carathéodory was born in Berlin and attended Belgium's École Militaire (1891–1895), then worked as engineer on the Asyut Dam in Egypt. In 1900 he begun to study mathematics at the University of Berlin. Transferred (1902) to Göttingen and received his Ph.D. (1904) there under **Hermann Minkowski**. He held professorships at various universities in Germany and, 1920–1924, in Greece. From 1924 he was at th University of Munich; where he stayed throughout the entire Nazi regime and WWII.

1909–1944 CE **Richard Martin von Mises** (1883–1953, Austria and U.S.A.). Applied mathematician. Contributed significantly to the fields of statistics, probability, mechanics, aerodynamics and philosophy of science.

His primary work in statistics concerned the theory of measure, and introduced the use of *statistical functions*. Suggested axiomatic systems for the logical foundation of the theory of probability [in his book: "Probability, Statistics and Truth"]. In aerodynamics, he made fundamental advances in boundary-layer-flow theory and air-foil design. In elasticity theory, he originated criteria for fracture (*Von Mises yield-criteria*).

Von Mises was born to Jewish parents in Lvov, Poland and was educated in Vienna. He was a professor of applied mathematics at the University of Strasbourg (1909–1916). He served as a pilot in the German army during WWI. After the war he moved to the University of Dresden and then became professor of applied mathematics and director of the Institute for Applied Mathematics at the University of Berlin (1920–1933). With the rise of the Nazis to power in 1933 he became a professor of mathematics at the University of Istanbul (1933–1939). Finally, in 1939, he joined the staff of Harvard University, where in 1944 he became professor of aerodynamics. His philosophical views are summarized in his book: "*Positivism*: *A Study in Human Understanding*" (1951).

1909–1915 CE **Howard Robard Hughes, Sr.** (1869–1924, USA). Inventor. Revolutionized the process of drilling for oil with his invention of the first *rotary rock bit*.

Hughes was born in Lancaster, Missouri and spent his boyhood in Keokuk, Iowa, where his father maintained a law practice. He studied law at Harvard University and the University of Iowa, but in 1901 he joined the 'Oil Rush' in Texas.

Around 1906, Hughes became interested in finding a solution to the problem of drilling through hard rock formations and began experimenting. While working in 1908 in Oil City, Louisiana with his business associate, **Walter Sharp**, Hughes produced a small wooden model of a roller-type bit with cone-shaped tooth cutters. The following year, he successfully tested the first rotary bit in an oil well at the Goose Creek field, just east of Houston. Since it was the first cone-type rock bit featuring rolling cutters, capable of drilling faster and more efficiently, he formed, with Walter Sharp, the Sharp-Hughes Tool Company to manufacture and market his new bit and tool joints.

Hughes is credited with the invention of numerous other time and money saving drilling services. With his operation headquartered in Houston, his early advances in rotary drilling technology focused attention on the city as the world's leading manufacturer of drilling equipment and tool joints. After Sharp's death in 1912, Hughes bought Sharp's share of the business, and in 1915 renamed the firm the Hughes Tool Company.

Hughes died at the age of 54, leaving the bulk of his million dollar oil well drilling equipment firm to his son **Howard Robard Hughes, Jr.**[236] (1905–1976), an 18-year old student at Rice Institute.

1909–1949 CE **Maria Montessori** (1870–1952, Italy). Physician and educator. Developed a special method of teaching young children through

[236] Aviation-pioneer film producer and industrialist. At one time he owned the *Hughes Tool Company*, the *Hughes Aircraft Company*, *RKO Pictures Corporation*, and a controlling interest in *Trans World Airlines*. At the time of his death, his financial empire was worth about two billion dollars, becoming one of the richest men in the world.

He designed and raced airplanes and set several speed records including (1938) around-the-world mark of 3 days, 19 hours, 14 minutes. In the 1940's he designed the largest plane ever built up to that time. This 8-engine wooden flying boat (nicknamed the *Spruce Goose*), had room for 700 passengers and weighed about 200 tons.

His aircraft company pioneered many innovations in aerospace technology. In the 1950's and beyond, Hughes manufactured spy satellites.

In the mid-1950's, Hughes deliberately dropped out of sight. He became a mysterious figure who never appeared in public and even refused to be photographed.

Hughes died en route by private jet to a hospital in Houston. His drastically changed appearance and the fact that he had been seen by so few people for so long forced the Treasury Department to use fingerprints to identify his body.

Four hundred prospective heirs tried to inherit his $2 billion estate, but it eventually went to 22 cousins on both sides of the family. Texas, Nevada and California claimed inheritance-tax in disputes reviewed by the Supreme Court three times. *Hughes Aircraft* ended in the hands of *Hughes Medical Institute*, which sold it to *General Motors* (1985) for $5 billion.

Hughes never graduated from high-school. Nonetheless, his father arranged for him to audit mathematics and engineering classes at CalTech in Pasadena, California, by donating money to the school.

Houston's airport was renamed in his honor.

work rather than play, and aimed at creating a scientific pedagogy. According to the *Montessori method*, children should be helped to learn by themselves and gain confidence in themselves while making use of their abilities.

Maria Montessori was born in Ancona and was the first woman in Italy to earn a medical degree (1894). She became a professor of anthropology (1904–1908) and opened the first Montessori school for children in Rome (1907). Later she traveled throughout the world, writing and lecturing about her teaching method. She inspired many devoted supporters in the USA, Britain and on the Continent who sought to implement her ideas in schools, societies and associations.

1910 CE, May 20 *Comet Halley*[237] came within 23 million km (0.153 AU) of earth, traveling with relative velocity of 83 $\frac{\text{km}}{\text{sec}}$ (52 $\frac{\text{km}}{\text{sec}}$ w.r.t. sun). On May 21, earth passed through the tail of the comet with no ill effects; many people feared that the inhabitants of earth would be wiped out by cyanogen gas detected in the nucleus of the comet.

1910 CE *The International Geological Congress at Stockholm* first made the majority of geologists familiar with the existence of a warm period interlaced between the ice-age and the present. Up to the turn of the 20^{th} century the post-glacial period was supposed to show merely a more or less rapid warming up to the present level, followed by a long period in which the climate of the different parts of the world were exactly as we now find them.

About the same time (1908), a number of investigations in different countries combined to prove that the ice-age itself was not so remote as it had seemed to be, and that in fact the post-glacial "geology" of Europe was partly contemporaneous with the "history" of Egypt. The beginning of the "period of unchanging climate" has advanced later and later until it stopped only a few centuries BCE.

Moreover, it became clear that the present does not differ from the past in the sense that variations of climate are still in progress, which are similar in kind, though not in extent, to the climatic vicissitudes of the ice-age. There is, however, one point in which the "historical" period may be said to differ from the "geological" periods — any climatic changes in the "historical" period

---

[237] Mark Twain told his biographer, Albert Bigelow Paine (1909):
"I came in with the Halley Comet in 1835. it is coming again next year, and I expect to go out with it. The Almighty had said, no doubt: 'Now here are these two unaccountable freaks; they came in together, they must go out together.' Oh! I am looking forward to that."
As fate would have it, it happened just that way.

must be attributed to *non-geographical* factors, and most probably due to variations in solar radiation.

1910 CE **Georges Claude** (1871–1966, France). Chemist, physicist and inventor. Invented *neon light* (first used commercially in 1923). Showed that acetylene dissolved in acetone can be safely transported (1897). Produced liquid air by expansion method (1902) and separated from it the various gases of the air; invented new method for synthesis of ammonia (1917). Imprisoned (1945–1949) as Nazi collaborator in WWII.

1910 CE **L. Southerns** showed that the ratios between mass and weight for uranium oxide and lead oxide, respectively, differed at most by 5 parts per million. Since the binding energy of uranium oxide is particularly high, this experiment proves that the proportionality of inertial and gravitational mass ("weak equivalence principle") applies also to atomic binding energy (via $E = mc^2$).

1910–1913 CE Bubonic plague in China. Death toll reached millions.

1910–1927 CE **Thomas Hunt Morgan** (1866–1945, U.S.A.). Geneticist. Proposed a theory of sex-linked inheritance including the *principle of linkage*. Established the importance of the gene and the chromosome in transmitting inherited characteristics. From his examination of hundreds of mutant characters in *Drosophila* he established that inherited characters are connected to paired Mendelian factors or *genes* and that genes are linearly joined into chromosomes. Although the inheritance of characteristics from genes positioned along different chromosomes occurs independently, as in **Gregor Mendel**'s second law, this does not apply for characteristics from genes along the same chromosome. These later characteristics tend to be inherited as a group.

Morgan was born in Lexington, KY. He was professor at Columbia University (1904–1928) and from 1928, at CALTECH. Awarded the Nobel prize for physiology or medicine (1933).

1910–1928 CE **Ernst Steinitz** (1871–1928, Germany). Mathematician. Made substantial contributions to the algebraic theory of fields (Steinitz's '*replacement theorem*'), algebraic geometry and the theory of polyhedra.

Steinitz was born to Jewish parents in Silesia and was educated at the University of Breslau (Ph.D., 1894). He began his career at the Technical College in Berlin-Charlottenburg and ended it at the University of Kiel.

1910–1939 CE **Jan Lukasiewicz** (1878–1956, Poland). Influential mathematical logician. One of the founders of the school of logicians in Poland after WWI. Made important contributions to *modal logic* (in which 'is possible' is allowed as a fundamental notion) and *many-valued logics* (in which truth-values additional to 'true' and 'false' are admitted). In particular he developed a *three-valued propositional calculus* (1917) and devised a notation system for syllogistic propositions. Made detailed study of Aristotle's syllogistic (1910) and reevaluated ancient and medieval logic by employing modern formal techniques of logic. He also introduced into logic the '*Polish notation*' which has found favor in computing for its avoidance of brackets.

Lukasiewicz was born in Lvov (Lemberg). Was Polish Minister of Education (1919) and professor at Warsaw University (1920–1939). When the Russians occupied Poland (1945), Lukasiewicz was politically persecuted and had to seek asylum in Dublin (Irish Republic), where he was appointed to the Royal Irish Academy. He died in Dublin.

1910–1943 CE **Janusz Korczak** (1878–1943, Poland). Physician, child psychologist, writer and educator. Founder of an original system of education and one of the finest examples of selflessness and caring for others in human history.

Born in Warsaw as **Henryk Goldszmit**, he was one of the few Jews to be accepted for medical studies of the University of Warsaw, graduating in 1905. He continued his training in pediatrics both in Berlin and Paris under Virchow, Marfan and Charcot. During the Russo-Japanese War he served in field hospitals and wards in the Ukraine and in Manchuria.

Early in his medical career he began to write poetry and fiction under the pseudonym Janusz Korczak. In 1910 he decided to give up both his successful pediatric practice and his literary career to become the director of orphanages. In these "children's republics" he experimented with his progressive ideas by allowing children to govern themselves with as much independence as possible. Disinterested in personal affairs, he lived a monastic existence.

With the German take-over of Poland, the orphanages were closed on Aug 06, 1942 and Korczak with his two hundred children were deported to Treblinka where they perished in the Gas-Chambers on August 5, 1943. (Because of his fame,, he was offered safe passage out of the Warsaw Getto, but he refused a chance to save himself and was voluntarily deported with the children).

1910–1940 CE Pre WWII Western music. Its leading composers are:

- Ermanno Wolf-Ferrari 1876–1948
- Earnst Bloch 1880–1959
- Bela Bartok 1881–1945
- Zultan Kodály 1882–1967

• Igor Stravinsky	1882–1971
• Joseph Achron	1886–1943
• Arthur Honegger	1892–1955

1911 CE **Robert Andrews Millikan** (1868–1953, U.S.A.). Distinguished experimental physicist. Determined the charge of the electron and established it as a fundamental unit of electricity. Verified the Einstein photoelectric equation, and obtained a precise value for the Planck constant.

Prior to 1911, the ratio e/m of the electron's charge to its mass had been determined experimentally by **J.J. Thomson** and others. It remained to find the magnitude of the charge (e) so that the mass (m) of a single particle might be calculated.

In his famous 'oil-drop experiment'[238] Millikan obtained the first *direct* and compelling measurement of the electric charge of a *single* electron, with an accuracy of one percent [owing to errors in the viscosity coefficient as applied to very small droplets].

Millikan found that the charge of an oil drop is an integral multiple, ne, of some basic unit, which is identified as the charge on one electron. The most important feature of the 'oil-drop experiment' is its clear demonstration that electric charge is *quantized*. With the aid of e and $\frac{e}{m}$, the electronic mass could finally be fixed, and was found to be $\frac{1}{1837}$ of the mass of a

[238] A vertical electric field E (which could be switched on and off) was set up between two parallel plates. The upper plate had at its center a few small perforations through which oil drops, produced by an atomizer, could pass. Most of the oil drops were charged by friction with the nozzle of the atomizer. With the electric field switched off, a single droplet of mass $m = \frac{4\pi}{3}r^3\rho$, density ρ, and radius r is acted upon by its own weight mg and the opposing frictional Stokes-force $6\pi\eta rv$. In equilibrium (no acceleration), the drop's downwards terminal velocity is $v_1 = \frac{2r^2g}{9\eta}(\rho - \rho_a)$, where ρ_a is the air density accounting for buoyancy. With the (upward) field switched on, the new terminal velocity (upward) is $v_2 = \frac{neE}{6\pi\eta r} - v_1$, where ne is the charge (taken positive). Expressing r in terms of v_1, η, g and $(\rho - \rho_a)$, one finds $ne = \frac{6\pi\eta(v_1+v_2)}{E}\sqrt{\frac{9\eta v_1}{2g(\rho-\rho_a)}}$.

neutral hydrogen atom. The electron is by far the most important particle in theoretical chemistry, as well as in atomic physics.

Millikan was born in Morrison, Illinois. After studying at the Universities of Berlin and Göttingen, he joined the faculty of the University of Chicago. In 1921 he became director of the Norman Bridge Laboratory of Physics at the California Institute of Technology, Pasadena. He won the Nobel prize for physics in 1923.

1911 CE **Heike Kamerlingh Onnes** (1853–1926, Holland). Dutch physicist. Discovered '*superconductivity*'[239] of metals with the aid of liquefied helium. Won the Nobel prize for physics in 1913 for his work on low-temperature physics and his production of liquid helium (1908).

---

[239] The complete and sudden vanishing of electrical resistance in certain pure metals, when cooled to a temperature near absolute zero. For materials that are good conductors, such as copper and silver, the resistivity decreases essentially linearly with temperature down to 10 K. As the temperature decreases further, the resistivity assumes a constant value that is maintained up to the lowest temperatures investigated (ca 0.05 K). In certain materials, called *superconductors*, there occurs at low temperatures a remarkable interaction among the electrons and the ionic lattice. In the superconducting state, *pairs* of electrons with spin and momenta *antialigned*, develop an extremely weak electrical attraction for each other by interaction with the lattice [the attraction of the two electrons may be thought of as a two-step process in which the passage of one electron creates a distortion in the lattice to which the second electron is attracted]. The bound state of the two electrons is called a *Cooper pair*. The size of the Cooper pair is far larger than the size of an atom, and they all have the same center-of-mass drift speed. A Cooper pair is bound by an energy of the order 10^{-3} eV, and the energy required to break this bond is not available at low temperatures. Thus, at least in principle, the mean free path of the pair becomes infinite and the resistivity becomes zero (not just very small, but *zero*!). The temperature that marks the transition between the normal phase and the superconducting phase of a material is called the *critical temperature* T_c (e.g. 4.15 K for mercury, observed by Onnes). A current, once initiated in a superconducting material, will continue to flow (essentially) forever, even in the absence of any driving electric field.

The superconductors discovered by Onnes are not merely *perfect conductors*, they have the additional property that there is a zero magnetic field inside the superconductor (except for a thin surface layer). This class of superconductors is called *type-1*. Thirty pure elements (Be, Al, Ti, V, Zn, Ga, Zr, Nb, Mo, Tc, Ru, Rh, Cd, In, Sn, Lu, Hf, Ta, W, Re, Os, Ir, Hg, Tl, Pb, La, Gd, Th, Pa, U) are type-1 superconductors at low temperatures.

During 1871–1873 Kamerlingh Onnes studied and worked at Heidelberg University, notably with **Kirchhoff**. From 1882 to 1923 he served as professor of experimental physics at the University of Leyden.

1911 CE, July 24 **Hiram Bingham** (1875–1956, USA). Explorer, historian, archaeologist and politician. Found the "lost city" of *Machu Picchu* near Cuzco in the Peruvian Andes, the fortified city that was the sanctuary of the Inca king Pachacuti (d. 1470). It lies in the saddle between two peaks, 660 m above the rapids of the Urubamba river. Machu Picchu was one of a series of stone-laid cities which constituted a veritable chain of fortress-sanctuaries, built to defend the empire from raids of the wilder jungle tribes. All the cities, approximately 15 km apart, are bound together by a stone-laid road.

Machu Picchu was never mentioned by the Inca to the Spaniards, and dates from the first Inca, about 1000 CE.

Bingham was born in Honolulu. He graduated from Yale University and later taught history there. From 1926 to 1933, he served as a Republican U.S. Senator from Connecticut.

1911 CE **Victor Hess** (1883–1964, Austria). Physicist. Discovered *cosmic radiation* (cosmic rays) by sending electroscopes aloft in balloons. He was able to show that the ionization effect was more pronounced at high altitudes rather than less so. To explain this phenomenon, Hess advanced the hypothesis that the ionizing radiation responsible for the observed effects is incident upon the earth's atmosphere from *outside*.

1911–1914 CE **Elmer Ambrose Sperry** (1860–1930, U.S.A.). Inventor and industrialist. Developed the gyrocompass and the gyroscopic stabilizer for ships and aircraft. From his gyrocompass, Sperry developed the gyropilot, which steers a ship automatically. Later he installed giant gyroscopes which could steady the rolling motions of ships. He also produced an aerial torpedo controlled by a gyroscope. Today's naval gunnery methods would be impossible without inventions which grew out of Sperry's original gyroscope. His inventions were equally important for use in navigating aircraft.

Sperry was born in Cortland, New York. He set up his Sperry Gyroscope Company in Brooklyn in 1910. His gyrocompass was first installed on the U.S. battleship **Delaware** in 1911. In his lifetime, Sperry founded 8 manufacturing companies and took out more than 400 patents.

1911–1919 CE **John Edensor Littlewood**[240] (1885–1977, England). Distinguish mathematician. Made significant contributions to the theory of

[240] For further reading, see:
- Du Sautoy, M., *The Music of the Primes*, Perennial, 2004, 335 pp.

functions, theory of numbers, summability of series, inequalities and Fourier series theory. Along with **G.H. Hardy**, with whom he collaborated for 35 years, he was instrumental in establishing the school of mathematics in 20^{th} century Great Britain[241]. The Hardy-Littlewood partnership was extremely successful and the individual contributions are mostly inseparable, especially as far as proofs of the theorems are concerned[242].

In 1912, Littlewood showed that $\int_2^n \frac{dx}{\log x}$ switches from being an overestimate (to the number of primes less than or equal to n) to an underestimate, and back again, an infinite number of times as n keeps increasing (Littlewood's theorem)[243].

Littlewood was born in Rochester, England. He entered Trinity College, Cambridge in 1903, and started research in 1906 under the tutorship of **E.W.**

---

241 Compared with the mathematics of continental Europe, 19^{th} century British mathematics was rather barren of significant figures, and was most emphatically subordinate to the natural sciences.

242 **Norbert Wiener** (1894–1964) spend the early years of his career working in England. The story goes that when he met Littlewood he said: "*Oh, so you really exist. I thought that 'Littlewood' was just a pseudonym that Hardy put on his weaker papers*". It is also told that **Edmund Landau** (1877–1938) so doubted the existence of Littlewood that he made a special trip to Great Britain to see the man with his own eyes.

243 **Gauss** conjectured that the logarithmic integral $Li(N)$ would *always overestimate the number of primes* – it would never predict that there were fewer primes than there really were in the range from 1 to N.
Littlewood proved Gauss to be wrong (although Gauss' conjecture held true (1912) for all numbers up to 10 million!). He proved that as you counted higher, you would eventually come to regions of numbers where Gauss' guess would switch from overestimating to underestimating the number of primes.

S. Skewes proved in 1955 that the first switch occurs *before* n reaches $10^{10^{10^{34}}}$, though he had to assume the truth of the Riemann conjecture. This is known as the *Skewes number* [by way of comparison — there are "*only*" about 10^{80} protons in the observable universe]. **G.H. Hardy** thought it '*the largest number which has ever served any definite purpose in mathematics*', and suggested that if a game of chess was played with all the particles in the universe as pieces, one move being the interchange of a pair of particles and the game terminating when the same position recurred for the third time, the number of possible games would be about Skewes' number.
In 1986, **H.J.J. te Riele** demonstrated that the "*Littlewood constant*" can be much better bounded, to some n below 6.69×10^{370}, still an enormously large number, well beyond human grasp. [A computer search, made as far as 10^9, failed to reach the first switch.]

Barnes (1874–1953), who assigned to him the problem of proving the Riemann hypothesis(!) [It is an amazing illustration of the insularity of British mathematics at that time that Barnes should have thought it suitable for a research student to tackle this problem.]

Characteristically, Littlewood was able to report: "*As a matter of fact this heroic suggestion was not without result... there was a consolation prize*". During 1915–1919, Littlewood collaborated with Hardy in Cambridge. He authored a steady flow of papers well into the 9^{th} decade of his life. Many of the later papers are on differential equations, and many show his interest in astronomy, physics and probability, as well as in problems of pure analysis which filled most of his life. His power at the age of 85 was shown when he solved a problem which "*raised difficulties which defeated me for some time. I have now overcome them*".

Some of his keen observations, based on long experience, are: (quoted from his publication "*The Mathematician's Art at Work*", 1967)

- "*Try a hard problem. You may not solve it, but you will prove something else*".
- "*There are four phases in mathematical creativity*: *preparation, incubation, illumination and verification. Preparation needs roots in an intense curiosity; the essential problem, stripped of its accidentals, must be brought and kept before the mind. The resulting drive is communicated to the subconscious*, '*which does all the real work and would seem to be always on duty*'. *Incubation is the work of the subconscious during the waiting time, which may be several years. Illumination, which can happen in a fraction of a second, is the emergence of the creative idea into the conscious*".
- "*Mathematics is very hard work, and dons tend to be above the average in health and vigor. Below a certain threshold a man cracks up, but above it — hard mental work makes for health and vigor* (*also — on much historical evidence throughout the ages — for longevity*)".
- "*A Ph.D. was a degree which you had to take if you failed to get a Research Fellowship, just to show that you had been at Cambridge*".

1911–1935 CE **Julius Edgar Lilienfeld** (1881–1963, Germany and USA). Physicist and inventor. Pioneer of semiconductor devices. Proposed the basic principle behind the MOSFET[244] (Metal – Oxide – Semiconductor Field Effect Transistor) in 1925, some twenty years ahead of **Shockley** and **Bardeen**. Patented a high-vacuum X-ray tube with hot tungsten filament in 1911, five years ahead of **W.D. Coolidge** in the USA.

Lilienfeld was born in Lemberg, Galicia (now Lvov, Ukraine) to Jewish parents. He entered the Polytechnic University of Berlin (1899) and earned a Ph.D. degree in experimental physics (1905). He then joined the Physics Institute at the University of Leipzig and patented a high-vacuum X-ray tube (1911). At the same time he operated the first large-scale hydrogen liquification facility used to fill the Zeppelines and for cryogenic research.

He continued to work on electrical discharges, extending his investigations to field-emission of electrons, and applied this to the development of cold-cathode high-vacuum X-ray tubes. He discovered (1919) a polarized light coming from the vicinity of the target of an X-ray tube due to time variation of the virtual *dipole* between the electrons and their image charges formed near the surface of the tube's target.

In 1926, Lilienfeld resigned his professorship position at Leipzig and emigrated to the USA. He then began experimenting with solid-state electronic devices. During 1925–1928 he developed and patented (1930) several devices which could now be referred to as *field-effect* (or, *point junction*) *transistors*[245].

---

[244] A *unipolar* device where current flows through a narrow *channel* between two electrodes (the *gate*) from one region called the *source*, to another called the *drain*. A modulating signal is applied to the *gate* (Figure 5.3).

In practice, a wafer of a semiconductor material has two highly doped regions of opposite polarity diffused into it, to form a source and drain regions.

An insulating layer of silicon oxide is formed on the surface between these regions and a metal conductor is evaporated on to the top of this layer to form the *gate*.

When a positive voltage is applied to the *gate*, electrons move along the surface of the p-type substrate below the gate, producing a thin surface of n-type material, which forms the *channel* between the *source* and the *drain*. This surface layer is called an *inversion layer*, as it has opposite carriers to that of the substrate. The number of induced electrons is directly proportional to the gate voltage, thus the conductivity of the channel *increases* with gate voltage.

[245] The word 'transistor' had its beginning in 1946 at the Bell Telephone Laboratories that used high-purity germanium to create solid-state amplifying devices. While Lilienfeld's devices did not perform to todays standards, signal amplification was detected. In 1935, **Oscar Heil** described a structure similar to the junction field-effect transistor. However, practical implementations were impossible until 1960 due to material-related problems. The technology to produce such devices on a commercial basis did not yet exist.

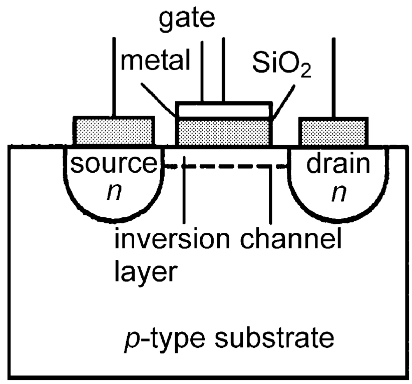

Fig. 5.3: MOSFET

In 1928, Lilienfeld began work on the *electrochemistry* of anodic aluminum-oxide films and their application in the manufacture of *electrolytic capacitors*, essential compounds in much electronic components. In 1935, he moved with his wife to the US Virgin Islands, where he died in 1963.

Although Lilienfeld's work on high-vacuum X-ray tubes and on field-effect transistors came at the wrong time to bring him fame, he deserves recognition as a pioneer scientist and prolific inventor.

In 1988, the American Physical Society established the Julius Edgar Lilienfeld Prize, in recognition of a most outstanding contribution to physics.

1911–1938 CE **Alfred North Whitehead** (1861–1947, England) and **Bertrand Arthur William Russell** (1872–1970, England), both mathematicians, logicians, metaphysicians and philosophers, published their joint work: "*Principia Mathematica*" — an attempt to anchor arithmetic to a system of formal procedures, based on Peano's axioms and symbolic logic. The program, intended to prove that all pure mathematics can be derived from a small number of fundamental logical principles, is in line with Russell's view that mathematics is indistinguishable from logic.

This system left unanswered Hilbert's query whether the numerical continuum can be considered a well ordered set, to which Gödel in 1931 gave a definite answer.

Whitehead was born at Ramsgate, Isle of Thanet, Kent, England. His father, a vicar, taught him at home until he was 14. He was then sent to Sherborne School, Dorset, where he received classical education. In 1880 he entered Trinity College, Cambridge. He met **Russell** in 1890 when the latter was a freshman studying mathematics at Trinity. Gradually, the two men became close friends.

In 1910 Whitehead left Cambridge: his future there was uncertain, since he did not produce any discoveries that could earn him a Cambridge professorship in mathematics [his interest was always philosophical, grasping the nature of mathematics in its widest aspects and organizing its ideas rather then discovering new theorems]. He moved to London and became a teacher of applied mathematics at the Imperial College of Science and Technology (1914). He became interested in education, university administration, and philosophy of science. His shrewdness, common sense and goodwill put him in great demand as a committee man.

Whitehead was a pacific man but not a pacifist; he felt that WWI was hideous but that England's part in it was necessary. His elder son, North, fought throughout the war, and his daughter, Jessie, worked in the Foreign Office. In 1918 his younger son, Eric, was killed in action, and after that it was only by immense effort that Whitehead could go on working. To Whitehead, Russell's pacifism was simplistic; yet he visited him in prison, remained his friend, and, as Russell later said, showed him greater tolerance than he could return.

Whitehead emigrated to the U.S. in 1924 and became a professor of philosophy at Harvard University (1924–1938). His metaphysical system was influenced by **Plato**, **Aristotle**, **Leibniz**, **William James**, **Bergson**, **Minkowski** and **Einstein**. He set out in his philosophy to rectify what he considered to be the great error in the philosophical tradition — the doctrine of the duality of reality (which held that reality is a compound of mind and matter). This "bifurcation of matter", as he called it, was initially posited by **Descartes**, and, according to Whitehead, had poisoned philosophical thinking ever since.

Whitehead claimed that there is only *one reality*: reality consists only in what appears, in what is perceived, in whatever is in the experience of a subject (subject meaning any actual entity). There are neither concepts nor substances in the world: only a network of events. All such events are actual extensions of the unified whole of the space-time relation. Hence, reality is based on the patterned process of events.

His writings did much to narrow the gap between philosophy and science. He insisted that scientific knowledge, though precise, is incomplete. It must be supplemented, he said, by philosophical principles and the insight of poets(!)

Whitehead's nephew, **J.H.C. Whitehead**[246] (1904–1960, England), was a mathematician who specialized in topology and applied the subject to the study of generalized spaces. He was born in Madras, India and taught at Oxford (1932–1960).

Bertrand Russell was born near Trelleck, Wales. His father was a viscount and his grandfather, John Russell, was twice prime minister and became the 1^{st} Earl Russell. His parents died when he was 3 years old, and he and his brother were brought up by their grandparents. He entered Trinity College in 1890, where he graduated in 1894. His first wife was a Quaker from Philadelphia (1894). He married again in 1921.

Russell outspokenness and liberal views involved him in many controversies. During WWI he was dismissed from Cambridge University and imprisoned because of his pacifist views. In 1940, protests against his radical views on religion and morals caused the college of the city of New York to cancel his appointment as a professor, and he was almost dismissed from Harvard University. In 1961 he was imprisoned for his political activities.

Russell maintained that logic is not a function of philosophy but a general theory of science. He further insisted that the proper function of philosophy is to deal with the problems raised by the sciences, not with theological or ethical problems. Hence, philosophy should devote itself to analyzing the empirical data of science, because the primary problems of human life consist in the relation between individual experience and general scientific knowledge. Knowledge itself is a relatively unimportant feature of the universe; It can also be a corruptive influence in the search for truth, since it is so subject to the interpretations of human experience. To counter this, philosophy must limit itself to simple, objective descriptions of the phenomena of the world, keeping such descriptions free of the self-same corrupt influences of experience.

Russell defined himself thus: "*Liberal, anarchistic, left-wing skeptical atheist*".

[246] J.H.C. Whitehead was often asked for his views on the work of his uncle. Eventually he developed a standard answer. When asked "*What do you think of your uncle's philosophy*?", he would reply "*I really haven't thought much about it — but what do you think of your uncle's philosophy*?".

Worldview XXXI: Russell

* * *

"Aristotle maintained that women have fewer teeth than men; although he was twice married, it never occurred to him to verify this statement by examining his wives' mouths."

* * *

"The desire to understand the world and the desire to reform it are the two great engines of progress."

* * *

"It can be shown that a mathematical web of some kind can be woven about any universe containing several objects. The fact that our universe lends itself to mathematical treatment is not a fact of any great philosophical significance."

* * *

"The fact that all Mathematics is Symbolic Logic is one of the greatest discoveries of our age; and when this fact has been established, the remainder of the principles of mathematics consists in the analysis of Symbolic Logic itself."

* * *

"With equal passion I have sought knowledge. I have wished to understand the hearts of men. I have wished to know why the stars shine. And I have tried to apprehend the Pythagorean power by which number holds sway about the flux. A little of this, but not much, I have achieved."

* * *

"A good notation has a subtlety and suggestiveness which at times make it almost seem like a live teacher."

* * *

The conventional wisdom is that systems of reasoning must be consistent. That is, no statement can be both true and false. If so, then the system collapses because there remain no restrictions on what is true or false: every statement can be proved true (and false as well!).

When Bertrand Russell once made this claim during a public lecture he was challenged by a skeptical heckler to prove that the questioner was the Pope if twice 2 were 5. Russell replied, 'if twice 2 is 5, then 4 is 5, subtract 3; then 1 = 2. But you and the Pope are 2; therefore you and the Pope are one.'!

* * *

"How dare we speak of the laws of chance? Is not chance the antithesis of all law?"

* * *

"Mathematics takes us into the region of absolute necessity, to which not only the actual word, but every possible word, must conform."

* * *

"Perhaps the oddest thing about Modern Science is its return to Pythagoreanism."

* * *

"At the age of eleven, I began Euclid, with my brother as my tutor. This was one of the great events of my life, as dazzling as first love. I had not imagined there was anything so delicious in the world. From that moment until I was thirty-eight, mathematics was my chief interest and my chief source of happiness."

Worldview XXXII: Whitehead

* * *

"The aim of science is to seek the simplest explanation of complex facts. We are apt to fall into the error of thinking that the facts are simple because simplicity is the goal of our quest. The guiding motto in the life of every natural philosopher should be 'seek simplicity and distrust it'."

* * *

"The aims of scientific thought are to see the general in the particular and the eternal in the transitory."

* * *

"Now it cannot be too clearly understood that, in science, technical terms are names arbitrarily assigned, like Christian names to children."

* * *

"Not ignorance, but ignorance of ignorance, is the death of knowledge."

* * *

"We think in generalities, we live in detail."

* * *

"Everything of importance has been said before by somebody who did not discover it."

1911–1942 CE **Sergei Natanovich Bernstein** (1880–1968, Russia). Mathematician. Contributed to the theory of probability and the theory of approximation of functions. There are polynomials[247], an inequality and a constant named after him.

Bernstein was born in Odessa to Jewish parents. He went to Paris (1898) and studied at the Sorbonne. In his doctoral dissertation (1904) he solved Hilbert's 19th problem (to determine whether the solutions of "regular" problems in the calculus of variations are necessarily analytic). On his return to Russia (1905) he had to do a second doctorate (1913) in order to qualify for a university post. Through this work he solved Hilbert's 20th problem (concerning the analytic solution of Dirichlet's problem for a wide class of non-linear elliptic equations). Bernstein then taught at Kharkov University (1907–1932), Leningrad University, the Mathematical Institute of the USSR Academy of Sciences (1933–1942), and Moscow University (1943–1950).

1911–1947 CE **Charles Franklin Kettering** (1876–1958, USA). Engineer and inventor. Developed such varied industrial products as a self-starter for automobiles (1911), engine ignition system, ethyl gasoline, lightweight two-cycle diesel engine for trams, a high-compression automobile engine, four-wheel brakes, safety glass, the refrigerant *Freon* and many other items.

Kettering was born near Loudonville, Ohio. Bad eyesight slowed his education, but he graduated from Ohio State University in 1904 as an engineer and then joined the National Cash Register Company. In 1909 he left NCR and set up the Dayton Engineering Laboratories Company or Delco, where he invented his most significant engine devices. Kettering's engine-driven generator, named the 'Delco', provided electricity on millions of farms.

1911–1950 CE **Theodore von Kármán** (1881–1963, Hungary, Germany and U.S.A.). Founder of aeronautical and astronautical sciences in the 20^{th} century. Father of the supersonic age. Made important contributions to fluid mechanics, turbulence theory, supersonic flight, mathematics in engineering,

---

[247] Let $f(x)$ be defined on $[], 0, 1\,]$. The n-th ($n \geq 1$) *Bernstein polynomial* for $f(x)$ is given by

$$B_n(f;x) = \sum_{k=0}^{n} f\left(\tfrac{k}{n}\right)\binom{n}{k} x^k (1-x)^{n-k}.$$

Notice that $B_n(f;0) = f(0), \qquad B_n(f;1) = f(1).$

$B_n(1;x) = 1; \qquad B_n(x;x) = x; \qquad B_n(x^2;x) = \frac{1}{n^2}\binom{n}{1}x + \frac{2}{n^2}\binom{n}{2}x^2;$

$B_n(e^{\alpha x};x) = [xe^{\alpha/n} + (1-x)]^n; \qquad \lim_{n\to\infty} B_n(f;x) = f(x).$

The Bernstein expansion often provides useful *approximations* to various functions.

aircraft structures and wind erosion of soil. In 1940 he showed together with **Frank J. Malina**, for the first time since the invention of the black-powder rocket in China in 969 *CE*, that it was possible to design a stable, long-duration, solid-propellant rocket engine.

Von Kármán participated in a number of major contributions to rocket technology, America's first assisted takeoff of aircraft with solid- and liquid-propellant rockets, flight of an aircraft with rocket propulsion alone, and development of spontaneously igniting liquid propellants of the kind that were to be used in the Apollo Command and Lunar Excursion modules in the late 60's.

Von Kármán was born in Budapest to Jewish parents, and was educated in Budapest and Göttingen. He became an assistant to **Ludwig Prandtl** on dirigible research, and came under the influence of **David Hilbert** and **Felix Klein**. The latter stressed the fullest use of mathematics and the basic sciences in engineering to increase technological efficiency.

In 1911 he discovered that at large Reynolds-numbers, the eddies in the wake behind an elliptic cylinder do not remain stationary with the cylinder but shed alternatively to form the '*Von Kármán vortex street*' (consisting of two staggered rows of counter-rotating vortices). In 1921 he obtained an approximate solution for two-dimensional laminar boundary layer flow, which he converted into a momentum integral equation (*Kármán-Polhausen equation*).

A law describing the shear forces which *turbulent flows* exert at boundaries was proposed by von Kárman (1930) and **Prandtl** (1933). It states that a fluid's average velocity is proportional to the logarithm of the distance from the boundary and known as Universal *Law of the Wall*. The logarithmic velocity distribution was first found for flow between two walls, but it could be applied to the calculation of the skin friction of a flat plate which is covered by a *turbulent boundary layer*[248].

In 1912 he became director of the Aeronautical Institute at Aachen, Germany, remaining there until 1930. He then moved to the United States, assuming the direction of the Guggenheim Aeronautical Laboratory at the California Institute of Technology, which in 1944 became the NASA Jet Propulsion Laboratory in Pasadena. Shortly after his arrival at CALTECH, his laboratory became a Mecca of the world of aeronautical sciences.

In 1932 he extended the *Joukowski transformation* so as to obtain an airfoil with a finite trailing edge [Kármán-Trefftz airfoil]. In 1938 he put forward a statistical theory of isotropic turbulence [*Kármán-Howarth theory*],

---

[248] Some scientists claimed that the law may be in disagreement with experiment by up to 65 per cent, but this conclusion remains controversial.

and in 1941 he advanced the *Kármán-Tsien approximation* for steady two-dimensional subsonic flow. Also in 1941, von Kármán participated in the founding of the Aerojet General Corporation, the first American manufacturer of liquid- and solid-propellant rocket engines. In 1960, his efforts brought into being the International Academy of Astronautics. A crater on the moon has carried his name since 1970.

Von Kármán was a unique man in many ways: as a classroom teacher his clarity and imagination were superbly effective. At the blackboard he would run into, and extricate himself from, mathematical traps and blind alleys of his own making with such agility as to make the class hold its breath and then applaud. Mathematical equations were almost alive, performing like puppets before the class.

As head of the Aeronautical Institute of Aachen, and late of CALTECH's Guggenheim Aeronautical Laboratory at Pasadena, von Kármán guided two generations of scientists and engineers into pioneering areas that led to the establishment of aviation and astronautics on firm scientific foundations. His vivid and dynamic personality held people spellbound with his Old World wit, showmanship, and crusty insights into natural phenomena and human nature. The following story serves to illuminate both his wisdom and the 'name of the game' in applied mathematics:

Once, during a laboratory session, a student reported that he had made a peculiar observation which he couldn't explain. Von Kármán adjusted his hearing aid and listened intently. Then he gave a plausible explanation for the student's puzzling observation. The fellow thanked him profusely. As he turned to leave, von Kármán called him back. "*Wait*", he said. "*Just in case you made a mistake and the effect is negative* [*just the opposite*], *then the explanation is as follows*", and he proceeded to give an equally clear and plausible explanation for the opposite effect.

Von Kármán expected great respect from the students, and he had clever ways of chiding those who were deceived by his gentle ways and tried to take advantage of him. Once a student came to class, unfolded a newspaper and proceeded to read while the professor was lecturing. He did this for several days, and each day von Kármán's annoyance grew. Finally, unable to stand the inattention any more, he hired a boy to bring up a cup of coffee and set it in front of the offensive student. The class roared with laughter. The poor fellow never opened his paper in class again.

When President Kennedy presented him with a special medal in the White House (February 1963), von Kármán responded:

"I hope that I have shown that the college professor is of use."

1912 CE, April 14–15 The *Titanic* disaster; the largest ship in the world at the time (269 meters long; 46,328 tons), struck an iceberg on its maiden voyage from England to New York City, and sank to a depth of 4000 m. The *Titanic* sighted the iceberg just before the crash (11:40 PM ships-time, April 14; 2570 km northeast of New York), but too late to avoid it. The lifeboats held less than half of the approximately 2200 passengers. The ship sank at 41°44′N, 49°57′E in 2^h40^m hours (02:20 AM). The liner *Carpathia* picked up 705 survivors. Among the victims were 670 crew members, including the captain E.J. Smith. It was a moonless night and the iceberg was *not seen*.

Not until 1985, searches led by oceanographer **Robert Ballard** revealed the *Titanic* resting in two pieces on the ocean floor.

In 1914, International Ice Patrol was established as a result of the sinking of the *Titanic*. Thirteen maritime nations, using shipping lanes in the ice regions, met at the International Conference on the Safety of Life at Sea, and on January 20 signed an agreement to establish the patrol and pay its expenses.

1912 CE **Max Theodor Felix von Laue** (1879–1960, Germany). Physicist. Discovered the diffraction of X-rays in crystals and as a result was able to measure the wavelengths of X-rays and to study the structure of crystals. Contributed to the developments of the theories of relativity, electromagnetism, and diffraction of light. Awarded (1914) the Nobel prize for physics.

Prior to 1912, X-rays had resisted being diffracted even by the most precise gratings. While studying the theory of 3-D gratings, von Laue recognized that since atoms had dimensions and separations that were so much smaller than the wavelength of visible light, a crystal might very well serve as a *natural diffraction grating* for X-rays. Accordingly, his associates directed a beam of X-rays at a crystal of copper sulfate (they also later tested zinc sulfate, diamond, rock salt, and copper) and exposed a photographic plate for several hours to the *transmitted* radiation. The outcome was a remarkable concentric pattern of spots that showed that the X-rays were indeed subject to diffraction.

By working backwards from the observed diffraction angles, it became possible to deduce the geometry of the "grating". These experiments confirmed the electromagnetic wave nature of X-rays, allowed measurements of their wavelengths, *and* opened the way to the determination of interatomic distances in crystals. It was one of the most important scientific discoveries of the 20^{th} century, and illustrates once again the role of *creative imagination* in scientific discovery.

Far from simply "looking at the facts", a popular misconception of the scientific method, Max von Laue was inspired to a new world of facts to examine.

His discovery immediately led to Moseley's investigation of X-ray spectra and his discovery of atomic number. Many scientists were soon working in the new field of crystal structure determination, and X-ray crystallography rapidly expanded into a major branch of chemistry[249] and physics.

Von Laue's method had some series disadvantages and has been superseded by other methods in which X-rays of a single wavelength are *reflected* from crystal faces. Because X-rays penetrate deeply into the crystal, the geometric condition for diffraction differ from that of optical diffraction: the grating or *lattice* has 3 effective dimensions instead of only two, and the diffraction angles θ are determined by the ratio of wavelength λ to the spacing d between parallel planes through sites occupied by atoms in the crystal according to *Bragg's equation* (1912) for *constructive interference*: $2d\sin\theta = n\lambda \ (n = 1, 2, 3, \ldots)$. If monochromatic X-rays were used, then, even if their wavelength is not known, the *relative* interplanar spacing for different set of planes within the crystal can be determined[250].

[249] Some of the most exciting applications of X-ray diffraction have been in *molecular biology*: **J.C. Kendrew** and **M.F. Perutz** were awarded the Nobel prize in chemistry (1962) for their studies of myoglobin and hemoglobin. The award for 1964 went to **Dorothy Crowfoot Hodgkin** for her solution of the structure of vitamin B_{12}, work that required the application of an electronic computer to analyze the complex crystallographic data.

[250] Absolute determination of d requires, however, a preknowledge of λ. Early attempts to measure the wavelength of X-rays with ruled gratings failed because of the large disparity between the grating spacing (several thousands Ångstroms) and the wavelengths (a few Ångstroms). Finally, **Compton** (1923) was successful in obtaining diffraction patterns when X-rays fell on ruled gratings at *grazing incidence*: by passing the radiation in a fine beam very close to the surface of the grating it is possible to obtain *total reflection* of the beam. In addition to the reflected rays, *diffracted beams* of different orders are found and these are used to standardize the X-ray wavelengths in terms of metric units. In this way lattice constants can be measured very accurately from X-ray crystal diffraction patterns and the method further leads to a determination of the electronic charge via the ionic theory of solids.

Crystals and Quasicrystals

For the majority of chemical compounds, a most striking aspect of the solid state is crystallinity: the solid consists of crystals having a recognizable natural shape, bounded by plane surfaces which meet at characteristic angles. Because of the forces acting between the atoms or ions of the solid (crystal), a stable equilibrium is possible only if constituents are arranged in a regular repetitive geometric pattern called a crystal lattice. Group-theoretical methods show that there is a finite but large number of crystal systems which are possible arrangements of the lattice constituents in a crystal. In which one of these systems a particular material crystallizes, depends upon the size of the atomic or ionic constituents and upon the magnitude and orientation of the forces acting between them. The same material may crystallize in different configurations depending upon the type of binding forces (carbon, for example, can crystallize in the graphite or diamond lattice).

A fundamental property of crystals is their symmetry. It is possible to pick the smallest part of the structure that has all the symmetry elements of the entire 3*-dimensional pattern. This is called the unit cell, or elementary cell, and the entire crystal can then be built by translational repetition along the crystal axes. In the cubic NaCl crystal, for instance, the elementary cell is a small cube. For a cubic lattice, the smallest distance of two equivalent constituents is designated as the lattice constant a; the distance of two neighboring lattice planes as the lattice distance, d. If a coordinate system is introduced with its axes parallel to the edges of the crystal, each crystal plane (and thus the whole crystal as determined by the crystal planes) may be characterized by specifying the lengths from the origin to the intersections of the crystal plane with the axes. These lengths are measured in units of the corresponding edges of the elementary cell.*

The principal classification of crystals is on the basis of their symmetry. An object has symmetry if some operation can be carried out on it that converts it into itself. For example, a three-bladed propeller can be rotated about its axis by 120° *(one-third of a revolution), and it is then indistinguishable from its original condition, provided that the three blades are exactly identical to one another. Similarly it can be rotated by* 240° *(two-thirds of a revolution), again becoming indistinguishable from its original condition. These operations of rotation by $\frac{1}{3}$ of a revolution and rotation by $\frac{2}{3}$ of a revolution, together with the original operation involving no change — constitute the symmetry group corresponding to a* 3*-fold axis of symmetry.*

Only a few symmetry elements are manifested by crystals. These include: center of symmetry, 2*-fold axis,* 3*-fold axis,* 4*-fold axis,* 6*-fold inversion axis,* *3-fold inversion axis, and symmetry plane (a 5-fold axis does not occur in crystals because the angle of a pentagon, 108°, is not a factor of 360°).*

There are 32 combinations of these symmetry elements that are represented by crystals. These combinations are called the 32 crystal classes. They can be divided in 6 crystal systems, as follows:

(a) *Cubic crystals, with both 3-fold and 4-fold symmetry axes (the 4-fold axis can be of the rotation-inversion type); three equal mutually orthogonal axes of symmetry. The body-centered cubic lattice has one lattice point at each corner plus one lattice point in the center of the cubic volume. The face-centered cubic lattice has one lattice point at each corner plus one lattice point at the center of each of the 6 faces of the cube [octahedral, tetrahedral and dodecahedral crystals belong to the cubic system].*

(b) *Tetragonal crystals, with one 4-fold axis; two equal symmetry axes with length a, and a third axis with length c, all at right angles.*

(c) *Hexagonal (or trigonal) crystals (including rhombohedral crystals), with one 6-fold axis or 3-fold axis; two equal axes of symmetry with length a and oriented at 120° to each other, and a third axis with length c, at right angles to the other two [bipyramidal, rhombohedral and trigonal trapezohedral crystals belong to the hexagonal system].*

(d) *Orthorhombic crystals, with two or three planes of symmetry or twofold axes at right angles to each other; three axes, with lengths a, b, c at right angles to one another.*

(e) *Monoclinic crystals, with one plane of symmetry, or one twofold axis, or both; two axes of symmetry, a and c, at the angle β with one another, and the third axis b, at right angles to a and c.*

(f) *Triclinic crystals, with either a center of symmetry or none; three axes of symmetry a, b, c, with angles α, β and γ between them.*

The faces of the crystals must be related to the axes in a rational way; the intercepts of a face with the three axes are related to the lengths of the axes a, b, c, in the ratio of integers.

The use of symmetry arguments can tell us whether a molecule has a dipole moment and along which line it lies. Since a symmetry operation leaves a molecule in a configuration physically indistinguishable from the one before the operation, the direction of the dipole moment vector must also remain unchanged after the symmetry operation. Therefore, if a molecule has a n-fold axis of rotation, the dipole moment must lie along this axis. But if we have two or more non-coincident symmetry axes, the molecule cannot have a dipole moment because it cannot lie on two axes at the same time.

Methane (CH_4) has 4 non-coincident axes and therefore has no dipole moment. If there are several symmetry planes, the dipole moment must lie along their intersection. In ammonia (NH_4) the dipole moment lies along the 3-fold symmetry axis which is also the intersection of 3 symmetry planes. A molecule having a center of symmetry cannot have a dipole moment, since inversion reverses the direction of any vector.

X-ray diffraction studies have shown that nearly all metallic *elements crystallize in either a* cubic face-centered *lattice,* hexagonal close-packed *lattice, or a* body-centered cubic *lattice.*

The noble gases neon, argon, krypton and xenon at sufficiently low temperatures crystallize in a face-centered cubic lattice.

Quasicrystals

Until the early 1980's, scientists believed that all *crystal solids were arranged* periodically *at a* microscopic level. *It was assumed that the only way to achieve order in the bulk is by having some basic structural unit which repeats itself infinitely in all directions, filling up all space. This is much like the way in which a floor can be covered in patterns of identical squares or hexagons, without leaving gaps. However, covering the floor with pentagon or decagons results in a patchwork of empty space because under this arrangement the tiles cannot stretch to infinity in a regularly repeated pattern, i.e. the pattern lacks* periodicity. *(In periodic patterns, if one tile is surrounded, say, by six neighbors, then* every *tile is surrounded by six neighbors.)*

In nature we observe this regularity in the way in which bees arrange their honeycombs in periodic hexagonal arrays. (The artist ***M.C. Escher*** *has exhibited many periodic 2D and 3 D structures in his drawings.)*

A perfect crystal consists of a space-filling array of periodically repeated identical copies of a single structural unit containing some distribution of matter and charge. In the simplest case, the structural unit contains a single atom. More generally, it may contain many different atoms or a continuous variation in the mass density about some mean. The repeated structural unit is called the unit-cell.

Equivalent points in unit cells in a D-dimensional perfect crystal lie on a periodic lattice*, called a* Bravais lattice*, consisting of a* mathematical *array of points.*

Any lattice point can be specified by an integral linear combination of independent translation vectors $\boldsymbol{a}_1, ..., \ \boldsymbol{a}_D$

$$\boldsymbol{R}_l = l_1\boldsymbol{a}_1 + l_2\boldsymbol{a}_2 + \cdots + l_D\boldsymbol{a}_D$$

where $\boldsymbol{l} = (l_1...l_D)$ *is a D-dimensional vector with components* l_i *(*$\boldsymbol{l}$ *indexes a particular unit cell,* $\boldsymbol{R}_l$ *specifies its position in real space). The set of vectors* $\boldsymbol{a}_1...\boldsymbol{a}_D$ *completely define the mathematical lattice. A translation vector (or lattice vector) connects equivalent points in the lattice:*

$$\boldsymbol{T} = \boldsymbol{R}_l - \boldsymbol{R}_{l'}.$$

If an infinite crystal is translated through a lattice vector $\boldsymbol{T}$*, it will be absolutely indistinguishable from the untranslated crystal to a fixed observer in some laboratory frame of reference.*

Translations by lattice vectors are symmetry operations that leave the physical properties of the crystal invariant. The set of all lattice translations form a (commutative) group*, and the crystal is said to be invariant under operations of this group.*

Crystals are also invariant under point-group *operations consisting of* rotations*,* reflections*, and* inversions *about special* symmetry *points.*

Molecules and other finite size objects can have symmetry axes of arbitrary order. But the requirement that a crystal be invariant under translations through any vector on its lattice (the set of which can be shown to contain no vector shorter than some minimum length vector) places severe restrictions on possible rotational symmetries. Thus, e.g., it is impossible for a periodic crystal to have a 5-fold symmetry*, i.e. to be invariant w.r.t. rotations through* $2\pi/5$.

To see this assume that a crystal does have 5-fold symmetry and let $\boldsymbol{a}_0 = (1, 0)$ *be the shortest vector in the lattice. Since the crystal is assumed to have a 5-fold symmetry, the vectors*

$$\boldsymbol{a}_n = \left(\cos\frac{2\pi n}{5}, \ \sin\frac{2\pi n}{5}\right),$$

with n *an integer, must also be in its lattice. But by the closure property of any lattice, the vector*

$$\boldsymbol{T} = \boldsymbol{a}_4 + \boldsymbol{a}_1 = \left(\cos\frac{8\pi}{5} + \cos\frac{2\pi}{5}, \ \sin\frac{8\pi}{5} + \sin\frac{2\pi}{5}\right) = \tau^{-1}(1, 0) = \tau^{-1}\boldsymbol{a}_0$$

where

$$\tau = 2\cos\frac{\pi}{5} = \frac{1}{2}(1+\sqrt{5}),$$

must also be in the lattice, [$\tau^2 = \tau + 1$, τ = the golden mean].

However, $\boldsymbol{T}$ is shorter than $\boldsymbol{a}_0$, contradicting the assumption that $\boldsymbol{a}_0$ was the shortest vector in the lattice. Thus, it is impossible for a periodic lattice in two dimensions to have a 5-fold symmetry. Similar arguments rule out all periodic lattices in two dimensions with other than 2-, 3-, 4-, or 6-fold symmetry. It can be shown that these restrictions lead to only five distinct two-dimensional Bravais lattices: square, oblique, rectangular, centered rectangular and hexagonal.

In three dimensions, the existence of a periodic crystal with the point-group symmetry of an icosahedron[251] *(six 5-fold, ten 3-fold and fifteen 2-fold axes) is similarly ruled out.*

As a result, a fundamental tenet of classical crystallography[252] *was that* MATERIALS EXHIBITING ICOSAHEDRAL SYMMETRY COULD NOT EXIST.

*In 1984, **Dan Schechtman** and his colleagues shook the foundation of crystallography*[253] *when they reported an electron diffraction pattern for an alloy of aluminum and manganese formed by rapid cooling of a mixture of two molten metals; it showed a clear point-group symmetry of an icosahedron, namely: 5-, 3-, and 2-fold axes characteristic of icosahedral symmetry. The density of Bragg peaks in each plane was* higher *than one would expect from*

---

[251] One can stack atoms together in 3D lattice arrays that have 3-fold, 4-fold and 6-fold symmetries, but 5-fold symmetric periodic stacking is not possible: A cubic lattice – a stacking of perfect cubes – exhibits not only the easily recognized 4-fold symmetry, but also 3-fold, when viewed along cube *diagonals*. But the two regular polyhedra with 5-fold symmetry – the *dodecahedron* and *icosahedron* – cannot be stacked together in a way that fills 3-dimensional space without gaps.

[252] The idea that crystals are periodically ordered first emerged in the works of **Kepler** (1619) and **Hooke** (1660) as a direct result of the advent of microscopy. These ideas were then formalized into the theory of *crystallography* by **René-Just Haüy** (1822). With the discovery of X-ray diffraction in crystals (**von Laue**, 1912) and the subsequent development of X-ray crystallography (**W.H. and W.L. Bragg** 1915), the periodicity of crystals received an unequivocal stamp of approval because light diffracted from crystals produced sharp, crisp patterns indicative of periodicity.

[253] **Linus Pauling**, however, was not convinced and in the ensuing years slowed the bandwagon. Finally his alternative theory lost to the prevailing views of quasicrystalists.

a periodic crystal[254]*. There were 10 bright spots in the ring around the bright central blob, implying that the alloy was a crystal with a "forbidden" 10-fold symmetry. Rotating the crystal lattice by 72° would leave it unchanged.*

The aluminum/manganese alloy, as well as many other metal alloys that have since been found to produce diffraction patterns with forbidden 5-, 8-, 10-, and 12-fold symmetries, cannot be true crystals in the sense of possessing a genuine unit cell which repeats throughout the material. In other words, the position of their constituent atoms cannot be orderly over large distances. The geometric ban on crystals with these symmetries is mathematically absolute.

These alloys, which appear to be neither crystalline nor wholly noncrystalline, have been given the name "quasicrystals"[255] *(short for "quasiperiodic crystals").*

We have seen that the closure property of any lattice implies that a lattice with 5-fold symmetry has collinear vectors with irrational magnitude ratios, and has vectors with arbitrary small separations. However, atoms in real space cannot be arbitrary close together. In a periodic solid, the existence of a shortest length in a unit cell ensures that distances between atoms are greater than some minimum distance. How can there be a minimum distance in a quasicrystal?

The answer is provided by tiling of a 2-dimensional plane with 5-fold symmetry invented by ***Roger Penrose***[256] *(1974) and by their generalization to*

---

[254] Disordered, amorphous materials, in contrast, produce smeared-out scattering patterns, from which rather little can be deduced about the structure. Symmetry properties of the diffraction pattern give an indication of that of the crystal.

[255] In 1991 the International Union of Crystallography decided to *redefine* the term "crystal" to mean any solid having an essentially discrete diffraction diagram, thereby shifting the essential attribute of crystallinity from position space to Fourier space. This broader definition reflects our current understanding that *microscopic periodicity* is a sufficient but not a necessary condition for crystallinity.

One can also use the diffraction diagram to distinguish between periodic crystals and quasicrystals as follows: Each Bragg peak in the discrete diffraction diagram defines a *wave vector* which points from the center of the diagram to the peak, and at which the density has a nonvanishing coefficient in its Fourier expansion.

[256] **Penrose**, a mathematical physicist, had become captivated by the post-WWII work of artist **Maurits C. Escher**. His tilings represent an exploration of ways in which a plane can be filled completely by identical tiles *without* producing long-range order (that is, in an aperiodic manner).

*icosahedral symmetry in 3 dimensions. The basic idea here is to fill the plane with two types unit cells (tiles) rather than a single unit cell required to tile a plane periodically. Adjacent tiles must be joined so that they obey certain matching rules. There is a shortest distance between tile vertices and it is possible to "decorate" the tiles with atoms in such a way that the atoms have a minimum separation. The diffraction pattern (Fourier transform), first calculated by **D. Levine and P.J. Steinhardt** (1984), of the icosahedral generalization of Penrose tiles, agrees well with the experimental observed pattern.*

Why do atoms form a complex, quasiperiodic pattern rather than a regularly-repeating, crystal arrangement? Scientists suggested that the conditions necessary to form quasicrystals are significantly more complex than conditions for forming crystals. Yet, the energetics of the process are as yet not well understood.

There is no doubt that quasicrystals represent a new kind of a solid. Much of the research now focuses on how their unusual structure affects properties such as electrical conductivity or magnetism. A stimulating aspect of the discovery of quasicrystals is that it has led to a new appreciation of the importance of 5-fold symmetric objects in many spheres of science, from the shape of viruses[257] *and flowers to the patterns of fluid flow close to the onset of turbulence.*

[257] Simian virus 40 (SV40) is an example of a DNA virus. It appears to be spherical, but it is actually an icosahedron, a geometric figure with 20 faces that are equilateral triangles. The genome of this virus is a closed circle of double-stranded DNA, with genes that encode the amino acid sequences of five proteins. Three of the five proteins are coat proteins. Of the remaining two proteins, one, the large-T protein, is involved in the development of the virus when it infects a cell. The function of the fifth protein, the small-T protein, is not known. In the complete virus particle (called a virion), the coat proteins are packed around the DNA to give the observed icosahedral shape.

1912 CE **Casimir Funk** (1884–1967, Poland, U.S.A.), and **Frederick G. Hopkins** (1861–1947, England, 1906) independently discovered the vitamin concept. Funk isolated the crystalline B-complex and named it *vitamine* (= vit amine = amine essential to life). Later, the name was changed to *vitamin* when it was determined that the labeled substances were not all amines.

1912 CE **Chaim Weizmann** (1874–1952, England and Israel). Chemist and statesman. Found (1912) a bacterium *Clostridium acetobutylum* which would convert carbohydrate into acetone. This process proved of great importance in WWI as acetone is used in large quantities to plasticize the propellant cordite.

Weizmann was born in Motol, Russia. He obtained his Doctorate from the University of Fribourg, Switzerland (1899) and then moved to the University of Geneva, where he produced a number of patents on dyestuffs (1901). By this time he was already an important figure in the Zionist movement. In 1904 he moved to Manchester, England, to work with **William Henry Perkin, Jr**.

Weizmann became the president of the World Zionist Movement (1921). He founded (1934) the *Weizmann Institute of Science* in Rehovot and became the first President of Israel (1948).

1912–1924 CE **Franz Kafka** (1883–1924, Czechoslovakia). Novelist and one of the most influential thinkers of the 20-th century. Virtually unknown during his lifetime, his surreal works have become synonymous with the grotesque alienation of modern man in an unintelligible, hostile, or at least indifferent world.

In his novels '*The Trial*' (1914–1916, published posthumously 1925) and '*The Castle*' (1922–1924, published posthumously 1926), one finds authority a hierarchical, abstract, and impersonal "apparatus" whose operation is controlled by procedures which remain shadowy even to those carrying out its orders and *a fortiori* to those being manipulated. A modern citizen realizes that his fate is being determined by brutal, petty, and sordid characters (the bureaucrats), who themselves are cogs in this machine.

Kafka's critique of the state touches anonymous impersonal character insofar as this alienated, hypostatized and autonomous bureaucratic system is becoming transformed into an end-in-itself.

Kafka had a profound insight into the way the bureaucratic machine operates like a blind network of gears. When he speaks to us of the *state*, it is in the form of "administration" or "justice" as an impersonal system of domination which crushes, suffocates, or kills individuals. This is an agonizing, opaque, and unintelligible world where unfreedom prevails.

"*The Trial*" is often presented as a prophetic work. With his visionary imagination, the author had foreseen the 'justice' of the totalitarian state and the Nazi or Stalinist show trials.

It is no accident that the word *"kafkaesque"* has entered our current vocabulary. The term denotes an aspect of social reality that sociology and political science tend to overlook. With his libertarian sensibility, Kafka has succeeded marvelously in capturing the *oppressive* and *absurd* nature of the bureaucratic nightmare, the opacity, the impenetrable and incomprehensible character of the rules of the state hierarchy as they are seen *from below and the outside*. This runs contrary to social science which generally confines itself to examining the bureaucratic machine from the "inside" and taking the point of view of those "at the top."

Social science has not yet formulated a concept for the "oppressive effect" of a reified bureaucratic apparatus which undoubtedly constitutes one of the most characteristic phenomena of modern societies which millions of men and women run across daily. Meanwhile, this essential dimension of social reality will continue to be conjured up by reference to Kafka's work.

In his story "*Penal Colony*" (1915), written three months after the outbreak of WWI, the main character is the machine itself — a sinister apparatus which does not exist to execute a man, but rather the victim exists for the sake of the apparatus. Thus saw Kafka the Great War as an "apparatus of Authority," sacrificing human lives.

The work of Franz Kafka cannot be reduced to a political doctrine of any kind. The symbolic world of literature cannot be reduced to the discursive world of ideologies. It is not an abstract conceptual system similar to philosophical or political doctrines, but rather the creation of a concrete imaginary universe of individuals and things.

Kafka's works have been interpreted through certain schools as literary criticism such as *existentialism*, *Marxism*, *anarchism*, *Freudianism* and *Judaism*. It seems, however, that a combination of major biographical factors permeated and dominated the Kafkaesque world. These are

- Ill-health and consequent perpetual fear of physical and mental collapse. He was a bit of hypochondriac and anorexic. His prodigious consumption of unpasteurized milk was the source of his tuberculosis, which finally killed him at age 41.

- The complex relations with his father. Herman Kafka was a domestic tyrant, who directed his anger against his son. Kafka himself attributed much of his outlook on life to the affects of the relationship with his father. In *Letter to His Father* (1919) he stated: "My writing was all about you; all I did there, after all, was to bemoan what I could not bemoan upon your breast. It was an intentionally long-drawn-out leave-taking from you." His work was often fraught with cold, authoritarian figures that persecuted and threatened for reasons barely understood and often unexplained — a situation which perfectly summed up Kafka's childhood sense of his own father.

- The institutionalized system of control of the post Austro-Hungarian Empire, composed of: "a stand of soldiers, a sitting army of officials, a kneeling priests, and creeping army of informers."

- The Virgin/Whore complex[258] that made him virtually incapable of a "normal" sexual affair with a "nice girl" owing to his neurotic attitude toward sex.

- The historical Hassidic-Kabbalistic Jewish mystique.[259]

- The pervasive Czech-German anti-semitism in Prague [Kafka grew up in an atmosphere of familial tensions and social rejection that he experienced as a member of Prague's Jewish minority].

Franz Kafka was born in Prague to the Jewish family of Hermann (1852–1931) and Julie Loewy (1856–1934), who operated a small business for linen thread and cotton. In 1901 he graduated from a German High School and went on to the Karl Ferdinand University in Prague, where he graduated (1906) with a doctorate in law. During 1908–1922 he was employed by the "Institute for Worker Accident Insurance" in Prague. There he made reports on industrial accidents and health hazards. His profession marked the formal, legalistic language of his stories which avoided all sentimentality and moral interpretations — all conclusions are left to the reader.

---

[258] In this syndrome, every woman is either a "nice girl" or slut, with no room in between. So a normal adult affair with a woman he liked and respected would prove all but impossible, as **Felice Bauer** soon found out.

[259] Kafka was not a religious writer, and at face value, his writings have nothing to do with Judaism. However, his works incorporate and reinterpret many Jewish religious themes. Kafka had a positive relationship vis-à-vis his Judaism – it was not one of rejection or apathy. He had a strong Jewish identity albeit a highly troubled one.

He attended synagogue but four times a year, spoke mainly German and had little cultural involvement with the Jewish community, with the exception of Jewish theater groups. In 1911 he made a trip to Paris, Italy and Switzerland.

Kafka had three sisters: Gabriele (Eli): 1889–1942, Valerie (Vali): 1892–1943 and Ottilie (Ottla): 1890–1943. All of them, with their families, perished in the Nazi Holocaust: Eli and Vali at the Lodz Ghetto and Ottla gassed in Auschwitz on Oct 5, 1943.

His attitudes toward sexuality was marked by extreme neurosis. Unable to reconcile his physical urges (which were visited upon prostitutes and loose women) with his romantic longings, he had a series of prolonged, probably chaste, engagements that invariably ended in his breaking off the relationship. Despite this fact, and despite his being overwhelmed with feelings of inadequacy and self-loathing, he was much liked by friends (including women friends[260]) for his gentle, cool demeanor, his wry wit, and his obvious intelligence. He was further viewed not as weak and repulsive, his own fear, but as boyishly good looking, as well as neat and austere.

During 1907–1923, Kafka had intimate relations with at least eight women, some of whom impacted his creative work in one way or another. In order of occurrence they are:

- Hedwig Weiler (1887–1953), 1907–1908
- Flice Bauer (1887–1960), 1912–1917; engaged to
- Greta Bloch (1892–1944), 1913–1915
- Gerti Wasner (1895–?), 1913
- Julie Wohryzek (1891–1944), 1919–1920; engaged to
- Minze Eisner (?–?), 1920
- Milena Jesenská (1896–1944), 1920–1922

260 He once met a little girl in the streets of Berlin — five years old, or something like that — who was crying, and he asked her why she was crying, and she said it was because she'd lost her doll. And he said, 'You haven't lost your doll; she's gone on holiday.' And for the next weeks, Kafka wrote letters as from the doll to this little girl. Well, a man who can do that has a heart as big as all outdoors, as they say. So it was no wonder that his friends loved him, there's no wonder that his girlfriends loved him, despite all this maddening neuroticism and indecision.

- Dora Diamant (1898–1952), 1923–1924; lived with

Of these, Gerta Bloch, Julie Wohryzek and Milena Jesenska perished in the Holocaust.

Franz Kafka died in 1924 in the Kierling Sanatorium from complications related to tuberculosis. It has been noted that due to the great pain in his throat, from this condition, he was unable to eat and barely to drink in his last days. He often complained of thirst in his letters home to his father, and at the end may have simply starved to death. His body is buried in Prague, in the Jewish section of the Strasnice cemetery.

He remained self-deprecating about his writing, as he was about himself in general, and on his death bed asked his close lifelong friend **Max Brod** to burn all his unpublished works, including journals and correspondence. It was a promise Brod did not keep. Instead Brod, who had always been impressed with Kafka's literary abilities, edited a portion of what remained and had it published. Interest in Kafka's work soared and, over the years, has continued to garner a following. While Kafka holds a considerable following among existentialists, who find in his gloom and doom anxiety about life an expression of deepest truth (that we are meaningless and alone, yet can't help but yearn for it all to matter), he also finds sympathetic response among magical realists and others who favor an absurdest, surreal representation of life.

Kafka has become an icon of sorts, emblematic of modern times. His popularity increased exponentially after publication of his stories in the 20s and 30s of the 20^{th} century. He is now an institution, his own adjective. In 1995, somebody bought the manuscript of *The Trial* for to two million dollars, not bad for an uncompleted manuscript meant for the flames. Few writers had such an effect on their times as he had.

The asteroid 3412 Kafka, a small main belt bolide (discovered 1988) was named after him.

Worldview XXXIII: Franz Kafka

* * *

Logic is doubtless unshakable, but it cannot withstand a man who wants to go on living.

(The Trial)

* * *

The metaphysical urge is only the urge toward death.

(1912)

* * *

Beyond a certain point there is no return. This point has to be reached.

* * *

In the fight between you and the world, back the world.

* * *

Every revolution evaporates and leaves only the slime of a new bureaucracy.

* * *

The chains of the tortured humanity are made of the official papers of ministers.

* * *

If it had been possible to build
the Tower of
Babel without ascending it, the
work would
have been permitted.

* * *

Anyone who believes cannot experience miracles. By day one cannot see any stars.

* * *

We were expelled from Paradise, but Paradise was not destroyed. In a sense our expulsion from Paradise was a stroke of luck, for had we not been expelled, Paradise would have had to be destroyed.

* * *

You are free and that is why you are lost.

* * *

Anything that has real and lasting value is always a gift from within.

* * *

Either the world is so tiny or we are enormous; in either case we fill it completely.

* * *

All knowledge, the totality of all questions and all answers is contained in the dog.

* * *

There is a goal, but no way; but what we call a way is hesitation.

* * *

In science one tries to tell people, in such a way as to be understood by everyone, something that no one ever knew before. But in poetry, it's the exact opposite.

* * *

Altogether, I think we ought to read only books that bite and sting us. If the book does not shake us awake like a blow to the skull, why bother reading it in the first place? So that it can make us happy, as you put it? Good God, we'd be just as happy if we had no books at all; books that make us happy we could, in a pinch, also write ourselves. What we need are books that hit us like a most painful misfortune, like the death of someone we loved more than ourselves, that make us feel as though we had been banished to the woods, far from any human presence, like a suicide. A book must be the ax for the frozen sea within us. That is what I believe.

* * *

To die would mean nothing else than to surrender a nothing to the nothing, but that would be impossible to conceive, for how could a person, even only as a nothing, consciously surrender himself to the nothing, and not merely to an empty nothing but rather to a roaring nothing whose nothingness consists only in its incomprehensibility.

(1913)

* * *

It is entirely conceivable that life's splendor forever lies in wait about each of us in all its fullness, but veiled from view, deep down, invisible, far off.

(1921)

* * *

Youth is happy because it has the ability to see beauty. Anyone who keeps the ability to see beauty never grows old.

* * *

Discoveries have forced themselves on people.

(1913)

* * *

The meaning of life is that it stops.

* * *

The life of society moves in a circle. Only those burdened with a common affliction understand each other.

(1914)

* * *

We are sinful not merely because we have eaten of the tree of knowledge but also because we have not eaten of the tree of life.

* * *

Many a book is like a key to unknown chambers within the castle of one's own self.

(1903)

* * *

Writing sustains me. But wouldn't it be more accurate to say that it sustains this kind of life? Which does not, of course, mean that my life is any better when I don't write. On the contrary, at such times it is far worse, wholly unbearable, and inevitably ends in madness. This is, of course, only on the assumption that I am a writer even when I don't write — which is indeed the case; and a non-writing writer is, in fact, a monster courting insanity.

(1922)

* * *

When it became clear in my organism that writing was the most productive direction for my being to take, everything rushed in that direction and left empty all those abilities which were directed toward the joys of sex, eating, drinking, philosophical reflection and above all music.

(1912)

* * *

God doesn't want me to write, but I — I must.

* * *

These revolting doctors! Businesslike, determined and so ignorant of healing that, if this businesslike determination were to leave them, they would stand at sickbeds like schoolboys. I wished I had the strength to found a nature-cure society.

(March 5, 1912)

* * *

The priest: "We are not obliged to accept everything he says as true. It suffices that it is accepted as necessary."

Josef K.: “A mournful opinion; It elevates the lie to the stature of a world principle.”

* * *

Coitus is the punishment for the happiness of being together.

On Kafka

* * *

The look in Kafka's eyes was always a little puzzled, full of the wisdom of children and of melancholy slightly counterpointed by an enigmatic smile. He always seemed to be somewhat embarrassed.

John Urzidil

* * *

The fact is we all seem capable of living, because at some time or other we have taken refuge in a lie, in blindness, in enthusiasm, in optimism, in some conviction, in pessimism or something of the sort. He has never taken refuge in anything. He is absolutely incapable of lying, just as he is incapable of getting drunk.

Milena Jesenská

* * *

He marvels at everything, including typewriters and women. He will never understand.

Milena Jesenská

* * *

My Franz was a saint.

Felice Bauer

* * *

I couldn't read it for its perversity. The human mind isn't complicated enough.

Albert Einstein, after returning a Kafka novel loaned to him by Thomas Mann.

* * *

And his is — on another plane — the curse and grace of an almost saint-like abstemiousness . . . a readiness to let go, not to cling, which may be offensively modest and gentle in its inevitable gesture of refusal — a saintly, mild, almost Christlike gesture which is nonetheless ambiguous since it arouses, at the same time, the suspicion of a diabolical arrogance to the point where one would want to shout at him: "Don't pretend to be that small, you are not that great!"

Peter Heller

* * *

To do justice to the figure of Kafka in its purity and its peculiar beauty, one must never lose sight of one thing: it is the purity and beauty of a failure.

Walter Benjamin

* * *

In Kafka we have the modern mind, seemingly self-sufficient, intelligent, skeptical, ironical, splendidly trained for the great game of pretending that the world it comprehends in sterilized sobriety is the only and ultimate real one — yet a mind living in sin with the soul of Abraham. Thus he knows two things at once, and both with equal assurance: that there is no God, and that there must be God.

Erich Heller

* * *

A final paradox decrees that Kafka's books are among literature's least difficult. There is nothing subjective, arbitrary, or doubtful in them: Amerika *is not the truth according to Karl, or* The Trial *the truth according to Joseph K. Dickens is hard to understand, not Kafka. We have only to keep in mind all the events and characters of* Amerika *or* The Trial *or* The Castle *— a truth that stands far above or lies much deeper than Karl, Joseph K., K. and Kafka — will burst forth by itself, dazzlingly.*

Pietro Citati

* * *

1912 CE **Charles** (**Thomson Rees**) **Wilson** (1869–1959, England). Physicist. Invented the *Wilson Cloud Chamber*. This device made the tracks of high-speed atomic and nuclear particles *visible*, by means of trails of water droplets condensed on the ions produced along particle paths. For this achievement he won the physics Nobel prize in 1927. Wilson was born in Glencorse, Scotland.

1912–1925 CE **Henry Norris Russell** (1877–1957, U.S.A.). One of the leading astrophysicist of the era when physical understanding of stars was first emerging. Discovered, independently of **Hertzsprung**, the main sequence of stars by plotting the absolute magnitudes of stars against their spectral classes[261].

In 1912 he presented the earliest systematic analysis of the variation of the light received from eclipsing binary stars; he later pointed out the importance of the motion of the periastron of the orbit which provides information about the internal structure of the component stars. On the basis of his parallax studies, Russell developed the theory of stellar evolution that at the time was in good agreement with the data. This work stimulated **Eddington** and other astrophysicists. In 1925 Russell presented a reliable determination of the abundance of various chemical elements in the solar atmosphere. This work provided clear evidence of the predominance of hydrogen in the sun and, by inference, in most stars.

Russell was born in Oyster Bay, New York. He graduated from Princeton University in 1897 and remained there to obtain his doctorate in 1900. During 1902–1905 he stayed at Cambridge University, and since 1911 served as a professor of astronomy at Princeton. In 1921 Russell began his association with the Mt. Wilson Observatory, where he was a research associate until his retirement.

---

[261] The spectral types O, B, A, F, G, K, M and N, are essentially measures of the surface temperatures of the stars, running from about 20,000° at spectral class B to about 2500° at class N.

Fundamental Stellar Properties — H–R Diagrams

A number of fundamental quantities characterize a star; these include luminosity, temperature, radius and above all, mass. It is also important to know the distance to stars — in order to determine luminosity from apparent magnitude.

The luminosity *of a star is the* total *rate of energy it emits from its surface, and is usually measured in units of ergs per second. To measure it, it is necessary to take into account the distance to a star and the radiation received from it at* all *wavelengths, not just those to which the human eye responds. While stellar magnitudes (both apparent and absolute) refer to visible light, the bolometric magnitude is based on the star's radiation emitted over a much broader wavelength band than the eye can see. On the other hand, the wavelength at which the star emits most strongly depends on its* temperature. *Thus, by measuring a star's brightness at two different wavelengths, it is possible to learn something about its temperature.*

One can thus speak about a B (blue) magnitude and a V (visual, or yellow) magnitude. Since a hot star emits more light in blue than in yellow, its B magnitude is smaller *than its V magnitude. For a cool star, the situation is reversed. The difference between the B and V magnitudes is called the* Color index. *Stellar surface temperatures range from about 2000 K for the coolest M stars to $50,000$ K or more for the hottest O stars.*

In the first decade of the 20^{th} century ***E. Hertzsprung*** *and* ***H.N. Russell*** *began to consider how luminosity and spectral class might be related to each other. Each gathered data on stars whose luminosities (or absolute magnitudes) were known, and found a close link between spectral lines (temperatures) and absolute magnitudes (luminosities). This relationship is now called the Hertzsprung-Russell or H-R diagram. In this plot of absolute magnitude (on the vertical scale) versus spectral class (on the horizontal scale), stars fall into narrowly defined regions, rather than being randomly distributed.*

A star of a given spectral class cannot have just any absolute magnitude, and vice versa. In fact, the great majority of stars fall into a diagonal strip running from the upper left (high temperature, high luminosity) to the lower right (low temperature, low luminosity) of the H–R diagram. This strip has been given the name main sequence.

One group of a few stars fails to fall on the main sequence but appears in the upper right (low temperature, high luminosity) of the diagram. The *only way one star can be much more luminous than another of the same temperature is if it has a lot more surface area. Hertzsprung and Russell realized that these extra-luminous stars sitting above the main sequence must be much larger than those on the main sequence, and they called them* giants *and* supergiants*. Another group of stars appear off the main sequence in the lower left (high temperature, low luminosity) of the diagram. Since these stars are hot but not very luminous, they must be very small, and they have been given the name* white dwarfs*.*

The H–R diagram can be used to find the distance to a star, provided we can place it on the H–R diagram by determining its spectral class (i.e. as long as we know whether it is on the main sequence or is a giant, supergiant or dwarf). Once it has been placed on the diagram, its absolute magnitude is read off the vertical axis. A comparison of its absolute magnitude with its observed apparent magnitude then yields the star's distance from earth.

In a telescope all stars appear simply as points of light, so it is usually impossible to measure the size of a star directly. The radii of a few stars have been measured with an instrument called a stellar interferometer. Others can be deduced for stars that are members of binary systems. For most stars, however, the H–R diagram provides means to estimate their size in the following way: since luminosity is related to total surface area, a star's position in the H–R diagram depends partly on its size. We know that the Stefan-Boltzmann law specifically relates the three quantities luminosity, temperature and radius; use of this law allows the radius to be determined if the other two quantities are known[262]*.*

It has already been noted that the temperature attained by a star depends almost entirely on the initial mass *of the star. Indeed, studies of* binary stars *have provided knowledge of the masses of over a hundred individual stars. When the masses and luminosities of those stars for which both of these quantities are determined are compared, it is found that, in general, the more*

---

[262] The Stefan-Boltzmann law states that the emitted flux (measured in units of erg·cm^{-2}·sec^{-1}) is related to the temperature (in kelvins) by $E = \sigma T^4$ where $\sigma = 5.67 \times 10^{-5}$ erg·cm^{-2}sec^{-1}($^\circ$K)$^{-4}$ is the Stefan-Boltzmann constant. The corresponding luminosity is $L = 4\pi R^2 \sigma T^4$, where R is the star's radius. Solving for R we find $R = \frac{1}{T^2}\sqrt{\frac{L}{4\pi\sigma}}$. Scaling the quantities L, R, and T to those of the sun, we obtain $\frac{L}{L_\odot} = \left(\frac{R}{R_\odot}\right)^2 \left(\frac{T}{T_\odot}\right)^4$. These relations make it possible to transform the original H–R diagram into another in which the horizontal scale is not the temperature but the radius. In this representation (radius-luminosity relation), the main characteristics of the H–R diagram are retained, but the sequences are tilted in slightly different manner.

massive stars are also more luminous. This observation is known as the mass-luminosity relation.

The law seems to be $L \propto M^{3.7}$. *It provides a useful means of estimating the masses of stars of known luminosity that do not happen to be members of visual or eclipsing binary systems. The range of stellar masses seems to be between 0.1 and 50 solar masses. According to the mass-luminosity relation, the corresponding luminosities range from* 0.01 *to* 10^6 *solar luminosities — a much greater range indeed.*

During 1913–1962, *a large amount of information has been accumulated concerning the parameters of stars. It was then deduced that the relations are* statistical *in nature; actually there are very few, if any, parts of the radii-masses-luminosities space which are "prohibited", i.e. representative points may be found in many parts of the R-M-L octant which where previously believed to be completely empty. This result should not be confused with the well-established* statistical tendency *of the stars* in our galaxy *to occur in preferential bands within the model.*

It has been estimated that approximately 10^{11} *stars of the Milky Way system belong to the main sequence and obey the mass-luminosity relation. The total number of white dwarfs may be one hundred times less. The giants are probably* $10,000$ *times less frequent than the main sequence stars.*

1912 CE **Henrietta Swan Leavitt** (1868–1921, U.S.A.). Astronomer. Elucidated the properties of a class of pulsating stars (Cepheid variables[263]) via predictable relation between period and intrinsic brightness and used them for calculating distances to remote and even extra-galactic stars. This enabled **Hubble** in 1929 to formulate his law of expansion.

Leavitt graduated from the women's college that was affiliated with Harvard College, in 1892. In 1902, after working as a volunteer research assistant, Leavitt became a permanent staff member of the Harvard College Observatory. She conducted studies of stellar magnitudes (star brightness) and became head of the department of photographic stellar photometry.

[263] Pulsating stars that vary regularly in brightness, with periods ranging from a few days to several months. First identified in the 18^{th} century. We now know that the variations are caused by periodic expansions and contractions of the stellar surface.

In 1912, after about five years of single-minded study, she found that the periods of the Cepheids were proportional to their luminosity. Such a relationship can be calibrated for nearby Cepheids, where the distance is known. Then it can be used to gauge the distances to remote Cepheid stars. If it is necessary to know the distance to a globular cluster or nebula or galaxy, the astronomer simply has to identify a Cepheid star inside it. For this reason, Leavitt's relationship became important to the measurement of interstellar and intergalactic distances. Leavitt also discovered four novae (stars that suddenly become brighter and within a few months gradually fade away) and more than 2,400 variable stars.

1912–1913 CE **Gunnar Nordström** (1881–1923, Finland). Physicist. Presented a pre-general-relativity theory of gravitation, which was the first logically consistent relativistic field theory of gravitation ever formulated. The theory is Lorentz invariant, and satisfies the conservation laws, but the equivalence principle appears in it as a statistical law. Later (1914) Nordström proposed to use a five-dimensional space for the unification of electromagnetism with a *scalar* gravitational field[264].

1912–1915 CE Einstein's work stimulated an outpouring of short-lived abortive gravitational and unified-field theories, by physicists and mathematicians alike. Noted among them were **Max Abraham** (1875–1923), **Gustave Mie** (1868–1957) and **David Hilbert** (1862–1943).

1912 CE Opening of the *Kaiser-Wilhelm Institutes* in Berlin-Dahlem, Germany, marks the pinnacle of German science. A year earlier (1911) the Kaiser Wilhelm Society was established. The first president of the Society and the Institute was the historian **Adolf von Harnack**[265] (1851–1930), to be followed by Max Planck.

The first institute was that of *chemistry*, including **Ernst Beckman**, **Richard Willstätter**, **Otto Hahn**, and **Lise Meitner**. The second institute was that of *physical chemistry* of which **Fritz Haber** became the director. The third institute was that for *experimental therapy* under the directorship of **August von Wasserman**. The building of the fourth institute, for *biology*, was finished in 1915. Einstein was supposed to be the director of the institute for *physics*, but the plans were suspended because of the War and taken up only in the 1930s, when it was built with the financial support of the Rockefeller Foundation. When it was finished, Einstein had already left.

---

264 This is one of the abortive 'STR gravitation' theories.

265 Harnack belonged to a large family, prominent in universities, industry, and government. Because of its well-known liberal and progressive attitude many members of the family were executed by the Nazis.

The Kaiser Institutes were destined to become one of the greatest and most brilliant centers of that era.

After the turmoil of the first postwar years, an extraordinary renaissance also took place in literature, art, music, theaters, operas and other areas. It is thus not surprising that Berlin, in the 1920s, impressed visitors from abroad as the scientific and intellectual capital of the world, in spite of the lost war. Indeed, in the mid 1920s the Kaiser Wilhelm Institutes became one of the world's greatest centers, particularly in chemistry, physical chemistry, and the biological sciences.

In physics there were centers of great attraction, especially in atomic physics:

at the University of Berlin, with **Planck**, **Einstein**, **Schrödinger**, **von Laue**, and **Nernst**;

at the University of Göttingen, with **Franck** and **Born** and their intimate collaboration with the famous mathematicians there;

at the University of Hamburg, with **Otto Stern**;

at the University of Munich, with **Sommerfeld**;

and at the University of Leipzig, with **Werner Heisenberg**.

1912–1922 CE **Alfred Lothar Wegener** (1880–1930, Germany). Meteorologist, geophysicist and Arctic explorer who mixed research with adventure. First to propound in exhaustive detail his then-revolutionary hypothesis of *continental drift* based on fossil and glacial evidence.

He contended that evidence of past climates, supported by evidence from widely scattered disciplines, could not be reconciled with the fixed position of the continents and of the north and south magnetic poles.

Wegener was then led to assume that the now-separated continents must at one time have formed a single large mass, which he named *Pangaea* (pan=all, gaia=earth; meaning "all land"). He maintained that some 200 million years ago, Pangaea began breaking into smaller continents that "drifted" to their present position. Ancient climatic similarities, fossil evidence, and rock structures — all seemed to bridge together these now separate landmasses.

Other geologists refined Wegener's theory, arguing that Pangaea first split into two smaller supercontinents they called *Laurasia* and *Gondwanaland*, separated by what was called the *Tethys.* Gondwanaland later split into Africa and South America, while Laurasia divided to become North America and Eurasia. The Mediterranean Sea, according to this theory, is a surviving remnant of the ancient Tethys Sea.

Wegener was born in Berlin and took his doctorate in astronomy. He was a Renaissance man, also studying meteorology, biology, paleontology and much besides. He was selected as meteorologist to a Danish expedition to northeast Greenland. A second expedition to Greenland in 1912, included the longest crossing of the ice cap ever undertaken.

Wegener first presented his continental-drift hypothesis in 1912 in a lecture before the German Geological Association in Frankfurt am Main. His fuller development of the theory appeared in his 1915 book *Die Entstehung der Kontinente und Ozeane* (The Origin of Continents and Oceans).

Wegener's ideas were initially met with ridicule and scorn and he suffered criticism from the pillars of orthodoxy in geophysics and geology. His theory was too radical for the time, and his book brought him more notoriety than praise. Although it was generally accepted that the continents do float in a denser, somewhat plastic mantle beneath them, few could accept the idea that entire continents could move around the earth at speeds that must be as great as several centimeters per year. He was also ridiculed for failing to explain the origin of a force that would permit "continents of granite to flow through oceans of rock".

Wegener lost his life on the Greenland ice sheet during a mission to establish a mid-ice observatory. The proofs he was seeking were found years later, quite by chance and on another frontier — at the bottom of the sea.

Continents Adrift[266] *(1912–1968)*

The idea of continental drift is very old[267]*; the notion that continents, particularly South America and Africa, fit together like pieces of a puzzle has*

---

266 For further reading, see:

- Tarling, D. and M. Tarling, *Continental Drift*, Anchor Books: New York, 1975, 142 pp.

267 Genesis **1**, 9–10 "And God said, Let the waters under the heaven be gathered together unto one place, and let the dry *land* appear: and it was. And God called the dry *land* Earth; and the gathering together of the waters called he Seas: and God saw that it was good".

Genesis **10**, 25: "And unto Eber were born two sons: the name of one was Peleg; for in his days was the earth divided". [Also, *Chronicles* **1**, 19.]

been around as long as world maps. ***Francis Bacon*** *(Novum Organum, 1620) had already wondered about the coincidence of coastlines. In* 1668 *a French monk,* ***Francois Placet****, suggested that the continents had been broken apart by the Deluge. Another theological scholar,* ***Theodore Lilienthal*** *(1756), also found biblical evidence for the separation of a single land mass into the present continents.*

In 1858, ***Antonio Snider-Pelligrini*** *made the first geological (as opposed to geometrical) survey of similarities of the continents on either side of the Atlantic. Charles Darwin found convincing signs of* vertical *movements of land masses, but did not see evidence for large-scale horizontal movements. His son,* ***George Howard Darwin*** *(1845–1912), suggested in* 1878 *that the moon originated by being thrown off from the Pacific area of the spinning earth or being drawn from it by gravitational attraction of a passing star. This idea was extended by* ***Osmond Fisher*** *in* 1882, *when he suggested that the continents broke up at the same time of the moon's separation, and subsequently readjusted their positions to the new shape of the earth.*

In 1908 ***Frank B. Taylor*** *(U.S.A.) suggested that the tidal pull of the moon might have tugged the continents about on the surface of the planet. In 1911,* ***Howard B. Baker*** *(U.S.A.) revived Darwin's idea that the continent might have been set in motion by the planet Venus, who had swooped close enough to tear out a chunk of the Pacific floor, which became the moon.*

Wegener's intriguing idea did not die with him. After decades of skepticism, evidence has come to light to confirm the essence of his theory. Indeed, during the years that followed his proposal, great strides in technology permitted mapping of the ocean floor, and extensive data on seismic activity and the earth's magnetic field became available. By 1968 *these developments led to the unfolding of a far more encompassing theory, known as* plate tectonics. *It became one of the most important geological discoveries of the* 20^{th} *century; in essence it is the realization that our planet has an active, constantly changing crust. This crust is divided into huge* plates *that jostle each other, producing earthquakes, volcanoes and oceanic trenches. Plate tectonics is responsible for many details of the earth's surface, including mountain ranges.*

A careful examination of the currently active features of the land and the ocean floor has suggested that the earth now consists of 6 *large blocks which are in motion relative to each other. These are:*

- The Pacific block *consists of most of the Pacific Ocean and includes small fragments of the west coast of North America.*

- *The American block* consists of North and South America as well as the western half of the Atlantic Ocean. The Caribbean region forms a small subblock.
- *The Eurasian block* is almost entirely continental, consisting of all of Europe and most of Asia, including the East Indies and the Philippines.
- *The African block* consists of the continent of Africa, Madagascar, the eastern half of the South Atlantic Ocean, and the western half of the Indian Ocean.
- *The Indian block* stretches from the Arabian peninsula to New Zealand. The block contains the portion of Asia south of the great mountain range from Turkey on the west to the Himalayas, and the west coast of Burma on the east. The eastern half of the Indian Ocean, New Guinea, and Australia are included in this block.
- *The Antarctica block* consists of the continent of Antarctica and the Southern Ocean. It includes a strip of the Pacific between the East Pacific Rise and the west coast of South America.

The differential motions of these 6 blocks lead to the formation of new ocean floor where the blocks are moving apart, and to a loss of surface where the blocks are forced against each other. The areas where new surface is created correspond to the *mid-ocean ridges*. Where all blocks are driven into each other, the surface expression is more complex: Some of these areas correspond to ocean trenches. Along other segments where the blocks are pressing against each other, we find active mountain belts, such as the Himalayas. While these appear to be compressional features, trenches seem to be the result of tension.

It appears that the rigid surface of the earth, the *lithosphere*, which is tens of kilometers thick, rests on a weaker layer, the *asthenosphere*. The lithosphere is divided in large blocks which move relative to each other. The boundaries between the blocks are zones of weakness, where earthquake activity reveals relative motion. The fact that the present blocks have existed for *tens of million of years* indicates that the breaks in the lithosphere tend to be preserved. However, over long periods, these breaks heal and new breaks develop; thus the pattern of blocks may change.

The existence of a more plastic asthenosphere under the relatively rigid lithosphere (though elastic as far as seismic waves are concerned) facilitates the motion. Nevertheless, frictional forces at the bottom of the blocks and at the points where the blocks are converging would tend to stop the drift in the absence of a driving force.

The main force within the earth is thermal energy, which results from the radioactive decay of uranium, thorium, and an isotope of potassium. This *outward flux of heat amounts to about* $1.5 \times 10^{-6}\ \frac{\text{cal}}{\text{sec}\cdot\text{cm}^2}$. *This is much less heat than is received from the sun, so that the heat flux from the interior does not directly affects the climate on earth. The total* heat flux, *however, is* $60\ \frac{\text{ergs}}{\text{sec}\cdot\text{cm}^2}$, *which is* 10^9 *times the kinetic energy of the lithosphere in motion.*

The heat from the interior can be transferred by conduction, radiation, and convection. Of these, only convection is associated with motion, and so could be the driving force *for continental drift.*

Convection currents result if a fluid is heated from below. The density difference between the heated and cool fluids results in vertical motion, since the heated fluid rises and the cooled fluid sinks. The vertical motions become spatially organized and result in a pattern of vertical convection cells. *The horizontal motion at the top of the asthenosphere exert forces on the blocks of the lithosphere. The direction of the net force will depend on the disposition of the blocks relative to the convection cells*[268].

---

[268] Although the theory of *plate tectonics* is well established, the engine that drives the motion of the lithospheric plates continues to defy easy analysis because it is so utterly hidden from view.

Among the regions offering the best access to the earth's insides are the mid-ocean ridges. These ridges dissect all major oceans. They actually make up a system that winds around the globe, stretching a total of more than 60,000 km. The *Mid-Atlantic Ridge* (MAR) is a part of that global ridge system; a huge north-south scar in the ocean floor, it forms as the eastern and western parts of the Atlantic move apart at a speed of roughly $1\ \frac{\text{cm}}{\text{year}}$. In addition to the frequent earthquakes that take place there, the summit of the MAR spews out hot magma during frequent volcanic eruptions. The magma cools and solidifies, thus forming new oceanic crust. The magma that rises in the MAR originates in the upper mantle and forms a common kind of rock known as *basalt*. It is known, however, that the upper mantle is made of *peridotite* which consists mostly of three silicon-based minerals: *olivine* (a dense silicate containing magnesium and iron); *orthopyroxene* (a similar and less dense mineral); *clinopyroxene* (incorporates some aluminum and calcium) and *spinel* (an oxide of chromium, aluminum, magnesium and iron).

Hot peridotite rises under the mid-ocean ridges from depths exceeding 100 km below the seafloor. As it moves upward, it decompresses and partially melts. The melted part takes on the composition of basaltic magma and separates from the peridotite that did not melt.

1912–1925 CE **Vesto Melvin Slipher** (1875–1965, U.S.A.). Astronomer. Made systematic observations of radial velocities of spiral galaxies[269] (then known as Nebulae). These observations provided the first evidence supporting the expanding-universe theory.

Slipher was born at Mulberry, Indiana. In 1901 he joined the staff of the Lowell Observatory at Flagstaff, Arizona, and in 1916 became its director. There he organized and guided the search that resulted in the discovery of Pluto, the ninth known planet of the solar system. Slipher's extensive investigations led to the determination of the rotational periods of several planets. His discovery of dark absorption bands in the spectra of Jupiter, Saturn, and Neptune led to the identification of some of the chemical constituents of their atmospheres. He demonstrated that many diffuse nebulae (clouds of dust and gas) shine by the reflected light of nearby stars.

1912–1930 CE **Eduard Helly** (1884–1943, Austria and USA). Mathematician. Worked on functional analysis and proved the *Hahn-Banach theorem* (1912), 15 years before Hahn published essentially the same proof, and 20 years before **Banach** gave his new setting. He is remembered for the *Helly Theorem*[270] (published by him in 1923).

Helly came from a Jewish family in Vienna. He studied at the University of Vienna and was awarded his doctorate in 1907 after writing his thesis under the direction of **Mertens**. He worked in the field of mathematics until he enlisted in the army at the beginning of World War I. He was wounded in September 1915 and became a Russian prisoner of war in Siberia. After returning to Vienna in 1920, Helly was unable to secure permanent employment as a mathematician and worked as a bank clerk and insurance actuary until 1938 when Austria was taken into the Third Reich and Helly and his family escaped to the U.S. He was able to work at various mathematically-related positions until his death of a heart attack in 1943.

Had Helly succeeded in staying in the mainstream of mathematics, as an academician who published and participated in seminars, he would have undoubtedly have capitalized on his earlier contributions. He not only might

---

[269] He found that the Andromeda galaxy approaches us at a speed of 200 km/sec ('*violet shift*').

[270] It states that if there are given n convex subsets of a d-dimensional euclidean space with $n \geq d+1$ and if each collection of $d+1$ of the subsets has a point in common, then there is a common point of the n subsets. His 1912 paper also includes the *Helly Selection principle* which says that given a sequence of functions of bounded variation which are of uniform bounded variation and uniformly bounded at a point, then there exists a subsequence which converges to a function of bounded variation.

have seen to it that proper credit should be ascribed, but it is likely that he would have extended his results further. In most careers there are some disappointments and failures, but Helly's career derailed early, and life never gave him a chance to get back on the right track.

1912–1933 CE **Edwin Howard Armstrong** (1890–1954, U.S.A.). Inventor and electrical engineer who made important contributions to radio communications. He developed the superheterodyne circuit which became widely used in radio receivers (1918). In 1933 he invented the *frequency modulation* (FM) system for short-wave broadcasting. Armstrong was born in New York city.

His invention of the regenerative (feedback) circuit[271] in 1912, while he was still in college, was challenged by **Lee de Forest** in a series of lengthy patent suits. Although Armstrong lost the case, the scientific community continued to support his claims. His invention of the heterodyne principle (1918) was also challenged in a patent suit. In poor health, with most of his money gone, he committed suicide[272].

Armstrong has posthumously received increasing recognition for his many important inventions. He was the father of FM radio, the grandfather of radar and a great grandfather of space communication.

1912–1935 CE **Otto Heinrich Warburg** (1883–1970, Germany). Distinguished biochemist and cell-physiologist. His researches had a seminal effects

---

[271] When the feedback was increased beyond a critical level, the triode tube turned into an *oscillator* (instead of just being a receiver) which not only amplified radio signals but generated them as well, and this advance made all the difference. As a radiowave generator (transmitter), this circuit is still at the heart of all radio-television broadcasting. By the end of WWII, Armstrong developed his continuous wave FM radar to a point where he was able to bounce a radio signal 400,000 km to the moon and back again. He had proven that FM waves, unlike AM waves, could penetrate the ionosphere. That paved the way to radio communication in space.

[272] By 1934, Armstrong had helped create an industry which was worth almost 2 billion dollars. Thus, RCA, Zenith, Philco, Magnavox and everybody else were all turning fantastic profits, using Armstrong inventions without paying him royalties. In 1948 he took RCA to court but legal fees exhausted his assets. After his suicidal death, RCA offered his widow a million dollars (much less than one percent of their profits from Armstrong inventions), the same amount David Sarnoff (RCA president) offered Armstrong in 1940. In effect Sarnoff had finally got an answer to the question: "Do you want me to pay you, or your widow?"

on the development of biochemistry throughout the 20^{th} century. Elucidated the main biochemical processes of *respiration*, *fermentation* and *photosynthesis*, together with the enzymatic mechanisms that activate them. Discovered the respiratory enzymes (1912–1923) and was first to note the action of *coenzyme* (1935).

Warburg's major achievements:

- Devised techniques, particularly of manometry[273] and spectrophotometry, which have been the mainstays of many biochemical laboratories over a span of 60 years and used them to investigate oxidative processes occurring in living cells. In particular, developed a method of studying respiration in thin slices of tissue.
- Clarified the biocatalytic function of *iron* in the enzymes of biological oxidation. Discovered the 'respiration ferment'[274] in which he saw the activator of the molecular oxygen for the absorption of hydrogen from the substrate (dehydrogenization).
- Isolated and characterized many of the enzymes and their coenzymes, thus laying much of the foundation on which rests the present understanding of the *cell's energy metabolism*. The methods he devised for the isolation of enzymes have found widespread industrial applications and the techniques he developed for their assay are still widely used, especially in clinical diagnosis.
- Developed a theory for the biochemical basis of *cancer* formation. This theory was not fully verified[275] but fertilized the biochemical research of tumors.

---

[273] Metabolic processes are accompanied by production or absorption of gases. The manometric method accurately measures changes in the pressure of these gases. His manometric apparatus became a standard tool for measuring metabolism in living cells.

[274] Oxidation-reduction reactions are concerned with the production of heat and energy in the body. The enzymes involved include the *oxidases*, which activate molecular oxygen; the *dehydrogenases*, which catalyze the removal of hydrogen of a substrate to an easily reducible substance; and the *peroxidases*, which catalyze the decomposition of organic peroxides and hydrogen peroxide. Warburg's 'respiration ferment' was identified with the *cytochrome oxidase*, at the end of the oxidation chain.

[275] Warburg's intolerance of criticism and obsession with some of his own theories estranged him from the mainstream of thought in these areas. Toward the end of his life he was clinging to views almost universally rejected by other scientists.

Warburg was a descendant of an illustrious Jewish family of scientists, bankers and philanthropists, whose ancestors came to the town of Warburg in Westphalia from Bologna, Italy in the 17^{th} century. His father **Emil** (1846–1931), a known physicist in Strasbourg and Berlin, converted to Christianity. His uncle **Otto** (1859–1938), professor of botany, became the president of the World Zionist Organization (1912–1920).

Warburg was born in Freiburg-im-Breisgau. Studied chemistry under **Emil Fischer** (Ph.D.: Berlin, 1906) and medicine at Heidelberg (M.D.: 1911); professor in Berlin (1915–1952), Göttingen (1953 ff.). Awarded two Nobel prizes in physiology or medicine (1931, 1944[276]).

Warburg continued to work during the whole duration of the Nazi regime and was never disturbed or harmed by the Nazis. According to Nazi ideology, he would be considered as a *half-Jew* (his father was baptized and his mother came from an old distinguished non-Jewish German family). However, influential friends succeeded in convincing Hitler that Warburg was the only scientist who offered serious hope of producing a cure for cancer some day. Hitler apparently suffered from a strong phobia of cancer, and this factor induced Göring to arrange a recalculation of Warburg's ancestry — with the result that he was considered to be a *quarter-Jew*.

In 1943, air attack made his life in Berlin dangerous and Warburg moved his laboratory to an estate 50 km north of Berlin. Here he worked undisturbed until 1945, when the Russians occupied the area and removed all the equipment from the laboratory. The Russian commander-in-chief, Marshall Zhukov, told Warburg in the name of the Russian government that the dismantling of the laboratory was an error. Although the Marshall ordered the return of the equipment and the books, they could not be traced.

Enzymes

None of the chemical reactions taking place in the human body such as digestion, respiration and metabolism, would be possible without enzymes, which are the most important tools of the living cell. It has been estimated

[276] By Hitler's decree he was unable to receive the second.

that there are as many as 1000 separate enzymes in a single cell, each responsible for a specific chemical reaction. The absence or inaction of a single enzyme can disrupt a key process and result in dysfunction or death of the organism.

Enzymes are organic catalysts formed by living cells, but their actions are independent of the presence of living cells. All enzymes have been found to be proteins in nature. While some enzymes consist entirely of proteins, other require non-protein components in order to be active. The component firmly attached to the enzyme that makes it active is said to occupy the active site. If the activating component is easily separated, it is known as a coenzyme. Several vitamins of the B complex group have been found to be constituents of certain coenzymes. The most important coenzymes are:

Nicotinamide adenine dinucleotide (NAD),

Nicotinamide adenine dinucleotide phosphate (NADP),

Flavin mononucleotide (FMN),

Flavin adenine dinucleotide (FAD),

Coenzyme A (CoA).

The first four coenzymes are involved in oxidation-reduction reactions. NAD and NADP accept hydrogen atoms from a substrate and transfer them to FMN and FAD, and FMN and FAD transfer the hydrogen atoms to the cytochromes. The cytochromes in turn transfer the hydrogen atoms to an enzyme called cytochrome oxidase, which activates oxygen so that it may combine with the hydrogen to form water.

Coenzyme A is involved in the metabolism of carbohydrates (citric acid cycle) and the biological synthesis and degradations of fatty acids.

Some enzymes are first produced in an inactive form. Such a precursor of an active enzyme is called a proenzyme (or zymogen). The proenzyme must be activated by some other substance. For example: the inactive proenzyme pepsinogen is converted into active pepsin by the HCl in the gastric juice.

The generally accepted theory for enzyme action is that the enzyme (E) first combines with the substrate (S) to form an enzyme-substrate complex (ES). The enzyme substrate complex undergoes a chemical change and then dissociates, yielding the reaction products and liberating the original enzyme: $E + S \to ES \to E + \text{products}$.

Enzyme specificity has been explained by the lock and key theory, which postulates that each enzyme has an active catalytic center of precise chemical structure or surface shape to which the substrate fits perfectly.

Enzymes catalyze a reaction by lowering the activation energy required to initiate it. Without enzymes, chemical reactions in the body would proceed too slowly to maintain life.

Unlike inorganic catalysts, such as platinum, which catalyze many reactions, enzymes are highly specific in their action. Thus lipase will catalyze the hydrolysis of lipids, but not of carbohydrates or proteins. Sucrase will hydrolyze sucrose, but not lactose or maltose.

Enzymes are also more efficient than inorganic catalysts. Sucrase, for example, is 10^6 times more powerful than the hydrogen ion in the hydrolysis of sucrose. Another difference between enzymes and inorganic catalysts is that enzymes are easily destroyed by heat, while inorganic catalysts are not affected by high temperatures. Among the factors influencing the rate of enzyme action are: the concentrations of the substrate and of the enzyme, the temperature, the pH, and the accumulation of end products which slow down the reaction according to the law of mass action.

Some enzymes require the presence of a metallic ion for their activity (e.g. Fe^{+2}, Fe^{+3}, Co^{+2}, Zn^{+2}, Mn^{+2}, Mg^{+2}, Mo^{+2}).

Certain chemicals have a toxic or inhibitory effect upon enzyme activity. Among these are formaldehyde, chloroform, carbon tetrachloride, arsenic compounds, cyanides, and heavy metals like mercury and silver.

Other inhibitors include antibiotics (streptomycin, auremycin), antienzymes (e.g. antitrypsin from soybeans), and antimetabolites (such as sulfanilamide).

Example of a specific enzyme: oxygen enters the red blood cells where it combined with hemoglobin to form oxyhemoglobin. This oxyhemoglobin reacts with bicarbonates to form carbonic acid (H_2CO_3) and a basic form of oxyhemoglobin. The carbonic acid, in the presence of the enzyme carbonic anhydrase, decomposes into carbon dioxide and water:

$$H_2CO_3 \xrightarrow[\text{unhydrase}]{\text{carbonic}} CO_2 + H_2O$$

The basic oxyhemoglobin is carried to the tissues by the blood. Because of the low partial pressure of oxygen in the tissues (40 mm Hg as against 100 mm Hg in the lungs), the basic oxyhemoglobin decomposes to oxygen and basic hemoglobin. The oxygen, thus released, diffuses into the tissue cells where it enters into metabolic reactions. The reduced hemoglobin returns to the lungs in the venous blood.

The CO_2 formed by metabolic reactions in the tissues diffuses into the plasma and enters the red cells where the enzyme carbonic anhydrase, now working in reverse, catalyzes its combination with water to form H_2CO_3. The *carbonic acid reacts with the basic hemoglobin to form bicarbonates and acid-reacting hemoglobin. As the bicarbonate ion concentration increases, these ions diffuse out of the red cells and into the plasma. To balance the loss of the negative ions from the red cells, an equal number of chloride ions enter the red cells from the plasma. CO_2, mainly as bicarbonates, is returned to the lungs.*

1912–1942 CE **Milutin Milankovitch**[277] (1879–1958, Yugoslavia). Applied mathematician, engineer and astronomer. Proposed (1920) an astronomical theory of Ice Ages. He concluded that variations in *summertime* radiation at high latitudes in both hemispheres result primarily from variations in *axial tilt* (41,000 year cycle), but include also the effect of equinoxial precession (22,000 year cycle). Taking into account changes in the reflective power of the earth, he calculated how the geographic positions of ice-sheet margins varied over the past million years. The essential feature of the Milankovitch theory is a curve that shows how the intensity of *summer sunlight*[278] varied over the past 600,000 years at any given latitude. He identified certain low points on the 65° curve with 4 European Ice Ages.

[277] For further reading, see:

- Milankovitch, M., *Canon of Insolation and the Ice-Age Problem*, Translated from German by the Israel Program for Scientific Translations, Jerusalem, 1969, 484 pp.
- Imbrie, J. and K. Palmer Imbrie, *Ice Ages: Solving the Mystery*, Enslow Publications: New Jersey, 1979, 224 pp.

[278] He reasoned that changes in winter radiation could hardly have much effect on the annual snow budget, because temperatures in Arctic regions are cold enough for snow to accumulate even in modern times. During the summer, however, modern glaciers melt. Therefore any decrease in the intensity of summer sunlight would inhibit melting, render the annual snow budget positive, and lead to glacial expansion.

The effect of tilt on the distribution of sunlight was as follows: when the tilt is decreased from its present value of $23\frac{1}{2}^\circ$, the polar regions receive less sunlight than they do today. When the tilt is increased, polar regions receive more sunlight. The possible limits of these effects (never actually achieved) would be a tilt of 0°, when the poles would receive no sunlight and a tilt of 54°, when all points on earth would receive the same amount of sunlight annually.

With the publications of these radiation curves, geologists understood for the first time how two of the astronomical cycles influenced the pattern of incoming solar radiation: It was now clear that *the strength of these effects varied systematically with latitude*.

The influence of the tilt cycle (41,000 years) is large at the poles and decreases towards the equator. In contrast, the influence of the precession cycle (22,000 years) is small at the poles and becomes large near the equator. This meant that the curves calculated for high latitudes are dominated by the 41,000-year cycle, while those for low latitudes are dominated by the 22,000-year precession cycle[279].

---

[279] The radiant energy available at the top of the atmosphere at latitude φ, is a single-valued function of the *solar constant* S_0, the *semi-major axis* a of the earth's elliptic orbit in the ecliptic, its *eccentricity* $e = \sqrt{a^2 - b^2}$, the earth's axial tilt (*obliquity*) relative to the normal to the ecliptic, ϵ, and the *longitude of the perihelion* $\varpi = \Pi + \Psi$, measured from the *moving* vernal equinox. [Ψ is the precession in longitude which describes the absolute motion of the vernal equinox along the earth's orbit relative to the fixed stars. Π is the longitude of the perihelion, measured from the reference vernal equinox of 1950 CE, and describes the absolute motion of the perihelion relative to the fixed stars.]
The time variation of insolation thus requires the long-term variations of the orbital elements of the earth. These are expanded in trigonometric series

$$e = e_0 + \sum E_i \cos(\lambda_i t + \phi_i),$$
$$e \sin\varpi = \sum P_i \sin(\alpha_i t + \beta_i),$$
$$\epsilon = \overline{\epsilon} + \sum A_i \cos(\gamma_i t + \delta_i),$$

with $e_0 = 0.028\,706$, $\overline{\epsilon} = 23.320\,556\,^\circ$ and time $t = 0$ refers to 1950 CE. In these series, the values of the $\{E_i, \lambda_i, \phi_i, P_i, \alpha_i, \beta_i, A_i, \gamma_i, \delta_i\}$ have been calculated for many terms. The series provide us directly with a power spectral analysis of the time variation of the orbital elements. It turns out that the four largest terms of the *precessional component* $e \sin\bar{\omega}$ have period of 23,716; 22,428; 18,976; 19,155 years. The first two and the last two clearly correspond, respectively, to the 24,000- and 19,500-years periods found in 1976 in *deep sea cores*.
In the obliquity term, not only does the dominant component has a period of 41,000 years, but also 5 of the next 10 largest components have periods very close to 41,000 years.
For the eccentricity the situation is more complicated: the *mean period* over the past 5 million years is 95,800 years, while the leading first term has a periodicity of 412,085 years — too long to stand out clearly in the analysis of deep-sea cores.

Milankovitch had acquired his Ph.D. in 1904 at the Vienna Institute of Technology. After graduating he worked for five years as a practical engineer. In 1909 he joined the University of Belgrade as a professor of applied mathematics. He started to work on Ice Age problems in 1911 and it took him 25 years to complete his calculations. Basing his work on earlier results of **Pilgrim**[280], he still had to calculate how much solar radiation strikes the surface of the planet during each season and at each latitude, taking into account its spinning, revolving, wobbling and tilting motions. Later he wrote: "*I set out on this hunt in my best years. Had I been somewhat younger I would not have the necessary knowledge and experience. Had I been older I would not have had enough of that self-confidence that only youth can offer in the form of rashness*".

The most valuable feature of the Milankovitch theory was that it made testable predictions about the geological record of climate. It predicted how many Ice-Age deposits geologists would find, and it pinpointed when these deposits had been formed during the past 650,000 years.

During the 1930's and 1940's, most European geologists were won over to the Milankovitch theory since both the radiation diagrams and the climatic diagrams matched at four Pleistocene Ice Ages. But the early 1950's saw a dramatic about-face. By 1955 the astronomical theory was rejected by most geologists: the downfall of the theory was the development of the radiocarbon dating method[281] developed by **Willard F. Libby** during 1946–1949.

Geologists, by using the radiocarbon dates beyond the reliable range of the method (40,000 years), and basing their case solely on evidence collected from the surface of the land, have found that major glacial advances occurred 60,000, 40,000, and 18,000 years ago. Only the youngest of these advances had been predicted by Milankovitch. There were more glacial advances during an interval of time *they believed to be* the last 80,000 years than could be explained by the Milankovitch theory. By 1965, the astronomical theory of the Ice Ages had lost most of its supporters.

---

280 The German **Ludwig Pilgrim** calculated in 1904 how the eccentricity, tilt and precession of the earth's orbit varied over the past million years.

281 A radioactive isotope of carbon, ^{14}C, is produced in small quantities in the upper atmosphere by cosmic rays. Eventually, the radiocarbon atoms in the atmosphere are absorbed into the bodies of all living plants and animals. But organisms continue to acquire ^{14}C only as long as they live. *After death*, the radiocarbon atoms in the organic tissues disintegrate, changing into stable-nucleus atoms of nitrogen at a measurable rate. Libby reasoned that it should be possible to use this rate to calculate the *time of death* for any fossil: all that was necessary was to measure what proportion of carbon atoms in the fossil were still radioactive.

However, during 1965–1976 a global record of Pleistocene climate was extracted from *deep-sea cores*. This investigation established that major changes in climate have followed variations in earth's tilt and precession over the past 500,000 years — as predicted by the astronomical theory of the Ice Ages[282]. In 1950, **Dirk Brouwer** and **A.J.J. van Woerkom** recalculated Milankovitch solar radiation curves on the basis of more recent solutions for the planetary masses and orbital coefficients, and showed, among other things, how sensitive such computations can be to small errors when extended over periods of geologic time.

1912–1943 CE **Max Wertheimer** (1880–1943, Germany and USA). Psychologist and philosopher. Founded Gestalt[283] Psychology when he published *Experimental Studies of the Perception of Movement* (1912). Gestalt psychology was concerned with the organization of mental processes. It believes that humans (and animals) tend to perceive organized patterns, not individual parts that are merely added together. Accordingly, relationships between different parts of a stimulus, which we perceive as a pattern, gives it perceived meaning. This applies to seeing, hearing and feeling. In contradistinction, the *structuralists*' view is that experience can be broken down into its component parts.

Gestalt theory applies to all aspects of human *learning*, although it applies most directly to perception and *problem-solving*. The classical example is the illusion that there is apparent movement when a series of separate still images are seen rapidly (the basis for 'movies' at a rate of 28 frames per second).

Wertheimer was born in Prague to Jewish parents. After studying philosophy and psychology at the universities of Prague, Berlin and Würzburg (1901–1904), he received his doctorate in 1905. He then became a professor at Berlin (1918) and Frankfurt (1929). The rise of the Nazi regime in Germany forced him to emigrate to the United States (1933), where he settled in the New School for Social Research in New York City (1933–1943).

Gestalt psychology came under attack from bio-psychologists and neuropsychologists. Authorities such as **John Searle** and **Patricia Smith Churchland** claim that there is no need to suppose that there are any rules on top of the *neurophysiological structures*. They claim that mental states may be functional states, but this does not imply that the specification of their

---

[282] Spectral analysis of the isotopic record of two Indian Ocean cores showed a dominant climatic peak at a 100,000-year cycle and three other peaks at 43,000 years, 24,000 years, and 19,000 years long — confirming predictions of the Milankovitch theory. [J.D. Hays, J. Imbrie, and N.J. Shackelton, Variations in the earth's orbit: pacemaker of the ice ages, *Science* **194**, 1121–1132, 1976.]

[283] *Gestalt* is a German word which loosely means "form", "shape", "pattern".

functional profile based on *folk psychology* is correct, either in general or in detail. Nor does it imply that psychology cannot be reduced to *neuroscience*.

1912–1962 CE **Ludwig von Mises** (1881–1973, Austria and USA). Economist and social philosopher. One of the most influential economists of the 20^{th} century. Best known for his part in a debate that raged during the early part of the 20^{th} century about the possibility of successful economic coordination under *socialism*: Misses claimed (1920) that socialism must fail economically, i.e. a socialist government (state ownership of the means of production) could never make the best assignment of capital goods, due to the absence of a market price system to calculate profits and losses. He was vindicated by history.

In the course of a long and highly productive life, he developed an integrated, deductive science of economics based on the fundamental axiom that individual human beings act purposely to achieve desired goals. Mises concluded that the only viable economic policy for the human race was a policy of unrestricted *laissez-faire*, of free markets and the unhampered exercise of the right of private property, with government strictly limited to the defense of person and property within its territorial domain.

Mises was able to demonstrate that:

- Free markets, the division of labor, and private capital investment is the only possible path to the prosperity and flourishing of the human race.
- Socialism would be disastrous for modern economy because the absence of private ownership of land and capital goods prevents any sort of rational pricing or estimate of costs.
- Government intervention, in addition to hampering and crippling the market, would prove counter-productive and cumulative, leading inevitably to socialism unless the entire tissue of interventions was repealed (*Libertarian*[284] economic view).

[284] *Libertarians* favor separation of government and economy and oppose all collusion between government and corporations that would override the free market and would seek to forcibly redistribute resources in an egalitarian manner. They believe that welfare programs serve as a perverse incentive to keep individuals from working to earn a living and that they tend to perpetuate unemployment and poverty. Government interventions such as taxation and regulation are at best necessary evils.

Holding these views, and hewing to truth indomitably in the face of a century increasingly devoted to statism and collectivism, Mises became famous for his intransigence in insisting on a non-inflationary gold standard and on laissez-faire.

The major works of Ludwig von Mises are:
The Theory of Money and Credit (1912); *Nation, State and Economy* (1919); *Socialism* (1922); *Liberalism* (1927); *Critique of Interventionism* (1929); *Epistemological Problems of Economics* (1933); *Bureaucracy* (1944); *Omnipotent Government* (1944); *Human Action* (1949); *Planning for Freedom* (1952); *Theory and History* (1957); *The Ultimate Foundation of Economic Science* (1962).

Mises was born to Arthur Mises and Adele neé Landau, devout practitioners of their Jewish faith. The year he was born (1881), his grandfather was ennobled with the title *Edler* (The Noble), a distinction for Jews in the Austro-Hungarian Empire. His birthplace, *Lemberg*, became "Lwow" (a part of Poland) after WWI, and after WWII, "Lvov" (a part of Ukraine in the USSR); then in December 1991, "Lviv" in the newly independent republic of the Ukraine.

Ludwig's father[285], educated at Zürich Polytechnic, was a construction engineer, employed in the Austrian Railroad Ministry. Ludwig was the oldest of three boys, one died as a child; **Richard von Mises** became well known as an applied mathematician.

He moved to Vienna with his family and attended there a gymnasium (1892–1900) and the University of Vienna[286], where he was awarded his Dr.Jur. (1906). He was a front-line soldier in WWI (1914–1918), an unsalaried lecturer at the University of Vienna (1913, 1918–1934), a member of the Austrian Chamber of Commerce (1918–1938) and a professor of Economics in the Graduate Institute of International Studies (Geneva, Switzerland, 1934–1940).

---

[285] The recorded history of the Mises family as real estate owners and businessmen in Lemberg goes back to the 17^{th} century. Before WWII, Jews made up 50 percent of the business community in Central Europe and 90 percent of the business community in Eastern Europe. In Eastern Europe, modern civilization was predominantly an achievement of Jews.

[286] In the 1890s, during Mises' time at the school, 44 percent of the student body was Jewish. In the first decade of the 20^{th} century, almost 21 percent of the student body of the Vienna University was Jewish. Professors of Jewish descent constituted 37 percent of the law faculty, 51 percent of the medical faculty, and 21 percent of the philosophy faculty.

He emigrated to the United States (1940) and was a visiting professor at the New York University Graduate School of Business Administration (1945–1969). He married Margit Sereny (1938) in Geneva.

Mises was effectively barred from any payed university post both in Austria and the U.S., i.e. he never became a full professor. In Austria it was pure antisemitism. In the U.S., he seemed an eccentric 'Germanic' thinker with far too systematic, rigid and uncompromising way of reasoning which would not "assimilate" to his surroundings.[287] During those years his salary was paid by a private foundation. His work was continued by others, notably by **F.A. von Hayek**[288].

Worldview XXXIV: Ludwig von Mises

* * *

The essential characteristic of Western civilization that distinguishes it from the arrested and petrified civilizations of the East was and is its concern for freedom from the state. The history of the West, from the age of the Greek polis down to the present-day resistance to socialism, is essentially the history of the fight for liberty against the encroachments of the officeholders.

---

[287] Mises' ideas on economic reasoning and on economic theory were out of fashion during the *Keynesian revolution* that took over American economic thinking during ca 1935–1965. A resurgent Austrian school in the United States owes itself in no small part to Mises' persistence.
Many brilliant minds were not connected with the university, e.g.: **Schopenhauer**, **Freud**, **Spengler**. Mises quickly discovered that in the U.S., academic America was rearing to the left.

[288] **Friedrich August von Hayek** (1899–1992), Austrian-born British economist found solutions to problems proposed by Keynesian economics. Held that inflation, unemployment and recession result from government interference. Awarded the Nobel Prize in Economics for *Misesian Cycle theory* in 1974 (one year after Mises' death!).

* * *

Human civilization is not something achieved against nature; it is rather the outcome of the working of the innate qualities of man.

* * *

Science does not give us absolute and final certainty. It only gives us assurance within the limits of our mental abilities and the prevailing state of scientific thought.

* * *

Each epoch has found in the Gospels what it sought to find there, and has overlooked what it wished to overlook.

* * *

The criterion of truth is that it works even if nobody is prepared to acknowledge it.

* * *

The methods of the natural sciences cannot be applied to human behavior because this behavior... lacks the peculiarity that characterizes events in the field of the natural sciences, viz., regularity.

* * *

Against nature and within nature there is no freedom.

* * *

Education rears disciples, imitators, and routinists, not pioneers of new ideas and creative geniuses. The schools are not nurseries of progress and improvement, but conservatories of tradition and unvarying modes of thought.

* * *

... economic history is a long record of government policies that failed because they were designed with a bold disregard for the laws of economics.

* * *

Economics is not about things and tangible material objects; it is about men, their meanings and actions.

* * *

Economics is a theoretical science and as such abstains from any judgment of value. It is not its task to tell people what ends they should aim at. It is a science of the means to be applied for attainment of ends chosen, not, to be sure, a science of the choosing of ends. Ultimate decisions, the valuations and the choosing of ends, are beyond the scope of any science. Science never tells a man how he should act; it merely shows how a man must act if he wants to attain definite ends.

* * *

The rich adopt novelties and become accustomed to their use. This sets a fashion which others imitate. Once the richer classes have adopted a certain way of living, producers have an incentive to improve the methods of manufacture so that soon it is possible for the poorer classes to follow suit. Thus luxury furthers progress. Innovation "is the whim of an elite before it becomes a need of the public. The luxury today is the necessity of tomorrow." Luxury is the roadmaker of progress: it develops latent needs and makes people discontented. In so far as they think consistently, moralists who condemn luxury must recommend the comparatively desireless existence of the wild life roaming in the woods as the ultimate ideal of civilized life.

* * *

Profits are the driving force of the market economy. The greater the profits, the better the needs of the consumers are supplied.

* * *

. . . it is solely bigness in business which makes it possible to supply the masses with all those products the present-day American common man does not want to do without. Luxury goods for the few can be produced in small shops. Luxury goods for the many require big business.

* * *

If history could teach us anything, it would be that private property is inextricably linked with civilization.

* * *

There is in the universe something for the description and analysis of which the natural sciences cannot contribute anything. There are events beyond the range of those events that the procedures of the natural sciences are fit to observe and describe. There is human action.

* * *

People do not cooperate under the division of labor because they love or should love one another. They cooperate because this best serves their own interests. Neither love nor charity nor any other sympathetic sentiments but rightly understood selfishness is what originally impelled man to adjust himself to the requirements of society, to respect the rights and freedoms of his fellow men and to substitute peaceful collaboration for enmity and conflict.

* * *

Facts per se can neither prove nor refute anything. Everything is decided by the interpretation and explanation of the facts, by the ideas and the theories.

* * *

Reason's biological function is to preserve and promote life and to postpone its extinction as long as possible. Thinking and acting are not contrary to *nature; they are, rather, the foremost features of man's nature. The most appropriate description of man as differentiated from nonhuman beings is: a being* purposively *struggling against the forces adverse to his life.*

* * *

Society cannot contribute anything to the breeding and growing of ingenious men. A creative genius cannot be trained. There are no schools for creativeness. A genius is precisely a man who defies all schools and rules, who deviates from the traditional roads of routine and opens up new paths through land inaccessible before. A genius is always a teacher, never a pupil; he is always self-made.

* * *

Society is joint action and cooperation in which each participant sees the other partner's success as a means for the attainment of his own.

Science Progress Report No. 13
The Piltdown Forgery, or — the 'War of the Skulls', or — the greatest scientific fraud of all time (1912–1953)

Piltdown was an archaeological site in England where in 1908 and 1912 fossil remains of human, ape and other mammals were found. In 1913 at a nearby site was found an ape's jaw with a canine tooth worn down like a human's. To make a long story short, papers were published and the general community of paleoanthropologists came to accept the idea that the fossil remains belonged to a single creature who had a human cranium and an ape's jaw. The lower jaw was too big for a human skull but, significantly, the upper jaw was entirely missing, and with it part of the lower jaw — and the important lower canine teeth. Also missing were the mating parts for the jaw hinge. That which was missing was exactly that which would have shown

(1) whether or not the lower jaw, which was ape-like, was from a human or a ape and

(2) whether the lower jaw fitted with the upper skull bones, which were obviously human.

The skull itself had only several pieces. This meant that the size of the braincase could not be determined. The pieces might fit a larger braincase or a small one; there was no way of knowing.

With this miserly collection of a few bone fragments, the scientists "reconstructed" the entire head of what they proudly proclaimed to be "Piltdown Man." Here at last, they triumphantly declared, was the "long-awaited missing link." Since Latin names are always supposed to prove something, they named it Eoanthropus Dawsoni, *which stands for "Dawson's Dawn Man." That name made everything sound scientific.*

On December 16, 1912, the discovery was officially announced at the Geological Society. The press went wild. Here was a sensation that would sell newspapers. Many people accepted it; many others did not.

By August 1913, when the British Association for the Advancement of Science discussed the Piltdown bones, another molar tooth and two nasal bones "had been found" in that same gravel pit. It was marvelous how many pieces of bone kept appearing in that gravel pit!

Here we have bones well-preserved after 300,000 years in that damp gravel, whereas all the other millions upon millions of bones of animals and men who had lived and died in that area during that supposed time span were not to be found. Just that one set of skull pieces, jawbone, and teeth, and that was it. So close to the surface.

In their final reconstruction of the bones, the men put their solitary canine tooth on the right side of the lower jaw at an angle suggestive of an ape. That helped the cause! It does not take much to fool people, and the reconstructionists worked with care and forethought. With a human skull and an ape skull jaw before them as they worked, they shaped the plaster to produce an "ape-man."

At first, fraud wasn't even suspected. The fossils were, after all, cleverly done, and no money was involved. There were other European finds — Neanderthal, Cro-Magnon, and Heidelberg — so another European "missing link" wasn't too surprising. But not all were satisfied. Some scientists argued that the jaw and skull did not belong to the same individual. It was also observed that the few skull pieces could be arranged in a number of shapes and sizes to match any desired braincase and head shape that might be desired.

In reality, that is exactly what had been done. The parts had been carefully selected with consummate skill to provide only certain evidence while omitting certain other facts. The objective was to afterward reconstruct the head along ape lines, for the nearer the "reconstruction" could be pushed toward the brute beast, the more convincing it would appear as "scientific evidence" of evolution.

The objections offered were tossed aside and given little attention in scientific societies and even less in the public press. A whole generation grew up with "Piltdown Man" as their supposed ancestor. Textbooks, exhibits, displays, encyclopedias — all spread the good news that we came from apes after all.

Oil paintings of the discoverers were executed. The bones were named after Dawson, and the other men (Keith, Woodward and Grafton) were knighted by British royalty for their part in the great discovery.

As for the bones of Piltdown Man? Too many people were finding fault with them, so they were carefully placed under lock and key in the British Museum. Even such authorities as Louis Leakey were permitted to examine nothing better than plaster casts of the bones. Only the originals could reveal the fraud, not casts of them. Plaster casts of the half-man / half-ape "reconstruction" were sent to museums all over the world.

As recently as 1946, the Encyclopedia Britannica (Vol. 14, p. 763) stated authoritatively:

"Amongst British authorities there is agreement that the skull and jaw are parts of the same individual."

More than 500 articles, memoirs (including Doctoral Dissertations!) have been written about the Piltdown man.

Adding to the embarrassment of a government and nation, three years before the expose the National Nature Conservancy had spent a sizable amount of taxpayers' money in transforming the area in and around that pit into the Piltdown Gravel Pit National Monument.

Turn-of-the-century evolutionary theory predicted and believed in the imminent discovery of the "missing link", an ape-man earlier than Neanderthal, who would truly connect modern man with beast. What was needed was a half-million-year-old half-ape / half-man. And indeed, this 'magnificent discovery' came at just the right time: Suddenly, in 1912, the fossil-prophet appeared, not in Africa or Asia, but conveniently in Sussex, England. And what better a place to find such old bones than in perpetually damp England, where even bones half a century old normally have already turned back to dust.

The Piltdown forgery is perhaps the most engaging display of ratiocination since The Gold Bug. It beats Sherlock Holmes at its best. Indeed, a Darwinian might have said that if Piltdown man did not exist, we'd have to invent him. The hoax was so successful that for 40 years, anatomists, paleontologists, theologicians and brilliant academics everywhere attempted to define when Eoanthropus Dawsoni (man-like cranium, ape-like jaw) *fit in the evolutionary scheme. Yet the 'evidence' that early Man developed intelligence before developing in certain other way — sunk in.*

In 1953, chemical tests proved that the fossils were frauds. Someone had taken a slightly odd "modern" human skull, and the jaw of an orangutan. They had been stained, filed, smashed, and so on, in a fairly clever way. The fluorine test is a method of determining whether several bones were buried at the same time or at different times. This is done by measuring the amount of fluorine they have absorbed from ground water. It cannot give ages in years, but is a high-tech method of establishing ages of bones relative to each other.

Microscopic analysis of the wear found on the molars determined it to be unnatural. In fact it looked very much like the type of wear one would expect not from the normal chewing process but from a metal file. Other tests revealed that the specimens had been covered with an ochre colored paint to make them look more authentic. Obviously Piltdown was a well planned out forgery and hoax.

Additional examination revealed that the bones of Piltdown Man had been carefully stained with bichromate in order to make them appear aged. Drillings into the bones produced shavings, but should have produced powder if the bones had been ancient; powder, however, was not produced. Then that canine tooth was brought out — and found to have been filed, stained brown with potassium biochromate, and then packed with grains of sand. No *wonder it took so long before the discovery could be announced; a lot of work had to first be done on those bones and teeth.*

The House of Commons was so disturbed by the announcements of the fraud, that it came close to passing a measure declaring "that the House has no confidence in the Trustees of the British Museum ... because of the tardiness of their discovery that the skull of the Piltdown Man is a partial fake". A member of the British Parliament proposed a vote of 'no confidence' in the scientific leadership of the British Museum. The motion failed to carry when another member of Parliament reminded his colleagues that politicians had 'enough skeletons in their own closets'.

We will never be completely sure why anyone would try to fool the world into believing that Piltdown was the long sought – after Missing Link. We do know that whoever it was that planned such a scheme had to have a pretty extensive understanding of chemistry, geology and human anatomy in order to pull it off at all. They also had to have contacts that would provide them with access to bones outside Great Britain, for many of the animal bones found at the site came from places such as Malta and North Africa.

So, who dunnit? The list of suspects includes the following characters:

- ***Charles Dawson**, a Sussex lawyer and amateur archaeologist, who brought the first cranial fragments from Piltdown; a person with a long record of fraud.*

- ***Sir Arthur Smith Woodward** (1864–1944), head of the Department of Geology at the British Museum of Natural History (BMNH). Woodward was motivated by his desire to obtain the directorship of the BMNH. What better mean to obtain public acclaim than discovering the "missing link" on English soil, thus creating the English cradle of humankind.*

Given the many possible risks to his reputation and career, Arthur Smith Woodward has been considered an implausible confederate to Charles Dawson in the Piltdown affair. Woodward's seeming lack of motive has distracted many. Yet it is clear that ASW did serve to benefit from the acclaim of the "discovery" and had undertaken many other questionable practices in order to advance his desire to be appointed to the Directorship of the Natural History Museum.

Woodward maintained a thirty year association with Charles Dawson, which suggests a close and complex relationship beyond that of any other "suspect". Without such ties the trust essential for the conspiracy to occur would have been inexplicable. Dawson had access to the Sussex localities but lacked appropriate specimens and expertise to succeed alone. Woodward's close association with sites that serve as plausible sources for materials used *in the fraud provide important physical evidence pointing toward his involvement.*

Woodward's participation in the fraud also explains many of the puzzling episodes and "oversights" that surround the discoveries. A Dawson-Woodward nexus appears to draw together all the necessary elements to provide a satisfying resolution of the Piltdown fraud.

Woodward was with Dawson on the day he found the all-important jawbone at the gravel pit. As Woodward looked on — Dawson dug down and there it was!

- ***Sir Arthur Keith**, MD (1866–1955). Anatomist. One of the most highly respected scientist in England. Author of several classic works. Fellow of the Royal College of Surgeons, President of the Royal Anthropological Institute and member of the British Association for the Advancement of Science.*

- ***Grafton Eliot Smith**, a renown brain specialist.*

- ***Pierre-Tielhard de Chardin** (1881–1955). Philosopher and paleontologist. Accompanied Dawson on Aug 29, 1913 to the Piltdown pit where they 'discovered' the missing link canine teeth. It was duely reported in the 1913 meeting of the British Geological Society.*

- ***W.J. Solass**. Professor of Geology at Oxford.*

- ***Martin A.C. Hinton**, a curator of zoology. A trunk with Hinton's initials was recently found in an attic in London's Natural History Museum. The trunk contained bones stained and carved in the same way as the Piltdown fossils.*

- ***Arthur Conan Doyle** (1859–1930). Physician and writer. Creator of Sherlock Holmes. It is believed that he was along with Dowson in initially developing the idea for the fraudulent placement and later "discovery" of the bones.*

1913 CE **Archibald Vivian Hill** (1886–1977, England). Physiologist. Discovered that muscle cells respire (use oxygen) *after* contraction is finished. Awarded the Nobel prize for physiology or medicine (1922).

The muscle, after having become charged with lactic acid during anaerobic glycolysis, consumes oxygen while resting, at a rate greater than normal. The oxygen that would ordinarily have produced energy by combining directly with glucose, and which was short-circuited during the glycolysis, is now making up for what it had missed ("oxygen debt"). Oxygen is supplied as rapidly as possible to discharge the debt[289].

Hill was a professor at Manchester (1920–1923) and University College, London (1923–1925) and secretary of the Royal Society (1935–1945).

1913 CE **Leonor Michaelis** (1875–1949, Germany and U.S.A.). Physiologist and chemist. Discovered the first important mechanism of *enzyme kinetics*. Worked out the *Michaelis-Menton*[290] *equation* that describes the dependence of the rate at which *enzymes* catalyze reactions on the concentration of the substrate. In developing the theory, Michaelis adopted the assumption[291] that the enzyme and the substrate form an intermediate temporary complex. [It was only in 1965 that this mechanism was verified at the atomic level by **David Phillips** and his coworkers in London.]

Michaelis was born in Berlin, Germany to Jewish parents. He was assistant to **Paul Ehrlich** (1898–1899). During 1902–1926 he worked in various research centers, and later at Johns Hopkins University and the Rockefeller Institute (1929–1940).

1913 CE **William Henry Bragg** (1862–1942, England) and his son **William Lawrence Bragg** (1890–1971, England). Physicists. Shared the Nobel prize in 1915 for research on the structure of crystals by means of X-rays. They developed the *X-ray spectrometer*, and discovered much about the structure of the atom and the atomic arrangement in crystals[292].

---

289 The debt is discharged by the breakdown of *lactic acid* to water and carbon dioxide, releasing 650 kilocalories per mole. This yields 18 times more energy than that which arises from the conversion of glucose to lactic acid.

290 **Maud Menton** (1879–1960), Michaelis' assistant.

291 First suggested (1902) by the French biochemist **V. Henri**. The *enzyme-substrate* free radical is a far more stable system than the substrate free radical. The net effect is that the enzyme successfully catalyzes the reaction.

292 X-rays of wavelength λ are incident on a crystal face, at angle θ to the normal. The face plane contains rows of surface atoms spaced at nearest-neighbor distances ℓ. The waves are scattered, and by Huygens' principle reinforce each other in the direction making the angle θ with the normal, such that the scattered beams obey the law of reflection. If successive atom layers lie beneath each other at spacing d, the path difference between waves scattered by a surface atom and its interior neighbor at angle θ to the normal is simply $2d\cos\theta$.

Bragg the elder was born at Wigton, Cumberland, and studied at Cambridge University. He served as a professor of physics at the universities of Adelaide, Leeds and London and became professor of chemistry at the Royal Institution, director of the Davy-Faraday Research Laboratory, and director of the Royal Institution.

1913 CE **Frederick Soddy** (1877–1956, England). Chemist. With **Rutherford** he developed the theory of radioactive elements. Investigated the origin and nature of *isotopes*, the name of which he coined himself (*Isotope* = 'same place' in Greek). Their existence was discovered after nearly a decade of experimenting with naturally radioactive materials[293].

Isotopes of a given element are atoms with the same number of protons and electrons but different numbers of neutrons. Having the same number of electrons, they are almost identical in chemical behavior, and having different number of neutrons, they differ in weight. Certain isotopes are unstable and undergo a process of decay during which they emit ionizing radiation. Such isotopes are called *radioisotopes*.

Soddy began his career in McGill University, Montreal, where he did research in radioactivity with Rutherford (1900–1902). He worked at the Universities of Glasgow (1904–1914) and Aberdeen (1914–1919) before moving to Oxford[294] (1919–1936). He was awarded the Nobel prize for chemistry in the same year that Albert Einstein got it for physics (1921).

If this path difference is an integral multiple of the wave length, strong *Bragg reflection* peak will occur from this crystal face; the condition is that $2d\cos\theta = n\lambda$ $(n = 1, 2, 3, \ldots)$. Hence d can be measured by observing the angles where reflection peaks, provided λ is known.

293 **William Crookes** (1832–1919, England) speculated (1886) that not all atoms of a given element have the same atomic weight. **J.J. Thomson** (1910, 1911) showed (by measuring deflections of positive rays in a cathode ray tube) Neon, with average atomic weight 20.183, to consist of appropriate proportions of isotopes of masses 20 and 22.

294 In one of his extracurricular activities, Soddy rediscovered a geometrical theorem, which he published in the form of a poem in *Nature* (**137**, 1021; June 20, 1936). The theorem states that if 4 circles touch each other externally, and if ϵ_1, ϵ_2, ϵ_3, ϵ_4 denote their curvatures (that is, the reciprocals of their radii), then the following relation holds between them: $2(\epsilon_1^2 + \epsilon_2^2 + \epsilon_3^2 + \epsilon_4^2) = (\epsilon_1 + \epsilon_2 + \epsilon_3 + \epsilon_4)^2$. The theorem is an interesting one because it can be viewed from a number of different mathematical angles. Furthermore, it can be generalized to n hyperspheres in $(n-2)$-dimensional Euclidean space $(n \geq 3)$, such that each is tangent to all the others at distinct points. The theorem then states: "Let $C_1, \ldots, C_n$ be the centers of these spheres; $r_1, \ldots, r_n$ their radii, and $\epsilon_1, \ldots, \epsilon_n$ their curvatures. Then either all of the spheres touch each other externally, or one of them contains all the oth-

1913–1914 CE **Henry Gwyn-Jeffreys Moseley** (1887–1915, England). Atomic physicist. First to discover a definite way of determining the atomic number of elements. It enabled scientists to determine the atomic number of unknown elements and to correct Mendeleev's periodic table. Discovered experimentally a simple relation between the atomic number of an element and its corresponding X-ray radiation frequency, thus establishing conclusively that the atomic number does truly represent the number of electrons of each neutral atom.

Moseley belonged to a scientific family; his father and his two grandfathers were fellows of the Royal Society. He entered Eaton at the age of 13 and Trinity College, Oxford at 18. He graduated in 1910 and soon after was appointed lecturer in the Physics Department of the University of Manchester, working under the guidance of **Rutherford**. His life work was done in four years.

---

ers, and the curvatures satisfy the formula $\left(\sum_{i=1}^{n}\epsilon_i\right)^2 = (n-2)\sum_{i=1}^{n}\epsilon_i^2$ [for $n = 4$ we have 4 circles in 2D, for $n = 5$ we have 5 spheres in 3D, etc.]. The radius and curvature of a containing sphere (if any), are taken to be negative. Soddy published the theorem for $n = 4$ with no proof. It was later found that the theorem for this case was known to **Descartes** and **Steiner**. A simple proof, using just vector algebra was given by S. Brown [*Am. Math. Monthly* **76**, 662, 1969] and runs as follows: Let $\boldsymbol{x}_1, \boldsymbol{x}_2, \ldots, \boldsymbol{x}_{n-1}$ be vectors from C_n to $C_1, \ldots, C_{n-1}$ respectively. The *tangency conditions* are

$$\begin{aligned} x_i^2 &= (r_i + r_n)^2 \qquad (i = 1, \ldots, n-1) \\ (\boldsymbol{x}_i - \boldsymbol{x}_j)^2 &= (r_i + r_j)^2 \qquad (i \neq j). \end{aligned}$$

On the other hand, since the vectors lie in a space of $n-2$ dimensions, they are linearly independent, and therefore $\det[\boldsymbol{x}_i \cdot \boldsymbol{x}_j] = 0 \quad (i, j = 1, \ldots, n-1)$. From the above tangency conditions, we find

$$\begin{aligned} x_i^2 &= \frac{(\epsilon_i + \epsilon_n)^2}{\epsilon_i^2 \epsilon_n^2} \qquad (i = 1, \ldots, n-1) \\ (\boldsymbol{x}_i \cdot \boldsymbol{x}_j) &= \frac{(\epsilon_i + \epsilon_n)(\epsilon_j + \epsilon_n) - 2\epsilon_n^2}{\epsilon_i \epsilon_j \epsilon_n^2} \qquad (i \neq j). \end{aligned}$$

With these relations, the determinant can be reduced to

$$\det[\boldsymbol{x}_i \cdot \boldsymbol{x}_j] = \frac{2^{n-2}}{\epsilon_1^2 \cdots \epsilon_n^2}\left[\left(\sum_{i=1}^{n}\epsilon_i\right)^2 - (n-2)\sum_{i=1}^{n}\epsilon_i^2\right]$$

which proves the theorem. The converse of the theorem is also true.

When WWI broke out, Moseley was offered work suited to his scientific capacity at home, but he preferred to share with others the dangers of active service. He took part in the severe fighting of the *battle of Sari Bair* against the Turks in the Dardanelles, and was killed on Aug. 10, 1915. Because of this loss, Britain restricted its scientists to noncombat duties during WWII.

In a paper *The high-frequency spectra of the elements* [*Phil. Mag.* **26** (*1913*) *1024–1034*. Part II: *Ibid.* **27** (*1914*) *703–713*] Moseley investigated the X-ray spectra of over 50 elements and found that the wavelength of the shortwave principal line K_α became shorter in a regular manner in going from the light to the heavy elements. He determined the frequency ν of the K_α lines of all atoms to be $\nu = \frac{3}{4}R(N-1)^2$, where R is the so-called Rydberg constant and N increases by one in going from one element to the next in the Periodic Table, and was identified with the atomic number N of the element. It was shown a little later that Moseley atomic number N was identical with the charge of the Nucleus Z, a conclusion confirmed (1920) by the scattering experiment of **Chadwick**.

Upon the reordering of the periodic table according to the atomic numbers N rather than atomic weights, hydrogen remains the first element, with atomic number 1, but a few elements do change position (e.g., argon now precedes potassium), improving the periodicity.

Moseley predicted the discovery of 3 missing elements, those with atomic numbers 43, 61 and 75.

While the Braggs were using X-rays to explore the intricacies of crystalline structure, Moseley used them to detect the fundamental modes of vibration of the atoms. His discovery completed the new atomic theories.

1913–1917 CE **Johann Radon** (1887–1956, Germany and Austria). Mathematician. Contributed to measure theory (1913), but is mainly known today for his discovery of the *Radon transform*[295] (1917), which furnishes

[295] The 3D *surface integral*

$$\widehat{f}(p,\boldsymbol{\xi}) = \int f(\boldsymbol{x})\delta(p-\boldsymbol{\xi}\cdot\boldsymbol{x})d^3\boldsymbol{x}$$

is known as the *Radon transform* of a function $f(x_1,x_2,x_3)$ over the plane

$$p = \boldsymbol{\xi}\cdot\boldsymbol{x} = \xi_1x_1+\xi_2x_2+\xi_3x_3.$$

Geometrically, p is the perpendicular distance from the origin to the plane, and $\boldsymbol{\xi}$ is a unit vector along p, that defines the orientation of the plane. The symbol δ denotes the Dirac δ-function.

This transform has a unique inverse and is linked to $F(\boldsymbol{k})|_{k\boldsymbol{\xi}}$, the 3D Fourier the basic mathematical framework common to a large class of reconstruction (imaging) methods, such as the modern computer assisted tomography (CAT).

Born in Tetschen (Bohemia), Radon was educated at the University of Vienna. Taught mathematics at the Universities of Brno and the École Polytechnique and later became a professor at the Universities of Hamburg (1919), Greisswald (1922), Erlangen (1925) and Breslau (1928). He returned to Vienna in 1947.

---

transform of $f(\boldsymbol{x})$, via the one-dimensional Fourier integral

$$F(k\boldsymbol{\xi}) = \int_{-\infty}^{\infty} \widehat{f}(p, \boldsymbol{\xi}) e^{ikp} dp.$$

When the Radon transform is defined in 2 dimensions, it reads

$$\widehat{f}(p, \boldsymbol{\xi}) = \int_D f(x, y)\delta(p - \xi_1 x - \xi_2 y) dx dy.$$

Here $p = \xi_1 x + \xi_2 y$ is an equation of a *line* L whose normal is $\boldsymbol{\xi}$. The Radon transform for this case reduces to a *line integral* of $f(x, y)$ along L.
Introduce the normal form of the line L, $p = x\cos\phi + y\sin\phi$, where $\boldsymbol{\xi} = (\cos\phi, \sin\phi)$ and (p, s) are Cartesian axes, rotated by an angle ϕ relative to (x, y).
Suppose that we can evaluate the line integral of the unknown function $f(x, y)$ along the given direction ϕ in the xy plane, and for a fixed value of p, i.e.

$$\widehat{f}(p, \phi) = \int_L f(x, y) ds = \int_{-\infty}^{\infty} f(p\cos\phi - s\sin\phi, p\sin\phi + s\cos\phi) ds.$$

As we move the line L parallel to itself, the corresponding line integrals of $f(x, y)$ will define $\widehat{f}(p, \phi)$ for all p-values but fixed ϕ. The fundamental *Projection-Slice theorem* (**R.N. Bracewell**, 1956), then states: the one-dimensional Fourier transform of $\widehat{f}(p, \phi)$ w.r.t. p is equal to the two-dimensional Fourier-transform of $f(x, y)$ in the (K_x, K_y) plane, along the slice $\phi = \mathrm{tg}^{-1}(K_y/K_x)$. When this process is carried out for all angles ϕ, we may calculate $F(K_x, K_y)$ in the whole (K_x, K_y) plane. The Fourier inversion of F then recovers $f(x, y)$.
In medical applications, for example, $f(x, y)$ may be identified with some physical property of tissues on a plane section of the organ under examination.

- Deans, S.R., *The Radon Transform and Some of Its Applications*, John Wiley & Sons: New York, 1983, 289 pp.

Radon's original paper went almost unnoticed for half a century. The major developments in areas of application of the transform, did *not* come as a result of Radon's work and were already highly developed before connection with Radon's transform were recognized. It was **Bracewell** (1956) who truly illuminated the connection between the Radon and the Fourier transforms. During 1956–1971, there were many *rediscoveries* of Radon's results throughout the applied literature. These rediscoveries ended in 1972 when it was pointed out that Radon's work was fundamental to the problem of reconstruction from projections (**Allan M. Cormack**, Nobel prize address, 1979).

Indeed, it was found since then that reconstruction problems in optics, astronomy, molecular biology, geophysics, magnetic resonance imaging, material science and medicine, may be united within the framework of the theory of Radon's transform in Euclidean space. The common denominator to the situations that arise in these diverse fields is the need to determine (reconstruct) certain structural properties of an object, utilizing data obtained by methods that leave the entity under consideration in an undamaged and undisturbed state.

Computerized Tomographic Imaging[296] *(1895–1985)*

Since 1956 there has been renewed interest in what is known as the reconstruction problem. *This is the problem of determining the internal structure (or, more precisely, some property of the internal structure) of an object without having to cut, crack, or otherwise macroscopically damage the object.*

Various probes, including: X-rays, gamma rays, visible light, microwaves, sound waves, electrons, protons, neutrons, heavy ions, *and* nuclear magnetic resonance signals *have been used to study a large variety of objects whose size vary over an enormous range, from* complex molecules *studied by the electron microscopist to distant* radio sources *studied by the radio astronomer.*

[296] To dig deeper, see:

- Kak, A.C. and M. Slaney, *Principles of Computerized Tomographic Imaging*, IEEE Press, 1988, 327 pp.

These nondestructive reconstruction methods have been applied to a wide range of fields such as: medicine, astronomy, astrophysics, geophysics, molecular biology, electron microscopy, optics, aerodynamics, archaeology, material science, engineering (e.g. stress analysis, air-pollution monitoring), plasma physics, and various military applications.

Perhaps in no other field of modern science were the results so overwhelming as in medicine. *Here the advent of the digital electronic computer and new imaging techniques such as* ultrasound, magnetic resonance imaging *and* computerized tomographic imaging, *have combined to create an explosion of diagnostic techniques in the past 25 years.*

Tomography *refers to the cross-sectional imaging of an object from either transmission or reflection data collected by illuminating the object from many different directions. The impact of this technique in diagnostic medicine has been revolutionary, since it has enabled doctors to view internal organs with unprecedented precision and safety to the patient. The first application utilized X-rays for forming images of tissues based on the spatial distribution of their X-ray attenuation coefficient*[297]. *More recently, however, medical imaging has also been successfully accomplished with* radioisotopes, ultrasound, *and* magnetic resonance; *the imaged parameter being different in each case.*

There are numerous nonmedical imaging applications which lend themselves to the use of methods of computerized tomography. Researchers have already applied this methodology to the mapping of underground resources via cross-borehole imaging, some specialized cases of cross-sectional imaging for nondestructive testing, *the determination of brightness distribution over a celestial sphere, and* 3-dimensional imaging *with electron microscopy.*

Fundamentally, tomographic imaging deals with reconstructing an image from its projections. *In the strict sense of the word, a projection at a given angle consists of the integrals of the image along many parallel lines at the common direction specified by that angle (in the 3D case two angles are required, of course). However, in a loose sense, projection means the information derived from the transmitted energies, when an object is illuminated from a particular angle.*

---

[297] X-ray photons interact with matter in several ways. At photon energies in the neighborhood of 70 keV, which are typical of CT scanners, the combined effects of *scattering* (Compton effect and Rayleigh scattering) and *absorption* (photoelectronic effect) result in exponential attenuation of the beam as it passes through homogeneous matter. The great drawback to *X-ray photographs* of the body is that they provide only an integrated value of the attenuation coefficient along lines of sight, which makes 3D reconstruction non-unique.

In recent years, the X-ray image formation technique has been extended to nuclear medicine and magnetic resonance on the one hand, and ultrasound and microwaves on the other.

In nuclear medicine, our interest is in reconstructing a 3D radioactive isotope distribution *within the human body. In imaging with magnetic resonance we wish to reconstruct* the local magnetic properties of the object. *In both these cases, the problems can be set up as reconstructing an image from its projections, as in X-ray tomography.*

This is not the case when ultrasound *and* microwaves *are used as radiant energy sources, though the aim is the same as with X-rays (viz. to reconstruct the cross-sectional images of, say, the attenuation coefficient). In body tissues, X-rays are* nondiffracting, *i.e. they travel in straight lines, whereas microwaves and ultrasound are diffracting. When an object is illuminated with a diffracting source, the wave-field that impinges on the object is* scattered *in practically all directions. When, however, the inhomogeneities are much larger than the wavelength, one might be able to get away with the assumption of straight-line propagation.*

For situations when one must *take diffraction effects into account, tomographic imaging can in principle be accomplished for weakly diffracting objects if reconstruction theory is based on the* wave equation *rather than on ray theory (geometric optics).*

Timeline

1895 ***Wilhelm Röntgen*** *(Germany) discovered X-rays; produced the first radiation image of the body (his wife's hand).*

1897 ***Pierre and Marie Curie*** *(France) isolated* radium.

1900 *Chest X-ray used to diagnose tuberculosis; Radiology began as a medical sub-specialty.*

1903 ***Willem Einthoven*** *(Holland) created the prototype of the modern* electrocardiograph *(EKG) to monitor and record the electric signature of the heart.*

1906–1912 *Contrast media agents were administered (orally or via vascular injection) to help visualize organs and blood vessels with better image contrast.*

1917 ***Johann Radon*** *(Germany) discovered the Radon transform. He thus laid the foundation for the basic mathematical framework common to a large class of image reconstruction problems. His paper went unnoticed for 40 years.*

1924–1958 *Development of radiology: primary examination creates an image by focusing X-rays through the body part of interest and directly onto a single piece of film inside a special cassette. In the earliest days, a head X-ray could require up to 11 minutes of exposure time (now, modern X-ray images are made in milliseconds and the X-ray dose currently used is as little as 2% of what was used then). Radiographic imaging of the gallbladder, bile duct and blood vessels began in 1924 and coronary artery imaging was first done in 1945.*

The next development involved the use of fluorescent scans and special glasses so that the doctor could see X-ray images in real time. In 1946, the film cassette changer allowed a series of cassettes to be exposed at a movie frame rate of 1.5 cassettes per second. By 1953, this technique had been improved to allow frame rates up to 6 frames per second.

In 1955, an X-ray image intensifier was developed which allowed the pick-up and display of the X-ray movie using TV camera and monitor. Together with the cut-film changer, the image intensifier opened the way for a new radiological sub-specialty known as angiography, allowing the routine imaging of blood vessels and the heart (1958).

1932 *Transmission electron microscope constructed by* ***M. Knoll*** *and* ***E. Ruska*** *(Germany).*

1956–1971 *Rediscoveries of* ***Radon's*** *results throughout the applied literature.*

1956–1979 ***Ronald N. Bracewell*** *and* ***Allan Cormack*** *(1956) show how* ***Radon's*** *theory could be used for image reconstruction. Bracewell (1956) illuminated the connection between the Radon and Fourier transforms ('Projection-slice theorem'). He then applied the theory to obtain a solution to a practical problem in radio-astronomy, namely, to map the regions of emitted microwave radiation from the sun's disc (1956–1979)*[298].

---

298 From solar eclipse observations, it was clear by the early 1950's that microwaves were emitted from rather compact regions in the chromosphere and lower corona. But due to the inadequate resolving power of microwave antennas, it was not possible to study these emissions in much detail during the period

1972 **Godfrey Hounsfield** *(England) invented the computed tomography scanner or CT scanner — the first practical tomographic machine for clinical use. He showed that it is possible to compute high quality cross-sectional images with an accuracy of 1 part in 1000. Hounsfield used gamma rays (and later X-rays) and a detector mounted on a special rotating frame together with a digital computer to create detailed cross-sectional images of objects. His original CT scan took hours to acquire a single slice of image data and more than 24 hours to reconstruct data into a single image (today's state of the art CT systems can acquire a single image in less than a second).*

1973–1984 **Paul Lauterbur** *(England) developed magnetic resonance imaging or MRI (1973). It is a tomographic techniques in which for example the density distribution of hydrogen nuclei is reconstructed. The proton density in turn is diagnostic of tissue structure*[299]*. MRI of the brain was first done on a clinical patient in 1980. It was cleared for commercial clinical use by the FDA in 1984 and its use throughout the world has spread rapidly since.*

---

between two eclipses.

As seen from earth, the angular diameter of the sun is about 30 minutes of arc. To map the emitted microwave radiation over the solar disc, an antenna with an angular resolution small compared to 30 minutes of arc is needed. Adequate spot resolution using a single antenna would require an antenna of enormous dimensions, impractical to construct. The way around this is to use several antennas along a line, thus achieving good resolution in one direction and poor resolution in a perpendicular direction. It thus proved practical to construct *arrays* of antennas with a beamwidth, 3 minutes of arc. Such an array would be sensitive to microwave radiation from sources inside a narrow strip in the sky, 3 minutes of arc wide and several degrees long. In radio astronomy, a reception pattern of this type is known as a *fan beam*. When the fan beam system is aimed toward the sun, the received signal approximates a line integral of microwave intensity. Since the antenna array is attached to the earth, the sensitive strip region sweeps across the sun as the earth rotates, and the received power as a function of angle represents a two-dimensional map of microwave intensity. To obtain scans for different angles, it is only necessary to allow some time and do the scan again. As time passes, the position angle ϕ varies automatically and may be computed from $\cot\phi = (\sin\delta)(\tan h)$, where δ is the declination and h the hour angle of the source.

[299] "Chemical shifts" in the resonance radio frequency yields further data about the molecular environment of the H atoms.

1974–1980 *Ultrasound computer tomography* was developed by **J.E. Greenleaf** and **S.A. Johnson** *(1974) to look at the abdomen and kidneys, fetal tissues, carotid blood vessels and the heart. The process involves placing a small device (transducer) against the skin of the patient near the region of interest. The transducer produces inaudible high frequency sound waves which penetrate into the body and bounce off the organs inside. The transducer detects the echo from the internal structures and contours of the organs.*

When diffraction effects are ignored, ultrasonic CT is similar to X-ray tomography: in both cases a transmitter illuminates the object and a line integral of the attenuation can be estimated by measuring the energy on the far side of the object.

Ultrasound, however, differs from X-rays because the propagation speed is much lower and much more dependent upon medium composition, and thus it is possible to measure and extract information from not only the attenuation *of the pressure field but also the time-delay of the signal induced by the object. This yields* both *the* attenuation coefficient *and the* refractive index *of the object.*

Most medical ultrasonic images are done using reflected signals *and the discipline belongs to the field of* reflection tomography. *As in radar, the* echoes *are sent along a* narrow beam *and the image is formed by displaying the reflected signal as a function of time and direction of the beam. It is not necessary to encircle the object with transmitters and receivers for gathering the 'projection' data; transmission and reception are now done from the same side.*

1978–1985 *Emission computed tomography (ECT): Isotopes are administered to the patient in the form of radio-pharmaceuticals either by injection or by inhalation. The decay of these radio isotopes is associated with the emission of quanta, which in turn yields information on their distribution (location and concentration) as a function of time. The radioactive isotopes used are characterized by the emission of* gamma-ray photons *or* positrons. *The concentration of such an isotope in any cross section changes with time due to radioactive decay, flow, and biochemical kinetics within the body.*

This implies that all the data for generating one cross-sectional image must be collected in a time interval that is short compared to the time constant associated with the changing concentration. By analyzing the images taken at different times for the same cross-section we can determine the functional state of various organs in a patient's body. There are two types of emission CT:

(a) *Single Photon Emission Computed Tomography (using e.g. Iodine-131, technetium-99m) or SPECT (1979)*

(b) *Positron Emission Tomography (e.g. Carbon-11; Oxygen-15) or PET (1985). Two gamma-ray photons, traveling in opposite directions, are created by the annihilation*[300] *of an electron and a positron.*

1913–1922 CE **Elmer Verner McCollum** (1879–1967, USA). Biochemist and nutritionist. Pioneered in the study of *vitamins* and originated the letter system of naming them. Identified (with **Margaret Davis**) vitamin A (1913). Collaborated in the discovery of vitamin D in cod liver oil (1922), and used it for treating rickets.

McCollum was born in Fort Scott, Kansas and studied at Yale University. From 1917 he was Professor of Biochemistry at John Hopkins University.

1913–1928 CE **Irving Langmuir** (1881–1957, U.S.A.). Versatile scientist, engineer and inventor. Invented the high-vacuum electron tube and the gas-filled incandescent electric lamp[301] at atmospheric pressure. Used the term *plasma* for the first time to describe a collection of charged particles in his

[300] *Pair annihilation* is the opposite phenomenon of *pair production*. A pair of oppositely charged particles – an electron and its anti-particle, a *positron* – briefly attract one another to form a kind of "atom" called *positronium*. Within 10^{-10} seconds, the two particles spiral into one another and annihilate. In their place two (or occasionally three) γ-ray photons are produced. In the positronium rest frame, the two γ-rays move away from each other in opposite directions with equal energies, frequencies, and wavelengths. Therefore, the vector sum of their linear momenta is zero (just one γ-ray could not have zero momentum, so two or three must be created). Since the orbital e^- and e^+ speeds prior to annihilation are negligible, the conservation of mass-energy yields $m_0^2c^2 + m_0^2c^2 = 2h\nu_{\min}$ or $m_0c^2 = h\nu_{\min}$. The minimum γ-ray energy is thus 0.511 MeV, equal to an electron's rest-mass energy; for proton-antiproton pair annihilation it is 938.3 MeV.

[301] He found that the higher pressure did reduce evaporation of the tungsten, but so much heat was conducted away by the gas that the lamp efficiency was reduced. He discovered that coiling the filament decreased the effective area exposed to the gas and thus minimized the loss of heat. Coiled filament gas-filled lamps in 500, 750 and 1000 watt sizes were introduced in 1913. They gave a much better light at higher efficiency with the same life as former lamps. Nitrogen

study of oscillations in electric discharges. He realized that the matter inside the glow discharge was different from ordinary gases.

Langmuir had an unusually wide range of interests: While he is known to physicists for his work with plasmas, he won in 1932 a Nobel prize in chemistry for studies on molecular surface effects that have had important applications in medical research. Toward the end of his life he pioneered experiments on weather modification, and was the guiding force behind the first successful cloud seeding in which man-made snow was produced.

Langmuir was born in Brooklyn, NY and studied at Columbia University (1903) and in Göttingen, Germany under **Nernst** (1906). He conducted research in General Electric Laboratory in Schenectady, NY during 1909–1950.

Langmuir was a man of brilliant ideas, for which he always sought practical applications. With the rapid advance of technology, his scientific achievements were used for the developments of many instruments and production processes.

1913–1931 CE **George David Birkhoff** (1884–1944, U.S.A.). The only American mathematician of his generation with major international reputation. Birkhoff proved in 1913 a conjecture made by Poincaré in 1912 (known as Poincaré last "theorem")[302]. In 1923 he proved a theorem which states that any spherically symmetric vacuum solutions of Einstein equations must be static and must agree with the Schwarzschild solution, apart from a coordinate transformation. This means that when the spacetime surrounding any object has spherical symmetry and is free of matter and of all fields other than gravity, then one can introduce coordinates in which the metric is that of Schwarzschild.

Thus, the exterior field of *any* electrically-neutral, spherical *star* (regardless of whether it is static, collapsing, expanding or pulsating), satisfies the conditions of Birkhoff's theorem.

---

gas was used in the first lamps but argon was substituted in 1914. Argon has lower heat conductivity than nitrogen. These lamps could be made smaller than carbon lamps and produced three times the light per watt.

302 The conjecture, which Poincaré did not live to prove, belongs to the field of *topological dynamics*: if a one-to-one continuous transformation carries the ring bounded by two concentric circles into itself in such a way as to preserve areas and to move the points of the inner circle clockwise and those of the outer circle anticlockwise, then at least two points must remain fixed. This theorem has important applications to the classical problem of 3-bodies. Birkhoff astonished the French, who had not believed that Americans were mathematically capable. Birkhoff later told a student that he had lost thirty pounds working out that proof.

The theorem generalizes to the case where the exterior space is spherically symmetric, free of matter *but* allowed to have an electromagnetic field. In this case the exterior metric must be (again, in appropriate coordinates) the *Reissner-Nordström* metric (characterizing a *charged* black hole).

In 1931, Birkhoff proved the *general ergodic theorem*, building on the *mean ergodic theorem* proven earlier by **John von Neumann**. Birkhoff systematically kept Jews out of his department and acted generally to hinder their entry into Harvard. He thus opposed the appointment of **Oscar Zariski** (1926). He vehemently objected to the appointment of **Solomon Lefschetz** for president of AMS (1934) on the grounds that the Jews "... will use the Annals as a good deal of racial prerequisite. The racial interests will get deeper as Einstein's and all of them will do".

Albert Einstein said: "G.D. Birkhoff is one of the world's great anti-semites".

1913–1935 CE **Georg (György) Karl von Hevesy** (1885–1966; Hungary, Switzerland and Denmark). Chemist. The first[303] (1913) to use a radioactive isotope to follow the steps of chemical and biological processes, for which he won the Nobel Prize for Chemistry (1943). Discovered (1923, with **Dirk Coster**) the element *Hafnium*[304].

Hevesy was born to Jewish parents in Budapest and educated in Germany, Switzerland and England, studying in Manchester under **E. Rutherford** (1911). He moved to Vienna (1912), and after service in the Austro-Hungarian army during WWI, he worked in Copenhagen (1920–1926) under **N. Bohr**. He then became a professor at Freiburg (1923–1933), Copenhagen (1933–1942), and Stockholm (1942–1945) to where he fled during WWII. He died in Freiburg.

Hevesy's work on isotopes has been very influential in physics, chemistry and medicine: he worked to find ways of separating isotopes by physical means. Thus in 1934 he used radioactive *phosphorus* isotope to study phosphorus metabolism in plants and in the human body and used heavy water to study the mechanism of water exchange between goldfish and their surroundings, and also within the human body. He then showed that chemical changes are continually taking place in all living tissues. In 1935 he began to calculate the relative abundance of elements in the universe.

---

303 With **K.A. Paneth** he used *radioactive lead* to trace the solubility of lead salts, demonstrating that even a small amount of the chemical can be used as a radioactive tracer.

304 The Latin name for Copenhagen, where the discovery was made.

1913–1928 CE **William Mulholland** (1855–1935, USA). Chief architect of the *Owens Valley Aqueduct* that brought water to semi-arid Los Angeles from the lush Owens Valley (1913), thus making this modern metropolis possible and forever changing the course of Southern California's history. His career was ended on March 12, 1928 with the collapse of the St. Francis Dam (over 400 people killed and damage estimated at $20 million).

William Mulholland was born in Belfast, Ireland. In 1877 he arrived in Los Angeles, having worked his way from Ireland as a sailor, lumberjack, Apache fighter and mine prospector. He would, in time, engineer a historic feat and have a great impact upon the future of Los Angeles.

Mulholland saw that a burgeoning and thirsty Los Angeles would soon need much more water than it had available and foresaw the need of opening a new water source by tapping into the Eastern Sierra water from the Owens Valley, thus becoming obsessed with an engineering challenge of epic proportions.

Although he possessed no formal training in engineering, Mulholland pursued intense personal interest in geology, hydraulics and engineering by educating himself at the public library. Living in a shack, he worked as a ditch tender. By 1886, he had worked his way up to become the City Water Company's superintendent.

After the City of Los Angeles bought out the Los Angeles City Water Company (1902), Mulholland oversaw the formation of the new Los Angeles Bureau of Water Works and Supply (which would eventually become Los Angeles Department of Water and Power in the 1920s). He was the department's first superintendent and chief engineer. He also became the first American engineer to build a dam utilizing *hydraulic sluicing* (Silver Lake Reservoir, 1906).

Calling forth the deepest resources of his character: organization, vision and dogged determination, he would, over the next years, be entrusted with building a 375 km *aqueduct* (the world's longest at the time), to bring water from the Owens River north of Los Angeles to the San Fernando Valley, where developers awaited conversion of dry land into farms and housing tracts.[305]

[305] While Mulholland began to look longingly at the *Owens River*, more than 320 km away, the residents of *Owen Valley* had plans for the water as well. Most of them raised crops and ranched, and they were anticipating an economic bonanza once the newly-founded *Reclamation Service* completed its Owens Valley irrigation project. Mulholland realized that to acquire the Owens River for Los Angeles, they would have to put an end to this irrigation project. Thus started "the Owens Valley War" which reached its climax in 1924. It was a struggle for economic and political power between the landowners of the San Fernando

The project required massing of 3900 workers and digging and blasting of 164 tunnels, almost 86 km in all, over desert and mountain terrain. It called for carving out sluiceways, clearing roads, laying railroad tracks and running power lines. When machines broke down, Mulholland used mules, when men perished, he hired more. He was creating one of the engineering marvels of the age, and nothing would get in his way. No wonder, this project was dubbed the "Panama Canal of the West". It was the largest and most difficult municipal engineering project in U.S. history at the time.

The first Owens River water flowed into a San Fernando Valley reservoir on Nov 5, 1913. At the ceremony marking the occasion, the laconic Mulholland uttered to exuberant crowds what may be the five most famous words in the city's history "*There it is. Take it.*". This was the first step toward making Los Angeles into an international metropolis: the achievement gave the city the ability to grow beyond a population of 500,000 and leverage water to expand city territory into San Fernando Valley and other surrounding communities. The massive project was completed ahead of schedule under budget of $24.5 million in municipal bonds approved by voters.

In 1923, the City of Los Angeles honored Mulholland by means of a new scenic highway that ran along the spine of the Santa Monica Mountains. It was named Mulholland Drive.

Five years later, on March 12, 1928, Mulholland's career took a tragic turn when the St. Francis Dam, one of several dams built to increase storage of Owens River water, collapsed, sending about 50 million m^3 of water into the Santa Clara Valley, north of Los Angeles — one of the greatest civil disasters in American history.[306]

Valley growers (who benefited from Mulholland's plan) and the Owen Valley farmers and ranchers.

At the end the residents of the Owens valley were out-maneuvered by Mulholland and his aids, who eventually took ownership of 95 percent of farmland and towns of Owen's Valley.

The film "*Chinatown*" (starring Jack Nicholson) portrays in fictional form some of the events surrounding Mulholland's quest for water. Mulholland's persona in the film is loosely split between two characters in the film: water department chief Hollis Mulwray and water tycoon Noah Cross (played by John Huston).

306 The waters swept through the Santa Clara Valley toward the Pacific Ocean, about 87 km away. 104 km of Valley was devastated before the water finally made its way into the Ocean between Oxnard and Ventura. At its peak the wall of water was said to be 23 m high. By the time it hit Santa Paula, 67 km south of the dam, the water was estimated to be 8 m deep. Almost everything in its path was destroyed: livestock, structures, railways, bridges and orchards. By the time it was over, parts of Ventura County lay under 20 m of mud and debris.

In the end, the jury found that the disaster was caused by the failure of the rock formations on which the dam was built, but responsibility was placed on the governmental organizations behind the construction of the dam, and on its chief designer, William Mulholland. No criminal charges were brought against him. A 1992 examination of the disaster concluded that, given the geological knowledge of the time, Mulholland was in fact innocent of criminal negligence — that the break was caused by the anchoring of the dam's eastern edge to an ancient landslide impossible to detect in the 1920's.

Mulholland was forced to resign in disgrace. He took full responsibility, saying: "If there is an error of human judgment, I am human". His final years were lived in the shadow of the disaster. He died in 1935.

1913–1940 CE **Igor Ivanovich Sikorsky** (1889–1972, Russia and U.S.A.). An aircraft designer and manufacturer. Pioneered in multi-engine airplanes, helicopters and transoceanic flying boats. Designed the world's first 4-engine aircraft in 1913. Built the first practical single-rotor helicopter in 1939 and flew it in 1940.

Sikorsky was born in Kiev, the Ukraine. He was educated at the Petrograd Naval College and at engineering schools in Paris and Kiev. He rose to prominent position in Russian aviation, designing one of the most successful bombers of WWI.

Sikorsky came to the United States in 1919. In 1923 he founded a company which produced flying boats. He then designed and built helicopters.

1913–1942 CE **Bela Schick** (1877–1967, Austria and U.S.A.). Distinguished physician. Known for a skin test for diphteria immunity which carries his name (*Schick Test*, 1913)[307]. Did important research on such childhood diseases as scarlet fever, tuberculosis, serum sickness.

---

[307] In the *Schick Test* a very small amount of diphteria toxin is injected under the skin. There is no effect if the person is immune to the disease, but the area around the injection becomes inflamed if he is not.

Clemens von Pirquet (Austria), pediatrician, discovered that the adverse reaction of the diphteria antitoxin was caused by the *horse serum* in which the antitoxin was carried.

Von Pirquet devised the term "*allergy*" by combining two Greek words: *allos* (= different or changed) and *ergos* (= work or action). An allergy denoted that, in this adverse reaction, the action of a substance in the body was somehow changed.

Schick worked in Vienna with **Theodor Escherich** and **Clemens von Pirquet**. With the latter he laid the foundation of our knowledge of serum sickness and allergy.

Schick was born in Bogllár, Hungary to Jewish parents. He was a clinical professor of childhood diseases at the University of Vienna (1902–1923). Came to the United States (1923) and became chief pediatrician at Mt. Sinai Hospital, N.Y.C. (1923–1943) and professor of medicine at Columbia University (1923–1942).

Prequantum Atomic and Subatomic Physics

During the 20^{th} century the detailed study of atomic and nuclear structure has developed into a subject of immense scope and forbidding complexity. But the atomic theory of matter is over two thousand years old, having originated in the philosophy of the ancient Greeks. For centuries the idea that matter consists of indivisible atoms was a commonplace of speculative thought, but the concept became valuable only when it could be applied quantitatively — to an explanation of the gas laws (commencing in the 18^{th} century) and the laws of chemical combination (in the early 19^{th} century).

Even in the 1900's scientists as eminent as ***Mach*** *and* ***Ostwald*** *could still regard the existence of atoms as a hypothesis, with little experimental support. In the same period, however, a series of brilliant discoveries opened the way to novel investigations that established the atom as the smallest unit of a chemical element, although it could no longer be thought of as indivisible.*

The atomic theory of matter originated in the speculations of ***Leucippos*** *and* ***Democritos****, who lived in Greece during the 5^{th} century BCE. Nowadays we may wonder why these philosophers should have adopted so bold a theory without possessing any experimental evidence on the subject. The answer may lie in the difficult logical questions raised by the Eleatics, an earlier school of philosophers headed by* ***Parmenides****. The Eleatic thinkers became famous for their use of uncompromising logic in analyzing the nature of matter and motion, and they certainly reached some astonishing conclusions.*

As an example of Parmenides' arguments we may consider his contention that all space is filled with matter, that is, a vacuum cannot occur. The *statement was based on the proposition “That which does not exist does not exist”. If we accept this and the additional hypothesis that no two bodies can occupy the same place, it follows that motion is impossible, or at best illusory. This conclusion was supported by* ***Zeno****, a disciple of Parmenides, in four famous “paradoxes” concerning the concepts of time and space.*

Possibly the most significant paradox concerns a flying arrow. The arrow is imagined to be at rest at any given instant of time; but, if it is stationary at all possible instants, how can it ever move from place to place? Of course the validity of such a result depends on the assumption granted — in this case, the concept of an “instant” is essential to the analysis. In their historical context, Zeno’s paradoxes were powerful arguments for treating space and time as intrinsically continuous, whatever the nature of matter may be.

The work of the Eleatics caused a crisis in Greek thought and out of this crisis new theories of matter arose. Leucippos and Democritos boldly postulated the existence of a vacuum separating the indivisible atoms of matter. In this way they were able to account for the compression and rarefaction of gases, and also to explain the properties of different substances as being due to different atomic species. Democritos clearly enunciated the principle of conservation of matter, based on the indestructibility of atoms.

Later, the ideas of the atomists were revived by ***Epicuros****, and they found remarkable expression in* ***Lucretius****’ poem* De Rerum Natura*, which includes a sustained panegyric on the beauties of atomic theory.*

However, several philosophers, including ***Aristotle****, argued in favor of a continuous theory of matter, partly on the grounds that atoms separated by a vacuum cannot conceivably interact except at contact. In the third century BCE the* Stoic *philosophers observed waves spreading on the surface of water and supposed that sound travels in a similar way through air. By considering the propagation of waves in a medium, they were led to postulate the existence of a rarefied continuum, later called “the ether”, pervading all space and linking material bodies together in some way. Ideas based on the properties of a continuum were not easily reconciled with the tenets of atomic theory.*

It is important to recognize that the existence of particles in the physical world raises complex problems when we try to describe their behavior mathematically. For example, relativity theory is framed in terms of point-particles and continuous electromagnetic fields, but a charged point-particle should have infinite self-energy if the self-reaction of its electromagnetic field is taken into account. Moreover, the entire question of interaction between different particles requires elaborate treatment in the context of any field theory.

These difficulties persists in modern physics, were we have, on the one hand, field theories (such as Maxwell's electromagnetic theory and its quantum extension, QED*) and, on the other, particles interacting with and emitting, absorbing or annihilating each other, and also produced in pairs from the vacuum. Despite the many successes of quantum mechanics and of quantum field theories, the interactions of particles and fields are still not described completely satisfactorily in mathematical terms.*

The philosophical problems raised by Zeno still require consideration, although the original mathematical difficulties he raised in his paradoxes have been resolved. It can be argued that, in our range of experience, all actual events are atomic or discrete in nature, but potential occurrences must be described in terms of continuity. Thus a particle is regarded in quantum mechanics as potentially located anywhere in the universe, yet its existence is recognized experimentally only by discrete events localized in space-time. Some kind of reconciliation between these two paradigms is necessary for any understanding of present-day physics; needless to say, the last paper on the subject has not yet been written.

The study of nuclear physics commenced in 1896 *with the discovery of* ***Becquerel*** *that salts of uranium emit rays which penetrate matter to some extent and affect photographic plates. The study of* radioactivity *was pursued energetically by* ***Pierre*** *and* ***Marie Curie****, who isolated the new radioactive elements Polonium and Radium, and by* ***E. Rutherford****, who with various collaborators investigated radioactive series and the properties of alpha rays. Remarkable features of the new phenomenon were the apparently spontaneous release of considerable amounts of energy, and the random sequence exhibited by individual radioactive decay processes. It was found that the activity displayed by a given quantity of a radioactive element is quite unaffected by chemical combination and by normal changes in physical conditions. Moreover, radioactive characteristics differ markedly from one isotope to another of the same element; it follows that radioactivity is a property of the massive, positively-charged part of an atom.*

Although immense progress was made between 1900 *and* 1910 *in the quantum theory of radiation, no successful model of atomic structure was evolved, possibly because too much importance was attached to the old concept of the atom as an impenetrable entity. The essential new idea was provided in* 1911 *by Rutherford, who analyzed the results of alpha-particle scattering experiments and showed that the positive charge in an atom is concentrated in a very small* nucleus *at the center. It then became possible to regard the electrons as loosely bound planetary particles, organized into shells by virtue of their orbital motion.*

In 1913 ***Niels Bohr*** *succeeded in giving a description for electron orbits in terms of quantized angular momentum and action, and he used this model to explain the spectrum of atomic hydrogen. Despite the inconsistencies of the Bohr theory, it remains a major landmark in scientific thought and it is still valuable as a model for calculating the orders of magnitude of classically conceived quantities, such as electron speeds and orbital radii, in simple atoms (the so-called "semiclassical" analysis of a quantum system).*

1913–1915 CE **Niels** (**Henrik David**) **Bohr** (1885–1962, Denmark). One of the leading physicists of the 20^{th} century. Linked the new quantum physics to the structure of atoms (and later of molecules). Major contributor to the development of quantum physics for almost 50 years. Suggested a model for the hydrogen atom with discrete energy levels for the orbiting electron, which enabled him to explain the '*Balmer lines*' (discovered in 1885). He is also responsible for the liquid-drop model of the atomic nucleus.

The great achievement of the Rutherford group in establishing the existence of a small positively charged nucleus in each atom, led physicists to the next problem — to discover the correct description of the possible electron orbits about the nucleus. In 1912 **J.W. Nicholson** showed that the angular momentum of a "planetary" electron should change by a definite amount whenever it emitted or absorbed radiant energy. The quantum law of spectroscopy $\hbar\omega_{mn} = E_m - E_n$ [ω_{mn} — angular frequency of spectral line emitted or absorbed when the atom makes a transition from state m of energy E_m to state n with energy E_n] was known to be accurate in several instances, including the infrared spectra of molecules.

The combination of these ideas enabled **Bohr** to expound the first partially successful theory of atomic structure. In a series of papers between 1913 and 1915, Bohr outlined an elementary *semiclassical* theory of orbital electrons, which accounted for the spectrum of the hydrogen atom and certain other phenomena in atomic physics. His theory was based on two postulates:

(1) Each electron in an atom revolves about the nucleus in a fixed orbit satisfying the condition that the angular momentum is an integral multiple of the quantum unit $\hbar = \hbar/2\pi$. The rational for this quantization law comes from the Hamilton-Jacobi formulation of mechanics. Imposing it guarantees that the photon emitted when the orbiting electron transitions from orbit $(n + 1)$ to orbit n, has a frequency approximating that of the two orbits for $n \gg 1$ (classical limit).

(2) An electron does *not* radiate while occupying one of the quantized orbits, but light is emitted or absorbed when an electron changes from one orbit to another, the angular frequency of the radiation ω_{mn} being given by the known equation $\hbar\omega = E_m - E_n$.

Bohr made no attempt to describe the process whereby electrons are assumed to change from one orbit to another. Moreover, the basic postulate of fixed orbit for electrons is *contrary to the classical electromagnetic theory*, since any electron which is accelerated should radiate energy away, and the continual loss of energy would cause the electron to eventually spiral into the nucleus. Nonetheless, the theory remained classical in the sense that details of the electron motions are worked out mechanically, in close analogy with the system of planets revolving the sun[308].

Bohr's theory failed to explain the *fine structure* of the spectral lines. **Sommerfeld** was able to explain it by treating the electrons as *relativistic particles*. Later, the *hyperfine* structure of the spectral lines was explained in terms of the very small *magnetic* interaction between the spins of the electron and the nucleus. This type of interaction is often important in determining the structure of spectral lines emitted by *heavy* atoms.

---

[308] In the single-electron hydrogen atom, the attractive Coulomb force e^2/r^2 supplies the centripetal acceleration, i.e. $e^2/r^2 = mr\omega^2$ where (e, m) are the electron's charge and mass respectively, r is the radius of its (assumed circular) orbit and ω is the orbit's angular frequency. The quantization of its angular momentum reads $mvr = n\hbar$ where $v = \omega r$ is its orbital speed. The two equations yield $r_n = \frac{h^2 n^2}{4\pi^2 me^2}$; $\omega_n = \frac{8\pi^3 me^4}{h^3 n^3}$; $v_n = \frac{2\pi e^2}{hn}$. In the hydrogen atom, the first orbit $(n = 1)$ has a radius $r_1 = 0.5291\text{Å}$ in which the electron moves with the velocity $v_1 = 2.2 \times 10^8$ cm/sec. The energy of the atom, E_n, is the sum of the kinetic and potential energies, the sum being negative for any bound electron [on this energy scale, the zero corresponds to the case of an electron at rest at an infinite distance from the nucleus, and the negative E values are referred to as *binding energies* of the electron]. Thus $E_n = \frac{1}{2}mv_n^2 - \frac{e^2}{r_n} = -\frac{2\pi^2 me^4}{h^2 n^2}$, with $E_1 = -13.6$ electron-Volts. The expression for the wavenumbers of the spectral lines of the H atom (reciprocal wavelengths) is $\frac{1}{\lambda_{\ell n}} = \frac{1}{hc}(E_\ell - E_n) = \frac{2\pi^2 me^4}{h^3 c}\left(\frac{1}{n^2} - \frac{1}{\ell^2}\right)$, $\ell > n$. When this relation was compared with the empirical formula for the Balmer series for visible hydrogen spectral lines, $\frac{1}{\lambda} = R\left(\frac{1}{2^2} - \frac{1}{n^2}\right)$, $n = 3, 4, 5, \ldots$, the constant R [known as the *Rydberg constant*] was found to be equal to $\frac{2\pi^2 me^4}{ch^3(1+m/M)}$ [corrected for the motion of *both* electron and proton about their common mass-center]. The calculated value of $109,677.576 \pm 0.012$ cm^{-1} for R was found to be in excellent agreement with the empirical spectroscopic value. This was an outstanding triumph for the Bohr theory.

Bohr was the son of the physiologist Christian Bohr and a Jewish mother. He studied physics at Copenhagen, earning his doctorate in 1911. He then went to England, and worked at Cambridge under **J.J. Thomson** and in Manchester under **E. Rutherford**, where he stayed until 1916, returning to Copenhagen in 1916 as professor, and in 1922 was awarded the Nobel prize for physics. Bohr took active part in the anti-Nazi resistance movement (1940–1943). In 1943, under threat of immediate arrest, he escaped to Sweden on his family fishing boat.

Bohr's brother, **Harald August Bohr** (1887–1951, Denmark), was an outstanding mathematician, known for his studies of the Riemann zeta function and *almost-periodic functions*[309]. Bohr's son **Aage Niels Bohr** (b. 1922) is a physicist who shared the Nobel prize for physics in 1975 for his work in determining the asymmetrical shapes of certain atomic nuclei.

Bohr contemplated the philosophical significance of quantum physics, especially the cognitive contradictions inherent in the wave-particle duality. He thus came to suggest his *principle of complementarity* stating that the model we use is determined by the nature of the measurement: if a measurement proves the wave character of radiation or matter, then it is impossible to observe the particle character in the same measurement, and conversely. Hence, radiation and matter are not simply waves nor simply particles. A more general and complicated model is needed to describe their behavior, even though in extreme situations a simple wave model *or* a simple particle model may apply.

---

309 *Almost periodic function*: a function which satisfies $f(x+\tau) = f(x)$ with an error that can be made arbitrary small, when τ denotes any number of an infinite set of values spread over the whole range $(-\infty, \infty)$ in such a way as not to leave empty intervals of arbitrary great length.

Example: $f(x) = \sin px + \cos qx$, where p and q are noncommensurable numbers. Indeed, let integers (m, n) be found such that $p\tau = 2\pi n + \epsilon$, $q\tau = 2\pi m + \epsilon$ where ϵ is arbitrarily small positive number. Then

$$f(x+\tau) = \sin(px+\epsilon) + \cos(qx+\epsilon) = \sin px + \cos qx + 2\theta\epsilon, \quad |\theta| < 1.$$

An almost periodic function can be expanded in a series $f(x) = \sum_{n=0}^{\infty} A_n e^{i\lambda_n x}$ provided $\sum |A_n|^2$ converges. This is a special case of *Dirichlet series*, which in turn includes *Fourier series* as a special case. The *Bohr-Landau theorem* (1914) describes the conditions under which the *Riemann zeta function* is equal to zero. Bohr founded the theory of *almost periodic functions* in 1924 through his studies of representation of functions by *Dirichlet series*. He was a professor at the Copenhagen College of Technology (1915–1930) and then a professor of mathematics at the University of Copenhagen.

Bohr was also preoccupied with the philosophy of biology, regarding life, free will and consciousness as manifestations of a principle that deviates from the domain of the physical sciences.

Spectroscopy (1666–1913)

The history of science is intimately connected with the history of tools and instruments. With a telescope *he had made,* ***Galileo*** *observed the four small bodies which revolve around the planet Jupiter — a miniature solar system which helped substantiate the Copernican theory. Indeed, without optical and radio telescopes, modern astronomy would be virtually nonexistent. Bacteriology is equally dependent on the* microscope. *Cloud,* bubble *and* drift chambers *trace the paths of invisible subatomic particles. The* cyclotron *and its descendants infuse them with energies which result in wholly new phenomena. The atomic* clock *and the* interferometer *provide measurements of extraordinary accuracy. The* camera *fixes visual evidence for permanent study and reference. The* computer *analyzes data and models with a thoroughness and speed otherwise impossible.*

One of the most important of scientific instruments is the spectroscope. *Spectroscopy is the scientific development of the simple fact of observation that light has different colors. In essence, the spectroscope is a sophisticated development of the triangular glass prism which* ***Isaac Newton*** *used in* 1666 *to discover that "white" light is a combination of all other colors.*

Thomas Melville *(1752), observed that a flame in which a salt or metal was placed, gave out a spectrum of bright lines whose pattern varied with the material used; however, it was not until* 1823 *that* ***John Herschel*** *made the seemingly obvious suggestion that the technique might be applied to chemical analysis. Meanwhile,* ***Whollaston*** *(1802) had observed that the solar spectrum contained a number of dark lines.* ***Fraunhofer*** *(1814) perfected the spectroscope by using several prisms to increase the dispersion of light, substituting a slit for a hole, and using a telescope for observation. He also made the first diffraction gratings by ruling glass plates with diamond points. As a result of these improvements he discovered many hundreds of dark lines in the solar spectrum — still known as* Fraunhofer lines *— mapped them carefully, and noticed that certain lines varied from star to star.*

In 1859, *the two types of observation, terrestrial and astronomical, made contact.* ***Bunsen*** and ***Kirchhoff*** *showed that a double line — the D line — in the solar spectrum was due to the element sodium and concluded that it must therefore be present in the sun; and by similar methods that lithium could be present, if at all, only in quantities too small for them to observe. Now it became possible to determine the constituents of objects hundreds of millions of miles away in space! In the course of their investigations, the collaborators discovered two new elements,* caesium *and* rubidium.

In 1868, ***Lockyer*** *and* ***Frankland*** *went further still. Observing a hitherto unknown line in the sun's spectrum, they attributed it to an undiscovered element which they named helium. In* 1895, ***Ramsey*** *discovered the new element as a constituent of the mineral* cleveite. *A thorough history of spectroscopy would include numerous other scientists, such as* ***Anders Jonas Angström*** *(1814–1874, Sweden) who worked out accurate measurements of wavelengths;* ***Henry Augustus Rowland*** *(1848–1901, U.S.A.) who invented the concave diffraction grating; and* ***George Ellery Hale*** *(1868–1938, U.S.A.) whose spectroheliograph offered a new technique for observation of the sun. The discoveries made possible by these developments were startling. Among other achievements, they contributed to the founding of the modern science of astrophysics.*

Prior to ***Bohr*** *(1913), physicists failed to interpret the physical mechanisms underlying discrete spectra. In the first place, they did not conceive the possibility of discrete states for an atom. They simply assigned dipole radiation due to orbital revolutions of the electron, and identified the frequency of this revolution with the frequency of the emitted light. Consequently, they attributed the whole spectrum simultaneously to each atom.*

1914 CE **Adrian Daniel Fokker** (1887–1972, Holland). Dutch physicist. Derived the Fokker-Planck equation for Gaussian-Markov processes[310]. Collaborated with Einstein on his first treatment of general relativity.

[310] Consider unrestricted random walk on a discretized x-axis, with spacing Δx and discrete time-step Δt, starting at $x = 0$, at $t = 0$ with probabilities p, $q = 1 - p$ of a transition at any stage of one unit to the right or left. Let $u(x, t)$ be a *probability* that the particle be at coordinate x at time t. In this Markov process $u(x; t + \Delta t) = pu(x - \Delta x; t) + qu(x + \Delta x, t)$, since the coordinate x can be reached either from the left *or* the right. The boundary conditions are $u(0, 0) = 1$, $u(x, 0) = 0$, $x \neq 0$. The particle makes $[t/\Delta t]$

Fokker was born in Buitenzorg, Dutch Indies. He received his Ph.D. in 1913 under **Lorentz**. His thesis dealt with Brownian motions of electrons in a radiation field and contained an equation which later became known as the *Fokker-Planck equation.* After this work was completed, Lorentz sent Fokker to Zürich to work with **Einstein**. Their collaboration led to a brief paper, which contains Einstein's first treatment of a gravitation theory in which general covariance is strictly obeyed. In later years, Fokker wrote several papers on relativity. He held a professorship at Leyden.

---

independent steps during time t, each taking the value Δx or $-\Delta x$ with probabilities p and q respectively. Each step thus has a mean $(p-q)\Delta x$ and variance $4pq(\Delta x)^2$. The overall mean and variance of the displacement in time t are therefore approximately $t(p-q)\frac{\Delta x}{\Delta t}$ and $4pqt\frac{(\Delta x)^2}{\Delta t}$, respectively. If the mean and variance are to remain finite in the continuum limit $\Delta x \to 0$, $\Delta t \to 0$, we must have $(\Delta x)^2/\Delta t = O(1)$, $p-q = O(\Delta x)$. These conditions will be satisfied if $\frac{(\Delta x)^2}{\Delta t} = 2D$, $p = \frac{1}{2} + \frac{c}{2D}\Delta x$, $q = \frac{1}{2} - \frac{c}{2D}\Delta x$ where $2c$ and D are constants with the interpretations of *drift velocity* and *diffusion coefficient*, respectively. The mean and the variance are now given in the limit by $2ct$ and $2Dt$ respectively. Expanding the Markov equation by means of Taylor's theorem yields $\frac{\partial u}{\partial t}\Delta t = \frac{\partial u}{\partial x}(q-p)\Delta x + \frac{\partial^2 u}{\partial x^2}\frac{(\Delta x)^2}{2!}$, neglecting terms on the left of order $(\Delta t)^2$ and on the right of order $(\Delta x)^3$. The limiting form then yields the *Fokker-Planck equation*

$$\frac{\partial u}{\partial t} = -2c\frac{\partial u}{\partial x} + D\frac{\partial^2 u}{\partial x^2}$$

for diffusion with drift. In this continuum limit, $u(x,t)$ becomes a probability *density.* It has the particular solution

$$u(x,t) = \frac{1}{\sqrt{4\pi Dt}}e^{\frac{-(x-2ct)^2}{4Dt}}.$$

For $c = 0$ one finds

$$\int_{-\infty}^{\infty} u(x,t)dx = 1, \quad \int_{-\infty}^{\infty} xu(x,t)dx = 0 \ \ \textit{and} \ \ \int_{-\infty}^{\infty} x^2 u(x,t) = 2Dt = \langle x^2 \rangle.$$

If one interprets the single particle probability density $u(x,t)$ as the number of particles per unit volume around x at time t, the Fokker-Planck equation then becomes *Einstein's diffusion equation* for the *Brownian motion* with $\langle x^2 \rangle = 2Dt$, where $2D = \frac{kT}{3\pi\eta a}$. Today we could say that in 1905, Einstein treated diffusion as a Markovian process, thereby establishing a link between the random walk of a single particle and the diffusion of an ensemble of Brownian particles.

1914 CE **Edgar Buckingham** (1867–1940, U.S.A.). Physicist. Developed the present basic philosophy of the nature of dimensions, and the algebraic theorems[311] involved in the applications of dimensional analysis[312]. These ideas were presented in his paper: *On Physically Similar Systems* (*Phys. Rev.* **4**, 345, October 1914), which he authored while working at the National Bureau of Standards.

1914 CE **James Franck** (1882–1964, Germany and USA) and **Gustav Ludwig Hertz** (1887–1979, Germany). Physicists. Confirmed experimentally Bohr's atomic theory, for which they received the Nobel Prize for physics (1925); in their simple experiment (1914) they rendered one of the most striking proofs of the existence of stationary atomic states by means of *inelastic collisions* between electrons and atoms. In this process, part of the kinetic energy of the electron is transferred as internal energy of the target atom.

Their experimental arrangement was thus: a heated filament F emits electrons which are accelerated toward the grid G by a variable potential V. The

---

311 *Buckingham's Pi Theorem*: If a physical phenomenon involves N_1 variables, and if these variables can be expressed in terms of N_2 fundamental dimensions, the physical law describing the phenomenon can be expressed as a function of $(N_1 - N_2)$ dimensionless products of the variables, called "Pi terms" (π).
Stated as an equation, $F(\pi_1, \pi_2, \pi_3, \ldots, \pi_n) = 0$, where $n = N_1 - N_2$.

312 The concept of *dimensional analysis* can be traced back at least as far as 1822, when **Joseph Fourier** used it in his *Theorie Analytique de la Chaleur*. Various scientists, notably **Osborne Reynolds** and **Lord Rayleigh** made use of some form of dimensional technique in the latter half of the 19^{th} century. All physical quantities can be reduced to combinations of basic properties which are referred to broadly as dimensions. The dimensions M (mass), L (length), and T (time) are sufficient for all branches of mechanics. In electrical and electromagnetic measurements, it is necessary only to add one dimension — that of electric charge Q — to the M, L, and T dimensions of mechanics in order to create a system which will provide dimensional combinations for all electrical and magnetic entities. In thermal problems, we need to add only the dimension of temperature — symbolized usually by θ — to M, L, and T.
Specifically, *dimensional analysis* involves the deduction of information about a physical phenomenon from the premise that it can be described by an equation defined only dimensionally and relating the pertinent dimensional variables in a *homogeneous*, linear algebraic form (although dependencies on dimensionless quantities can be much more complicated). The analysis entails the formation of complete sets of *dimensionless* monomials of the variables. These products are often called *numbers* and, because of their frequent use in engineering analysis and physical theory, have come to be recognized by the names of their inventors — **Reynolds**, **Cauchy**, **Prandtl** etc.

space between F and G is filled with mercury vapor. Between the grid G and the collecting plate P a small retarding potential V', of approximately 0.5 Volt, is applied so that those electrons which are left with very little kinetic energy after one or more inelastic collisions, cannot reach the plate and are not registered by the galvanometer. As V increases, the plate current I fluctuates, the peaks occurring at a spacing of about 4.9 Volts. The first dip corresponds to electrons that lose all their kinetic energy after one inelastic collision with the mercury atom, which is left in an excited state. The second dip corresponds to those electrons that suffered two inelastic collisions with two mercury atoms (one with each) losing all their kinetic energy, and so on.

The excited mercury atoms return to their ground state by emission of a photon according to $\mathrm{Hg}^* \rightarrow \mathrm{Hg} + h\nu$ with $h\nu = E_2 - E_1$. From spectroscopic evidence we know that mercury vapor, when excited, emits radiation whose wavelength is 2536 A, corresponding to a photon of energy $h\nu$ equal to 4.86 eV. Radiation of this wavelength is observed coming from the mercury during the passage of the electron through the vapor.

Thus, the quantized energy transfer from kinetic energy to electromagnetic light energy was demonstrated. It proved the reality of the energy quantum, postulated by **Planck** (1900), adopted by **Einstein** (1905) and modeled by **Bohr** (1913).

James Franck was born in Hamburg to a Jewish rabbinical family. He received his Ph.D. at the University of Berlin (1906) where he met his younger colleague, Gustav Hertz (1911). He was a professor at Göttingen (1920–1933).

His position as the leading experimental physicist in Germany, a holder of a Nobel Prize and his active military duty as an officer in the German army in WWI meant nothing to the Nazis. What counted was his "non Aryan" status. He left Germany (1933) and emigrated to the United States (1935), settling eventually in the University of Chicago (1938–1949). He died in Göttingen.

Gustav Hertz was also born in Hamburg to a half-Jewish family; his uncle was **Heinrich Hertz**, the physicist who demonstrated the existence of electromagnetic waves. He studied mathematics and mathematical physics under **Hilbert** at Göttingen and under **Sommerfeld** in Munich and received his Ph.D. in experimental physics in Berlin (1911).

During WWI, Hertz was gravely wounded and returned to academic life only in 1925 at Halle (1925–1928). He then moved to Berlin (1928–1945) and when the Nazis came to power he refused to take the loyalty oath and was removed (1934) from his position — to them he was a Jew. He became the chief physicist of the Siemens concern. After WWII he went to the Soviet Union (1945–1954) to help build the atom bomb for Stalin. He returned to East Germany (1954–1961) to the University of Leipzig.

1914–1917 CE **Ernest Dunlop Swinton** (1868–1951, England). Military engineer, historian and inventor. Invented and designed the first *tank* — a motor driven combat vehicle enclosed in an armor plate, mounted on heavy caterpillar tracks and carrying heavy and light weapons, such as cannon, machine guns, and flame throwers.

Swinton took part in the South African war as commander of the 1st railway pioneer regiment (1904). After the outbreak of WWI he went to France as the official military correspondent. His proposals (1914) became the first link in the evolution of the tank. He became the secretary of the war cabinet (1915) and had much to do with the preparation of the first tank. Appointed (1925) professor of military history at Oxford University.

The prototype '*Little Willie*' was built with the collaboration of Lieutenant **Walter Gordon Wilson** and **William Tritton** in Lincoln, UK. For secrecy's sake, they were called '*Water Carriers*', hence the word '*tank*'. The British first used the tanks in the *Battle of the Somme* (1916). These tanks were slow and clumsy (Mark I), but they terrified the Germans. By Nov. 1917 some 450 improved British Mark IV tanks attacked the Hindenburg Line at Cambrai. Finally, in the decisive *battle of Amiens* (22 August 1918), 580 tanks overrun the German lines and inflicted the coup de grace.

Tanks can cover any kind of ground. They can climb and descend slopes as steep as 35 degrees. They can travel 48 km/hour on level ground, and turn in their own length. They can travel in water and in land. Others can be carried to the front by air. Modern military tanks combine fast-moving attack with the fire-power of light artillery. Tanks are used against infantry, to destroy armored vehicles, and to demolish positions.

Leonardo da Vinci (1482) designed a tank-like vehicle.

1914–1919 CE **Felix Hausdorff** (1868–1942, Germany). Distinguished mathematician. Extended the work of Fréchet and introduced the concept of topological and metric spaces. In 1919 he discovered the '*Hausdorff dimension*', the forerunner of todays concept of '*fractal dimension*'[313]. He also worked in set theory and introduced the concept of *partially ordered set* (1906–1909).

Hausdorff was born in Breslau to a Jewish family. He studied mathematics and astronomy at Leipzig, Freiburg and Berlin, receiving his Ph.D. from Leipzig in 1891. Until the age of 35, he devoted most of his time to philosophy, poetry, writing, directing plays and similar endeavors. In 1902 Hausdorff

---

[313] A *fractal* is by definition a set for which the Hausdorff-Besicovitch dimension strictly exceeds the topological dimension.

became associate professor at Leipzig. In 1910 he went to Bonn, where he wrote the monograph *Grundzüge der Mengenlehre*, which appeared in 1914.

Felix Hausdorff perished with his family in the Nazi Holocaust.[314]

1914–1920 CE **Srinivasa Ramanujan Aiyangar**[315] (1887–1920, India). An extraordinary mathematical genius who left a remarkable arithmetic legacy to posterity. His contribution to mathematics could have been much greater had he received a proper university education, and had his health not failed him at the age of 32. Few individuals in the annals of human intellectual endeavor have excited more admiration for their sheer genius and their achievements under adverse conditions.

An obscure and poor young Hindu, from a sequestered town in India, wrote a letter to **Godfrey Harold Hardy** (1877–1947), the leading English mathematician of the day. Hardy, accustomed to receiving crank mail, was inclined to disregard Ramanujan's letter at first glance the day it arrived, January 16, 1913. But after dinner that night, Hardy and a close colleague,

---

[314] *Sins of omission*: Modern textbooks often hide from their readers certain gruesome biographical facts. Thus, in "*Elementary Linear Algebra*" (Wiley, 2000), the authors Howard Anton and Chris Rorrers write (p. 663):

"In 1919 the German mathematician Felix Hausdorff (1868–1942) defined the '*Hausdorff dimension*'..."

The fact that the Nazis exterminated Hausdorff in 1942 just for being a Jew AND IN SPITE OF HIM BEING a 'German mathematician' does not merit mention. Instead, the innocent reader is led to believe that Hausdorff died naturally in 1942. In this connection, it is of interest to mention that the Nazis denounced Hausdorff's dimension as being a '*fraudulent Jewish mathematics*' as opposed to their '*Pure Arian mathematics*'.

John E. Littlewood, sat down to puzzle through a list of 120 formulas and theorems Ramanujan had appended to his letter: The letter betrayed signs of inadequate training, it was intuitive and disorganized, but Hardy recognized in it brilliant pearls of mathematics. Consequently he invited Ramanujan to London on a special fellowship in 1914. Through these efforts Ramanujan became known to the mathematical world.

One of the "pearls" which Ramanujan challenged Hardy to prove was the continued fraction [g is the *golden ratio*, $\frac{1}{2}(5^{1/2}+1) = 1.618\cdots$]

$$1+\cfrac{e^{-2\pi}}{1+\cfrac{e^{-4\pi}}{1+\cfrac{e^{-6\pi}}{1+\cdots}}} = e^{-\frac{2\pi}{5}}(5^{1/4}g^{1/2}-g)^{-1}.$$

Another magic result is the following: given the infinite continued fractions,

$$u = \cfrac{x}{1+\cfrac{x^5}{1+\cfrac{x^{10}}{1+\cfrac{x^{15}}{1+\cfrac{x^{20}}{1+\dots}}}}}, \quad v = \cfrac{\sqrt[5]{x}}{1+\cfrac{x}{1+\cfrac{x^2}{1+\cfrac{x^3}{1+\cfrac{x^4}{1+\dots}}}}}, \tag{1}$$

x can be eliminated (!) to tie u and v in the simple algebraic relation

$$v^5 = u\frac{1-2u+4u^2-3u^3+u^4}{1+3u+4u^2+2u^3+u^4}. \tag{2}$$

Nobody knows how Ramanujan arrived at this result. He was always fearful that English mathematicians would steal his secrets while he was in England. It seems that not only did English mathematicians not steal his secrets, but generations of mathematicians since have not discovered his secrets either.

Nine years after Ramanujan's death, G.N. Watson (1929), going through the late mathematician's notebooks, constructed a proof that Ramanujan *could have* concocted. Using certain known identities of Euler and Jacobi, plus new identities of his own, Watson reduced the problem to the relations

$$u^{-1}-1-u = x^{-1}\prod_{m=1}^{\infty}\left(\frac{1-x^m}{1-x^{25m}}\right); \quad u^{-5}-11-u^5 = x^{-5}\prod_{m=1}^{\infty}\left(\frac{1-x^{5m}}{1-x^{25m}}\right)^6;$$

$$v^{-5}-11-v^5 = x^{-1}\prod_{m=1}^{\infty}\left(\frac{1-x^m}{1-x^{5m}}\right)^6.$$

Of (1) and (2) Hardy commented: "*It defeated me completely; I had never seen anything in the least like it before. A single look at it is enough to show that it must be true because, if it were not true, no one would have had the imagination to invent it*".

Another result of Ramanujan,

$$\int_0^\infty e^{-3\pi x^2}\frac{\sinh(\pi x)}{\sinh(8\pi x)}dx =$$
$$= \frac{1}{e^{2\pi/3}\sqrt{3}}\sum_{n=0}^{\infty}\frac{e^{-2n(n+1)\pi}}{[1+e^{-\pi}]^2[1+e^{-2\pi}]^2\cdots[1+e^{-(2n+1)\pi}]^2},$$

prompted G.N. Watson to say: "*It gives me a thrill which is indistinguishable from the thrill which I feel when I enter the Sagrestia Nuova of the Capella Medici and see before me the austere beauty of the four statues representing* '*Day*', '*Night*', '*Evening*', *and* '*Dawn*', *which Michelangelo has set over the tomb of Giuliano dé Medici and Lorenzo dé Medici*".

Ramanujan, like his great predecessors Euler and Jacobi, was a grand master of summation and integration. Many of his unique results are still buried in his *Notebooks*[316]. These are personal records in which he jotted down

---

316 Ramanujan arrived, for example, at the following bizarre identity: $\tan^{-1}\left\{e^{-\frac{\pi n}{2}}\right\} = \frac{\pi}{4} - \left\{\tan^{-1}\frac{n}{1} - \tan^{-1}\frac{n}{3} + \tan^{-1}\frac{n}{5} - \cdots\right\}$. He apparently worked his way *backwards* from a known infinite sum through integration term by term: $\frac{-\frac{\pi}{2}e^{-\frac{\pi n}{2}}}{1+e^{-\pi n}} = -\left[\frac{1}{1+(\frac{n}{1})^2} - \frac{1/3}{1+(\frac{n}{3})^2} + \frac{1/5}{1+(\frac{n}{5})^2} - \cdots\right]$. This can be recast as the well-known result: $\frac{1}{\text{ch}\, x} = 4\pi\sum_{\ell=0}^{\infty}\frac{(-)^\ell(2\ell+1)}{4x^2+(2\ell+1)^2\pi^2}; \qquad x = \frac{\pi n}{2}$.

Another example is: given $f(\lambda) = \sqrt{\lambda}\int_0^\infty \frac{e^{-x^2}}{\text{ch}\ \lambda x}\,dx$, to show that $f(\lambda) = f(\frac{\pi}{\lambda})$. This he proved as follows: since

$$\frac{1}{\text{ch}\,\lambda x} = 2\int_0^\infty \frac{\cos 2\lambda xz}{\text{ch}\,\pi z}\,dz,$$

then

$$\sqrt{\lambda}\int_0^\infty \frac{e^{-x^2}}{\text{ch}\,\lambda x}\,dx = 2\sqrt{\lambda}\int_0^\infty\int_0^\infty e^{-x^2}\frac{\cos 2\lambda xz}{\text{ch}\,\pi z}\,dx\,dz$$
$$= \sqrt{\lambda\pi}\int_0^\infty \frac{e^{-\lambda^2 z^2}}{\text{ch}\,\pi z}\,dz = \sqrt{\frac{\pi}{\lambda}}\int_0^\infty \frac{e^{-z^2}}{\text{ch}\left(\frac{\pi z}{\lambda}\right)}\,dz$$
$$= \sqrt{\frac{\pi}{\lambda}}\int_0^\infty \frac{e^{-x^2}}{\text{ch}\,\frac{\pi}{\lambda}x}\,dx.$$

his formulas, which embody subtle relations among numbers and functions. Others have had to compile, edit and prove them (Ramanujan did not bother to include formal proofs). One such result from his *Notebooks* is

$$\zeta(3) = 1 + \cfrac{1}{2.2 + \cfrac{1^3}{1 + \cfrac{1^3}{6.2 + \cfrac{2^3}{1 + \cfrac{2^3}{10.2 + \cdots}}}}}.$$

Ramanujan's unique capacity for working intuitively with complicated formulas enabled him to plant seeds that are only now coming into bloom: some of his results are being applied today in other fields and even in theoretical physics. Some of his conjectures have just recently been verified[317].

Hardy on Ramanujan

"He had been carrying an impossible handicap, a poor and solitary Hindu, pitting his brains against the accumulating wisdom of Europe".

"... a man whose career seems full of paradoxes and contradictions, who defies almost all the canons by which we are accustomed to judge one another, and

---

317 *The tau conjecture*: In 1916, Ramanujan was studying the arithmetical function $\sigma_s(n)$, which denotes the sum of the s^{th} powers of the divisors of n (1 and n included). Through his efforts to calculate $\sigma_s(n)$, he was led to define the *tau function* $\tau(n)$ via the relation

$$\sum_1^\infty \tau(n)x^{n-1} = \left[(1-x)(1-x^2)(1-x^3)\cdots\right]^{24} = [1 - 3x + 5x^3 - 7x^6 + \cdots]^8.$$

He calculated the first 30 values of $\tau(n)$ [1; −24; 252; −1472; 4830; −6048; −16, 744; 84, 400; −113, 643; −115, 920; etc.] and conjectured that

$$\tau(n) = O(n^{\frac{11}{5}+\epsilon}).$$

This conjecture was proved only in 1974 by Pierre Deligne (b. 1944, Belgium), using tools supplied by algebraic geometry.

about whom all of us will probably agree in one judgment only, that he was in some sense a very great mathematician".

"He would probably have been a greater mathematician if he could have been caught and tamed a little in his youth; he would have discovered more that was new, and that, no doubt, of greater importance. On the other hand he would have been less of a Ramanujan, and more of a European professor, and the loss might have been greater than the gain".

"It was Littlewood who said that every positive integer was one of Ramanujan's personal friends[318]*. I remember going to see him once when he was lying ill in Putney. I had ridden in taxi-cab No.* 1729*, and remarked that the number seemed to me rather a dull one and that I hoped that it was not an unfavorable omen. "No", he replied, "it is a very interesting number; it is the smallest number expressible as a sum of two cubes in two different ways"* $(1729 = 12^3 + 1^3 = 10^3 + 9^3)$.

"It was his insight into algebraical formulae, transformation of infinite series, and so forth, that he was most amazing. On this side most certainly I have never met his equal, and I can compare him only with Euler and Jacobi... with his memory, his patience, and his power of calculation he combined a power of generalization, a feeling for form, and a capacity for rapid modification of his hypotheses, that were often really startling, and made him, in his own peculiar field, without a rival in his day".

[318] On this, Littlewood remarked:
I read in the proof sheets of Hardy on Ramanujan: "As someone said, each of the positive integers was one of his personal friends." My reaction was, "I wonder who said that; I wish I had." In the next proof-sheets I read (that now stands), "It was Littlewood who said...".

Ramanujan's Approximation to π

The theory of the modular functions had its origin in the pioneering works of ***John Landen***[319] *in* 1771–1775 *and* ***A.M. Legendre***, ***C.G.J. Jacobi*** *and* ***N.H. Abel*** *during* 1825–1829. *Later developments were due to* ***L. Kronecker*** *(1857–1863),* ***K.T.W. Weierstrass*** *(1860),* ***H. Weber*** *(1842–1913, Germany, 1881) and* ***F. Klein*** *(1890).*

Just how much of this 'accumulated wisdom of Europe' was known to Ramanujan in 1913, *is a great mystery. On this issue,* ***L.J. Mordell*** *surmised that the English textbooks by Greenhill and A. Cayley on the subjects of elliptic functions were easily accessible to him. But even so, his own innovations and intriguing results in the field of modular functions surpassed those of his predecessors.*

In 1914 *he developed new ways of calculating π with extraordinary efficiency. His starting point was the interesting result that for any given rational number n, the infinite product*

$$G_n = 2^{-\frac{1}{4}} e^{\frac{\pi\sqrt{n}}{24}}(1+e^{-\pi\sqrt{n}})(1+e^{-3\pi\sqrt{n}})(1+e^{-5\pi\sqrt{n}})\cdots$$

can always be expressed as the root of an algebraical equation. (Explicit values of G_n are known for many n's, e.g. $G_1 = 1$; $G_3 = \sqrt[12]{2}$; $G_5 = \left(\frac{1+\sqrt{5}}{2}\right)^{1/4}$; $G_7 = \sqrt[4]{2}$; $G_9 = \left[\sqrt[4]{2}(1+\sqrt{3})\right]^{1/3}$; $G_{13} = (3+\sqrt{13})^{1/4}$.)

The G_n's have the remarkable property that $G_n = G_{1/n}$, namely,

$$q^{-1/24}(1+q)(1+q^3)(1+q^5)\cdots = p^{-1/24}(1+p)(1+p^3)(1+p^5)\cdots$$

where $p = q^{1/n} = e^{-\pi/\sqrt{n}}$. For large values of n,

$$G_n = 2^{-\frac{1}{4}} e^{\frac{\pi\sqrt{n}}{24}}\left[1 + O(e^{-\pi\sqrt{n}})\right],$$

and hence $\pi \approx \frac{24}{\sqrt{n}}\log_e(2^{1/4}G_n)$, with an error of nearly $\frac{24}{\sqrt{n}}e^{-\pi\sqrt{n}}$. For[320] $n = 1225$, *this value of π is correct to 47 decimals. (39 places of π suffice*

[319] English surveyor (1719–1790) whose interest in mathematics was a leisure activity. Elected fellow of the Royal Society (1766).

[320] $G_{1225} = \frac{1+\sqrt{5}}{2}(6+\sqrt{35})^{1/4}\left\{\frac{7^{1/4}+\sqrt{4+\sqrt{7}}}{2}\right\}^{3/2}\left[\sqrt{\frac{A+43}{8}}+\sqrt{\frac{A+35}{8}}\right]$, where $A = 15\sqrt{7} + (8+3\sqrt{7})\sqrt{10\sqrt{7}}$.

for computing the circumference of a circle girdling the known universe with an error no greater than the radius of a hydrogen atom.)

When Ramanujan was dealing with these large values of n (for which no modular equation was even available), he must have been guided by his superb intuition. For otherwise, how could one produce an exact solution to an algebraical equation of degree 1225*, without even having the equation on hand? G.N. Watson believed that Ramanujan was in possession of general formulae by means of which he constructed his solutions.*

Although this evaluation is not without a certain charm, it is not in itself a milestone in the history of π for two reasons: Firstly, the method of approximating π by means of equations $e^{\pi\sqrt{n}} = m$ (where m is nearly an integer), was already known to ***C. Hermite*** *(1859); and secondly, the value of π was known correctly to* 527 *decimals, as early as* 1853*.*

But Ramanujan's paper[321]*, barely exposed the tip of the iceberg. In his Notebook*[322]*, he combined it with an iterative algorithm, through which π was calculated in* 1987 *on superfast computers, to many millions of digits*[323]

This algorithm led Ramanujan from the innocent-looking
$\pi \approx \frac{24}{\sqrt{n}} \log_e(2^{1/4}G_n)$ *to the formidable expression for π that appears in his Notebook, namely,*

$$\frac{1}{\pi} = \frac{\sqrt{8}}{9801} \sum_{n=0}^{\infty} \frac{(4n)![1103 + 26390n]}{(n!)^4(396)^{4n}}.$$

It was found that each successive term in this series adds roughly 8 *more correct digits [a pocket calculator yields for the first term $\pi = 3.141\ 592\ldots$].*

Science Progress Report No. 14
World-War I (July 28, 1914 – Nov. 11, 1918) — The Inauguration of Chemical Warfare

The era of the splendor and glory of Europe came abruptly to an end: two pistol shots signaled the start of a war that ended four years later. The 'central powers' of Austria-Hungary, Bulgaria, Germany and the Ottoman Empire fought and lost against the 'allied forces' of Belgium, Brazil, the British Empire, China, Costa Rica, Cuba, France, Greece, Guatemala, Haiti, Honduras, Italy, Japan, Liberia, Montenegro, Nicaragua, Panama, Portugal, Romania, Russia, San-Marino, Serbia, Siam and the United States.

65 *million servicemen on both sides were engaged in the war. By the end of hostilities,* 9 *millions had died,* 20.5 *millions were wounded and* 7.2 *millions were prisoners or missing in action; among the dead — two million Frenchmen (of a population of* 38 *million) and over two million Germans (of a population of* 70 *million). This large-scale slaughter*[324] *wiped out a whole generation, among them the elite and the many geniuses in all fields. In addition,* 5 *millions civilians*[325] *died in areas of actual combat and about* 30 *million people*

[324] The appalling bloodbaths of WWI were augmented by the introduction of the first truly *automatic machine-gun*, invented in 1884 by **Hiram Stevens Maxim** (1840–1916; USA and England). It spewed more than 600 rounds a minute. The British learned its devastating power the hard way, loosing 60,000 men on the first day of the *Battle of the Somme* (July 01, 1916).

The 19^{th} century officers and commanders were accustomed to thinking in terms of human intrepidity and courage as the most important attributes to carry the day in the battlefields. Machine-guns were the first specific application of the technique and logic of the industrial revolution in military combat. Firing an inordinate stream of bullets, machine-guns came to be the definitive symbols of the machine age in military history, regardless of marksmanship or easy targets. Nevertheless, ingrained beliefs die hard. The militaries in all major powers continued to cling to the idea of the irreplaceability of the infantry and cavalry charges, with bayonets, swords and lances, as the final judge of victory or defeat in military matters.

The first *mechanical-gun* (hand-turned) was invented in 1861 by **Richard Jordan Gatling** (1818–1903, USA), firing 616 shots in two minutes. This gun was used late in the *American Civil War* and by the British army in the *Matabele War* (1893–1894), where 50 soldiers fought off 5,000 Zulu warriors with just four Maxim guns.

[325] The historian Eric Hobsbawm ("Age of Extremes", 1994) wrote:

"The first World War led to the killing of an uncounted number of Armenians *died in India, Europe, USA and South Africa of the Spanish influenza epidemic that broke out in 1918 as a direct result of undernourishment and lack of coal caused by the war*[326]. *Costs of the war (both direct and indirect) amounted to 337 billion dollars.*

In 1919, Austria-Hungary was no more; Vienna, once the imperial center of 50 million subjects of mixed race, was now a capital of a small, impoverished and insignificant Alpine republic of little more than six million, mostly German, inhabitants[327].

*WWI interfered with the full implementation of the momentous discoveries of the turn of the century. Also, among the war casualties were scientists, artists and poets of the first rank (**Franz Marc**, **Egon Schiele**, **Rupert Brooke**, **Henri Gaudier**, **Karl Schwarzschild**[328], **Henry Gwyn-Jeffreys Moseley**).*

---

by Turkey – the most usual figure is 1.5 millions – which can count as the first modern attempt to eliminate an entire population."

326 This pandemic was one of the worst disasters in history! Influenza deaths tolled as many as 650,000 in the United States alone. World War I killed 15 million in four years, flu killed twice as much in six months. Even bubonic plague did not kill so many people so fast. The word "influenza" entered English from Italian in 1743. It means influence of the stars. Individual pandemics have often been named for their supposed origins, sometimes accurately (Asian flu) and sometimes not (Spanish flu). The infection's ultimate origin is farm animals (pigs, ducks and horses). Human flu probably dates no further back than their domestication in the period 2000–5000 BCE. The virus owes much of its biological success to surface mutation that occur as it shuttles between humans and various domesticated animals.

The first pandemic probably occurred in the 16th century; there were 5–10 more in the 18th and 19th centuries. Most of these began in Russia and Central Asia and traveled by land and by ship, even to remote Pacific Islands. The pandemic of 1833 was especially virulent in European cities. The one of 1889 moved with the speed of trains and steamships. The mortality rate is usually 0.01 percent, mostly from ensuing pneumonia.

327 In 1919 the majority voted for *Anschluss* with Germany. The option was denied them by the Allies, who also, through the war reparations demanded by the Treaties of Versailles and St. Germain, ensured that the German people of both German states would remain poor, resentful and revengeful throughout the inter-war period.

328 100,000 Jews fought on the German side, 80,000 of them in the trenches. Of these, 12,000 died for the '*Vaterland*' and 35,000 merited decorations [as compared with 7000 Jewish patriots who fought in the 19th century against France and Austria]. Among the slain were many university teachers and students. The greatest War Ace of WWI, **Baron Manfred von Richthofen** (1892–

WWI was a scientific disaster for France: more than half the students of École Polytechnique and École Normale Supérieure were killed (among them the two sons of Jacques Hadamard and the son of Emile Durkheim).

The major reason why there was little movement on many fronts during the first world war was that defensive strategy and weapons were better developed than those of an offensive nature.

The opposing armies found it better to stay put than to attempt to advance. When an army did attempt to advance, the defensive capabilities of the opposing army meant that massive casualties would occur for the sake of a few hundred meters gain of ground[329].

This situation beget chemical gas warfare, intended to force soldiers out of their trenches: on April 23, 1915, the Germans first used poison gas *(chlorine) in the Second Battle of Ypres. They then used the more potent* mustard gas *(1917) in the Third Battle of Ypres. About 100,000 perished by gas during the war*[330].

The alliance between the natural sciences and the military has a tradition of at least 2200 years, if one can believe the stories of the terrifying stone

---

1918), who shot down 80 enemy warplanes, was of Jewish descent. This did not prevent the German generals who lost the war to blame the defeat on a "stab in the back" by the Jews. But the fact was that the German armed forces had mutinied, unwilling to die for either Kaiser or *Vaterland*! The *Wehrmacht* mutiny did not begin with exhausted soldiers on the front, but with sailors resting in Kiel, where the German Navy had been tucked away ever since its inglorious defeat by the British in 1916. There were no Jews on the decks of those German warships, only Arian Germans hoisting the Red flag of rebellion that spread through German military columns. Even the Kaiser's most trusted regiments deserted. Not even the Kaiser was willing to die for the *Vaterland*; In the dark of the night he slipped across the frontier of Holland, begging asylum, and Germany sued for peace.

[329] By the time World War Two had arrived, the offensive capability of the military had overtaken the defensive capabilities of the opposing army, allowing new tactics such as the Blitzkrieg, (lightning war).

[330] The following gases were also used: Acrolein, Benzyl Bromide, Blue-Cross Gas, Bromacetone, Bromo-Benzyl-Cyanide, Chloropicrin, Cyanogen Bromide, Cyanogen Chlorine, Dimethyl Sulphate, Diphenylchlorarsine, Ethyldichlorarsine, Green Cross Gas, Phenyldichlorarsine, Phosgene, Xylyl Bromide. *For example*, Dimethyl Sulphate, $(CH_3O)_2SO_2$, known also as $DMSO_4$, is a colorless liquid having a vapor with faint onion-like odor. It is extremely toxic — a few whiffs could be fatal. Corrosive to tissues and carcinogenic. Lethal concentrations as low as 97 ppm/10 minutes have been reported in humans.

slings and burning mirrors which ***Archimedes*** *is said to have built for the defense of Syracuse against the besieging Romans (215 BCE). Clearly, war was a stimulus in the development of modern physics: the study of parabolic trajectories by* ***Niccolo Tartajlia*** *and* ***Galileo Galilei*** *stemmed from the need to calculate the trajectories of cannonballs.*

Fritz Haber *had inaugurated chemical warfare, to be used subsequently by Italy in Ethiopia (1935–1936), by the Nazis in the gas chambers of Poland (1942–1945), by Egypt in Yemen (1962–1965) and by Iraq in Iran (1980–1987).*

WWI showed that science could play an important role in the outcome of a war. In Germany, more than 100 laboratories were involved in scientific research for the military. During the years after the war, governments east and west started actively funding science, thus speeding up the growth of applied science during the 20^{th} *century, especially in the United States.*

The rapid growth of German chemical industry occurred during the 19th century. It led her to become the world's greatest chemical power. The German solution to industrial scale up involved teaming research chemists and mechanical engineers to take a reaction from the laboratory bench to the factory floor. They believed that this allowed the research chemist to remain creative by not being tied down with the drudgery of engineering practice. Because of this method the chemical engineer *was entirely unneeded, being instead replaced by a chemist and a mechanical engineer.*

Thus, prior to WWI, Germany had reigned supreme in organic chemistry and chemical technology. It was said that in 1905 America lagged 50 years behind the Germans in organic chemical processing. Even America's chemistry and chemical engineering professors had been primarily trained in German universities, and a working knowledge of the German language was essential to keep up with the latest chemical advances. All in all, America's chemical industry was very narrow, concentrating in only a few high volume chemical products, such as sulfuric acid[331]*.*

[331] American Chemical Society (ACS) was organized in 1876. However, the *American chemical industry* was *fundamentally different* from the German industry in several ways. Instead of specializing in fine chemicals or complicated dyestuffs (often made in batch reactors, something all chemists are familiar with), the American industries produced *only a few simple but widely used chemicals* such as sulfuric acid and alkali (both made in continuous reactors, something chemists have little experience with). These bulk chemicals were produced using *straightforward chemistry*, but required *complex engineering* set on vast scales. American chemical reactors were no longer just big pots, instead they involved complex plumbing systems where *chemistry and engineering were*

When the war started in Europe in 1914, only 528 workers were employed in U.S. plants producing such coal-tar chemicals as dyes and drugs. America was importing more than 90 percent of its dyes, mainly from Germany. There was not one U.S. plant for extracting nitrogen from the air and transforming it into the chemicals so vital for the armed forces, agriculture and industry in general. The U.S. depended on Chile for natural nitrates used in fertilizers and explosives. Starting almost from scratch to gain independence from foreign producers during the war, the U.S. chemical industry moved to a position of world leadership in the years thereafter.

After the war, many large corporations established laboratories in which scientists were encouraged to seek knowledge for its own sake without worrying about whether their work would be of practical use. Most advances in more abstract fields, such as physics, however, continued to be made in university environments.

1914–1921 CE About 3 million people in Europe die of *typhus*[332]. At the start of WWI (Nov 1914 – April 1915) it wiped out 150,000 soldiers in Serbia,

inseparably rolled together. Because of this, the chemistry and engineering aspects of production could not be as easily divided as they were in Germany. The *chemical engineer therefore found a role to play in America* despite their absence in the German system.

The *American chemical industry* (initially following the German example) *employed chemists and mechanical engineers* to perform the functions that would later be the chemical engineer's specialty. However these chemists were of an entirely different nature. The *prominent research chemists* employed in Germany were almost non-existent in *America* until after World War I. *Instead* the American chemical industry employed *analytical chemists* (involved in materials testing and quality control) and a few *production chemists*.

With the goal of claiming their industrial territory, the American Institute of Chemical Engineers (AICHE) was formed in 1908 to bridge the gap between laboratory processes and full-scale industrial production.

332 In the years 1490–1920 typhus had killed more people than armies had. Bacteriologist **Hans Zinsser** (1878–1940, USA) wrote:

"Soldiers have rarely won wars. They more often mop up after the barrage of epidemics. And typhus, with its brothers and sisters — plague, cholera, typhoid, dysentery, — has decided more campaigns than Caesar, Hannibal, Napoleon and the inspectors general of history. The epidemics get the blame for defeat, the generals get the credit for victory. It ought to be the other way around."

virtually removing that region from the war. Typhus later spread through eastern Europe, accelerating with the collapse of civil order in Russia. From 1917 through 1921, it infected 20 million Russians and killed 2.5–3 million. At the height of the epidemic, Lenin declared, “Either socialism will defeat the louse or the louse will defeat socialism”. The louse lost, but it had been a close call.

Public health, hygiene and social developments prevented further outbreaks in the Soviet Union during WWII. However, Italian soldiers returning from North Africa and Sicily brought the disease to Naples (1943). The disease was also common in many of the Nazi concentration camps.

H. da Roche Lima isolated the causative bacteria (1916) and named it after the American **Howard Taylor Ricketts** who died while investigating the disease. The epidemic spread by the human body louse. Crowding, uncleanliness, and human misery (malnutrition and sordid living conditions) during wartime favor the transfer of the infection from one person to another.

1914–1955 CE **Beno Gutenberg** (1889–1960, Germany and USA). Geophysicist. Made the first correct determination of the size of the earth’s core (1914), which he concluded to be liquid[333].

He deduced the existence of a global low-velocity zone in the earth’s upper mantle (1955) from the analysis of travel-times and amplitudes of seismic waves.

Gutenberg was born in Darmstadt, Germany to Jewish parents and gained his doctorate from Göttingen University (1911). Professor, Frankfurt (1926–1930); to U.S. (1930); professor, California Institute of Technology (1930–1957).

1915–1917 CE **Frederick William Twort** (1877–1950, England) and independently **Felix d’Herelle** (1873–1949, Canada) discovered *bacteriophage*[334] (viruses that attack bacteria).

---

[333] The existence of some sort of core had already been deduced by **Richard Dixon Oldham** (1906). In 1936 **Inge Lehman** produced the first evidence of the existence of an *inner solid core* with a radius of ca 1400 km.

[334] A fictional but relatively accurate account of the discovery of bacteriophages and of efforts to use them to treat plague epidemic is included in *Arrowsmith*, a novel by **Sinclair Lewis** (1885–1951, USA). As in Lewis’ story, phage therapy did not prove effective.

Twort, a bacteriologist, superintendent of Brown Animal Sanatory Institute, London (1907–1944), was first to describe a bacteriophage (1915).

d'Herelle, a microbiologist, conducted field studies in Guatemala and Mexico (1901–1909) and later worked as assistant at Pasteur Institute, Paris (1909–1921), professor at Leiden (1921–1923), director of Bacteriological Service, Egypt (1923–1927), and professor at Yale (1928–1934). He discovered and *named* the bacteriophage (1916–1917); Author of *Le Bacteriophage* (1921).

1915–1919 CE **James Hopwood Jeans** (1877–1946, England). Mathematician, theoretical physicist and astronomer. Produced a theory for the formation of galaxies and clusters of galaxies by *gravitational instability* ('Jeans instability'): small, large-scale density fluctuations are enhanced and finally result in the formation of a star, a galaxy or even a cluster of galaxies. The minimum mass required for the onset of instability is the 'Jeans mass' with a 'Jeans radius' (1915).

In 1919 he applied the collisionless Boltzmann transport equation to galactic dynamics, in particular for models of evolution of spherical stellar systems.

Jeans was first to propose that matter is continuously created throughout the universe. His work included investigations of spiral nebulae, the source of stellar energy, binary and multiple star systems, and giant and dwarf stars. He also analyzed the breakup of rapidly spinning bodies under the stress of centrifugal force and concluded that the nebular hypothesis of Laplace, which stated that the planets and sun condensed from a single gaseous cloud, was invalid. He proposed the catastrophic or tidal theory, according to which a star narrowly missed colliding with the sun and, in passing, drew away from the sun stellar debris that condensed to form the planets. (However, Laplace's hypothesis now appears to have been correct.)

Jeans was born in London. He taught at Cambridge (1904–1905, 1910–1912) and Princeton (1905–1909). During 1923–1944 he stayed at Mt. Wilson Observatory, Pasadena, California.

History of Creation Theories — I (2500 BCE–1916 CE)

In cosmology an attempt is made to answer several questions. How is the universe built up as a whole? Do the laws of nature, which we derive from experience gained in our 'neighborhood' — be it the earth, solar system or the galaxy — remain applicable if we imagine this 'neighborhood' extended until it comprises the whole universe? is an infinite world *compatible with the laws of nature, or must we restrict the universe to a finite size if we wish to avoid insurmountable difficulties of principle?*

Cosmology has to face the problem of infinity not as a mathematical abstraction but as physical reality. This has always conferred on all its problems a particularly speculative character and, at the same time, a particular attraction. Through the history of science men were anxious to obtain the answer to these questions.

Prologue: Epoch of Early Myths *(2500–600 BCE)*

The earliest creation myths that we know of were written down in Mesopotamia and Egypt about 2500 BCE. These civilizations were based on extensive irrigation agriculture, organized by a centralized priesthood headed by an all-powerful and divine king. The creation stories tell of these societies' origin, how their people had organized the lands (between the Tigris and the Euphrates rivers and in the Nile valley) by literally separating the earth from the waters by channeling swamps into canals. It was this channeling which superseded the chaos of agriculture dependent on fickle and sparse rains. The priests gave the credit for this vast social enterprise to the gods.

According to these myths the task was accomplished not with reason and planning, but by fertility-based magic; *creation is a magical-biological reproduction: gods emerge from a primeval ocean and mate with one another to produce additional deities — the earth, the sky, the heavens, and the oceans.*

Thus, although the earliest civilizations developed essential inventions such as metallurgy, writing, arithmetic, geometry, and astronomy — their societies had little use for reason. And so, once these agricultural improvements were instituted by neolithic farmers or by the first priesthoods that organized the irrigation works, these societies persisted without further technical advance for over 1500 years. The social organization set up to create the irrigation *works — a king and priesthood directing the works of thousands of peasants — itself prevented further progress.*

The peasants who grew food and the artisans who worked in royal workshops were totally isolated from the literate priesthood, who held absolute power. The material traditions of peasants and artisans, and the scientific knowledge of the priesthood, separated from each other, were passed unchanged from generation to generation mystified by ritual and magic. So the myths of the priests gave divine sanction to the workings of society. The kings and priests inherited magical powers from the gods and this justified and enforced their absolute power over society. Magic and ritual ruled here on earth, and so it must have been in the heavens, in the beginning[335].

Act I: The Greek Secular Infinite Universe — Observation vs. Pure Reason *(600–150 BCE)*

With a fixed technical basis, the priestly authorities of the Bronze Age civilization could support its increasing population only by expanding geographically, and when the natural limits of cultivation within the alluvial valleys were reached — it began to collapse. The efforts of kings and pharaohs to squeeze more wealth out of a stagnant production systems led to rapid depletion of the population, decay of irrigation works, and finally the disintegration of society.

Egypt and the Near East, however, gave rise to a new society which sprang into existence out of the ruined shell of the old. The new society brought with it new technology related to new perceptions of the cosmos. It required new ideas, because it was based on trade *and, in part, on* free labor*. While reliance*

---

[335] The *Hebrew* account of creation as reflected in *Genesis*, recalls Babylonian, Ugaritic and Canaanite cosmogonies. [From *Isaiah II* (**40**, 26–28; **42**, 5; **45**, 7, 12, 18; **54**, 9) we gather that the Biblical creation narrative must have been *canonized* by 550 BCE at the latest. In fact, some modern Biblical scholars believe that these texts had previously been *written* by the scribes of the early Judean kings.] But while most non-Biblical myths deal with gods and goddesses who take sides in human affairs, each favoring rival heroes — the Bible acknowledges only a single universal God who created the heavens and the earth by *organizing a preexisting chaos*. (The Bible nevertheless still harbors vestigial accounts of ancient gods and goddesses — disguised as men, women, angles, or demons.) In contradistinction to the *Platonic* creation stories (ca 400 BCE), Genesis demotes the sun and the moon to mere functional objects, created in the same manner as the earth.

on authority may suit a priesthood, it is a poor guide for an enterprising trader or craftsman. Instead, the merchant had to learn by observing the world around him — the winds and tides. And the free craftsmen learned by changing nature, by experimenting with new materials and methods.

The strict division between those who learned and those who worked began to break down; learning was democratized to serve the needs of independent merchants and artisans. The economical Phoenician alphabet superseded the elaborate hieroglyphics and cuneiforms of the ancient priests. Nowhere were the changes so thorough as in the trading colonies established by Greeks in Ionia. As is generally the case with colonies, the inherited social patterns were left behind in favor of a more adventurous setup.

By 700 BCE, *the Ionian trading cities, increasingly dependent on trade in specialized agriculture and craft products such as textiles, had thrown off the earlier subordination to the great landowners of mainland Greece. They established new societies of traders, craftsmen, and free-holding peasants — the first limited attempts at democracies and republics. They needed new ideas to run such new societies.*

This change is evident in the Ionian conception of the universe and its origin. Around 580 BCE ***Thales****, a native of the trading and textile center of Miletos, first asserted that the world was formed by natural processes which could be* observed *in the world. He secularized the old creation myths — natural processes without divine intervention.*

While Bronze Age priests had seen a static society ruled by the unchanging cycles of the seasons, the Ionian saw a society in the midst of convulsive changes as aristocratic landholders, merchants, artisans, and peasants battled for power. Having experienced tumultuous overthrows of government, ***Heraclitos*** *(ca 500 BCE) concluded that the universe was in constant flux, like a fire, ever changing. After Ionia was conquered by the Persians, the new ideas spread to Athens in mainland Greece. Here some of the most striking theories of early cosmology were born.*

Anaxagoras *(ca 460 BCE) derived his theory of origins from close observations of nature: Seeing how whirlpools in nature order the chaotic flow of water and separate materials of different densities — mud and wood are drawn to the center, while stones and pebbles are flung outward — he reasoned that such vortices, driven by primeval power, could separate by air from the earth. The sun and stars would have been torn loose from earth, flung outward, and heated by friction to their present fiery state. Stars, he correctly guessed, are suns too far away from us to feel their heat*[336]*. Then from observations of*

336 In his own words (ca 450 BCE): "*The formation of the world began with a vortex, formed out of chaos by energy. This vortex started at the center and*

whirlpools, the glowing hot metal of the blacksmith's forge, the distant light of merchant's signal fires — he hypothesized a naturalistic theory of cosmic origins which was essentially correct in its broad outline.

In Anaxagoras' view the universe is infinite, populated by a host of different worlds — many of them inhabited. His cosmos, imagined by extrapolation of his earthbound observations to remote parts of the universe, was unlimited in space and time. Thus, the Ionian school of Thales, Democritos and Anaxagoras assumed a world knowable by observation, where thought and work joined together. It was the world view of the free craftsman and peasant. Knowledge was available to all.

On the other hand, Plato's doctrine described a cosmos knowable only by pure reason of the few — who thus had the right to rule over the many, even as the heaven rules earth, the soul rules the body, or as the master rules the slave. According to the cosmology of ***Plato*** *(ca 385 BCE) the creator molded preexisting, chaotic matter into approximations of ideal geometrical forms, creating a universe ruled by eternal mathematical laws.*

The battle between these two views of the cosmos have been linked to the most crucial questions of society and history: Is progress, the continual betterment of human life, possible? Must there always be rulers and ruled, or should those who work decide what work is to be done?

In hindsight view, neither authoritarian Sparta nor free Ionia became the model for the social evolution of the Mediterranean world. Instead, slavery, free labor, and expanded trade all coexisted in the centuries that followed the fall of Athens. Similarly, there resulted a synthesis of the two rival cosmologies, incorporating mathematical myth with the observational method into one system.

How did all this come about? Where Athenian imperialism failed, Macedonian imperialism succeeded spectacularly. Beginning in 330 BCE, Alexander the Great conquered the area now occupied by Turkey, Syria, Israel, Jordan, Iraq, Iran, and Egypt, and established colonies of Greek freeholders,

---

gradually spread. It separated matter into two regions, the rare, hot, dry and light material, the ether, in the outer regions, and the heavier, cooler, moist material, the air, in the inner regions. The air condensed in the center of the vortex, and out of the air, the clouds, water and earth separated. But after the formation of earth, because of the growing violence of the rotary motion, the surrounding fiery ether tore stones away from the earth and kindled them to stars, just as stones in a whirlpool rush outward more than water. The sun, moon and all the stars are stones on fire, which are moved round by the revolution of the ether".

artisans, and merchants. The free population increased, Mediterranean-wide trade flourished, and living standards rose.

Unlike the nobles of Sparta, the merchants of the Hellenistic world needed observations of nature to speed their ships across the Mediterranean and to ports in India. Even before Alexander's conquests, Plato's students had begun systematic astronomical observations in order to convert his ideas about perfect circular motions into an explanation of the observed motions of the planets. One such disciple, ***Eudoxos*** *(ca 360 BCE), created a system of moving spheres, with the earth at their center, which carried the planets, sun, and moon on their complex travels. This was the cosmological system of perfect motion that* ***Aristotle*** *then popularized (ca 340 BCE).*

Following Alexander's death, the ruling Ptolemies in Egypt established the Museum at Alexandria as a liberally endowed research library to generate and centralize systematic observations. Alexandrian astronomy, for example, used observation to solve practical problems of navigation.

From these observations, startling theoretical results followed. Using ***Euclid****'s discoveries in geometry,* ***Aristarchos*** *(ca 250 BCE) estimated from astronomical observations that the sun was 8 million km away and 6 times as large as the earth (the correct figures being each about 18 times larger). To him, the idea that a much larger sun should circle at a great distance around a small earth did not seem sensible. More important, the increasing accuracy of observations led him to conclude that the idea of heavenly bodies moving in perfect circles around the earth must be wrong. Instead, observation could be much better accounted for if it was assumed that the earth and planets orbit the sun, the moon orbits the earth, and the earth spins on its axis.*

Aristarchos' correct views were rejected by other ancient astronomers including ***Hipparchos*** *(ca 150 BCE), who himself calculated that the sun is far larger than even Aristarchos thought. The time was simply not ripe yet for the acceptance of the heliocentric system. Since the astronomers could neither abandon the Platonic hierarchy of the heavens and the earth, nor wholly accept Plato's disdain for observations, they compromised — and in the process forged a scientific method which contained within it the tensions of ancient society: On one hand, the basic assumptions about the universe must come from pure reason, which can accommodate the perfect mathematical laws of the heavens. On the other hand, observation serves to correct these basic mathematical laws (uniform motion in a circle etc.) in practice, modifying them as needed to "save the phenomenon" or to fit observations.*

Interlude: Geocentric, Static and Finite Universe *(100 BCE–200 CE)*

The immense accumulation of wealth in the Mediterranean after 100 *BCE were based on conquest and imperialism. In the battle over Alexander's empire Rome emerged to swallow up the whole of the Mediterranean. The Roman legions enforced ruinous taxation, looting existing wealth but creating none. Slavery was massively extended and living standards dropped precipitously throughout the empire. Hellenistic society's dependence on slavery prevented any further advance in the technologies of production.*

By the end of the first century CE Roman defeats at the hands of the Germanic tribes terminated the northern expansion of the empire. With the supply of slaves cut off, Rome's internal depredations increased: taxes soared and the population began to decline. Toward the end of the second century CE, the empire entered a period of crisis and revolt, and persecution spread everywhere.

Against this stormy background, the advance of the cosmological ideas of the Greeks which culminated in the brilliant discoveries of Aristarchos, was arrested. Rather than junking geocentricism and the Platonic philosophy that went with it, Hipparchos and his successors — notably ***Ptolemy*** *(ca 150 CE) — added new assumptions consistent with their mathematical ideas of how best to bridge the gap between theory and observations.*

Act II: Creation 'ex nihilo' *(200–400 CE)*

The early Christians began attacking slavery together with Platonic dualism, thus eroding the main ideological, social, and economic obstacles that had impeded scientific advance in the preceding centuries. In the long epoch of increasing misery and oppression that extended through the first two centuries CE, Christianity became the only empire-wide opposition to Rome's slave system.

The early Christian message of universal brotherhood of all humanity, the antithesis of the legion's robber-rule, appealed to the enslaved and the poor. As wider sections of the population defected from allegiance to Rome, educated Christians formulated a potent antidualistic rationalistic argument against the ideology that justified the empire.

Clement of Alexandria *(150–200 CE) attacked the Platonic division between heaven and earth, freeman and slave. While he admired Plato's glorification of reason, he denied the Platonic view of matter as the origin of evil. It was in this social context that the Biblical idea of creation from* *nothing (Genesis,* **1***) was revived by the early Christians who, being clearly related to second Temple Judaism and of partially Jewish stock, were deeply versed in the Hebraic story of creation.*

According to this doctrine the universe had begun at a moment in time, out of nothing, and it would end at a certain moment, returning to nothing. Although such statements were later quoted in the Talmud, they were first clearly formulated by ***Tertullian***[337] *(ca 200 CE). Creation ex nihilo was for him what separated the finite and decaying earth from the infinite and divine heaven*[338].

Augustine *(ca 400 CE) adopted this doctrine as a cosmological justification for his political philosophy of the reconciliation of Christianity with the worldview of pagans who ran the empire, the new alliance of church and state. The foundation of this doctrine was a new cosmological myth, and creation ex nihilo was central to that myth. Thoroughly impregnated with the Judaic notion of creation out of nothing, Augustine set himself the task of countering the Greek pantheistic view, for which God is the world, and adopt the creator of the Old Testament, a God outside the world, a timeless spirit, not himself subject to causality or historical development; when he created the world, he created time and eschatology along with it.*

Interlude: Dominance of the Hierarchical Christian Cosmos *(400–1400 CE)*

The medieval universe in men's minds, finite in time and space, graded into celestial spheres, and knowable through reason and authority was hostile to

337 **Quintus Septimius Florens Tertullianus** (155–222 CE). Latin ecclesiastical writer. Born at Carthage. Worked as jurist in Rome; returned to Carthage and converted to Christianity (190 CE). Withdrew (210 CE) from the orthodox church and formed his own sect.
Tertullian embraced Platonic dualism but rejected its rationalism. To him, as to the pagan neoplatonists, the material world is evil. Such a world could have been created by an omnipotent and beneficent God only for a limited period of time; finiteness implies imperfection, source of evil, and eventual decay. By contrast, only God, who is eternal and infinite, can be wholly good and divine.

338 Modern cosmology, thermodynamics and quantum physics – while neutral in matters of good and evil – support the inherent connection between an initial preparation of a physical system and its tendencies to decay – although they *also* allow for the possibility of local order and life arising *spontaneously* (if only for a limited cosmological epoch).

the least vestige of science. Yet, during the long dark ages that preceded the Renaissance and Reformation, there were three abortive attempts to develop a new scientific view of the universe:

- *Revival of the ancient Ionian idea of a nature knowable by* observation and experiments *by* **Pelagius** *(409 CE)* and **John (Joannes) Philoponus** *(500 CE).* **Severus of Antioch** *(518 CE) revived the idea of* causality, *countering the anti-historical Platonic-Augustinian worldview. His philosophical notions implied a cosmos that unified heaven and earth, a universe not created by fiat, but developing by a historical process.*

- The Muslim renaissance *(1000–1100 CE), centered around the scientific achievements of* **Alhazen** *and* **Avicenna**. *But despite the great strides made by Islamic science, their renaissance lacked a staying power; the* 11^{th} *century thinkers had attacked an important part of the existing worldview, but had not formulated a comprehensive alternative. Their scientific method did not probe too deeply into matters that, in the Islamic east as well as in the Christian west, were so closely linked to religious orthodoxy. For the Muslim empires were just as closely linked to religious hierarchies as were the European feudal states. And while the Muslims encouraged trade, and, to a limited extent, manufacturing, political power rested with a land-lording class, whose power was centralized in the powerful caliphs.*

The conflicts between the wealthy landlords, who exploited enserfed peasants and slaves, and tradesmen and manufacturers, who relied on free labor, broke out again in violent struggle. In the end, the power of the caliphs was gathered into the hands of the invading Turks, who crushed the budding merchant economies and dispersed the scientific institutions they had supported. Fundamentalists attacked philosophers like Ibn Sina as impious and heretical. The first serious effort to establish self-sustaining scientific enterprises had failed. The crucial breakthrough — a new scientific cosmology — would be achieved by the West.

- **Robert Grosseteste** *(1220 CE)* and **Roger Bacon** *(1267 CE), under the influence of the scientific method of Islam, advocated observations and experimentation, and asserted that the highest purpose of scientific work is its eventual practical application. This new trend in Western thinking reflects the rise of more developed technology, economic growth, free labor, and expansion of trade. Yet, the scope of technological and economic expansion was limited by the old order and the scientific theory of Bacon was more utopian than practical. On the social front — feudalism needed new lands to cultivate.*

As arable land became scarce around 1300, *the nobility borrowed on a grand scale to finance their luxuries and wars, taxing their subjects to pay* *the debts. Peasant grain reserves were squandered, famine repeatedly swept over Europe, hunger pervaded the filthy towns, and in 1348 feudal society collapsed in the grip of the Black Death. This catastrophic event cleared the way for the development of science and for modern society. Over the next 300 years, the old cosmology crumbled and a new worldview took over.*

Act III: Revival of the Ionian Non-Geocentric Infinite Universe *(1440–1660 CE)*

The catastrophe of the Black Death undermined the ideological authority of both church and state. The tremendous shortage of labor created by the plague made serfdom unworkable in much of Europe. The doctrines of Augustine and Aquinas, in which the people owed obedience to secular and ecclesiastical authority, no longer held sway. Revolts in England and continental Europe shook the trading towns. The free towns of artisans, merchants, and manufacturers, allied with the free peasants, clashed with the great lords and bishops, kings, and popes.

The first serious attempt to undermine the basic notions of the hierarchical geocentric medieval cosmos was made by a German-born bishop, ***Nicolas of Cusa****. In his major work entitled* On Learned Ignorance *(1440 CE) he returned to the central idea of* ***Anaxagoras*** *— an infinite, centerless universe, unlimited in space and time. The earth, he reasoned, is no different from the stars, moving like everything else in the universe. Although his work (radical as it was in its implications) remained abstract philosophy — his influence spread in a number of parallel channels. It finally led through* ***Leonardo da Vinci*** *(1482 to 1519) to the modern experimental method, and to the cosmology of* ***Copernicus*** *(1543).*

While Copernicus worked, the voyages of discovery provided a sharp incentive for a new astronomy — moreover, a practical *astronomy. If the motions of the moon and planets could be accurately known, they could act as a celestial clock, enabling sailors to gauge their course precisely in crossing the Atlantic. For this task the Ptolemaic system with its epicycles and deferents was far too cumbersome and inaccurate.*

During the centuries-long effort to conform the geocentric worldview to the observations of planetary motions, complexity after complexity had been added. It was well known that the geocentric view accounted approximately for the positions of the planets and moon. Yet the obvious changes in their brightness *(a direct consequence of their changing distance from earth) was inexplicable. For the moon, whose distance is actually nearly constant, the epicycles introduced a variation in the distance — thus in its apparent size —*

that was not observed. It was so absurd that King Alfonso of Spain remarked, "If I had been present at the creation, I could have rendered profound advice".

Nicolaus Copernicus *studied in Italy from* 1501 *until* 1506*. There he absorbed the writings of Aristarchos, Nicolas of Cusa's idea that the earth moves, and Leonardo's conception that the sun is immobile. It is likely that he connected these new-old ideas with the well-known inadequacy of the Ptolemy system; indeed, before Copernicus left Italy, he had developed the basis of the heliocentric system.*

So radical were the implications of Copernicus' view that the leaders of the Reformation rejected it in horror, even as their followers in the universities turned to it with interest. But in England, where the power of the church had been uprooted by Henry VIII's decrees, the new ideas found fertile soil.

Yet despite its widespread acceptance in England, there was still relatively little observational evidence for the Copernical model. ***Tycho Brahe****, the most accurate observer of his day, formulated a compromise alternative in which the planets revolve around the sun, which in turn revolves around an immobile earth.*

After Brahe's death ***Johannes Kepler*** *used his observations, which were* 100*-fold more precise than Ptolemy's, to find an accurate description of the solar system. Starting with the traditional conception of perfect circles, Kepler labored for years. After enormous struggle he broke with this last remnant of the ancient cosmology.*

By trial and error, he discovered in 1609 *that the planets moved in ellipses, not circles, about the sun and not at constant speeds, but at such a rate that the areas swept by the sun-planet line in a given time remained constant throughout the orbit of a given planet. Furthermore, a simple algebraic formula governs the relation of the planetary orbital periods to their sizes. According to the later mechanistic understanding of these three laws of Kepler by Newton: As a planet approaches the sun, which occupies one focus of its elliptical orbit, the gravitational attraction increases, and it speeds up; when it has passed the perihelion (closest approach to the sun), its trajectory carries it further away from the sun, and the (weakened) force of gravity then slows it down. The immensely complex system of epicycles, deferents, and eccentric spheres was replaced by simple ellipses.*

Kepler's system was far more accurate than any other. It could not be translated to Tycho Brahe's, since then the paths of the planets would not be simple ellipses but complex compound motions.

That same year, ***Hans Lippershey*** *introduced the telescope in Holland. Within a year,* ***Galileo*** *in Italy and other astronomers had trained the new instrument upon the heavens. Galileo discovered the existence of the moons* *of Jupiter, the phases of Venus, and the mountains of the moon. The changeless, perfect heaven so crucial to Aristotelian cosmology was shattered by observation.*

Armed with his new observations, Galileo immediately became a propagandist for the Copernical worldview, actively trying to win over the Catholic hierarchy. Cardinal Bellarmine, warned by the case of Bruno, moved to quash Galileo's effort. No conflict with the literal interpretation of scripture is possible, he informed Galileo: the sun is described in the Bible as moving, rising, and setting — anything else is heretical. In 1616 Copernicus' work was added to the index of prohibited works: the new doctrine was officially condemned.

Galileo, however, continued his efforts, which culminated with the publication in 1632 *of his great defense of Copernicus, the* Dialogue on Two World Systems*. The response came swiftly: he was forced, with the example of Bruno before him, to recant and was placed under house arrest. The new science remained forbidden in Catholic countries for over a century.*

It was only in those countries where the new society was victorious that the new science became self-sustaining — above all, in England.

Act IV: Infinite, Gravitating, Evolutionary, Quasi-Static, Euclidean Universe *(1687–1860 CE)*

The English revolution of 1642 *led to a decisive (though to some extent temporary) defeat of the aristocratic landowning classes and their absorption into the new mercantile and manufacturing regime. During the period of the Commonwealth the revolutionaries, though led by Bible–inspired Puritans, also proudly identified their movement with scientific rationalism and the rejection of myths and superstitions. English scientists rapidly synthesized Kepler's laws of planetary motion with Galileo's investigations in mechanics, published in* 1638.

Taken together, these two scientific developments led ***Robert Hooke*** *and others in England to ask whether planetary motion could be explained by attraction spreading from the sun with an inverse-square dependence on the distance (1679).* ***Isaac Newton*** *(1680 to 1687) elevated the notion from the merely speculative to the quantitatively predictive, and extended the realm of its application to universal gravitation.*

Thus, the scientific revolution of the 16^{th} *and* 17^{th} *centuries had, at least in England, displaced the hierarchical, finite universe with an infinite one, and the appeal to authority and pure, scholastic reason with the observational method. But, unlike the Ionians,* 17^{th}*-century scientists had not developed a* *naturalistic theory of the origins of the world, an alternative to the creation from nothing of the medieval cosmology. Philosophers such as Nicolas of Cusa and Giordano Bruno had advocated the idea of a universe unlimited in time and space, eternal and without beginning. But no scientist could corroborate these notions with hard data.*

For many scientists, it was in this realm of origins that religion still intersected with science. Isaac Newton, for example, argued that God is needed to form the solar system and to maintain it.

In the period after the English revolution, the Restoration, and the ensuing Glorious Revolution (ushering in constitutional monarchy), English society settled into a conservative phase. The idea of change, implicit in any concept of evolution in nature, lost its popularity. The universe was a finished product brought into being by events that could not recur.

It was not until the middle of the 18^{th} *century, when the winds of change started to blow in Europe and America, that the problem of origins was again tackled. In* 1755 *the philosopher* ***Immanuel Kant*** *formulated a naturalistic explanation for the origin of the earth and solar system in many ways strikingly similar to that of Anaxagoras.*

Kant, who was familiar with the latest astronomical research, argued that observation showed that stars are not randomly scattered throughout the universe, but appear to be grouped into a huge disc, the Milky Way. He speculated, correctly, that the distant fuzzy nebulae astronomers were then studying are similar vast agglomerations of stars, what we now term galaxies. By analogy he reasoned that these, too, probably formed still larger systems of clusters — once again a guess later confirmed by observation.

Starting with this concept of an infinite universe, arranged into a hierarchy of larger and larger spinning agglomerations of matter, Kant proposed the idea that in the remote past the universe was a nearly homogeneous, infinite gas. Certain regions, which by accident happened to be denser than others, started to attract matter by gravitation. The random motions of the gas gave to each agglomeration a slight spin, creating huge vortices, within which galaxies, then stars, then planets coalesced[339]*. Since Kant assumed that this process started in one place in the universe, and spread outward, he believed that creation was and remains a continuous process, which spreads through the infinite universe.*

339 Newtonian mechanics, as well as further astronomical research, confirmed these mechanisms, basing them upon *conservation of angular momentum* and *growth of gravitational instabilities*.

In the years following Kant's "Theory of the Heavens", Europe and America were convulsed by sweeping revolutions that sought to complete the overthrow of the old hierarchical societies and to replace them with democracies. By the century's end, the spectacular changes of government and society brought about by these revolutions led their supporters to conceive of a general and continual process of human social change — the idea of *progress*. To both the Founding Fathers in the United States, and the French revolutionaries, their respective revolutions were part of the inevitable advance of society, perfecting its institutions and improving without limit the material well-being of mankind.

The revolutionary political concept that society is not a fixed entity, that it continuously evolves through effort and struggle, through science and technology, toward higher forms of organization and material well-being, was swiftly taken up in the field of science. In late-18^{th}-century England geological knowledge advanced rapidly as coal became central to the steam-powered industry of the industrial revolution. Geological observation led **James Hutton**, an amateur scientist, to develop a theory of the continuous evolution of the earth itself.

By observing such processes as the compaction of clay into sedimentary rock, Hutton concluded in his 1795 work, *Theory of the Earth*, that mountains, rivers, oceans, and the sedimentary and igneous rocks of the world today were formed over many millions of years, not by miraculous floods or one-time cataclysms. He emphasizes that a scientific history of the world can be obtained only by examining current processes and working backward in time, not by speculating about origins and working forward. The idea of a world finite in time, with a supernatural origin, is rejected: "The result, therefore, of this physical inquiry is that we find no vestige of a beginning, no prospect of an end".

Within a decade, the French mathematician **Pierre Simon de Laplace** had taken Hutton's approach a step further into the past and given a firm scientific basis to Kant's vortex theory of origin. Using Newtonian mechanics, Laplace demonstrated in 1796 that, if the sun had condensed from a spinning sphere of gas, it would have thrown off material as it contracted, since as it contracted it would have spun faster (by angular–momentum conservation). The material thrown off would form into rings, which would, in turn, condense gravitationally into planets. The nearly circular orbits of the planets would therefore be neatly accounted for.

Hutton and his supporters rapidly accepted Laplace's nebular theory, producing an integrated approach to the history of the world since its origins. Others quickly applied the historical approach to the development of life itself. **Erasmus Darwin** (Charles' grandfather), in the same year as Laplace's *theory, proposed that the fossils found in geological strata represent the evolution of various species of animal from one another, leading to a greater and greater perfection of life over vast stretches of time.*

By the 1840s the new geology and cosmology enjoyed widespread acceptance among scientists and the public, and socialist concepts of societal evolution spread throughout Europe.

In 1859 ***Charles Darwin*** *systematized and popularized the theory of biological evolution, ironically seizing on Malthus' theory of limited resources to formulate a vision of continual evolution and change. By the 1860s, despite continued religious opposition, the evolutionary and historical approaches in the sciences had become dominant, as had the related idea of human progress.*

Neither religion nor philosophy could place limits on the natural universe in time or space, yet it was clearly evolving, not static. The triumph of the scientific revolution was the triumph of the infinite universe — a universe of unlimited progress from an infinite past to an infinite future.

Interlude: Vestige of a Beginning and Prospect of an End *(1823–1916 CE)*

The concept of an infinite universe was questioned even after the scientific revolution. Newton was undecided on whether his laws of gravitation preclude an infinite collection of matter. He thought that only a divinely precise positioning of all the stars could prevent such an infinite collection of matter from collapsing into a series of heaps.

The efforts to solve the cosmological problem within the framework of Newton's Law of Gravitation and Newtonian mechanics met a serious obstacle; if space is infinite and the density of matter is everywhere finite, an infinite world filled with an infinite amount of gravitating matter would result. Is such a universe conceivable? Are we permitted to perform this transition to infinity without encountering difficulties of principle[340]*?*

If the world contained infinitely many bright stars, then, if one's line of sight were extended far enough in any direction from earth, it would intersect a star. This implied that the sky should be uniformly bright — as bright as the surface of the sun, which it obviously is not.

---

[340] In a world in which the mean density ρ of matter is finite, even if its value is as small as we please, the gravitational potential $\phi = \int_V \rho \frac{dV}{r}$ has no definite value when V, the volume, tends to infinity. Also, the expression for the gravitational stress becomes indefinite.

This objection (Olbers paradox) was first raised by ***J.P.L. de Cheseaux*** *(1744) and again by* ***H.W.M. Olbers*** *(1826). It can be removed, within the realm of classical physics, by applying the idea of a hierarchic structure of the universe which prescribes a special type of distribution of the infinite amount of matter over the infinite Euclidean space, such as to avoid the singularities mentioned above. The first idea in this direction came from* ***J.H. Lambert*** *(1761).*

By a "hierarchic structure" the following is meant: matter is distributed in space so that the stars combine to form greater systems, star-systems or galaxies; galaxies again combine to form still greater systems, supergalaxies and so on. From each rank on the hierarchic ladder we can step to a rank of higher order consisting of elements of the preceding rank, and so forth to infinity. If we impose certain additional restrictions on such a hierarchy[341]*, the singularities mentioned above need not appear. In the resulting universe the mean density of matter becomes zero.*

In this hierarchic regime, the gravitational potential at each point converges to a finite value in spite of the infinity in the universe's size, mass, and number of stars. Likewise, the brightness of the night sky could be kept sufficiently low, providing a solution to Olbers' Paradox. In such a universe the mean density of matter, taken over a volume increasing toward the infinite Euclidean space, converges to zero, although the total amount of matter would increase to infinity. [The hierarchic structure was hypothesis revived in the 20^{th} *century by* ***Hugo von Seeliger*** *(1909) and* ***C.V.I. Charlier*** *(1922).]*

Another difficulty which was encountered in the first attempts to solve the cosmological problem, was the expectation of unduly high velocities in an infinite universe containing an infinite amount of matter. However, at the time when the idea of a hierarchic world order was developed, the high and systematic velocities of distant spiral systems were still unknown — and the necessity had not yet been realized of formulating the cosmological problem as a dynamical[342]*, and not a static problem.*

---

[341] Let us attribute to all systems spherical shapes of radii $R_0, R_1, R_2, \ldots, R_i, \ldots$, each system having the total mass $M_0, M_1, M_2, \ldots, M_i, \ldots$ and consisting respectively of $N_0, N_1, N_2, \ldots, N_i, \ldots$ objects such that $M_1 = N_1 M_0$, $M_2 = N_2 M_1 = N_1 N_2 M_0$ etc. Then the condition is $\frac{R_i}{R_{i-1}} \geq \frac{1}{\gamma} N_i$, where $\gamma < 1$. The convergence of the gravitational potential can be shown to be independent of the assumption of the spherical shape of each system.

[342] The universe could be called '*static*' if — despite local motions of celestial bodies (for instance, the orbital motions of the planets around the sun) — no large-

*The idea that the universe had a finite lifetime also existed in the mid-*19*th* *century, although only on the popular fringes of science. The first suggestion that the universe originated in a creative explosion — the first Big Bang — actually came from the pen of* ***Edgar Allan Poe*** *in* 1849*. Poe was not only a well-known poet and writer, he was also a scientific popularizer who kept himself up-to-date on the latest in astronomical research. In the book-length essay Eureka Poe rejected the idea of an infinite universe, citing Olbers' objections. He reasoned that a universe governed by gravitation would collapse in a heap if not kept apart by some form of repulsion. He postulated that God had, in an enormous explosion at the creation, thrust all the stars apart. Like a rocket racing into the sky, the universe of stars and galaxies would first expand, and then contract into a final catastrophe, the end of the world.*

*However, questions about the infinity of the cosmos remained marginal to the mainstream of science through the mid-*19*th* *century. The swift advance of technological progress and the equally swift transformation of society convinced most scientists that the basic methods of science correctly yield results provable in practice, and that the thesis of an unlimited, evolutionary universe is valid. It was not until social and economic progress slowed that the corresponding scientific assumptions came under serious attack.*

In the latter third of the 19*th* *century, from around* 1870 *on, the nature of the rapid social and economic evolution of Western society began to change. By this time, the last institutional vestiges of compulsory labor had been wiped out by social revolutions in Europe, the Civil War in the United States, and the liberation of the serfs in Russia. After the defeat of the Paris Commune — the* 1871 *attempt to establish a workers' rule — Europe entered a period of relative political stability.*

The sixty years from 1820 *to* 1880 *witnessed the fastest economic growth in history. But by* 1880*, the limits of capitalist markets were being reached: European and American goods were penetrating virtually every corner of the*

scale changes in the distribution of matter in the universe were occurring. In such a "*static*" world, the mean density in the distribution of matter would remain constant when referred to sufficiently large volumes of space and sufficiently long intervals of time.

When our knowledge extended far beyond the limits of our galaxy and the high velocities of distant spiral stellar systems were discovered, not small even when compared with the velocity of light — these velocities were of a character very different from the high velocities expected on account of increasingly large potential differences. This discovery, together with the new methods of determining stellar distances, extended our "neighborhood" far beyond the limits reached until then and changed the whole outlook on the cosmological problem to such an extent that all previous results had to be completely revised.

globe, as Britain, France, and Germany rushed to carve up the only remaining land — Africa. While the actual need for goods remained immense, the market for goods that could be sold at a profit was nearing the end of its growth. For centuries, millions of new farmers and peasants had been drawn into the developing capitalist market system as feudal regimes fell apart and as new colonies were conquered and absorbed. When this expansion lost its frontiers with the formation of the first global market at the end of the 19^{th} *century, the industrial economies could no longer continue their vigorous expansion.*

After 1880, *the production of iron and steel and the laying of new rail lines practically ceased their growth. Real wages continued to increase, but more slowly, peaking in Europe by* 1900. *Manufacturers turned to the European states for new markets, leading to the growth of a gigantic arms industry. Manufacturers found that two battleships are always better than one, unlike two railroads from Liverpool to London. These arms, in turn, were used to maneuver for a greater share of the precious world markets and of the resources of the colonies.*

It was in this era of slowing growth that the first real scientific challenge to the unlimited universe appeared. Steam power had developed throughout the 19^{th} *century, as did the study of heat and its transformations — thermodynamics. In the early part of the century, scientists had discovered that energy can be transformed in various ways, but never created or destroyed, a fundamental principle that came to be known as the* first law of thermodynamics.

In 1850, ***Rudolf Clausius*** *discovered another fundamental principle, the* second law of thermodynamics. *A quantity (macroscopic state–variable) which Clausius dubbed "entropy", always exhibits an overall increase in any transformation of energy — for example, in a steam engine. This principle encodes the* irreversible *aspect of thermal processes. The entropy of a physical subsystem was defined by its infinitesimal change — the quantity of heat transferred into the subsystem from the outside, divided by its absolute temperature.*

In 1877, ***Ludwig Boltzmann*** *attempted to derive the macroscopic second law from the newly emerging atomic theory of matter. He redefined entropy as a function of the probability distribution of* microscopic *states compatible with a given* macroscopic *state of matter and energy: if the microstates are more numerous for one macrostate then for another, the former macrostate has a higher entropy. Thus, if a million atoms of oxygen mixed with a million atoms of nitrogen, it would be far more probable to find them evenly mixed than segregated. The well-mixed state has a higher entropy; and left to itself, a container with oxygen on one side and nitrogen on the other will rapidly go to the higher entropy state of an even mixture.*

Boltzmann, using his new definition of entropy, went on to demonstrate, so he claimed, that all closed systems tend toward a state of thermodynamic equilibrium — defined as the state in which there is no net flow of energy. Thus a hot object and a cold object placed in contact are not in equilibrium, since heat will flow from one to another until they are at the same temperature, which is a state of equilibrium — and also a state of maximal entropy if the two-object system is isolated from its environment.

From this proof, Boltzmann propounded a new concept with profound cosmological implications. The universe as a whole must, like any closed system, tend toward an equilibrium state of maximal entropy: it will be completely homogeneous, the same temperature everywhere, the stars will cool, their life-giving energy flow will cease and their atoms and molecules will evaporate to fill space. The universe will suffer a "heat death". Any closed system must thus go from an ordered to a less ordered state — the opposite of progress.

Boltzmann was aware that his ideas contradicted the notion, then widely accepted, of a universe without beginning or end. The present-day universe is far from a state of equilibrium, comprising as it does hot stars and cold space. If all natural systems "run down" to disorder, the present state of order must have been created by some process that violates the second law at a finite time in the past. Conversely, at a finite time in the future, the universe will become a lifeless homogeneous mass: human progress is but an ephemeral and inconsequential episode in a universal decay.

Boltzmann found his results disturbing. Since he rejected a supernatural origin of the universe, he tried to argue that, in an infinite amount of time, extremely improbable events do occur, such as the spontaneous organization of a universe, or a large section of it, from a prior state of equilibrium. The second law is, after all, a statistical one stating what is likely to happen, not what must *happen. Just as there is an incredibly small chance that all the air molecules in a room will rush to one side, there is a smaller chance that all the atoms in a homogeneous part of an infinite universe will suddenly rush together into one spot of low entropy. Boltzmann's argument did not much impress his fellow scientists, since by his own theories the probability of these occurrences was, in fact, so tiny that it was equivalent to an impossibility.*

But scientists had other reasons for not accepting the second law's implication that the universe necessarily had a beginning from which it was now running down. The predictions of thermodynamics appeared to contradict what was known of geological and biological evolution. In the 1890s *a debate broke out between thermodynamicists and geologists over the age of the earth. The physicist* ***Lord Kelvin*** *argued that, from the cooling rate of the earth as estimated from measurement of heat in mines, the earth must have been nearly molten as recently as twenty million years ago. Geologists countered* *that the formation of certain rock deposits must have taken at least twenty times as long, four hundred million years. Backed up not by theory but by a vast accumulation of observation, geologists doubted the physicists' theories.*

In addition, some thermodynamicists pointed out that Boltzmann had proved far less than he claimed. He assumed that gas began in a high degree of disorder, close to equilibrium, and never got far from it. Moreover, he only allowed for atomic collisions, but took no long-range forces, such as electromagnetism or gravity, into account. In most real physical situations, though, these restrictions are not valid, so Boltzmann's proof is not applicable. A century later scientists were to demonstrate that Boltzmann's law of increasing disorder does not apply to systems far from any state of equilibrium.

Beyond these scientific objections, though, were cultural ones. At any moment, scientists must decide which problems or apparent paradoxes are worthwhile and which should simply be dismissed — it is here that the ideology of the age — of society as a whole — sometimes affects what scientists feel "makes sense". And Boltzmann's concept of a world running down simply did not make sense to most 19^{th}*-century scientists.*

In the late 19^{th} *century, while material advance had slowed and the ominous trends leading toward the crises of the* 20^{th} *century were beginning to emerge, progress remained the overwhelmingly dominant idea of the epoch. Standards of living continued to rise, albeit more slowly, until* 1900. *Technological progress was more rapid than at any other time in human history: someone born in* 1870 *would have grown up in a world of gaslight and horse-drawn carriages, but by age forty he or she would live in a world of electricity, telephones, phonographs, movies, radio-telegraphs, automobiles, and airplanes.*

Science, too, advanced dramatically in the same period. Biology and medicine were transformed in the 1880*s by the germ theory of disease, leading to the widespread use of antiseptics in surgery, and the general use of vaccination. Physics saw the blossoming of the study of electromagnetism, put on a firm foundation in* 1865 *by* ***James Clerk Maxwell****, and later radioactivity, X-rays,* ***Einstein****'s special theory of relativity, and the beginning of quantum theory.*

The reality of progress in science and society was so apparent to the average scientist, that Boltzmann's vision of a universe in continual decay seemed too bizarre. In practice, Boltzmann's laws were very useful in dealing with steam engines and simple gaseous systems, and were widely applied. But his broad generalizations about cosmology, which implied that the universe must have had a beginning, must have been "wound up"and will inevitably wind down and decay — had no significant impact for more than a generation.

Nevertheless, the finite universe did *return: The European and American confidence in progress was shattered in August of* 1914*. In the following four years the vast economic power and technological achievements of the prior century were thrown into the barbaric enterprise of slaughtering twenty million human beings. In the wake of war came revolution and counter-revolution: working-class living standards had plummeted during WWI, and workers' movements had seized power in Russia and tried to do so in Germany. Throughout Europe and America, employers and governments battled strikers.*

At this very moment in history, came the first public announcement of the observational verification of Einstein's Theory of Relativity. On Nov. 9, 1919*, the* New York Times *announced that the solar eclipse of May* 29, 1919 *had confirmed Einstein's prediction of the bending of light from distant stars by the sun's gravity.*

1915–1925 CE **Bedrich Hrozny** (1879–1952; Czechoslovakia). Archaeologist, orientalist and philologist. Deciphered the Hittite language and laid the foundation to a new scientific branch — Hittitology.

Born in Lysa na Labem (near Prague), and attended grammar school in Prague and in Kolin. He then studied in Vienna Semitic and Oriental Philology and worked there as librarian and lecturer (1905–1918). During 1919–1952 he was a professor at Charles University in Prague.

Working with inscriptions from the *Hittite royal archives* discovered (1906) at the ancient capital site of Hattusas (near the Turkish village of Bogazköy, east of Ankara), Hrozny concluded (1915) that Hittite was an Indo-European language because of the similarity of its endings for nouns and verbs to those of other early Indo-European languages. Hittite has provided significant information about the early Indo-European sound system. Some years earlier the existence of an Indo-European idiom in some cuneiform[343] letters found

[343] *Cuneiform*: system of writing used in the ancient Middle East. The name, a coinage from Latin and Middle French roots meaning "wedge-shaped", has been the modern designation from the early 18th century onward. Cuneiform was the most widespread and historically significant writing system in the ancient *Middle East*. Its active history comprised the last three millennia BCE; its long development and geographic expansion involved numerous successive cultures and languages. Its overall significance as an international graphic medium of civilization is second only to that of the Phoenician-Greek-Latin alphabet.

in the Egyptian diplomatic archives of the 18th dynasty at Tell el-Amarna, had been suspected by **Johan Knudtzon** (1902).

The Hittite language is the most important of the extinct Indo-European languages of Anatolia; it was closely related to Luwian, Lydian, Lycian, and Palaic. Hittite is known primarily from the approximately 25,000 cuneiform tablets or fragments of tablets preserved in the archives of Bogazköy, the majority of which are from the period of the Hittite empire (c. 1400–c. 1190 BCE) and are concerned with religious and other subjects. Old Hittite texts, from about 1650 to 1595 BC, are preserved in copies from the empire period and are the earliest Indo-European texts that have thus far been found.

In his *Sprache der Hethiter* (1915) and *Hethitische Keilschrifttexte aus Boghazköi* (1919), Hrozny substantiated his claim by translating a number of documents, including a Hittite legal code. In 1925 he led a Czechoslovak expedition to Kültepe, Turkey, recovered some 1,000 Old Assyrian tablets nearby, and excavated the ancient city of Kanesh, revealing much about its everyday life. During the remainder of his career, he addressed himself to problems of deciphering.

1915–1938 CE **Adolf Otto Reinhold Windaus** (1876–1959, Germany). Chemist. Discovered the structure of *cholesterol*[344] (1932), its relation to *vitamin D* and linked the roles of sunlight and vitamin D in the prevention of *Rickets*. Isolated vitamin D_1 from yeast, and discovered *histamine*.

Received the Nobel Prize for Chemistry (1928). Windaus' influence on junior colleagues, led to studies of steroidal sex hormones by **Adolf Butenandt** (1903–1995, Germany) and the study of the stereochemistry of steroids by **Erich Hückel** (1896–1980, Germany).

Windaus first studied medicine at the University of Berlin (1895) but abandoned medicine for chemistry (1899). He was professor of medical chemistry at Freiburg (1905–1913), Innsbruck (1913–1915) and Göttingen (1915–1944).

1915–1975 CE **Harold Jeffreys** (1891–1989, England). Mathematician, geophysicist and astronomer. Discovered the discontinuity between the

[344] *Cholesterol* ($C_{27}H_{46}O$) is synthesized in the liver and is present in edible food. It is found particularly in the brain, nerve tissues, and gallstones of animals. It aids in absorption of fatty acids from the small intestine. Since it does not produce ions, and therefore does not carry a current, cholesterol is a good electrical insulator in the brain and the nervous system. It is also essential for the production of sex hormones, vitamin D, and the adrenal cortex hormones. It is suspected that excessive ingestion of carbohydrates may result in cholesterol deposits on the wall of the blood vessels, leading to heart disease.

Earth's upper and lower mantle, found evidence for the fluid nature of the core and did much pioneering work on the shape and strength of the earth. His analysis of seismic travel times was published as the *Jeffreys-Bullen Tables* (1940), which remains a standard reference. This work led him to Bayesian theory of probability applicable to a wide range of sciences, including econometrics and statistics. Among his works are *The Earth: Its Origin, History and Physical Constitution* (1924); *Methods of Mathematical Physics* (1946; with B.S. Jeffreys).

Jeffreys was born in Fatfield (near Durham), England. He was educated in Armstrong College, Newcastle upon Tyne, and St. John College, Cambridge, where he graduated in 1913. Jeffreys worked in the Cavendish Laboratories on war related work (1915–1917) and then joined the Meteorological Office (1917–1922), working on hydrodynamical problems. Returning to Cambridge (1922), he held various teaching appointments and later became Plumian Professor of Astronomy (1946–1958). He was knighted in 1953.

1915–1939 CE **David Sarnoff** (1891–1971, USA). A Pioneer in radio and television broadcasting (1915); formed *National Broadcasting Corporation* (1926) as subsidiary of RCA; established experimental television station (1928); gave demonstration of television at New York World's Fair (1938).

Sarnoff was born in Minsk, Russia to Jewish parents. Emigrated to USA (1900); a myth has it that while a telegraph operator (from 1906), was first to pick up distress signal from the *Titanic* (1912). Rose from commercial manager (1919) to president of Radio Corporation of America (RCA, 1947–1970).

Sarnoff, largely self-taught, was perhaps the key figure in the shaping of the modern broadcast and communication system in USA. He was involved with the whole history of 20th century communication system from marine telegraphy, through radio to television. He was not an engineer and never held a single patent, but he had a crucial flair for foreseeing and shaping the applications of the new electronic technology.

1916, February 21–December 19 CE *The Battle of Verdun*: Perhaps the bloodiest and most demanding battle in history, between Germany and France. In the end, the front lines were nearly the same as when the battle started while over 260,000 French and Germans were killed and over 750,000 were wounded.

During the *First World War*, Verdun was a fortified French garrison town on the River Meuse 200 km east of Paris. The town, surrounded by a ring of forts, was an important stronghold that projected into the German lines and guarded the direct route to Paris. Rather than a traditional military victory, Verdun was planned as a vehicle for destroying the French army on account of its holding a great symbolic value in the minds of the French people. The German plan was to subject Verdun to intense bombardment (1,000,000 artillery shells were fired by 1200 guns on a front of 40 km on the day of 21, February 1916, alone!), thus drawing in and diverting French troops from all over the Western Front to the 12 km wide front around Verdun. On the first day of the German attack, a million troops faced only about 200,000 French defenders.

Vowing that "they shall not pass", the French were eventually able to stop the German advance, and after ten months of bloody combat the German gains had been virtually wiped out.

Verdun was a "victory" that would haunt French military and political leaders for a generation.

1916–1918 CE Physicists **H. Reissner** (Germany, 1916) and **Gunnar Nordström** (1881–1923, Finland, 1918) presented a study of the gravitational field of an electrically-charged, non-spinning point mass (i.e., a point singularity of the Einstein field-equation) with an energy-momentum tensor due to its electromagnetic field. This is known as the *Reissner-Nordström solution.*

1916–1923 CE **Gilbert Newton Lewis** (1875–1946, USA). Theoretical physical chemist. Advanced the theory of the *chemical bond.* Did pioneering work on the electronic theory of *valency*, in which he developed the concept of *electron-pair bond.* Broadened the definitions of *acids* and *bases.* In the field of *chemical thermodynamics* he listed the free energies of 143 substances. His later work was on deuterium (heavy hydrogen), photochemistry, and the excited electron states of organic molecules. Through these studies he contributed to the understanding of the *color* of organic substances, and the complex phenomena of *phosphorescence* and *fluorescence.*

Lewis was born in Weymouth, MA, USA and obtained his Ph.D. from Harvard University (1899). He later worked at Leipzig (under **Ostwald**), and Göttingen (under **Nernst**), and MIT (1905–1912); he subsequently moved to the University of California, Berkeley, where he remained until his death.

Lewis showed (1916) the significance of completed shells of 2 and 8 electrons. He defined a *base* as a substance that supplies a pair of electrons for a chemical bond, and an *acid* as a substance that accepts such a pair. He postulated that the atoms of elements whose atomic mass is higher than Helium's have *inner shells* of electrons with the structure of the preceding rare gas. The valency electrons lie outside these shells and form ionic bonds, preferably *covalent bonds.* The covalent bond was identified with a pair of electrons shared by two atoms and occupying jointly an outer-shell orbital belonging to each atom (1919, with I. Langmuir).

Lewis coined the name 'photon'.

"I hope I shall not shock the experimental physicists too much if I add that it is also a good rule not to put over-much confidence in the observational results that are put forward until they been confirmed by theory."

Arthur Eddington

1916–1926 CE **Arthur Stanley Eddington** (1882–1944, England). A leading astronomer of the first half of the 20^{th} century and the most distinguished astrophysicist of his time.

His work on the internal constitution of stars formed the prelude to the whole development of modern astrophysics. Following the older work of **J.H. Lane** (1819–1880, U.S.A.; 1870), **A. Ritter** (1878–1889), **R. Emden** (1862–1940, Switzerland; 1907) and **K. Schwarzschild** (1906–1914), Eddington succeeded in combining their classical results with the theory of *radiative equilibrium* and Bohr's theory of atomic structure (which had meanwhile been developed) into a set of equations governing stellar interiors and luminosities[345].

[345] Normal stars are assumed to be in hydrostatic equilibrium and thermodynamic steady state. Hydrostatic equilibrium arises when there is a balance between the attractive force of gravity and the outward force caused by the pressure gradient $\frac{dP}{dr}$. If spherical symmetry is assumed, only spherical mass shells need be considered. Assuming the temperature gradients are sufficient to trigger convection, and ignoring non-radiative diffusive heat conduction, the standard equations of the theory of the internal constitution of stars are as follows (see legend below):

(1) Hydrostatic equilibrium $\frac{dP}{dr} = -\rho\frac{GM(r)}{r^2}$; $\quad \frac{dM(r)}{dr} = 4\pi\rho(r)r^2$;

(2) Net steady-state energy-flux balance equation $\frac{dL}{dr} = 4\pi r^2\rho\epsilon$;

(3) Radiative energy transfer $\frac{dT}{dr} = -\frac{3}{16\sigma}\frac{\chi\rho}{T^3}\frac{L(r)}{4\pi r^2}$;

(4) Convective energy transfer $\frac{dT}{dr} = \left(1 - \frac{1}{\gamma}\right)\frac{T}{P}\frac{dP}{dr}$, $\quad \gamma = \frac{c_p}{c_v}$;

Eddington empirically verified Einstein's prediction of the deflection of starlight in the sun's gravitational field (1919). In 1920 he suggested that the sun might derive its energy from the fusion of hydrogen into helium. In 1923 he tried to unify electromagnetism and gravitation via a geometrization of the electromagnetic field.

In 1924 he formulated the mass-luminosity law for stars and defined the *Eddington limit* (critical luminosity above which radiation pressure exceeds gravity, preventing further accretion by small-particle infall). He then estimated the size of a *white dwarf star* — one such being the companion of Sirius. (White dwarves were identified ca. 1913 by **Hertzsprung**.)

Also in that year, he put the Schwarzschild solution (to the field equations of GTR) in a new form, from which the later **Kerr** solution for the spacetime metric outside a spinning mass could be derived (1963).

Yet, since 1935, **Eddington** rejected *Chandrasekhar's limit* and never accepted it. He saw that it would lead to the '*black hole*' concept, which he thought to be a physical absurdity. Eddington's shortsightedness regarding black holes delayed the development of this field some 30 years, due to his supreme authority at that time.

Eddington was born in Kendal, England. He was educated at Owen's College, Manchester and Trinity College, Cambridge, where he was senior Wrangler in 1904 and Smith's prizeman in 1907. From 1906 to 1913 he held the post of chief assistant at the Royal Observatory at Greenwich. In 1913 he became Plumian professor of astronomy at Cambridge and in the same year was elected fellow of the Royal Society.

His work on stellar evolution, relativity, gravitation and cosmology led him to search for a relationship between all the fundamental constants of nature[346].

---

(5) Gas equation of state $P_g = \rho RT/\mu$;

(6) Nuclear rate equation $f(\epsilon, \rho; T) = 0$.

The functions and parameters appearing in (1)–(6) are: T (absolute temperature), P_g (gas partial pressure), P (combined gas *and* radiation pressure), ρ (mass density), M (mass), r (radial coordinate), μ (mean molecular/ionic weight), L (luminosity, in ergs per second), σ the Stefan-Boltzmann constant, ϵ (energy generated per second per gram of stellar matter by nuclear reactions at T, ρ), χ (mass absorption coefficient of radiation); c_p and c_v denote the specific heats at constant pressure and volume, respectively.

[346] Eddington's quest was a remarkable combination of the profound, the mystic and the fantastic, setting in motion a never-ending progression of attempts to explain constants of nature by feats of pure Pythagorean numerology. He

Eddington wrote several books that explained the nature of the universe in popular terms. In one of them, "The Nature of the Physical World" (1928) he said: "*I know passages written in mathematical symbols which in their sublimity might vie with a sonnet of Shakespeare*".

1916–1928 CE **Thomas John I'Anson Bromwich** (1875–1929, England). Mathematical physicist. Contributed significantly to the theory and applications of the operational calculus (*The Bromwich Integral*).

Bromwich spent his youth in Natal and was educated in Durban. He studied at Cambridge and became a university lecturer from 1909 to 1926. He died by suicide.

1916–1932 CE **Willem de Sitter** (1872–1934, Holland). A noted Dutch astronomer and cosmologist. Solved Einstein's field equations for a static universe and found that his solution possessed the peculiar property that light from great distances is redshifted. In 1928 **Howard Percy Robertson** (1903–1961, U.S.A.) showed the de Sitter's universe could be mathematically transformed into an expanding universe.

In 1916, de Sitter applied GTR to the earth-moon-sun system to find the modification of the moon's orbit required by the new law of gravitation. He found that Einstein's theory predicted new radial and transverse perturbing forces *in addition* to Newtonian dynamics. Accordingly, the leading correction to the lunar theory obtained from Einstein's equations is a *precessional motion* in which the moon's node and perigee advance about 0.02 arcseconds per year.

---

thus 'proved' (1930) that the reciprocal of the *fine structure constant*, α (modern experimental value: $\alpha^{-1} = 137.035989561\ldots$) is a whole number equal to $\frac{16^2-16}{2} + 16 + 1 = 137$. He also concocted a "theory" (1935) for the mass ratio of the proton and electron (experimental value = 1847.6...), according to which this number is equal to the ratio of the solutions of the quadratic equation $10m^2 - 136m + 1 = 0$, the form of which he believed to be dictated by the number of directions that characterize our 4 dimensions of space and time.

Few if any of Eddington's peers and colleagues accepted his views. The great theoretical physicists of his day, such as **Einstein**, **Dirac**, **Bohr** and **Born**, found his approach useless and politely confessed that they couldn't understand it. Yet, his attempts to 'explain' the constants of nature by algebraic and numerical gymnastics had enduring effects on readers of his popular books; for he conveyed to them the overwhelming impression that it might be possible to unlock some of the most deeply hidden secrets of the universe by a little bit of inspired 'Kabbalah-style' guesswork and numerology. Indeed, the physicist V. Weisskopf jokingly pointed out that the numerical value of the Hebrew word "Kabbalah" itself equals 137!

According to GTR this phenomenon is a property of the space surrounding the earth — a *precession of the inertial frame* in this region relative to the asymptotic inertial frame of the sidereal system. This was first pointed our in 1918, by **Jan A. Schouten** (1883–1971, Holland), and later by **Eddington**.

Sitter was born at Sneek, Holland and was educated at the University of Gröningen. He went (1897) to the Cape of Good Hope to work at the Cape University for 2 years. He became professor of astronomy at the University of Leyden (1908) and the director of its observatory (1919–1934). His papers, published in London during WWI, aroused scientific interest in Einstein's GTR among British scientists.

During Einstein's second visit to California (1932) he published a joint note with de Sitter in which a spatially flat universe (Euclidean space, curved spacetime) was proposed without a cosmological term and with zero pressure.

1917 CE, Nov. 07 The so-called *October*[347] *Revolution* began in Russia. A forerunner (the so-called *February Revolution*) began on March 08 with strikes, riots, and mutinies by the troops in the capital Petrograd (later called Leningrad, now called St. Petersburg). The unrest was sparked by Russian defeats in WWI and bad governance which had led to food shortages.

The revolution strongly affected the history of Europe and the rest of the world during the next 70 years. Under Communism, free thought and expression were suppressed in Russia (and after WWII — in Eastern Europe and East Germany too) for three generations. During this time, acceptable science was exclusively that endorsed by the Communist party of the USSR, whose intellectual despotism rivaled that of the Catholic Church in the Middle Ages. Consequently, the development of certain sciences was arrested and even perverted. For example, the whole of biology (especially genetics) was ravaged by ideological conflict; serious scientists were pilloried, and laboratories were closed or transformed into havens of 'Communist-style' biology led by the agronomist Trofim Denisovich Lysenko[348] (1898–1976).

The Bolshevik Revolution was the *bloodiest ever in human history*. About 30 million people were executed in the Soviet Union during 1917–1987, es-

---

[347] Oct. 25 in Russia was the same as Nov. 7 elsewhere. By 1917, the Russian calendar was 13 days behind the rest of the world; the new regime brought it into line, but the old name for the uprising, persisted.

[348] With Joseph Stalin as his chief supporter, Lysenko gained control of Soviet biological research (1928–1965), and imposed his view regarding heritability of acquired characteristics.

pecially under the dictatorships of Lenin[349] (1870–1924) and Stalin[350] (1879–1953).

1917 CE, Dec. 06 *The Halifax Explosion*, Nova Scotia, Canada. Largest, most devastating man-made explosion in the pre-nuclear age.

During WWI, A Belgian ship, *Imo*, collided with a French ammunition ship, *Mont Blanc*, causing an explosion of about 200 ton of TNT in the city's harbor. The unfortunate disaster killed about 2000 persons, injure 9000 more, and wrecked much of Halifax (about 1630 houses were obliterated and 12,000 more damaged).

1917 CE **Albert Einstein** (1879–1955, U.S.A.) established the theory of spontaneous and induced (stimulated) radiative transitions resulting from the interaction of radiation with atoms. During 1953–1960, this theory was applied to develop *masers* and *lasers*.

Consider two atomic or molecular states of energies E_1 and $E_2 > E_1$, occupied by N_1 and N_2 atoms (or molecules), respectively. The photons corresponding to transitions between these two levels must have an energy close to $h\nu = E_2 - E_1$, ν being the photons' frequency. Atoms at level E_2 may jump spontaneously into level E_1, emitting a photon. Let us call A_{21} the corresponding spontaneous emission transition probability per unit time per atom. If ambient radiation of frequency ν is present and its energy density is $\epsilon(\nu)$, absorption transitions from E_1 into E_2 are also produced.

It is natural to assume that the number of such transitions per unit time is proportional to the energy density $\epsilon(\nu)$; that is, the induced absorption transition probability per unit time is $B_{12}\epsilon(\nu)$, where B_{12} is the transition

[349] Born in Simbirsk, Russia, the son of Ilya Nikolaevich Ulyanov (1831–1886, a Russian civil service official) and Maria Alexandrovna Blank (1835–1916). Her father was **Srul Moishevich Blank**, born to a Jewish family in Zhitomir and baptized as Alexander Dimitrievich Blank. Vladimir Ulyanov, renamed himself *Lenin* after the River Lena. He was 1/4 Jewish, 1/4 German, 1/4 Mongol and 1/4 Russian.

[350] Jews played a major part in the Bolshevik Revolution. Among them: **Leon Trotsky** (Bronstein) 1879–1940; **Lazar M. Kaganovich**, 1893–1991; **Grigory Zinoviev** (Apfelbaum), 1883–1936; **Maxim Litvinov** (Wallach), 1876–1951; **Lev Kamenev** (Rosenfeld), 1883–1936; **Nikolai Yezhov**, 1895–1939; **Alexei Rykov**, 1881–1938; **Genrikh Yagoda**, 1891–1938; **Yakov Sverdlov** (Solomon), 1885–1919; **Mikhail I. Kalinin**, 1875–1946; **Yuri Andropov**. Also, **Stalin**, **Molotov**, **Kruschev**, **Voroshilov** and **Brezhnev** — were married to Jewish women.

probability per unit time, unit intensity of the radiation, and per single lower-level atom.

But the radiation, because of its interaction with excited atoms at level E_2, also produces emission transitions from E_2 to E_1 with an induced emission transition probability per unit time and per atom $B_{21}\epsilon(\nu)$. Therefore the total emission probability per atom per unit time from level E_2 to level E_1 is $A_{21} + B_{21}\epsilon(\nu)$. If there are N_2 atoms in level E_2, the mean number of atoms that jump per unit time from E_2 to E_1 is $[A_{21} + B_{21}\epsilon(\nu)]\, N_2$. At the same time, the mean number of atoms that jump from E_1 to E_2 per unit time is $B_{12}\epsilon(\nu)N_1$. If N_1, N_2 are large enough, the statistical uncertainties in these rates are small as fractions of the rates themselves, and the *actual* jump (transition) rates may be taken to equal the respective *mean* rates.

Therefore the net change per unit time of the atom population in level E_2 is equal to the rate of gain by absorption minus the rate of loss by emission, or

$$\frac{dN_2}{dt} = \underbrace{B_{12}\epsilon(\nu)N_1}_{\text{Absorption}} - \underbrace{[A_{21} + B_{21}\epsilon(\nu)]N_2}_{\text{Emission}}$$

with an equal (but opposite) gain for the lower level.

When equilibrium is established between the atoms and the radiation (which will eventually occur at fixed thermodynamic conditions), we must have $-dN/dt = dN_2/dt = 0$, or $B_{12}\epsilon(\nu)N_1 = [A_{21} + B_{21}\epsilon(\nu)]\, N_2$, so that the numbers of absorption and emission transitions per unit time (that is, the transition rates, in the $1 \to 2$ and in the $2 \to 1$ directions) are the same.

If the atoms are in thermal equilibrium and follow Maxwell-Boltzmann statistics (which is a reasonable approximation in most cases), then

$$N_1/N_2 = e^{(E_2-E_1)kT} = e^{h\nu/kT},$$

so that

$$B_{12}\epsilon(\nu)e^{h\nu/kT} = A_{21} + B_{21}\epsilon(\nu)$$

or

$$\epsilon(\nu) = \frac{A_{21}/B_{12}}{e^{h\nu/kT} - B_{21}/B_{12}}.$$

When we compare this spectrum with Planck's formula

$$\epsilon(\nu) = \frac{8\pi h\nu^3}{c^3}\frac{1}{e^{h\nu/kT} - 1},$$

which gives the energy density for electromagnetic radiation in equilibrium with matter, we find that

$$\frac{A_{21}}{B_{12}} = \frac{8\pi h\nu^3}{c^3} \qquad \textit{and} \qquad \frac{B_{21}}{B_{12}} = 1,$$

a result first obtained by Einstein in 1917. The second relation shows that the induced emission and absorption probabilities per unit time are equal and actually follows merely from time-reversal symmetry plus the wave aspect of light. The above calculation does not allow us to obtain the absolute values of A_{21}, B_{21}, and B_{12}; they must be derived using quantum-mechanical considerations. With $B_{12} = B_{21}$, we obtain the ratio between the spontaneous emission probability rate A_{21} and the induced emission probability rate $B_{21}\epsilon(\nu)$ when matter is in equilibrium with radiation as

$$\frac{\text{Spontaneous emission probability}}{\text{Induced emission probability}} = \frac{A_{21}}{B_{21}\epsilon(\nu)} = e^{h\nu/kT} - 1.$$

Therefore, if $h\nu \gg kT$, spontaneous emission is much more probable than induced emission, which can then be completely neglected. This usually holds true in the case of electronic transition in atoms and molecules and in the case of radiative transitions in nuclei unless a far-from-equilibrium regime is set up (e.g. by *inverting* the normal level populations, as done by *pumping* in lasers and masers). But if $h\nu \ll kT$, as in the microwave region of the spectrum at room temperature, induced or stimulated emission becomes important.

In the same year[351], Einstein found a coordinate-invariant generalization of the *Bohr-Sommerfeld semiclassical quantization conditions* for a system with l degrees of freedom.

Bohr obtained the semiclassically–stable orbits of an electron revolving around the nucleus, for the case of circular orbits, by assuming that the total *orbital angular momentum* of these orbits must be quantized, i.e. be an integer times $\hbar = \frac{h}{2\pi}$. But it was soon realized that more generally, the quantity which should be quantized is the (classical) *action* — i.e. $\oint p\,dq = nh$ where p is the relevant canonical momentum and q the conjugate coordinate, integrated over a cycle (period) of the motion. This was an acceptable answer for *circular* orbits, which could be characterized by a single parameter, namely the radius of the orbit. But we can equally well have elliptical orbits, which had to be characterized by two parameters (apart from the space orientation of the orbit).

Generally, the question arose as to how to quantize systems of arbitrary numbers of degrees of freedom. Sommerfeld gave a partial answer for the case

---

351 'Zum Quantensatz von Sommerfeld und Epstein'. *Verh. Deutsch. Phys. Ges. 19*, 82, 1917. A little known remark of Einstein, made in a lecture at a meeting of the German Physical Society and only published in its proceedings. He never returned to this subject nor, for a long time, did others show much interest in it. However, since 1980, the importance and pioneering character of this work has been recognized by mathematicians, quantum physicists and quantum chemists.

of '*separable systems*'. This is the case in which the classical Hamiltonian function could be written as a sum of functions, each one involving only a pair of conjugate variables:

$$H = H_1(p_1, q_1) + H_2(p_2, q_2) + \cdots + H_k(p_k, q_k).$$

In this case we could write down the necessary and sufficient quantization conditions as $\oint p_i \, dq_i = n_i h, \quad i = 1, 2, \ldots k$. Thus, the conditions, if at all realizable, depend on the choice of a particular coordinate system. Moreover, such a procedure was not *unique* since if a system was separable in different coordinate system (e.g., an isotropic 3-D harmonic oscillator is separable in both Cartesian *and* polar coordinates), inequivalent quantization rules might be obtained.

Einstein could not believe that the particular coordinate system, in which the Hamiltonian function was accidentally separable, should have a decisive significance for the physical phenomenon. He found a *coordinate-invariant generalization* of these quantization conditions which, moreover, did not require the motion to be separable, but only *multiply periodic*; he formed the *sum* of all the equations $\oint p_i \, dq_i = n_i h$, obtaining $\oint \sum_{i=1}^{k} p_i \, dq_i = nh$, where n is a new integer. Since $p_i = \frac{\partial S}{\partial q_i}$ with S the Hamilton-Jacobi *action*, we obtain

$$\oint \sum_{i=1}^{k} p_i \, dq_i = \oint \sum_{i=1}^{k} \frac{\partial S}{\partial q_i} \, dq_i = \oint dS = \Delta S = nh,$$

where the integral is taken over *any* possible closed path in configuration space. The '*action*' function S has absolute meaning. If S were a single-valued function, then, traversing a periodic orbit in configuration space and returning to the initial point, ΔS would be zero. But S is, in fact, a *multivalued function.*

While classically it is in principle possible to proceed along *any* closed circuit, in quantum theory only those circuits in configuration space have physical significance for which the change of S in this process is equal to a multiple of h. If we now choose a path for which all coordinates remain constants except p_1 and q_1, then we obtain the first quantum condition, and so on. Thus, Einstein's single condition is equivalent, in (any) separable classical phase–space coordinates, to the entire set of the Bohr-Sommerfeld quantum conditions[352].

352 Einstein, of course, was not aware at the time of wave mechanics and the Schrödinger Equation (1924), and therefore missed the connection between the Bohr-Sommerfeld semiclassical theory and the exact (fully quantum-

The General Theory of Relativity[353]

During 1915–1917 **Albert Einstein** *presented the general theory of relativity (*GTR*), on which he had been working since 1907. It is an extension of his special theory to include gravitational effects*[354].

In addition to electromagnetic fields, there exist in nature long-range fields of another type — so-called gravitational fields, or fields of gravity. These fields have the basic property that all (small and light enough) test bodies move in them in the same manner, independent of mass, composition or charge, provided the initial conditions are the same. For example, the laws

---

mechanical) picture, yielding (in the WKBJ or semiclassical approximation) $\oint dS = (n + k/2)h$. Interestingly enough, *Einstein's remark* became relevant in recent years to *classical chaos theory* in the following way: In a holonomic *integrable* mechanical system the number of conservation laws is equal to the number of degrees of freedom of the system. Here, the trajectory can be written analytically and no chaos is possible. A necessary condition for the existence of chaos is that the number of conservation laws is less than the number of degrees of freedom. But each quantum number corresponds to a certain conservation law. Hence the connection between integrability, conservation, chaos and quantization conditions.

[354] If we regard his STR paper (1905) as the unification of the concepts of *space* and *time*, and his $E = mc^2$ paper (1905) as the unification of the concepts of *energy* and *matter*, then GTR (1915) is the unification of the above four concepts with gravitation and with the Newtonian concept of *inertial frames.* GTR is the greatest discovery in connection with gravitation that has been made since Newton first enunciated his universal law of gravitation.

of free fall in the gravity field of the earth (in vacuo) are the same for all bodies; whatever their mass, all acquire one and the same acceleration under identical initial conditions.

The theory of gravitational fields, constructed on the basis of this principle and the local applicability of the theory of Special Relativity, is called the general theory of special relativity *(GTR). It was established by Albert Einstein and finally formulated by him in 1916. It represents the most pristinely beautiful of all existing theories in the natural sciences. It was developed by him in a purely deductive manner from a small set of axioms and assumptions, and only later was substantiated by astronomical observations.*

GTR is the culmination of theories of time and space in modern times; like STR before it, it is also a framework *into which non-gravitational forces and fields may be accommodated. Three roads led to this summit:*

- *the* physics *trail with the beacons of* ***Galilei*** *(1609),* ***Newton*** *(1687) and* ***Maxwell*** *(1873).*
- *The* mathematics *trail of* ***Gauss*** *(1827),* ***Riemann*** *(1854) and* ***Ricci*** *(1887).*
- *The* Philosophy *trail of* ***Spinoza*** *(1676) and* ***Mach*** *(1872).*

Einstein's theories of relativity (special and general) represented – and precipitated further – major revolutions in physics and astronomy during the 20th century. They introduced to science the modified concept of 'relativity', thus superseding the 200 year old Newtonian mechanics. Einstein showed that we reside not in a flat Euclidean space and uniform absolute time of everyday experience, but in another environment: curved, locally Minkowski space-time. The theory of STR played a role in advances in physics that led to the nuclear era, *with its potential for benefit as well as for destruction. Its unification with* quantum *mechanics led to QED and other* quantum field theories, *predicted* antimatter, *and made possible an understanding of the microworld of* elementary particles and fields *and their interactions. The differential geometry of GTR inspired quantum field theories based upon the* Gauge Principle, *and GTR itself has also revolutionized our view of* cosmology *with its predictions (alone and in conjunction with nuclear and particle physics) of apparently bizarre astronomical phenomena such as the* big bang, neutron stars, *cosmological constant (dark energy), (primordial and eternal) inflation,* black holes[355], *gravitational lensing and gravitational waves.*

[355] Albert Einstein's general theory of relativity and the discoveries by himself and others in quantum theory are the foundation for all speculations about the

Einstein was not satisfied with STR *because it arbitrarily selected a certain class of reference frames, namely, inertial frames, among which the laws of physics are invariant. He believed that physical laws should not depend at all upon the choice of reference frame. He was also strongly influenced by Mach's criticism of the foundations of mechanics, and the resulting Mach Principle according to which inertial forces have their origin in the total distribution of mass in the universe. For example, Newton had argued that the centripetal force of a rotating mass was a demonstration of its absolute motion. Mach, however, ascribed that (and other inertial) force to motion w.r.t. other masses in the universe, especially those of the fixed stars.*

Einstein knew that it is possible to make gravity disappear in certain localized *regions in space and time by a nonlinear transformation of the reference frame. For example, freely falling sky divers (with acceleration = g) do not initially observe the force of gravity in their* moving *reference frame. Similarly, observers in an orbiting space shuttle are weightless, as the shuttle is free-falling and has a constant acceleration directed towards the earth and shared by its passengers. These results are consequences of the equivalence of gravitational mass and inertial mass, but there is no single accelerated frame of reference that can cause gravity to disappear* at all points of space-time.

Thus Einstein asked himself, "Is it possible to find a geometry of spacetime that accounts for all the gravitational effects of the masses in the universe, and yet in a small enough region of spacetime reduces to an ordinary accelerated, instantaneously inertial, STR frame of reference?"

Part of the mathematical answer to this question was already at hand, in the generalized geometry of curved spaces devised by Riemann in 1854. For example, the surface of a sphere is a 2-dimensional curved space embedded in an Euclidean space of 3 dimensions. A very small area of the surface has essentially the properties of a flat Euclidean space. Einstein required a 4-dimensional curved space-time. Such a space-time can be embedded in a 10-dimensional Euclidean space, but it is much easier to deal with the intrinsic curvature of 4 dimensions and to discard Euclidean (or even Minkowskian) geometry altogether.

Einstein used tensor calculus in the mathematical *formulation of* GTR, *since both are concerned with the behavior of various entities under the transition from a given coordinate system to another. In his own words (1915):*

---

physics of black holes. Yet Einstein rejected the idea of such bizarre singularities and repeatedly argued against their existence. In the late 20^{th} century numerous galactic – center and stellar black hole candidates have been identified by astronomers, but the close observation (let alone manipulation or creation) of black holes with empirical verification of their more exotic properties – remain a distant dream.

"Sie (the gravitational equations) bedeutet einem wahren triumph der durch Gauss, Riemann, Christoffel, Ricci, ..., begründeten methoden des allgemeinen differentialkalkulus".

Through this theory, tensor analysis came into vogue. The combined efforts of ***Grassmann****,* ***Riemann****,* ***Christoffel****,* ***Ricci****,* ***Minkowski*** *and others were blended here in harmony to form the most beautiful physical theory yet concocted by the human mind. It gave a great impetus to tensor theory and opened wide new areas in theoretical physics and applied mathematics.*

After 1916, with the advent of general relativity, the several special brands of vector analysis were supplanted by tensor algebra and analysis. Riemann and ***Clifford****, in the intermediate stage leading from Grassmann to tensors, had presciently predicted the 20th century* geometrization of some parts of mathematical physics.

This remarkable prophecy was indeed realized in Einstein's theory of gravitation and its developments since 1916, as well as in the 'non-Abelian' generalizations of electrodynamics (Yang-Mills field theories) partially inspired by it. Furthermore, in the 1920's, the general theory of relativity stimulated development of differential geometry.

Underlying principles

Newton's law of gravitation, which requires instantaneous *action at a distance is* not compatible *with STR (= Special Theory of Relativity) since the latter requires that the velocity of signal propagation be* finite *and that the gravitational laws be* Lorentz-covariant. *During 1912–1918 various physicists*[356] *attempted to formulate gravitation within the framework of STR. But all these theories employ fields that inhabit the same Minkowski space-time as does the Maxwell field, and as such suffer from two fatal flaws — no* gravitational redshift *and no* light deflection. *They are thus untenable by our current experimental knowledge.*

Einstein based his theory upon four basic principles:

- *The principle of* equivalence

356 **Max Abrahem** (1912); **G. Nordström** (1918) and others. In these attempts gravitation was formulated as carried by a scalar, vector or even a tensor field, inhabiting the same Minkowski space-time as does the Maxwell field.

- *The principle of general covariance (alternate form of Equivalence Principle)*
- *The principle of correspondence*
- *The principle of minimal gravitational coupling*

In Newtonian theory, a system in a homogeneous gravitational field is completely equivalent to a uniformly accelerated reference frame from a mechanical point of view [famous 'elevator in free fall thought – experiment']. Einstein then postulated that this equivalence be extended to all physical processes embedded in a locally homogeneous gravitational fields. This is the restricted form of the principle of equivalence.

Combining this postulate with STR, Einstein derived the result that the rate of clocks at points of lower gravitational potential is slower than that for higher gravitational potential, and already then he pointed out that this entails a shift toward the red spectra of light emitted by the sun, compared with that emitted by terrestrial sources. A further result was that the velocity of light is not constant[357] *in a gravitational field, so that light rays curve (Fermat's principle). He also argued that on the strength of the equivalence principle and STR, energy E must be ascribed not only an inertial mass but also a gravitational mass* $m = E/c^2$.

The next step was to generalize the principle of equivalence to apply to inhomogeneous gravitational fields. This, he claimed, can be done in an infinitesimally small region of space-time. Here gravitation can be transformed

---

[357] In GTR the principles of STR hold in any instantaneous, local, inertial Lorentz frame. In particular, this implies the *local* constancy of the speed of light. However, when one describes the geodetic world line of light ray or massive particle, *any* curvilinear coordinate system used, cannot be a Lorentz frame, because it extends over a *finite* volume of spacetime.

Therefore, any experiment in GTR that involves finite lengths and time–intervals will, in general, violate the postulates of STR. This was demonstrated quite clearly in the sun – grazing radar – ranging experiment by **I. Shapiro** (1970s), in which radar beams were found to slow down in the vicinity of the sun relative to a reference frame defined by earth and Mars, as predicted by GTR.

The converse effect may also occur: in a de Sitter universe, any two particles of matter recede from each other exponentially fast, and thus transluminally, as reckoned by an extended reference system. The now-accepted inflationary version of Big–Bang cosmology states that such a de Sitter phase indeed occurred in the very early universe and satellite observations in the 1970s showed that we may be entering a new de Sitter phase.

away in a local coordinate system realized by a freely falling, sufficiently small cabin, which is not subjected to any external forces apart from gravity. The formulation of the equivalence principle in this case is:

"For every infinitely small world region, in which spatial and temporal variations of gravity can be neglected, there always exists a coordinate system in which gravitation has no influence either on the motion of particles or any other physical processes".

*This 'transforming away' is only possible because the gravitational field has the fundamental property that it imparts the same acceleration to all bodies, or stated differently, because the gravitational mass is always equal to the inertial mass (**Newton**, **Eötvös**). This is sometimes called the 'weak equivalence principle' when the falling mass (or cabin) has a low enough mass for self-gravity to be negligible.*

These two different statements are equivalent: When gravitation acts on a body, it acts on the "gravitational mass", but the result of the Newtonian gravity force is an acceleration determined by the body's inertial mass. Both statements imply at once that the path followed by a test particle in space and time under purely gravitational forces is independent of the mass and composition of the test-particles. Moreover, the curvature of space-time is a direct consequence of the fact, evident in Newtonian gravity, that the equivalence principle breaks down over finite world-volumes for a non-uniform gravitational field ("tidal effects").

When Einstein proposed his equivalence principle in 1907, he was not aware of all the experiments that predated him, and arrived at it by noticing that inertial forces (centrifugal, Coriolis) share the same property as gravitational forces, in that they all are proportional to the masses they act upon, unlike electric or magnetic forces. This similarity makes it impossible to tell them apart in the small cabin postulated above.

The equality of inertial and gravitational mass for different materials is quite mysterious in Newton's work.

At this point, Mach's principle comes to mind as a feasible explanation of the identity of gravitational and inertial mass, via Mach's idea that the origin of inertia is gravitational. Indeed, in 1912 Einstein calculated the effect of a heavy spinning spherical shell on an enclosed particle. The calculations showed that the effect of the rotating massive shell is to change the inertial frame in the spatial vicinity of the particle, which now tends to rotate in the same sense as the shell. This calculation foreshadowed the 'Lense-Thirring effect' (1918).

With the aid of the equivalence principle, STR was reinstated as a tool for handling physical problems in the presence of gravity on a local basis. *An alternative statement for the principle of equivalence is:*

"The laws of special relativity hold locally in a space-time, in a sufficiently small, freely falling frame of reference".

Clearly, the Principle of Equivalence is strictly valid only in the presence of a static homogeneous gravitational field. Had the gravitational field depended on $\boldsymbol{r}$ *or* t*, we would not have been able to eliminate it from the equation of motion by the acceleration. For example, the earth is in free fall about the sun, and for the most part we on earth do not feel the sun's gravitational field, but the* slight inhomogeneity *in this field (about 1 part in 6000 from noon to midnight) is enough to raise impressive tides in our ocean. Even the observers in Einstein's freely falling cabin would, in principle, be able to detect the earth's field because objects in the cabin would be falling radially toward the center of the earth, and hence would approach each other laterally as the elevator descended.*

Nevertheless, it is sufficient for the construction of GTR *(General theory of Relativity) to accept the* weak Principle of Equivalence *stating the* observed *equality of gravitational and inertial mass for systems of small enough mass.*

Equivalently, the Principle of Equivalence says that at any point in space-time we may erect a locally inertial coordinate system in which matter and energy satisfy the laws of special relativity.

In this form, there exists a certain resemblance to the Gauss assumption that at any point on a curved surface we may erect a locally Cartesian coordinate system in which distances obey the laws of Euclid Pythagoras. Because of this analogy, we should expect the laws of gravitation to bear strong resemblance to the formulas of Riemannian geometry.

In particular, Gauss' assumption implies that all intrinsic geometric properties of a curved surface *can be described in terms of the quantities* g_{ij} *(metric tensor) in some "atlas" of overlapping, mutually-transformable, local coordinate systems.*

In light of this analogy, the principle of equivalence can be reformulated as the principle that gravitation is just an effect of the curvature of Minkowskian spacetime *— a principle from which Einstein's theory of gravitation follows almost uniquely.*

An alternative version of the Principle of Equivalence is known as the Principle of General Covariance. *It states that a physical equation holds in a general gravitational field if two conditions are met:*

(1) The equation holds in the absence of gravitation, i.e. it agrees with the laws of special relativity when the metric tensor $g_{\alpha\beta}$ equals the Minkowski tensor $\eta_{\alpha\beta}$ (i.e. $diag\{-1,1,1,1\}$ in the real–0^{th}–component representation) and when the affine connection $\Gamma^{\alpha}_{\beta\gamma}$ vanishes.

(2) The equation is generally covariant; i.e., it preserves its form under a general local coordinate transformation.

It should be stressed that part (2) of general covariance by itself is devoid of physical content. Any law of nature can be made *generally covariant by writing it in any one coordinate system, and then working out what it looks like in other arbitrary coordinate systems. Indeed, physicists have long been familiar with the appearance of physical equations in non-Cartesian systems, such as polar coordinates, and in noninertial systems, such as rotating coordinates. The significance of the Principle of General Covariance lies in its statement about the effects of gravitation: that a physical equation, by virtue of its general covariance, will hold in a gravitational field if its flat–Minkowski–space limit represent the correct dynamics in the absence of gravitation and if, in the latter case, it is Lorentz* covariant *and obeys the principles of Special Relativity.*

The meaning of general covariance can be elucidated by comparing it with Lorentz invariance/covariance. Just as any equation can be made generally covariant, so any equation can be made Lorentz-covariant, by writing it in one inertial coordinate system and then working out what it looks like after a Lorentz transformation.

However, if we do this with a nonrelativistic equation like Newton's second law, we find after making it Lorentz-covariant that a new quantity has entered the equation, which of course is the velocity of the coordinate frame with respect to the original, privileged reference frame. The requirement that this velocity not appear in the transformed equation is what we call the Principle of Special Relativity, or "Lorentz invariance" for short, and this requirement places very powerful restrictions on the original equation. Thus part (1) *of the General Covariance Principle is what bestows content upon it.*

Similarly, when we make an equation generally covariant, new entities will enter — that is, the metric tensor $g_{\mu\nu}$, the affine connection $\Gamma^{\lambda}_{\mu\nu}$, the Riemann curvature tensor, and its covariant derivatives. The difference is that we do not require that these quantities drop out at the end, and hence we do not obtain any new restrictions on the equation we start with; rather, we exploit the presence of $g_{\mu\nu}$ and $\Gamma^{\lambda}_{\mu\nu}$ to represent gravitational fields.

To put this succinctly: The Principle of General Covariance is not *an invariance principle, like the Principle of Galilean or Einsteinian (Special) Relativity. Taken together with part (1), however, it becomes a statement* *about the effects of gravitation and its local (approximate) equivalent to acceleration relative to STR inertial frames. In particular, part (2) of general covariance does not imply Lorentz invariance — there are generally covariant theories of gravitation that allow the construction of inertial frames at any point in a gravitational field, but that satisfy Galilean relativity rather than special relativity in these frames.*

Any physical principle, such as general covariance, which takes the form of a local covariance principle but whose content actually involves the introduction of a new class of interactions into otherwise known dynamics, is called a dynamical local symmetry*. There are other dynamic symmetries of importance in physics, such as the GTR-inspired* local gauge invariance*, which governs the interactions of the electromagnetic field and all nuclear and subnuclear forces save gravitation.*

The Principle of General Covariance can only be applied on a scale that is small compared with the space-time distances typical of the gravitational field, for it is only on this small scale that we are assured by the Principle of Equivalence of being able to construct a coordinate system in which the effects of gravitation are absent. However trough the magic of differential geometry, this allows one to deduce gravitational effects at all *scales, provided a few other simple assumptions are made.*

There are in general many generally covariant systems of equations, that reduce to a given special-relativistic theory (e.g. the Maxwell–Lorentz equations) in the absence of gravitation. However, once two additional assumptions are made – namely, that Newton's theory of gravity is recovered for speeds $v \ll c$ *and weak fields, and that only* $g_{\mu\nu}$ *and its first and second order partial derivatives enter our generally covariant equations – we shall see that the Principle of General Covariance makes an almost unambiguous statement about the effects of gravitational fields on any physical system (planets, galaxies, fluids, or even the universe as a whole).*

Observers are intimately tied up with their reference systems or coordinate systems. One ramification of GTR is that any observer can discover the laws of physics, employing any coordinate system. The situation is somewhat different in special relativity, where, because the metric is flat and the connection integrable, there exists a set of canonical *or preferred coordinate systems; namely, Minkowski coordinates. In a curved space-time, that is, a manifold with a non-flat metric, there is in general no canonical coordinate system. This is just another statement of the non-existence of a global inertial frames.*

However, this statement needs to be treated with caution, because in many applications, there will be preferred coordinate systems. For example, many problems possess symmetries and the simplest thing to do is to adapt the coordinate system to the underlying symmetry.

Any new theory must be consistent with any acceptable earlier theories within their range of validity. GTR must therefore agree on the one hand with STR in the absence of gravitation and on the other hand with Newtonian gravitational theory in the limit of weak gravitational fields and low velocities (compared with the speed of light). This gives rise to a correspondence principle *for general relativity.*

The principles discussed so far almost suffice to obtain equations governing systems in general relativity when the corresponding equations are known in special relativity. The principle of minimal gravitational coupling *– which is somewhat stronger than the above restriction on the number of times the metric is differentiated – is a* simplicity principle *or Occam's razor that essentially states that we should not add unnecessary terms in making the transition from the special to the general theory.*

Consider, for example, the law of local conservation of energy-momentum in STR

$$\frac{\partial T^{\mu\nu}}{\partial x^{\mu}} = 0$$

The simplest generalization of this to GTR is the tensor equation

$$\nabla_{\mu} T^{\mu\nu} = 0$$

where ∇_{μ}, denotes covariant differentiation. However, we could equally well posit

$$\nabla_{\mu} T^{\mu\nu} + g^{\nu\lambda} R^{\mu}_{\alpha\mu\beta} \nabla_{\lambda} T^{\alpha\beta} = 0$$

since the Riemann curvature tensor $R^{\mu}_{\alpha\mu\beta}$ vanishes in STR.

Einstein, although not stating it explicitly, used this minimal-coupling principle in establishing the gravitational field equations.

The principle of minimal gravitational coupling can thus be stated: "no terms explicitly containing the curvature tensor should be un-necessarily introduced in making transition from STR to GTR, and no covariant derivatives of the curvature tensor shall be introduced at all".

This 'principle' is equivalent to the a priori assumption *that the equations of general relativity must be* second-order partial differential equations *in the metric tensor and in all non-gravitational dynamical fields and variables and that they are linear in second-order partial derivatives of $g_{\mu\nu}$. In 1915 – and indeed to this day – the most important equations of non-gravitational fundamental theoretical physics were second-order PDE's obeying this restriction, including of course, the Maxwell equations themselves.*

Any terms in the curved–spacetime equation involving non-minimal gravitational couplings would not make much of a difference in any astronomical *observations. Einstein could have made his equations fourth-order differential equations, but he did not. In this sense Einstein's theory, as we view it today, is an approximation valid at long distances, and as such, cannot be expected to deal successfully with infinities and singularities — any more then the Navier–Strokes PDEs of fluid dynamics can be expected to account for the molecular motions at the center of a vortex flow.*

We note that arbitrary coordinate transformations obviously include a subset of transformations that take us locally from any non-inertial frame to an inertial frame. In the latter frames — locally freely–falling frames — gravitational forces on small enough objects are negligible; this is nothing but the equivalence principle. The abstract form of this statement is "general covariance" — if a generally covariant equation is known to be true in a locally inertial frame (in absence of gravitation, curvature or connection), it is true in every frame, i.e. the equation is true in the presence of gravitation.

This is not strictly true for finite laboratories. The precise statement is that gravitational forces are not detectable in the limit where:

(I) the freely–falling laboratory, containing the measuring apparata, is infinitesimally small;

(II) the total mass of the said laboratory is also infinitesimal.

Gravitational effects are *observed in a* non*-ideal 'locally inertial' frame, such as Einstein's famous freely-falling elevator. Such an elevator is not infinitesimal — it encompasses a sufficient volume of space-time to reveal tidal effects in any realistic (non-uniform) gravitational field.*

We must dwell on this important issue in some detail: Consider a non-spinning space capsule, whose center of mass moves in a free-falling orbit of instantaneous distance r from the earth of mass M (or other attracting center of mass). A test particle at the center of the capsule, will experience a zero-g environment: it is 'weightless', acted upon by no gravitational force as reckoned in the capsule frame.Thus, the astronaut does not know whether he is falling in a gravitational field or at rest in some region far away from any attracting masses. (Clearly, this elimination of the earth's gravitational field is only possible under the assumption of equivalence of inertial and gravitational mass for all bodies.

Now, to another observer, at rest relative to the (idealized) "fixed stars", the capsule is in accelerated motion, and such an observer will refute the astronaut's claim that he is in an inertial frame by saying that both the space capsule and the test particle in it are falling at the same rate and that the astronaut is being fooled by appearances.

Suppose, however, that the astronaut places a drop of liquid of radius R at the center of the capsule. He will find that this drop is not exactly spherical *but has two bulges; one bulge points toward the earth, one away. Since, in the absence of external forces, surface tension would make the drop spherical, the deviation from a sphere indicates the existence of a gravitational field. The bulges result from the* inhomogeneity *of the gravitational field; the capsule as a whole is accelerated toward the mass M by an amount $a_G = \frac{GM}{r^2}$, the end of the drop nearer to the earth is subjected to a slightly larger acceleration $a_{\text{near}} = \frac{GM}{(r-R)^2}$, while the far end experiences the slightly smaller acceleration $a_{\text{far}} = \frac{GM}{(r+R)^2}$.*

Accordingly, the relative acceleration of the two ends will cause them to drift away from each other and the center. *Assuming $R \ll r$, each will drift with a* tidal acceleration $a_{\text{tidal}} = \frac{1}{2}(a_{\text{near}} - a_{\text{far}}) \approx 2\frac{GMR}{r^3} = a_G \frac{2R}{r}$. *Similarly the tidal effect on two diametrically opposite points on the drop's surface which lie on the plane* perpendicular *to the first pair, is shown to be $a_G \frac{R}{r}$, and these points will tend to drift* toward each other *at one-half the former ('longitudinal') rate.*

Thus, the drop experiences a deformation due to a quadrupole *force-field such that it is stretched at its 'poles' and compressed at its 'equator'. Next, imagine the drop is a planetesimal, devoid of surface tension but held together by its self-gravity. Denote by g the acceleration of gravity that the drop produces at its own surface, and by Δh the differential tidal deformation (difference between 'high-tide' and 'low-tide'). The equilibrium equation $g\Delta h = \frac{GMR^2}{r^3}[2 - (-1)] = \frac{3GMR^2}{r^3}$ in which $g = \frac{4\pi}{3}\rho GR$, then yields $\frac{\Delta h}{R} = \frac{9M}{4\pi\rho r^3}$. This shows that the* shape *of the tidal ellipsoid is independent of its size. Even in the limit $R \to 0$, the tidal deformation persists. We can therefore regard the prolateness of the tidal ellipsoid as a* local *measure of the gravitational tidal force.*

This principle has been embedded in a sensitive instrument known as the gravity gradiometer *(***R.L. Forward***, 1971). The device consists of a Greek cross with four masses at the ends of its arms. The arms are held together at the center by a torsional spring; when the arms are pressed together and then released they oscillate with their own natural frequency. If the cross is placed in a tidal field, it will be deformed.*

The tidal force is then used to drive the cross at resonance*, where large amplitudes can be built up. Such an instrument, if made small enough, can be used to make* local *measurements of the tidal field, in an arbitrarily small neighborhood of a given point. The limitations on the minimum size of the neighborhood that is needed to perform measurements of a given precision do* *not arise from any intrinsic properties of the gravitational field; rather, these limitations arise from the* quantum nature *of matter.*

To summarize, local *experiments can distinguish between a reference frame in free fall in a gravitational field and a truly inertial reference frame placed far away from all gravitational fields. Gravitational effects are* not truly equivalent *to the effects arising from the observer's acceleration. Thus, the equivalence of gravitation and acceleration is only true in a limited sense: they are equivalent only as far as the translational motion of infinitesimal-mass point particles is concerned.*

If the rotational degrees of freedom of the motion of masses are taken into account, then the equivalence fails in yet other ways. However, the unambiguous equality $m_I = m_G$ *is necessary and, to a large extent, sufficient for the construction of* GTR. *And this becomes a* physical principle *when one posits that all physical laws (including gravitational dynamics itself) are expressible via generally – covariant equations, and that* STR *holds in local free–falling frames for any non–gravitational experiment. This reformulation is very important because it is strictly valid in general relativity; whereas the equivalence principle itself, which inspired it, is not even strictly true in Newtonian mechanics — as the above example demonstrates.*

On the other hand, one way ask whether residual gravitational effects within a small enough frame – such as the tidal effects in the liquid drop discussed above, or a Cavendish–type experiment to measure G – can reveal the difference between a free–falling frame and an inertial frame far from any external masses. If so, we say that the strong *equivalence principle (*SEP*) hold; and it has indeed been shown to hold in* GTR.

The principle of general covariance gives us a precise[358] *prescription through which we can introduce gravitational forces into a physical situation, if we know the equations describing the system in the absence of gravitation. For the latter equations, one takes the laws of special-relativistic physics. To modify these non–gravitational dynamical equations in the presence of gravitation, one takes the corresponding Lorentz–covariant equations and renders them generally covariant. As for gravitation itself, one chooses the minimally–complicated generally covariant extension of Newtonian gravitation, in which Newton's gravitational potential becomes an element in the metric tensor.*

[358] Though not unique: one may add to the covariantized physical equations any number of arbitrary–coefficient, covariant terms involving the Riemann curvature tensor or its covariant derivatives, since such terms vanish in the absence of gravitation. Such terms can, however, be estimated and bounded, and their effects are negligible in all post-Newtonian observational and experimental tests of GTR carried out to date.

The mathematical tool through which the principle of general covariance can be easily implemented and verified is that of general tensor calculus.

In Newtonian mechanics, the trajectory of a free particle is a straight spatial (Euclidean) line, traversed with constant velocity. In STR *it is a straight line in the Minkowski spacetime. In* GTR*, the world line of an infinitesimal inertial (freely falling) observer is a time-like curve with extremal proper time — the* geodesic *curve, or locally* straightest world line*. Along this line the* proper time *of the particle (the register of a clock attached to it) is extremal.*

The geometrical interpretation of the gravitational field is that a gravitating body actually distorts the very fabric of space-time around it. A small test-body entering the vicinity of another, finite mass merely responds to the distortion of space-time that it encounters. This distortion is the geometrical curvature of space-time.

In GTR *the earth, for example, does not rotate around the sun because of the sun's gravity. Instead, the earth is moving in a locally-straight line, but in a space-time curved by the mass of the sun.*

The Field Equations

The other crucial ingredient of Einstein's GTR*, apart from general covariance, is the prescription that determined exactly* how *a given matter distribution distorts space-time. The prescription consists of the* Einstein gravitational field equations[359] *— consisting, in any local spacetime coordinate system, of 10 nonlinear, second order, partial differential equations, for the ten components of the metric tensor.*

The field equations determine the Ricci tensor *of space-time (contracted Riemann curvature tensor) in terms of the energy-momentum tensor, and require local energy-momentum conservation (in local freely falling frames) for consistency. If one extends the equivalence principle to also mean that* gravitational *experiments in the small, freely-falling cabin yield the same results as Newtonian theory (for slowly-moving, sufficiently small masses), it is in fact possible to derive the* minimal GTR *field equations from this emended equivalence principle.*

[359] According to Einstein: "*Fields* are not states of a medium (the ether) and are not bound down to any bearer, but they are independent realities which are not reducible to anything else".

Let us take a brief look at the mathematics underlying space-time-gravitation. In a non-Euclidean but locally Euclidean (Riemannian) space in two dimensions, in any local coordinate system (x_1, x_2), *an infinitesimal vector is drawn from a point* P *to a point* Q. *The square of the distance between* P *and* Q *is a quadratic form in* dx_1 *and* dx_2, $ds^2 = g_{11}dx_1^2 + 2g_{12}dx_1dx_2 + g_{22}dx_2^2$. *For a space of any dimension, the corresponding expression is* $ds^2 = g_{ij}dx_idx_j$, *where* g_{ij} *is the metric tensor and the Einstein summation convention is understood. The* g_{ij} *are functions of* x_k *— they may vary from point to point in spacetime. The metric tensor provides a distance definition between neighboring points in space. Thus Riemannian geometry is a metric geometry.*

In GTR, *the curvature of space-time is quantified by the curvature tensor*[360] *(sometimes known as the Riemann-Christoffel tensor), which is de-*

---

[360] The anti-symmetric part of the *affine connection* $\Gamma^{\nu}_{\beta\mu}$, namely $T^{\nu}_{\beta\mu} = \Gamma^{\nu}_{\beta\mu} - \Gamma^{\nu}_{\mu\beta}$ is the *torsion tensor*. It is – aside from the curvature tensor and their contractions, covariant derivatives and combinations thereof – the tensor that can be formed from the affine connection. $\Gamma^{\alpha}_{\beta\gamma}$ is *not* a tensor. If the torsion tensor vanishes, then the connection is *symmetric*. Einstein formulated his theory of gravitation in terms of the symmetric (Schwartz–Christoffel) connection derived from the spacetime metric tensor, partly because the spin of the electron was as yet unknown in 1915.

In the simplest extension of GTR to include torsion, it couples to intrinsic spin, but has no direct effect on cosmology/astrophysics because torsion vanishes outside stars and planets. That leaves open the possibility of some torsion effects *inside* stars or in the *early universe*. Although torsion appears to play no significant role in the *macroscopic* realm, it features prominently in *supergravity* models of quantum fields. In these models, when one looks at the *Planck scale* of distances, times and energies, conventional GTR is modified. One feature of *supergravity field theories*, is that any spinning particle creates a torsion in spacetime in addition to curvature. So far (2008), supergravity theories were not shown to be valid.

The classical spin of a *Kerr black hole*, as well of a spinning planet or galaxy etc. does not count as far as torsion goes, because torsion is only excited by genuinely *intrinsic* spin, whereas the former examples are all manifestations of *orbital* spin.

As far as observational signatures in the real world go, torsion turns out to be a disappointment — the deviations it causes from GTR are miniscule, and are only significant in extreme conditions, such as the *Planck or GUT eras* right after the Big Bang.

fined by

$$R^{\alpha}_{\beta\mu\nu} = \Gamma^{\alpha}_{\beta\nu,\mu} - \Gamma^{\alpha}_{\beta\mu,\nu} + \Gamma^{\alpha}_{\sigma\mu}\Gamma^{\sigma}_{\beta\nu} - \Gamma^{\alpha}_{\sigma\nu}\Gamma^{\sigma}_{\beta\mu},$$

where the spacetime manifold is now locally Minkowskian, and Greek indices (covariant and contravariant) range from 0 through 3. Covariant and contravariant Greek "world" indices are converted into one another via contractions with the metric tensor, and $g^{\alpha\beta}$ *is the inverse* 4×4 *matrix to* $g_{\alpha\beta}$*. The* Γ*'s, called Christoffel symbols, are related to partial derivatives of the components of the metric tensor:*

$$\Gamma^{\nu}_{\beta\mu} = \frac{1}{2} g^{\alpha\nu} (g_{\alpha\beta,\mu} + g_{\alpha\mu,\beta} - g_{\beta\mu,\alpha}),$$

where $g_{\alpha\beta,\mu} \equiv \frac{\partial g_{\alpha\beta}}{\partial x^{\mu}}$.

The distribution and flux of mass-energy-momentum-stress *in the world is represented by the* energy-momentum tensor*,* $T_{\alpha\beta}$*, defined as the flux of* α *component of 4-momentum across a surface of constant* x_{β} *(since* x^0 *is the time coordinate, and* $T_{\alpha 0}$ *is a 4–momentum density. Yet by symmetry* $T_{\alpha 0} = T_{0\alpha}$ *so it is also a 4–current–density of energy. Thus, for free Maxwell fields in a locally free-falling frame* $T_{\mu\nu}$ *is the electromagnetic energy–momentum–stress tensor (cf. Minkowski and STR entries).*

Einstein was striving to relate the curvature of space-time to the distribution of $T_{\alpha\beta}$*. He found that the only two tensors related to space-time geometric structure that follow the (covariant) divergence-theorem (local conservation) of the energy-momentum tensor (and involve at most* 2^{nd}*-order spacetime derivatives of the metric — and is linear in those) are* $g_{\mu\nu}$ *and*

$$G_{\mu\nu} = R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu}.$$

Here $G_{\mu\nu}$ *is called the Einstein tensor,* $R_{\mu\nu}$ *is the Ricci tensor (a contraction of the curvature tensor), and* $R = g^{\mu\nu} R_{\mu\nu}$ *is the curvature scalar (covariant trace of* $R_{\mu\nu}$*). Thus, he set* $G_{\mu\nu}$ *proportional to* $T_{\mu\nu}$*;*

$$R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} \equiv G_{\mu\nu} = \kappa T_{\mu\nu}.$$

Due to a now–irrelevant cosmological prejudice against an expanding-universe solution, Einstein later added a term $\lambda g_{\mu\nu}$ *where* λ *was called* *the cosmological constant*[361]*, thus obtaining the final form of his field equations as*

$$R_{\mu\nu} - \frac{1}{2}Rg_{\mu\nu} + \lambda g_{\mu\nu} = \kappa T_{\mu\nu}$$

Requiring that this reduce to Newtonian gravity for slowly ($v \ll c$) *moving masses, sub-cosmological distances and low spacetime curvatures, it is found that* $\kappa = \frac{8\pi G}{c^4}$, *where* G *is Newton's gravitational constant.*

If the tensor $T_{\mu\nu}$ *is zero everywhere, that is, if there is no matter-energy in the universe, one solution of the field equations is the Minkowski "flat" space-time. Another relatively simple exact solution of the field equations concerns a spherical body in an empty space.*

If we consider the sun as a spherically symmetric, finite-radius mass–energy–momentum–stress distribution, and assume that space is empty around it, the field equations render the curvature of space-time in that space. The metric tensor around the sun is called the Schwarzschild metric (1916)

---

361 The cosmological constant of GTR physically represents the possibility that there is an energy density and pressure associated with "empty" space. The relative sign and magnitude of mass–energy density and pressure are dictated by the STR relativity principle, as applied to the vacuum in locally free-falling frames. The inclusion of this term (although first allowed by Einstein as a mathematical fix) can greatly affect cosmological theories. In its simplest form, GTR predicts that the universe must either expand or contract. Einstein thought the universe was *static*, so he added this new term to balance the self-gravitational collapse of a uniform dust (pressure-free) universe. **Friedmann** realized that this was an unstable solution and proposed an expanding universe model, now part of the *Big Bang* theory. When Hubble's survey of galaxies showed that the universe was expanding, Einstein regretted having modified his elegant theory and viewed the cosmological constant term as his "greatest mistake". The net effect of a *positive* cosmological constant is to create a *repulsive* gravitational force that acts to expand the universe (eventually at an exponential rate). Also, λ need not be an actual constant; it is now thought to have been evolving, as a function of local proper time. Modern field theory associates this term with the *energy density of the vacuum*. Modern observational cosmology has revealed that the cosmological constant today ("dark energy") comprises about 70% of the energy density of the universe, implying that the extrapolated *age* of the universe is larger then for $\lambda \equiv 0$. Adding an early-universe cosmological constant term during a very brief cosmological era (when the proper–time age of the universe was much less than a picosecond) is a hallmark of *inflationary models* (a class of extensions of the Big Bang theory); such models appear to be consistent with the observed large-scale distribution of galaxies, and with the observed microwave background fluctuations.

and corresponds to a line element which, in a particular *system of polar coordinates (one of many!) is*

$$ds^2 = c^2\left(1 - \frac{r_s}{r}\right)dt^2 - \frac{dr^2}{\left(1 - \frac{r_s}{r}\right)} - r^2(d\theta^2 + \sin^2\theta d\varphi^2)$$

where $r_s = \frac{2GM}{c^2}$ *is the Schwarzschild radius.*

We observe that if the total mass M *of the body which gives rise to the gravitational field is very small, relative to* $\frac{rc^2}{G}$ *at a given distance* r *from the body's center of symmetry, space-time geometry is approximated there by the Minkowski space-time. As a next step we omit terms of relative order* $\frac{1}{c^2}$ *assuming that* $\frac{2GM}{c^2} \ll r$, *and obtain*

$$ds^2 \approx \left(c^2 - \frac{2GM}{r}\right)dt^2 - dr^2 - r^2(d\theta^2 + \sin^2\theta d\varphi^2).$$

When working with this line-element to lowest order in $\frac{GM}{c^2 r}$ *this is the* Newtonian approximation, *because it reproduces the results of Newton's theory for the motion of the planets. That is, in this approximation the orbits of the planets are the ellipses given by Newton's law of gravitational attraction. However, gravitational red-shifts already appear, even at this level of approximation (although no gravitational bending of light).*

Einstein did not 'derive' his field equations from pre-existing principles, nor was he guided by a need to explain particular sets of experimental data or observations. He was guided only by his quest for two abstract ideals: beauty and simplicity. The equivalence of gravitational and inertial mass and the need to make all the equations independent of any particular choice of coordinates were basic requirements as well as the conditions that Newton's theory be recovered in the small-G, large-c regime; and that STR be locally recovered in the fixed $-c, \quad G \to 0$ *limit.*

The second and fourth of these four conditions are met automatically through the general covariance of GTR, and the fact that it predicts a vanishing Riemannian curvature at spacetime regions far from matter and energy. The first condition was met by requiring that the dynamic paths of bodies be geodesics *in a pseudo-Riemannian space-time whose curvature is determined by the distribution of mass-energy. And we have just seen how the* 3^{rd} *condition is verified (although this needs to be, and has been, generalized to any non-symmetric mass distribution).*

As an added Occamian bonus, Einstein and **Infeld** *have shown that the geodetic motion of test particles is a* consequence *of the field equations!*

As mentioned above, one may always add to the gravitational field equations (as to the covariant matter equations of motion) an infinity of non-minimal terms which cannot be determined by the principles discussed here.

The Einstein field equations in the presence of matter-energy are the simplest possible under the above postulates of GTR, *but they lack the stark beauty of the empty-space field equations, since the source term (proportional to the energy-momentum tensor) is non-geometrical. It is this esthetic and conceptual blemish that unified theories, from Kaluza-Klein to superstring models, have sought to redress.*

In 1919 Einstein suggested that perhaps electrically-charged particles are held together by gravitational forces, such that electromagnetism constrains gravitation. This idea may be considered Einstein's first attempt at a unified field theory[362]*. Since this idea implies that the energy momentum tensor* $T_{\mu\nu}$

[362] Einstein did not contribute much to the progress of physics after 1926: the last thirty years of his life were largely devoted to a search for a so-called *Unified Field Theory* that would unify Maxwell's theory of electromagnetism with GTR. Einstein's attempt was not successful, and with hindsight we can now see why this was so: *electromagnetism* and *gravitation* were the only forces that were known when Einstein was young, but we know today that there are other kinds of forces in nature, including the weak and strong *nuclear forces*. Indeed, the progress that has been made toward unification has been in unifying Maxwell's theory of the electromagnetic force with the theory of the weak nuclear force, not with the theory of gravitation, which is a much harder problem to solve.

A solution of the coupled Einstein–Maxwell (EM) equations representing a source possessing mass, electric charge, and an angular momentum was given by **E.T. Newman** (1965). The solution has a *ring singularity* on a circle lying in a plane normal to the direction of the angular momentum. **F.J. Ernst** (1968, 1974) showed that the coupled EM equations can be reduced to the solution of two coupled equations for a pair of complex potentials $\mathcal{E}$ and Φ

$$(\text{Re}\ \mathcal{E} + \Phi\Phi^*)\nabla^2\mathcal{E} = (\nabla\mathcal{E} + 2\Phi^*\nabla\Phi)\cdot\nabla\mathcal{E}$$

$$(\text{Re}\ \mathcal{E} + \Phi\Phi^*)\nabla^2\Phi = (\nabla\mathcal{E} + 2\Phi^*\nabla\Phi)\cdot\nabla\Phi$$

In 1925, Einstein missed the opportunity of predicting the positron (antielectron) before **P.A.M. Dirac**. In his paper entitled *Electron and General Relativity* he proved that for every elementary particle of mass m and charge e there must exist an "antiparticle" of the same mass m but with charge $-e$. If only Einstein had interpreted his theorem to mean that alongside the negative electron there must also exist an as yet undiscovered positively charged "antiparticle" of identical mass, he would have predicted antimatter! This was left to P.A.M. Dirac in 1928.

is due purely to electromagnetism, Maxwell–Minkowski energy-momentum-stress tensor is substituted for $T_{\mu\nu}$ in Einstein's field equations. The result is known as the Einstein-Maxwell equations. In 1927, Einstein wrote a further short note on the mathematical properties of this model, but never returned to it again. Others, however, have continued since then to seek solution to this hybrid theory.

Light rays follow curvilinear paths in space (and spacetime) when bent in the presence of gravitational fields, and their velocity may vary accordingly (although not as reckoned by a locally inertial frame!). Thus, GTR *extends the Faraday-Maxwell field concept as it does the Galilei-Newton principle of equivalence.*

The GTR *has much to say about the possible structure and history of the universe as a whole. In 1917, Einstein began to apply his theory to the large-scale features of the entire universe. At that time, this was a bold step, because it was not yet known whether there was anything but void outside our own Milky Way galaxy. Thus, the Andromeda galaxy (then called a nebula) was still believed to lie inside the Milky Way. Yet Einstein assumed that the universe could be idealized as a homogeneous distribution of matter. Eventually, this assumption was seen to be valid, at least to first approximation. For a variety of philosophical reasons, he chose a model for the universe having a 3D geometry that is spatially closed (in the sense of a spherical surface: finite but unbounded), and for which both 3-geometry and mean–energy distribution are static (unchanging with time).*

Since his theory did not admit static solutions, but only expanding or contracting universes, he felt compelled to modify the original field equations by adding an ad hoc term called the cosmological constant term[363]*. The modified*

Other ramifications of GTR are:

- Feynman derived the Einstein Field Equations without the use of curved massless space. He only assumed the equivalence principle and the existence of a spin-2 (dyadic) graviton field, minimally coupled.

- Using an idea of Einstein-Infeld (1932–1934), **A. Papapetru** generalized the relativistic point-mass into a small extended particle, obtaining a *relativistic version of McCullagh moments–expansion*. He achieved this via a multipolar expansion for the motion of a small mass in an external field. The first term is a geodesic and the *second term* in the *momentum expansion* is the first interesting one.

[363] Ad hoc yet *unique*: it is the only term that can be added to Einstein field equations without violating any of his assumptions and principles, although it does have an undetermined constant coefficient – the cosmological "constant", which is now knows to actually exist and to *not* be constant (it varies with the

equations did accommodate a static universe. The discovery of cosmological expansion by Hubble and his colleagues in the 20's seemed to obviate the need for this term, but its small observed value (discerned only in the 1990's) remains an enduring mystery for cosmologists and particle theorists to resolve.[364]

The non-linear field equations of GTR *can accommodate a variety of mathematical solutions, among which physicists must choose those that can be verified by observations. Cosmological solutions applying to the universe as a whole and based on the assumption that the large-scale structure of the universe is uniform (homogeneous and isotropic) are said to obey the 'cosmological principle'.*

Before relativity, Lorentz had conjectured (1900) that gravitation "can be attributed to action which does not propagate with a velocity larger than that of light". The term gravitational wave (onde gravifique) appeared for the first time in 1905, when Poincaré discussed the extension of Lorentz invariance to gravitation. In June 1916, Einstein became the first to cast these qualitative ideas into explicit forms, showing that gravitational waves are a direct consequence of the GTR *field equation. In standard Newtonian theory, gravitational interaction between two bodies in instantaneous, but according to* STR *this should be impossible, because no process can propagate with a velocity higher than c. Since* GTR *was designed to be compatible with* STR*, it must incorporate such a limiting velocity for gravitational interaction.*

It was not until the 1960's, with the revival of astronomical interest in GTR*, that physicists began to look for ways and means to detect gravitational waves.*

Einstein was greatly influenced by Spinoza, to whom he is bound ideologically and philosophically. In fact, Einstein completed the Copernican revolution and the work which Spinoza had started, namely: destroying the mechanistic, anthropocentric concepts of a dogmatic universe and adopting a holistic-deterministic view into which space (geometry), time and matter are integrated. Yet he said: "The most incomprehensible thing about the world is that it is comprehensible".

---

local, proper–time age of the universe). It is believed that when we know the full, correct quantum field theory (including gravitation) governing the evolution of our observable universe, it will be possible to predict the cosmological evolution of this term in Einsteins GTR field equations.

[364] Generic quantum field theories predict a value of λ so large as to explode any macroscopic sample of matter, and space itself, to emptiness within a small fraction of a second. The observed value of λ is extremely small in comparison.

He sided with Newton in the matter of causality: "It is only in the quantum theory that Newton's differential method becomes inadequate, and indeed strict causality fails us. But the last word has not yet been said".

Einstein was motivated by the quest for simplicity (Occam's Razor), beauty and unity and he was unique among scientists of the 20^{th} *century in the degree to which his work bears the mark of his individual identity.*

Asked how he would have felt had there been no experimental confirmation of his general theory of relativity, Albert Einstein remarked, "Then I would have felt sorry for the dear Lord — the theory is correct"[365,366].

---

365 Planck embraced STR and was the first to apply relativity to quantum theory. But when Einstein told him in 1913 what he was trying to accomplish in his GTR, he reacted: "*As an older friend I must advise you against it for in the first place you will not succeed, and even if you succeed, no one will believe you*".

366 Most physicists today agree that GTR must be modified in order to accommodate the consequences of Big-Bang theory, singularities due to gravitational collapse, (if true) quantum field theory and string theory:

- Big-Bang theory, combined with the singularity theorems of **Hawking** and **Penrose** (1973–1980), lead to the conclusion that unless GTR is modified, there existed (early enough in the history of the Universe) places and times at which physical quantities (density, pressure, temperature etc) *diverge* — an unacceptable attribute of any physical theory (such divergences are called "singularities"). This problem also arises in the GTR description of the formation of *Black Foles* in the gravitational collapse of heavy stars and galactic centers.

- Since, by the equivalence principle, all forms of matter couple to the metric tensor, the existence of any *quantum field* leads automatically to modifications of Einstein field equations caused by *quantum vacuum fluctuations*. It is well known that finite "*radiative corrections*" to GTR can eliminate singularities. However, no one has been able to tame the short–distance divergences in any quantum version of GTR, so we do not yet know how to compute such radiative corrections.

- The currently popular *String Theory* of *quantum gravity* modifies the *field* concept, by replacing point-particles with extended *strings*. This tends to smear any singularity over a finite region of spacetime, and there is mathematical evidence that this might render all physical quantities finite. However three decades of intense work by thousands of people has not yet unified these scenarios into a single, well–defined and predictive theory, and there is recent evidence that string theorists are despairing of ever achieving this goal, or of making contact with experiment.

Experimental Tests of General Relativity (1919–1975)

Because the effects predicted by GTR are very small in the solar vicinity, they are difficult to establish experimentally. However, the so-called 'crucial tests' (predicted by Einstein himself) have been confirmed with reasonable accuracy. They are:

(1) The perihelion advance of Mercury.

(2) The relativistic red-shift.

(3) The gravitational deflection of starlight rays grazing the sun.

These three tests of GTR are not equally stringent: (2) only tests the weak equivalence principle, while (1) and (3) also test Einstein's field equations[367].

We next review the status of these tests, and others devised later.

The earliest attempts to provide experimental proofs of GTR were made by Einstein's disciple, assistant and colleague, the astronomer ***Erwin Finlay Freundlich***[368] *(1885–1964, Germany and Scotland), during* 1911–1918. *Years before the theory was perfected and published in* 1916, *Einstein was advising and encouraging Freundlich, an astronomer at the Royal Observatory in Berlin, to conduct experiments to measure effects (1) and (3) that could prove or disprove his revolutionary concept of space, time and gravitation. Freundlich was perhaps the first scientist to become thoroughly acquainted with the fundamental principles of Einstein's theory. As such he was a moderately important figure in Einstein's career during its early years.*

---

367 The *qualitative* fact that light is deflected in a gravitational field, though, *does* follow from the equivalence principle alone. This can easily be seen by considering a small, freely falling frame in which we shine a beam of light. The equivalence principle then demands that the beam describes a straight line in this frame, which implies that the beam is bent in a non-inertial frame.

368 Freundlich was born in Biebrich, Germany to a German father and Scottish mother. After earning a doctorate at Göttingen University, he went to work at the Berlin Observatory, where he was introduced to Einstein, who at the time was having trouble finding astronomers to search for experimental proofs to his still unpublished general theory. In 1918, Freundlich became Einstein's full-time assistant. After the war time he raised money to establish the Einstein Observatory in Potsdam, becoming its first director and working alongside Einstein. Freundlich left Germany after the Nazis came to power and wound up his career as an astronomer at St. Andrew University in Scotland.

Freundlich's telescopic studies between 1911 *and* 1913 *confirmed that Mercury's position conformed to Einstein predictions based on the equations of GTR as they pertained to the sun's gravitational effect in warping space-time. These Mercury results left Einstein speechless for several days with excitement, but remained controversial until they were duplicated by* ***Eddington*** *(1916).*

In 1914*, Freundlich was in Russia on his way to the Crimea to observe a total eclipse of the sun, to test (3), when the outbreak of WWI canceled the whole project. Not until* 1919 *was the crucial eclipse test conducted by Eddington, applying the very technique elaborated by Freundlich in 1914. (Eddington later said: "It seems unfair that Dr. Freundlich, who was first in the field, should not have had the satisfaction of accomplishing the experimental test of GTR".)*

Freundlich drew attention to test (2), though he lacked the facilities for making the necessary observations.

A. Perihelion/Periastron advance of planets or stellar companions

Astronomical observation show that the elliptical orbit of the planet Mercury rotates in its plane of motion about $5,599.7$ *seconds of arc per century. Using Newtonian mechanics, one can ascribe this phenomenon to the perturbing effects of other planets, mostly Venus, and obtain a theoretical value of* $5,557.2$ *seconds of arc per century. The difference of about* $43''$*/century, has puzzled astronomers since* 1860. *An oblateness of the sun amounting to* .028 *percent could account for this "anomalous" precession, but would lead to additional phenomena which have not been detected.*

Einstein has shown that GTR predicts an added $\Delta\Phi = 43''$*/century [*$\Delta\Phi = 6\pi GM/ac^2(1-e^2)$ *per revolution, with* M *the solar mass,* $GM/c^2 = 1.4$ *km,* $a = 58 \times 10^6$ *km, (semi-major axis of Mercury's orbit), and* $e = 0.2$ *(that orbit's eccentricity)]. Other planets, such as Venus or earth, have smaller GTR-caused precession rates; Mercury is most suitable because of its proximity to the sun.*

In 1972 ***Irvin I. Shapiro*** *(b.* 1929*, U.S.A.) et al., succeeded in a determination of the anomalous perihelion advance of Mercury, after five years of observation with Haystack (Massachusetts) and Arecibo (Puerto Rico) radio telescopes. They found that the observed and GTR-calculated values agreed to within the uncertainty of the observation (*$\sim$ *2%).*

In 1975 ***Hulse*** *and* ***Taylor*** *measured the periastron advance of the binary pulsar, PSR* $1913+16$*, and found it to agree with the GTR value within the observational error. Further observations of this system over the following* *two decades, have improved the agreement.What is more,* ***Hulse*** *and* ***Tylor*** *found an additional anomalous effect in this stellar system – a slow secular orbital decay unaccounted for by any known process – which agrees very well with kinetics energy loss due to gravitational-wave radiation as predicted by GTR.*

Previously, ***Clemence*** *(1947) showed that the Mercury precession produced by the solar oblateness is negligible because of the non-uniform density of the sun, but the final verdict is not yet in on this issue.*

B. Gravitational time dilation (red shift)

According to GTR, the gravitational field effects the rate of clocks ['clock' in this context stands for any localized time measurement procedure], such that $\Delta\tau_2 = \Delta\tau_1\left[1 + \frac{\Delta\Phi}{c^2}\right]$ *where* $\Delta\Phi$ *is the change in gravitational potential*[369] *difference between clock II (time interval* $\Delta\tau_2$*) and clock I (time interval* $\Delta\tau_1$*).*

Hence, if clock II is at the higher potential $(\Delta\Phi > 0)$, *then* $\Delta\tau_2 > \Delta\tau_1$*. The signals sent out from clock I at (say) one-second intervals, are measured by clock II to arrive at intervals larger than one second. Clock I, which is closer to the source of the field, is thus observed to run slow. If the two clocks are near the earth's surface,* $\Delta\Phi \approx g(\Delta r)$ *where* Δr *is the vertical distance (altitude difference) between the clocks. If we denote* $\Delta\tau_1 = T$, $\Delta\tau_2 - \Delta\tau_1 = \Delta T$, *the above relation will yield* $\Delta T/T \approx g\frac{\Delta r}{c^2}$, *which can be verified experimentally with modern atomic clocks. In terms of clock-rate, or frequency,* $\frac{\Delta\nu}{\nu} \approx -\frac{\nabla T}{T} \approx -g\frac{\Delta r}{c^2}$.

369 Gravitational potential is a Newtonian concept. What is meant here is that, when the two clocks are infinitesimally close and at rest in a *static* space time which is nearly Newtonian (such as that outside the sun), then their rates are related in the above manner – which follows simply from the weak equivalence principle (no need to invoke the field equations).
By considering a string of neighboring clocks, we can define $\Delta\tau_2/\Delta\tau_1$ for any two stationary clocks, even far apart. The relation $\Delta\tau_2 = \Delta\tau_1\left[1 + \frac{\Delta\Phi}{c^2}\right]$ is then modified to $\Delta\tau_2 = \Delta\tau_1\sqrt{\frac{g_{00}(2)}{g_{00}(1)}}$. In the 'post Newtonian' (weak gravity) approximation, which holds in the solar system, $g_{00}(\boldsymbol{r}) \approx 1 + \frac{2\Phi(\boldsymbol{r})}{c^2}$, and the previous expression is recovered.

It then follows that a periodic signal emitted at r_1 in step with the ticking of clock I, will appear to have reduced its frequency when it arrives and is measured at r_2 by clock II. In particular, the spectral lines in the light emitted by an atom placed deep in a gravitational potential, should be found to be red-shifted when compared with the spectral lines emitted by an identical atom placed at higher in the potential[370].

The experimental tests of this effect serve as direct evidence that space-time is not flat but curved. Two kinds of earth-bound experiments were performed. In the first, by ***Pound*** *and* ***Rebka*** *(1959), an emitter of γ-rays (the isotope Fe^{57}) was placed at ground level, and these γ-rays detected via absorption by another Fe^{57} sample, placed at the top of a tower $\Delta r = 22.6$ m above the emitter $\left[\frac{\nabla\nu}{\nu} = -g\frac{\Delta r}{c^2} = -2.46 \times 10^{-15}\right]$. The measurement of such a small frequency shift necessitates a high-Q resonant absorption of Fe^{57}; the experiment thus relies on the Mössbauer effect to prevent shifts of the γ's energy through recoil of the nuclei during emission or absorption. The most recent version of the experiment (****Pound*** *and* ***Snider****, 1964) gave the result $(\Delta\nu)_{\text{exp}}/(\Delta\nu)_{\text{theo}} = 1.00 \pm 0.01$.*

In the second kind of experiment, ***J.C. Hafele*** *and* ***R.E. Keating*** *(1972) took Cesium-beam clocks on flights around the world in commercial jets. The clocks, carried to high altitude by the aircraft, were found to have* gained *time when brought back to a laboratory clock that stayed on the ground [purely gravitational 'gain' was obtained from the 'apparent gain' after subtracting special relativistic time-dilation ('kinematic correction')]. Here $(\Delta\nu)_{\text{exp}}/(\Delta\nu)_{\text{theo}} = 0.9 \pm 0.2$.*

Gravitational red-shifts have also been measured for light emitted by atoms on the surface of the sun $\left[\frac{\Delta\nu}{\nu} = -\frac{GM_\odot}{R_\odot c^2} = -2.12 \times 10^{-6}\right]$ by ***J.W. Brault*** *(1962) and* ***J.L. Snider*** *(1971), and found to be in good agreement with theory.* ***Greenstein*** et al. *(1971) measured red-shifts of H lines on Sirius B, with a figure of merit 1.07 ± 0.2.*

Such measurements are sometimes difficult, since the gravitational red-shift is masked by large and uncertain kinematic Doppler shifts.

---

[370] *In other words*: the wavelength of light should be increased while climbing a strong gravitational well such as the sun's, owing to a loss of some energy by photons (recall $E = h\nu$) as the light or any other radiation escapes the gravitational field.

C. Deflection of light by the gravitational field of a star

The GTR value for the angular deflection of light that passes at distance $b \geq R$ *from the center of a spherical mass* M *of radius* R*, is* $\alpha = 4GM/c^2b$ *radians. For a ray grazing the limb of the sun, this amounts to 1.75 seconds of arc. A simple calculation of this effect, based on Newtonian gravitation theory*[371] *and the corpuscular theory of light (**Soldner**, 1801), yielded half the above value. [He evaluated the transverse momentum acquired by a photon in passing the sun, by integrating the component of the gravitational force normal to the approximated linear trajectory.]*

*The first relevant astronomical measurement was done by **A. Eddington** and **Frank Dyson** during the solar eclipse of May 29, 1919 on the islands of Sobral (off Brazil) and Principe (Gulf of Guinea). They photographed the star field around the sun during total eclipse, and measured the displacement of star image relative to those on plates taken when the same stars are supposed to appear in the same place in the night sky (about six months later or earlier). The observational problems were:*

(1) observations are limited to $b > 2R$ *because of glare from the Corona;*

(2) 'paths of totality' for solar eclipses usually do not pass through observatories with big telescopes;

(3) it is necessary to compare separate plates acquired and developed independently at an interval of some months.

During that time the magnification of the system must be kept constant to within one part in 10^4*! Because of the extreme difficulty of the experiment, the systematic errors are much larger than the errors indicated by the consistency of the data.*

The experiment has been performed 12 times in the interval between 1919 and 1973, and the results have the spread $1.3''$–$2.7''$*. It may be taken as consistent with* $\alpha(R) = 1.75''$ *to within an error ∼25%.*

More precise results have been obtained during 1970–1975 with the use of radio-waves rather then optical light. In this case it is not necessary to wait for an eclipse; rather one must wait for the sun's limb to approach a radio source. Results were consistent with $\alpha(R) = 1.75''$ *with errors ∼10%, and*

---

[371] Newton, in the appendix to his book *Opticks* (1704) asked:

"Do not bodies act upon light at a distance, and by their action bend its rays, and is not this action, strongest at the least distance?"

In view of Newton's concept of light as a stream of minute particles, this seemed a reasonable question.

provided evidence against the Brans–Dicke scalar-tensor theory of gravitation (an alternative to GTR).

The technology of these radio-wave measurements utilized long baseline interferometry to determine the change in the apparent position in the sky of the quasar[372] $3C279$ *during its annual occultation by the sun (October 8). The relative phase of the signals received by two radio telescopes is monitored during occultation and compared with the relative phase of the signals received from the quasar* $3C273$ *when it is not occulted, and is* $9.5°$ *away from* $3C279$*. The wavelengths used are in the range* 3–15 *cm, and most baselines are in the range* 1–845 *km.*

---

372 *Quasars*: With the advent of new radio telescopes in the late 1950s and the improvement of the techniques for using them, radio astronomers were able to map more accurately the coordinates of radio sources in the sky.

In 1960, **Thomas Matthews** (CalTech, U.S.A.) discovered the first QUASAR denoted 3C48 (*Qua*si-*S*tell*ar* *S*ource; a double misnomer since they are quasi-stellar only in the sense that they were first mistaken for stars, and most are not radio sources. By the time that quasars were better understood, it was too late to change the term).

Allan Sandage (U.S.A.), **Jesse L. Greenstein** (U.S.A.) and **Maarten Schmidt** (U.S.A.) investigated the line spectra of observed quasars and found that the lines could be identified, provided huge Doppler *red-shifts* were assumed. These in turn indicated that quasars could be among the most distant objects known — billions of light years away. An absorption line in the 21 centimeter region showed that quasars were indeed beyond the hydrogen cloud constellation Virgo (40 million light years away). It was deduced that quasars must be of small volume but extraordinary luminosity (30 to 100 times that of an entire typical galaxy) to be able to emit such huge quantities of microwaves and visible light.

The possibility that quasar red-shifts were not caused by Hubble–expansion velocity at all but were gravitational in origin (GTR effect) was dismissed since no characteristic side effects supporting it were observed. The year 1960 also saw the establishment of the *Kitt Peak National Observatory* (Arizona, U.S.A.; 2096 m). It houses the largest solar telescope in the world (146 m diameter): It uses a system of three mirrors to produce a real image of the sun that is 86 cm in diameter. A flat mirror, called a '*heliostat*', 208 cm in diameter, follows the path of the sun. It reflects the sun light to a curved mirror 152 cm in diameter at the bottom of the 146 m telescope shaft. Another mirror reflects the sun's image into an observing room. Astronomers use the telescope to study sunspots and solar flares, both of which affect radio communication on earth.

In 1973, an optical telescope with a main mirror of 401 cm in diameter started to operate for the study of faint galaxies, quasars and other objects important to man's understanding of the universe.

D. Retardation of light

GTR predicts that gravitation reduces the speed of propagation of light signals grazing the sun (this velocity change is frequency independent — no dispersion]. This is an "effective" retardation, measured with respect to asymptotically-Minkowskian standards of time and length, far from the source of the gravitational field. An observer measuring the speed of light in situ, near the sun, with local clocks and length standards, would find the usual speed of 3×10^{10} *cm/sec. The theoretical extra time delay for the round trip of a sun-grazing radar signal bounced off one planet from another is* $\left\{2GM \log \frac{4z_1 z_2}{b^2}\right\}$, *where* b *is the grazing distance (closest radar-beam approach to sun's center) and* z_1, z_2 *are the distances of the two planets from the sun (they are assumed to be on diametrically opposed sides of the sun).*

For the earth-sun-Mercury system the maximum possible extra time delay is about 0.11 *milliseconds. To compare this value with experiment, one must make a correction to convert the above expression to proper time on earth by multiplying it by* $\left\{1 - \frac{GM}{rc^2}\right\}$, *where* r *is the radius of the earth's orbit. In addition, since the earth is moving, the time-dilation of special relativity must also be taken into account. Further, non-gravitational corrections must be made for the change of velocity of propagation of the radio signal caused by the solar corona and interplanetary plasma.*

Shapiro et al. *(1968, 1971) measured delays of radar echoes from Mercury, Venus and Mars, using the Haystack and Arecibo radio telescopes. The theoretical and experimental values agreed to within two percent.*

E. Gyroscopic precession

This test of GTR was proposed by ***Georg E. Pugh*** *(U.S.A.) and* ***Leonard I. Schiff*** *(1905–1971, U.S.A.) in* 1959.

The experiment (launched in spring 2004 and still taking data) consists of two gyroscopes in a 800*-km polar orbit around the earth (period of revolution* $\simeq 1.5$ *hours). The first gyroscope, with its spin axis in the orbital plane, is subjected to the so-called 'geodetic precession', namely a slow rotation of its inertial spin axis relative to the inertial axes at infinity (or the background microwave radiation frame, or some fixed stars*[373]*) about the normal to the polar orbital plane. The direction of this 'precession' is in the same sense as that of the orbit, i.e.: after one orbit, the direction of the gyroscope axis has rotated relative to its initial direction in the same sense. The cumulative net*

[373] In the actual experiment, an on-board telescope is used to measure the precession w.r.t. a star.

effect over one year (5000 orbits) is ~ 6.9 *arcseconds*[374]. *It amounts to a full rotation of* 360° *in* $200,000$ *years. This effect depends only on the earth's mass but not on its spin.*

The gyroscope is in a freely falling frame, but the principle of equivalence [which translates the problem into an equivalent STR one in a locally flat inertial frame, in which the spinning mass is instantaneously at rest] must be applied with caution, since the 'Einstein elevator' has a window through which the telescope watches a fixed star! In fact the non-flat *metric causes the gyroscope to precess at a rate that is* three fold *faster than the ordinary, (STR) Thomas precession.*

The second gyroscope has its spin axis parallel *to the equatorial plane of the earth and normal to the plane of its orbit around the earth. A classical GTR spin-orbit interaction cause the gyroscope's spin-axis to rotate slowly with the angular velocity vector* $\boldsymbol{\Omega} = \frac{G}{c^2 r^3}[3\boldsymbol{e}_r(\boldsymbol{e}_r \cdot \boldsymbol{J}) - \boldsymbol{J}]$, *where* $\boldsymbol{e}_r$ *is a unit radius vector from earth's center to the gyro and* $\boldsymbol{J}$ *is the angular momentum vector of the earth. When the gyro is at the pole,* $\boldsymbol{\Omega} = \frac{2G}{c^2 r^3}\boldsymbol{J}$, *and when it is at the equator* $\boldsymbol{\Omega} = -\frac{G}{c^2 r^3}\boldsymbol{J}$, *with the opposite sign. The net precession is* $0.055'' \left(\frac{R}{r}\right)^3$ *sec/year, where* R *is the earth's radius. This is precisely the* Lense-Thirring *effect of* frame-dragging *— the partial dragging of the local, free–falling inertial frames at the gyroscope's instantaneous location to the earth's spin — that can be thought of in terms of the so-called Mach principle (it also plays the same role for a gravitational orbit as does the* hyperfine interaction *in an atomic orbital caused by electromagnetism).*

According to this way of thinking, the gyroscope's inertial frame is acted upon by the earth: the inertial frame fixed to the gyroscope tries to follow the rotation (spin) of the earth, but lags behind due to the persistent interference of the cumulative effect of the entire universe.

The goal of the combined experiment is to measure both the geodetic precession and the fame-dragging effect to an accuracy better than a milliarcsecond per year, which is of order 2 percent of the smaller frame-dragging effect. The task of building an orbiting gyroscope laboratory that can measure such tiny effects has put scientists at the very frontiers of experimental physics and precision-fabrication technology.

---

374 The theoretical value of this precession is $\frac{3}{2}\frac{GM}{c^2r^2}\sqrt{\frac{GM}{r}} \approx 6.9''/year$, where M, r are the earth's mass and the gyro's orbital radius, respectively. The above expression can also be written as $\left(\frac{R}{r}\right)^{5/2} \times 8.4''/year$, R being the earth's radius.

The gyroscopes are spheres of fused quartz, about 4 cm in diameter. Their uniformity in shape and density must be better than one part in 10^7 in order to prevent interaction of stray gravitational forces with material irregularities, which can cause enormous precessions[375] *relative to the effects sought. The gyros are coated with a thin uniform layer of niobium, a material that becomes a superconductor when cooled to temperatures approaching absolute zero. Eddy currents trapped in this layer create a magnetic field that is aligned with the spin axis of the ball.*

Very precise (so called SQUID) magnetometers, also utilizing superconductors and likewise operating near absolute zero, can determine the orientation of the magnetic field, and thereby the spin axis. The gyros are suspended in free fall to keep them away from the walls of the satellite. A liquid helium Dewar surrounding the gyros keeps the balls at the required low temperature. Each ball is sprayed tangentially with tiny jets of helium, using friction to set them spinning. The air around the gyros was pumped, so that they spin in an almost perfect vacuum; their rotation should slow down by less than one part in 10^3 per year.

Since the gyros precess relative to distant stars, a very accurate telescope aboard the spacecraft is constantly kept trained on the bright star Rigel in the constellation Orion. The instantaneous orientation of the gyros is continually determined relative to this fixed direction to the desired milliarcsecond-level (per year) precision.

This experiment is believed to be the most important ever to be performed in space, and a crucial test for GTR. In recent years there was a growing feeling among physicists that GTR has never been completely *verified. The difficulties encountered in unifying it with quantum mechanics and its mathematical complexity added to the feeling that the theory is incomplete*[376]*. It is hoped that the result of this experiment may help to decide some of these crucial issues, although no mere post-Newtonian measurement is likely to shed much light on the puzzles of quantum gravity.*

[375] If any of these spheres could be inflated to the size of the earth, its highest mountain would not surpass 64 centimeters!

[376] Although some physicists believe that it is *quantum mechanics* which is to blame for the difficulties in unification, and that gravitational physics must underline quantum mechanics itself!

F. Black holes[377]

A black hole is a self-gravitating object whose gravitational field is so strong that even light cannot escape. The event horizon is the surface where light loses the ability to escape from the black hole. Nothing that crosses to the interior of the event horizon can ever get back out again — not even light.

Black holes can be created by the gravitational collapse of large stars that are at least twice as massive as our sun. Normally, stars balance the gravitational force with the pressure from the nuclear fusion reactions inside. When a star gets old and burns up all of its hydrogen into helium, and then fuses the helium into heavier elements (carbon, oxygen, and eventually iron and nickel), it can have three fates. The first two fates occur for stars less than about twice the mass of our sun (and one of them will be our sun's eventual fate). These two fates both depend on the fermionic (Pauli-exclusion) repulsion pressure prescribed by quantum mechanics –two same – species fermions cannot be in the same quantum state at the same time. This means that the two possible stable destinies for the collapsing star will be:

> *(1) A white dwarf supported by the fermionic repulsion pressure of the electrons in the heavy atoms in the core.*
>
> *(2) A neutron star supported by the fermionic repulsion pressure of the neutrons in the nuclei of the heavy atoms in the core (all the protons having been 'squeezed' into reverse-beta-decaying to neutrons, positrons and neutrinos by the collapse pressure).*

If the mass of the collapsing star is too large (bigger than twice the mass of our sun), the fermionic repulsion pressure of the electrons and the neutrons are not enough to prevent the ultimate gravitational collapse into a black hole.

The estimated age of the universe is several times the lifespan of an average star. This means there must have been many stars heavier than twice the mass of our sun that have burned their nuclear fuel and collapsed since the universe began. Our universe ought to contain many black holes, if the model that astrophysicists use to describe their formation is correct. Black holes created by the collapse of individual stars should only be about 2 to 100 times as massive as our sun.

---

[377] For further reading, see:

- Shapiro, S.L. and S.A. Teukolsky, *Black Holes, White Dwarves and Neutron Stars*, Wiley, 1983, 645 pp.

Another way that black holes can be created is the gravitational collapse of the center of a large cluster of stars. These types of black holes can be very much more massive than our sun. There may be one of them in the center of every galaxy, including our galaxy, the Milky Way. There is one in the middle of the galaxy called NGC 7052, surrounded by a bright cloud of dust 3,700 light-years in diameter. The mass of this black hole is about 300 million times the mass of our sun.

The Schwarzschild solution (1916)

Certain problems in GTR can not be treated by a linear approximation of the field equations and require an exact solution. The first and most important exact solution was found by ***Schwarzschild*** *(1916). It is a metric for the spacetime around a spherically symmetric mass distribution of total mass m.*

Near a body of mass m (e.g., the sun), spacetime is curved. The world lines of particles and lightrays in the gravitational field of m are approximately geodesics.

To find these, it is necessary to know the metric tensor $g_{\mu\nu}$ in some useful coordinate system. We choose x^0 to be the time and (x^1, x^2, x^3) to be some type of spherical polar coordinates (r, θ, ϕ) with the mass m at the origin 0.

Thus, we have a series of concentric spheres which, in a flat 3D space, would have radii r and surface areas $4\pi r^2$. If m were zero spacetime would be flat and Minkowskian and thus, from STR, the pseudo–norm of the separation of two infinitesimally close events would be

$$\eta_{\mu\nu}\,\Delta x^\mu \Delta x^\nu = (\Delta t)^2 - \frac{1}{c^2}\left[(\Delta x)^2 + (\Delta y)^2 + (\Delta z)\right] = (\Delta t)^2 - \frac{(d\sigma)^2}{c^2} \quad (1)$$

with $g_{\mu\nu} = \eta_{\mu\nu}$, the Minkowski metric tensor. For $m = 0$ the 3-space is Euclidean, and it has the metric

$$(d\sigma)^2 = (dr)^2 + r^2\left[d\theta^2 + sin^2\theta d\phi^2\right]. \quad (2)$$

If we can now 'switch on' the mass m, two things happen: the position (3D) space become curved, so that the r-spheres no longer have radii related to the respective areas via $A = 4\pi r^2$; and clocks on each r-sphere are no *longer observed from other r-spheres to run at the same rate. To allow for these effects we write the separation pseudo–norm as*

$$g_{\mu\nu}\,\Delta x^\mu \Delta x^\nu = e(r)(\Delta\tau)^2 - \frac{1}{c^2}\left[f(r)(\Delta r)^2 + r^2(\Delta\theta)^2 + r^2 sin^2\theta(d\phi)^2\right], \quad (3)$$

where $e(r)$ and $f(r)$ are positive functions to be determined, subject to the boundary conditions that far from m spacetime is asymptotically flat, so that $e(\infty) = f(\infty) = 1$. We have chosen a coordinate system where a 3-sphere of radius $\sqrt{f(r)}$ has area $4\pi r^2$.

Schwarzschild, by rigorously solving the Einstein field equations, obtained

$$e(r) = 1 - \frac{2Gm}{c^2 r}; \qquad f(r) = \frac{1}{1 - \frac{2Gm}{c^2 r}} \quad (4)$$

The corresponding metric tensor, known as the 'Schwarzschild metric', is

$$g_{\mu\nu} = \begin{pmatrix} 1 - \frac{2Gm}{c^2 r} & 0 & 0 & 0 \\ 0 & -\frac{1/c^2}{1-\frac{2Gm}{c^2 r}} & 0 & 0 \\ 0 & 0 & -\frac{r^2}{c^2} & 0 \\ 0 & 0 & 0 & -\frac{r^2 \sin^2\theta}{c^2} \end{pmatrix} \quad (5)$$

and

$$g_{\mu\nu}\,\delta x^\mu \delta x^\nu = d\tau^2 = \left(1 - \frac{2Gm}{c^2 r}\right) dt^2 - \frac{1}{c^2}\left(\frac{dr^2}{1 - \frac{2Gm}{c^2 r}} + r^2 d\theta^2 + r^2 sin^2\theta d\phi^2\right) \quad (6)$$

In (6), dt is the interval of time between two events at the same distance from the mass centroid (e.g. events aboard a spaceship held at fixed r by firing its rockets towards the $r = 0$ mass centroid), as measured by an observer using a clock which is in a region remote enough that space-time is effectively flat. However, $d\tau$ (when a real number) is the proper time interval measured on a clock carried by someone moving in such a way as to be present at the two events labeled as (t, r, θ, ϕ) and $(t + dt, r + dr, \theta + d\theta, \phi + d\phi)$. (This is only possible if the two events have a timelike separation: $d\tau^2 > 0$.)

Note that the metric components do not depend on time, and so the Schwarzschild metric is static. It can, however, be shown that even when the mass distribution is undergoing spherically symmetric radial motions or flows, the external structure of space-time is described by the Schwarzschild metric *and is hence static. This result applies in the case of a stellar core collapsed to a neutron star or to a black hole while maintaining perfect spherical symmetry.*

Furthermore, it is believed that the gravitational collapse *of any nonrotating, electrically neutral star will necessarily lead to the Schwarzschild geometry; any deviation from the symmetric field will ultimately be radiated away in the form of gravitational waves.*

The solution in the interior *of a mass distribution can be carried out analytically only in some exceptional cases, such as the case of a fluid without pressure (cloud of dust). The solution for the case of matter with a realistic equation of state can usually only be carried out numerically.*

The dimensionless quantity $\frac{Gm}{rc^2}$ *appearing in* (5) *and* (6) *may be regarded as a measure of the local strength of the gravitational field. This quantity enters into the formulae for* light deflection, light retardation, redshift, perihelion precession, *etc.*

Note that the Schwarzschild solution develops a singularity *at* $r \to \frac{2Gm}{c^2}$ $(g_{00} \to 0, \quad g_{11} \to -\infty)$. *The quantity*

$$r_s = \frac{2Gm}{c^2} \tag{7}$$

is called the Schwarzschild radius *of the mass. For the mass of the sun* ($m = 2 \times 10^{33} g$) *we calculate* $r_s = 3.0$ *km. The corresponding value for earth is 8.86 mm. In most cases* r_s *is far smaller than the actual radius of the body concerned. However, the Schwarzschild metric applies only in the space* outside *the gravitating body; inside, a different formula holds, and there* g_{11} *is not singular at* r_s. *Furthermore, even if the sphere* $r = r_s$ *is exterior to the mass distribution, it can be shown that the* $r = r_s$ *singularity is only* apparent *– an artifact of the coordinate choice. The '*Schwarzschild singularity*' is thus unphysical (a small enough object can fall through the event horizon with no ill effects, though it can never exit again, nor communicate to the outside universe). However, but a real physical singularity occurs at* $r \to 0$ *when the mass distribution is pointlike. That in itself is unremarkable, as it is the case in Newtonian gravitation too.*

However, astrophysicists have calculated that the ultimate stage in the evolution of stars several times more massive than the sun would be 'gravitational collapse'. In this process, the star has exhausted its nuclear fuel and no longer radiates, and the pressure of its matter cannot resist the gravitational self-attraction of the star, which therefore shrinks down within its Schwarzschild sphere at $r = r_S$. *Such collapsed stars, and other objects smaller than their Schwarzschild radii, are called* black holes. *No known mechanism can halt such a collapse, and GTR must be somehow modified to describe the fate of the collapsed energy–matter near* $r = 0$.

Black holes are very strange objects. Their most astonishing property is that anything inside the Schwarzschild sphere must fall into the center $r = 0$. This applies to the matter constituting the star whose collapse formed the black hole, and implies that the collapse continues until the star is a point singularity at $r = 0$. (The implication holds if general relativity remains valid in the unimaginably dense and hot conditions near the end point of the collapse. If quantum or other effects intervene, the singularity might be avoided. However, no consistent theory of 'quantum gravity' has yet been devised, and this is still very much an open question.) Thus, the $r = 0$ singularity is worse in GTR than in Newton's physics, as nothing can prevent it.

The 'collapse' property also applies to any light emitted by the star when its radius is less than r_S, and implies that no light can escape, so that these objects cannot be seen from outside – hence the name 'black holes'. (This is not to say that black holes exert no influence on their surroundings; their gravitational effects on external bodies are perfectly normal, because these effects arise from the Schwarzschild metric for $r > r_S$.)

The simplest (Schwarzschild) black holes have no angular momentum or charge. The most general black hole known mathematically has mass, angular momentum (spin) and electric charge, and is a solution of the Einstein–Maxwell field equations. Anyone outside a black hole cannot follow what happens to material or energy once they cross the horizon. This raises the question of whether it is possible to make any distinction between black holes, beyond differences in mass.

***Hawking** (1972) and others have proven rigorously that a full description of any black hole requires just three parameters; these are the total mass M, the total charge Q, and the total angular momentum or spin J of the black hole. In a neat phrase, black holes are said to 'have no hair', which means that they have no externally observable detailed features*

As far as we know, matter on the large scale, and in particular stellar matter, appears to be electrically neutral – though it is almost always spinning (and thus, so are astrophysical black holes). The space-time around a neutral, but rotating collapsed star is described by the Kerr metric (1963).

1917 CE **Gerhard Hassenberg** (1874–1925, Germany). Mathematician. Stressed the advantages of representing tensors as homogeneous invariant multilinear forms in primary base-vectors (polyadic form), and consequently as hyper-numbers in the Grassmannian sense.

1917 CE **D'Arcy Wentworth Thompson** (1860–1948, England). Classical naturalist and scientist, whose impact thrives in evolutionary biology, biomechanics and architecture. Was mainly concerned with the explanation of biological growth and form in physico-mathematical terms and disregarded the mainstream reductionist approach based on *biochemistry* and *genetics*. He believed that forms are shaped by *physical causes*, such as gravity, surface tension etc., and that growth is governed by *physical laws*.

In his masterpiece *On Growth and Form*, he pursued the undeniable unity of living organisms, and tried to reduce all patterns to a single system of generating forces. He thought of life as always in motion, always responding to rhythms — the "deep-seated rhythms of growth" which he believed created universal forms. He seemed to sense what this unity, if proven, might mean for the science of organic form. Moreover, he argued that *mathematical patterns* exist in living organisms, and that these patterns must therefore have *mathematical causes*!

In this sense, modern biology bypassed him; at the turn of the century, biology was already turning toward methods that reduced organisms to their constituent functioning parts: *Reductionism* prevailed in molecular biology, everywhere from evolution to medicine. Processes in cells were being interpreted in terms of membranes, nuclei, proteins, enzymes and chromosoms.

Against this tide, Thompson valiantly put his credo: "*It may be that all the laws of energy, and all the properties of matter, and all the chemistry of all the colloids are as powerless to explain the body as they are impotent to comprehend the soul. For my part, I think not*".

On Growth and Form has become a classic in natural philosophy. Biologists have conceded that it has had a great, though "*intangible and indirect*", influence. Mathematicians, on the other hand, were and still are fascinated by Thompson's considerations.

Worldview XXXV: D'Arcy Thompson

* * *

"The reflection of mathematical beauty is such that whatsoever is most beautiful and regular is also found to be most useful and excellent."

* * *

"Forms are not simply the result of heredity and behavior, but are shaped by physical forces."

* * *

"We known immeasurably more about the universe than our ancestors did, and yet it increasingly seems they knew something more essential about it than we do."

* * *

"Ancients knew the stars far better than we do; our city streets shut out the sky, and new lamps blind us to the old. Our calendar is ready-made for us, and ask not how."

* * *

"It behooves us always to remember that in physics it has taken great men to discover simple things. They are very great names indeed which we couple with the explanation of the path of a stone, the droop of a chain, the tints of a bubble, the shadows of a cup."

On D'Arcy Thompson

* * *

"An aristocrat of great learning whose intellectual endowments are not likely ever again to be combined in one man."

Peter Medawar (1958)

* * *

"Hovered, as it were, on the fringes of both the scientific and the classical worlds, making, apparently, no deep impression on either."

"He ignored chemistry, misunderstood the cell, and could not have predicted the explosive development of genetics... No modern biologist has to read him. Yet somehow the greatest biologist find themselves drawn to this book. This classicist, polyglot, mathematician, zoologist tried to see life whole, just as biology was turning so productively towards methods that reduced organisms to their constituent functioning parts. Reductionism triumphed."

Ruth Thompson (1958)

* * *

"Thompson is no Euclid of the plant world, and there is no Thompson's equation for an animal. Nonetheless, circumstantial evidence in every corner of the living world convinced Thompson that there is real mathematical patterns in living organisms and that the organic world is just as mathematical as the inorganic world."

Ian Stewart (1998)

The mathematics of life[378] — *structures, patterns and processes*

The universe has its endless gamut of great and small, of near and far of brief and enduring, of sudden and slow; of many and few. Yet, the physical laws that govern it, depend to a large extent on the relative scales of the physical entities that partake in these laws.

It was known already to ***Archimedes*** *(ca 250 BCE), that in similar figures the surface increases as the square, and the volume as a cube, of the linear dimensions. Thus, a fish, in doubling in length and breadth, multiplies its weight no less than eight times. Some physical forces are proportional to the surface area of the body on which they act (such as the wind force on a ship's sail or the lift of a bird's wing) or else, like gravity, exert a force proportional to the volume (actually mass) of the body.*

*It was **Galileo** (1638) who first laid down the general principle of similitude; and he did so with the utmost possible clarity, and with a great wealth of illustrations drawn from structures in both the animate and inanimate worlds. He said that if we tried building ships, palaces or temples of enormous sizes, yards, beams and bolts would cease to hold together; or can nature grow a tree nor construct an animal beyond a certain size*[379]*, while retaining the proportions and employing the materials and design principles which suffice in the case of smaller structures. The thing will fall to pieces of its own weight unless we either change its relative proportions (which will at length cause it to become clumsy, monstrous and inefficient) or else find new materials, harder and stronger than used before*[380] *(e.g., the discoveries of cement and steel).*

---

379 A trivial, but amusing, example concerns the size limits on prehistoric creatures. We know that the largest land animal of all time was the giant sauropod dinosaur named *diplodocus*. It has been compared to a walking suspension bridge with an overall length of 40 meters, height of 18 meters (as high as a 6-story building), and weighing about 100 tons. It lived in the Jurassic (208–114 million years ago) and became extinct some 65 million years ago. Managing its vast bulk was partly an engineering problem and partly mechanical, a matter of force and leverage. It needed powerful muscles, solidly anchored, for walking, running and eating.

It is clear that the interplay of gravity and the strength of biological materials imposes limits on the size to which animals can grow. To calculate this we construct the following toy model: A land animal is, basically, a mass (the trunk) $M \approx \rho L^3$ standing in a column (the legs combined) of height h, having a square section of side $d \leq L$, where ρ is the density.

To support the animal trunk above ground level requires the expenditure of energy $\rho h d^2 Q$, where Q is the amount of energy per unit mass required by the support. If the structure collapses under its own weight, then gravity will supply an energy Mgh, where g is the acceleration of gravity at earth's surface. If the structure is to survive under its own weight $\rho d^2 h Q > Mgh$, whence: $\frac{d}{L} > \sqrt{L}\sqrt{\frac{g}{Q}}$. The smaller the animal, the thinner its legs can be; inversely, the larger it is, the fatter the legs. An ultimate limit is reached when the legs are as thick as the trunk — but then the animal becomes immobile.

At this limit $\left(\frac{d}{L} \approx 1\right)$ we have $L(m) \approx \frac{Q(\mathrm{m}^2 \cdot \mathrm{sec}^{-2})}{g(\mathrm{m} \cdot \mathrm{sec}^{-2})}$. For typical biological structures $\frac{Q}{g} \approx 44$ m, which is close to the right answer. This shows that the size of a land animal is strictly limited; it also shows that structures can be studies without knowing the details of their constitution and construction, just some general principles and constraints.

380 Galileo was, of course, careful to explain that besides the questions of pure stress and strain there is the important question of *bending moments* which affect the whole form of the skeleton, and set limits to the height of a tall tree.

Another phenomenon, and one which is observed throughout the whole field of morphology, is the tendency (due to some definite cause) for body surface to keep pace with volume, through some alteration of its form. The lobulation of the kidney in large animals, and the vast increase of respiratory surface in the air-sacs and alveoli of the lung, are a few of the many cases in which more or less constant ratios tends to be maintained between mass and surface. A leafy wood, a piece of sponge, a reef of coral, are all instances of a like phenomenon, namely, devices for an increased surface in order to stimulate diffusion of molecules or absorption of energy.

Consider, for example, an organ of azimuthal symmetry, whose cross-section in the plane $\phi = const.$ *is given by the polar equation* $r(\theta, t) = a(t)f(\theta)$, *with the origin at* $r = 0$. *Assume that the material, needed for growth, is drained from this center toward the periphery at a rate independent of the polar angle* θ *in such a way that the quantity deposited per unit time per unit diameter length is fixed*[381]. *What is the expected shape of* $f(\theta)$? *Clearly,* $f(\theta) = const.$ *would correspond to a sphere. But the above condition can accommodate a wider class of plane curves, since it is required only that at any given moment* t *we shall have*

$$r(\theta) + r(\theta + \pi) = D = const.$$

One can show that the general solution has the form

$$r(\theta) = b_0 + \sum_{1,3,5,\ldots}^{\infty} (a_n \sin n\theta + b_n \cos n\theta).$$

Apart from a circle $(a_n = b_n = 0,\ n = 1, 3, 5)$, *the simplest such curve is the leaf-shaped* $r(\theta) = a[1 + \sin\theta]$. *This figure has all its diameters the same — yet it is obviously not round! The brain, heart and kidney possess shapes approximated by this equation.*

Another example is the Fibonacci sequence 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, … *manifested in the number of petals, sepals, stamens, and other components of flowers. For instance, lilies have* 3 *petals, buttercups have* 5, *delphiniums have* 8, *marigolds* 13, *asters* 21, *and most daisies have* 34, 55, *or*

[381] The majority of *marine shells* are based on a spiral form. e.g. the *Nautilus* has a shape known to mathematicians as the *logarithmic spiral*, first studied by **Jacob Bernoulli**. It has this shape because the animal pattern of growth increases by a *fixed proportion* as the growing shell turns through a *fixed angle*. On the other hand, the shell of the fossil *Ammonite* (an extinct relative of *Nautilus*) is closer to an Archimedean spiral, in which the growth increases by *fixed amounts* for a *fixed angle*.

89. *Fibonacci numbers are also hidden in sunflower-seed patterns. Although the biological origin of these numbers is not understood, their pattern might provide the plant with some evolutionary advantage, or it may have evolved through certain physical constraint (i.e. constraints imposed by the laws of physics) on what biology can do, in the same sense that the form of a bird's tail depends heavily on aerodynamics.*

The human body contains about 10^{14} cells, of more than a hundred types — nerve cells, blood cells, liver cells, bone cells, muscle cells and so on — but the body is not merely a vast cellular conglomerate. In order to function collectively as a human being, those cells must be put together in a specific, complex manner. The human brain, for instance, has abilities that the largest supercomputer cannot match — such as being able to recognize a face, or look at a landscape and instantly pick out a sheepdog in a distant field. No human–devised technology can as yet assemble a single human cell.

D'Arcy Thompson was concerned with some mathematical aspects of cell-division. He assembled some of the microscopists' pictures and discerned, amidst the daunting complexity, clear patterns and regularities.

He noticed arithmetical patterns in the arrangement of those organelles known as chromosomes, *which contain (most of) the cell's genetic material. He pointed out analogies between cell division and the theories of electricity and gravitation; he also found analogies with chemical diffusion, in a homely experiment using ink in salt water. The shape of a cell — just before, during, and just after division — is mathematical. In cross section, the shape is a simple curve: a circle that develops a waist, which narrows, pinches into a figure-eight shape, and breaks apart to create two circles. This simple shape indicated to Thompson that there must be a connection between the division of cells and the physical principles that govern the forms of soap bubbles and foams.*

One of the key principles of physics is the idea that the inorganic world generally behaves in whatever manner that requires the least expenditure of energy. The energy of a soap bubble comes from the tension that holds its molecules together. (In blowing a balloon one has to provide energy to set up elastic tension in the balloon's rubber surface. The formation of soap bubbles requires much the same type of expenditure of energy). Just as it takes more effort to inflate a bigger balloon than a smaller one, it takes relatively more energy to produce a soap bubble or film with a larger surface area than a smaller one — so soap films with the least energy also have the least surface area.

The French mathematical physicist ***Joseph Plateau*** *discovered that the form of soap bubbles and films can be deduced completely from the principle that they adopt the shape that has the smallest surface area subject to* *boundary – curve or volume constraints. For example, an isolated bubble is spherical because the surface of a sphere is the smallest surface area that contains a specified volume of trapped air. Dividing cells start as a sphere and end as two, passing from one minimal-area surface to another. The figure-eight shape in between is also a minimal-area surface, but a more esoteric one.*

Thompson was fascinated by such surfaces, and he saw them — or at least thought he saw them — everywhere in living creatures. He glimpsed them in cell membranes, in the shapes of jellyfish, in algae, in fungi — even in the skeletons of microscopic creatures. When four soap bubbles meet, they do so along six common surfaces, meeting each other in pairs at an angle of $109°$*. If a fifth, smaller bubble is trapped at the common intersection, it distorts into a rounded pyramid. Exactly the same shape, with the correct angles, can be seen in the silica skeleton of the diminutive organism* Callimitra agnesae.

Thompson saw other mathematical patterns, too. There were obvious ones in radiolarians, which are also microscopic marine creatures with a hard silica skeleton. The bodily scaffolding of these tiny animals displays innumerable and beautiful mathematical patterns, some of which bear a striking resemblance to Euclid's regular solids — the octahedron, dodecahedron, and icosahedron.

Clearly, his discussion made no contact with what is now the dominant theme in modern biology: genetics. What Thompson could not possibly have known is what Crick and Watson recognized in 1953. Their epic discovery was that every cell of every living organism contains a symbolic recipe for that kind of organism, written in a molecular code. This recipe is the organism's genome*, its total genetic makeup, written in the language of DNA.*

DNA plays two linked but distinct roles that make living organisms different from the rest of the physical universe. First, DNA prescribes the growth and the form — and indeed even the behavior — of the organism, using a molecular code. Second, that code recombines and occasionally mutates — changes because of random chemical mistakes — allowing the organism to evolve. So instead of the first–principles mathematics of growth with which D'Arcy Thompson was familiar, life is perpetually and blindly tinkering with its own mathematical basis — nudging its development in preferred directions and away from undesirable ones.

How much of the mathematics of growth survives this nudging? The DNA sequence for an organism can, in principle, create any physically realizable form or pattern — and, in principle, any form whatsoever can also evolve, provided the evolutionary change offers an advantage.

Yet Thompson's key argument is still valid — mathematical patterns exist in living organisms, and these patterns must therefore have mathematical causes.

There are known today (2008 CE) good reasons why the underlying mathematics should have survived such tinkering: living creatures make use of the structures and processes that unfettered physics provides, but those processes have to be modified and controlled before a true living organism can result. Chemical reactions, for instance, tend to slowly run out of important ingredients and grind to a halt.

Organisms solve this problem by replenishing their supply of key chemicals, a trick known as "food." No simple physical or chemical system goes looking for food, but some *of the necessary ingredients of such a system can be found in the inorganic world. Chemicals can diffuse, spread out from their source; the farther away you are from that source, the weaker the concentration of the chemical is. Reversing that process, anything looking for that chemical can climb the gradient, moving in whichever direction increases the concentration. So the physical universe supplies a trick that* could *be used by an organism to search for food.*

Genes come into the picture by making sure that this trick is *used. Genes add a lot of flexibility to growth and form because they control and select the physical patterns that the organism needs. With the help of evolution, any genetic tinkering that works — does something new and useful — may gradually becomes more and more sophisticated. Nevertheless, most of the time, nature employs relatively uncontrived mathematical patterns: spots, stripes, patches, blobs, and other patterns of a type that are explainable by mathematical models. The surface markings of tropical fish, despite their intricacy, are similar to those produced by entirely straightforward mathematical processes, and the same goes for markings on seashells, insects, and mammals.*

It is true that in birds, the forms and patterns do indeed become considerably more exotic. Birds of paradise, for instance, are famous for their fringes, curlicues, spikes, and crests. Also, the basic unit of bird pattern is the feather, which is not a shape traditionally employed by mathematicians. Bird pattern can even change, often in dramatic ways, when the bird changes its position and alters the register *of the feathers — the way they are configured next to each other.*

Nevertheless, the patterns found on birds are made from mathematical ingredients. *The pattern-making mechanism fits those ingredients together in rather arbitrary ways — but that's because evolutionary pressures on markings seem to have been very strong for birds. An exotically marked bird is* *rather like what would be produced by a mad mathematician with a big pattern book and a pair of scissors — a collage of different mathematical forms, rather than a unified whole. Nonetheless, the mathematics is still present.*

Although genetics and evolution are very flexible, they cannot actually do anything. *They can find clever ways to harness physical laws to counterintuitive ends, such as reproduction, but they can't* break *those laws.*

Consider also the hemoglobin molecule, which picks up oxygen from our lungs, carries it in our bloodstream, and releases it where it is needed. Hemoglobin is a highly complex molecule, a protein made by sticking together a large number of units known as "amino acids." A complete hemoglobin molecule acts rather like a pair of pincers: It snaps shut around an oxygen molecule, holds it in its jaws, and opens to release it again sometime later. These abilities depend very sensitively on the precise shape of the hemoglobin molecule, and on its ability to click into slightly different positions — open and shut, so to speak.

Genes prescribe the amino acids that must be put together to make a hemoglobin molecule, but they do not prescribe its actual shape. Indeed the protein folding problem — to predict the three-dimensional geometry of a protein molecule from its sequence of amino acids — lies at the very frontiers of today's science, and we do not understand it at all well. We do understand, however, that the shape of a protein molecule is controlled by more than its genetic code. The shape is a consequence of deep laws of physics and chemistry, which are expressible in mathematical form. So, ultimately, the shape of hemoglobin depends on mathematics.

Genes are not the laws of life; they are what the laws use to operate. As a loose analogy, the current state of the solar system is determined by two things: mathematical laws of motion and gravitation, plus *a list of initial conditions that tell us where all the planets were at some chosen instant. Plug the initial conditions into the laws, and all of the intricacies of the solar system follow.*

There is a strong tendency to think of genes as constituting the laws of biological development, but that's not so; their role is much closer to that of initial conditions. In other words, genes are not the *key to life. They are* a *key, and an enormously important one, but behind them lies something much deeper. There must be more fundamental theories, the true laws of biology, the mathematical rules into which the genetic code is plugged.*

Physics provides a range of patterns and structures that are available. Evolution and genetics can modify those structures and patterns, fine-tune them, and put them together in ways that would not be natural for raw physics; nevertheless, the mathematical patterns provide building blocks and a point *from which genetics and evolution can operate. Moreover, if it so happens that these freely available forms do their job effectively without modification, then evolution will select them, and genetics will respect them. In this manner, these structures and patterns have been built into the very fabric of life.*

Quantification of Nonlinear Biological Phenomena (1917–1985)

Biology deals with phenomena that are intrinsically more complex and more difficult to investigate than those normally studied in the 'hard' sciences such as physics, and not everything which seems obvious is true. Consequently, it is more susceptible to the introduction of hypotheses whose correctness cannot be adequately tested.

Furthermore, mathematical models of biological systems, with their inherent propensity for simplification and idealization, are sometimes so speculative that they have only the merest pretense of accounting for to biological observations.

One must therefore take the mathematical models of these phenomena only as metaphors, and not as "laws" as in astronomy or physics. Nevertheless, there is a body of mathematical ideas and models that is so closely intertwined with biological observations, that it has established a place in the literature of modern biology. The day, furthermore, may come when biological forms and processes can be described with the same mathematical precision as those in physics.

We shall treat here eight topics:

- *Dynamics of non-interacting populations.*
- *Dynamics of interacting species and stability theory.*

- *The Fisher-Kolmogorov equation.*
- *Enzyme kinetics.*
- *Heart-beat equation.*
- *General models of epidemics*
- *Cellular slime molds*
- *Chemotaxis*

Dynamics of non-interacting populations

The use of mathematics in attempts at formulating biological principles has a long history. As far back as 1202, ***Leonardo of Pisa*** *(**Fibonacci**)had clearly thought about population growth in connection with rabbit populations.* ***Giovanni Alfonso Borelli*** *(1608–1679, Italy) presented a quantitative geometrico-mechanical approach to animals' motion in his book De motu animalium (posthumous,* 1680*; several years before Newton's Principia).*

During the 19^{th} *century there was an upsurge of interest in interdisciplinary research among several of the great mathematicians and scientists of the age.* ***D'Arcy Thompson****, influenced by the* 19^{th} *century attempts at more rigorous biological formalisms, published (1917) his work On Growth and Form, a book which marks the advent of modern theoretical biology.*

The works of ***Hardy*** *(1908),* ***Lotka*** *(1920),* ***J.B.S. Haldane*** *(1892–1964, England, 1924),* ***Volterra*** *(1926, 1931),* ***R.A. Fisher*** *(1930)* and ***N. Rashevsky***[382] *(1933 to 1946) advanced the diffusion of mathematical tools and techniques into biological research. In return, biology has confronted mathematicians with a variety of challenging problems which have stimulated developments in the theory of nonlinear (ordinary and partial) differential equations. A few typical examples, chosen from the vast literature of classical mathematical biology, illuminate some of the scenes of nature's drama of life.*

---

382 **Nicolas Rashevsky** (1899–1972, U.S.A.). Pioneering mathematical biologist. Among the first to model the detailed structure of *individual organisms* and the relations of the fundamental parts of each organism to the physical inorganic world. Contributed to mathematical biophysics of *nerve conduction, excitation and inhibition*.

Let N *represent the number of individuals* $N(t)$ *in a given spatial region at any time* t. *The growth law* $\frac{dN}{dt} = g(N) = N\lambda(N)$, *represents the excess of birth rate over death rate, and* $\lambda(N) = \frac{1}{N}\frac{dN}{dt}$ *is the growth rate. If* $\lambda = \text{const} > 0$, *the ensuing law* $N(t) = N_0e^{\lambda t}$ *predicts an exponential growth without limit (**Euler** 1760; **Malthus** 1798), where* $N(0) = N_0$ *is the initial size of the population.*

Although this law may accurately reflect experiments in the early stages of population increase, it obviously cannot hold over an infinitely long period[383]*. For once the population grows sufficiently large, it will begin to interact with the environment, with itself, and with other species due to limited sources of nutrients and also due to competition. All this will cause the birth rate to decrease, the death rate to increase, or both. Thus, crowding may have the same effect as limiting the food supply; space can be considered necessary to sustain life for many species. The simplest model of this kind (**Verhulst**[384], 1838) assumes that normal growth is inhibited by a term proportional to* N^2.

At the beginning of the 20^{th} *century, mathematical models were widely used for describing the growth of bacterial populations and the progress of various diseases, such as malaria. These problems were discussed in terms of ordinary differential equations in which time is the dependent variable and the unknown functions are the average values of the populations densities.*

An example is the growth of a microbial colony; when cells divide, they grow in number but as we know, a colony of bacteria or other microorganisms embedded in a nutrient medium will not grow indefinitely. There are many possible reasons for this: first, multiplication in numbers introduces crowding effects. Biochemically, this may be due to lack of nutrients, shortage of oxygen, the appearance of toxic substances, or changes in ion concentration in the medium, especially pH. Whatever the cause, the natural growth is inhibited due to inter-cell interaction.

---

383 The bacterium **E. Coli** would, under ideal circumstances, divide (on average) every 20 minutes. In this way, one cell (mass $\approx 3 \times 10^{-10}$ gm) could produce $2^{144} \approx 2 \times 10^{43}$ cells within 48 hours — a supercolony whose size and weight are comparable to those of the sun! This never actually happens, for the simple reason that growth cannot continue indefinitely under "ideal circumstances". Even in the absence of competition and predators, nutrients runs out and oxygen runs out: local conditions within the colony change and check the growth of the organisms.

384 **P.F. Verhulst** (1804–1849, Belgium). Initiated his investigations under stimulation from **L.A.J. Quetelet** (1796–1874, Belgium), a statistician and astronomer. The term '*logistic*' was first used by **Edward Wright** (1599) to describe an S-shaped curve.

Thus, the population $N(t)$ *at any time* t *is represented by the ordinary differential equation* $\frac{dN}{dt} = \lambda N - \beta N^2, \ \lambda > 0, \ \beta > 0$. *Here again, the term* λN *represents the excess of the birth rate over the death rate in the absence of interactions. Since the number of intercellular interactions of* N *cells is of the order* N^2, *the plausibility of the inhibition term is explained (e.g.: a given cell detects the cumulative toxic effect of all* N *cells, if the toxic material diffuses freely throughout the intercellular medium. Thus, the toxic effect on a given cell is proportional to* N. *The toxic effect on all* N *cells is* N *times the effect on one cell and hence proportional to* N^2*).*[385]

The stationary value $\left(\frac{dN}{dt} = 0\right)$ *occur at both* $N = 0$ *and* $N_e = \frac{\lambda}{\beta}$, *of which the first is an unstable equilibrium point while the second is stable*[386]. *The exact solution is known as the logistic* law *of growth*

$$N(t) = \frac{N_e}{1 + (\frac{N_e}{N_0} - 1)e^{-\lambda t}}.$$

As $t \to \infty$, *a stable population* $N = N_e$ *is asymptotically attained, with zero growth. The logistic law found applications to various problems in chemical kinetics, biology and economy. In ecology, the growth of populations is inhibited by intra-species deleterious paired encounters (due to competition for food, habitat and other limited resources) proportional to* N^2.

The alternative functional dependence $\lambda(N) = a_1 + a_2 N - a_3 N^2$ $(a_1, a_2, a_3 > 0)$ *found a biological application in populations having a maximum growth rate at intermediate density, an effect that may stem from a difficulty of finding mates at very low density of population.*

A law similar to the Verhulst model applies to the law of mass action *in the chemical kinetics of reactions of the second order:* $\frac{dN}{dt} = \lambda(A - N)(B - N)$, *where* $\lambda, A, B > 0$, λ *now being the* specific reaction rate *at a constantly held temperature. A solution satisfying the initial condition* $N(0) = 0$ *is*

$$N(t) = A\left[1 + \frac{B - A}{A - Be^{\lambda(B-A)t}}\right].$$

When $t \to \infty$, N *tends either to* A, *if* $A < B$, *or to* B, *if* $A > B$.

---

385 Thus, population-dynamics differential equations — whether it be of genome allele frequencies, cells or larger organisms — bear a strong resemblance to *chemical kinetics* equations, governing reaction rates of species of simple *molecules*.

386 In general, the equilibrium points of a system governed by the differential equation $\frac{dN}{dt} = g(N)$ are determined from $g(N_e) = 0$. Near each of these points $g(N) \simeq g'(N_e)(N - N_e)$, from which the stability can be determined by the sign of $g'(N_e)$.

The autocatalytic reaction $\frac{dN}{dt} = \lambda(N + N_0)(B - N)$, *with* $N(0) = 0$, *yields the logistic curve* $N_0 + N = \frac{B+N_0}{1+\frac{B}{N_0}e^{-\lambda(B+N_0)t}}$. *Here, an initial concentration* $N(0) = 0$ *increases initially, as the molecular species in question is produced and eliminated by several pathways: production from steadily–supplied reagents (with or without its own participation), and its elimination (via reactions involving one or two molecules of the species).*

The law $\lambda(N) = -\lambda_0 \ln N$ *(**Gompertz**[387], 1825) is popular in clinical oncology. It is also used by actuaries to estimate the risk of death in life insurance.*

Dynamics of two interacting species

In most ecosystems the conflict between different species must be taken into account, since the growth and decline of populations in nature is strongly affected by the struggle of species to predominate over or prey upon one another. In addition, environmental effects, chance random effects, and spatial heterogeneity, cannot be ignored.

Deterministic mathematical models for the behavior of two interacting species (e.g., trees in a forest, fishes in the oceans, animals on land, etc.) are governed by a system of differential equations

$$\frac{dN_1}{dt} = g_1(N_1, N_2),$$

$$\frac{dN_2}{dt} = g_2(N_1, N_2).$$

387 **Benjamin Gompertz** (1779–1865, England). Mathematician and actuary. Collected data on mortality by natural causes (number of surviving individuals as a function of time).
Gompertz was self-educated, reading Newton and Maclaurin, since he was denied admission to universities on account of being Jewish. He showed (1825) that mortality rate increases in a geometric progression. He became a Fellow of the Royal Society (1819). **Gompertz** — an illustrious Jewish family (since 1600) in Germany, Holland, Britain, United States and Austria-Hungary. The name derived from **Gumpel** — a medieval nickname for **Mordechai**.

If we ignore the effects of each population on itself, there are three distinct types of interaction between two species: both populations enhance each other (symbiosis), both populations conflict with each other (competition), and the hybrid predator-prey interaction such as the plant-herbivore system, the parasite-host system and the fish-shark system.

In 1925, the Italian biologist ***Umberto d'Ancona*** *observed a puzzling biological trend in the fish population of the upper Adriatic: During WWI (1914–1918), commercial fishing in the Adriatic Sea fell to rather low levels. It was anticipated that this would cause a rise in the availability of fish for harvest. Instead, the population of commercially available fish declined on average while the number of sharks and other voracious species, which are their predators, increased! The two populations were also perceived to oscillate. D'Ancona then interested his mathematical colleague,* ***Vito Volterra***[388] *in this problem, and the latter suggested (1926) a somewhat naive model to describe the predator-prey interaction:*

Let $N_1(t)$ denote the fish population (prey) and $N_2(t)$ the predator (shark) population at any given time t. The fish population finds ample food (plankton) all the time, and if not for the sharks would grow in proportion to their number $N_1(t)$. However, their number is constantly reduced due to encounters with sharks, and this decrease rate is proportional both to their density and the density of their predators. Hence

$$\frac{dN_1}{dt} = aN_1 - bN_1N_2 \qquad a, b > 0.$$

On the other hand, in absence of prey, shark will naturally be demised at a rate proportional to their own number. Their rate of increase will depend solely on their food intake, which is again proportional to the rate of encounters with their prey, namely in proportion to N_1N_2.

All told

$$\frac{dN_2}{dt} = -cN_2 + dN_1N_2 \qquad c, d > 0.$$

These two simultaneous differential equations in $\{N_1, N_2\}$, known as the Lotka-Volterra predator-prey equations, have no exact solutions in terms of elementary functions. (The most that can be shown through a straightforward

---

388 Volterra, V., Variazioni e fluttuazioni del numero d'individui in specie animal conviventi, *Mem. Acad. Lincei* **2**, 31–113, 1926.

A similar set of equations was independently derived by **Alfred James Lotka** (1880–1949, U.S.A.) to model observed oscillations in concentrations observed in second order chemical reactions. [Undamped oscillations derived from the law of mass action, *J. Amer. Chem. Soc.* **42**, 1595–1599, 1920.]

analysis is that $t = \int \frac{dv}{vu(v)}$, *where* $u(v)$ *is a solution of the implicit transcendental relation* $(a-u)^a e^u = Ke^{cv}v^{-c}$, $K =$ *integration constant, and* $N_1 = \frac{c}{d}v$. *Similar results are obtained for* N_2, *and* $u = a - bN_2$.*)*

Yet, Volterra was able to extract the salient features of the system's behavior without the explicit knowledge of $N_1(t)$ *and* $N_2(t)$. *Denoting* $x(t) = N_1$, $y(t) = N_2$ *and excluding the trivial solution* $x = 0$, $y = 0$, *there is one nontrivial, static solution with equilibrium populations* $x_e = \frac{c}{d}$, $y_e = \frac{a}{b}$. *Effecting a small perturbation* $x = x_e + X$, $y = y_e + Y$ *about equilibrium, the linearized equations yield the small-amplitude solution*

$$X = \sqrt{x_e Q_x}\cos[\omega(t-t_0)],$$

$$Y = \sqrt{y_e Q_y}\cos\left[\omega(t-t_0) - \frac{\pi}{2}\right],$$

with

$$Q_x = \frac{(x_0-x_e)^2}{x_e} + \frac{(y_0-y_e)^2}{y_e}\frac{b}{d},$$

$$\omega = \sqrt{ac} = \frac{2\pi}{T}, \quad Q_y = \frac{d}{b}Q_x.$$

This result means that, starting from given initial populations $\{x_0, y_0\}$ *at time* t_0, *the trajectories of* $x(t)$ *and* $y(t)$ *are closed curves enclosing* (x_e, y_e), *whose scales shapes asymptotically become ellipses as they shrink to size zero; moreover, the motion* $[x(t), y(t)]$ *becomes simple harmonic motion in that regime, and the family of ellipses are centered at* (x_e, y_e). *The initial state places the system at a point on an approximate ellipse and this point moves, with increasing time, on the ellipse, completing one revolution with a period* $T = \frac{2\pi}{\sqrt{ac}}$.

Volterra then proceeded to show that the qualitative behavior of the system at points which are not necessarily near equilibrium retains the same character: the paths in the xy plane are still closed curves enclosing the equilibrium point, meaning that both $N_1(t)$ *and* $N_2(t)$ *are periodic functions of time, with* N_1 *lagging a quarter of a period behind* N_2. *Thus*

$$N_1(t+T) = N_1(t) \quad , \quad N_2(t+T) = N_2(t).$$

Integrating $\frac{\dot{N}_1}{N_1} = a - bN_2$ *from* 0 *to* T, *we find*

$$\frac{a}{b} = \frac{1}{T}\int_0^T N_2(t)dt = \textit{average value of } N_2(t)$$

over one cycle. Likewise,

$$\frac{c}{d} = \textit{average value of } N_1(t) \textit{ over one cycle.}$$

Thus, both populations vary periodically such that their time-averages coincide with their respective equilibrium values.

This mathematical picture is reasonable: assuming the population of the fish to increase, the sharks would have enough food to sustain a larger population and thus pose a severe threat to the fish. Eventually the population of the plankton-eating fish would diminish. After a while food becomes sparse for the sharks, causing their own population to decrease. A shortage of predators then leads to a resurgence of the fish population. This process may continue indefinitely, in which case, the ecosystem would consist of periodic population variations — an example of biological rhythms.

Fishing *decreases the populations of both species. To account for this we modify the equations of the system into*

$$\dot{N}_1 = aN_1 - bN_1N_2 - \epsilon N_1,$$

$$\dot{N}_2 = -cN_2 + dN_1N_2 - \epsilon N_2,$$

where ϵ is a parameter that reflects the density of fishing (number of boats, nets, etc.). For $a - \epsilon > 0$, the new system is of the same type as before with new average values $\overline{N}_1 = \frac{c+\epsilon}{d}$, $\overline{N}_2 = \frac{a-\epsilon}{b}$ and a new period. So, on average, a moderate amount of fishing increases *the number of fish*[389] *and* decreases *the number of sharks. If, however, fishing is reduced from the new fiducial level*

---

389 The consequence that the prey always recovers more rapidly from a catastrophic event that decimates both species in proportion to their population sizes (e.g., overhunting, fishing, forest fire, etc.), is known as the *Volterra principle*.

A remarkable confirmation comes from the cottony cushion *scale insect* (Icerya purchasi), which, when accidentally introduced from Australia in 1868, threatened to destroy the American citrus industry. Thereupon, its natural Australian predator, a *ladybird beetle* (Novius Cardinalis) was introduced, and the beetles reduced the scale insects to a low level. When DDT was discovered to kill scale insects, it was applied by the orchardists in the hope of further reducing the scale insects. However, in agreement with Volterra's principle, the effect was an increase of the scale insect. Sometimes the predator is so efficient that no cycle emerges at all, though other unexpected side effects may evolve:

An island in the Pacific was a pleasant place and fertile but it had one drawback; it was infested by snakes. In desperation, the natives imported a cage full of mongooses, brought by some sailors especially for them. In no time, the mongooses bred and lived on the snakes to the complete satisfaction of the is-

$\{c+\epsilon, a-\epsilon\}$, *then w.r.t. this new level, the number of sharks will* increase, *and the number of food fish will decrease. This explains the observations of d'Ancona.*

These are somewhat counter-intuitive results. For assume a situation where farmers are dissatisfied with the large number of rabbits in a fox-rabbit ecosystem. Their instinctive impulse would be to introduce more foxes. But the above theory shows that this will only increase the magnitude of the oscillation without changing the mean-values of both species. Only a gradual elimination of both *species by (selective!) animal traps will do. Thus, man's intervention in the role of a superpredator, preying with equal or unequal intensity on* both *species, can changes nature's delicate balance.*

Volterra's theory has spectacular applications to insecticide treatments which destroy both insect predators and their insect prey. It implies that the application of insecticides will actually increase the population of those insects which are kept in control by other predatory insects. Oddly enough, many ecologists and biologists refused to accept Volterra's model as accurate.

One objection is based on the fact that the model predicts an oscillation whose amplitude *is sensitive to the* initial conditions. *Although this seems reasonable for the sharks and fish of the Adriatic, it is entirely unbelievable that lynx and hare populations should oscillate in a manner determined by events a hundred (or more) years ago. Thus a predator-prey model is sought which perhaps indicates oscillation of a type inherent to the* system *rather than determined by initial conditions. (Predator-prey models can be constructed in which the amplitude of oscillation decay as time goes on, as though nature seeks to restore predators and prey to an ecological balance.)*

A more general model of predator-prey interaction is the system

$$\dot{x} = ax - bxy - ex^2,$$

$$\dot{y} = -cy + dxy - fy^2,$$

which include competition among prey for their limited external resources, and also competition among the predators for the limited number of prey. The solutions of this system are not in general periodic. Indeed, if $a, b, c, d, e, f > 0$

landers. But as the snakes were disappearing, the mongooses were multiplying. There were none of their natural enemies on the island, so there was no check to their growth. With diminishing snakes and increasing mongooses, food for the later grew scarcer and they started to feed on the islander's chickens. So the last state of these islanders was worse than the first. They ended up trying to import some animal that kills mongooses...

and $x(0) > 0$, $y(0) > 0$, *every solution approaches the equilibrium solution* $x = \frac{a}{e}$, $y = 0$ *as* $t \to \infty$ *if* $\frac{c}{d} > \frac{a}{e}$.

Finally, special atypical types of predators have their own equations; and several predator-prey interactions in nature cannot be modeled by any system of ODE. *These situations occur when the prey are provided with refuge that is inaccessible to the predators. In these situations it is impossible to make any definitive statements about the future numbers of predators and preys, since we cannot predict how many prey will be stupid enough to leave their refuge. In other words, this process is* random *rather than* deterministic, *and therefore cannot be modeled by a system of* ODE.

Not all species form predator-prey relationship. Two species in an ecosystem may compete for the same *limited source of nutrients. It is assumed that the effect of competition is to reduce each species' growth-rate by an amount proportional to the other species' population. Consequently,*

$$\dot{N}_1 = aN_1 - bN_1^2 - kN_1N_2,$$

$$\dot{N}_2 = cN_2 - dN_2^2 - \sigma N_1N_2.$$

Volterra showed that if $\frac{k}{d} < \frac{a}{c} = \frac{b}{\sigma}$, *species* N_2 *will die out and* N_1 *will approach the value* $\frac{a}{b}$. *This is known as the* Volterra principle of competitive exclusion.

The stability theory *of the* Volterra-Lotka *equations is analyzed with the aid of the* Lyapunov function. *Consider the nonlinear system of ODE governing the interaction of* n *species*

$$\dot{N}_i = k_iN_i + \frac{1}{\beta_i}\sum_{j=1}^{n} a_{ij}N_iN_j = N_i\left[k_i + \frac{1}{\beta_i}\sum_{j=1}^{n} a_{ij}N_j\right]$$

where $a_{ii} \le 0$, $\beta_i > 0$, $i = 1, 2, \ldots, n$, $\det|a_{ij}| > 0$ *and* $a_{ij} = -a_{ji}$ *(a loss for one species in an interaction produces a gain for the other).*

The different efficiencies of the species are accounted for by the factors β_i. *If we set* $V_i = \ln\left(\frac{N_i}{q_i}\right)$, *where* $q_i > 0$ *are arbitrary, then*

$$\dot{V}_i = k_i + \frac{1}{\beta_i}\sum_{j=1}^{n} a_{ij}q_je^{V_j}.$$

Assume (without loss of generality) that $k_i\beta_i = -\sum_{j=1}^{n} a_{ij}q_j$ *is satisfied. Then*

$$\beta_i\dot{V}_i = \sum_{j=1}^{n} a_{ij}q_j(e^{V_j} - 1),$$

and $V_j = 0$ *is the only fixed point. Following* **Volterra**, *we multiply the last equation by* $(e^{V_i} - 1)q_i$ *and sum on* i *to obtain (using* $a_{ij} = -a_{ji}$ *and* $a_{ii} \le 0$*),*

$$\frac{d}{dt}\sum_{i=1}^{n} \beta_i q_i \left[e^{V_i} - V_i\right] \le 0$$

But since $(e^{V_i} - V_i) \ge 1$ *for all values of* V_i*, the definition of the new function*

$$L(V) = \sum_{i=1}^{n} \beta_i q_i \left[e^{V_i} - V_i - 1\right]$$

ensures $L(0) = 0$, $L(V) > 0$ *and* $\frac{dL}{dt} \le 0$ *for all* $|\boldsymbol{V}| > 0$.

Hence $L(V)$ *is a global Lyapunov function. Since no* V_i *can become arbitrarily large, the system is of bounded stability under the said conditions.*

Moreover, if $a_{ii} < 0$ *(does not vanish),* $V_i = 0$ *is asymptotically stable.*

Stability of food chains: an ecosystem is composed of n *members (chains with up to 6 members are found in nature). The first population is the prey for the second, which is a prey for the third etc. ... up to the* n*-th, which is at the top of the food chain. Taking competition within each species into account, and assuming interaction terms with constant coefficients, one obtains*

$$\dot{N}_1 = N_1(k_1 - a_{11}N_1 - a_{12}N_2),$$
$$\dot{N}_j = N_j(-k_j + a_{j,j-1}N_{j-1} - a_{jj}N_j - a_{j,j+1}N_{j+1}), \qquad j = 2, \ldots, n-1,$$
$$\dot{N}_n = N_n(-k_n + a_{n,n-1}N_{n-1} - a_{nn}N_n).$$

If all $k_j, a_{ij} > 0$*, it can be shown that the above system of ODE admits a stable equilibrium point, just as in the case of the prey-preditor case* $n = 2$.

Cyclic competition: If three or more species compete, a rather curious thing can occur. It may look for some time as if species 1 were bound to be the unique survivor; then, suddenly, its density drops, species 2 takes its place and seems to dominate the ecosystem; after some time, it in turn collapses, and leaves the field to species 3, which appears to be the ultimate winner; but then, species 1 suddenly rallies and outcompetes its rivals, and so another "round" starts. The species supersede each other in cyclic fashion: the time *spans during which one species predominates grows larger and larger. Such a behavior is represented by the ODE system:*

$$\dot{N}_1 = N_1(1 - N_1 - \alpha N_2 - \beta N_3),$$
$$\dot{N}_2 = N_2(1 - \beta N_1 - N_2 - \alpha N_3),$$
$$\dot{N}_3 = N_3(1 - \alpha N_1 - \beta N_2 - N_3)$$

The special symmetry assumption behind the model is that of a cyclic interaction between the species: if we replace 1 *by* 2, 2 *by* 3 *and* 3 *by* 1, *the equation will remain unchanged. The system admits a unique* interior rest point $\boldsymbol{m}$ *at* $m_1 = m_2 = m_3 = \frac{1}{1+\alpha+\beta}$.

The Jacobian at the point $\boldsymbol{m}$ *is the* circulant matrix[390]

$$\frac{1}{1+\alpha+\beta}\begin{bmatrix} -1 & -\alpha & -\beta \\ -\beta & -1 & -\alpha \\ -\alpha & -\beta & -1 \end{bmatrix}.$$

Its eigenvalues are $\gamma_0 = -1$ *[with eigenvector* $(1,1,1)$*] and*

$$\gamma_1 = \bar{\gamma}_2 = \frac{1}{1+\alpha+\beta}(-1 - \alpha e^{\frac{2\pi i}{3}} - \beta e^{\frac{4\pi i}{3}}).$$

The real part of γ_1 *and* γ_2 *is thus* $\frac{1}{1+\alpha+\beta}(-1 + \frac{\alpha+\beta}{2})$, *assumed positive. Hence* $\boldsymbol{m}$ *is a* saddle point. *There are four other rest points: the origin* 0 *and the saddles* $\boldsymbol{e}_1$, $\boldsymbol{e}_2$, $\boldsymbol{e}_3$ *(the coordinate axes unit vectors).*

A study of stability in the $N_1N_2N_3$ *space then shows that the state remains for some time close to the rest-point* $\boldsymbol{e}_1$, *then travels to the vicinity of the rest-point* $\boldsymbol{e}_2$, *lingers there for a still longer time, then transitions to the vicinity of*

---

[390] An $n \times n$ matrix is said to be a *circulant* if it is of the form

$$\begin{bmatrix} c_0 & c_1 & c_2 & \dots & c_{n-1} \\ c_{n-1} & c_0 & c_1 & \dots & c_{n-2} \\ \vdots & \vdots & \vdots & & \vdots \\ c_1 & c_2 & c_3 & \dots & c_0 \end{bmatrix},$$

where a cyclic permutation sends the elements of each row into those of the next one. Its *eigenvalues* are $\gamma_k = \sum_{j=0}^{n-1} c_j \lambda^{jk}$, $k = 0, \dots, n-1$ and *eigenvectors* $y_k = \left(1, \lambda^k, \lambda^{2k}, \dots \lambda^{(n-1)k}\right)$ where λ is the nth root of unity $\lambda = e^{2\pi i/n}$.

the rest-point $\boldsymbol{e}_3$, *and so on in cyclic fits and starts. This model thus suggests a surprising mechanism for sudden upheavals in ecological communities.*

The Fisher-Kolmogorov equation

A single species grows to saturation and diffuses according to the partial differential equation

$$\frac{\partial u}{\partial t} = D\frac{\partial^2 u}{\partial x^2} + au - bu^2, \qquad D > 0, \quad a > 0, \tag{1}$$

where D *is the diffusion coefficient (diffusivity) and* (a, b) *are the parameters of the logistic growth.*

This equation describes nonlinear evolution of a population u *in a one-dimensional habitat. It was introduced by* ***R.A. Fisher*** *(1936) to describe the propagation of a virile mutant in an infinitely long habitat. It also represents, with a minor variation, a model equation for the evolution of a neutron population in a nuclear reactor (a finite domain). A complex version (Nonlinear Schrödinger Equation) models laser dynamics in a medium of two-state atoms or molecules.*

Equation (1) describes a balance between linear diffusion and nonlinear local multiplication and admits shock-like solutions.

Special case:

$b = 0$ *(simple growth with diffusion)* $0 \le x \le L$ *(finite region).*

Diffusion is proportional to surface area while growth (reproduction) is proportional to volume. For a sphere of radius R, *the ratio of surface area to volume is proportional to* $\frac{1}{R} \approx \frac{\text{diffusion}}{\text{growth}}$. *As* R *decreases, diffusion plays an increasingly important role and eventually a limit is reached beyond which growth can no longer compensate for loss due to diffusion. This is the critical size* $L_c = f(D, a)$. *Dimensional analysis yields*

$$[D] = L^2T^{-1}, \quad [a] = T^{-1}, \qquad \Rightarrow \qquad L_c = \gamma\sqrt{\frac{D}{a}} \quad \text{or} \quad (a - \gamma^2\frac{D}{L_c^2}) = 0,$$

where γ *is a non-dimensional constant of order unity. Assuming boundary conditions* $u(0, t) = u(L, t) = 0$ *and initial condition* $u(x, 0) = f(x)$, *a Fourier-series solution for the one-dimensional case is*

$$\left.\begin{aligned} u(x,t) &= \textstyle\sum_{n=1}^{\infty} A_n \sin(\frac{n\pi x}{L}) e^{(a-\frac{D\pi^2 n^2}{L^2})t} \\ A_n &= \textstyle\frac{2}{L}\int_0^L f(x)\sin(\frac{\pi n x}{L})\,dx \end{aligned}\right\}$$

If $a < \frac{D\pi^2}{L^2}$*, the population will be unable to maintain itself against diffusion and disappear. If* $a > \frac{D\pi^2}{L^2}$*, at least the first term will increase indefinitely with time. Therefore*

$$L_c = \pi\sqrt{\frac{D}{a}} \qquad \text{in one dimension}$$

and it can be shown that:

$$L_c = 4.81\sqrt{\frac{D}{a}} \qquad \text{in two dimensions} \tag{2}$$

Now, the exact solution of $\frac{\partial u}{\partial t} = D\frac{\partial^2 u}{\partial x^2} + au$, $a > 0$ *with* $u(x,0) = f(x) = u_0\delta(x)$ *(Dirac delta–function) and as the boundaries are removed to infinity, is*

$$u(x,t) = \frac{u_0}{2\sqrt{\pi D t}} \exp\left(at - \frac{x^2}{4Dt}\right).$$

The exponent is zero at $\frac{x}{t} = 2\sqrt{aD} = V$ *(defined). We can say that the surface* $u = \text{const}$ *propagates with approximate velocity* v*. A similar result holds in higher dimensions.*

Traveling wavefront solutions (Kolmogorov, 1936)

The substitution

$$u = \frac{a}{b}\bar{u}, \qquad t = \frac{1}{a}\bar{t}, \qquad x = \sqrt{\frac{D}{a}}\bar{x}$$

transforms the Fisher equation into the nondimensional *form*

$$\frac{\partial \bar{u}}{\partial \bar{t}} = \frac{\partial^2 \bar{u}}{\partial \bar{x}^2} + \bar{u}(1-\bar{u}) \tag{3}$$

We seek solutions of (3) *which have a 'plane wave' form of speed c:*

$$\bar{u}(\bar{x},\bar{t}) = U(\bar{x}-\bar{t}) = U(s), \qquad c = \sqrt{aD}\,\bar{c}, \quad \bar{c} > 0 \tag{4}$$

Substitution into (3)*, shows* U *to satisfy equation of the* ***Liénard*** *type*

$$U'' + \bar{c}U' + U(1-U) = 0, \tag{5}$$

where $\bar{c}$ *is chosen such that*

$$\begin{aligned} &U(\infty) = 0 \text{ (before wavefront's arrival)}, \\ &U(-\infty) = 1 \text{ (after front's departure)}. \end{aligned} \tag{6}$$

Eq. (5) can be replaced by a system of two coupled first-order ODEs

$$\left.\begin{aligned} \frac{dU}{ds} &= V \\ \frac{dV}{ds} &= -\bar{c}V - U(1-U) \end{aligned}\right\} \tag{7}$$

This flow has two singular points in the phase plane (U, V), *namely* $(0,0)$ *and* $(1,0)$, *which are obviously steady states:* $U' = 0$, $V' = 0$. *A linear stability analysis shows that the eigenvalues* λ *for the singular points are*

$$\begin{aligned} &(0,0) \qquad \lambda_{\pm} = \tfrac{1}{2}[-\bar{c} \pm \sqrt{\bar{c}^2 - 4}] \Rightarrow \quad \text{stable node} \quad \text{if} \quad \bar{c}^2 \geq 4 \\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{stable spiral} \quad \text{if} \quad \bar{c}^2 < 4 \\ &(1,0) \qquad \lambda_{\pm} = \tfrac{1}{2}[-\bar{c} \pm \sqrt{\bar{c}^2 + 4}] \Rightarrow \quad \text{saddle point} \end{aligned} \tag{8}$$

From this, one is able to show that for all wave speeds

$$c \geq c_{\min} = 2\sqrt{aD} \tag{9}$$

there exists a progressive wave that satisfies the Fisher equation such that $0 \leq U \leq 1$, $U(\infty) = 0$, $U(-\infty) = 1$. *The remarkable result here is that there is a continuum of waves, all having different speeds (as with solitary waves in hydrodynamics).*

A key question still to be answered is: what kind of initial conditions $u(x, 0)$ *for the original Fisher equation will evolve into a traveling wave solution, and if such a solution exists, what is its wave speed c.* ***Kolmogorov*** *(1937) gave the following answer:*

If $\bar{u}(\bar{x}, 0) = \begin{cases} 1 & \bar{x} \leq \bar{x}_1 \\ 0 & \bar{x} \geq \bar{x}_2 \end{cases}$ *where* $\bar{x}_1 < \bar{x}_2$ *and* $\bar{u}(\bar{x}, 0)$ *is arbitrary but continuous in* $\bar{x}_1 < \bar{x} < \bar{x}_2$, *then the solution* $\bar{u}(\bar{x}, t)$ *of (3) evolves to a traveling wavefront with* $\bar{z} = \bar{x} - 2t$ *(minimal speed). It can also be shown that in general, the wavefront solution of*

$$\frac{\partial \bar{u}}{\partial \bar{t}} = f(\bar{u}) + \frac{\partial^2 \bar{u}}{\partial x^2}, \tag{10}$$

[where $f(\bar{u})$ has only two zeros (say u_1 and $u_2 > u_1$), $f'(u_1) > 0$ and $f'(u_2) < 0$] evolve with $\bar{u}$ going monotonically from u_1 to u_2 with wave speeds

$$\bar{c} \geq \bar{c}_{\min} = 2\sqrt{f'(u_1)}. \tag{11}$$

Enzyme kinetics

Biochemical reactions are continually taking place in all living organisms and most of them involve large proteins molecules called enzymes, *which act as remarkably efficient* catalysts. *A catalyst accelerates the rate of a reaction but is not consumed in the overall process. Enzymes react selectively on definite compounds undergoing chemical reaction, called* substrates. *For example, hemoglobin in red blood cells is an enzyme and oxygen, with which it combines, is a substrate. Enzymes are important in regulating biological processes, for example as* activators *or* inhibitors *in a reaction.*

Biological catalysts differ from all other catalysts known to chemistry in two essential ways. First, they are exceptionally efficient *under the mild conditions holding in the normal physiological state: aqueous medium, standard pressure, and physiological pH and temperature ranges. Second, a single enzyme molecule can transform 10^3 to 10^6 molecules of substrate per minute. That is why their catalytic function in a cell can be performed* rapidly *and why* extremely small quantities *of enzyme suffice to enable cellular processes.*

One of the most basic enzymatic reaction mechanisms, first proposed (1913) for the yeast-catalyzed conversion of sucrose to glucose and fructose by **Leonor Michaelis** *(1875–1949,* Germany, U.S.A.*) and* **M.I. Menten** *[and later represented mathematically by* **Haldane** *(1925)], has been successful in describing most enzymatically controlled reactions.*

A substrate molecule S reacts with an enzyme molecule E to form a complex molecule C which in turn is converted into a product P and the enzyme. The reactions in question can be symbolized by

$$E + S \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} C \overset{k_2}{\rightarrow} E + P.$$

Let $e(t)$, $s(t)$, $c(t)$ and $p(t)$ denote the molar concentrations of the respective molecular species. Applying the law of mass action, *one finds that the* *following are the differential equations and initial conditions that correspond to the above reaction:*

$$\frac{ds}{dt} = -k_1 es + k_{-1}c,$$

$$\frac{de}{dt} = -k_1 es + (k_{-1} + k_2)c,$$

$$\frac{dp}{dt} = k_2 c,$$

$$\frac{dc}{dt} = k_1 es - (k_{-1} + k_2)c,$$

$$s(0) = s_0, \quad e(0) = e_0, \quad c(0) = 0, \quad p(0) = 0.$$

Since $e(t) + c(t) = e_0$, *and* $p(t) = k_2 \int_0^t c(t')dt'$, *the above system, after scaling out dimensionful quantities, reduces to the system*

$$\frac{du}{d\tau} = -u + (u + K - \lambda)v,$$

$$\epsilon\frac{dv}{d\tau} = u - (u + K)v,$$

$$u(0) = 1, \qquad v(0) = 0, \qquad \tau = (k_1 e_0)t,$$

$$u(\tau) = \frac{s(t)}{s_0}, \qquad v(\tau) = \frac{c(t)}{e_0}, \qquad \lambda = \frac{k_2}{k_1 s_0},$$

$$K = \frac{k_{-1} + k_2}{k_1 s_0}, \qquad \epsilon = \frac{e_0}{s_0}.$$

This system consists of two nonlinear differential equations in the unknown concentration of the substrate S and the complex C.

Biochemists commonly wish to determine the velocity of reaction, *which is usually defined as either the rate of appearance of the product P, or the rate of disappearance of the substrate S. Since an exact analytical solution is not available, and even the numerical solution of the equations is hampered*[391] *by the smallness of ϵ, an approximation is sought which renders a theoretical value for the measured initial velocity of reaction.*

An assumption is made that a quasi-steady state *("pre-equilibrium") is established very rapidly, so that the concentration of C is changing very*

---

391 ϵ is typically in the range 10^{-2} to 10^{-7}. Since ϵ multiplies the highest derivative in the second equation, this is a *singular perturbation problem* with an ensuing *boundary layer* near the time origin $\tau = 0$.

slowly with time. Thus, we assume that $\frac{dv}{d\tau} = 0$*. With this assumption the second equation becomes algebraic, rendering* $v = \frac{u}{u+K}$.

Substituting this value into the first equation we obtain $\frac{ds}{dt}\,|_{t=0} = -\frac{k_2 e_0 s_0}{s_0 + k_m}$, *where* $k_m = \frac{k_{-1}+k_2}{k_1}$ *is the Michaelis constant. This rate, based on the quasi-steady state hypothesis, is what is usually needed from a biological point of view.*

The above set of nonlinear equations serve to model a variety of reaction pathways in molecular biology; for example — the way in which bacteria consume organic substance such as glucose[392].

Thermodynamic principles can be invoked to show that catalysts lower the free energy of activation, thus exponentially increasing the effective reaction rate constant which, in turn, speeds up the process. Still, the lowering of the free energy barrier (activation energy) must be explained in terms of a plausible molecular physical mechanism*. Obviously, the energy that can be expended by the enzyme in order to speed up the reaction can come only from one source — it is a part of the free energy liberated upon binding of the substrate to the enzyme*[393]*. That energy is recovered when the enzyme separates from the reaction product(s), and the enzyme molecule is then ready to catalyze the next reaction.*

---

[392] Most water-soluble molecules are unable to pass through the hydrophobic environment of the cell membrane directly and must be carried across by special means. Typically, molecular receptors embedded in the bacterial cell membrane are involved in "capturing" these polar molecules in a *loose complex*, conveying them across the membrane barrier, and releasing them to the interior of the cell. The mechanism for nutrient uptake can be described by *Michaelis-Menten kinetics.*

[393] No universal *physical* model valid for all known enzyme reactions has been found. Thus, *electrostatic* dipole interactions were found to be important in *lysozyme* catalysis. In other cases, a hypothesis has been advanced, according to which the liberated free energy is transformed to the energy of *elastic vibrations* of the enzyme globule, which behaves like a liquid drop. The frequencies of such vibrations lie in the hypersonic region — up to 10^{13} sec^{-1}. The standing waves in the liquid drop can then activate the substrate molecule.

Heart-beat equations

The heart is a large hollow muscle which acts as a machine that pumps blood to all parts of the body. Tubes called veins *bring blood to the heart. Other tubes called* arteries *carry blood away from the heart. Four regulators called* valves *control the flow of blood through the heart itself. The heart is divided, lengthwise, by a muscular wall (*septum*). Two chambers, one above the other, are on each side of the septum. The upper chamber on each side is called an* atrium*. The atria collect the blood flowing into the heart from the veins. Below each atrium is another chamber called a* ventricle*. The two ventricles pump the blood into the arteries.*

The tricuspid valve *is between the right atrium and the right ventricle. The* mitral valve *is between the left atrium and the left ventricle. The* semilunar valve *controls the flow of blood from the ventricles to the arteries.*

The right hand side of the heart is a low pressure pump *that takes blood* from the body *and pumps it to the lungs (where carbon dioxide is removed and oxygen is added). It is a low-pressure circuit to avoid damaging the delicate membranes in the lungs.*

The left-hand side is a high-pressure pump *that collects blood from the lungs and delivers it* to the body*. The high pressure is needed in order for the blood to get down to the feet and up again.*

*The two sides of the heart simultaneously undergo two basic states: relax and fill (*diastole *state), contract and empty (*systole *state). The atria contract only a split second before the ventricles do. The action felt as a heartbeat is the systole. The sequence of events is divided into four phases:*

(1) *Blood flows into the heart from the veins, filling both atria. The tricuspid and mitral valves are closed.* The heart relaxes *in the diastolic phase.*

(2) The atria contract*. The mitral and tricuspid valves open, and through them the blood flows into the ventricles (one way only!). Ventricles are still relaxed.*

(3) Ventricles contract*, mitral and tricuspid valves shut, semilunar valves open. Blood enters the body via the aorta on the left side and to the lungs via the pulmonary artery on the right side.*

(4) Semilunar valves close *and the atria expand and fill with blood. A new diastole begins.*

The blood in the circulatory system is always under pressure, as is water in the pipes of a water system. Blood pressure depends upon the amount of *blood* in the system, the *strength and rate* of the heart's contraction, and the *elasticity* of the arteries. The *systolic pressure* is the blood pressure when the heart is contracted (high). The *diastolic pressure* is the pressure when the heart relaxes between beats.

What makes the heart beat is the presence of a *pacemaker* which is located on the top of the atria. It triggers an electrochemical impulse which spreads *slowly* over the atria, causing the muscle fibers to contract and push blood into the ventricles, and then spread *rapidly* over the ventricles causing the whole ventricle to contract into systole and deliver a big pump of blood down the arteries. The muscle fiber then rapidly relax and return the heart to diastole.

In order to develop a mathematical model which reflects the behavior of the heartbeat action described above, the following features are singled out:

I. The *rate of change of the muscle fiber* contraction depends, at any particular instant, on the tension of the fiber and on the chemical control.

II. *The chemical control changes* at a rate directly proportional to the muscle fiber extension.

III. The model must exhibit an equilibrium state corresponding to *diastole*.

IV. The model should contain a *threshold*, i.e., a definite point where the ventricles begin their rapid contraction. While this contraction is going on, the chemical control variable will be rising to a new value corresponding to a *systole*.

V. The model should reflect the rapid return to the equilibrium state.

Let $x(t)$ denote the length of a typical muscle fiber, and $y(t)$ the chemical control that governs the electrochemical pulse. A coupling that incorporates all the above features renders the *heart-beat equations*

$$\epsilon \frac{dx}{dt} = -(x^3 - ax + y),$$

$$\frac{dy}{dt} = x - x_0 + (x_0 - x_1)u = x - x_m.$$

Here, ϵ is a small parameter, which guarantees the rapid decrease of $x(t)$ (and at the same time the fast increase of $\frac{dx}{dt}$) through the transition from diastole (x_0, y_0) to systole (x_1, y_1). u is a control parameter associated with the pacemaker, and is defined as follows:

$$u = 1 \quad \text{for} \quad \begin{Bmatrix} y_0 \le y \le y_1 & \text{and } x^3 - ax + y > 0 \\ \text{or: } y > y_1 & \text{and all } x \end{Bmatrix}$$

$$u = 0 \quad \text{otherwise.}$$

The elimination of y from the above equations yields the Van der Pol equation[394] $\epsilon\ddot{x} - \dot{x}(a - 3x^2) + x - x_m = 0$.

[394] In 1927, **Van der Pol** was first to suggest a *relaxation oscillation* model of heartbeats. His electrical model of the heart consisted of three connected relaxation oscillators (one for the pacemaker, one for the atria, and one for the ventricles), each governed by the equation $\ddot{x} - \epsilon(1 - x^2)\dot{x} + \omega^2 x = 0$. The model given in the text is due to **E.C. Zeeman** (1972).

The Van der Pol equation also appears in certain ecological problems, where a population of herbivores interacts with vegetation in such a way that a *stable limit cycle* is established. The equations are $\frac{du}{dt} = \epsilon\left(u - \frac{u^3}{3}\right) + v$, $\frac{dv}{dt} = -u$, where ϵ is a fixed small, positive number, and $\{u, v\}$ are interpreted as (scaled) deviations of herbivore and vegetative biomasses from reference equilibrium values.

General models of epidemics

The Great Plague of London in 1665 *started in June; its peak came in September and its decline in October. The secondary rise occurred in November and cases of the disease were reported as late as March of the following year. The people of the city followed with anxiety the rise and fall in the number of deaths from the plague, hoping always to see the sharp decline which they knew from past experience indicated that the epidemic was nearing its end.*

When the decline came, the refugees, mostly from the nobility and wealthy merchants, returned to the city, and then for a time the mortality rose again as the disease attacked these new arrivals. The cause of these periodic outbreaks was, however, attributed to evil spirits. Even as late as 1865 *it was still believed in scientific circles that the periodicity of outbreaks of pestilence corresponds with the period of revolution of the lunar node.*

The first mathematical model, involving a nonlinear ordinary differential equation, was produced by ***Daniel Bernoulli*** *(1760), who considered the effect of cow-pox inoculation on the spread of smallpox.*

Some of the earliest classic works on the theory of epidemics is due to ***Kermack*** *and* ***McKendrick***[395] *(1927), who for the first time modeled some general aspects of disease transmission and the temporal development of epidemics. In their model, the total population is taken to be constant (the disease is of short duration relative to natural birth and death processes).*

Consider a host population, subdivided at time t *into three distinct classes according to the health state of its members:* $S(t)$ susceptible *individuals (not yet sick),* $I(t)$ infected *who may transmit the disease, and the* removed *class,* $R(t)$*, who can no longer contract the disease because they have recovered with immunity, have been placed in isolation, or have died. The progress of individuals is schematically described by* $S \to I \to R$*, and therefore the model is called the* SIR *model. The assumptions made about the transmission of the infection and incubation are these:*

(1) The gain of the infected class is at a rate proportional to the numbers of infected and susceptible.

(2) The rate of removal of the infected to the removed class is proportional to the number of infected.

---

395 **Kermack, W.O.** and **A.G. McKendrick**, 'Contribution to the mathematical theory of epidemics', *Jour. Roy. Statis. Soc.* **115**, 700–721, 1927.

(3) *The incubation period is short enough to be negligible; that is — a susceptible who contracts the disease is infected right away (not a valid assumption for many diseases!).*

(4) *Every pair of individuals has equal probability of coming into contact with each other.*

The rate equations then become

$$\frac{dS}{dt} = -\beta SI, \qquad \frac{dI}{dt} = \beta SI - \alpha I,$$

$$\frac{dR}{dt} = \alpha I, \text{ with } S(t) + I(t) + R(t) = N = \text{total size of population.}$$

$$\alpha, \beta > 0, \qquad S(0) = S_0, \qquad I(0) = I_0 > 0, \qquad R(0) = 0.$$

Here β is the rate of transmission while α is the rate of removal. A key question in any epidemic situation is: given $\{\beta, \alpha, S_0, I_0\}$, will the infection spread or not, and if it does — when will it start to decline.

As in many other examples of nonlinear differential equations, the exact analytical solution of the Kermack-McKendrick system cannot be presented in a form which renders answers to the above questions. On the other hand, the questions can be answered by squeezing out information from the equations themselves without actually solving them. The following logical steps are taken:

(A) *Since $S(t)$ is nonnegative, the equation $\frac{dS}{dt} = -\beta SI$ implies that for $t > t_1 > 0$, $S(t) < S(t_1) < S(0)$. Furthermore, the limit of $S(t)$ exists as $t \to \infty$. Only solutions for which $S(t) > 0$, $I(t) > 0$ are of concern.*

(B) *From $\frac{dI}{dt} = (\beta S - \alpha)I$ and (A), it follows that if $\beta S_0 < \alpha$, $\frac{dI}{dt} < 0$ for all t, $I_0 > I(t) \to 0$ as $t \to \infty$ and the infection is eventually wiped out, and no epidemic can occur.*

For a disease to spread (i.e., to have an epidemic), S_0 must exceed the critical threshold value $S_c = \frac{\alpha}{\beta}$. The term epidemic *means that $I(t) > I_0$ for some $t > 0$.*

In this model, as time proceeds, S decreases and I increases until $S = S_c$ and $I = I_{\max}$. The function $I(t)$ then starts to decrease *until $\lim_{t\to\infty} I(t) = 0$, so the epidemic asymptotically stops.*

(C) $\frac{dR}{dt} = \alpha I$ *tells us that* $R(t)$ *increases monotonically while* $R \leq N$. *Hence* $R(\infty)$ *exists, and so does* $I(\infty) = 0$. *The quantity* $\frac{1}{N}[I(\infty) + R(\infty)]$ *is a measure of the extent to which the infection swept through the population.*

(D) *From the first and the third equations we deduce* $\frac{dS}{dR} = -\frac{\beta}{\alpha}S$ *so that* $S = S_0 e^{-\frac{\beta}{\alpha}R}$. *Since* $R \leq N$, *it is true that* $S \geq S_0 e^{-\frac{N\beta}{\alpha}}$, *which in turn implies that* $S(\infty) > 0$, *i.e., the disease dies out from lack of potential infecteds and not from a lack of susceptibles.*

(E) *The first two equations yield, upon their division,*

$$\frac{dI}{dS} = -1 + \frac{\alpha}{\beta S}$$

whence

$$I = N - S + \frac{\alpha}{\beta}\log_e\left(\frac{S}{S_0}\right).$$

Clearly

$$I_{\max} = N - S_c + \frac{\alpha}{\beta}\log_e\left(\frac{S_c}{S_0}\right).$$

As time goes on $I(t)$ *declines and eventually* $I(\infty) = 0$. *The value of* $S(\infty)$ *is determined from the transcendental equation*

$$S(\infty) = S(0)e^{-\frac{\beta}{\alpha}[N - S(\infty)]}.$$

This equation is satisfied by only one positive value of $S(\infty) < \frac{\alpha}{\beta} = S_c$. *Once* $S(\infty)$ *is known,* $R(\infty)$ *can be calculated from* $R(\infty) = N - S(\infty)$.

(F) *The* exact *equation for* $R(t)$ *is*

$$\frac{dR}{dt} = \alpha\left[N - R - S_0 e^{-\frac{\beta}{\alpha}R}\right], \quad R(0) = 0,$$

which can be integrated numerically provided α, β, S_0 *and* N *are known.*

(G) *When the infection spreads to unacceptable levels, immunity can be introduced by means of* vaccination. *It is then assumed that vaccination removes the individual instantaneously from* S *to* R *without joining group*

I, and a screening is available which prevents the infected from being vaccinated. Consequently, the first equation is modified into

$$\frac{dS}{dt} = -\beta SI - \gamma(t),$$

while a fourth equation is added $\frac{dV}{dt} = \gamma(t)$, where $V(t)$ is the group of vaccinated individuals; the conservation constraint then becomes: $S + I + R = N - V$.

So far it has been assumed that the population is thoroughly mixed, so that there is no distinction between individuals in one place and those in another. When this is not so, the disease may spread faster in some regions than in others, and it is necessary to allow for the dependent variables to depend on space *as well as on* time*. The geographic spread of infections has indeed been well observed in the form of* spatial epidemic waves*, in addition to the temporal variation in specific regions that was discussed above.*

The best known historical example is the medieval Black Death of 1347–1350*. A less known example is the plague bacillus that was brought by ship to the northwest of America around* 1900*; It has been carried ever since, with an average speed of about* 55 *km/year, via a large number of wild native animals (rats, squirrels, coyotes, mice, bats and domestic pets). Epidemics such as Asian flu appear to travel like a wave across the earth.*

If the spatial dispersal of I and S is modeled by simple diffusion *with the same diffusion coefficient, and the population is assumed to consist only of susceptibles $S(x,t)$ and infecteds $I(x,t)$, the Kermack-McKendrick equations are generalized into*

$$\frac{\partial S}{\partial t} = -\beta SI + D\frac{\partial^2 S}{\partial x^2},$$

$$\frac{\partial I}{\partial t} = \beta SI - \alpha I + D\frac{\partial^2 I}{\partial x^2},$$

where $\alpha, \beta, D > 0$. The non-dimensionalization

$$\overline{I} = \frac{I}{S_0}, \qquad \overline{S} = \frac{S}{S_0},$$

$$\overline{x} = \left(\sqrt{\frac{\beta S_0}{D}}\right)x, \qquad \tau = (\beta S_0)t, \qquad \lambda = \frac{\alpha}{\beta S_0}$$

yields

$$\frac{\partial \overline{S}}{\partial \tau} = -\overline{I}\,\overline{S} + \frac{\partial^2 \overline{S}}{\partial \overline{x}^2}, \qquad \frac{\partial \overline{I}}{\partial \tau} = \overline{I}\,\overline{S} - \lambda\overline{I} + \frac{\partial^2 \overline{I}}{\partial \overline{x}^2}.$$

We assume the existence of a traveling wave solution of constant shape, through which the infection spreads spatially into a uniform population of susceptibles, i.e.,

$$I(x,t) = I(\overline{x} - \bar{c}\tau), \quad S(x,t) = S(\overline{x} - \bar{c}\tau),$$

where c *is the dimensionless wave speed, as yet unspecified. Substituting these into the above partial differential equations yields a pair of coupled nonlinear ordinary differential equations:*

$$\overline{I}'' + \bar{c}\overline{I}' + \overline{I}(\overline{S} - \lambda) = 0,$$

$$\overline{S}'' + \bar{c}\overline{S}' - \overline{I}\,\overline{S} = 0,$$

$$\overline{I}(\infty) = \overline{I}(-\infty) = 0,$$

$$0 \le \overline{S}(-\infty) < \overline{S}(\infty) = 1, \qquad I \ge 0, \qquad S \ge 0.$$

Here, a prime denotes differentiation w.r.t. $\xi = \overline{x} - \bar{c}t$.

It can be shown that the minimum (dimensionful) wave speed is given explicitly by

$$V = 2\sqrt{D(\beta S_0 - \alpha)} \quad \text{if} \quad S_0 > \frac{\alpha}{\beta} = S_c.$$

Also:

(1) There is a minimum critical population density $S_c = \frac{\alpha}{\beta}$ *necessary for an epidemic wave to occur (e.g., a sudden influx of population can raise* S_0 *above* S_c*, and hence initiate an epidemic).*

(2) For a given population S_0 *and mortality rate* α*, there is a critical transmission coefficient* $\beta_c = \frac{\alpha}{S_0}$ *such that for* $\beta < \beta_c$ *the infection cannot spread.*

(3) With a given transmission rate β *and an initial susceptible population* S_0 *there is a threshold mortality rate* $\alpha_c = \beta S_0$*, which if exceeded, prevents an epidemic. So, the more rapidly fatal the disease is, the less chance there is of an epidemic wave propagating through a population.*

During 1975–1985, advances were made by ***Robert May*** *and his coworkers in our understanding of the role of infectious diseases in the regulation of natural populations of plants and animals and the interactions between population of viruses and immune system cells.*

Slime molds

Occasionally during summer, gardeners notice a jelly-like mass situated on the lawn. The same type of matter is often seen in the woods on decaying logs.

Known as 'slime molds' these organisms live in cool, shady, moist places on decaying wood, leaves or other organic matter, retaining abundant moisture. Over 700 species are reported to exist.

The colonies of slime mold living on logs and bark mulch can be strikingly colorful in yellow, orange or red. Some produce cream-colored masses of cells along grass blades. Slime molds often appear in the same area of the lawn year after year, in 10 to 15 cm patches in various shades of purple, grey, white or cream.

Slime molds feed on decaying organic matter, bacteria, protozoa, and other minute organisms which it engulfs and digests.

*Historically, slime molds were first regarded as members of the Fungi Kingdom but later classified with the Protista (*Protoctista*) Kingdom. In a recent system of classification based on analysis of nucleic acid (genetic material) sequences, slime molds have been classified in a major group called the Eukarya Domain (*Superkingdom*) including the four kingdoms of* Protista, Fungi, Plantae *and Animalia.*

Mycologists now consider slime molds to belong to a class called Myxomycetes[396] *[*myxa = slime; myketes = fungi*].*

Slime molds have left almost no fossil record. However, fossils of members of the Kingdom Protoctista, known as Ediacaran biota, produced deposits that date back 600 million years ago. Some of these ancient protoctists may have been ancestral to certain animal and plant phyla.

There are two main groups of slime molds:

- *Plasmodial slime molds: basically enormous single cells with thousands of nuclei and no definite cell wall. They are formed when individual flagellated cells swarm together and fuse. The result is one large bag of cytoplasm with many diploid nuclei.*

---

[396] **Heinrich Anton de Bary** (1831–1888, Germany). Botanist and founder of the science of *mycology* and plant pathology. He called slime molds *Mycetozoa* (1887), form the Greek *myketes* (fungi), and zoon (animals). This name was in use until the 1970's.

- *Cellular slime molds spend most of their lives as separate single-celled amoeboid protists, but upon the release of a chemical signal, the individual cells aggregate into a great swarm. Cellular slime molds are thus of great interest to cell and developmental biologists, because they provide a comparatively simple and easily manipulated system for understanding how cells interact to generate a multicellular organism.*

What these two groups have in common is a life cycle. Before entering the reproductive stage, a plasmodium moves to a drier, better-lit place, such as the top of a log. In the amoeba-like or cellular slime molds, up to 125,000 individual cells aggregate and flow together, forming a multicellular mass called a pseudoplasmodium that resembles a slug and crawls about before settling in a location with acceptable warmth and brightness. When conditions become unfavorable, these slime molds form sporangia clusters of spores, often on the tips of stalks. Spores from the sporangia are dispersed to new habitats, "germinate" into small amoebae, and the life cycle begins again.

Certain aspects of the 'life' of a slime molds lend themselves to mathematical formulation.

***Marston Morse** (1949) mentioned slime molds as an example of "equilibria in nature". **Evelyn Keller** and **Lee A. Segel** (1970), using classical PDE ideas in a biological context, first formulated and analyzed equations to show how aggregation might be regarded as an instability of secreting chemotactic cells.*

***Athanasius F.M. Marée** and **Paulien Hogeweg** (2001) have provided a computer simulation of the transformation of slug into fruiting body by a process of self-organization.*

We now present a simplified model governing the slime mold amoebae aggregation as an instability. Let us first recapitulate the essential behavioral and anatomical data:

As mentioned above, slime molds have a complex life cycle that may be divided into an animal-like motile phase (in which growth and feeding occur) and a plantlike, immotile, reproduction phase. The motile phase is commonly found under rotting logs and damp leaves where cellulose is abundant. It consists in the cellular slime molds of solitary, amoeba-like cells, and in Myxomycota of a multinucleate mass of protoplasm called plasmodium, which creeps about by ameboid movement.

Plasmodia often grow to a diameter of several inches. Both types ingest solid food particles using a process called phagocytosis. They feed on living microorganisms, such as bacteria and yeasts, as well as decaying vegetation.

In the reproductive stage, the plasmodium or pseudo-plasmodium is transformed into one or more reproductive structures called fruiting bodies, each consisting of a stalk topped by a spore-producing capsule that resembles the reproductive structure of many fungi.

Eventually, the cellulose-walled spores are released and dispersed; They germinate in wet places, releasing naked cells. In a typical plasmodial slime mold, the germinated spores go through an ameboid or flagellated swimming stage, followed by sexual fusions and cell-divisions. The diploid ameboid cell grows and its nucleus divides repeatedly, resulting in the formation of a new plasmodium. Under adverse conditions, a plasmodium may be transformed into a hard, dry, inactive mass which becomes a plasmodium again when favorable conditions return.

In the case of the cellular slime molds, each spore released becomes a single amoeba, which feeds individually until starving cells release a chemical signals that causes them to aggregate into new pseudo-plasmodium, and the progress is repeated.

In sexual reproduction two haploid amoeba fuse, then engulf surrounding amoebas, forming a single organism called a macrocyst. It then undergoes meiosis and released haploid individuals.

In the morphogenetic development of many species of cellular slime mold (Acrasiales) some interesting effects of long-range intercellular interaction can be observed. The interaction may be of a repulsive or attractive nature, depending on the stage of the cells' life cycle. Immediately following germination, the cells disperse as if acting under a mutual repulsion. When a source of food (bacteria) is present, the cells move toward it with a high positive chemotactic index. After exhausting their food supply, the amoebae first tend to distribute themselves uniformly over the space available to them, but later they begin to aggregate in a number of "collecting points" or centers. At each center a slug forms, migrates and eventually forms a multicellular fruiting body.

The basic biological facts which serve as a basis for the mathematical model are:

- *Amoebae spread out uniformly when sufficient food (bacteria) is available.*
- *Shortage of food causes the amoebae to start secreting a certain chemical (an attractant) which attracts other amoebae.*
- *Further depletion of the food supply leads to an aggregation followed by formation of spores.*

- *Spores develop into new amoebae when conditions are favorable.*

It is therefore necessary to quantify the following statements describing the aggregation process:

- *Amoebae diffuse due to concentration gradients*
- *Amoebae move towards higher concentration of attractant*
- *Amoebae secrete more attractant when there is shortage of food*
- *The attractant breaks down in time due to a chemical reaction*
- *The attractant itself diffuses in the solution due to diffusion gradients*

We thus define:

$a(x, y, t) =$ *concentration (mass per unit area) of amoebae. The function is continuous (and sufficiently differentiable) in the two-dimensional spatial coordinates (x,y) and the time t.*

$\rho(x, y, t) =$ *concentration of attractant.*

We now invoke:

(i) The conservation (continuity) equations for the concentration of amoebae $a(x, y, t)$ *and the chemical attractant* $\rho(x, y, t)$*;*

(ii) The linear dependence of the transport flux of amoebae upon both diffusive amoeba concentration gradient and the concentration gradient of the attractant.

These statements translates into a pair of coupled nonlinear partial differential equations (two space, one time dimension):

$$\frac{\partial a}{\partial t} = div[D_2 \text{grad } a - D_1 \text{grad } \rho], \tag{1}$$

$$\frac{\partial \rho}{\partial t} = -k(\rho)\rho + af(\rho) + D_\rho \nabla^2 \rho. \tag{2}$$

The term $D_2 \nabla a$ *represents a diffusion-like contribution to the amoebae flux due to random motion, where* $D_2(\rho, a)$ *is a measure of the vigor of the random motion of the individual amoebae; while* $D_1(\rho, a)$ *is a measure of the strength of the influence of the attractant gradient on the flow of the amoebae. The signs of the terms in (1) are chosen so that* D_1 *and* D_2 *will be positive, since amoebae flow toward a relatively high value of attractant concentration* *and a relatively low value of amoebae concentration. In (2),* $af(\rho)$ *is the formation rate of attractant by the amoebae, and* $-\rho k(\rho)$ *is the decay rate, while* D_ρ *is the constant attractant diffusivity.*

Eqs. (1)–(2) possess uniform equilibrium solutions

$$a = a_0, \qquad \rho = \rho_0, \tag{3}$$

where

$$a_0 f(\rho_0) = k(\rho_0)\rho_0. \tag{4}$$

We now look for solutions of (1) and (2) near equilibrium. Of particular importance is the time dependence of these solutions. If the deviations $\rho-\rho_0,\ a-a_0$ *decrease with time, then any random perturbation which might occur in the equilibrium state would decay. If, on the other hand, we found a solution which these deviations increased with time, the appearance of any spontaneous perturbation would mark the onset of instability. The perturbation would grow until the system could no longer be described by equilibrium or near-equilibrium equations.*

Near equilibrium, we assume that the right-hand sides of equations (1) and (2) can be replaced by Taylor expansions in ρ *and* a *around the equilibrium point* (ρ_0, a_0). *That is, we consider small perturbations of* a_0 *and* ρ_0

$$\begin{aligned} a &= a_0 + \overline{a}(x,y,t) \qquad & |\overline{a}| << a_0, \\ \rho &= \rho_0 + \overline{\rho}(x,y,t) \qquad & |\overline{\rho}| << \rho_0 \end{aligned} \tag{5}$$

and expand any term in which a *and* ρ *appear as follows*

$$F(\rho,a) = F(\rho_0,a_0) + \left(\frac{\partial F}{\partial \rho}\right)_{\rho_0,a_0} \overline{\rho}(x,y,t) + \left(\frac{\partial F}{\partial a}\right)_{\rho_0,a_0} \overline{a}(x,y,t) + \cdots$$

As long as $\overline{a}$ *and* $\overline{\rho}$ *are small we can ignore higher order terms containing factors such as* $\overline{a}^2,\ \overline{a\rho},\ \overline{\rho}^2,\ \overline{a}^3$ *etc. The linearized (small–signal) equations which result are*

$$\frac{\partial \overline{\rho}}{\partial t} = -\overline{k}\overline{\rho} + a_0 f'(\rho_0)\overline{\rho} + f(\rho_0)\overline{a} + D_\rho \nabla^2 \overline{\rho}, \tag{6}$$

$$\frac{\partial \overline{a}}{\partial t} = -D_1(a_0,\rho_0)\nabla^2\overline{\rho} + D_2(a_0,\rho_0)\nabla^2\overline{a}, \tag{7}$$

where prime denotes differentiation and $\overline{k} = k(\rho_0) + \rho_0 k'(\rho_0)$. *We look for solutions to (6) and (7) of the form*

$$\overline{a} = \hat{a}\cos(q_1 x + q_2 y)e^{\sigma t}; \qquad \overline{\rho} = \hat{\rho}\cos(q_1 x + q_2 y)e^{\sigma t}, \tag{8}$$

where σ, $\hat{a}$, $\overset{\wedge}{\rho}$, q_1, q_2 *are constants. Substitution of (8) into (6) and (7) leads to a quadratic equation for* σ

$$\sigma^2 + b\sigma + c = 0$$

with

$$\begin{aligned} b &= (q_1^2 + q_2^2)D_2(a_0, \rho_0) + [\overline{k} + (q_1^2 + q_2^2)D_\rho - f'(\rho_0)a_0] \\ c &= -(q_1^2 + q_2^2)D_2[f'(\rho_0)a_0 - \overline{k} - (q_1^2 + q_2^2)D_\rho] - (q_1^2 + q_2^2)f(\rho_0)D_1 \end{aligned}$$

The roots of the quadratic equation are real (since $b^2 > 4c$*) and will both be negative iff* $b > 0$ *and* $c > 0$*. It thus follows that instabilities (*$\sigma > 0$*) can arise when:*

- *The diffusive mobility of the amoebae is low.*
- *The decay of attractant is slow.*
- *The production of attractant is high.*
- *The mobility of the amoebae is high.*

It is conceivable that this mechanism is qualitatively related to what we see in reality. However, the form of the aggregation patterns may be quite complicated. Yet, the central contribution of the theory is the idea that the onset of slime mold aggregation can be regarded as an instability of the uniform distribution, triggered when the amoebae cease feeding. The merit of this point of view is independent of the particular simplifying assumptions which the model employs.

Chemotaxis

A taxis is an innate response by an organism (or cell) to a stimulus from a particular direction, whereby the motile organism moves either toward or away from the stimulus. For example, flagellate protozoans of the Genus Euglena move towards a light source – a phenomenon known as phototaxis (a response to light stimulus). Many other types of taxis that have been identified are: Anemotaxis (stimulated by wind); Barotaxis (stimulated by pressure); Chemotaxis (stimulated by chemicals); Galvanotaxis (stimulated by electrical current); Geotaxis (stimulated by gravity); Hydrotaxis (stimulated by moisture); Rheotaxis (stimulated by current flow); Thermotaxis (stimulated by temperature change); Thigmotaxis (stimulated by contact).

Taxis is classified as klinotaxis when an organism continuously samples the environment to determine the direction of the stimulus.

In an assembly of particles (cells, bacteria, chemicals, animals) each particle moves around in a random way. When this microscopic irregular movement results in some macroscopic gross regular motion of the group, it is manifested as a diffusion process governed by the diffusion equation in the continuum limit.

A large number of insects and animals rely on an acute sense of smell for conveying information between members of the species. Chemicals which are involved in this process are called pheromones. For example, the female silk moth Bombyx mori exudes a pheromone, called bombykol, as a sex attractant for the male, which has a remarkably efficient antenna filter to measure the bombykol concentration, and it moves in the direction of increasing concentration. This chemically directed movement, that is chemotaxis, directs (unlike diffusion) the motion up a concentration gradient.

It is not only in animal and insect ecology that chemotaxis is important. It can be equally crucial in many biological processes, e.g.:

(a) A bacterium find food (e.g. glucose) by swimming towards the highest concentration of food molecules, or employs the opposite behavior to flee from poisons (e.g. phenol).

(b) Leukocyte cells in the blood move towards a region of bacterial inflammation, to counter it, by following a chemical gradient caused by the infection.

(c) Single-cell amoebae in the slime mold Dictyostelium discoideum move toward regions of relatively high concentration of a chemical called cyclic-AMP, which is produced by the amoebae themselves.

The first erudite description of chemotaxis and phototaxis was made by the German botanists ***T.W. Engelmann*** *(1881) and* ***W.T.P. Pfeffer*** *(1845–1920, 1884) in bacteria and the American biologist* ***H.S. Jennings*** *(1868–1947, 1906) in ciliates.* ***Eli Metchnikov*** *(1845–1916) also contributed to the study of the field with investigations of chemotaxis as an initial step of phagocytosis.*

The kinetics involved in (c) can be derived via a continuum model equation for the global behavior in terms of a particle concentration:

Assume that the presence of a gradient in an attractant concentration, $a(\boldsymbol{x}, t)$*, gives rise to a movement, of cells say, up that gradient. We then write the chemotaxis–caused flux vector* $\boldsymbol{j}$ *of cells as*

$$\boldsymbol{j_{chemotaxis}} = n\chi(a)\,\mathrm{grad}\,a, \tag{9}$$

where $\chi(a)$ is a function of the attractant concentration. The conservation of matter equation for $n(\boldsymbol{x}, t)$, then becomes

$$\frac{\partial n}{\partial t} + div\, \boldsymbol{j} = f(n), \tag{10}$$

where $f(n)$ represents the growth term for the cells, and

$$\boldsymbol{j} = \boldsymbol{j_{diffusion}} + \boldsymbol{j_{chemotaxis}} = -D\,\mathrm{grad}\, n + n\chi(a)\,\mathrm{grad}\, a. \tag{11}$$

Here D is the diffusion coefficient of the cells. Combining (10) and (11) one obtains a PDE for chemotaxis

$$\frac{\partial n}{\partial t} = f(n) - div[n\chi(a)\,\mathrm{grad}\, a] + div[D\,\mathrm{grad}\, n] \tag{12}$$

Since the attractant $a(\boldsymbol{x}, t)$ is a chemical, it also diffuses and is produced (by the amoebae), so we need a further equation for $a(\boldsymbol{x}, t)$. Typically it takes the form

$$\frac{\partial a}{\partial t} = g(a, n) + div[D_a\,\mathrm{grad}\, a], \tag{13}$$

where D_a is the diffusion coefficient of a and $g(a, n)$ is the source term. Normally we would expect $D_a > D$. In many cases: $f(n) = 0$, $g(a, n) = hn - ka$, $\chi = \chi_0 = const.$ and D, D_a, h, k are also constants. Then, the model in one space dimension is governed by the system

$$\frac{\partial n}{\partial t} = D\frac{\partial^2 n}{\partial x^2} - \chi_0 \frac{\partial}{\partial x}\left(n\frac{\partial a}{\partial x}\right); \quad \frac{\partial a}{\partial t} = hn - ka + D_a\frac{\partial^2 a}{\partial x^2} \tag{14}$$

Note the sign difference in (12) and (14), between the diffusion and chemotaxis terms. Each has a Laplacian contribution. Whereas diffusion *in generally a stabilizing force,* chemotaxis *is generally destabilizing – a negative diffusion, as it were. It is therefore reasonable to suppose that the balance between stabilizing and destabilizing forces in the model system (14) could result in some steady-state spatial patterns in n and a, or in the appearance of nonuniform spatial patterns in the cell density.*

1917–1919 CE Worldwide *Influenza* epidemic; estimates of deaths range as high as 50 million. *Typhus* claims as high as 3 million lives in Russia.

1917–1921 CE **Albert Wallace Hull** (1880–1966, U.S.A.). Physicist and inventor. Discovered (1917), independently of **Peter Debye** and **P.H. Scherrer** [1916; Swiss physicist, 1890–1969], the method of diffraction analysis in

X-ray crystallography. Invented the *thyratron*[397] and *magnetron* (1921) electron tubes.

The Hull *magnetron* consisted of an electron-emitting cathode surrounded concentrically by a cylindrical anode. Electrons move from the cathode to the anode under the action of an applied voltage V and form a current I in the external circuit. The path of the electron is radial. If a magnetic field B is applied in the direction of the tube axis, the electron will travel in curved path, and if the field strength is increased, a condition will be reached in which no electrons reach the anode and the current is cut off. Since the velocity of thermal agitation is small in comparison, all electrons will have approximately the same velocity. Thus there will exist a critical field B_c, above which the anode current is wholly suppressed. The Hull magnetron could therefore be used as a relay, but was not meant to act as an oscillator. Sometimes, however, by setting B to barely exceed B_c, feeble oscillations were found to be generated at very high frequencies.

The physical basis of the Hull *magnetron* hinges on the theory of motion of charged particles in crossed electric and magnetic fields: Let a particle be emitted from a surface in the plane $x = 0$ and accelerated by a uniform electrostatic field E toward a collector plate in the plane $x = \ell$. A uniform magnetic field B is applied parallel to the OZ direction with the result that the particle is deflected in the negative OY direction. The motion of a particle of mass m and charge e in the XY plane is then described by the coupled ODE

$$m\ddot{x} = eE - Be\dot{y}; \qquad m\ddot{y} = Be\dot{x}.$$

Applying the initial conditions $\dot{x}(0) = \dot{y}(0) = 0$, the solution of the above ODE system yields the cycloid

$$x(t) = x_0(1 - \cos\omega t), \qquad y(t) = x_0(\omega t - \sin\omega t)$$

$$x_0 = \frac{E}{\omega B}, \qquad \omega = \frac{eB}{m}.$$

The cut-off condition $x_{\max} = \ell = 2x_0 = \frac{2mE}{B_c^2 e}$ yields $B_c^2 = \frac{2mV}{e\ell^2}$, where $V = E\ell$ is the interplate voltage-drop.

---

[397] A gas-filled triode with a thermionically heated cathode. It operates under arc discharge conditions: The gas ionizes when sufficient current flows, reducing the internal resistance. When the grid is sufficiently negative no electron current flows. Less negative potential values cause electrons to flow, ionizing the gas; the valve conducts heavily until the anode potential is reduced. The valve can thus be used as a relay, or as a rectifier of variable output.

A similar procedure may be followed in analyzing a cylindrical magnetron, with the approximate result $B_c^2 = \frac{8mV}{er_a^2}$, where r_a is the anode radius.

Further study of the oscillations generated by the Hull magnetron led a group of Japanese physicists (1927) to devise the *split-anode magnetron*. The *multi-cavity magnetron* was developed in England (1941) by several research groups for use in wartime RADAR systems.

Hull was born in Southington, CT. He was on the research staff of General Electric Co. (1914–1950).

1917–1930 CE **Harlow Shapley** (1885–1972, U.S.A.). Astronomer. Revolutionized galactic astronomy by obtaining the first realistic estimate for the actual size of the Milky Way galaxy and "removing" the solar system from its center. This was achieved through Shapley's investigation of the distribution of the *globular clusters*[398].

In 1917–1918, Shapley determined the location of the solar system in the Milky Way galaxy. In 1930 he calculated the diameter of the galaxy to be about 100,000 light years. Shapley developed a method to measure the distance to globular clusters using variable stars as yardsticks.

It is possible to determine the distance to an object if both its absolute and apparent magnitudes are known. It was discovered in 1912, through observations of *variable stars* in the Magellanic clouds, that there is a definite relationship between the pulsation period of these stars and their luminosities. For *Cepheids*, the period increases with increasing luminosity (or decreasing absolute magnitude) while with another type of pulsating variable, the *RR Lyrae stars*, all have the same luminosity. This had a profound implication:

When a star is recognized as a variable belonging to one of these classes, its absolute magnitude can be determined simply by measuring its period and using the established period-luminosity relations. Once the absolute magnitude is known, the distance can be found by comparing the absolute and apparent magnitudes. Because Cepheids are giant stars, they are very luminous, and

---

[398] Before Shapley, the galaxy was generally believed to be centered approximately at the sun and to extend only a few thousand light years from it. Shapley placed the sun near the galactic central plane, at the outer edge, some 30,000 light years away from the center. Globular clusters are immense, densely packed groups of stars (some containing as many as a million members). Because of their brilliance and the fact that they are not confined to the central galactic plane (where they would be largely obscured by interstellar dust), they can be observed out to very large distances.

can be observed out to great distances. This makes them very powerful tools for measuring distances beyond those reached by other techniques.

From their directions and derived distances, Shapley, was able (1917) to map out the 3-dimensional spatial distribution of the 93 globular clusters then known. He found that the clusters formed a roughly spheroidal system, with the highest concentration of clusters at the center. *That center was not near the sun*, but a point in the middle of the Milky Way in the direction of *Sagittarius*.

Shapley was born in Nashville, MO. He joined the staff of the Mt. Wilson Observatory, California, in 1914. He became professor of astronomy at Harvard University and director of its observatory (1921–1952).

1917–1933 CE **Tullio Levi-Civita**[399] (1873–1941, Italy). Outstanding mathematician. One of the founders of the tensor calculus. Introduced the concept of *parallel displacement* in Riemannian spaces; this was instrumental in the development of the modern differential geometry of generalized spaces.

Parallel displacement (or *parallel transport*): Let C be a curve in three-dimensional space $\mathbb{R}^3$ and let the coordinates $x^i(t),\ t \geq 0 \qquad i = 1, 2, 3$ of a point P on C be functions of a parameter t along it (e.g., arc-length, time, etc.), in any particular (possibly curvilinear) coordinate system.

Define[400] a contravariant vector field $\boldsymbol{A}(P) = A^k(x)\boldsymbol{g}_k(x)$ at a general point P in $\mathbb{R}^3$, with $\boldsymbol{g}_k$ the natural basis of contravariant vectors (frame) corresponding to the given[401] coordinate system. A^k are the components of $\boldsymbol{A}$ in this system.

---

[399] For further reading, see:

- Levi-Civita, T., *The Absolute Differential Calculus*, Dover, 1977, 452 pp.
- McConnell, A.J., *Applications of Tensor Calculus*, Dover, 1957, 318 pp.

[400] We employ the *summation convention*: pairs of identical-symbol indices are summed over.

[401] The definition of parallel transport readily generalizes to any n-dimensional manifold, not necessarily equivalent topologically to $\mathbb{R}^n$; thus the coordinates and frames might need to be differently defined on different "patches" of the manifold, with suitably smooth *transition functions* furnished between any pair of coordinate systems on the overlap of their respective patches. Furthermore, such a multiplicity of coordinate–systems patches may be required even in an $\mathbb{R}^n$ manifold, in the case of curvilinear coordinates (e.g spherical coordinates in $\mathbb{R}^3$).

The contravariant – vector basis $\{\boldsymbol{g}_k\,(x)\}$ is in general not orthogonal, but we can construct a *dual base* $\{\boldsymbol{g}^k(x)\}$, such that $\boldsymbol{g}^j \cdot \boldsymbol{g}_k = \delta^j_k$ (Kronecker delta) at each point in $\mathbb{R}^3$; this dual basis is a local basis (frame) for *covariant* vectors, in the same coordinate system.

Next, we construct at every point $P\big(x(t)\big)$ of C a vector equal in magnitude to $\boldsymbol{A}(Q)$ (where $Q \equiv P\big(x(0)\big)$ and parallel to it in direction (in the Euclidean $\mathbb{R}^3$ geometry). We thus obtain a contravariant vector field $\boldsymbol{B}(t|C)$ on the curve C, where t is a parameter along C.

Clearly, while this curve–restricted vector field is a constant in absolute terms [$\boldsymbol{B}(t|C) \equiv \boldsymbol{A}(Q)$ is $t-$independent], its *local components* $B^k = \boldsymbol{B} \cdot \boldsymbol{g}^k\big(x(t)\big)$ will vary along C, since they are measured at each point w.r.t a local base that changes along the curve. There changes are determined by the equation

$$\frac{d\boldsymbol{B}}{dt} = \frac{d}{dt}(B^k \boldsymbol{g}_k) = \left[\frac{\partial B^k}{\partial t} + \frac{dx^i}{dt} B^j \Gamma^k_{ij}\right] \boldsymbol{g}_k\big(x(t)\big) \equiv 0,$$

where we have used the chain rule of differentiation along the curve C,

$$\frac{d\boldsymbol{g}_k\big(x(t)\big)}{dt} = \frac{dx^i}{dt}\,\frac{\partial \boldsymbol{g}_k}{\partial x^i} \quad ,$$

and defined anywhere in $\mathbb{R}^3$:

$$\Gamma^k_{ij}(x) \equiv \boldsymbol{g}^k(x) \cdot \frac{\partial \boldsymbol{g}_j(x)}{\partial x^i} \; .$$

It can be shown that $\Gamma^k_{ij} \equiv \Gamma^k_{ji}$.
The condition of parallel transport of a vector along C – which defined $\boldsymbol{B}(t|C)$ – thus results in the system of coupled linear ODE's:

$$\frac{dB^m}{dt} + \frac{dx^\ell}{dt} B^k \Gamma^m_{k\ell} = 0.$$

for the components $\{B^k(t|C)\}$, in any given coordinate system.

The solution of this system of differential equations yields the parallel vector field along C for given fiducial point Q and $\boldsymbol{A}(Q)$.

Expressed in other terms, if we are given a *closed curve* and, starting with a given vector at a point of this curve, we parallel-transport the vector along the curve, then there is no *a priori* reason why we should arrive at the same initial vector when we have completed the circuit! In fact, the parallel transport of a vector round a closed circuit in a curved Riemannian space generally results in a *new vector* when we have returned to at the initial point.[402]

Consider, for example, the curved-triangle boundary of one octant of a sphere: as we move a vector parallel to itself along the equatorial side of the curved triangle (one quarter of the equatorial circumference) such that it is always normal to the equator (say, pointing north), our intuitive concept of parallelism is not violated. If, however, we further parallel–transport the vector along the *two meridional portions of the closed curve*, then when we

---

[402] The concept of parallel vector fields along a curve embedded in Euclidean $\mathbb{R}^3$-space (E_3) was generalized by Levi-Civita to curves embedded in a (possibly curved) Riemannian space (manifold) of dimension n: The Riemannian space has an *affine connection* $\Gamma^i_{jk}(x)$, which defines the *covariant derivatives* $A^m_{;l} = \frac{\partial A^m}{\partial x^l} + \Gamma^m_{lk} A^k$, transforming as a tensor under a general coordinate transformation (while Γ is *not* a tensor, nor is $\frac{\partial A^m}{\partial x^l}$).
For an infinitesimal displacement dx^i of P along C, $DA^m = A^m_{;l}(P)\,dx^l$ can be interpreted geometrically as the difference between $A^m(x+dx)$ and the *parallel transport* of $A^m(P)$ to the point P' with coordinates $x+dx$. The coordinates x^i, dx^i depend on an arbitrary choice of local coordinate system and the local patches in which they hold; yet the *points* P, P', and the *tensor* of which A^m and $A^m_{;l}$ are local components, are genuine and invariant *geometrical entities* on the manifold. In a *curved* region of a Riemann space, a vector field A^m not identically zero cannot satisfy $A^m_{;l} \equiv 0_j$. One *can* however, create a new field $\tilde{A}^m(t)$, defined only along C, by parallel-transporting A^m from $t = t_1$ to any point along C; and this construction is *covariant* under change of coordinates[403]. $\tilde{A}^m$ satisfies the 1st-order system of nonlinear ODE's

$$\frac{D\tilde{A}^m}{Dt} \equiv \frac{d\tilde{A}^m}{dt} + \Gamma^m_{ij}\,\frac{dx^i(t)}{dt}\,\tilde{A}^j(t) = 0,$$

with initial conditions $\tilde{A}^m(t_1) = A^m\big(x(t_1)\big)$.
When $n = 3$ (x^1, x^2, x^3) is Euclidean space, $A^m(x)$ is the velocity field and t is Newtonian time, one example of parallel transport (in a flat space) is free-streaming in fluid dynamics, where $\frac{D}{Dt}$ is the *material* (*comoving*) derivative. For $n = 3N$, an example is the *Boltzmann transport equation* (for N particles) without collision and external-field terms.
In GTR, $n = 4$, t becomes proper time, and the parallel-transport condition is an approximation to the equations of motion (for 4-velocity, intrinsic spin and other energy-momentum moments) in the case of a small object free-falling in an external gravitational field.

[403] Indeed, the variation of tensor fields caused by parallel transport around infinitesimal closed loops at different points P, can be used to define and fully characterize the rank-4 *Riemann curvature tensor* on the manifold.

return to the equatorial starting point, it is easily seen that the vector, originally pointing north, now points parallel to the equator. This is, obviously, due to the uniform scalar curvature of the sphere.

Levi-Civita's researches covered a vast field in the no-man's land between pure and applied mathematics. Their subjects include the absolute differential calculus, integral equations, differential geometry, general relativity (1929), hydrodynamics, partial differential equations, N-body problems and problems of engineering.

Levi-Civita was born in Padua, Italy to a Jewish family, a son of Giaccomo Levi-Civita and his wife Bice Lattis. The family was a wealthy one, well known for its strong liberal tradition. His father was a barrister, jurist and politician and was for many years Mayor of Padua and a Senator of the Kingdom of Italy. As a young man he had fought with Garibaldi in the campaign of 1866.

At the age of 17 Tullio entered the University of Padua. One of his teachers was Ricci-Curbastro, with whom he later collaborated. In 1902 he became a professor of rational mechanics, and in 1918 he was called to the chair of mechanics at the University of Rome, a post which he held for another 20 years.

Levi-Civita was a man of small stature, handicapped throughout his life by defective eyesight. Nevertheless, he was very robust and in his younger days was an avid mountaineer and cyclist. In 1914 he married Libera Trevesani, a former pupil. He always remained true to the liberal tradition of his family. The bond between him and his father was very close, and the father's portrait always hung, beside that of Garibaldi, in his study. He viewed with strong displeasure the advent of fascism in Italy.

His scientific renown protected him from persecution until the introduction of the anti-Jewish laws in Italy in 1938, when he was removed from his chair in Rome. This was a heavy blow to him, from which he never recovered. He received offers of asylum from many parts of the world, but severe heart trouble prevented his traveling to accept any of these. He died in Rome as a result of a stroke.

1917–1953 CE **Hermann Staudinger** (1881–1965, Germany). Organic and macromolecular chemist. Deciphered the polymer structure. His pioneer work on macromolecular chemistry constitutes a major foundation of modern molecular biology.

His early (1917) synthesis of the hydrocarbon isoprene (the constituent monomer of rubber) led him to the long-chain-molecule theory of the structure of polymers (1920). As early as 1926, Staudinger appreciated the importance of macromolecules to biology and visualized the molecular biology of the future (1947). Recognition of his work as a whole came belatedly with the award of a Nobel prize in 1953.

Before Staudinger it was accepted that polymers consist of an aggregate of small molecules connected through mysterious secondary forces that nobody could define. Staudinger was first to put forward a model through which the molecular chain is held together by *covalent* bonds. Subsequently he produced in his laboratory synthetic polymers used as models for natural polymers. Thus was born the concept of polymer as a *macromolecule*. This breakthrough led to a wide theoretical, experimental and industrial development of macromolecular chemistry.

1917–1971 CE **Robert Robinson** (1886–1975, England). Organic chemist. One of the founders of modern organic chemistry. Made fundamental contributions in four major areas: the structure of natural substances (many of major biological importance); synthesis; biosynthesis; and mechanistic organic chemistry. For his work on natural products of biological importance he was awarded the Nobel prize in chemistry (1947). It covered alkaloids [*morphine* (1925), *strychnine* and *tropinone*], the plant pigments of the *anthocyanin* and *anthoxantin* group, *steroids* and *penicillin*.

His work led to the elucidation of *patterns of biosynthesis;* he suggested the importance of the aldol condensation of carbinolamines in alkaloid biosynthesis, and emphasized that the biosynthesis of organic compounds follows recognizable chemical reactions and mechanisms. He also worked out an *electrochemical* (electronic) *theory of organic reactions*.

Robinson was born in Chesterfield, Derbyshire, England. From 1912 he held a series of appointments at Sydney, Liverpool (1915–1919), St. Andrews (1920), Manchester (1922), University College, London (1928), and culminating in his appointment at Oxford (1930–1955).

The Third 'Copernican Revolution' — The Extragalactic Universe (1918–1924)

In 1543, ***Copernicus*** *shifted the center of the universe from the earth to the sun. In* 1610, ***Galileo*** *described his telescopic observations of the Milky Way, which showed it to be composed of a multitude of individual stars. In* 1750 ***Thomas Wright*** *published a speculative explanation which turned out to be substantially correct — that the sun is located within a disc-shaped system of stars, and that the Milky Way is the light from the surrounding stars that lie more or less in the plane of the disc. The disc shape of the stellar system to which the sun belongs (the galaxy*[404]*) was demonstrated quantitatively in* 1785 *by* ***Herschel's*** *"star gauging".*

At the opening of the 20th century, very little was known about our galaxy's size and shape and where we are located in it, let alone that there were galaxies beyond our own. ***Harlow Shapley*** *established in* 1918 *the existence of clusters of stars out at the edge of the Milky Way and "pushed" the sun away from the center of the galaxy towards its rim. He insisted, however, that the visible nebulae did not extend beyond the Milky Way.*

Heber Doust Curtis *(1872–1942, U.S.A.) discovered in* 1918 *that the great spiral nebula in Andromeda was far beyond our galaxy*[405]*. On April* 27, 1920 *these two astronomers met in a formal debate before the NAS in Washington D.C., to decide whether the newly observed so-called nebulae, were inside (Shapley) or outside (Curtis) the 'Milky Way'. Shapley used correct arguments but came to the wrong conclusion. Curtis, whose intuition was better in this case, gave a rather weak and sometimes incorrect argument but reached the correct conclusion. The nebulae were indeed distant galaxies.*

Curtis' findings substantiated the predictions of ***Kant*** *(1755) and* ***Eddington*** *(1914), and were finally confirmed at a meeting of the American Astronomical Society by* ***E.P. Hubble*** *(1924). Before long, astronomers had determined that many of the faint nebulae were, in fact, entire galaxies. With*

[404] From the Greek *galaxias* = gala-aktos = milk. The word *Galaxy* pertains to the *Milky Way*, which contains about 10^{11} visible stars, as well as 10^{10} solar masses ($M_\oplus$) of gas, distributed in tens of thousands of gas clouds with a wide range of masses and sizes ($M_\oplus = 1.99 \times 10^{33}$ gram).

[405] The diameter of the '*Milky Way*' is about 10^5 LY; the center of *Andromeda* is at a distance of 2×10^6 LY from earth; the farthest star in the *Local Group* is about 3×10^6 LY from earth.

this knowledge came a new and larger view of the cosmos. Attention turned to galaxies.

On average, galaxies are separated by about 10^7 *light-years, or about* 100 *times the diameter of one galaxy. Thus, space would appear to be mostly empty, with islands of stars, scattered here and there.*

From another perspective, however, galaxies are far closer together than stars. Individual stars in a galaxy, are separated by an average toll of 10 *light-years, or* 10^8 *times the diameter of one star*.

1918 CE **Hans Thirring** (1888–1976, Austria) and **J. Lense** (Germany). Physicists. Tested whether the theory of general relativity incorporates the 'Mach principle'. They solved the GTR linear 'weak field approximation' inside a large spherical shell rotating relative to an asymptotic inertial frame[406] in an otherwise empty universe.

A small dragging effect from the shell, partially tugging the interior local-inertial frames, was found — in accord with Mach's principle; i.e. a test mass inside the shell behaves as if it was acted upon by centrifugal[407] and other inertial forces usually attributed to absolute space, but caused by the rotating shell. The predicted effect is known as the *Lense-Thirring effect* or *frame dragging*.

1918 CE **Paul Finsler** (1894–1970, Germany). Mathematician. Provided a generalization of Riemannian geometry, in which the metric form is replaced by a more general function of the coordinates and the differentials. The restrictions on this function $F(x, dx)$ are mostly those that insure the regularity of the problem of minimizing the integral $\int F\left(x, \frac{dx}{dt}\right) dt$. His work is related to that of **Emmy Noether** (1882–1935) on differential invariants.

Many attempts have been made since 1918 to reformulate the theory of the gravitational field on the basis of Finsler's metric, but there is yet no

406 Far outside the matter distribution, space-time is Minkowskian and one can choose a fiducial STR-type inertial frame covering this exterior region. The Minkowskian approximation becomes asymptotically exact in this region.

407 A sphere of mass M and radius R rotating with angular velocity ω w.r.t. the distant stars produces near its center a centrifugal acceleration of amount $\omega^2 r\left(\frac{GM}{c^2 R}\right)$.

experimental evidence to suggest that Riemannian geometry should be supplanted by the Finslerian generalization to describe the properties of physical space-time.

1918 CE **Otto Fritz Meyerhof** (1884–1951, Germany and U.S.A.). Biochemist. Broke new grounds in the field of conversion and transport of energy in biological systems. Showed that muscular activity involves the anaerobic conversion of glucose and glycogen (a process known as *glycolysis*) into *lactic acid*[408]. During muscle rest lactic acid combines with oxygen to restore glycogen level.

Furthermore, Meyerhof showed that *yeast* and muscle possessed the same *coenzymes*. This made it appear possible that both types of cells broke down glucose by similar series of reactions. It was the beginning of the demonstration that the metabolic pathways of all organisms were essentially similar. All researches since Meyerhof's time have strengthened this view.

Meyerhof was born in Hanover to Jewish parents. He first studied psychology and philosophy but later switched to medicine and biochemistry. Professor of physiological chemistry at the University of Kiel (1918–1924); member of Kaiser Wilhelm Institute for Biology, Berlin (1924–1928); director of department of physiology there (1929–1938).

Fled Germany (due to Nazi persecutions) to Paris (1938–1940). Came to the U.S. in 1940 and became professor at the University of Pennsylvania (1940–1951). Awarded the Nobel prize for physiology or medicine (1922).

1918–1920 CE **Gaston Maurice Julia** (1893–1979, France). Mathematician. Forefather of modern *dynamical system theory* and is best remembered for his *Julia set*. Opened the floodgates of what is now known as '*fractal geometry*'.

---

[408]
$$\begin{array}{ccccccc} & & \mathrm{H} & & \mathrm{OH} & & \\ & & | & & | & & \\ \mathrm{H} & — & \mathrm{C} & — & \mathrm{C} & — & \mathrm{COOH} \\ & & | & & | & & \\ & & \mathrm{H} & & \mathrm{H} & & \end{array}, \qquad \text{or simply } C_3H_6O_3 .$$

It is formed in *sour milk* (its taste!) when lactose (milk sugar) is fermented by bacteria. Lactic acid is used for leavening dough (a process where dough is made to rise) because the acid reacts with the sodium bicarbonate to produce carbon dioxide, which lightens the dough by raising it (increase of volume). In the fermentation action of *yeast*, lactic acid is subjected to a further split $C_3H_6O_3 \rightarrow C_2H_6O$ (ethyl alcohol) $+ CO_2$.

With **Pierre Fatou**[409] (1878–1929) he was first to study the iteration in the complex plane of the mapping $z \to z^2 + c$, where $z = x + iy$ and c is a complex parameter. However, making his debut some 63 years before the advent of computer graphics, he could not visualize the startling results and the striking beauty of his maps.

Julia was born in Sidi-Bel-Abbès, Algeria. As a soldier in the first World War, Julia was severely wounded in a German attack on the French front designed to celebrate the Kaiser's birthday. Consequently he lost his nose and had to wear a leather strap across his face for the rest of his life.

Between several painful operations he carried on his mathematical researches in the hospital. In 1918 Julia published *Memoir sur l'iteration des functions rationalles* [*Journal de Math. Pure et Appl. 8*, 47–245], for which he received the Grand Prix de l'Academie des Sciences.

In this work he gave a precise analytical description of the set of complex points in $\mathbb{C}$ for which the nth iterate of the function $f(z)$ stays bounded as $n \to \infty$. Seminars were organized in Berlin (1925) to study his work, which included the first visualization of a Julia set. Although Julia became famous in the 1920's, his work was essentially forgotten until **Benoit Mandelbrot** brought it back to prominence in the 1970's through his computer experiments.

Deterministic Chaos and Fractal Geometry[410] — *the Map is the Treasure*

Most natural phenomena are nonlinear*; yet even today, theoretical analysis of physical systems is usually based on linear mathematical models, or ones allowing only small deviations from linearity. Linear models are still routinely used because they are much easier to solve than the correct nonlinear ones. Within the last several decades, however, both theoretical and experimental investigations of nonlinear phenomena have shown that often, behavior which* appears *to be random or chaotic is actually deterministic in its origin. Nonlinear deterministic systems under these conditions are predictable only for short times. This paradoxical situation exists because the deterministic solutions depend very sensitively on initial conditions. Such systems are said to exhibit deterministic chaos.*

It has also been found that several classes of systems show universal behavior at the onset of chaos[411]*. Thus, systems as diverse as a dripping faucet and a heart in ventricular fibrillation show many common features in their dynamics.*

Fractal structure

A set of points which fully (or "almost" fully, in a measure-theoretical sense) covers a line segment is said to be of topological dimension *unity; a set of points which fills a plane area is of* topological dimension *2, etc. One may, however, construct sets of points which intuitively may be assigned a fractional 'dimension'.*

Consider the following example: start with a line segment of unit length, which we shall call the zeroth generation *curve $(n = 0)$ or the* initiator*. From this initiator we construct the* generator *curve by removing the inner third of the initiator and replacing it by the two other sides of an equilateral triangle, built with the removed segment serving as the base; each new side also has length $\frac{1}{3}$. This is the* first generation *curve $(n = 1)$: it has $N_1 = 4$ segments, each of length $\delta_1 = \frac{1}{3}$ and total length $L_1 = \frac{4}{3}$ [the initiator had $\delta_0 = 1$, $N_0 = 1$, $L_0 = 1$].*

We now take each *segment of the generator and build upon it the* same *pattern reduced by a factor of 3; we then obtain a second generation curve with $N_2 = 4^2$ segments, $\delta_1 = \frac{1}{3^2}$ and $L_2 = \left(\frac{4}{3}\right)^2$.*

By replacing with a suitably reduced generator each segment of a given generation of the curve, a new generation is obtained. The n^{th} generation of this construction is a normal polygonal curve with a finite length, having the parameters $N_n = 4^n$, $\delta_n = 3^{-n}$ and $L_n = \left(\frac{4}{3}\right)^n$.

The set of points defined in the limit of infinite number of iterations $(n \to \infty;\ \delta_n \to 0)$, known as the Koch curve[412]*, is a curve for which* length *is not a useful parameter $(L_n \to \infty)$. It is continuous but does not possess a tangent at any point!*

---

[411] The word *chaos* was first used in a technical context by **T.Y. Li** and **J. Yorke** in Amer. Math. Monthly **82**, 985–992, 1975.

[412] **Helge von Koch** (1870–1924, Sweden). Mathematician. Principally known for his work on the theory of infinite systems of linear equations. **E.I. Fredholm** used his results in his method of solution of linear integral equations.

Instead of length, we define a new characteristic parameter in the following way: we force N_n *into the algebraic form* $N_n = (\delta_n)^{-d}$, *where* d *is found from* $\log N_n = -d \log \delta_n$. *This yields the Hausdorff-Besicovitch dimension*

$$d = \frac{\log N_n}{\log\left(\frac{1}{\delta_n}\right)}.$$

In our example $d = \frac{\log 4}{\log 3} \simeq 1.262\,8\ldots$. *The definition leads to* $L_n = \delta_n N_n = (\delta_n)^{1-d}$ *(the normalization is such that for* $d = 1$, $L_n \to$ *constant, as the case should be for a curve whose length is independent of* n, *i.e. independent of the resolution at which it is studied, in the continuum limit* $n \to \infty$*). A fractal*[413] *is a shape made of parts similar to the whole in some way. The Koch curve is a fractal set with a fractal dimension* $d = \frac{\log 4}{\log 3}$. *Note that if the initiator is an equilateral triangle of unit side with the same generator as above, the resulting shape is the Koch 'snowflake' curve, having the same fractal dimension. In this variant, while again* $L_n \to \infty$, *the enclosed area tends to a limit* $S_n \to \frac{8}{5} S_0$.

---

413 **Georg Cantor** (1833) thought up the oldest *fractal*. This is the so-called *Cantor point-set*. To construct an example, we start with a line-segment (including its end points). Of this we leave out the middle third, but not its end points. We are then left with two line-segments with a total of 4 endpoints. We treat each of these two line-segments like the original one: the middle thirds are removed, so that a total of 4 line-segments with 8 end-points remain. We continue this procedure. Eventually we will be left with discrete points only: the Cantor point-set (or *fractal*) built up from discrete points. It is now called a Cantor set or *Cantor dust*. If we take the length of the original line-segment as 1, then after n steps we have generated 2^n line-segments, each of length 3^{-n} with total length of $\left(\frac{2}{3}\right)^n \to 0$ as $n \to \infty$. Clearly, the Cantor set consists of the real numbers $x = \sum_{k=1}^{\infty}(a_k/3^k)$, where each base-3 digit a_k equals either zero or two (but not one). In base three fraction notation this becomes $x = .a_1a_2\ldots$. Note, for example, that the point $x = \frac{1}{3}$, which is in the Cantor set, is given by $x = 0.022\ldots$, because the above sum becomes $\frac{(2/3^2)}{1-\frac{1}{3}} = \frac{1}{3}$.

Kolmogorov (1958) defined the *capacity* of a point-set on a straight line [which Mandelbrot later (1977) called the *fractal dimension*] as $d = \lim_{h\to 0} \frac{\log N(h)}{\log\left(\frac{1}{h}\right)}$ where $N(h)$ is the smallest number of neighborhoods of size h needed to cover the set. In our example $h = 3^{-n}$, $N(h) = 2^n$, leading to $d = \frac{\log 2}{\log 3} = 0.6309\ldots$.

While sets of fractional Hausdorff dimension have been studied for many years in harmonic analysis, geometric measure theory and in the theory of singularities, the new term 'fractal' was coined and popularized by ***Benoit Mandelbrot*** *(1975).*

However, fractal geometry is today at the stage perhaps analogous to that at which the Newtonian calculus was in the days of ***George Berkeley*** *(1734): it is still a discipline with few rigorous definitions or theorems, and – unlike the early calculus – not a single problem has been solved by it. In fractal geometry one uses some mathematics to generate a picture — which generates more pictures. Then one asks more questions about the new picture, and so on. It thus consists mainly of algorithmic techniques for generating graphic images on a computer systems.*

The Logistic Map

The simplest model for continuous growth of a species with population $N(t)$, *limited by self-interaction effects (such as competition for food supply, or toxicity effects), is* $\frac{dN}{dt} = cN(1 - \frac{N}{k})$, $N \geq 0$, *where* c *and* k *are positive constants and the initial condition satisfies* $0 \leq N_0 = N(0) \leq k$. *This so-called logistic model (**Verhulst**, 1845), an example of the Riccati equation, is a relatively unexciting equation, having the deterministic solution*

$$N(t) = \frac{N_0 k e^{ct}}{k + N_0(e^{ct} - 1)} \to k \qquad \text{as} \quad t \to \infty.$$

The form of an ordinary differential equation presupposes that population variations at any given time t *only depend upon their instantaneous values at that same time. (It also assumes that the population itself is sufficiently numerous to allow a continuous, non-stochastic approximation.) However, in most natural populations the delayed effects of a number of regulating factors prove to be fairly important. Thus, presentation of a population in the form of discrete variable* N_t, *taking on different values at fixed times (e.g. at yearly intervals), is more realistic.*

This scheme exactly reflects the census-taking process for natural populations (in laboratory or field studies), which is usually realized at discrete points in time. The appropriate mathematical tool is thus that of difference *equations, where the population at time t depends in some definite way upon its values in a discrete set of past times.*

Consider the case where the population of every successive generation N_{t+1} depends only on the population of the previous generation N_t, namely $N_{t+1} = f(N_t)$ $(t \geq 0$ integer). Of course, this is valid only under the assumption of non-overlapping generations, i.e. when a new generation reaches maturity, the previous one already declines to extinction. It is also assumed that the main environmental properties are unchanging (thus no explicit t dependence), and that no part of the population is laid aside in diapause for a length of time that exceeds the span of one generation.

Some restrictions on f immediately follow from obvious considerations:

Since for biological reasons $N_t \geq 0$, clearly $f(N) \geq 0$ for all possible $N > 0$. Naturally $f(0) = 0$, and at small N the population increases (natural competition, negligible competition).

On the other hand, resource limitations require that $f(N) \to 0$, as $N \to \infty$.

Substituting $\frac{\Delta N}{\Delta t}$ for $\frac{dN}{dt}$, where $\Delta N = N_{t+1} - N_t$ and $\Delta t = 1$, the above logistic equation becomes

$$N_{t+1} = N_t \left[1 + c(1 - \frac{N_t}{k}) \right].$$

If at some time $N_t > k(1 + \frac{1}{c})$, this equation yields a negative value of N_{t+1}, which is not the case in the continuous model. From this point of view the discrete analogue of the continuous logistic growth model is biologically incorrect. But even if we disregard this, it turns out that their solutions are very different. The reason for this is that since t increases in discrete steps, there is an inherent delay in the development of changes, and the difference equation is in fact equivalent to a delay functional equation which is known to have oscillatory solutions [e.g. $N(t) = \frac{1}{a}N(t - T)$, $t \geq T$, $a \geq 1$ is solved by $N(t) = e^{-\frac{\ln a}{T}t} f(t)$, with $f(t)$ periodic with period T such that $f(t) = a^{t/T} N(t)$ in the initial interval $0 \leq t < T$].

Our logistic difference equation can be simplified into

$$x_{n+1} = r x_n (1 - x_n),$$

where $r = 1 + c$, $t = n$ units of time, and $N_t = k(1 + \frac{1}{c}) x_t$.

In this form it is known as the logistic map. Here $x_n \geq 0$ is a dimensionless measure of the population of the n-th generation and $r > 0$ is the *intrinsic growth rate, appearing as an adjustable parameter; a realistic solution must have* $x_n \leq 1$ *as well, to ensure* $x_{n+1} \geq 0$*. Though* $r = 1 + c > 1$ *in the above derivation, the logistic map is usually studied for all* $r > o$*.*

Given and initial population value $x = x_0$*, and a particular value of* r*, the equation is solved numerically by iteration to any desirable* n *value. The graph of* $rx(1 - x)$ *is a parabola with a peak value* $\frac{r}{4}$ *at* $x = \frac{1}{2}$*, restricting the control parameter* r *to the range* $0 \leq r \leq 4$ *(to ensure* $x_n \leq 1$*). It will map the interval* $0 \leq x \leq 1$ *into itself, so the iteration will not take us out of the interval* $[0, 1]$*.*

Suppose that we fix r*, choose some initial population* x_0*, and then use* $x_{n+1} = rx_n(1 - x_n)$ *to generate the sequence* $x_1, x_2, x_3, \ldots x_n, \ldots$

What happens?

Numerical experiments exhibit the following results:

- *The initial value* $x_0 = 0$ *invariably renders* $x_n \equiv 0$ *at all later times (*n *values* ≥ 1*) and for all* r *values. The initial value* $x_0 = 1$ *likewise yield the same result.*

- *For small growth rate* $r < 1$*, the population always goes extinct:* $x_n \to 0$*. We say that 0 is an attractor (limit point). Thus, extinction is nature's 'punishment' for insufficient fertility.*

- *For* $1 < r < 3$ *the population grows and eventually reaches a nonzero steady state, as can be seen when we plot the resulting time-series* x_n *vs.* n*. Let us take a closer look at this interval:*

Define an equilibrium point $\bar{x}$*, of the system as a fixed point of the map, i.e. one for which* $x_n = \bar{x}$ *guarantees* $x_{n+1} = x_n = \bar{x}$*. Mathematically it means that* $\bar{x} = r\bar{x}(1 - \bar{x})$*. This equation has two roots, one at* $\bar{x} = 0$ *(which we already encountered before) and the other at* $\bar{x} = 1 - \frac{1}{r}$*. For* $r < 1$*, the second fixed point renders negative values for* x_n*, which we dismiss as being unrealistic.*

For $r > 1$*, however, there will be two fixed points, one at* $\bar{x} = 0$*, and the other at* $\bar{x} = 1 - \frac{1}{r}$*. Now, an equilibrium (fixed) point may be either stable or unstable, according as small perturbations about the point result in dynamics that drive the numbers back to it or away from it, respectively.*

It can be shown that in the general case $\left|\frac{df(x)}{dx}\right|_{\bar{x}} < 1$ *implies stability (attractor), while* $\left|\frac{df(x)}{dx}\right|_{\bar{x}} > 1$ *implies instability (repeller). In our case, since* $f'(x) = r(1 - 2x)$*, we have for the first fixed point* $f'(0) = r$ *and for the second* $f'(1 - \frac{1}{r}) = 2 - r$*.*

Consequently, when $r < 1$, $\bar{x} = 0$ *is the only fixed point, and it is stable;*

But for $1 < r < 3$, *the origin becomes an unstable fixed point (repeller), while the second fixed point is stable (attractor). The map at* $r = 1$ *represents a bifurcation in the systems behavior: as* r *passes through this value, the single, stable fixed-point* $\bar{x} = 0$ *splits continuously into two fixed points – an unstable one remains at* $\bar{x} = 0$*, while the new fixed point (at* $\bar{x} = 1 - \frac{1}{r}$*) is stable.*

Similarly, there is a second bifurcation at $r = 3$ *corresponding to the onset of instability of the non-zero equilibrium point at* $\bar{x} = 1 - \frac{1}{r}$*.*

Thus, for $1 < r < 3$ *there are two equilibrium points of which the origin is unstable, and the other is stable. For* $2 < r < 3$ *numerical experiments show that the sequence* $x_1, x_2, x_3, \ldots$ *approaches the limit value* $1 - \frac{1}{r}$ *through oscillations on both sides of this limit. Our biological model is stable — there is balance in nature.*

However, as soon as r *becomes even a little greater than 3, a new phenomenon appears: the population builds up again and oscillates about the fixed point, alternating between a large population in one generation and a smaller population in the next. This type of oscillation, in which* x_n *repeats every two iterations, is called a period 2-cycle.*

Thus at $r = 3.1$, *after 200 iterations,* x_n *repeatedly hops back and forth between the two values* $0.76456\ldots$ *and* $0.55801\ldots$*, while the (now unstable) fixed point* $\bar{x} = 1 - \frac{1}{3.1} = 0.6774\ldots$ *remains unapproached. The 2-cycle orbit is stable*[414] *up to* $r = 1 + \sqrt{6} = 3.449\ldots$

---

[414] Asking for a fixed point of the *second-iterate map*, $f[f(\bar{x})] = f^2(\bar{x}) = \bar{x}$, renders a quartic polynomial equation for $\bar{x}$. However since $f(\bar{x}) = \bar{x}$ implies $f^2(\bar{x}) = \bar{x}$, the two solutions of the first-iterate map [namely, $\bar{x} = 0$, $\bar{x} = 1 - \frac{1}{r}$] are automatically included. After factoring out x and $x - (1 - \frac{1}{r})$ by long polynomial division, the equation $f^2(x) - x = 0$ simplifies to a quadratic equation with the solutions

$$p, q = \frac{1}{2r}[(r+1) \pm \sqrt{(r-3)(r+1)}],$$

which are real for $r > 3$. Thus a 2-cycle exists for all $r > 3$ as claimed,and $f(p) = q$, $f(q) = p$. At $r = 3$, the roots coincide and equal $\bar{x} = 1 - \frac{1}{r} = \frac{2}{3}$, which shows that the 2-cycle bifurcates *continuously* from $\bar{x}$. For $r < 3$ the roots are complex, which means that a 2-cycle does not exist.
To determine the r region of *stability* for the 2-cycle, we impose that p and q are stable fixed points of the second-iterate $f^2(x)$. Analytically,

$$\frac{d}{dx}\left(f^2(x)\right)_{x=p} = f'[f(p)]f'(p) = f'(q)f'(p) = 4 + 2r - r^2.$$

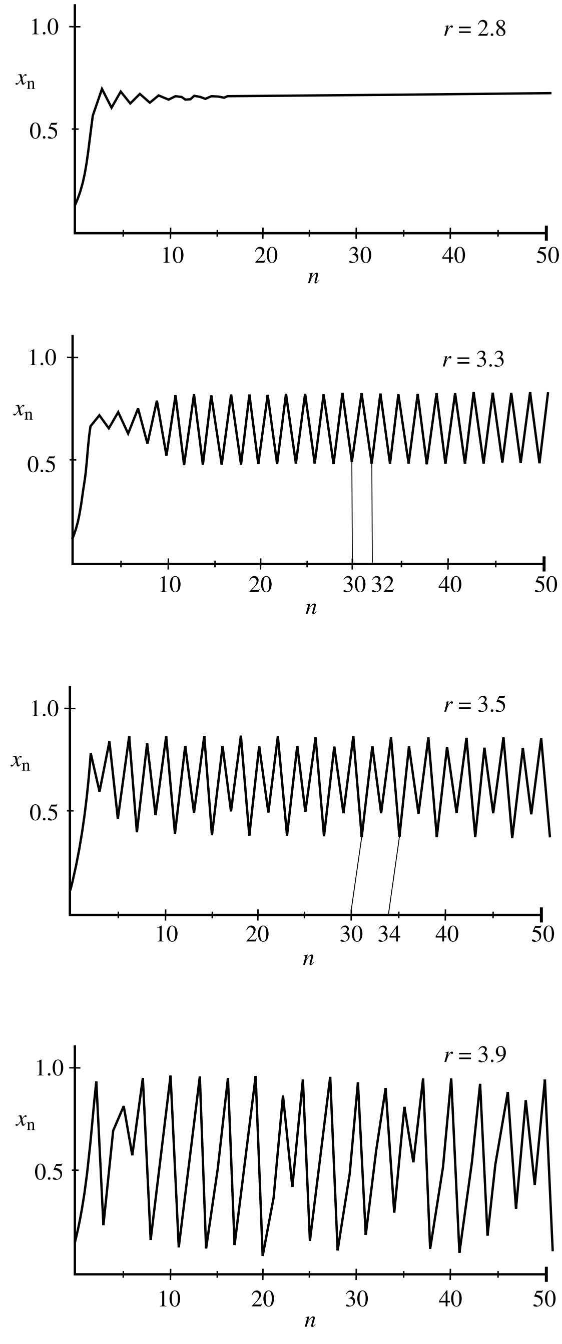

Fig. 5.4: The solution sequence of the Logistic – map recursion $x_{n+1} = rx_n(1 - x_n)$ for some values of the parameter r

At still larger r, the population approaches a stable cycle that now repeats every four generations: the previous cycle has doubled its period to period-4 [e.g. at $r = 3.45$ we find the values $0.87499\ldots$; $0.38281\ldots$; $0.82694\ldots$; $0.50088\ldots$, while the fixed point is at $0.71014\ldots$]. Further bifurcations results in progressive period-doubling to stable cycles of period 8, 16, 32... as r increases, each cycle becomes unstable at the $r-$value at which the next, longer-period cycle continuously "peels off" it – replacing it (until the next bifurcation) as the stable limit cycle.

Specifically, let r_n denote the value of r where a 2^n-cycle first appears. Computer experiments reveal that these threshold parameter values are:

$r_1 = 3$	(period 2 is born)
$r_2 = 3.449\cdots = 1+\sqrt{6}$	4
$r_3 = 3.54409\ldots$	8
$r_4 = 3.5644\ldots$	16
$r_5 = 3.568759\ldots$	32
$\vdots$	$\vdots$
$r_\infty = 3.569946\ldots$	∞

Note that the successive bifurcations occur at progressively smaller r intervals as we sweep through increasing values of r. Ultimately the sequence r_n converges to a limiting value r_∞. The convergence is asymptotically geometric: in the limit of large n, the distance between successive transitions shrinks by a constant factor

$$\delta = \lim_{n\to\infty} \frac{r_n - r_{n-1}}{r_{n+1} - r_n} = 4.669\ldots$$

We list the attractors corresponding to the various r-values:

Therefore the 2-cycle is linearly stable for $|4 + 2r - r^2| < 1$, i.e. for $3 < r < 1 + \sqrt{6} = 3.449\ldots$.

Interval	*Attractor at fixed point X*
$0 \leq r \leq 1$	$X = 0$
$1 < r \leq 3$	$X = 1 - \frac{1}{r}$
$3 < r \leq r_2$	2^1*-cycle*
$r_2 < r \leq r_3$	2^2*-cycle*
$r_3 < r \leq r_4$	2^3*-cycle*
...	...
$r_k < r \leq r_{k+1}$	2^k*-cycle*
...	...
$r_\infty = 3.56994\ldots$	

The limit ratio δ is called the Feigenbaum number[415]*, after the physicist who discovered the properties of this map (M. Feigenbaum, 1978). Beyond*

---

[415] The emergence of *chaos* as a research subject unto itself was a story not only of new theories and new discoveries, but also of the belated understanding of old ideas. Many pieces of the puzzle had been understood long ago by **Poincaré**, **Maxwell**, even by **Einstein** — and then forgotten. But when **Feigenbaum** first discovered the universality of chaos, the discovery was greeted with surprise, disbelief, and excitement. It soon became evident that there were structures in nonlinear systems that are fundamentally the same if one looked at them the right way. However, reserved attitudes still prevailed among mathematicians, who were unhappy with numerics and demanded a proof. In 1979, Feigenbaum supplied a 'reasonable proof' that finally convinced the diehards[416].

[416] The *universality* of certain scaling laws – manifested in period–doubling bifurcation sequences when general, iterated nonlinear maps are varied – is closely related to the universality of scaling laws of physical observables as a *phase transition* is approached in quasi–equilibrium, many-body interacting systems, such as condensed matter systems. Many such phenomena are known empirically; the longest-known example is the $\sqrt{T - T_c}$ behavior of bulk magnetization as a ferromagnetic sample's temperature T approaches the critical Curie temperature, T_c, from below.

Through the pioneering work of **L. Kadanoff**, **K. Wilson**, **Migdal** and others in the 1970s (involving theory and simulations), it was found that such *critical behavior* involving *power laws* is usually universal, in the sense that many dis-

r_∞ chaotic evolution can occur ("strange attractor"); that is, the long-term behavior of the iterated sequence $\{x_n\}$ does not settle down to any simple periodic motion.

The interval $(r_\infty, 4)$ contains an infinite number of narrow windows of r-values for which there exist stable m-cycles. The first such cycles to appear beyond r_∞ are of even period. Next odd cycles appear in descending order. The period 3-cycle[417] *first appears for $r = 3.828427\dots$ and stays stable up to $r = 3.841499\dots$. At the end of the 3-window begins a stable 6-cycle*

---

parate condensed–matter physical systems – each with a different microscopic Hamiltonian (classical or quantum) – all undergo the same dynamics near criticality. And through the deep analogy between condensed–matter systems and relativistic Quantum Field Theories – especially the mathematical correspondence between *partition sums* and *path integrals* – such critical behavior analyses were also fruitfully applied to the physics of elementary particles and their fields, the quantum vacuum, astrophysics and the early universe.

Apart from advance Monte-Carlo computer simulations, the main mathematical tool used in such studies is the *renormalization* group: a method of iteratively mapping the relevant effective Hamiltonian or action across many scales of space and or time. The universality of critical behavior was thus related to fixed points and asymptotic behaviors of nonlinear maps in various dimensions. The dimensions referred to here are those of thermodynamic phase diagrams; but renormalization–group methods were also applied to condensed–matter and quantum-field systems in various numbers of spacetime dimensions. These methods rely on the fact that thermodynamical phase transitions involve cooperative phenomena at many distance scales (fluctuations, excitations, correlations etc.)

The idea of universal bifurcation, fixed points, limit cycles, stability analysis, etc., was also extended to continuous – time maps (e.g. systems of ODEs describing mechanical, optical, chemical or biological systems), and to the dynamics of systems continuous in both space and time. For example, **I. Prigogine** and coworkers applied these methods to the study of the spontaneous emergence of spatial and temporal order and structure in far–from–equilibrium open thermodynamic systems, described by nonlinear systems of PDEs (Reaction – Diffusion – Advection equations).

In general, bifurcations – whether in the discrete Logistic map or more complex systems – are intrinsically *topological* in nature.

417 The period-3 window that occurs in $3.8284\dots \le r \le 3.8415\dots$ is the most conspicuous. Suddenly, against a backdrop of chaos, a stable 3-cycle appears out of the blue. This is explained as follows: starting from an n-iterate $x_{n+1} = f(x_n)$, we generate the next iterate $x_{n+2} = f(x_{n+1}) = f^2(x_n)$. Similarly $x_{n+3} = f^3(x_n)$. Now, any point p in a period-3 cycle repeats every three iterates, by definition. So such points satisfy $p = f^3(p)$ and are therefore

followed by further period doubling. The same is true for all other stable cycles of odd order. Figure 5.4 exhibits the behavior of the solution $x_n(n,r)$ *for some* r *values in the parameter range* $2.8 \le r \le 3.9$.

Outside the windows there are no stable periodic orbits, although there are an infinite number of unstable cycles. The dynamic behavior of the map is then called chaotic. The most chaotic case, $r = 4$*, deserves special attention since in that case the iterative map can be represented explicitly by an elementary function. Indeed,* $x_{n+1} = 4x_n(1 - x_n)$ *is solved exactly by* $x_n = \sin^2(2^n\theta_0\pi)$*, where* $0 \le \theta_0 < 1$*,* $\theta_0 = \frac{1}{\pi}\sin^{-1}\sqrt{x_0}$*. It is helpful to write* θ_0 *in base-2 form as*

$$\theta_0 = 0.b_1b_2b_3\cdots = \frac{b_1}{2^1} + \frac{b_2}{2^2} + \ldots$$

where

$$x_0 = \sin^2(\pi\theta_0), \qquad x_1 = \sin^2(2\pi\theta_0)\ \ldots etc.$$

Then at each iteration step the foremost binary digit is lost. If x_0 *is an arbitrary starting point, then as a rule* θ_0 *is an irrational number with an infinite string of zeros and ones, as in tossing a coin. This means that as a rule the orbit is aperiodic. Periodic orbits, always unstable, are produced by rational values of* θ_0*. Indeed, defining* $\theta_n = 2^n\theta_0 \pmod 1$ *we have* $x_n = \sin^2(\pi\theta_n)$.

For example, if $\theta_0 = \frac{1}{3}$ *(or* $x_0 = \frac{3}{4}$*), then* $\{\theta_n\} = \{\frac{1}{3}, \frac{2}{3}, \frac{1}{3}, \frac{2}{3}, \ldots\}$ *and* $x_n = \frac{3}{4}$ *is a fixed point. If* $\theta_0 = \frac{1}{5}$*, then* $\{\theta_n\} = \{\frac{1}{5}, \frac{2}{5}, \frac{4}{5}, \frac{3}{5}, \frac{1}{5}, \frac{2}{5}, \ldots\}$ *and* x_n *settles on the 2-cycle* $\frac{5\pm\sqrt{5}}{8}$*. For* $\theta_0 = \frac{1}{7}$ *we have the 3-cycle* 0.188*;* 0.611*;* 0.950*, and for* $\theta_0 = \frac{1}{9}$ *the 3-cycle* 0.117*;* 0.413*;* 0.970.

fixed points of the third-iterate map. Since $f^3(x)$ is an 8-th degree polynomial, we cannot solve it explicitly for its fixed points. We may however plot $y = f^3(x)$ vs x in the interval $0 \le x \le 1$ and intersect it with the diagonal $y = x$. There are in general 8 intersections, of which two are imposters [period-1 points for which $f(\bar{x}) = \bar{x}$]. Of the remaining six, only 3 are consistent with the stability of the cycle, while the other 3 are unstable. The graphical solution shows that as r decreases through $1 + \sqrt{8} = 3.8284\ldots$, the graph of $f^3(x)$ becomes tangent to the diagonal. At this critical value of r, the stable and unstable pair of period-3 limit cycles (which have been continuously approaching each other as r decreases) *coalesce and annihilate in a* so called *tangent bifurcation*! This transition marks the beginning of the periodic window. As as r increases it lasts until r exceeds $3.84149\ldots$

All the periodic sequences are unstable, because each rational value of θ_0 *is arbitrary close to an irrational value of* θ_0 *which generates an aperiodic sequence* $\{\theta_n\}$*. This means that the sequence* $\{x_n\}$*, for large values of* n*, depends sensitively on the initial value* x_0*, with exponentially growing separation of neighboring orbits.*

This sensitivity was demonstrated above for the special value $r = 4$ *because there it can be made explicit, but a similar situation occurs for other values of* r *for which there is an attractor which is infinite. The attractor is the same set for all initial values within the domain of attraction, but the* position *of* x_n *within the attractor for a given large value of* n *depends so sensitively upon* x_0 *as to be, in effect, random. Many other one-dimensional and higher-dimensional nonlinear ordinary differential equations and other nonlinear systems also display sensitive dependence on initial conditions.*

An issue associated with the logistic map is of fundamental importance that goes beyond this particular example:

A given recursion equation determines x_n *precisely in terms of* x_0*, yet in some respects a sequence* $\{x_n\}$ *which wanders nearby an infinite set of unstable limit–cycles may be regarded as a sequence of random numbers. Thus, although a particular value* x_n *may depend sensitively on* x_0*, the* statistical *properties of the sequence* $\{x_n\}$ *are the same for all values of* x_0 *which correspond to irrational values of* θ_0*. And yet, for a given value of* x_0*, the sequence* $\{x_n\}$ *is* in principle *determined completely and precisely by an algorithm, namely iteration of the map* f*.*

But in practice the sequence may be indistinguishable from a sequence of random numbers. In laboratory experiments, however careful, observations are not absolutely precise, and there is no possibility of distinguishing an irrational from rational value of a datum. Also, numerical errors (such as round-off error) are inevitable in the practice of processing the data to find x_{n+1} *from* x_n*.*

So we could not predict the precise long-range future of a chaotic system, even if we had an exact model on which to base our predictions. The errors in prediction grow exponentially in time (or in n*, in the discrete-time case at hand) because of our lack of exact knowledge of the present, so that doubling the accuracy of our measurements and data processing will avail only a little: we may predict with confidence only the near future of chaotic solutions and their statistical properties over a long time. It is because of this feature that such chaos is called* deterministic chaos*.*

It is therefore possible to make such statements as: "In the next 100 iterations, the following approximate state values are more likely to occur than others. . . ."

Though they are less exact than one might expect of deterministic time series, such predictions are potentially valuable nonetheless. Even though it may never be possible to precisely predict phenomena like the weather, earthquakes, population dynamics, the stock market or the sudden collapse of sand piles, one might foresee the global patters of their behavior — the "order within the chaos".

The logistic map is the simplest example that exhibits chaotic dynamics, and indeed serves as a paradigm for chaos.

It has been shown that other maps $x_{n+1} = f(x_n)$, *behave in a similar manner with the same scaling law. Thus, the phenomenon of period-doubling coupled with bifurcation-parameter scaling is an example of a* universal *property for a certain class of one-dimensional difference equations modeling dynamic processes.*

Moreover, period doubling and Feigenbaum scaling have been observed in many physical experiments.

The forgoing analysis shows that simple and fully deterministic models in which all the biological parameters are exactly known, *can nonetheless (if the nonlinearities are sufficiently severe) lead to population dynamics which are in effect indistinguishable from sample drawn from a* random process. *Apparently chaotic population fluctuations need not necessarily be due to random environmental or genetic fluctuations, or sampling errors, but may reflect the workings of some* deterministic, *but strongly density dependent, population model.*

Taking a practical point of view we can say that randomness *occurs to the extent that something cannot be predicted.* Unpredictability *can arise for many reasons; prime among these is shear ignorance: If we do not know the forces that cause something to change, then we cannot predict its behavior. For example, a common way to choose something randomly is to* flip a coin: *In the absence of any other information "heads" is just a likely as "tails", and the outcome is unpredictable. However, if we made precise measurements of the motion of the coin as it left our hand, we could predict the final outcome. People who are skilled in flipping a coin properly can do this.*

Another classical example of randomness is the game of roulette *— the final resting position of the ball is uncertain, but in fact the motion of roulette balls* can *be predicted using simple physical laws, to a sufficient degree of accuracy to give a significant advantage over the house. Thus we see that when one knows the dynamics and has enough information about the state of the system, some classical examples of randomness cease to be random.*

Aside from ignorance, three basic causes of randomness are known (at this point of time):

- *Quantum mechanics: there exists an intrinsic limit to the accuracy of measurements and to our knowledge of, or even the in-principle* knowability *of, intermediate physical variables between measurements. These are limits that no observer, sentient or automated, can go beyond, no matter how much we know or how careful we are.*

- *Complexity: a dynamic system that involves many irreducible degrees of freedom as measured in terms of the* dimension *of the motional phase or* state space*, e.g. the motion of gas particles or atoms in condensed–matter systems. Even setting Quantum Mechanics aside, we can never hope to keep track of all degrees of freedom in such a system, even if we know all relevant microscopic interactions. Yet, the simplest collective modes of behavior of the system – such as spatially smooth wave excitations, low-order statistical moments of various distributions, and the like – may be described by simple physical laws and their behavior predicted through tools such as equilibrium or near–equilibrium statistical mechanics, Landau–Ginsburg effective field theory, etc.*

Consequently, while the behavior of the individual particles is random, many bulk properties of the system are not.

Sometimes, however, microscopic fluctuations interact with collective dynamics at many scales of space and times, to produce complex behavior that is difficult to analyze; an example of this is turbulence *in fluid dynamics.*

- *Chaos: a sensitive dependence on initial conditions. For a* deterministic *dynamical system, chaos occurs when on the average, nearby trajectories separate at an exponential rate. This is measured by the* Lyapunov exponents: *if any of them are positive, then there is exponential separation and the system is chaotic. Chaos can cause random behavior even in systems with only a few degrees of freedom (such as the logistic map, the Lorentz, attractor – a dissipative nonlinear system of 3 coupled ODE's – or the* kicked rotor*). Here randomness emerges through the agency of deterministic evolution, without the need for a large number of system components, ignorance–caused uncertainties or quantum effects.*

Chaos and complexity by no means preclude each other. Chaos also occurs in systems with many degrees of freedom. On the other hand, complex dynamical systems can often be approximately truncated into simplified systems with only a few degrees of freedom, thereby losing much of their complexity, while maintaining chaos and randomness. Thus, some of the randomness of turbulent motion derives from chaos.

If in the recursive logistic map $x_{n+1} = rx_n(1 - x_n)$ *we change variable to* $x_n = \frac{1}{2} - \frac{1}{r}z_n$, *we obtain the new form* $z_{n+1} = z_n^2 + c$, *where* $c = \frac{r}{2} - \frac{r^2}{4}$. *In the logistic map,* x_n *and* r *are, of course,* real *numbers since they typically represent populations and reproduction rates.*

Fatou *(1906) and* ***Julia*** *(1918) formally extended such maps into the complex plane by letting* $z = x + iy$, $c = c_r + ic_i$, *in the hope of discovering new dynamic features and gaining better understanding of the classical logistic case.*

Indeed, the compact form $z_{n+1} = z_n^2 + c$ *then splits into a system of two coupled equations in real variables:*

$$\begin{aligned} x_{n+1} &= x_n^2 - y_n^2 + c_r \\ y_{n+1} &= 2x_n y_n + c_i \end{aligned}$$

This map produces dynamics in the so-called phase plane (x, y) *which depends on the value of the parameter* c *in the* control plane (c_r, c_i). *For fixed* c, *the set of points in the phase plane which remain bounded for all* n *is called the filled-in Julia set. Points which start outside this set rapidly iterate away to infinity. The* boundary *of the filled-in Julia set is often itself called the Julia set. For some points of the control plane set may not have any interior points (as occurs for a* cloud *of points or a curve).*

If $c = 0$, *all point in the* z*-plane either go to* $z = 0$ *[if* $|z_0| < 1$*], to* $|z| = \infty$ *[if* $|z_0| > 1$*] or to* $|z| = 1$ *[if* $|z_0| = 1$*]. Thus, the* unit circle *is the boundary between the two* basins of attraction *at* $z = 0$ *and* $z = \infty$.

However, if $c \neq 0$, *regions of the filled-in Julia set can take on an incredible variety of forms, highly self–similar, that may resemble clouds, branches of a bramble bush, sea horses, etc.*

In 1982, mathematicians extended the logistic map even further, into the field of quaternions *— iterating* $Q_{n+1} = Q_n^2 + q$, *where for each* n $Q_n = a_0 + a_1\boldsymbol{i} + a_2\boldsymbol{j} + a_3\boldsymbol{k}$ *is a 4-dimensional variable quaternions and* q *is a constant quaternion; a 2-dimensional slice in the* (a_0, a_2) *plane at fixed* (a_1, a_3), *then exhibits beautiful Julia sets.*

*The beauty of these sets has stimulated the esthetic senses of mathematicians, scientists, and artists alike (**Gaston Julia** himself, never* saw *a Julia set!) Using computer graphics it was found, for example, that if* $c = -0.124 + 0.565i$, *the Julia set has a* fractal structure *which is a self-similar connected set, in the sense that any arbitrary piece of the set can be used to* *construct the entire set by finite number of iterations. For $c = 0.12 + 0.74i$, the Julia set becomes more involved but is still connected.*

***Benoit Mandelbrot** (1980) was first to consider the changes in the Julia set as a function of the complex control parameter. Just as we can distinguish two sets of points in the phase-plane (x, y), two sets can also be distinguished in the control-plane. In the c-plane the Mandelbrot set is the set of points (c_r, c_i) such that $z_0 = 0$ yields a bounded sequence of planar points z_n.*

Like the Julia set, the Mandelbrot set is a connected set, but it has an amazingly complex structure in the c-plane. A new geometry, known as fractal geometry, thus emerged. More general studies involve the complex maps $z_{n+1} = z_n - \frac{f(z_n)}{f'(z_n)}$, known as Newton maps[418], since Newton's method of obtaining the zeros of $f(z)$ is based on the convergence of the iterates of the above recursion to a complex root of the function $f(z)$.

1918 CE, Dec.–1921, Apr. Sixty thousand Jews were killed in the Ukraine in antisemitic riots.

In March and April 1918 the Ukraine declared its independence and the "independent" citizens killed the Jews. Subsequent fightings between the Bolsheviks and the Ukrainian separatists led to the worst riots that had taken place since the 17^{th} century.

---

[418] Consider the first-order differential equation $\frac{dx}{dt} = f(x)$. Choosing h as a suitable small positive number, we define $x_n = x(nh)$ for $n = 0, 1, \dots$ and approximate the derivative $\frac{dx}{dt}$ at $t = nh$ by the Euler forward difference $\frac{1}{h}(x_{n+1} - x_n)$. It follows that $\frac{x_{n+1} - x_n}{h} = f(x_n)$ approximately, or $x_{n+1} = x_n + hf(x_n)$. Numerical analysts have studied the efficiency of this method and its convergence as the 'time' step $h \to 0$. Yet if we seek only equilibrium solutions, then we need only seek the zeros of $f(x)$. A well-known equation follows by the *Newton-Raphson method*. For this we assume that $f(x)$ is continuously differentiable, take x_n to be estimates of zeros of $f(x)$ and construct an improved estimate x_{n+1} by approximating the curve $y = f(x)$ by its tangent $y = f(x_n) + (x - x_n)f'(x_n)$ at the point $(x_n, f(x_n))$. This gives the next approximation $x_{n+1} = x_n - f(x_n)/f'(x_n)$, if $f'(x_n) \neq 0$. In practice, we start by *guessing* x_0 from what knowledge of $f(x)$ we have at the start, and compute successive approximations $x_1, x_2, \dots$, stopping when we have reason to believe that x_n approximates the exact zero with desired accuracy.

1918–1922 CE **Oswald Spengler**[419] (1880–1936, Germany). Philosopher of history and a mathematical scholar. His reputation rests on his book *The Decline of the West* (*Der Untergang des Abendlandes*), conceived before WWI, and finished in 1917.

Spengler sought to initiate a 'Copernican revolution' in historiography: history is devoid of any fixed point of reference or unifying meaning. The unit of history is not a nation but a *civilization*, and instead of the traditional linear succession of ancient, medieval and modern times he regarded history as a study of comparative *cultures* or *civilizations*[420].

Each culture was, in his view, an organism which like any other living thing went through a regular and *predictable* life cycle[421] of birth, growth, maturity and decay. *History has not happened to others*; Western civilization and its scientific revolutions are no less vulnerable than the now extinct civilizations of the Aztecs and the Incas, the Sumerians and the Hittites, the early civilization

---

- Spengler, O., *The Decline of the West* (Abridged Edition by A. Knopf), New York, 1962, 415 pp.

[420] Spengler makes a distinction between *culture* and *civilization*; the former is a period of creative activity of a society where the '*soul*' of the country-side predominates. It comprises the spring, summer, and autumn of a society. Civilization is the era of theoretical elaboration and material comfort, dominated by the '*intellect*' of the city. It comprises the winter of the society. Most civilizations continue hundreds, even thousands of years after their creativity is spent; so long as the culture phase lasts, the leading figures in a society manifest a sure sense of artistic 'style' and a personal 'form'. The breakdown of style and form most clearly marks the transition from culture to civilization. In this sense Rome is the civilization stage of the Greek culture. Together they form the classical world.

[421] As a cyclic historian, Spengler's three precursors were: The monk **Joachim of Floris** (1145–1202, Italy). He taught that each stage of history rose to its own climax, and each successive stage represents a higher level of spiritual development. Yet within each stage, the course of its unfolding bore a detailed resemblance to the course of its predecessor. The second precursor was **Giambattista Vico** (1668–1744, Italy), who advanced (1725) the doctrine that history is a *spiral of progress*: every turn is higher than the one before; history never repeats itself because it is viewed from a loftier position than before, enabling us to see wider horizons; history is the process of total liberation of human spirit, with each spiral bringing it closer to freedom.

The third precursor, **Nikolai Danilevsky** (1822–1885, Russia), most directly anticipated Spengler's major theories.

of China, and the so-called Greco-Roman civilization. The West is doomed to extinction, and another Chinese civilization, having entered its proper phase, will in time replace it.

Each culture is deeply rooted in its natural environment. It is a spiritual phenomenon, manifested in a world-view common to a specific society. If engulfs the entire field of its activity and is characterized by a *specific perception of depth and space*. Of these cultures, the two about which he knew most were the classical Greco-Roman and his own Western society. What was traditionally accepted as ancient history Spengler redefined as the history of the classical culture, plus a brief sketch of two preceding cultures, the Egyptian and the Babylonian, and the garbled account of a successor culture, which he called Magian (Iranian, Hebrew, Arabic).

Similarly, the conventional medieval and modern periods, together formed the history of the West, with side-glances at such non-European societies as China, India, and Aztec-Mexico. Every culture formed a distinct bloc of spiritual and physical reality, clearly delimited from its predecessors, contemporaries and successors. Yet each one went through the same *morphological stages*.

Within each culture, certain basic attitudes permeated all of life and thought. Properly defined and understood, these attitudes would give the key to the history of the whole culture. While they could most readily be identified in the realm of aesthetics (in the plastic arts and music, and above all in architecture) they exercised an equally pervasive influence over the forms of economics, war, and politics, and even over so unlikely a field as *mathematics*). Taken together, these basic attitudes formed a master pattern — a characteristic cast of human spirit working itself out in the history of every culture of which any record remains.

Spengler calls the first stage in the life cycle of a culture, a *spring*: Agricultural-based economy, life centered around the village in a feudal system. Its people exist in a 'precultural stage', characterized by mystical symbolism and primitive expressions. There is yet no philosophy, ideology, or technology.

Next comes *summer*: an effervescent aristocracy living in provincial towns brings about the decline of religion and the rise of science (the Greek Polis, the Renaissance). This period culminates in the first philosophical frameworks and new intellectual clubs.

It is followed by *autumn*, the zenith of intellectual creativeness, the era of big systems. Power is shifted from elite to business, from property to money. It is the era of *maturity*, the final attempt to refine all forms of intellectual development. Culture showing signs of fatigue is centered in big cities — a centralized monarchistic regime (Athens at its peak; 18^{th} century in Western Europe.)

The only way to go from here is down to the final *winter* stage: Culture declines into a civilization that exploits materialistic and organizational accomplishments. Uprooted proletariat inhabit world-cities subjected to expansionist war-mongering despots (e.g. Caesar, Napoleon). It is a dying culture characterized by a cult of science, degradation of artistic creativity and abstract thinking, dissolution of old norms, meaningless luxuries, outlets in sports, and rapidly changing fashions.

Each new cycle, however, was not simply a repetition of its predecessor. In the meantime, fresh cultural elements had appeared, which gave new spiritual content to the cycle. Thus the *Apollonian* man (classical culture) invented geometry, *Magian* man algebra, and *Faustian* man (Western) the calculus. For different culture, numbers mean totally different things. The space perception of the Apollonian man was local and limited and its artistic expression was the free-standing nude statue. It was manifested also in the political structure of the city-state.

The Faustian man, on the other hand, experienced the endless vistas of limitless space. He has lived in eternal restlessness, and was longing for the unattainable. It began with skyward striving of the medieval cathedrals, found a new outlet in the perspective and color of Renaissance and 17^{th} century painting, and ended in music, which alone spoke a language sufficiently abstract to convey a sense of spiritual infinity. In the will to conquer distance, Faustian man has created his most eloquent symbols: *the Copernical view of the universe, the faith of the explorer, and the machines that decade by decade have produced more and traveled faster than ever their inventors had considered possible*. The entire activity of the Faustian man aims to fill his unlimited, endless space.

For Spengler, Western history does not start, as in schoolbooks, with the fall of Rome in 476 *CE*. The first 5 centuries of medieval history he regards as a kind of twilight era, in which the memories of Greco-Roman civilization, the omnipresence of the Judeo-Islamic forms, and the stirrings of a new indigenous spirit, struggled for possession of the Western European soul.

It was not until the 10^{th} century that the Faustian culture was born. With the reform of the Papacy, the reestablishment of an imperial authority, the articulation of feudal society, and the emergence of Romanesque architecture, the new culture manifests itself in clear and vigorous form. Its focal point is Christianity — an aspiring faith which gives to the Middle Ages, the springtime of Western culture, a quality of high tension overflowing with the excitement of passionate deeds and spiritual discovery.

After unfolding its full possibilities in the triumph of Ghotic architecture, and the theological constructions of scholastics and mystics, the summer phase of Faustian culture breaks down in internal contradictions. One of these is the so-called ‘Renaissance’ (essentially an affair of the *nobility*). Its spiritual counterpart, the Reformation, represented a change of orientation for the *clergy*. It formed part of the shift in the cultural center of gravity from the countryside to the city, and provided a religious foundation for a third social class, the new *bourgeoisie*.

In the new society of the cities, Faustian culture reached its maturity. The artistic embodiment of ripe culture is the architecture of the Baroque and the art of the great painters of the 17^{th} century. Ultimately the Faustian spirit found its manifestation in the realm of music which, since ca 1670, dominates the cultural life of the West. Intellectually, the era is one of free inquiry and scientific speculation. Its characteristic thinker is Descartes, the philosophical equivalent of the pre-Socratic.

The 18^{th} century is the autumn of the Faustian soul. It offers the last, most exquisite creations of fully-realized style and form: the art of the Rococo; the music of Mozart, the philosophical writings of Kant and Goethe, who like Plato and Aristotle in the Apollonian world, give a *conclusive formulation* to the deepest speculation of their culture.

As against this positive, creative aspect, the contrasting tendency of criticism and destruction comes more and more to predominate as the century advances. Where earlier a host of cities, strongly differentiated and with intense local consciousness, produced the most varied artistic and intellectual life, now a few great cities like Paris and London draw all aspiring talents into an ever-tightening circle. The century ends in the great 1789 revolution in which the middle class assumes authority. In the struggle between the monarchy and its enemies, the victory goes to Napoleon — the “romantic” tyrant and “contemporary” of Alexander the Great.

With the 19^{th} century begins the winter of the West, the ‘civilization’ phase of the Western spirit. Its 900 years of ‘culture’ have passed, and there is no creativity left in it: The popular preachers of materialism and skepticism are to the 19^{th} century what the Cynics and Epicurians were to antiquity. Socialism — a philosophy of resignation — performs the same function of ethical transvaluation as Stoicism in the Apollonian world and Buddhism in China.

Equally meaningless are the forms of political life. The most characteristic of them, parliamentarism, is nothing more than a transition device, serving to obscure with hollow rhetoric the basic political reality — the triumph of money. Before the power of financial speculation, everything else must give way: Politicians have no choice but to become the paid agents of the financiers.

With the 20^{th} century an age of wars is opening. This phase, which regularly occupies at least the first two centuries of each ‘civilization’, has actually been in progress ever since the time of Napoleon. As opposed to the old wars between national armies, they will be the battles grouped around born leaders of rare political and military talent — the new Caesars, struggling for the mastery of the world. Eventually one of the Ceasars will win out over all his rivals and establish a universal imperium.

Long before this time, life will have descended to a level of general uniformity, in which local and national differences will have virtually ceased to exist. The only places that will matter will be a handful of world-cities — the 'megalopolis', like New York or London, as opposed to the 18^{th}-century city of culture, which still retained some connection with the living tradition. These 'barrack cities' will be what Hellenistic Alexandria and imperial Rome were to the ancient world — vast assemblages of people living all on top of each other, a shiftless mob, willing to obey any leader who will keep them amused.

Their life will be a meaningless repetition of purely mechanical tasks and vulgar brute diversions. Even intellectual activity will have become mechanized, practical, cold, and merely 'clever'. The educated will have lost their feeling for language, and the same 'basic' speech will be on the lips of intellectuals and common laborers alike. Eventually, when every trace of form and style will have disappeared, a new primitivism will begin to pervade all human activity. Even the feeling for scientific norms — which will have survived the dissolution of culture — will grow vague and uncertain. Men will be ready to believe anything; they will regain their appetite for the mysterious and the supernatural. In vulgar credulity, they will find an escape from the universal drabness and mechanization. Out of the desolation of the cities there will arise a 'second religiosity', a fusion of popular cults and the memory of nearly forgotten piety.

We cannot choose our destiny, and we have no alternative but to make the best of the historical situation in which we have been placed. But within the established master-plan, there still is room for individual initiative[422]: the 'themes' are foreseen, but their 'modulations' — the precise fashion is which predetermined development will play themselves out in the actual performance of history — depend on the character and capacities of the individual players.

Hopefully, the Vico-Spengler cyclic 'law' can be modified and generalized such that we can still *buy time* to develop the proper methodology and employ it to improve our long-term chances to stem the tide of decay.

Oswald Spengler was born at Blankenburg, in the Harz, Germany. On his father's side he came from a line of mining technicians, to which he owed his

[422] In line with the famous maxim of **Rabbi Akiva** (ca 100 CE) "All is foreseen and free will is given".

mathematical and scientific talents. His mother's family provided the artistic bent. After his graduation from a classical high school in Halle, Spengler followed the customary German practice of attending two or three universities in turn: Münich, Berlin and finally Halle, majoring in mathematics and the natural sciences. Meanwhile he had upheld another tradition of making several trips to Italy, which the august example of Goethe had established as the goal of the young German's cultural pilgrimage.

This rare blend of education in mathematics, physics, natural history, history and art is the foundation of the peculiar character of Spengler's work. In it, unexpected parallels between scientific truths of physics and mathematics and the artistic and other cultural achievements of an epoch of history, are drawn.

Spengler received his doctor's degree from the University of Halle in 1904. In 1908 he received a teaching appointment in a Hamburg high school, teaching mathematics, science and history. In 1911 he gave up his teaching career and moved to Münich, making his living as a private scholar. With the outbreak of the First World War, Spengler fell into serious financial difficulties. Since he suffered from both a heart condition and acute nearsightedness, he was never called up for military service.

During the war years, Spengler lodged in a dreary slum, took his meals in cheap working-class restaurants, and wrote much of the *Decline* by candlelight. As a bachelor and city-dweller, he found it difficult to obtain even the bare necessities of food, heat and clothing. He was sustained by the conviction that a great, inchoate idea was germinating inside him and that he must fight his way through the laborious process of bringing it to expression.

In the summer of 1918, only a few months before the final defeat of the German Empire in WWI, the *Decline* began to appear in the bookstores of Germany and Austria. After a few weeks of public hesitation, the book started to sell, and it has continued to sell ever since.

The year 1919 was the "Spengler year". Everyone seems to be reading him; everyone was wondering just who he was. Within 8 years after the original publication, total sales had reached 100,000. Spengler, like Schopenhauer and Nietzsche before him, had become the philosopher of the hour. Quite understandably, the *Decline* appealed to lay people who where frantically seeking rationalizations for the despair they already felt. The scholars and specialists, however, recoiled from the notion of predetermined future, and reproached him for shallowness, incompetence and charlatanism.

As early as 1920, the general public had begun to lose interest, and by 1924 even the scholarly furor had largely subsided. The German public — driven to distraction by a galloping inflation and endemic civil war — had turned to more immediate and practical concerns. Spengler never won an academic appointment and his attempts to establish himself as a political commentator were unsuccessful. His political ideas had some affinity with those of the National Socialists (which fact they indeed exploited), but his hopes of influencing them came to nothing: after their rise to power he was denied, and later died in isolation.

In retrospect, one may conclude that Spengler's failure to establish a number of vital links in the sequence of future events (relative to 1923), reflects the inadequacy of his personal preconceptions. His faulty economics, his 'metaphysical' and unrealistic definition of social classes, drastically limit his comprehension of 20^{th} century political movements.

Yet, the basic idea is there, even when the formulation is faulty: More poignantly than any of his predecessors, Spengler has sensed the unprecedented character of our time — the resurgence of those primitive values that so sharply divide the 20^{th} century from the centuries that went before it.

Under the crude phraseology of a "colored peril", for example, Spengler expresses something of a tragic cultural misunderstanding between Asia and the West — an incompatibility far transcending the clash of political institutions and economic interests. And beyond this inter-continental struggle, he sees the terrible outlines of a whole world delivered over to conquest and virtually perpetual war. He grasps the dilemma of creative endeavor in an era of mass culture — its fatal division between a merely repetitive popular art and the esoteric experiments of the 'progressive' schools. And he understands the implications of mass culture itself.

He sees the whole 'phoneyness' of contemporary life — the depressing uniformity of great city society and its deadening effect on democratic procedures. Finally, he comprehends the emptiness and despair that are leading so many of our contemporaries — the untutored and the highly sophisticated alike — to seek solace in a return to dogmatic religion.

It is somewhere between literature and prophecy that the *Decline* has made its most telling contribution. It is a symptom, a synthesis, a symbol of a whole age that Spengler's book remains one of the major works of the 20^{th} century. Indeed, it has gained in stature as the passage of time has enabled us to place it in the context of the events of the past nine decades and the further catastrophes that many anticipate. For when everything else has been said, *The Decline of the West*, and the state of mind it expresses, set before us the spectre of a new barbarism. It formulates, more comprehensively than any other single book, the now familiar pessimism of the 21^{th} century West with regard to its own historical future.

Worldview XXXVI: Spengler

* * *

"Egyptian pyramids, Doric temples, and Gothic cathedrals are mathematics in stone".

* * *

"The sense of form of the sculptor, the painter, the composer, is essentially mathematical in its nature; The same inspired ordering of an infinite world which manifested itself in the projective geometry of the 17^{th} *century, could vivify, energize and suffuse contemporary music with the* harmony *that it developed out of sound physics, and contemporary painting with the principle of* perspective *(the felt geometry of space that only the West knows). For it was the wish, intensified to the point of longing, to fill a spatial infinity with sound which produced (in contrast to the classical lyre and reed) the two great families of keyboard instruments (organ, pianoforte etc.) and bow instruments, and that as early as the Gothic time. It was then that the organ was developed into the* space-commanding *giant that we know, an instrument the like of which does not exist in all musical history. The free organ-playing of Bach and his time was nothing if it was not analysis — analysis of a strange and vast tone-world".*

* * *

"When, about 540 BCE*, the circle of the Pythagoreans arrived at the idea that* number is the essence of all things*, a wholly new mathematics was born. It came forth from the depths of the Classical soul as a formulated theory, a mathematics born in one act at one great historical moment.*

To Euclid, the triangle is the bounding surface of a figure, never a system of 3 intersecting lines or a group of three points in 3-dimensional space. Euclidean geometry is only in agreement with the phenomenal world within the limits of the drawing board. For Euclidean parallels meet already at a line of the horizon (a simple fact upon which all our art perspective is grounded), let alone the triangle formed by an observer and two parallel lines to distant stars.

In the famous treatise on the grains of sand, Archimedes proves that the filling of Aristarchos' Cosmos with atoms of sand leads to very high, but not *infinite number. The exhaustion method of Archimedes through which he achieved the quadrature of the parabola section by means of inscribed triangles, are in sharp contrast to the idea of the Riemann integral. Nowhere else did the two mathematical ideas approach each other more closely then in this instance, and nowhere is it more evident that the gulf between the two is impassable. It was the instinct that guided Nicolaus Cusanus (ca 1450), from the idea of the* unendingness of God in nature *to the elements of the* infinitesimal calculus*".*

* * *

"The Cartesian geometry expresses the emancipation of geometry from servitude to optically realizable constructions and measurable lines. With that the analysis of the infinite became a fact. The clearest example of this is the conversion of angular functions into periodic functions*, and their passage into the realm of infinite numbers".*

* * *

"The time of the great *mathematicians is past. Our tasks today are those of preserving, rounding off, refining, selection — in place of big dynamic creation, the same clever detail which characterized the Alexandrian mathematics of the late Hellenism".*

* * *

"Only in the 19^{th} *century was the infinitesimal calculus made logically secure by Cauchy's definitive elucidation of the limit idea; the limit is no longer that which is approximated to but the approximation,* the process*, the operation itself. It is not 'an infinitely small quantity' but the 'lower limit of* every possible *finite magnitude — a relation".*

* * *

"The liberation of geometry from the visual, and of algebra from the notion of magnitude, and the union of both in the great structure of the theory of functions — this was the grand course of Western number — thought. The

constant number of the classical mathematics was dissolved into the variable. Geometry became analytical, replacing the mathematical figures by abstract spatial relations".

1918–1926 CE **Arthur Scherbius** (1878–1929, Germany). Electrical engineer and inventor of the rotary electro-mechanical enciphering machine, the *Enigma*. It played a major role in the Intelligence-war of WWII.

Scherbius was born in Frankfurt-am-Main and was the son of a small businessman. He studied electricity at the Technical College in Munich, and then went on to study at the Technical College in Hanover, finishing in March 1903. The next year, he completed a dissertation, "Proposal for the Construction of an Indirect Water Turbine Governor", and was awarded a doctorate in engineering.

Scherbius subsequently worked for several electrical firms in Germany and Switzerland. In 1918, he founded the firm of Scherbius & Ritter. He made a number of inventions, e.g. asynchronous motors, electric pillows and ceramic heating parts; his research contributions led to his name being associated with the Scherbius principle for asynchronous motors.

The Enigma machine was primarily intended to allow business to communicate confidential documents efficiently without the need for slow codebooks. There were several commercial models (1918–1923), and one of them (in somewhat modified version) was adopted by the German Navy (1926). Another modified version was adopted a few years later by the German Army. Scherbius was killed (1929) in a horse carriage accident.

The *Enigma* was essentially an electrical version of *Alberti's* cipher disc. The basic form of Scherbius' invention consists of 3 elements connected by wires: a keyboard for inputting each *plaintext* letter, a scrambling unit that encrypts each plaintext letter into a corresponding *ciphertext* letter, and a display board consisting of various lamps for indicating the ciphertext letter.

In order to encrypt a plaintext letter, the operator presses the appropriate plaintext letter on the keyboard, which sends an electric pulse through the central scrambling unit and out the other side, where it illuminates the corresponding ciphertext letter on the lampboard. Now, the scrambler disc automatically *rotates* by $\frac{1}{26}$ of a revolution each time a letter is encrypted. Thus, the cipher alphabet changes after each encryption. Consequently, the *encryption of the same letter is constantly changing.* With this rotating setup, the scrambler essentially defines 26 cipher alphabets, *implementing a polyalphabetic cipher that beats frequency analysis.*

However, as it stands, the machine suffers from one obvious weakness: typing a given letter 26 times will return the scrambler to its original position, and typing that letter again will repeat the pattern of encryption. In general, cryptographers are keen to avoid repetition because it leads to regularity and structure in the ciphertext, symptoms of a weak cipher.

Scherbius alleviated this weakness by introducing a second scrambler disc. Through this device, the pattern of encryption is not repeated until the second scrambler is back where it started, which requires 26 complete revolutions of the first scrambler, or the encryption of 26×26 letters in total. In other words, there are 676 distinct scrambler settings, which is equivalent to switching between 676 cipher alphabets.

For extra complexity, Scherbius added a *third disc*, providing $17,576$ distinct scrambler arrangements. Now, the *initial settings* of these 3 discs provide the *key*, and are dictated by a codebook, which lists the key for each day.

Once the scramblers have been set according to the codebook's daily requirement, the sender can begin encrypting. He types in the first letter of the message, sees which letter is illuminated on the lampboard, and notes it down as the first letter of the ciphertext. Then, the first scrambler having automatically stepped on by one place, the sender inputs the second letter of the message, and so on. Once he has generated the complete ciphertext, he hands it to a radio operator who transmits it to the intended receiver.

In order to decipher the message, the receiver needs to have another Enigma machine and a copy of the codebook that contains the initial scrambler settings for that day. He sets up the machine according to the book, types in the ciphertext letter by letter, and the lampboard indicates the plaintext. In other words, the sender typed in the plaintext to generate the ciphertext, and now the receiver types in the ciphertext to generate the plaintext — encipherment and decipherment are mirror processes.

It is clear that the key, and the codebook that contains it, must never be allowed to fall into enemy hands. It is quite possible that the enemy might capture an Enigma machine, but without knowing the initial settings used for encryption, they cannot easily decrypt an intercepted message. Without the codebook, the enemy cryptanalyst must resort to checking all the possible keys, which means trying all the 17,576 possible initial scrambler settings. The desperate cryptanalyst would set up the captured Enigma machine with a particular scrambler arrangement, input a short piece of ciphertext, and see if the output makes any sense. If not, he would change to a different scrambler arrangement and try again. If he can check one scrambler arrangement each minute and works night and day, it would take almost two weeks to check all the settings. This is a moderate level of security, but if the enemy set a dozen people on the task, then all the settings could be checked within a day. Scherbius therefore decided to improve the security of his invention by increasing the number of initial settings and thus the number of possible keys.

He could have increased security by adding more scramblers (each new scrambler increases the number of keys by a factor of 26), but this would have increased the size of the Enigma machine. Instead, he added two other features. First, he simply made the scramblers removable and interchangeable. So, for example, the first scrambler disc could be moved to the third position, and the third scrambler disc to the first position. The arrangement of the scramblers affects the encryption, so the exact arrangement is crucial to encipherment and decipherment. There are six different ways to arrange the three scramblers, so this feature increases the number of keys, or the number of possible initial settings, by a factor of six.

The second new feature was the insertion of a *plugboard* between the keyboard and the first scrambler. The plugboard allows the sender to insert cables which have the effect of swapping some of the letters before they enter the scrambler. For example, a cable could be used to connect the `a` and `b` sockets of the plugboard, so that when the cryptographer wants to encrypt the letter `b`, the electrical signal actually follows the path through the scramblers that previously would have been the path for the letter `a`, and vice versa. The Enigma operator had six cables, which meant that six pairs of letters could be swapped, leaving fourteen letters unplugged and unswapped. The letters swapped by the plugboard are part of the machine's setting, and so must be specified in the codebook.

Each month, Enigma operators would receive a new codebook which specified which key should be used for each day. For example, on the first day of the month, the codebook might specify the following *day key*:

(1) *Plugboard settings*: `A/L-P/R-T/D-B/W-K/F-O/Y.`
(2) *Scrambler arrangement*: 2-3-1.
(3) *Scrambler orientations*: `Q-C-W.`

Together, the scrambler arrangement and orientations are known as the scrambler settings. To implement this particular day key, the Enigma operator would set up his Enigma machine as follows:

(1) *Plugboard settings*: Swap the letter A and L by connecting them via a lead on the plugboard, and similarly swap P and R, then T and D, then B and W, then K and F, and then O and Y.

(2) *Scrambler arrangement*: Place the 2^{nd} scrambler in the 1^{st} slot of the machine, the 3^{rd} scrambler in the 2^{nd} slot, and the 1^{st} scrambler in the 3^{rd} slot.

(3) *Scrambler orientations*: Each scrambler has an alphabet engraved on its outer rim, which allows the operator to set it in a particular orientation. In this case, the operator would rotate the scrambler in slot 1 so that Q is facing upward, rotate the scrambler in slot 2 so that C is facing upward, and rotate the scrambler in slot 3 so that W is facing upward.

The following list shows each variable of the machine and the corresponding number of possibilities for each one:

Scrambler orientations. Each of the 3 scramblers can be set in one of 26 orientations. There are therefore $26 \times 26 \times 26$ settings:	$17,576$
Scrambler arrangements. The three scramblers (1, 2 and 3)can be positioned in any of the following six orders: 123, 132, 213, 231, 312, 321.	6
Plugboard. The number of ways of connecting, thereby swapping, six pairs of letters out of 26 is enormous:	$100,391,791,500$
Total. The total number of keys is the multiple of these three numbers: $17,576 \times 6 \times 100,391,791,500$	$\approx 10,000,000,000,000,000$

Scherbius believed that Enigma was impregnable. The Poles (1933) and the British (1940) proved him wrong.

1918–1929 CE **Alexander Marcus Ostrowski** (1893–1986, Germany and Switzerland). Mathematician. A leading contributor to the theory of p-adic numbers[423]. Established important theorems in the fields if algebraic

[423] *Ostrowki's Theorem*: The norms $|x|$ and $|x|_p$ $p = 2, 3, \ldots$ exhaust all nonequivalent norms on the field of rational numbers.

In 1918, Ostrowski created the novel concept of the *p-adic valuation*, defined as follows: For each integer $n \neq 0$ and fixed prime number p, the valuation $\nu_p(n)$ is the unique positive integer satisfying:

$$n = p^{\nu_p(n)} n' \qquad \text{with } p \text{ not dividing } n'.$$

geometry, and the theory of functions (quasi-analytic functions, meromorphic functions and convex functions).

Ostrowski was born in Kiev (Ukraine) to Jewish parents. Studied at the University of Marburg and Göttingen (Ph.D. 1921). Assistant to **Felix Klein** at Göttingen (1921–1923). Oxford and Cambridge Universities (1924–1926). Professor at Basel University since 1927. On the staff of the National Bureau of Standards, Washington D.C. USA, 1927–1958.

1918–1933 CE **Emmy** (**Amalie**) **Noether**[424] (1882–1935, Germany, U.S.A.). Distinguished mathematician. A founder of modern algebra. Her innovations gained her recognition as the most creative abstract algebraist of modern times.

During 1920–1927 her investigations centered on the general theory of *ideals* (special subsets of rings) for which her *residual theorem* is an important part. She put forward an axiomatic basis for a completely general theory of ideals. From 1927 on, Noether concentrated on non-commutative algebras, their linear transformations and their application to commutative number fields by means of the concept of cross-product. She also studied hypercomplex number systems and their representation. Much of her work appeared in the publications of students and colleagues. [**Emil Artin** (1898–1962); **Helmut Hasse** (1898–1979); **Richard Brauer** (1901–1977); **Werner Schmeidler** (1890–1969); **Van der Waerden** (1903–1996); **Max Deuring** (1907–1984); **Issai Schur** (1875–1941); **P.S. Alexandrov** (1896–1982); **L.S. Pontryagin** (1908–1988).]

Some of her pupils became famous algebraists in their own right and spread her ideas throughout the world. Oftentimes, a suggestion or even a casual

---

The p-adic *absolute value* of a rational number x is then defined via $|x|_p = p^{-\nu_p(x)}$ with $x = p^{\nu_p(x)}\frac{a}{b}$, p not dividing a, b.

remark revealed her great insight, and stimulated another to complete and perfect the idea.

In 1918, Noether discovered a theorem (*Noether's theorem*) in which she stated that conservation laws of certain physical systems are consequences of corresponding symmetry transformations (such as translations, rotations etc.). The theorem provides a method for constructing (under certain conditions) a complete set of integrals of motion for any system of fields for which the action integral is invariant with respect to a certain group of infinitesimal continuous transformations (*Lie group*).[425]

Emmy Noether was born in Erlangen, Germany. She was the daughter of the mathematician **Max Noether** (1844–1921). [Professor in Erlangen since 1875. One of the leaders of 19th century algebraic geometry.] She received her Ph.D. in 1907, with a dissertation on algebraic invariants. At Erlangen she published half a dozen papers, and had lectured to her father's classes from time to time when he was ill. She came to Göttingen in 1916. Being a woman, she could not obtain any academic position — in spite of the efforts made on her behalf by the greatest mathematicians of the day[426]. Finally, in 1919, she won formal admission as an academic lecturer. In 1922 she became an unofficial associate professor (with no salary and no obligations).

---

425 A *conservation law* is any rule, derived from the basic laws of physics, that says that the total amount of some quantity is constant and does not change with time. A notable example is energy which can be neither created nor destroyed but only transformed from one form to another. What Emmy Noether showed was that for every symmetry of the laws of physics there is a corresponding conservation law (with some exceptions). We *now* know that the converse is also true: Every conservation law must be associated with a corresponding symmetry.

Thus Noether's theorem can be promoted to *Noether's principle*: The laws of physics must be such that every symmetry of nature corresponds to a conservation law, and vice versa.

During the last 50 years it was discovered that many, and maybe all, of the laws of physics themselves can be generated from symmetry principles. It now seems that all the interactions of physics are caused by a special kind of field called a *gauge field*, whose structure and behavior are completely dictated by a new symmetry requirement of *local symmetry*.

426 Even Hilbert failed to avert the decision of the Göttingen senate, to which he reacted: "*Meine Herren, I do not see that the sex of the candidate is an argument against her admission as a Privatdocent. After all, the Senate is not a bathhouse*". He solved the problem of keeping her at Göttingen in his own way: Lectures would be announced under his name but delivered by Fräulein Noether.

When the Nazis came to power in 1933, Noether, along with many other Jewish professors at Göttingen, was dismissed. She then left for the United States, to become visiting professor of mathematics at Bryn Mawr College and to lecture and conduct research at the Institute for Advanced Study, Princeton, NJ.

She died at Bryn Mawr, PA following an operation. In his office at the Institute for Advanced Study, Einstein wrote a letter to the editor of The New York Times, in which he reported her death only briefly:

"*In the judgment of most competent living mathematicians, Fräulein Noether was the most significant creative female mathematician*[427] *thus far produced*".

Her brother, **Fritz Noether** (1884–1941), was a professor of mathematics at the Breslau Technical Highschool and left Germany in 1933 for a research institute in Tomsk, Siberia[428]. Thus, the Noether family is a striking example of the hereditary nature of mathematical talent.

---

427 **Edmund Landau**, when asked for a testimony to the effect that Emmy Noether was a great woman mathematician, said:
"I can testify that she is a great mathematician, but that she is a woman, I cannot swear."

428 Arrested (1937) in Tomsk by the NKVD and executed (shot) in the summer of 1941 on the charge of being a German spy(!). This became known only after the dissolution of the Soviet Union (1991).

Noether's Theorem — Symmetry and Conservation Laws

When the equations of motion of a physical theory are derivable from a variational principle (Hamilton's principle), a general and systematic procedure for the establishment of the theory's conservation theorems can be developed from a direct study of the integral over dynamical history ("action functional"), the variation of which is set to zero. Since the general equations of mechanics, electromagnetic theory, quantum field theories, GTR etc. are derivable from such variational principles, this procedure furnishes the most suitable basis for the systematic study of conservation laws in physics. NOETHER'S THEOREM *results from such considerations.*

Her theorem is used, for example, in classical or quantum electrodynamics to show that electric charge conservation is the result of the equations of motion of the field theory, rather then proving this directly. A simpler example is the derivation of the conservation of energy *from the invariance of a mechanical system under a* time-translation transformation $t \to t + \delta\tau$, *with* $\delta\tau$ *an infinitesimal real constant.*

Under this transformation, and assuming a closed system (no explicit *time dependence in the Lagrangian* $\mathcal{L}$*), the action integral is transformed from* $A = \int_{-\infty}^{\infty} \mathcal{L}(q_i, \dot{q}_i)\, dt$ *into*

$$A + \delta_\tau A = \int_{-\infty}^{\infty} \mathcal{L}\Big(q_i\{t + \delta\tau(t)\}, \frac{d}{dt} q_i\{t + \delta\tau(t)\}\Big)\, dt \,.$$

Noether's approach was to make the constant time shift $\delta\tau$ *into a function of* t, $\delta\tau = \delta\tau(t)$, *where* $\delta\tau$ *is still an infinitesimal —* although δA *vanishes identically only for* $\delta\tau = const.$

Redefining the integration variable to $t' = t + \tau(t)$, *and noting that by the chain rule:*

$$\frac{d}{dt} q_i(t + \delta\tau(t)) = \dot{q}_i(t + \delta\tau(t))(1 + \delta\dot{\tau}(t)),$$

we obtain (quadratic and higher order terms in $\delta\tau$ *ignored):*

$$\begin{aligned} \delta_\tau A \quad &= \int_{-\infty}^{\infty} \left(\sum_{i=1}^{n} \frac{\partial \mathcal{L}}{\partial \dot{q}_i} \dot{q}_i - \mathcal{L} \right) \delta\dot{\tau}\, dt \\ &= \int_{-\infty}^{\infty} \left(\sum_{i=1}^{n} p_i \dot{q}_i - \mathcal{L} \right) \delta\dot{\tau}\, dt \,, \end{aligned}$$

where $p_i = \frac{\partial \mathcal{L}}{\partial q_i}$ *are the generalized momenta ant* t' *has been renamed "*t*".*

Although δA *is not identically zero for any non-physical trajectory* $\{q_i(t)\}_{i=1}^n$ *if* $\delta\dot{\tau} \neq 0$, *it does vanish for any actual system trajectory, because the latter satisfying the equations of motion (Euler-Lagrange equations),*

$$\frac{\partial \mathcal{L}}{\partial q_i} = \frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_i} \, .$$

Thus, integrating by parts the above integral expression for δA *and assuming* $\delta\tau(t) \to 0$ *as* $t \to \pm\infty$, *we conclude that* $\frac{d}{dt}\left[\sum_{i=1}^n p_i \dot{q}_i - \mathcal{L}\right] = 0$ *for any actual system trajectory; thus*

$$H = \sum_{i=1}^n p_i \dot{q}_i - \mathcal{L} = const.,$$

which is the equation for the conservation of energy in a closed system (since H *is the Hamiltonian of the system).*

Other simple symmetry transformations and their attendant conservation laws are: rigid spatial translations (conservation of linear momentum); rigid spatial rotations (conservation of angular momentum); Lorentz transformations (rectilinear motion of relativistic center-of-mass). In any of these symmetry transformations, the "rigid" (spacetime independent) transformation parameters — such as displacement vector, rotation angles, frame velocity, etc. — are made time dependent, and the Noether method is then used to prove that the corresponding quantity is conserved for actual trajectories of the physical system, by using $\delta A = 0$.

In this connection, a brief discussion on the significance of the concepts of energy, momentum and angular momentum in modern physics is called for:

In quantum mechanics *in general, and in field theory (both classical and quantum) in particular, apart from the* orbital *part of the density of angular momentum, there is also the* spin density *of angular momentum; neither of these alone need be conserved — in general the conservation applies to their sum only. A scalar field possesses no spin. Furthermore, the conservation of orbital angular momentum in a scalar field theory implies that the canonical energy – momentum stress 4–tensor is of necessity* symmetrical *(and vice versa).*

In field theories involving non-scalar fields, there are sometimes several useful ways to define a conserved energy-momentum tensor — and some of these (e.g., the one resulting from a straightforward application of Noether's theorem) are indeed non-symmetrical.

The question as to which of these definitions is the 'correct' one is moot, since an experiment designed to measure, say, the energy content of an imaginary volume element, will change the field configuration. This is true even in classical electromagnetism, let alone in quantum physics, where the uncertainty principle renders the space-time localization of energy-momentum a notoriously tricky enterprise.

*The above is true for theories where gravitation is negligible. In the presence of gravitation (*GTR*),* global *energy, momentum, and angular momentum are not even well defined in general, let alone conserved, owing to the curvature of spacetime and the local nature of the Equivalence Principle.*

The only generally-valid vestige of these conservation laws is the local *conservation of the non-gravitational energy-momentum tensor in an infinitesimal, locally inertial spacetime frame. Through general covariance, this is translated into the statement that the absolute (covariant) 4-divergence of the energy-momentum–stress tensor vanishes.*

But as for global *conservation laws, there are only four special cases where one* can *extend the conservation of energy-momentum and/or angular momentum to* GTR*. These are:*

- Weak gravity *(post-Newtonian) approximation. Here, global conservation is restored by adding to the energy-momentum tensor a term representing the contribution of the gravitational field. This term, however, is coordinate-system dependent, and hence the resulting conserved global entities are* not *covariant.*
- Asymptotically-flat spacetimes*; this case occurs when the non-gravitational field–matter distribution is localized in space — although special care must be used in treating the contribution of outgoing radiation at infinity (both gravitational and electromagnetic) to the conserved quantities. This case includes the former as a special case.*
- Motion of localized energy-momentum packets *(either classical or quantum) through an external, slowly – varying (in space and time) and classical gravitational field. In this case the motion can be analyzed by the Maccullagh-like moment-expansion of the packets (the first moments are total 4-momentum, total angular momentum, relative to center–of–mass (classical or quantum spin), moments of inertia, etc.). In this formalism, the total momentum and angular momentum of the packet are* not *conserved, since they comprise a non-closed system due to the influence of the external (background) curved spacetime; however, the rates of change of these quantities can be calculated. This case includes the former two as special cases.*

- *Spacetimes with special symmetries; when spacetime has Killing vector fields (isometries), it also possesses true, covariant, global conservation laws — one for each Killing vector field. This correspondence stems from Noether's theorem. Each such symmetry, when it exists, is an extension to* GTR *of the invariance under shifting time or space by a constant, or rigid rotations of space, or other symmetry transformations (such as a combined shift and Lorentz–transformation (boost)* for certain expanding-*universe cosmologies).*

Thus, all homogeneous, isotropic, expanding-universe *spacetimes have versions of global linear and angular momentum conservations, but few of them enjoy a version of global energy conservation – because shifts of time coordinates can never leave the physics of such spacetimes invariant. Furthermore, since cosmological isotropy and homogeneity hold only in an average sense, none of these conservation laws is as useful as it is for sub-cosmological scales of space and time.*

The global conservation of energy, momentum and angular momentum are very useful concepts for describing terrestrial experiments, the dynamics of a star, or even the calorimetry, rotation, evolution and collisions of entire galaxies and galaxy clusters or super clusters — but they are apparently invalid *for the universe as a whole, or else hold only in an average (homogenized sense).*

Finally, it is of interest to note that there is an extension of GTR *in which intrinsic spin angular momentum is regarded as being as fundamental as energy-momentum. This is known as the* Einstein-Cartan-Kibble-Sciama *theory; in it the standard Einstein field equations are* augmented *by new ones, in which the r.h.s. represents* spin density *whereas the l.h.s. involves the* torsion *(i.e., the nonsymmetrical piece of the affine connection).*

In the 2^{nd} half of the 20^{th} century, the deep Noether relation between symmetries and conservation laws became a powerful tool in developing the new field theories needed to describe the interactions and structure of subnuclear particles and fields. At the same time, it was discovered that quantum effects sometimes lead to the breaking of Noether symmetries (and associated conservation laws) that hold in the classical limit. Such anomalies *often involve deep differential–geometric and topological principles, and play important roles in the Standard Model of Particle Physics, as well as in* string theory.

Table 5.4: Timeline of Symmetry in Mathematics, Physics and Chemistry

ca 400 BCE	Description of the *5 Platonic solids*.
ca 300 BCE	The 3D geometry of *polyhedra* described by **Euclid**.
1528 CE	'De symmetria partium' by **Albrecht Dürer**, a study of symmetry in art.
1596 CE	In 'Mysterium Cosmographicum' **Johannes Kepler** suggested that the orbits of the then – known planets are defined by nested inscribed Platonic solids.
1609 CE	**Kepler** published 'Astronomia Nova' where he announces his three famous laws of planetary motion. The second law we can now understand as the conservation of angular momentum, a consequence of the $SO(3)$ symmetry of the gravitational force from the sun.
1611 CE	In 'De nive sexangula' **Kepler** studied the hexagonal symmetry of *snowflake crystals*.
1669 CE	Investigation of crystal angles published in 'De solido intra sodium naturaliter contendo' by **Nicolaus Steno**. Probably the first instance of the 'law of constancy of angles' for quartz crystals.
1687 CE	'Principia' by **Isaac Newton**, where the first law states the conservation of momentum due to the homogeneity of space (translation invariance).
1770 CE	Permutations first studied by **Joseph-Louis Lagrange** in a paper on algebraic equations.
1772 CE	**Jean-Baptiste Rome de Lisle** published 'Essai de Cristallographie'. He confirmed the observations of Steno, and later tried to order crystals into symmetry classes.
1784 CE	**Rene-Just Hauy** published 'Essai d'une theorie sur la structure des cristaux' describing experiments on the cleaving of crystals. Proposed that a crystalline solid consists of replicas of a unit cell, and the 'law of rational indices'.

Table 5.4: (Cont.)

1830 CE	**J.F.C. Hessel** derived the 32 crystal classes, starting from the law of rational indices.
1832 CE	**Evariste Galois** is the first to understand the relation between the algebraic solutions of an equation and the structure of a group of permutations associated with the equation. This work was not published until 1846.
1844 CE	**A.L. Cauchy** studied the group properties of permutations. The permutations of a fixed number of N elements is now called the symmetric group S_N.
1849 CE	**Auguste Bravais** derived the 14 space lattices in 3 dimensions.
1860 CE	**Louis Pasteur** discovered the connection between optical activity and enantiomorphic molecular structures. Chiral molecules which are mirror images of one another rotate light in opposite senses.
1872 CE	**Felix Klein** proposed the Erlangen program where geometry is classified by invariance groups.
1878 CE	**Arthur Cayley** formulated the abstract *group concept*.
1890–1891 CE	Derivation of the 230 space groups in 3 dimensions by **A.M. Schonflies**.
1893 CE	**Sophus Lie** and **Friedrich Engel** published 'Theorie der Transformationsgruppen'.
1886–1904 CE	**FitzGerald** suggested what is later called the FitzGerald-Lorentz contraction.
	Larmor, **Lorentz** and **Poincaré** introduced the transformations which make up what is now called the Lorentz group. It was shown that they leave Maxwell's equations invariant. The Lorentz group (Lorentz transformations and rotations), together with spacetime translations, is a group of spacetime symmetry transformations often called the *Poincare group*.

Table 5.4: (Cont.)

1905 CE	In his most famous paper **Einstein** adduced a set of physical assumptions, from which the Lorentz transformations follow via a few simple thought experiments. He thus created *Special Relativity* as a physical theory and an alternative to the Newtonian theory. The latter uses a different set of symmetry transformations connecting the inertial reference frames — namely the Galilean group.
1895–1910 CE	**F.G. Frobenius** and **I. Schur** created the theory of group representations.
1912 CE	Experimental evidence for the lattice structure of crystals, following the discovery of X-rays diffraction in crystals by **von Laue**.
1918 CE	**Emmy Noether** showed the general connection between symmetries and conserved quantities in Lagrangian dynamics.
1918 CE	**Hermann Weyl** introduced a classical unified field theory for gravitation and electromagnetism. It includes invariance under local scale transformations, called gauge invariance, which implies the conservation of electric charge.
1924 CE	**S.N. Bose** introduced what is now called Bose-Einstein statistics for photons. In 1925, **Einstein** generalized the results to particles or quanta we now call *bosons*. Any two same–species bosons in a many-quanta state *are indistinguishable* by any labeling except momenta, positions, polarizations and the like; i.e. such states are invariant under all permutations among bosons.
1925 CE	**Wolfgang Pauli** proposed the 'exclusion principle' — later called the 'Pauli principle' — for the allowable quantum states of multi–electron systems.
1926 CE	**Max Born**, **Werner Heisenberg** and **Pascual Jordan** introduced the quantum theory of particles with angular momentum and spin 1/2.

Table 5.4: (Cont.)

1926 CE	*Fermi-Dirac* statistics introduced for half–integer–spin particles and systems (e.g. electrons) we now call *fermions*. Their many-particle quantum state vectors (wave functions) change sign under odd permutations. Later, the list of fermions grew to include many other elementary particles (such as protons, neutrons, quarks, neutrinos, antiparticles) besides electrons, as well as some nuclei and atoms – and similarly for bosons.
1927–1928 CE	**Fritz London** and **Weyl** introduced gauge transformations (and the associated local symmetry) into quantum mechanics, with total electric charge as the conserved quantity.
1928 CE	**Dirac** proposed a relativistic wave equation for spin 1/2 particles, i.e. one covariant under the *spinor representation* of the Poincaré group.
1928 CE	**Weyl** published 'Gruppentheorie und Quantenmechanik'.
1929 CE	**Felix Bloch** described the electron wave functions in periodic potentials, allowing a quantum–mechanical understanding of crystalline symmetry groups.
1929 CE	**Hans Bethe** derived the splitting of atomic levels resulting from the crystal field symmetry.
1930 CE	**Eugene Wigner** studied the effects of the symmetry of molecular configurations on their vibrational spectrum.
1931 CE	**Wigner** introduced the discrete *time–reversal* symmetry operation symmetry (T) into quantum theory and publishes 'Gruppentheorie und ihre Anwendung auf der Quantenmechanik der Atomspektren'.
1931 CE	**L.C. Pauling** studied the theory of chemical bonding using the symmetries of orbitals.
1932 CE	**W. Heisenberg** proposed an approximate internal (non-spacetime) a symmetry between protons and neutrons (to be understood as two "orientations", in an internal space, of a single fermion species — a *nucleon*), in nuclear theory, — later called *isospin symmetry*.

Table 5.4: (Cont.)

1932 CE	**Carl Anderson** discovered the *positron* in a cosmic ray experiment, the first of the antiparticles (predicted by Dirac in 1931).
1932 CE	**B.L van der Waerden**: 'Die gruppentheoretische Methode in der Quantenmechanik'.
1935 CE	**V. Fock** derived the spectrum of the hydrogen atom from an accidental SO(4) (4-dimensional rotation) symmetry possessed by its Hamiltonian operator.
1936 CE	**Heisenberg** introduced *charge conjugation* (C) as a discrete symmetry operation connecting particle and antiparticle states.
1936 CE	**Frederick Seitz** worked out the representation theory of space groups, the symmetry groups of crystal lattices.
1937 CE	**H.A. Jahn** and **E. Teller** derived a connection between the symmetries of molecular configurations and the stability of degenerate molecular electron orbitals (*Jahn-Teller effect*): for a non-linear molecule there is always a distortion into a shape of lower symmetry to remove any orbital degeneracy of its electronic state.
1939 CE	**Wigner** studied the unitary representations of the Poincaré group. The results allow the classification of all relativistic wave equations and of the transformation properties of quantum fields.
1940 CE	**Pauli** proved the spin-statistics theorem: particles with half-integer spin have Fermi-Dirac statistics, those with integer spin are Bosons.
1954 CE	**C.N. Yang** and **Roger Mills** introduced local isospin transformations as an internal symmetry, i.e. non–spacetime Lie–group transformations of fields which depend on the spacetime point. They showed how such a *non–Abelian local (gauge) symmetry* prescribes a minimal–Coupling dynamics, in a manner similar to the role of general covariance in GTR.
1954 CE	**G.C. Wick**, **A.S. Wightman** and **E. Wigner** introduced the notion of *superselection rule.*

Table 5.4: (Cont.)

1954–1955 CE	The CPT theorem was proved by **G. Lüders** and **W. Pauli**, involving space inversion of *Parity* (P), charge conjugation (C) and time reversal (T): in a local, relativistic quantum field theory the composition product CPT of these transformations is always an unbroken symmetry.
1956–1957 CE	A parity breaking weak nuclear interaction is proposed by **C.N. Yang** and **T-D. Lee** and verified experimentally by **C.S. Wu**.
1959–1961 CE	**W. Heisenberg**, **J. Goldstone** and **Y. Nambu** suggested that the ground state (vacuum) of a relativistic quantum field theory may lack the full global (rigid) internal symmetry manifested by the Hamiltonian, and that massless excitations (*Goldstone bosons*) must accompany this 'spontaneous symmetry breaking'. In 1964 **P. Higgs** and others find that for spontaneously broken *gauge* (local) symmetries there are no Goldstone bosons but instead massive vector mesons (*Higgs mechanism*).
1961 CE	**Murray Gell-Mann** proposed the Lie group of unit–determinant, unitary, complex 3×3 matrices – as a global (rigid) internal symmetry for the strong interactions (the *Eightfold Way*). This includes the isospin symmetry as part of a larger symmetry Lie group which also acts on the so-called *strangeness* quantum number. In 1964 Gell-Mann and **G. Zweig** proposed a new sub-nucleon level of quanta – which they named *quarks* – to account for the SU(3) symmetry.
1964 CE	The discrete–symmetry composition product CP — and thus, by the CPT theorem, also time -reversal symmetry, T — is found to be violated (broken); this is observed experimentally –via certain anomalous K-meson decays – by **J.W. Cronin** and **W.L. Fitch**.
1965 CE	**R.B. Woodward** and **R. Hoffmann** described how the conservation of orbital symmetry influences the course of molecular reactions, the 'Woodward-Hoffman rules'.
1973–1974 CE	The essential features of the presently accepted *Standard Model* of particle physics are established.

Table 5.4: (Cont.)

1977 CE	**Roger Penrose** mathematically demonstrated an *aperiodic tiling* of the plane using only two different tiles and an approximate 5-fold symmetry.
1984 CE	**Dan Schechtman** found the first *quasicrystal* phase in the laboratory, produced via slow cooling (annealing). Its X-ray crystallography exhibited a 5-fold symmetry – one not expected to exist by conventional wisdom.
1985 CE	**Robert F. Curl**, **Harold W. Kroto** and **Richard E. Smalley** produced the first observed C60 molecules by laser-vaporizing graphite in a jet of helium (Nobel Prize in chemistry, 1996). This useful "Buckyball" cage structure is highly symmetrical – a truncated icosahedron with 12 perfect–pentagon and 20 perfect–hexagon faces.

1918–1935 CE **Hermann Weyl** (1885–1955, Germany and U.S.A.). Distinguished mathematician. Made major attempts to embed the theory of the electromagnetic field into the geometric framework of an extended theory of general relativity. Established the importance of gauge invariance in classical and quantum electrodynamics (1929).

Weyl was first to construct a non-Riemannian geometry in an effort to produce the required unified field theory. Extended the concept of parallel displacement of a vector for manifolds in which the line element is undefined. He rendered a full treatment of spinors[429] with reference to finite rotations.

[429] The collective designation 'spinor' has been given to these quantities because of the role they play in the theory of the spinning electron. The name 'spinor' was coined by **Paul Ehrenfest** (1880–1933, Leyden) in 1929. In the same year, **van der Waerden** (1903–1996) introduced a notation of spinors by means of dotted and undotted indices. This latter formalism is based on the fundamental representation of the pseudorotation group in 4-dimensional Minkowski space (or, more precisely, of $SL\ (2, c)$, the maximal cover of the Lorentz group $SO\ (3, 1)$) in terms of *two* sets of Pauli spin matrices and complex rotation angles.

During 1923–1938 Weyl used Clifford algebras in order to obtain two-valued matrix representation of the group of rotation in n-dimensions, thus developing Cartan's theory of spinors in n dimensions. He evolved a general theory of continuous groups, and found that many of the regularities of quantum phenomena on the atomic level can be most simply understood using group theory. Weyl made original contributions in many areas of mathematics. His findings were fundamental to later progress in the analytic theory of numbers.

Weyl was born in Elmshorn, near Hamburg. As a student at Göttingen, he came under the influence of **Hilbert**[430]. He graduated in 1908 and in 1913 became a professor of mathematics at the Technische Hochschule, Zürich, where he was a colleague of **Albert Einstein**. In 1930 he was appointed a professor of mathematics at the University of Göttingen. The Nazi dismissal of many of his colleagues prompted him to leave Germany in 1933 and accept a position at the Institute for Advanced Study, Princeton. He became a U.S. citizen in 1939. After his retirement he divided his time between Princeton and Zürich.

---

[430] **H.A. Lorentz** conjectured in a Göttingen seminar (1910) that the asymptotic behavior of the eigenvalues for differential equations with constant coefficients does not depend on the shape but only on the size of the vibrating domain. His host, **Hilbert**, immediately predicted the problem to be unprovable in his lifetime. Weyl, who listened to the lecture in the audience, did not share Hilbert's pessimism. Indeed, within a short time (1912) Weyl was able to prove that, asymptotically, for large value of the frequency f and for 3D vibrating domains (e.g. a concert hall) with sufficiently smooth boundaries, but otherwise of *arbitrary shape*, the number of eigenvalues (room modes) whose frequencies are less than a given value of f is determined by $N_3(f) = \frac{4\pi}{3}V\left(\frac{f}{c}\right)^3$, where V is the domain volume and c is the wave velocity inside the domain. The corresponding formula for 2-dimensional enclosures is $N_2(f) = \pi A\left(\frac{f}{c}\right)^2$, where A is the area of the resonator. The result is asymptotically correct, to order f^2, again independent of the shape of the boundary (perimeter). These results are important in thermodynamics (for calculating specific heat of solids) and concert hall acoustics. It was later shown (1939) that Weyl's formula can be improved for *rectangular rooms* to yield $N_3(f) = \frac{4\pi}{3}V\left(\frac{f}{c}\right)^3 + \frac{\pi}{4}S\left(\frac{f}{c}\right)^2 + \frac{1}{8}L\frac{f}{c} + \frac{1}{8}$, where S is the total surface area of the room and L is the total length of the edges of the room. In the limit $V \gg \frac{3S}{16(f/c)}$, the first term predominates, independent of the room's shape.

The Gauge Principle

Introduction

Gauge theory developed, during 1917–1954, by a group of leading theoretical physicists and mathematicians, among them: ***A. Einstein*** *(1917);* ***T. Levi-Civita*** *(1917);* ***E. Noether*** *(1918);* ***H. Weyl*** *(1918, 1929);* ***Th. Kaluza*** *(1920);* ***E. Schrödinger*** *(1922),* ***E. Cartan*** *(1923).* ***O. Klein*** *(1926, 1939);* ***F. London*** *(1927);* ***V. Fock*** *(1927);* ***P. Dirac*** *(1928);* ***W. Pauli*** *(1933);* ***C.N. Yang*** *(1954);* ***R. Mills*** *(1954).*

Two interrelated concepts are involved:

- *Gauge principle: The requirement that all physical quantities, including actions and equations of motion, should be invariant or covariant under certain local internal transformations, known as gauge transformations. This property is called gauge invariance. It has evolved into a uniform organizing principle of the standard model of particle physics. The gauge principle can also be viewed as an algorithm used to build a dynamical (classical or quantum field) theory starting from the postulate of gauge-invariance.*

- *Gauge choice: A way to get rid of the ambiguity due to gauge freedom (the freedom of arbitrary local gauge transformations) by fixing the gauge [e.g. the Lorentz gauge or Coulomb gauge in EM theory].*

The gauge principle works differently in different theories. There are three basic kinds of relevant physical theories:

(a) *Macroscopic classical electrodynamics of particles or effective fields, currents and charges: i.e. Maxwell equations in free space and matter and/or plasma. These theories can be nonlinear, as in the case of MHD, nonlinear optics, Landau–Ginsburg effective field theories in superconductors, or models of ferromagnetic media.*

(b) *Classical or quantum electrodynamics of fundamental charged fields (always nonlinear).*

(c) *Non-Abelian Yang-Mills field theories (classical or quantum): there are several 4-potentials (gauge fields), with their associated field–strength* *tensors, interacting with one another and with (optional) matter fields. Always nonlinear.*

In theories of type (a), gauge invariance is just a mathematical artifice that is not essential, since $\boldsymbol{E}$ *and* $\boldsymbol{B}$ *are the observable fields. The vector potential* $\boldsymbol{A}$ *and scalar potential* Φ *need not appear explicitly in the field equations.*

In (c), even on the classical level alone and with no other non-gauge fields, the field equations can be written only by means of the covariant derivatives of (the several copies of) $\boldsymbol{E}$ *and* $\boldsymbol{B}$*, and these involve the (several) four-vector potential explicitly and non-linearly.*[431]

Electromagnetism as gauge theory

The variational formulation of electromagnetism was expounded by ***K. Schwarzschild*** *(1903),* ***A. Lorentz*** *and* ***H. Poincare*** *(1905–6), while the corresponding relativistic theory was developed by* ***H. Minkowski*** *(1908) and* ***M. Born*** *(1909). The theory of the classical electromagnetic field, that began with* ***Maxwell's*** *equations (1865–1873) and their simplification in the hands of* ***O. Heaviside*** *(1873–1888),* ***H.R. Hertz*** *(1884) and* ***J.H. Poynting*** *(1884) – was thus complete.*

We recall that in vacuum, Maxwell's equations are:

---

431 Similarly, in theories of type (b), A_μ appears in the field equations for the charged fields. In both cases (b) and (c) (and also some effective field theories in category (a)), A_μ plays the role that the *affine connection* does in GTR, but the corresponding differential-geometric structure is different: a *vector fiber bundle* together with a *Lie-group* principal fiber-bundle (In the special case of GTR, these are the *tangent* and *frame* bundles of the spacetime manifold, respectively).

In a field theory of type (b) or (c), the gauge potentials are *essential* not only to make the underlying differential geometry manifest, but in order for the dynamical wave equations (of the one or several EM-like field types and of the charged fields, if any) to be at all local. And if a theory of type (b) or (c) is *quantized*, the vector potentials become even more essential for the mathematical formulation of the dynamics. Thus in the *Aharonov–Bohm effect*, an electron wave function senses (and observably responds to) the $\boldsymbol{B}-$field in a thin current solenoid, even far from the $\boldsymbol{B} \neq 0$ region; this is most easily described as the electron being acted upon directly by $\boldsymbol{A}$, which is nonzero in that region.

$$curl\ \boldsymbol{B} = \frac{1}{c^2}\frac{\partial \boldsymbol{E}}{\partial t} + \frac{1}{c^2}\boldsymbol{j} \qquad \textit{Ampere's law} \tag{1}$$

$$div\ \boldsymbol{E} = \rho \qquad \textit{Coulomb's law} \tag{2}$$

$$-curl\ \boldsymbol{E} = \frac{\partial \boldsymbol{B}}{\partial t} \qquad \textit{Faraday's law} \tag{3}$$

$$div\ \boldsymbol{B} = 0 \qquad \textit{Gauss' law} \tag{4}$$

Here ρ is the charge density, $\boldsymbol{j}$ is the current density, and no magnetic monopole charges are present. From (1) and (2) one derives the local charge conservation

$$div\ \boldsymbol{j} + \frac{\partial \rho}{\partial t} = 0. \tag{5}$$

Since the last two of Maxwell's equations make no reference to charge or current (the so-called sourceless pair of field equations), they can be identically satisfied by introducing potentials *through the definitions [**Lord Kelvin** 1851, **Maxwell**[432] 1855]*

$$\boldsymbol{B} = curl\boldsymbol{A}, \qquad \boldsymbol{E} = -\frac{\partial \boldsymbol{A}}{\partial t} - grad\ \Phi \tag{6}$$

The potentials $\boldsymbol{A}$ and Φ are not uniquely determined, since the transformations

$$\boldsymbol{A} \to \boldsymbol{A} + grad\ \lambda, \qquad \Phi \to \Phi - \frac{\partial \lambda}{\partial t}, \tag{7}$$

where λ is an arbitrary function, leave $\boldsymbol{B}$ and $\boldsymbol{E}$ unchanged.

The transformed set of potentials is as acceptable as the original one since the fields $\boldsymbol{B}$ and $\boldsymbol{E}$ are the physically measurable EM fields, and they are unaffected. This arbitrariness in the choice of the potentials is called the gauge freedom *of the theory or* gauge invariance, *while the corresponding transformations are called* gauge transformations.

[432] The vector potential in $\boldsymbol{B} = curl\ \boldsymbol{A}$ was first introduced, as a mathematical artifice, by **W. Thomson** (Lord Kelvin) in 1851. **Maxwell** borrowed the idea from Thomson in 1855 when he wrote $\boldsymbol{E} = -\frac{\partial \boldsymbol{A}}{\partial t} - \nabla\Phi$, upon integrating **Faraday's law**: $curl\ \boldsymbol{E} = -\frac{\partial \boldsymbol{B}}{\partial t}$.

We exploit this freedom in the following manner: substitute (6) into (1) and (2) to obtain a pair of coupled partial differential equations for the potentials $\boldsymbol{A}$ *and* Φ*:*

$$-\left(\nabla^2 - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)\boldsymbol{A} = -\nabla\left(div\boldsymbol{A} + \frac{1}{c^2}\frac{\partial\Phi}{\partial t}\right) + \frac{1}{c^2}\,\boldsymbol{j} \tag{8}$$

$$-\nabla^2\Phi - \frac{\partial}{\partial t}\left(div\boldsymbol{A}\right) = \rho \tag{9}$$

We may now simplify (8)–(9) by utilizing the gauge freedom in defining the potentials. The two most convenient and common choices are:

I. The Coulomb gauge[433]

$$div\boldsymbol{A} = 0 \tag{10}$$

In this gauge (8)–(9) reduce to

$$\Box\boldsymbol{A} = \frac{1}{c^2}\boldsymbol{j} - \frac{1}{c^2}\frac{\partial}{\partial t}\left(grad\Phi\right), \qquad \Box \equiv -\nabla^2 + \frac{1}{c^2}\frac{\partial^2}{\partial t^2} \tag{11}$$

$$-\nabla^2\Phi = \rho \tag{12}$$

The equation for Φ *is just the same as that in electrostatics (Poisson equation): Hence the term 'Coulomb gauge'. If we take the divergence of (11), using the Coulomb gauge condition, and also use (12), we regain the law of local charge conservation, equation (5).*

II. The Lorentz gauge

$$div\boldsymbol{A} + \frac{1}{c^2}\frac{\partial\Phi}{\partial t} = 0 \tag{13}$$

In this gauge, the source differential equations for $\boldsymbol{A}$ *and* Φ *have the simpler form*

$$\Box\boldsymbol{A} = \frac{1}{c^2}\boldsymbol{j}, \qquad \Box\Phi = \rho. \tag{14}$$

---

433 This can be always chosen, because if one starts with $\boldsymbol{A_0}$ such that $div\boldsymbol{A_0} \neq 0$, the transformation $\boldsymbol{A_0} \to \boldsymbol{A_0} + grad\lambda$ leads to $\nabla^2\lambda = -div\boldsymbol{A_0}$, which can be solved for λ

Again, charge is locally conserved:

$$0 = \Box\left(div\boldsymbol{A} + \frac{1}{c^2}\frac{\partial\Phi}{\partial t}\right) = \frac{1}{c^2}\left[div\boldsymbol{j} + \frac{\partial\rho}{\partial t}\right] \tag{15}$$

Thus far we dealt with Maxwell's theory in its non-Lorentz-covariant form. In its real-0^{th}*-component Minkowski form, we compute the change in the skew-symmetric electromagnetic field-tensor* $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ *following the gauge transformation*

$$A_\mu(x) \to A'_\mu(x) = A_\mu(x) + \partial_\mu\lambda(x),$$

is

$$\begin{aligned} F_{\mu\nu} \to F'_{\mu\nu} &= \partial_\mu(A_\nu + \partial_\nu\lambda) - \partial_\nu(A_\mu + \partial_\mu\lambda) \\ &= \partial_\mu A_\nu - \partial_\nu A_\mu = F_{\mu\nu}; \end{aligned} \tag{16}$$

where $\partial_\mu \equiv \frac{\partial}{\partial x^\mu}$; $x^0 = ct$, $x^i = 3D$ *(spatial)* i^{th} *position component; Greek (Latin) indices range from* 0 *to* 3 *(*1 *to* 3*);*

$$\eta_{\mu\nu} = \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}$$

is the covariant–indices Minkowski (pseudo-) metric tensor; Minkowski ("world") indices are raised and lowered via $v^\mu = \eta^{\mu\nu}v_\nu$, $v_\mu = \eta_{\mu\nu}v^\nu$ *with* $\eta_{\mu\nu} = \eta^{\mu\nu}$ *numerically;* $\Box = \partial_\mu\partial^\mu = \eta^{\mu\nu}\partial_\mu\partial_\nu$ *and the summation convention is understood; and* $(c\ \rho, \boldsymbol{j}) = j^\mu$ $(\phi/c,\ \boldsymbol{A}) = A^\mu$ *are the 4-current and 4-potential, respectively*[434].

Note that the Coulomb gauge $div\boldsymbol{A} = 0$ *where* $\boldsymbol{A}$ *is a spatial 3-vector, is* not *invariant under a general gauge transformation; for* $\boldsymbol{A} \to \boldsymbol{A} + \nabla\lambda$ *to preserve this gauge, it is required that* $\nabla^2\lambda = 0$. *This restricts* λ *to be of the form (*λ_i *functions of time alone):*

$$\lambda = \lambda_0 + \lambda_1 x_1 + \lambda_2 x_2 + \lambda_3 x_3$$

if the gauge transformation is to hold throughout space.

---

[434] Eq. (16) confirms that the field strengths are gauge invariant. Note that $F_{0i} = \frac{1}{c}F_i$, $F_{ij} = -\epsilon_{ijk}B_k$, where ϵ_{ijk} is the 3D *Levi–Civita tensor*: $\epsilon_{ijk} = \epsilon_{jki} = -\epsilon_{jik}$, $\epsilon_{123} = 1$.

The Lorentz gauge, on the other hand, when applied to the Lorentz covariant 4-vector potential A_μ*, is invariant under the gauge transformation* $A_\mu \to A'_\mu = A_\mu + \partial_\mu \lambda$ *provided* λ *satisfies the wave equation*

$$\Box \lambda = 0, \tag{17}$$

Thus, the Lorentz gauge fixes the potentials modulo a sum of fictitious waves propagating with the speed of light.

The Lagrangian density for the EM fields in the presence of given external sources, is:

$$\mathcal{L} = -\frac{1}{4}(c^2 F_{\mu\nu} F^{\mu\nu} - j_\mu A^\mu), \tag{18}$$

This covariant form is due to Minkowski (1908) and Born (1909)

The action integral is then

$$S = \int d^4 x \mathcal{L} \tag{19}$$

Upon setting the variation of this action w.r.t. A_μ *to zero, the Euler–Lagrange equation again yield the two Maxwell equations with sources*

$$\partial_\mu F^{\mu\nu} = \frac{1}{c^2} j^\nu \tag{20}$$

Eq. (20) implies that the current is conserved $\partial_\mu j^\mu = 0$ *and this, in turn, leads to gauge invariance of the action (19) via integration by parts, provided* $\lambda(x)$ *decreases rapidly enough at spacetime infinity. Indeed, the action for the field* $A'_\mu = A_\mu + \partial_\mu \lambda$ *is equal to*

$$S(A') = S(A) + \int d^4 x j^\mu \partial_\mu \lambda \tag{21}$$

The last integral reduces, when $\partial_\mu j^\mu = 0$ *is taken into account, to an integral over an infinitely distant surface in 4-dimensional space-time*

$$\int d^4 x j_\mu \partial_\mu \lambda = -\int d\Sigma_\mu \lambda(x) j_\mu$$

Maxwell's equations have profoundly influenced most aspects of 20th *century technology. What may not have been sufficiently emphasized is that they have also, through their two invariances (symmetries), — profoundly* *shaped basic theoretical physics in that century. These invariances are the STR Lorentz invariance (invariance under a rigid, finite-dimensional Lie group of symmetry transformations) and gauge invariance (invariance under a local, infinite-dimensional Lie group of symmetry transformations).*

Gauge Theory of Charged Scalar or Spinor Fields

In 1926 **Schrödinger** *was endeavoring to generalize his wave–mechanical equation such that it becomes invariant under the Lorentz transformation, and thus suitable to govern the quantum matter-waves of a free particle that has speeds approaching that of light. Starting with the relativistic kinematical equation*

$$E = \sqrt{c^2\boldsymbol{p}^2 + m_0^2c^4} \qquad (m_0 = \textit{rest mass}) \tag{1}$$

and replacing $E \to \hbar\omega \to i\,\hbar\,\frac{\partial}{\partial t}$ *(Planck) and* $\boldsymbol{p} \to \hbar\,\boldsymbol{k} \to \frac{\hbar}{i}\,\boldsymbol{\nabla}$ *(de Broglie), one obtains a new Schrödinger equation:*

$$i\hbar\frac{\partial\Phi}{\partial t} = H\Phi = c\sqrt{m_0^2c^2 - \hbar^2\boldsymbol{\nabla}^2} \tag{2}$$

which, however, is fundamentally asymmetrical w.r.t space and time derivatives and hence not relativistic.

Schrödinger transformed (2) instead into

$$\boxed{\frac{1}{c^2}\frac{\partial^2\Psi}{\partial t^2} = \nabla^2\Psi - \frac{m_0^2c^2}{\hbar^2}\Psi} \tag{3}$$

to be known later as the Klein-Gordon wave equation. *For* $m_0 = 0$ *(e.g. a photon) it reduces to Maxwell's electromagnetic wave equation (but for the complex* single-photon probability amplitude *— although the real* $\boldsymbol{E}$, $\boldsymbol{B}$ *fields satisfy the same equation).*

In order to derive a relativistic Schrödinger-like equation for an electron matter-wave interacting with an external electromagnetic field, Eq.(1) is replaced by

$$(E - e\Phi)^2 = c^2\left(\boldsymbol{p} - e\,\boldsymbol{A}\right)^2 + m_0^2c^4, \tag{4}$$

where $\boldsymbol{A}$ *is the vector potential and* Φ *the scalar potential.*[435]

Putting again $\boldsymbol{P} \to \frac{\hbar}{i}\nabla, \quad E \to i\hbar\frac{\partial}{\partial t}$ *we obtain:*

$$\boxed{\left(\partial_\mu + \frac{ie}{\hbar}A_\mu\right)\left(\partial^\mu + \frac{ie}{\hbar}A^\mu\right)\Psi + \frac{m_0^2c^2}{\hbar^2}\Psi = 0} \tag{5}$$

where, as seen above $\partial_\mu\partial^\mu = \Box$

If we specify the Lorentz gauge condition $\partial_\mu\, A^\mu = 0$*, equation (5) is equivalent to*

$$\left(\Box + \frac{m_0\, c}{\hbar}\right)^2 \Psi = \frac{e^2}{\hbar^2\, c^2}\left(-c^2\, \boldsymbol{A}^2 + \Phi^2\right)\Psi - \frac{2ie}{\hbar}\left[\boldsymbol{A}\cdot\nabla\Psi + \frac{1}{c^2}\Phi\frac{\partial\Psi}{\partial t}\right], \tag{6}$$

which was Schrödinger's result for the interacting relativistic spinless Klein-Gordon (1926). However, at that time it was immediately rejected – along with its free ($A_\mu = 0$) *version – for two reasons: first, it possesses negative energy solutions (since it admits negative frequencies). Second, it leads to negative probability densities. Note that (5) is an inhomogeneous version of the free Klein–Gordon equation in which the four-indexed partial derivative operator* ∂_μ *is replaced by a gauge–covariant (and Lorentz covariant*[436] *spacetime derivative operator)*

$$D_\mu = \partial_\mu + \frac{ie}{\hbar}A_\mu \tag{7}$$

---

[435] This is justified at the classical (non-quantum) level by the fact that the relativistic Lagrangian of a charged point-particle in an external EM field

$$-m_0c^2\sqrt{1-\frac{\boldsymbol{v}^2}{c^2}} - e\Phi\left(\boldsymbol{r}(t),t\right) + e\boldsymbol{v}(t)\cdot\boldsymbol{A}\left(\boldsymbol{r}(t),t\right)\ ,$$

leads to the Hamiltonian

$$H = e\Phi + c\sqrt{\left(\boldsymbol{p} - e\boldsymbol{A}\right)^2 + m_0^2c^2}\ ,$$

where $\boldsymbol{p} - e\boldsymbol{A} = \frac{m_0\boldsymbol{v}}{\sqrt{1-\frac{v^2}{c^2}}}$ is the particle's *physical* 3-momentum and $\boldsymbol{p}$ is its *canonical* momentum (the one obeying the uncertainty principle).

[436] The correct *quantum* gauge transformation – under which both (5) and the Dirac Eq. (13) (below) are *covariant*, is $A_\mu \to A_\mu + \partial_\mu\lambda(x)$, $\Psi \to \Psi\cdot exp\{-\frac{ie}{\hbar}\lambda(x)\}$, the latter being a local phase change. In retrospect, gauge theories should have actually been named *phase* theories!

The foibles of the Klein–Gordon equation seemed at the time to make it a poor candidate for a matter–wave equation for the electron[437]*, but those imagined weaknesses helped to point Dirac in the right direction and to develop the correct relativistic field equation for the electron.*

The relativistic first-order Dirac equation (1928), which governs the electromagnetic interaction of the electron (or any other spin – 1/2 charged fermion) field, is

$$i\hbar\frac{\partial\Psi}{\partial t} = \left[c\,\boldsymbol{\alpha}\cdot\left(\frac{\hbar}{i}\boldsymbol{\nabla} - e\,\boldsymbol{A}\right) + \beta m_0 c^2 + e\,\Phi I\right]\Psi. \tag{8}$$

Here Ψ *is a 4-wave-component electron field* $\Psi = \begin{bmatrix}\Psi_1\\ \Psi_2\\ \Psi_3\\ \Psi_4\end{bmatrix}$,

(with spin, not spacetime, indices!); $e,\ m_0$ *are respectively the charge and rest-mass of the electron,* c *is the speed of light in vacuum, and* $\{\boldsymbol{\alpha},\beta\}$ *are the* 4×4 *complex hermitian matrices*

$$\alpha_1 = \begin{bmatrix}0&0&0&1\\0&0&1&0\\0&1&0&0\\1&0&0&0\end{bmatrix},\ \alpha_2 = \begin{bmatrix}0&0&0&-i\\0&0&i&0\\0&-i&0&0\\i&0&0&0\end{bmatrix},\ \alpha_3 = \begin{bmatrix}0&0&1&0\\0&0&0&-1\\1&0&0&0\\0&-1&0&0\end{bmatrix} \tag{9}$$

$$\beta = \begin{bmatrix}1&0&0&0\\0&1&0&0\\0&0&-1&0\\0&0&0&-1\end{bmatrix} \qquad I = \begin{bmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{bmatrix} \tag{10}$$

where $i = \sqrt{-1}$. *Introducing the further notation (*$\mu,\ k$ *are Minkowski and 3D Cartesian indices respectively)*

$$\gamma^\mu = (\gamma^0, \boldsymbol{\gamma}) \quad , \quad \gamma^0 = \beta \quad , \tag{11}$$

437 It was later realized that the correct interpretation for Ψ in (5) was the operator-valued quantum field of the (electron/positron or other) charged (or neutral if $e = 0$) particle–antiparticle pair – and, *not* a probability amplitude. Thus, today *both* the Klein-Gordon (KG) *and* the Dirac equations are used as operatorial field equations; both hold (with spin–dependent corrections in the KG) for the *electron*, while only the KG equation holds for *boson* fields.

we denote $m = \frac{m_0 c}{\hbar}$ *(the inverse reduced Compton wavelength of the spinor field), and recast (8) in the compact form*

$$(i\gamma^\mu D_\mu - mI)\,\Psi(x) = 0 \tag{12}$$

with the 4-vector of gauge–covariant spacetime derivatives, D_μ*, again given by (7); the* γ_μ *matrices form a Clifford Algebra*

$$\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2\eta^{\mu\nu} \tag{13}$$

Equation (12) – the Dirac equation for charged spinor field – is gauge covariant (as in (5)). It also looks *Lorentz covariant – as does (13). And they actually* are*, since a spinor version of the* $SO(3,1)$ *Lorentz–transformation Lie group exists.*

Thus, under a Lorentz transformation $x^\mu \to x'^\mu = \Lambda^\mu_\nu x^\nu$*, the electron (or any spinor) field transforms as* $\Psi(x) \to \Psi'(x') = U\Psi(x)$*, where the* 4×4 *unitary matrix* U *obeys* $U^{-1}\gamma^\mu U = \Lambda^\mu_\nu \gamma^\nu$*.*

Therefore, γ^μ *(the Dirac Matrices) can indeed be considered a Lorentz 4-vector.*

Upon left-multiplying both sides of (13) by the operator $(-i\gamma^\mu D_\mu - mI)$ *and taking into account the anti-commutation relations of the* γ*-matrices, we obtain*

$$\left(D_\mu D^\mu + m^2 I + \frac{e}{\hbar}\sigma_{\mu\nu}F^{\mu\nu}\right)\Psi(x) = 0 \tag{14}$$

where

$$\sigma_{\mu\nu} = \frac{i}{4}(\gamma_\mu\gamma_\nu - \gamma_\nu\gamma_\mu); \qquad F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu. \tag{15}$$

Eq. (15) *is just the electromagnetic Klein-Gordon equation Eq.(5) obtained by Schrödinger,* except *that it includes the missing* spin magnetic moment *term that is the result of the interaction of the electron (or other charged spinor particle) intrinsic spin with the external magnetic field. (Note that the relativistic Klein-Gordon does include the interaction of the electromagnetic field with the* orbital *angular momentum of the charged particle represented by the quantum field* Ψ*).*

In this connection, it is worth emphasizing that the appearance of the correct gyromagnetic ratio in the spin magnetic moment for the electron or positron in Dirac's theory – namely twice the classical value – is not only *due to the relativistic nature of the theory, but also due to the fact that the* *gauge principle is applied to obtain the minimal coupling*[438] *of a spin one-half charged field to an external EM field.*

Mathematically, the reason a 4D Dirac field has four components is that the all–important Clifford algebra [Eg. (13)] cannot be realized with smaller matrices[439].

Physically, these $4 = 2 \times 2$ *components represent two spin states for the electron, plus two for the opposite–charge antiparticle (positron).*

It can be shown that the correct action for the minimally-coupled electrodynamics of our charged Dirac field is the following: (from here on we use a unit system in which $\hbar = c = 1$, *so* $m = m_0$*).*

$$S = -\frac{1}{4}\int F_{\mu\nu}(x)F^{\mu\nu}(x)d^4x + \int \Psi^*(i\gamma_\mu D^\mu - mI)\Psi d^4x$$

where $d^4x = d^3\boldsymbol{x}\,dt$ *and* $\Psi^*(x)$ *is the hermitian conjugate of the field* $\Psi(x)$ *if* Ψ *is interpreted as an operator in Hilbert space, or the complex conjugate if* Ψ *is interpreted as a wavefunction; either way* Ψ *has a Dirac 4-value index, so e.g.*[440]

$$\Psi^*\gamma_\mu\Psi = \sum_{a=1}^{4}\sum_{b=1}^{4}\Psi_a^*(\gamma_\mu)_{ab}\Psi_b\ .$$

If Ψ *is instead a bosonic spin-0 charged field — e.g. the field of a charged pion, or the wavefunction of a Cooper pair of bound conduction electrons in a superconductor, etc. — the fundamental charged-field equation of motion is the gauge-covariant KG equation (15) (without the spin term); then the minimally coupled "Maxwell-Klein-Gordon" action becomes:*

$$S = -\frac{1}{4}\int F_{\mu\nu}(x)F^{\mu\nu}(x)d^4x + \frac{1}{2}\int \left[(D_\mu\Psi)^*(D^\mu\Psi) - m^2\Psi^*\Psi\right]d^4x \quad (16)$$

---

438 In both the Dirac and KG equations, minimal coupling to the EM field consist in simply replacing any spacetime derivative with its gauge covariant version. This minimal coupling to EM in exactly the same sense that one converts any STR–compatible theory to a GTR–compatible theory, by replacing spacetime derivative with generally covariant derivative.

439 The equality of this number to spacetime dimensionality is accidental; in general the Dirac field has $2^{[D/2]}$ components in D-dimensional spacetime, with $\lfloor x \rfloor \equiv$ *maximal integer* $\leq x$. This is relevant in higher–dimensional quantum theories – such as Kaluza–Klein, supergravity or superstring theories.

440 From here on, *Latin* indices will sometimes be used to represent non-spatial degrees of freedom. *Greek* indices will still represent Minkowski spacetime components.

The Euler-Lagrange equations corresponding to S are Maxwell's equations (1)–(4) (but in units $\epsilon_0 = 1$), and the spinless minimally coupled KG equation,

$$(D_\mu D^\mu - m^2)\Psi = 0 \ .$$

In (16):

$$\begin{aligned} D_\mu \Psi &= (\partial_\mu + ieA_\mu)\Psi \\ D_\mu \Psi^* &= (D_\mu \Psi)^* = (\partial_\mu - ieA_\mu)\Psi^* \\ (*) &= \text{ complex or hermitian conjugate} \end{aligned} \tag{17}$$

The accompanying Maxwell's equations are

$$\partial^\nu F_{\nu\mu} = j_\mu(x) \equiv \frac{ie}{2}\left[-\Psi(x)D_\mu\Psi^*(x) + \Psi^*(x)D_\mu\Psi(x)\right] \tag{18}$$

Eq. (17) are known as the gauge covariant derivatives of $\Psi(x)$. Note that in contradistinction to the classical Maxwell's equations, the four-current $j_\mu(x)$ depends explicitly on the gauge-potential A_μ as well as on the field $\Psi(x)$. Because of Noether's theorem, the invariance of the action (18) under the global symmetry operation represented by the transformation

$$\Psi(x) \to e^{i\epsilon}\Psi(x) \ , \tag{19}$$

where ϵ is an infinitesimal real constant parameter, implies the local conservation of the electric 4-current: $\partial_\mu j^\mu = 0$. This conservation (charge continuity equation) is also guaranteed from Eq. (18) by making use of the KG wave equation $(D_\mu D^\mu + m^2)\Psi = 0$. Note that the 4-current $j_\mu(x)$ is real.

Furthermore, the action (for either the Dirac or KG cases) is also invariant under the following simultaneous local transformations

$$\begin{aligned} \Psi(x) &\to e^{-i\Lambda(x)}\Psi(x), \\ A_\mu &\to A_\mu + \tfrac{1}{e}\partial_\mu\Lambda(x), \end{aligned} \tag{20}$$

where $\Lambda(x)$ is an arbitrary real function of space and time. The local gauge symmetry transformation (20) – already introduced as a symmetry under which both (5) and (12) are covariant – is known as an Abelian gauge transformation.

Mathematically, it is the analogue, in a general Fiber Bundle, to general coordinate transformation in a Riemannian manifold and its associated *frame bundle. It is readily verified that the gauge covariant derivative defined above is indeed covariant under the gauge transformation (20). In other words $D_\mu\Psi(x)$ transforms under the gauge transformation exactly as does $\Psi(x)$ itself. The covariant gauge derivatives are clearly analogous to the covariant derivatives of Riemannian geometry (and thus of general relativity), and the four-vector potential field $A_\mu(x)$ (also known as a 'gauge field') is thus analogous to the Christoffel symbols. Also, the field-strength tensor $F_{\mu\nu}$ plays the same role played by the Riemann curvature tensor in the tangent (or frame) bundles of Riemannian geometry.*

So far we have considered Lagrangians densities (in the action integral) which are quadratic in the charged fields Ψ; also, the purely EM part (first term) of the action (17) (or its Dirac counterpart) is quadratic in $\{A_\mu\}$ (although the minimally-coupled KG term in (17) is quartic in the full set of fields $\{A_\mu, \Psi, \Psi^*\}$). The Euler–Lagrange equation stemming from S thus lead to linear equations for the charged field Ψ for fixed external EM fields, for both the Dirac and KG cases.

However, when the Lagrangian contains terms of order higher then quadratic in the Ψ fields there arise field interactions with corresponding nonlinear terms in $\{\Psi, \Psi^*\}$ appearing in the KG or Dirac wave equation.

Such a theory of interacting fields will be invariant under translations (shifts) in space and time and under Lorentz transformation, if the Lagrangian – density term for the interaction is a Lorentz scalar which does not depend explicitly on space-time coordinates. The simplest example arises in the theory of a real scalar field, if for the Lagrangian of the interaction one chooses some non-quadratic function of the field, $V_I(\Psi)$, such that the action is

$$S = \int d^4x \left[\frac{1}{2}(\partial_\mu\Psi)^2 - V(\Psi)\right], \tag{21}$$

where

$$V(\Psi) = \frac{m^2}{2}\Psi^2 + V_I(\Psi).$$

V_I should contain terms of type Ψ^3,Ψ^4, etc.

In quantum field theory, compelling technical considerations (renormalizability) favor choosing $V_I(\Psi)$ to be a polynomial in Ψ of degree at most four in four-dimensional space-time (in two-dimensional space time there are essentially no restrictions on the form of $V_I(\Psi)$). We shall see in the next section that in generalizations of the "scalar electrodynamics" theory (18) obeying a non-Abelian local gauge principle, the action and wave equations of motion become inherently more nonlinear than in the Abelian (EM) case.

To lay the foundation for the non-Abelian case, we return to Eqs. (22) *and recast them in the form*[441]

$$\begin{gathered}\Psi(x) \to g^{-1}(x)\Psi(x) \\ eA_\mu(x) \to g^{-1}(x)eA_\mu(x)g(x) - ig^{-1}(x)\partial_\mu g(x)\end{gathered} \tag{22}$$

where $g(x) = e^{i\Lambda(x)}$.

One advantage of this notation is that $g(x)$ *at any point x can be interpreted as an element of an Abelian group* $U(1)$*, which is the multiplicative group of complex numbers of unit modulus. Then, the non-derivative parts of transformation* (24) *looks like a transformation of the fundamental representation of this group, whereas* $g^{-1}(x)\partial_\mu g(x)$ *at any point is an element of the Lie algebra (tangent space) of this group. Generalizations of the transformation* (23) *to cases of other (non-Abelian) Lie groups leads to non-Abelian gauge fields, and their associates transformation and dynamics, as we explore in the next section.*

We stress again that in the theory of interacting fields, the Lagrangian density contain both terms quadratic in the fields and terms of degree three, four and higher in the fields. The quadratic terms lead to equations linear in the fields, while higher-order terms lead to nonlinear terms. It is usually impossible to find general solutions of nonlinear field equations (integrable models form an exception).

In quantum field theories, excitations corresponding to elementary particles are sometimes small. In that case the nonlinear terms in the field equations are small in comparison with the linear terms and may be treated perturbatively.

Non-Abelian Gauge Theory – Yang-Mills Fields (1954)

Let us first restrict our attention to $SU(2)$, *the Lie group of unitary* (2×2) *complex matrices of unit determinant. By the well known Cayley-Klein*

[441] For the remainder of this and the next section, we restrict our attention (in the inherent of simplicity) to the KG (scalar matter field) case although the minimal coupling of Dirac matter fields to non-Abelian gauge fields is just as straightforward – and is, in fact, of more fundamental importance in particle physics.

parameters representation any such matrix can be thought of a representing a real, 3×3 orthogonal rotation matrix. The general Cayley-Klein $SU(2)$ matrix can be written as

$$G = e^{i \sum_{a=1}^{3} b_a \tau_a / 2} \tag{1}$$

where: b_a $(a = 1, 2, 3)$ are three real numbers related to the Euler angles of the corresponding 3D rotation matrices, and τ_a are the three 2×2 Pauli matrices:

$$\tau_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \tau_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \tau_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \tag{2}$$

obeying

$$\tau_a \tau_b = \delta_{ab} I + i\epsilon_{abc}\tau_c \tag{3}$$

where $I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$, δ_{ab} is the Kroneker delta and ϵ_{abc} is the Levi-Civita symbol, and the summation convention is henceforth understood over both Lorentz and internal ("isospin") indices — denoted by Greek and Latin indices ($\mu, \nu, \gamma, \ldots$ and $a, b, c, \ldots$), respectively.

Defining the hermitian matrix field

$$\Psi(x) = \Psi_a(x) \frac{\tau_a}{2} \tag{4}$$

with[442] $\Psi_a = \Psi_a^*$,*the Non-Abelian Gauge Transformation* law, *becomes*

$$\Psi(x) \to G^{-1}\Psi(x)G \tag{5}$$

[442] Ψ_a can either be *real* classical fields, or *hermitian* quantum field–operators. In the latter case(*) denotes *hermitian* conjugation, rather then *complex* conjugation. We emphasize that neither the 3D rotations nor the spin-like Pauli matrices referred to in this example, have anything to do with spatial dimensions $\mu = 1, 2, 3$ of Minkowski space, nor with angular–momentum spin. Rather, they pertain to continuous rotation-like transformations in an internal, mathematical space which is the so-called *fiber* of the Fiber–Bundle referred to above, at each spacetime point x. Minkowski space itself, M_4 is referred to as the *base manifold* of the Fiber Bundle. The internal fiber-space *could* arise from extra curled-up of a "primordial" Minkowski space M_N with $N > 4$ dimensions – as in Kaluza–Klein theories – but this need not be the case.

$$A_\mu \to G^{-1}A_\mu(x)G - \frac{i}{e}G^{-1}(\partial_\mu G) \tag{6}$$

where $G = G(x)$ *is a general spacetime-dependent element of* $SU(2)$,

$$A_\mu(x) \equiv A_\mu^a(x)\frac{\tau_a}{2} \tag{7}$$

are hermitian matrix-fields, $(A_\mu^a)^* = A_\mu^a$ *encode three copies of EM-like 4-vector potentials, and the non-Abelian gauge covariant spacetime derivative operators are defined as follows:*

$$D_\mu\Psi \equiv \partial_\mu\Psi + ie[A_\mu\Psi - \Psi A_\mu] \tag{8}$$

By (3), (4), (7) *and* (8)

$$D_\mu\Psi_a = \partial_\mu\Psi_a - e\epsilon_{abc}A_\mu^b\Psi_c \tag{9}$$

One readily verifies that the just-defined non-Abelian gauge covariant derivative via (8) – (9), *are indeed gauge–covariant, in the sense that* $D_\mu\Psi(x)$ *transforms just as* $\Psi(x)$ *does under the gauge transformations*[443] (5)–(6).

Recall that, the Abelian gauge-invariant action for the complex charged scalar matter field in an external Abelian ($U(1)$) *gauge field is given by the second term on the r.h.s. of Eq.* (18) *of the previous section, namely the second (Klein–Gordon) term in*

$$\begin{aligned} S_{total} &= S_{gauge\ field} + S_{matter} \qquad (10)\\ &= -\frac{1}{4}\int F_{\mu\nu}(x)F^{\mu\nu}(x)d^4x + \frac{1}{2}\int \left[(D_\mu\Psi)^*(D^\mu\Psi) - m^2\Psi^*\Psi\right]d^4x. \end{aligned}$$

This can be generalized to the non-Abelian case (for instance, to the $SU(2)$ *gauge group of the present example) by replacing the real fields* $Re\,\Phi, Im\,\Phi$ *by the three real fields* Ψ_a $(a = 1, 2, 3)$, *and then updating the covariant derivatives* $D_\mu\Psi_a$ *to their non-Abelian* $SU(2)$ *versions (Eq. (9)):*

---

[443] It is also straightforward to verify that equations (4) through (7) are equivalent to the non-Abelian transformations law (23) of the previous section, provided A_μ and Ψ of that latter equation are now interpreted as the matrix $iA_\mu^b\epsilon_{abc}$ and the vector $\boldsymbol{\Psi_a}$, respectively, and we also identify the 3×3 matrix g^{-1} as

$$(g^{-1})ab = \frac{1}{2}tr(G\tau_a G^{-1}\tau_b).$$

$$S_{\text{matter}} = \frac{1}{2}\int d^4x\left[(D_\mu\Psi_a)(D^\mu\Psi_a) - m^2\Psi_a^2\right]. \tag{11}$$

The matter action in (11) is invariant under the general local gauge transformation (5)–(6)*, and is the $SU(2)$ non-Abelian version of the minimally coupled charged-field KG action term in (18) of the previous section. To complete the action formulation – i.e. to also extend the pure-gauge action term in (10) to the non-Abelian case – a non-Abelian version of the electromagnetic field strength tensor $F_{\mu\nu}$ is needed, which will be gauge covariant.*

It can readily be shown that the $SU(2)$ matrix $F_{\mu\nu}$ of spacetime skew-symmetric tensors

$$F_{\mu\nu} \equiv F^a_{\mu\nu}\frac{\tau_a}{2} = \partial_\mu A_\nu - \partial_\nu A_\mu + ie[A_\mu A_\nu - A_\nu A_\mu] \tag{12}$$

transforms in the same way as does $\Psi(x)$ under the local gauge transformations (6).

Note that (12) *consists of 3 real field tensors, $F^a_{\mu\nu}(x)$. Each of those is antisymmetric in its two spacetime indices $\mu\nu$, as in the $U(1)$ or Abelian (electromagnetic) case. However, these non-Abelian field-strength tensors are non-linear in the gauge potential fields.*[444]

We can also write

$$F^a_{\mu\nu} = (\partial_\mu A^a_\nu - \partial_\nu A^a_\mu) - e\epsilon_{abc}A^b_\mu A^c_\nu \tag{13}$$

The simplest possible ("minimal") non-Abelian generalization of the EM action is thus the pure Yang-Mills action:

$$S_{YM} = S_{gauge\ fields} = -\frac{1}{4}\int F^a_{\mu\nu}F^{a\mu\nu}d^4x \tag{14}$$

It can be proven that (14) is the unique action for the $SU(2)$ non-Abelian gauge fields which satisfies the following three conditions:

- *Invariant under the local gauge transformation* (6).

[444] From the differential-geometric point of view, the matrix-field skew-symmetric field strength tensor $F_{\mu\nu}(x)$ is interpreted as the Cartan curvature 2-form of the principal fiber bundle, with Minkowski space as its *base manifold*, and the Lie group $SU(2)$ (homeomorphic to the 3-sphere) as the fiber erected at each point x of Minkowski space (=spacetime).

- *Yields field equations which are 2^d order PDE and are linear in the highest-order spacetime derivatives.*
- *Reduces to 3 uncoupled non-interacting copies of Maxwell's EM theory in either the limit of weak gauge fields $(A_\mu^a \to 0)$ or the $e \to 0$ limit.*

We may now combine (14) with (11) *to yield the generalization of the total (gauge-fields plus charged no space matter) action (10) to $SU(2)$ non-Abelian YM gauge fields* minimally *coupled to a scalar charged field in the adjoint (vector) representation of the Lie group $SU(2)$:*

$$S = -\frac{1}{4}\int F^a_{\mu\nu}(x)F^{a\mu\nu}(x)d^4x + \frac{1}{2}\int\left[(D_\mu\Psi_a)(D^\mu\Psi_a) - m^2\Psi_a\Psi_a\right]d^4x \quad (15)$$

Because the field strength tensors $F^a_{\mu\nu}$ are nonlinear in the gauge potentials, even the pure Yang-Mills action term S_{YM} yields nonlinear field equations: The non-Abelian generalizations of Maxwell equations are nonlinear even in the absence of matter (non-gauge-fields) sources.

This establishes that the gauge fields act as their own source[445]*. In fact, the nonlinearity of the pure YM theory (means that the matter–independent currents in the three copies of Maxwell's equations are quadratic in the gauge fields).*

By infinitesimally varying both the gauge fields and the scalar fields in Eq. (15) and requiring that the action S be stationary under any such variation, the field equations for both types of fields are obtained as the Euler-Lagrange equations of the action S:

$$D_\mu F^{a\mu\nu} = e\epsilon_{abc}\Psi_b(x)D^\nu\Psi_c(x) \quad (16a)$$

$$(D_\mu D^\mu + m^2)\Psi_a = 0 \quad (16b)$$

Eq. $(16a)$*, the field equations for the gauge fields, is the $SU(2)$ non-Abelian version of* (20) *(previous section), while* $(16b)$*, the field equation for the scalar*

[445] Even in the Abelian theory, the conserved four-current $j_\mu(x)$ (Eq. (20), previous section) – which *generates* the gauge field strength through Maxwell's equations — itself *depends* on these same gauge fields – through the covariant derivative. However, in the Abelian case, the four-current vanishes when the charged scalar field does; whilst in the non-Abelian case, the gauge field strength can be entirely self-generated.

field, is the non-Abelian version of the minimally-coupled charged field KG wave equation.

Eq. (16b) *is also the free Klein-Gordon field equation in which partial derivatives have been replaced by non-Abelian gauge–covariant derivatives; the scalar charged field is thus said to be minimally coupled to the non-Abelian gauge fields in the action* (15).

It should be noted that although our derivation of the non-Abelian gauge (YM) theory and its underlying non-Abelian gauge principle (local gauge symmetry and minimal coupling) was developed for the particular gauge group $SU(2)$, *the main results – those expressed in matrix form – hold without modification for any gauge group, whether Abelian or not.*

These main results are as follows: the gauge transformation laws for matter and gauge fields, Eqs. (5), (6)*; the covariant derivatives for matter fields,* (8)*; the field-strength (a.k.a. fiber-bundle curvature) tensor in terms of the gauge potential fields,* (12)*; and the field equations* (16a)–(16b), *provided they are written in the following matrix form:*

$$D_\mu F^{a\mu\nu} = -ie[\Psi, D^\nu \Psi], \tag{17a}$$

$$(D_\mu D^\mu + m^2)\Psi = 0. \tag{17b}$$

1918–1936 CE **Leonid Isaakovich Mandelstam** (1879–1944; Russia). Physicist. Established the Soviet school of *nonlinear dynamics*. Did significant research in optics, radiophysics and quantum mechanics.

Discovered *Raman scattering* in crystals independently of Raman and Krishnan's work on liquids. Contributed to electrotechnology, including the theory of oscillators with time-varying parameters.

Mandelstam was born in Mogilev (now Belarus) to Jewish parents. Expelled from Odessa University after student riots in 1899, he continued his undergraduate and postgraduate studies in Strasbourg, returning to Russia in 1914. A variety of scientific and academic posts followed, culminating in the chair of Theoretical Physics at Moscow State University in 1925 and full membership of the Soviet Academy of Sciences in 1929.

Due to his Jewish ethnic origin and his close academic links to Germany, he was politically attacked during the Stalinist purges (1937–1938).

1918–1964 CE **Le Corbusier** [ps. of **Charles-Edouard Jeaneret-Gris** (1887–1965, Switzerland and France)]. Architect and city planner. Often considered the most important architect of the 20th century. Used certain characteristics of reinforced concrete construction to enclose and use space in new ways.

Le Corbusier was born in Switzerland and trained initially as an engraver and goldsmith. He was largely self-taught during travels in Greece, Italy, France, Germany. Settled in Paris (1917) and developed *purism* (1918) based on architectural equilibrium and functional simplicity, in which he expounded his revolutionary concept of mass-produced housing based on a ferroconcrete modular skeleton. In his *Vers une architecture* (1923) he developed a personal version of *International style*, utilizing pillar supports, roof terraces, unornamental facades, strip windows. It contained the idea of high-rise residential complexes surrounded by green spaces. This he implemented in numerous private residences in Europe, North Africa and South America.

In the 1920's Le Corbusier published the first of his town-planning projects for futuristic cities focused upon a central complex of identical skyscrapers. His new approach to a structure's form and use was part of what he called the *New Spirit* that man set free for his own full development (1920–1925).

During the 1930's and 1940's, Le Corbusier built few buildings and centered his interests on city planning. He proposed the demolition of urban areas and their complete rebuilding according to his ideas. His major achievement was his plan and design for the new city of Chandigrah, India in the 1950's.

After WWII, he moved away from functionalism to explore possibilities of an irrational, expressionistic sculptural style. In his final buildings (1952–1964), Le Corbusier continued to demonstrate his understanding for architectural forms interacting with a variety of functional and social conditions.

1919 CE **Karl Ereky** (Hungary). Agricultural engineer. Coined the word *Biotechnology*. He defined it as

- "*All lines of work by which products are produced from raw materials with the aid of living things.*"

Ereky envisioned a *biochemical age* similar to the stone and iron ages.

Newer and more comprehensive definitions are:

- “Any technique that uses living organisms to make or modify products, to improve plants or animals, or to develop microorganisms for specific purposes” (Office of Technology Assessment of the U.S. Congress)
- “The integration of natural sciences and engineering sciences in order to achieve the application of organisms, cells, parts thereof and molecular analogues for products and services” (European Federation of Biotechnologists)
- “A collection of scientific techniques that use living cells and their molecules to make products or solve problem intended to modify human health and the human environment”.
- “Systematic industrial use of biological processes to manufacture medical, agricultural and consumer products”.

Biotechnology Chronicles, I

I: Early Applications and Speculations
6000 BCE–1700 CE

Biotechnology is technology based on biology, especially when used in agriculture, food science and medicine. It includes the directed use of organisms for the manufacture of organic products[446].

Biotechnology is not new — humans have been manipulating living things to solve problems and improve their way of life for millennia.

The origins of biotechnology date back nearly 10,000 years ago to early agrarian societies in which people collected seeds of plants with the most desirable traits for planting the next year. There is evidence that Babylonians, Egyptians and Romans used these same selective breeding practices for improving livestock.

Certain practices that we would now classify as applications of biotechnology have been in use since man's earliest days. Nearly 6000 years ago, our ancestors were producing wine, beer, and bread by using fermentation, a natural process in which the biological activity of one-celled organisms plays a critical role.

In fermentation, microorganisms such as bacteria, yeasts, and molds are mixed with ingredients that provide them with food. As they digest this food, the organisms produce two critical by-products, carbon dioxide gas and alcohol.

In beer making, yeast cells break down starch and sugar (present in cereal grains) to form alcohol; the froth, or head, of the beer results from the carbon dioxide gas that the cells produce. In simple terms, the living cells rearrange chemical elements to form new products that they need to live and reproduce. By happy coincidence, in the process of doing so they help make a popular beverage.

---

[446] One aspect of biotechnology is the directed use of *organisms* for the manufacture of organic products. Examples include *beer* and *milk* products. For another example, naturally present *bacteria* are utilized by the mining industry in *bioleaching*. Biotechnology is also used to recycle, treat waste, clean up sites contaminated by industrial activities *(bioremediation)*, and produce *biological weapons*.

There are also applications of biotechnology that do not use living organisms. Example are *DNA microarrays* used in *genetics* and *radioactive* tracers used in medicine.

Bread baking is also dependent on the action of yeast cells. The bread dough contains nutrients that these cells digest for their own sustenance. The digestion process generates alcohol (which contributes to that wonderful aroma of baking bread) and carbon dioxide gas (which makes the dough rise and forms the honeycomb texture of the baked loaf).

Discovery of the fermentation process allowed early peoples to produce foods by allowing live organisms to act on other ingredients. But our ancestors also found that, by manipulating the conditions under which the fermentation took place, they could improve both the quality and the yield of the ingredients themselves.

By 4000 B.CE, the Chinese *were using lactic-acid-producing bacteria making yogurt, molds for making cheese and acetic acid bacteria for making wine vinegar.*

By 500 B.CE the Chinese *were using moldy soybean curds as an antibiotic treatment for pustules and open sores. By 250 B.CE* Greeks *practiced crop rotation to preserve soil fertility. One hundred and fifty years later the first insecticide was used by the* Chinese*, namely — that of powdered Chrysanthemum.*

The first millennia CE witnessed a consolidation of food processing technologies, with the Romans *in particular, diversifying and exploring cheese, and winemaking methods throughout their Empire. Beer making too, became more sophisticated and spread rapidly throughout Europe. The Dark Ages stemmed the flow of biotechnology and its products, with the Church coveting wine and beer making techniques. In 1300 CE the Aztecs in Mexico harvested algae from lakes as a food source. By 1400 CE, distillation of a variety of spirits from fermented grain was widespread. Egypt and Persia, however largely gave up brewing as a result of the influence of Islam. Fermented breads and cereals still maintained their hold in the African diet.*

By 1500 CE, plant-collecting expeditions became quite common across the globe. The collections led to the establishment of the first plant gene banks. Plants with desirable traits, including resistance to disease, were stored for future breeding purposes.

These examples suffice to show that humankind has been using Mother Nature's own remedies for thousands of years to preserve the environment and heal damage done to it.

It was not until 1590 that the first microscope was engineered and 75 years later, that ***Hooke*** *described cells. In 1675* ***Leeuwenhoek*** *discovered bacteria.*

Major events throughout the stage I *are summarized in Table 5.5.*

Table 5.5: Milestones in the progress of biotechnology 4000 BCE–1900 CE

ca 4000 BCE	• *Yeast was used to brew beer by Sumerian and Babylonians.* • *Egyptians discovered how to bake bread using yeast.* • *Other fermentation processes were established in the ancient world, notably in China: The preservation of milk by lactic acid bacteria resulted in yogurt. Molds were used to produce cheese, and vinegar and wine were manufactured by fermentation.*
ca 1000 BCE	*Babylonians celebrated the pollination of palm trees with religious rituals.*
ca 500 BCE	*The Chinese used moldy soybeans curds as an antibiotic to treat boils.*
ca 400 BCE	**Hippocrates d***etermined that the male contribution to the child's heredity is carried by a semen. He guessed there is a similar fluid in women, since children clearly receive traits from each in approximately equal proportion.*
ca 250 BCE	*The Greek practice crop rotation to maximize soil fertility.*
ca 100 CE	*Powdered chrysanthemum is used in China as an insecticide.*
ca 1000 CE	*Hindus observed that certain diseases may "run in the family" and that children inherit all their parent's characteristics.*
ca 1300 CE	*Aztecs in Mexico harvested algae from lakes as a food source.*
1590 CE	*The microscope was invented by* **Janssen** *in the Netherlands.*
1630 CE	**William Harvey** *speculated that plants and animals alike reproduce through the joining of an egg and sperm, 200 years before a mammalian egg was finally observed.*
1663 CE	*Cells were first described by* **Robert Hooke***: he observed the cellular structure of cork. But it was not until almost 200 years later hat scientists, armed with better microscopes, realized that the human body is divided into very small components.*

1660–1675 CE ***Marcello Malpighi*** *used the microscope to study details of blood capillaries, nerve fibers, silkworm anatomy and plant anatomy.*

1668 CE ***Francesco Redi*** *disproved spontaneous generation through pioneering controlled experiments.*

1673 CE ***Anton van Leeuwenhoek*** *used the microscope to discover protoza and bacteria. First to recognize that such microorganisms might play a role in fermentation.*

1701 CE ***Giacomo Pylarini****, the first immunologist, practiced inoculation*[447] *of children with smallpox in Constantinople.*

1724 CE *Cross-fertilization in corn was discovered.*

1750 CE ***Lazzaro Spallanzani*** *suggested preserving food by sealing it in heated containers.*

1797 CE ***Edward Jenner*** *vaccinated*[448] *a child with a viral vaccine to protect him from smallpox.*

1802 CE *The word "biology" first appeared.*

1809 CE ***Nicolas Appert*** *devised a technique using heat to sterilize and can food.*

1820 CE *First amino acid discovered.*

1827 CE *First observation of canine eggs.*

1830 CE *Proteins were discovered.*

1833 CE *The first enzymes were discovered.*

1836 CE ***Heinrich von Valdeyer-Hartz*** *coined the name chromosome.*

1847 CE ***Ignaz Semmelweis*** *used epidemiological observations to propose that childhood fever can be spread to mother by physicians.*

---

[447] *inoculation*: intentionally infecting humans with a putatively mild strain of smallpox to induce resistance to severe strain of the disease, thus preventing a serious case later in life.

[448] *vaccination*: intentionally infecting humans cowpox to induce resistance to smallpox.

1851 CE ***Charles Chamberland*** *discovered organisms smaller then bacteria, later known as viruses.*

1855 CE *The Escherichia Coli bacterium is discovered. It later became a major research, development and production tool for biotechnology.*

1855 CE ***Louis Pasteur*** *first to introduce the notion that microbes are the cause, not the result of a disease; asserted that microbes are responsible for fermentation (result of activity of yeasts and bacteria); invented the process of pasteurization (heating wine sufficiently to inactivate microbes, while at the same time not ruining the flavor of the wine); theorized that decayed organisms are found as 'germs' in the air; developed the germ theory of disease (1865); developed a rabies vaccine.*

1856 CE ***Karl Ludwig*** *discovered a technique for keeping animal organs alive outside the body, by pumping blood through them.*

1859 CE ***Charles Darwin*** *theorized his principle of "natural selection": only the creatures best suited to their environment survive to reproduce.*

1865 CE ***Gregor Mendel*** *discovered that traits were transmitted from parents to progeny by discrete, independent units, later called genes.*

Mendel's work remained unnoticed, languishing in the shadow of Darwin's more sensational theory (1859), until 1900, when ***Hugo de Vries***, ***Erich von Tschermak***, *and* ***Carl Correns*** *published research corroborating Mendel's mechanism of heredity.*

1868 CE ***Friedrich Miescher*** *successfully isolated nuclein, a compound that includes nucleic acid, from pus cells. He was not, however, investigating heredity. Instead, he was trying to identify the chemicals in cells. Several generations of scientists would pass before the connection would be made between the DNA found by Miescher and the laws of heredity described by* ***Mendel*** *just three years previously.*

1870 CE ***Walther Flemming*** *discovered the mechanism of cell division (mitosis) and the notion of chromosomes.*

1871 CE ***Ernst Hoppe-Seyler*** *discovered invertase, an enzyme that cuts disaccharide sucrose into glucose and fructose.*

1877–1885 CE ***Robert Koch*** *developed a technique for staining and identifying bacteria, a single most important discovery in the rise of bacteriology (1877).*

He also became the first to uncover the cause of a human microbial disease – tuberculosis (1882).

1878 CE *The term 'microbe' was first used.*

1882 CE ***Elie Metchnikoff*** *developed a cell theory to explain the action of vaccines.*

1883 CE ***August Weismann*** *asserted that chromosomes must be the bearers of heredity.*

1885–1895 CE ***Robert Koch*** *and* ***Paul Ehrlich*** *identified a host of human disease-causing organisms.* ***Emil von Behring*** *developed the first antitoxin for diphtheria.*

1887 CE ***Eduard van Beneden*** *discovered that each species has a fixed number of chromosomes; he also discovered the formation of haploid cells during cell-division of sperm and ova (meiosis).*

1892 CE ***Dmitri Ivanovsky*** *reported that the causal agent of the tobacco mosaic disease is transmitted and is smaller than bacteria. Such agents are later called viruses.*

1898 CE ***Friedrich Löffler*** *and* ***Paul Frosch*** *discovered that foot-and-moth disease is caused by viruses.*

1899 CE ***Walter Reed*** *established that yellow fever is caused by a virus.*

II: The Age of the Industrial Revolution 1700–1900

The 18th and 19th centuries witnessed technological and scientific explosions, the diversity and inventiveness of which will likely never be equaled. The Industrial Revolution was matched by the Scientific Revolution. These phenomena were to ultimately fuse in the later part of the 19th century, especially in the agricultural, medical and environmental settings. Thus, the empirical method and the Industrial Revolution brought monumental changes to farming and industry, while the biological sciences were inspired by the work of ***Darwin*** *and* ***Pasteur****. The microbial nature of many diseases was established.*

*The 18th century beheld the first inoculation techniques (****Pylarini****, 1701), successful vaccinations (****Jenner****, 1797) and an explosion in engineering processes. The 1800s were the dawning century of modern scientific thought. The word biology was coined in 1802,* ***Appert*** *invented the canning process (1809), proteins were discovered (1830), the first enzymes were isolated (1833), and during the 1850s industrially processed animal foods, inorganic fertilizers and a wide range of seed drill harrows, automated mowers, cultivators etc. came into use.*

In 1855 Escherichia coli was isolated, a bacterium which has remained an indispensable tool in a wide range of production and research fields. In 1856 ***Karl Ludwig*** *described a method by which animal organs could be maintained outside the body — necessary prerequisite to organ transplants and* in vitro *methods.* ***Mendel*** *laid the groundwork of the modem field of genetics in 1863, while in 1865,* ***Lister*** *began using disinfectants.*

1869 bore witness to the first isolation of DNA — from brown trout sperm — by ***Friedrich Miescher*** *(1844–1895) and a year afterwards,* ***Flemming*** *recorded mitosis. Between 1870 and 1880,* ***Hoppe-Seyler*** *discovered* invertase*, which is still widely used for making sweeteners;* ***Koch*** *(1893) developed staining methods for bacteria;* ***Lister****'s* antiseptic surgery *was an important leap in the understanding of infectious diseases; the word "microbe" was used for the first time; chromosomes were described by* ***Flemming****;* ***Pasteur*** *published his work on attenuated strains of bacteria, and the first centrifuge was manufactured by* ***C.G.P. de Laval****.*

From 1881–1900, the first rabies vaccines appeared, ***Metchnikoff*** *laid the foundations of the study of immunology;* ***Vavilov*** *mapped the worlds centers of biodiversity;* ***Galton*** *coined the term* eugenics*;* ***C. Gram*** *described his differential staining techniques for bacteria;* ***von Behring*** *developed the first antitoxin;* ***Petri*** *introduced the glass plates still widely used in microbiology; the self-propelled tractor was marketed, and nitrogen fixation described.*

Toward the end of the 19th century, **Buchner** *demonstrated that fermentation can occur with yeast extracts — a defining moment in modern biochemistry and enzymology.*

1919 CE

- First commercial airplane service between London and Paris.
- First transatlantic flight: *Vickers Vimy*, piloted by the British aviators Captain **John Alcock** and Lieutenant **Arthur Whitten-Brown** from Newfoundland to Ireland, taking almost 16 hours.

1919 CE **Heinrich Georg Barkhausen** (1881–1956, Germany). Physicist. Discovered that the magnetization of iron proceeds in small discrete steps accompanied by tiny clicks and devised a loudspeaker system to render this discontinuity audible. This phenomenon is now known as the *Barkhausen effect*[449]. It can be explained by the domain theory of magnetization: as small magnetic domains become aligned, one at a time,the magnetic field changes

---

449 Because the ferromagnetic elements Fe, Ni, and Co, have an unusual configuration of electrons orbital and spin states, the angular momenta of these atoms have *abnormally large electron spin components*. These produce a strong quantum mechanical and electrical interaction between neighboring atoms that leads to *maximum stability* when the atomic magnetic moments are aligned. This spontaneous tendency to align produces *mesoscopic regions* (*domains*) in which the moments are all aligned. In these domains, which have volumes of about order 10^{-7} mm^3 and 10^{15} atoms, the local magnetization has its maximum value Nm_0 [m_0 = atomic magnetic moment for a paramagnetic substance, typically about one Bohr magneton, m_B; $N = \text{atoms/m}^3$]. If an increasing external magnetic field is applied to an unmagnetized sample of iron below the critical (Curie) temperature, those domains that have moments aligned with the field, increase in size at the expense of those not favorably aligned. At first, when the applied field is relatively weak, this process is reversible. That is, if the external field is reduced to zero, the domain boundaries return to their original positions and the bulk sample is again unmagnetized. For stronger applied fields, however, the domain boundaries do not recover completely and the sample acquires a *permanent magnetism* that remains after the external field is removed.

A strong field can also produce permanent magnetization by causing unaligned domains to *rotate* and become nearly parallel to the field direction. The *shifts of the domain boundaries and the domain rotations both occur in discrete steps.*

induce electric pulses, and forces between neighboring domains also directly generate sound vibrations – causing the audible clicks. The Barkhausen effect is the main source of noise and hiss in almost all magnetic recording equipment.

Barkhausen was born in Bremen, son of a district judge. In 1911 he was appointed Professor of Low-Current Technology in the Technische Hochschule, Dresden, the first chair anywhere devoted to the relatively new field of electrical communication. He carried out fundamental research on electron tubes and electrical oscillations at ultra-high frequencies phenomena which were later utilized in high–power microwave devices. His Institute of High-Frequency and Electron-Tube Technology was destroyed by Allies bombing in 1945.

1919–1921 CE **Theodor Franz Eduard Kaluza** (1885–1954, Poland and Germany). Mathematician. A pioneer of unified field theories. First to suggest that unification of electromagnetism and gravitation might be achieved by extending space-time to a *five-dimensional cylinder world*. The electromagnetic vector-potential appears in his scheme as the cross components of the metric tensor (between the 5^{th}, compact dimension and the usual four spacetime dimensions). This scheme also gives rise to a scalar ('Brans-Dicke' or *dilaton* field), and the Einstein–Maxwell field equations in the four macroscopic space–time dimensions follow directly from the pure vacuum Einstein field equations of general relativity in 5 dimensions.

In April 1919, Einstein received a letter that left him speechless. It was from an unknown mathematician, Theodor Kaluza, at the University of Königsberg (today Kaliningrad in Russia). In a short article, only a few pages long, this obscure mathematician was proposing a union of Einstein's theory of gravitation with Maxwell's theory of light by introducing a 5th dimension (4 dimensions of space and one dimension of time). Kaluza's idea was to write down the pseudo-Riemann metric in 5 spacetime dimensions. The 5th column and 5th row are identified as the electromagnetic vector and scalar potentials of Maxwell, the g_{55} component is the Lorentz–scalar dilation field, while the remaining 4×4 block is the 4-dimensional metric of Einstein. It seemed incredible to Einstein that such a simple idea could explain the (then known) two fundamental forces of nature: gravity and electromagnetism.

In fact, it is possible to detect the *electric impulses* due to the induction effect as these realignments occur — this is called the *Barkhausen effect*.

The magnetization of an iron sample by an applied external field is a complicated *nonlinear process* that depends on the particular way that the sample was formed (cast, hot-rolled, alloyed etc).

After the initial shock of confronting the 5th dimension, Kaluza's theory was found to raise more questions than it answered. Since all observations and experiments – then as now – show that we live in a universe with $3+1$ dimensions of space-time, the embarrassing question: "Where is the 5th dimension?" still remained. Kaluza responded that the 5th dimension collapsed down to a *circle* so small that even atoms could not fit inside it. It was a *physical* dimension (not a mathematical trick) that provided the glue to unite the two fundamental long–range forces of nature, yet it was simply too small to measure. Since the universe (Kaluza claimed) is topologically identical to the direct product space $M^4 \times S^1$ (a type of "hyper cylinder") with M^4 the ordinary Minkowski 4-space (spacetime) of STR, and the 5th dimension topologically equivalent to a circle, anyone walking in the direction of the 5th dimension would find himself back where he started after traveling a subatomic (indeed subnuclear!) distance.

In 1926, **Oscar Klein** made several improvements upon the theory, stating that perhaps *quantum theory* could explain why the 5th dimension rolled up. On this basis he calculated that the 5th dimension should be of the order of 10^{-33} cm (The *Planck length*).

By the 1930's the Kaluza-Klein theory was "clinically dead" although destined to be resurrected, in the context of the other (weak and strong nuclear forces) 10 or 11 dimensions string–theory scenarios and Grand Unified quantum field theories, in the 1980's. On the one hand, physicists were not convinced that the 5th dimension really existed (Klein's conjecture was and still is untestable), and it has never been clear why the hidden (curled–up) dimensions should not expand to macroscopic – indeed cosmological–scales via a Big–Bang like process. On the other hand, the rising quantum mechanics challenged the smooth, geometric interpretation of forces, replacing it with stochastic quanta and Hilbert-space states and operators[450].

Kaluza was born in Ratibor, Germany (now Raciborz, Poland) to a family which had lived there for around 300 years. He was educated at the University of Köningsberg (1902–1909). After writing his habilitation thesis on Tschirnhausen transformation (1909) he became a Privatdozent and remained in that position for the next 20 years. Only after the intervention of **Einstein** on his behalf was he promoted to the rank of a professor at Kiel university (1929).

[450] The Kaluza-Klein theory furnished one of the several avenues – linking the *gauge principle* to differential geometry – along which Yang-Mills theories were ultimately discovered. It was recently revealed that Oscar Klein had independently invented the Yang-Mills field (1954) already in 1938! A Kaluza-Klein renaissance began in the 1980's as part of *supergravity* and *superstring theories*, but these remain untested (indeed, perhaps untestable), non-unique and mathematically ill-defined conjectures.

In 1935 he was made a full professor at Göttingen, where he remained until his death in 1954.

Merger of Gravitation with Electromagnetism – Kaluza-Klein Theory (1919–1926)

The ancient Greek philosophers began the quest for the source *of all material diversity from which all the different forms and laws of nature emerge. This quest for unification persisted throughout the evolution of physics, and was a major drive that motivated the great achievements of* ***Newton*** *(1687),* ***Maxwell*** *(1865) and* ***Einstein*** *(1917).*

Thus, in the mid 19th century ***James Clerk Maxwell*** *formulated the first genuine field – that of theory of electromagnetism, unifying the then separate classical phenomena of electricity, magnetism and optics. Then, in the early 20th century,* ***Albert Einstein*** *developed general relativity, a field theory of gravitation. Later, Einstein and others attempted to construct a unified field theory in which electromagnetism and gravity would emerge as different aspects of a single fundamental field.*

Back in 1919, the strong and weak nuclear interactions were unknown except in barest outline, and full–fledged quantum mechanics had not yet been discovered. In searching for a unified theory of fundamental forces, it was therefore natural to attempt to merge gravity with Maxwellian electrodynamics and generalize Einstein's GTR while remaining within the framework of pseudo–Riemannian geometry. The idea was that since the increase of dimensions from 3 to 4 had led to Einstein's gravitational theory, a further increase from 4 to 5, using the 5-dimensional version of ***Einstein****'s theory, might describe both gravitation* and *electromagnetism as (unified) geometrical effects.*

The first attempt at such a theory was made by ***Kaluza*** *in his 1921 paper.*

To construct a five-dimensional General Relativity, Kaluza considered a five-dimensional pseudo–Riemannian line element for which

$$ds^2 = \gamma_{jk} dx^j dx^k,$$

where the summation convention is understood; Latin indices will range from 0 *through* 4*, while Greek ones will range from* 0 *through* 3*. (Thus* x^4 *is the "fifth", curled–up dimension in this notation). The* $\binom{5}{2}+5=15$ *quantities* γ_{jk} *are the covariant components of a five-dimensional symmetric tensor. To relate them to the usual quantities* $g_{\mu\nu}$ *and* A_μ *of standard GTR and generally-covariant electrodynamics, one must make special assumptions.*

First, the extra spatial dimension x^4 *must coordinatize a topological circle. Second, the quantities* γ_{ik} *should not depend on this fifth*[451] *coordinate* x^4*.*

From this it follows that the permitted general coordinate transformations are restricted to the following group

$$\begin{aligned} x'^4 &= x^4 + \Psi\left(\{x^\nu\}\right), \\ x'^\mu &= x'^\mu\left(\{x^\nu\}\right) \end{aligned} \tag{1}$$

It can then easily be shown that γ_{44} *is a 4-dimensional scalar field w.r.t. the transformation (1). The assumption* $\gamma_{44} = const. = \alpha$ *is therefore permissible. It can also be shown that for fixed* x^4 $(\Psi = 0)$ *the four* $\gamma_{4\mu}$ *transform as the covariant components of a* 4*-vector. But if* x^4 *is transformed, yet* x^μ *are not, then the 4-gradient of the 4-scalar* $\alpha\Psi$ *is added:*

$$\gamma'_{4\mu}\left(\{x^\nu\}\right) = \gamma_{4\mu}\left(\{x^\nu\}\right) - \alpha\partial_\mu\Psi \ ,$$

So $\gamma_{4\mu}$ *can be interpreted as the EM gauge-potential 4-vector, with the 4-scalar* $\alpha\Psi$ *playing the role of the local gauge-transformation Lorentz scalar function. This means that the quantities*

$$\frac{\partial\gamma_{4\nu}}{\partial x^\mu} - \frac{\partial\gamma_{4\mu}}{\partial x^\nu}$$

transform like the covariant components $F_{\mu\nu}$ *of the electromagnetic field-strength skew-symmetric 4-tensor.*

In fact it is convenient to rescale:

$$\gamma_{4\mu} = \alpha\beta A_\mu, \qquad\qquad \beta = const. \tag{2}$$

---

[451] Since the fifth dimension is assumed to be curled-up into a circle of circumference $\sim 10^{-33}$ cm, all fields $\gamma_{ij}(x^\mu, x^4)$ $(\mu = 0, 1, 2, 3, 4)$ must be periodic in x^4. It can be shown that the non-constant (in x^4) Fourier components are Klein–Gordon fields in the ordinary spacetime dimensions x^4, with masses of order of the *Planck mass* $(10^{19} GeV/c^2)$, which can be neglected at normal scales of energy, space and time (and even those encountered in accelerators, cosmic rays and the most violent cosmological and astrophysical cataclysms known).

According to the generally-covariant formulation of electromagnetism, the electromagnetic field-tensor in a source-free medium is given by

$$F_{\mu\nu} = \frac{\partial A_\mu}{\partial x_\nu} - \frac{\partial A_\nu}{\partial x_\mu} \tag{3}$$

We would like to relate the 5D differential ds^2 *with the usual 4D relativistic one. We therefore combine* $ds^2 = \gamma_{jk} dx^j dx^k$ *with*

$$\gamma_{44} = \alpha \ , \quad \gamma_{4\mu} = \gamma_{\mu 4} = \alpha\beta A_\mu \ , \quad \gamma_{\mu\nu} = g_{\mu\nu} + \alpha\beta^2 A_\mu A_\nu \tag{4}$$

The 4D metric $g_{\mu\nu}$ *has been chosen so that in locally Minkowskian coordinates we have*

$$(ds^{(4)})^2 \equiv g_{\mu\nu} dx^\mu dx^\nu = -(dx^2 + dy^2 + dz^2) + c^2 dt^2 \tag{5}$$

There remains the problem of constructing field equations for the γ_{jk} *which will lead to the usual Einstein-Maxwell field equations for* $g_{\mu\nu}$ *and* A_μ*. To this end one constructs the Lagrangian density*

$$\mathcal{L} = \gamma^{jk} \mathcal{R}^l_{jkl}, \tag{6}$$

where γ^{jk} *are the contravariant components of the five-dimensional metric tensor determined by,* A_μ*, matrix-inversion and Eq. (4);* $\mathcal{R}^l_{jkl}$ *is the 5D Ricci tensor, and (6) is the generalization of the Hilbert-Einstein Lagrangian density of GTR to the Kaluza 5-dimensional world.*

As explained above, we assume that all γ_{jk} *(and thus* γ^{jk}*) components, and therefore the 5D Ricci tensor as well, are independent of* x^4 *and that* $\gamma_{44} = \alpha$*. Let us now consider the 5D Hilbert-Einstein action integral*

$$J = \int \sqrt{-\gamma}\, dx^0 dx^1 dx^2 dx^3 dx^4 \mathcal{L} \ , \tag{7}$$

taken over the five-dimensional space, where γ *denotes the determinant of* γ_{jk}*. We express* δJ *in terms of a variation of the quantities* γ_{jk} *and* $\frac{\partial \gamma_{jk}}{\partial x^l}$ *where the variation vanishes sufficiently rapidly at 4D spacetime infinity and* α *is regarded as constant (not varied). The variational principle* $\delta J = 0$ *then leads to the following Euler-Lagrange equations:*

$$R^{\mu\nu} - \frac{1}{2} g^{\mu\nu} R + \frac{\alpha\beta^2}{2} T^{\mu\nu} = 0 \ , \tag{8}$$

$$\frac{\partial\left(\sqrt{g} F^{\mu\nu}\right)}{\partial x^\mu} = 0 \ , \tag{9}$$

where R is the Einstein 4D scalar curvature, $R^{\mu\nu}$ are the contravariant components of the Einstein 4D Ricci tensor, $g^{\mu\nu}$ are the contravariant components of the 4D metric tensor, $T^{\mu\nu}$ are the contravariant components of the 4D electromagnetic energy-momentum-stress tensor, g is the determinant of $g_{\mu\nu}$, and finally $F^{\mu\nu}$ are the contravariant components of the electromagnetic field tensor. If we set

$$\frac{\alpha\beta^2}{2} = k \tag{10}$$

where $k = \frac{8\pi G}{c^4}$ is the usual 4D Einstein gravitational constant, we see that equations (8) and (9) are in fact identical with the matter-free field equations for the gravitational field (with only EM fields as sources) and the generally-covariant Maxwell equations, respectively.

While the Kaluza-Klein theory was an impressive accomplishment, it was a failure as a unification attempt, at least in its original form. This is because unlike Maxwell's unification (and the 20th century unifications of quantum mechanics with STR, and of Feynman et al.*'s QED with the weak nuclear force), no new physics is predicted (apart from the possible* scalar-tensor *or* Brans-Dicke *extension of GTR).*

Both the original Kaluza–Klein model and more modern versions (in which several *spatial dimensions are curled–up into compact, sub–nuclear–sized symmetrical spaces[452]) have the serious – and thus for unmet – challenge of explaining why the extra dimension or dimensions are curled up, and why nature would settle on a particular version of this "compactification" among the infinite possibilities.*

The enduring value of the Kaluza-Klein model to theoretical physics, however, lies in the tantalizing hint it provides that not only gravity, *but also* energy *and* matter *could be geometrical in origin. Furthermore, the connection – pointed to by this model – between the EM gauge principle and general covariance, helped point the way to the mathematical existence and physical relevance of* non-Abelian, *fiber-bundle-based gauge field theories.*

It's plausible, though by no means certain, that the varied and complicated chemical species and interactions necessary for life to arise would not be possible if one had fewer than three uncompactified spatial dimensions. similar "anthropic"–type arguments are nowadays adduced by many leading string

[452] In such higher–dimensional extensions of the Kaluza–Klein theory – motivated by *supergravity* and *superstring* candidate theories and studied in detail in the 1980s – GTR is unified, superficially at least, with all sorts of (matter and non-Abelian gauge–) fields. Such extensions are thought necessary in order to unify (at least) the four known forces, and all matter besides, into a single, geometrical framework.

theorists to attempt to pare down and choose among the myriad possible scenarios uncovered in their own higher–dimensional speculations. However, it is not clear that life could not thrive in a universe of more *than three open dimensions (although some philosophers have valiantly tried to adduce such arguments!). Perhaps one clue is that* non-Abelian gauge field theories *cannot be consistently quantized at low energies (of order those governing chemistry and nuclear physics) in any spacetime dimensions higher than 4, without fine-tuning the constants of nature at the Planck scale. (*This *is an example of a "Platonic" (first–principles) argument in physics that may – or may not – have anthropic overtones.)*

So if one were to imagine there were an infinite or very large number of universes (or different spacetime regions of one universe) with different numbers of dimensions or uncompactified dimensions, we would be looking at a biased sample – since our existing here to ask such questions, already implies that certain attributes and laws must locally hold in our observable universe.

In fact, even for fixed dimensionality, different compactifications schemes could result in different manifest laws of (4D) nature at low energy scales.

1919–1925 CE **Avraham (Adolf) Halevi Fraenkel** (1891–1965, Germany and Israel) Mathematician. Put set theory into an axiomatic setting that avoids paradoxes, improving the definitions of **Zermelo** and proving the independence of the *axiom of choice* within the Zermelo axiom system (1919). His system of axioms was modified by **Skolem** (1922) to give what is today known as the ZFS system[453] (Zermelo-Fraenkel-Skolem). The independence of the axiom of choice within this system was proved by **Cohen** (1963).

Fraenkel was born in Munich and studied at the Universities of Munich, Marburg, Berlin and Breslau. He became a professor of Mathematics at Marburg University (1922) and spent one year at Kiel (1928). Being a fervent Zionist he moved to the newly established Hebrew University of Jerusalem

[453] Within this system it is harder to prove the independence of the axiom of choice and this was not achieved until the work of **Paul Cohen** (1963). By virtue of *Gödel's incompleteness theorem*, there is no possibility of *proving* that the axioms of ZFS are consistent, but they certainly appear to avoid paradoxes, such as *Russel's paradox*, and most mathematicians believe that they will not lead to any contradictions at all.

(1929) and spent there the rest of his career. His major work is *Einleitung in die Mengenlehre* (1919).

1919–1927 CE **Francis William Aston** (1877–1945, England). Physicist. Discovered a number of isotopes in several nonradioactive elements by means of a *mass spectrograph*[454] of his own devising (1919). In all, discovered 212 out of 287 natural isotopes.

Aston was assistant to J.J. Thomson (1910–1919) and fellow of Trinity College, Cambridge (from 1919). Awarded the Nobel prize for chemistry (1922).

---

[454] J.J. Thomson (1913) demonstrated that charged particles with different masses (nuclei with the same number of protons but with different number of neutrons are *isotopes* of the same chemical element) can be separated by using combined electric and magnetic fields. Thomson's crude device was improved upon by Aston and by A.J. Dempster. By 1919, atomic masses were being measured with a precision of 1 part in 10^3; the best modern instruments are capable of precision of about 1 part in 10^7. The principle of operation of the mass spectrograph is as follows: positively charged ions are produced in a source chamber and are accelerated through a potential difference V. The ions enter a region with uniform magnetic field $\boldsymbol{B}$ such that they are deflected in semicircular arcs in the plane of motion.

The ions are then recorded on a photographic plate so that the distance x from the entrance slit (the diameter of the orbit) can be measured. The entire system is maintained under vacuum to prevent scattering of the ions by gas molecules. Consider singly ionized positive ion $(q = +e)$ with a mass M that enters the magnetic field with a velocity v obtained from $eV = \frac{1}{2}Mv^2$. Within the magnetic field the force on the ion is always perpendicular to its velocity vector, which thus has a constant magnitude (i.e. no work is done upon the charge by the magnetic field). Therefore, the ion follows a circular path with radius $R = \frac{1}{2}x$. The centripetal acceleration is provided by the magnetic field. Thus $a_c = \frac{v^2}{R} = \frac{v^2}{\frac{1}{2}x} = \frac{F}{M} = \frac{evB}{M}$. Expressing v in terms of V and solving for M gives $M = \left(\frac{eB^2}{8V}\right)x^2$. Thus, the mass of the ion is obtained from measurements of B, V, and x. The *relative* masses of two ions accelerated at the same time involve only measurements of x and so can be obtained with high precision.

Clearly, the mass spectrograph places each of the *isotopes* of the same chemical element at different distances x along the plate.

The Berlin Colloquia (1919–1933)

One of the most characteristic and central features of the scientific and intellectual life in Berlin-Dahlen Kaiser Wilhelm Institute became the famous Haber Colloquia, which took place every second Monday afternoon. There were many famous guests speakers in different fields and many of the department heads or senior scientists of different institutes presented papers.

Haber's aim was to break down the barriers between physics, chemistry, physical chemistry, and the biological sciences. The presentation of a paper was followed by a vigorous discussion, deliberately stimulated by Haber, in which scientists of different disciplines participated. Thus the discussions automatically stimulated interests beyond one's own field and frequently suggested ways for trying a new approach. Young people were encouraged to participate. Controversies were considered an essential element for clarifying a subject. The young people taking part in these colloquia became immunized against authoritative and dogmatic thinking. Science in all fields was in rapid expansion. Nobody could claim to have the right answers.

It was an illuminating experience to listen to the opposing views of so many illustrious people — a fascinating demonstration of the limitation of our knowledge, a warning to be flexible and to avoid rigidity of views. Moreover, non of these great scientists hesitated to admit errors. The spirit of searching for the truth, not worrying about reputation or prestige when one was wrong, was one of the most extraordinary features of the Colloquia. They became an intellectual center in the lives of scientists of various fields, outlooks, and interests of exchanging views and learning about developments in other fields.

Walter Nernst*'s department at the University of Berlin had similar Colloquia in which an exciting atmosphere prevailed and in which vigorous discussions and controversies took place*[455]*. Sitting in the front row were* ***Max Planck****,* ***Albert Einstein****,* ***Max Von Laue*** *and* ***Erwin Schrödinger****. Students sat in the back and for them it must have been an experience similar to that felt at the Haber Colloquia.*

[455] In Anglo-Saxon countries, controversies seem to be considered "unpleasant and distasteful". The Haber colloquia were a particularly great stimulus for the remarkable development of biological sciences in the Kaiser Wilhelm Institutes. In them, the revolutionary developments in the fields of physics, chemistry, and physical chemistry were brought to the attention of biologists, thus providing them with new insight and later with important tools for the analysis of the processes taking place in the living cell.

1919–1928 CE **Edgar Douglas Adrian** (1889–1977, England). Physician and psychologist. His studies on the electrophysiology of the brain and the nervous system provided a new quantitative basis of nerve's behavior.

Adrian was born in London and studied at Cambridge University. Was professor of Clinical neurology at Cambridge (1937–1951), master of Trinity College (1951–1965) and chancellor (1968–1975). Shared the Nobel Prize for physiology and medicine (1932) with **Charles Sherrington**.

1919–1938 CE **Léon Theremin** (**Lev Sergeyevich Termen**, 1896–1993, Russia). Inventor, electronic engineer and electronic music pioneer. Invented the *theremin*, one of the earliest fully electronic musical instrument. The theremin is unusual in that it requires no physical contact in order to produce music and was designed to be played without being touched.[456]

Léon Theremin was born in St. Petersburg. His ancestors were Huguenots who escaped France in 1572, following the Massacre of Saint Bartholomew's Day. His invention came at a time when his country was in the midst of the Russian Civil War. After a lengthy tour of Europe, during which time he demonstrated his invention to packed houses, he found his way to the U.S., playing the theremin with the New York Philharmonic (1928). He patented his invention (1929) and subsequently granted production rights to RCA. Although the RCA Theremin, released immediately following the Stock Market

[456] The original design resembled a gramophone cabinet on 4 legs with a protruding metal antenae and a metal loop. The instrument was played by moving the hands around the metal loop for volume and around the antenae for pitch. The output was a monophonic continuous tone modulated by the performer. The timbre of the instrument was fixed and resembled a violin string sound. The sound was produced directly by the heterodyning combination of two radio-frequency oscillators: one performing at a fixed frequency of 170,000 Hz, the other with a variable frequency between 168,000 and 170,000 Hz, the frequency of the second oscillator being determined by the proximity of the musician's hand to the pitch antenna. The difference of the fixed and variable radio frequencies results in an *audible beat frequency* between 0 and 2,000 Hz. The audible sound came from the oscillators, later models adding an amplifier and large triangular loudspeaker. This Theremin model was first shown to the public at the Moscow Industrial Fair in 1920 and was witnessed by **Lenin** who requested lessons on the instrument. Lenin later commissioned 600 models of the Theremin to be built and toured around the Soviet Union.

Crash (1929), was not a commercial success, it fascinated audiences in America and abroad. **Clara Rockmore** (1911–1998; born Reisenberg in Vilnius, Lithuania), widely considered the greatest therminist ever, met Theremin in 1927 and toured to wide acclaim, performing a classic repertoire in concert halls around the United States.

In 1938, Theremin was kidnapped from his New York apartment by Soviet agents, and forced to return to the U.S.S.R.. He was then sent to work in the gold mines in Kolyma and later put to work in a *sharashka*, together with **Tupolev**, **Korolev** and other well-known scientists and engineers on several tasks.[457] He was rehabilitated in 1956.

After his rehabilitation Theremin took up a teaching position at the Moscow conservatory of music. However he was ejected for continuing his researches in the field of electronic music. Post war Soviet ideology decreed that modern music was pernicious. Theremin was reportedly told that electricity should be reserved for the execution of traitors. After this episode Theremin took up a technical position, and worked upon non-music related electronics. Ironically his invention, the Theremin, was becoming vastly influential in America, a development of which he was completely unaware.

Before his death in 1993 Theremin made one final visit to America lecturing, and demonstrating his Theremin. Indeed the instrument is still being used today, and has an avid following of Theremin-o-philes[458].

1919–1953 CE **Lewis Fry Richardson** (1881–1953, England). Distinguished applied mathematician. A most original and versatile mind that

---

457 There he invented a sophisticated electronic eavesdropping device. His "bug" was the first to use induced energy from radio waves of one frequency to transmit an audio signal to another. This made the device difficult to detect since it did not radiate any signal unless it was actively being powered and listened to remotely. This feature also endowed it with (potentially) unlimited life.
"The Thing", as it was called, was very simple by today's standards, having only a capacitive membrane (a *condenser microphone*) connected to an antenna. Thus the *impedance* seen by the quarter-wavelength *antenna* was altered by sound, and the reflections of the 330 *MHz* signal impinging on the device were *modulated*, allowing the audio to be detected. A bug of this nature was embedded in a wooden plaque and presented to the American ambassador in Moscow by Russian schoolchildren where it hung in his office until detected by a professional bug sweeper. For this work Theremin was awarded the Stalin Prize.

458 The famous theme music of the original 1960's *Star Trek* television series, which seems to be hummed by a choir of female voices, is actually Theremin music!

concerned himself with the solutions of difficult problems, and made fundamental contributions in physics, mathematics, meteorology and psychology. Published about 90 papers and 4 books. His novel ideas have led to the following results:

- *Fractal geometry*[459]: Rechardson is certainly among the progenitors of the fractal concept, and had much influence on the genesis of fractal geometry.
- *Weather prediction by numerical process* (1922): He was the first man to compute the weather. Developed the application of the method of *finite differences* to the major problem of meteorology viz., the computation of the physical state of the atmosphere (rainfall, transfer of heat and moisture, etc.) for an epoch finitely subsequent to that for which the state is known by observations.
- *Atmospheric turbulence* (1920–1926). We are indebted to him for some of the most profound and most durable ideas regarding the nature of turbulence, notably the notion that over a wide range of scales, turbulence is decomposable into a hierarchy of self-similar eddies. He introduced a fundamental dimensionless parameter that controls eddy-diffusion in the atmosphere, later termed the *Richardson number*.
- *Studies of the causation of wars* (1919–1953). Developed the application of mathematics to the study of relations between nations, especially to elucidate the effects of armaments, trade, communications, rivalry and grievances on the stability of the regime and the feasibility of armed conflicts. He published 3 books on this subject [*Mathematical Psychology of War* (1919), *Arms and Insecurity* (1949), *Statistics of Deadly Quarrels* (1950)]. It was one of the first serious applications of science to human situations.

---

459 Richardson had noticed that the results of measuring the length of a coastline from a map depends heavily on the scale of the map used. Thus, he set out to make an experimental measurement of the west coast of Britain as a function of the map's scale. The same phenomenon can also be expressed by considering one map only, on which all detail can be seen, but using a smaller measuring unit each time. Denoting the measured length by L and the length of the measuring unit by ϵ, the plot of L against ϵ yielded the line: $\log_{10} L = -0.22 \log_{10} \epsilon + \log_{10} L_0$, where L_0 is the coastal length when using a measuring unit of 1 km. This can be expressed as $L = L_0 \epsilon^{-0.22}$ or as $L = L_0 \left(\frac{1}{\epsilon}\right)^{0.22}$. If we reduce ϵ by a factor of 32, s will double. Clearly $\lim_{\epsilon \to 0} L = \infty$. This is known as the *Richardson effect*, and denoted as $L(\epsilon) = L_0 \left(\frac{1}{\epsilon}\right)^{D-1}$, where D is now called the *fractal dimension* of that coastline.

Richardson constructed a mathematical model which describes the relation between two nations, each determined to defend itself against a possible attack by the other. Each nation considers the possibility of attack quite real, and reasonably enough, bases its apprehensions on the readiness of the other to wage war. The theory is not an attempt to make scientific statements about foreign politics or to predict the date at which the next war will break out. It only predicts what will occur if *instinct* and *tradition* were allowed to act uncontrolled.

Let $x = x(t)$ denote the war potential or armaments, of the first nation (called X) and let $y(t)$ denote the war potential of the second nation, Y. The rate of change of $x(t)$ depends on the war readiness $y(t)$ of Y and on the grievances that X feels towards Y. We represent these terms by ky and g respectively, where k and g are positive constants. On the other hand, the cost of armament has a restraining effect on $\frac{dx}{dt}$. We represent this term by $-\alpha x$, where α is a positive constant. A similar analysis holds for $\frac{dy}{dt}$. Consequently $\{x(t)\ y(t)\}$ is a solution of the linear system of ordinary differential equations

$$\frac{dx}{dt} = ky - \alpha x + g, \qquad \frac{dy}{dt} = \ell x - \beta y + h.$$

This model is not limited to two nations; it can also represent the relation between two alliances. Note also that these equations accommodate conflicting political theories about the *causes* of war. Those who maintain that armaments cause war (like **Thucydides**) will take $g \ll k,\ h \ll \ell,$ whereas those who believe that the grievance factor dominates will take $k \ll g,\ \ \ell \ll h$). The equations imply:

- If $g = h = 0,$ then $x(t) = 0,\ y(t) = 0$ is an equilibrium solution of the system, i.e., if x, y, g, h are all made zero simultaneously, then $x(t)$ and $y(t)$ will always remain zero. This ideal condition is *permanent peace by disarmament and satisfaction.*

- If at some time $t = t_0,\ x(t_0) = y(t_0) = 0,$ then at this stage $\frac{dx}{dt} = g$ and $\frac{dy}{dt} = h$. Thus, x and y will not remain zero if g and h are positive, and both nation will rearm. Hence: *mutual disarmament without satisfaction is not permanent.*

- If $y = 0$ at some time (unilateral disarmament), then at this time $\frac{dy}{dt} = \ell x + h$. This implies that y will not remain zero if either h or x remain positive. Thus, *unilateral disarmament is never permanent.*

- A race in armament occurs when the "defense" terms predominate. In this case $\frac{dx}{dt} = ky,\ \frac{dy}{dt} = \ell x,$ having the solution $x(t) = Ae^{\lambda t} + Be^{-\lambda t},$

$y(t) = \sqrt{\frac{\ell}{k}}[Ae^{\lambda t} + Be^{-\lambda t}]$, $\lambda = \sqrt{k\ell}$. Therefore, both $x(t)$ and $y(t)$ approach infinity if $A > 0$. This can be interpreted as war.

Richardson was born in Newcastle-on-Tyne, the youngest of seven children of a Quaker family, well known for owning a profitable leather works for about 300 years. He attended Cambridge University (1900), where he earned his B.A. in mathematics and the natural sciences (1903). His formal education then ended, but 20 years later he studied psychology as an external student of University College, London, where he received D.Sc. in physics on his published researches (1926), and a B.Sc. in psychology (1929). During 1903–1940 he held a sequence of different appointments as physicist and meteorologist in colleges and government institutions. In 1940 he retired to do research on wars and eddy-diffusion.

1919–1956 CE **Balthazar Van der Pol** (1889–1959, Holland). Applied mathematician. Pioneer in the field of radio; pursued the mathematical problems encountered in radio applications so far that his work has formed the basis of much of the modern theory of *nonlinear oscillations*[460] (1924). His name was given to a typical equation of that theory.

The *Van der Pol equation* is the differential equation of the *triode oscillator*

$$\ddot{x} - \epsilon(1 - x^2)\dot{x} + x = 0, \quad \epsilon > 0,$$

or with a forcing term

$$\ddot{x} - \epsilon(1 - x^2)\dot{x} + x = F \cos \omega t.$$

For arbitrary initial conditions, the solution to the unforced equation approaches a *limit cycle*, with radius approximately 2 and period approximately 2π. The limit cycle is generated by the balance between internal energy loss and energy generation, and the forcing term will alter this balance.

If F is small (weak excitation), its effect depends on whether or not ω is close to the natural frequency. If it is, an oscillation is generated which is a perturbation of the limit cycle. If F is not small (hard excitation) or if the natural and imposed frequencies are not close, the '*natural oscillation*' will be extinguished, as occurs with the corresponding linear equation.

Rayleigh (1883) was first to treat equations of this kind. He arrived at them in the following way: The solution of the equation

$$u'' + ku' + \omega^2 u = 0$$

defines a steady vibration if $k = 0$; but if $k > 0$, the vibrations will die down, and if $k < 0$ they will increase without limit. Let us add to the above equation a term proportional to the cube of u', i.e.,

$$u'' + ku' + \lambda {u'}^3 + \omega^2 u = 0.$$

If $k > 0$, $\lambda > 0$, the resulting motion will again die out, and if $k < 0$, $\lambda < 0$, the motion will increase without limit.

But if k and λ have *different* signs, then the two terms which contain them can be written $ku'(1 - a{u'}^2)$, $a > 0$ and the motion is no longer unidirectional. If k is initially negative and the initial value of u' is sufficiently small so that the term in parentheses is positive, the motion will expand until $(1 - a{u'}^2)$ becomes negative. Thereupon the motion will begin to damp, u' will diminish until the term $ku'(1 - a{u'}^2)$ is again negative, and the motion once more increases.

For small value of k and λ Rayleigh gave the following approximate solution

$$u = A \sin \omega t + \frac{\lambda \omega A^3}{32} \cos 3\omega t,$$

where A is defined by $k + \frac{3}{4}\lambda\omega^2 A^2 = 0$.

Writing Rayleigh's equation in the form

$$\frac{d^2u}{dt^2} + \left[-b + c\left(\frac{du}{dt}\right)^2\right]\frac{du}{dt} + \omega^2 u = 0,$$

the variables $pt = x$, $q\frac{du}{dt} = y$, yields $\frac{p}{q}\frac{dy}{dx} + \left(-b + \frac{c}{q^2}y^2\right)\frac{y}{q} + \omega^2 u = 0$. Differentiating this equation, simplifying, and introducing the notation $p = \omega^2$, $q = \sqrt{\frac{3c}{b}}$, $\epsilon = \frac{b}{p}$, we finally arrive at the *van der Pol equation*

$$\frac{d^2y}{dx^2} - \epsilon(1 - y^2)\frac{dy}{dx} + y = 0.$$

Van der Pol was born at Utrecht. He studied at the University of Utrecht during 1911–1916. In 1917 he worked at the Cavendish Laboratory in Cambridge under **J.J. Thomson**, and met with **E.V. Appleton** (1892–1965, England). From 1919 to 1922 he was assistant to **H.A. Lorentz** in Haarlem. He was concurrently head physicist in the Phillips Research Laboratory at Eindhoven and a professor of theoretical electricity at the Technical University, Delft.

1920 CE, July 12 Official opening of the *Panama Canal*, a 81.6 km long waterway that cuts across the Isthmus of Panama and connects the Atlantic and Pacific oceans. It ranks as one of man's greatest engineering achievements and is perhaps the greatest construction project in 4000 years.

The Panama canal was built by the United States at a total cost of 600 million dollars. Work started in 1904 with improving sanitary conditions and required the removal of 161 million cubic meters of earth and rock. The canal has three sets of *locks*, or water-filled chambers, that raise and lower ships from one level to another; each lock has a usable length of 300 m, a width of 34 m and a depth of 21 m. (U.S. Navy supercarriers are too wide to pass through the canal.)

Dreams of a canal cutting through the isthmus of Panama date from the 16th century. Concrete plans began to take shape in the American mind about 1825. The Mexican War and the discovery of gold in California turned the attention of the people of the United States to the importance of improvement of communications between the coasts. The French organized a company in 1876 to build a canal across the isthmus and began working in 1882, spending more than 200 million dollars on it. The Canal was only about 40 per cent complete when the United States took over the project in 1903. The French failed in their efforts to complete the canal because of improper financing, bad sanitary conditions (Yellow fever, malaria) that killed their workmen by the thousands and the lack of system for removal of excavation debris.

President Theodore Roosevelt gave great impetus to the project. Operations began in 1904 with the appointment of **John F. Stevens** (1853–1943), a railroad civil engineer, to direct the excavation and **William C. Gorgas** (1854–1920) to direct the effective eradication of the mosquitoes that transmit Yellow fever and malaria[461].

The physical difficulties at Panama were enormous: The climate is deadly to most races. On the Atlantic side a tempestuous river, the Chagras, had to be controlled. Next came the Continental Divide, a ridge over 100 meters high which must be sliced before the canal could be dropped down to the Pacific.

Stevens was the right man to overcome these difficulties and command the conquest of both nature and geography. Before resuming the excavation he directed a wide sanitation plan to eradicate the mosquitoes, built an adequate railway system for the removal of earth rocks and debris, acquired heavy dredging and excavation machinery and mobilized a new work force of over 100,000 men, He then blocked off the Chargas River by a huge earth dam, forming the inland Gatan Lake, at an elevation of 30 meters above sea level. A devious channel through this lake constitutes the middle half of the entire canal. Beyond the lake the Culbera Cut was sliced through the ridge.

Nothing like this excavation, carried to a total depth of 90 m, had ever been attempted anywhere. The excavation and transportation of the ridge material presented problems of a magnitude never before encountered. Since sea-level passage is not feasible under the said geographical conditions, Stevens devised the *lock gates system*, enabling ship transportation at a level of 30 m above sea-level by means of three steps of twin concrete locks with chambers 35×330 m built on the Atlantic side and three more on the Pacific side giving a total of twelve lock chambers in all, six in each direction. Stevens resigned in 1907, and his plans were completed by the United States Army Core of Engineers.

1920 CE, Dec. 16 A *landslide* in Kansu Province, China, kills ca 200,000 people.

---

461 The success of the American effort was due not only to adequate generous financing, but also of two monumental medical discoveries made in 1898 and 1900. The first was that the Anopheles mosquito transmits malaria from one person to another; the second was that the *Stegomyra fasiata* mosquito carries Yellow fever.

1920 CE Licensed radio broadcasts on a regular basis began in the United States.

1920 CE **Andrew Elliot Douglass** (1867–1962, USA). Astronomer, father of *dendrochronology* — a technique for dating objects based on the characteristic growth rings of trees in their given region.

Douglas was born in Windsor, Vermont. After research work at the Lowell Observatory at Flagstaff, Arizona, he became professor of Physics and Astronomy at Arizona University (1906) and later Director of the Stewart Observatory (1918–1938). He investigated the relationship between sunspots and climate by examining and measuring the annual growth-rings of long lived Arizona pines and sequoias; he noted that the variations in their width correspond to the specific climatic cycles, creating patterns which can be discerned in timbers from prehistoric archaeological sites providing a time-sequence for dating purposes. He coined the term '*dendrochronology*' (tree-dating).

1920–1940 CE **Thoralf Albert Skolem** (1887–1963, Norway). Mathematician. Did important work in Diophantine equations and helped to provide the axiomatic foundation for set theory in logic. Before such subjects as model theory, recursive function theory, and axiomatic set theory had become separate branches of mathematics, he introduced a number of the fundamental notions that gave rise to them. Contributed also to Diophantine equations, group theory and lattice theory. Wrote 182 scientific papers, but they remained largely unread.

Skolem was born at Sandsvaer and educated at Oslo, where he became professor (1938). His main work was in the field of mathematical logic. He created what is now known as the *Löwenheim-Skolem theorem*, one consequence of which is *Skolem's Paradox*[462]. In this work, Skolem was ahead of his time. From 1933 he did pioneering work in *metalogic* and contributed a nonstandard model for arithmetic.

1920 CE CE **Quirino Majorana** (1871–1957, Italy). Physicist. Proposed a modification of Newton's inverse-square law, including a factor of shielding. The weak equivalence principle is violated in his model.

---

[462] If an axiomatic system (such as Ernst Zermelo's axiomatic set theory, which intends to generate arithmetic, including the natural numbers, as part of set theory) is consistent, then it must be satisfiable within a countable domain; but Georg Cantor had shown the existence of a never-ending sequence of transfinite powers in mathematics (that is, uncountability). Skolem resolved this paradox by saying that there is no complete axiomatization of mathematics: certain concept must be interpreted only relatively, i.e. they can have no 'absolute' meaning.

1920–1927 CE **William Draper Harkins** (1873–1951, U.S.A.). Nuclear chemist. Discovered *nuclear fusion*[463], the fundamental process underlying stellar luminosity and the thermonuclear bomb. Previously, in 1920, he proposed (independent of simultaneous notions by Rutherford) the existence of the *neutron*. He believed that the neutron could be formed from a proton and an electron. Chadwick's discovery of the neutron (1932) confirmed his prediction. He also predicted the existence of deuterium, and introduced the concept of *packing fraction*, a measure of energy involved in the association of protons and neutrons within the nucleus.

Utilizing Einstein's concept of the equivalence of mass and energy, he demonstrated that by combining four hydrogen atoms to produce one helium atom, a small amount of mass would be converted to energy; he correctly theorized that this process was a source of stellar energy. Harkins made one of the first attempts to calculate the abundance of elements in the universe.

Harkins was born in Titusville, PA. He received his Ph.D. from Stanford University (1908) and spent most of his career at the University of Chicago.

1920–1933 CE **Otto Stern** (1888–1969, Germany and USA). Physicist. Demonstrated clearly and directly the fundamental fact of the dual nature of matter, i.e. the wave-like vs. matter property of elementary particles, thus verifying the space-quantization theory of atoms. For that he was awarded the Nobel Prize in Physics (1943).

Stern was born in Sohrau, Germany to Jewish parents. He studied physical chemistry at Breslau University (Ph.D. 1912) and later held posts at the Universities of Prague (1912), Zurich (1913), Frankfurt (1914–1921), Rostock (1921–1923) and Hamburg (1923–1933). He worked in Prague and Zurich with **Albert Einstein**. With the rise of the Nazis, he moved to the USA and appointed Professor at the Carnegie Tech., Pittsburgh (1933–1945). Stern's main experimental results are:

---

463 Fusion takes place when light nuclei fuse to form a heavier nucleus, releasing energy in the process. Fusion reactions are often called *thermonuclear* reactions because they are endothermic and are ignited only at temperatures higher than 100 million degrees. The sun's energy comes, essentially, from the fusion of light hydrogen atoms to form a helium atom. The energy of the hydrogen bomb comes from the fusion of deuterium and tritium (two heavy isotopes of hydrogen) into helium. Efforts have been underway for decades to achieve sustained *controlled* fusion in suitable reactors, a process that may become an important new source of energy for commercial use.

• 1920–1: by projecting a beam of neutral silver atoms through a non-uniform magnetic field [Stern-Gerlach[464] apparatus] showed that two distinct beams could be produced[465]. this provided proof of the quantum theory prediction that atoms possessing a magnetic moment could be oriented in two fixed directions to the external magnetic field [atoms and molecules behave like tiny magnets on account of the electric charges of the proton and the electron].

• 1933: Using molecular beams he measured the magnetic moment of the *proton* and *deuteron* and demonstrated that the proton's magnetic moment was 2.5 times greater than predicted by **P.A.M. Dirac**[466].

---

[464] **Walther Gerlach** (1899–1979, Germany).

[465] Since Bohr arrived at the appropriate energy levels for the hydrogen atom by postulating that *angular momentum* is quantized, it is reasonable to expect that in quantum mechanics *other quantities than energy might be subjected to quantum conditions*: A beam of neutral atoms is passed through an evacuated region between two specially designed magnetic pole faces which set up a strongly inhomogeneous field *transverse to the beam*. The field exerts a deflecting force on the magnetic-dipole moment $\boldsymbol{\mu}$ of each of the moving atoms of magnitude $F_z = \mu_z \frac{\partial B_z}{\partial z}$, where μ_z is the component of $\boldsymbol{\mu}$ along the *field-gradient* direction. Classically, the random orientations of the dipole moments should be expected to render *spreading* of the beam i.e a continuous range of deflections on either side of the original beam. Stern and Gerlach observed, however, a *splitting* of the beam into *two discrete components*, indicating the existence of *only two possible values for* μ_z. Now, according to quantum theory, spatial quantization requires the vectors to adopt only certain angles of orientation and the components μ_z must all be multiple of the *Bohr magneton*. Accordingly, the beam should split into $(2n+1)$ different beams, each one corresponding to a certain value of the magnetic quantum number m_n, where $\mu_z = m_n \mu_B$ with $\mu_B = \frac{e\hbar}{2m}$. The results of the experiment show that $n = \frac{1}{2}$. Since the experiment was done four years before the *intrinsic spin* angular momentum of the electron was suggested, the Stern-Gerlach experiment indicates that while the principal quantum number n fixes the energy levels in hydrogen-like atoms, it does *not* determine the angular momentum of individual electrons. In due course this result led to the recognition of the *electron spin* as an extra angular momentum variable, with an associated magnetic moment.
In hindsight we say that the since the Ag atom with its ground state ${}^2s_{\frac{1}{2}}$ has a total angular momentum $J = \frac{1}{2}$, the only possible orientations in the magnetic field are $M = \pm\frac{1}{2}$, i.e. $M = +\frac{1}{2}$ for one beam and $M = -\frac{1}{2}$ for the other.

[466] No existing theory of the proton is able to account for this discrepancy. However, physicists believe that it arises because the proton is, unlike the electron, not

The Ice-Age Mystery[467] *(1787–1987)*

"Great clocks of eternity beat ages as ours beat seconds".

Anon

The present is the key to the past, but there have been many strange meteorological situations for which we have no present parallel to guide us. Moreover, the meteorology of the present has yet to solve many problems of its own, and we are even encouraged to hope that the meteorology of the past may at times help in the study of the present. The theory of the circulation of the earth's atmosphere, for instance, is not yet complete; and it may be that data on modifications of the circulation during the varied climatic history of the globe, as deduced from past distributions of rainfall and temperature, will provide just the additional information required for a solution.

---

a point particle obeying the Dirac equation, but rather a composite, made up of 3 valence quarks, in addition to a so-called 'sea' of quark-antiquark pairs and gluons, as described by modern QCD (1964). The theory, however, is able to explain the observed *ratio* of the magnetic moments of the proton and the neutron, namely $\mu_P/\mu_N = 2.79/(-1.91) \approx -\frac{3}{2}$.

Victor Weisskopf told the following story: There was a seminar held by the theoretical group at Göttingen in 1920, and Otto Stern gave a talk on the measurements he was about to finish of the magnetic moment of the proton. He explained his apparatus, but did not tell us the result. He took a piece of paper and went to each of us, saying, "What is your prediction of the magnetic moment of the proton?" Every theoretical physicist from Max Born down to Victor Weisskopf said, "Well, of course the great thing about the Dirac equation is that it predicts a magnetic moment of one Bohr magneton for a particle of spin one-half." Then he asked us to write down the predictions; everyone wrote "one magneton." Then, two months later, he came again to give a talk about the finished experiment, which showed that the value was 2.5. He projected the paper with our predictions on the screen. It was a sobering experience.

Swiss naturalists, who lived and worked in the mountains, had long been coming into daily contact with evidence of an extensive past glaciation. As early as 1787, **Bernard Friedrich Kuhn** *(1762–1825, Switzerland), a Swiss minister, concluded that the Grindelwald glacier had been more extensive at some time in the past. In 1794,* **James Hutton** *(1726–1797) visited the Jura and reached the same conclusions, namely: that erratic boulders far downstream from current glaciers suggested the former existence of more extensive glaciation. In 1815,* **Jean Pierre Perraudin** *(1767–1858, Switzerland), a mountaineer and guide in the Swiss Alps, conjectured that Alpine glaciers formerly extended well beyond their present limits. In* 1829 *he announced to the Swiss Society of Natural Sciences his thesis that the glaciers of the Alps once covered the Jura Mountains and extended northward beyond the mountains into the plains. These and other early pioneers developed their ideas completely independently, through personal observation and deduction. On the other hand, until the* 18^{th} *century, it was conventional to assume that the observed blanket of glacial sediments had been transported and deposited by the great flood described in the Bible!*

So deeply entrenched was this accepted explanation, that none of these men was able to make their revolutionary ideas widely known. It would demand the combined efforts of some of the greatest scientific minds of the age, over a period of 25 *years, to overthrow the established "theory". It is not surprising that in such a religious age scientists and laymen alike believed that the local boulders had been transported by unimaginably huge currents of water and mud deriving from the biblical deluge of Noah's time.*

In 1834, **Johann (Jean) von Charpentier** *(1786–1855, Germany), in a talk before the Swiss Society of Natural Sciences, outlined evidence supporting the claims that Alpine glaciers have extended to lower elevations in the past. In* 1836 *he convinced* **Louis Agassiz** *(1807–1873, Switzerland and U.S.A.) that many features in the currently unglaciated landscape were formed in the past by glaciers. Once convinced, Agassiz assimilated the evidence, developed a broader-scale theory, and moved toward publication and vigorous advocation of the theory.*

In 1837*, Agassiz announced his theory of a Great Ice Age*[468] *at a meeting of the aforementioned society in Neuchatel. So it was that glacial theory — born from observations of amateur scientists, developed by* **Ignace Venetz** *(1788–1859, Switzerland, 1829–1836), and systematized by* **Charpentier** *— at last found a forceful spokesman in the person of Louis Agassiz. By* 1840*,*

[468] Defined as a period in the earth's history during which ice sheets covered large regions of land. The name *Eiszeit* was coined by **Karl Schimper** (1803–1867, Germany), in 1836.

Agassiz was able to convert the British geologists **William Buckland** *(1784–1856) and* **Charles Lyell** *(1797–1875) to his ice-age theory, and by* 1860*, most European geologists were on his side.*

Why did this theory, whose validity now seems self-evident, encounter so much resistance? In part, its slow acceptance may be attributed to natural resistance to new ideas — particularly if those ideas run counter to long-held scientific principles or to religious convictions. The Agassiz theory challenged both biblical dogma and scientific orthodoxy.

Once science was persuaded that an age of ice had occurred in the past, there began a period of intensive search for clues that would enable geologists to deduce details of what happened thousands of years earlier. It seemed that Agassiz had chosen an opportune moment in history to propose his theory. For in the prosperous years of Queen Victoria's reign, the wealth generated by the industrial revolution and the resources of a far-flung empire made possible the organization of geological expeditions to the farthest corners of the earth.

Victorian geologists had both theoretical and practical motives for searching so persistently for evidence about the ice-age world. There was, of course, a natural desire to fill in the pieces of the puzzle with which Agassiz had presented them, but economics *provided an additional motive: In every civilized country, geological surveys were organized to assess the potential economic value of little-known regions. (Nowhere is this better illustrated than in the United States where, in the years following the Civil War, the West was explored and mapped by geologists on horseback. To carry on this work, the U.S. Geological Survey was created by act of Congress in 1879.)*

Victorian geologists were surprised to find that the great ice sheets in the Northern Hemisphere had a northern, as well, as southern a boundary. Thus, Agassiz' idea that a single ice sheet had spread out to cover most of the Northern Hemisphere from a center at the North Pole, was found to be incorrect. In fact, individual ice sheets had expanded from different spreading centers.

Calculations showed that continental ice sheets in the Northern Hemisphere were about 1.5 *km thick. Worldwide lowering of sea levels caused shorelines to move downwards by about* 110 *m. By* 1875 *geologists had completed their initial survey of what the world of the last ice age was like. They had mapped its glaciers, measured its sea level, and determined which areas had been cold and wet, which cold and dry. They had also discovered that the ice age was* not *a unique event — that, in fact, there had been a succession of ice ages, each separated by warmer,* interglacial *ages similar to the present one. Armed with these observations geologists were ready to turn their attention from facts to theories.*

Since instrumental records of climatic elements go back only a couple of centuries (at best), how do scientists study climates and climatic changes prior to that time?

They must reconstruct past climates from indirect evidence, i.e., they must examine and analyze accessible records of phenomena that respond to and reflect changing atmospheric conditions.

Today the hippopotamus is confined to the tropics of East Africa, but $100,000$ *years ago herds of these giant mammals lived far to the north, in present-day England. The plant* Armeria sibirica*, found today only in the Arctic tundra of northern Canada, grew in southeastern Massachusetts* $12,000$ *years ago; clearly, England must have been more tropical, and Massachusetts must have resembled Arctic Canada during those respective epochs.*

The fossilized remains *of animal and plant life as those just cited, provide important clues from which inferences are made about the duration and geographic extent of climatic conditions in the geologic past. However, since fossil evidence is meager or nonexistent in the geologic record prior to about* 550×10^6 *years ago (the so-called* pre–Cambrian explosion *of new life–forms), the very history of our planet, from its formation* 4.6×10^9 *years ago until the start of the Paleozoic era, is not sufficiently well known to determine these most ancient climatic changes.*

In addition to fossils, other types of geological *evidence yield indications of past climatic conditions:* coral reef *terraces in New Guinea,* glacial features *in Africa,* solidified sand dune *outcroppings in humid regions, and countless other examples have been made available to climatology from the science of geology. Much of this evidence provides us with only a* broad and generalized picture *of past climatic changes on the scale of thousands to millions of years.*

Among the most interesting and important techniques for analyzing the climatic history on earth on time scales of 100*'s to* 1000*'s of years, are the study of* ocean floor sediments *and* oxygen isotope analysis*.*

Although seafloor sediments are of many types, most contain the remains of organisms that once lived near the sea surface (the ocean-atmosphere interface). When such near-surface organisms die, their shells slowly settle to the floor of the ocean where they become part of the sedimentary record. Working on the basic assumption that changes in climate in the ocean/atmosphere interface (i.e., temperature equilibrium between surface seawater and the air above it) should be reflected in changes in organisms living near the surface of the deep sea leads us to the notion that the temperature sensitivity of the shell organisms found in the sediments is somehow connected to climatic changes on earth.

The second technique, oxygen isotope analysis, is based on a precise measurement of the ratio between two isotopes of oxygen — ^{16}O *(which is the most common), and the heavier* ^{18}O*. Since the lighter isotope* ^{16}O *evaporates more readily from the oceans, precipitation (and hence the glacial ice that it may form) is enriched in* ^{16}O*. Of course, this leaves a greater concentration of the heavier isotope,* ^{18}O*, in the ocean water. Thus, during periods when glaciers are extensive, the concentration of* ^{18}O *in seawater increases. Conversely, during the warmer interglacial periods, when the amount of glacial ice drops dramatically, the ratio* $\{^{18}O/^{16}O\}$ *in ocean water also drops. As certain microorganisms secrete their shells of* $CaCO_3$ *which later settle in seafloor sedimentary layers, the prevailing* $\{^{18}O/^{16}O\}$ *ratio at the epochs in which the organisms lived and metabolized, can be inferred from the isotope ratios of corresponding layers. Consequently, periods of glacial activity can be determined from variations in* $\{^{18}O/^{16}O\}$ *found in the shells of microorganisms buried in deep sea sediments.*

A second use of the $\{^{18}O/^{16}O\}$ *ratio technique is applied to the study of cores taken from ice sheets, such as the one that covers Greenland. In this application another cause for variation of the oxygen isotope ratio is used, namely its temperature dependence; more* ^{18}O *is evaporated from the oceans when the temperatures are high and less is evaporated when temperatures are low. Thus, the heavy isotope is more abundant in the precipitation of warm eras and less abundant during colder periods. Using this principle, scientists studying the layers of ice and snow in Greenland have been able to produce a record of past temperature changes*[469].

---

[469] Since the 1980's several studies of ice cores drilled from thick glaciers in Greenland and Antarctica have offered evidence of a correlation between CO_2 and global climate. Those cores showed that CO_2 levels in the atmosphere were much lower during ice ages than during comparatively warm periods such as the present. The finding has amplified concerns regarding the allegedly ominous implications of the large quantities of CO_2 that humans continue to dump into the air. However, in 1993, the ice core data on atmospheric CO_2 have come under assault: an alternative method of extracting air from a 35,000-year-old ice sheet from the Greenland ice sample yielded 250 ppm of CO_2, only slightly below the modern but preindustrial levels of about 270 ppm. This indicates that the relation between CO_2 and ice ages is still far from clear.

Studies of ice cores also revealed that the *temperatures* recorded in the Greenland ice cores *fluctuated rapidly* during the last ice age, warming and cooling over the course of a decade or less. These short-term climate fluctuations may result from changes in atmospheric circulation patterns, which in turn may result from *variations in the brightness of the sun.*

The theories that have been proposed to explain climatic changes are many and varied. Four of the leading theories, unrelated to human activities, include changes brought about by: continental drift, volcanic activity, fluctuations in solar output and changes in the earth's orbital elements. No single theory explains climatic change on all time scales; A theory that explains variations over millions of years, for example, is generally not satisfactory when dealing with fluctuations over a span of mere hundreds of centuries.

It is now believed that during the geologic past, continental drift *accounted for many climatic changes as land masses shifted in relation to one another and moved to different latitudinal positions. Changes in oceanic circulation must also have occurred, altering the transport of heat and moisture, and consequently the climate as well.*

Since the rate of movement of the continent–carrying tectonic plates *is very slow (of the order of a few centimeters per year), appreciable changes in position of the continents occur only over great spans of geological time. Thus, climatic changes brought about by continental drift are extremely gradual and happen on a scale of millions of years. As a result, the theory of plate tectonics is not useful for explaining climatic variations that occur over periods less than, say, a million years.*

Some aspects of climatic variability can be explained by the volcanic dust theory: *Explosive volcanic eruptions emit great quantities of fine-grained debris into the atmosphere. Some of the biggest are sufficiently powerful to inject dust and ash into the stratosphere, where it is spread around the globe and where it may remain for several years. The basic premise of the volcanic dust theory is that this suspended volcanic material will filter out a portion of the incoming solar radiation which, in turn, will lead to lower air temperatures.*

For volcanic activity to have a pronounced impact, many great eruptions, closely spaced in time, would have to occur[470]*. (Episodes like the Krakatoa*

[470] About 50 to 100 major eruptions per century would be needed to maintain solar radiation levels at about 20 percent below normal. It has been calculated that the rate at which eruptions were occurring at the end of the last century was probably comparable with that during the last Ice Age. For example, many of the great volcanoes in the Andes seem to have been constructed wholly within the past few million years, but few of them show much evidence of activity *after* the end of the Ice Age — which lasted in all about a million years. Sediment cores obtained by the *Deep Sea Drilling Project* (1974) revealed evidence for a world-wide wave of volcanic activity during the period of the last Ice Age. However, there is always the possibility that an ice age could *cause* volcanic activity!

The eruption of Mt. Pinatubo in the Philippines on June 15–16, 1991 provided *event of Aug.* 27, 1883 *or the Mount St. Helens eruption of May* 18, 1980 *— do not count.) Since no such period of explosive volcanism is known to have occurred in historic times, the volcanic dust theory is most often mentioned as a possible cause for prehistoric climatic shifts, such as the Ice Ages.*

Although the analysis of deep-sea sediment cores indicated that there was a much higher rate of explosive volcanism during the past 2 *million years than during the previous* 18 *million years, the data is not sufficiently accurate to deal with glacial-interglacial episodes which require alternating periods of explosive volcanism. The* variable sun theory *is based on the idea that the sun is a variable star and that its output of energy varies through time. Unfortunately for the theory, no major variation in the total intensity of solar radiation has yet been measured outside the atmosphere, and each ground-based observation must be corrected for large atmospheric effects.*

Nevertheless some correlation has been established between climatic changes during the past 5000 *years and a certain aspect of solar activity, namely:* sunspot cycles[471]*. In 1890,* **Edward Walter Maunder** *(1851–1928, England), superintendent of the Royal Greenwich Observatory in London, after a search through old books and journals, discovered that during* 1645–1715*, sunspots and other solar activity had all but vanished from the sun (no induced aurora borealis activity and no coronal streamers). This meant that the sun was not the regular and predictable star as had previously been believed.*

---

definite evidence for the cooling of the earth's surface. The 20×10^6 tons of sulphur oxides that were ejected into the stratosphere caused dramatic climatic changes in the Middle East and Europe, manifesting itself through stormy winter and cooler summer in 1991–1992. The Pinatubo eruption affected also the *ozone layer*, through the emission of chlorine. Although volcanic eruptions tend to cool the earth, in contrast to greenhouse gases, Pinatubo is nonetheless providing critical data for climate models that seek to predict the effect of human induced changes.

Some mega-explosions of the past, however, dwarf the last century's eruptions. These biggest perturbations of climate really show what a large volcanic eruption can do. Eruptions of massive flood basalts, for example, seem to have been linked to mass extinctions of life. Huge asteroid impacts may also alter climate.

471 *Sunspots* — dark blemishes on the surface of the sun. Although their origin is uncertain, sunspots have been established to be huge magnetic storms that extend from the sun's surface deep into the interior. Further, these spots are associated with the sun's ejection of huge masses of particles which, upon reaching its upper atmosphere, interact with the gases there to produce auroral displays. Data since the early 1700's indicates an almost regular *cycle of 11 years* in annual number of sunspots.

The above sunspot-quiescence period is now known as the 'Maunder minimum'[472]. *This minimum corresponds very closely to the coldest portion of a 400-year interval known in climatic history as the 'Little Ice Age' (1450–1850 CE). It is a well-documented cold period that saw Alpine glaciers in Europe, Alaska and New Zealand advance farther than at any time since the last major glaciation* 15,000 *years ago*[473]. *There is a very powerful, modern technique that sheds further light upon this subject and enables us to extend the discussion to very ancient times.*

Radioactive ^{14}C *is continually formed in the upper atmosphere through the action of cosmic rays. When the sun is very active, its extended magnetic fields shield the earth from cosmic rays (beyond the shielding effect of earth's own field), with the result that very little* ^{14}C *is formed. When the sun is less active, as during the Maunder minimum, the reverse is true. It is fortunate that trees provide a record of the amount of* ^{14}C *in the atmosphere. By analyzing the wood in the annual growth rings of very old trees, the ratio of* ^{14}C *to the common stable isotope of carbon,* ^{12}C*, can be determined.*

From an analysis of ^{14}C *data over the past* 5000 *years it is found that there have been at least* 12 *solar excursions as prominent as the Maunder minimum; A search of old records of Alpine glacial advances and retreats correlates exactly with period of greater or lesser sunspot activity as determined from* ^{14}C *data. Therefore it appears that for the past* 5000 *years, all climatological curves rise and fall in response to the long-term level of solar activity.*

---

[472] In 1887, **Gustav Spörer** (Germany) noticed the sunspot-deficient period, and first brought it to the attention of Maunder. In 1977, J.A. Eddy *et al.* (*Scientific American* **236**, 80–92) compared old drawings of sunspots made by **Christoph Scheiner** in 1625–1626 with those made by **Johannes Hevelius** in 1642–1644, and concluded from these patterns that the rotation of the sun's equator speeded up (completing a rotation one full day faster than it had in 1625) just before the onset of the Maunder minimum! It is not known whether this was a cause or an effect of the Maunder minimum.

[473] Snow lay for months on the high mountains of Ethiopia (where it is now unknown). Global climate generally was 1 °C cooler than now. Colonists in New England endured winters far more severe than any today. The 17^{th} century Dutch grandmasters **Rembrandt van Rijn**, **Frans Hals**, and **Jan Vermeer** painted winter landscapes, which feature spectacular snowdrifts, *frozen canals*, and skaters everywhere. (The canals were built in the early 17^{th} century to link the Netherlands' biggest cities. During many winters in those days, the canals really were frozen and impassable, sometimes for as long as three months. Today, the canals of Holland rarely freeze over — yet the great painters did not lie.) The detailed books kept by French winemakers show that the abnormally cold period 1617–1650 were bad years for the wineries of Bordeaux.

In addition to solar variability, terrestrial climate could be affected by changes in earth's circumsolar orbit. ***Newton*** *(1687) worried that the behavior of the solar system (a many-body problem in celestial mechanics) is inherently unstable – and in order for it not to fly apart, he postulated that God might be obliged to step in every now and then to set things right.* ***Laplace****, however, proved (1773) in his treatise Mécanique Céleste that long-term stability of the solar system has "no need for that hypothesis". Laplace used perturbation theory (that he invented). It begins from planetary (planetary–moon) orbits that are precisely Keplerian, and then worked out the (assumed second–order) effects of perturbation – due to the gravitational effects or other planets and moons upon the exactly calculable,* $1^{st}-$*order orbits. In the case of the orbits of moons about their planets, the sun itself is viewed as one of the perturbing bodies.*

As late as 1820, ***William Buckland****, then an Oxford Professor of Mineralogy and Geology, wrote:*

> *[The objective of geology is] "to confirm the evidences of natural religion; and to show that the facts developed by it are consistent with the accounts of the creation and deluge recorded in the Mosaic writings."*

Yet in 1840 it was understood that one cause of climatic changes could be astronomy*. So when the existence of long-term changes of climate were discovered, it was natural to investigate whether they could be attributed to astronomical causes. Indeed, by the 1840s, astronomers had already shown that the orbit of the earth undergoes slow changes.*

It is not the same ellipse this year that it was last year. The orbit would be an unchanging ellipse, if the Sun were the only source of attraction[474]*. The main deviations come about because of the presence of the moon and other planets. Gravitational perturbations due to these objects means that the force on the earth is not a simple inverse square centered on the sun, and the natural result is that the orbit is not a simple repeating ellipse.*

However the effects of the planets are relatively small. Jupiter has 10^{-3} *of the mass of the sun, and it is, on average, about* 5 *times further away. Venus, although having a mass* 390 *times smaller than Jupiter, can come much closer, within* 0.28 *AU (where the Astronomical Unit, or AU, is the average earth-sun distance) vs.* 4.2 *AU for Jupiter. Since gravity varies as l/(distance squared) and tidal gradients vary as* $1/(\text{distance cubed})$*, the effect*

474 We ignore effects due to Einsteinian GTR, which are negligible for earth, and secular variations due to tidal forces which take billions of years to effect significant orbital changes.

of Venus is often more important than that of Jupiter. But all these effects are small enough that they can be treated as perturbations, small changes, to the classical elliptical orbit. A convenient consequence of this is that the earth's orbit is always approximately *an ellipse, and we can treat the perturbations of the planets as extra forces that gradually alter the parameters of that ellipse. For example, the major axis of earth's orbit slowly precesses (rotates) relative to the "fixed" stars. This effect is big enough that it was discovered experimentally in 120 BCE by the astronomer Hipparchos, who found differences between his own measurements and those of earlier Babylonian records.*

By 1749, ***Alexis Claude Clairaut*** *had shown, using Newton's laws, that the north pole of the earth precesses with a period of 25,800 years. So, for example, 13,000 years from now, the North Pole of earth will not be pointing towards the "North Star", but will be pointing in a direction close to the star Vega.*

This happens because the Sun and Moon exert a torque on the (spin–rotation caused) equatorial bulge of the Earth. This causes the axis of rotation of the Earth to wobble, an effect completely analogous to the wobble of a tilted top – spinning while supported on a table or pivot – under the torque exerted by terrestrial gravity.

This spin precession *causes a* precession of the equinoxes *– a gradual calendrical advance of the autumnal and vernal equinoxes, solstices and the seasons in general. This also implies that the signs of the zodiac change, or "advance". When astrology was defined, about two thousand years ago, a person born in January was said to be under the sign of Capricorn, since the sun was in the constellation Capricorn at that time of year. Since then, the precession of the axis of the earth has changed by* $2000/26000 = 1/13$ *of a cycle; this corresponds to a change by about one sign of the zodiac. This means that a person who is born in January any time in the last few hundred years, was born when the sun was actually in Sagittarius — not Capricorn. Nevertheless, following tradition, such a person is still said to be "born under the sign of Capricorn". The more educated astrologers are aware of this change (and, of course, claim that they compensate for it!).*

Another consequence of the Earth's precession, noted above, is that the celestial location of the sun at the spring equinox also changes. It is presently leaving the constellation Pisces and entering Aquarius. Astrologers say that this change could have a profound effect on our lives, and it is why they talk about the future (and sometimes the present; it depends on exactly where you draw the constellation boundaries) as "the Age of Aquarius".

The astronomical theory of climate variation is based on the idea that changes in the amount of solar energy received by the earth are caused by quasi-periodicities in the earth's orbital elements. These are[475]*:*

1. *Variations in the shape (eccentricity) of the earth's elliptic orbit about the sun, through a cycle of ca* 100,000 *years.*
2. *Changes in the season–controlling angle (obliquity) that the earth's elliptic axis of rotation makes with the plane of the ecliptic (plane of earth's orbit) during a cycle that averages about* 41,000 *years.*
3. *The slow axial precession of the earth's axis that takes place during a cycle of ca* 22,000 *years.*

This theory was originated by ***James Croll*** *(1864) and developed by* ***Milankovich*** *(1920). To establish the validity of the theory, the following questions must be addressed:*

- *Are the periodicities of the earth's orbital elements significantly reflected in the geological record?*
- *Is there a significant correlation between insolation curves (sunlight received at given latitude as a function of time) and geological data?*
- *Can these insolation changes be correlated with climatic changes?*

Although variations in the distance between the earth and sun are of minor significance in understanding current seasonal temperature fluctuations, they may play a very important role in producing global climatic changes on a time scale of tens of thousands years. A difference of only 3% exists between aphelion (∼July 4^{th}, in the middle of Northern Hemisphere summer), and perihelion (∼January 3^{rd}, in the middle of Northern Hemisphere winter).

This small difference in distance amounts to about 6% in excess solar energy. However, this is not always the case. The shape of the earth's orbit changes during a cycle that astronomers say takes between 90,000 *and* 100,000 *years: It stretches into a longer ellipse and returns to a more circular shape. When the orbit is very eccentric, the amount of radiation received at closest approach (perihelion) could be on the order of 20–30% greater than at*

[475] Apart from the just–discussed spin–axis precession, which shifts the seasons through the calendar. Both this and the ellipse – axis (perihelion) precession can vary the climate, since they both affect the synchronization of the interplay between earth's distance from the sun and the angle at which its rays fall.

aphelion. This would most certainly result in a substantially different climate from what we now have.

The theory predicts a change in obliquity (tilt of the rotation axis) that varies between $22.1\,^{\circ}$*–*$24.5\,^{\circ}$ *during a cycle of* $41,000$ *years (current value:* $23.5\,^{\circ}$*). The smaller the tilt, the smaller the temperature difference between winter and summer. It is believed that a* reduced seasonal contrast *(warmer winters, cooler summers) could promote the growth of ice sheets: since winters could be warmer, more snow would fall because the capacity of air to hold moisture increases with temperature. Conversely, summer temperatures would be cooler, meaning that less snow would melt. The result could be the growth of ice sheets.*

The combined equinoctial and elliptic–axis precessions eventually resulted (and will again in the future) in the Northern Hemisphere experiencing winter near aphelion and summer near perihelion. Thus, seasonal contrasts will be enhanced *in the future, because winters will be colder and summers will be warmer than at present.*

Using these factors, Milankovich calculated variations in insolation and the corresponding surface temperatures of the earth back into the past, in an attempt to correlate these changes with the climatic fluctuations of the Ice Ages. In explaining climatic changes that result from these orbital variations, it should be pointed out that they cause little or no variation in the total *annual amount of solar energy reaching the ground. Instead, their impact is felt because the same energy is redistributed in time and coordinates on the earth's surface, i.e., they change the degree of contrast between the seasons and the latitudes.*

Among studies that have added credibility and support to the astronomical theory is one in which deep-sea sediments were examined (1976). Through oxygen isotope analysis of certain climatically sensitive microorganisms, a chronology of temperature changes going back $450,000$ *years was established. This time – scale of climatic change was then compared to astronomical calculations of eccentricity, obliquity, and precession in order to determine if a correlation did indeed exist. It was found that major variations in climate over the past half a million years or so, were closely associated with changes in geometry of the earth's orbit.*

Clearly, any predictions based on these results cannot account for climatic changes over scales of tens to hundreds of years, because the cycles in the astronomical theory are too long for this purpose. Also, prediction apply only to the natural component of climatic change, since human influence when and if significant was ignored. In addition, the astronomical theory does not provide the full mechanisms *via which the climate is modified by the orbital* *variables – only the insolation changes, which are assumed to trigger these mechanisms.*

If the astronomical theory does indeed explain alternating glacial-interglacial periods, the question may arise as to why glaciers have been absent throughout most of the earth history. The advent of plate-tectonics can supply the answer: since glaciers can form only on the continents, land masses must exist somewhere in the higher latitudes before an ice age can commence. Long-term temperature fluctuations are not great enough to create widespread glacial conditions in the tropics. Consequently, ice ages have only occurred when the earth's shifting crustal plates have carried the continents from tropical latitudes to more poleward positions.

The results of all studies indicate that the earth may have undergone 6 *to* 20 *glaciations during the past* 2 *million years. A typical glaciation lasted about* 40–60 *thousand years, and a typical interglacial lasted about* 40,000 *years. The last ice retreat began less than* 20,000 *years ago. In North America, the main center was near Hudson Bay. Ice piled up from* 2400 *to* 3000 *meters thick. The pressure of its weight caused the ice to flow westward and southward. It spread over most of North America down to about the present valleys of the Missouri and Ohio rivers. In Europe, the Scandinavian Peninsula was the center of glaciation, and it flowed southeast about* 1300 *km, almost to Moscow. It also covered northern England, Denmark, and Germany. As the glaciers retreated, the low places they had scoured out filled up with water, forming lakes, such as the Great Lakes of North America.*

During the Ice Ages Europe was for long periods extensively connected to Africa, either across the Straits of Gibraltar or by way of the Italian peninsula via Sicily and Malta. Likewise North America was connected to Asia via the Bering Strait; when the icecaps pushed down from the North, they drove the animals southward. Then, during interglacial periods, the animals could follow the melting ice northward. The ancestors of today's horse and camel originated in North America, then crossed the Bering Strait millions of years ago and spread into Asia.

Putting together all the information gathered over the last two centuries on past climates, we have learned that changes of various durations occurred. The planet has gone through alternating periods of cold and warm climates. Some changes extended over millions of years, others over tens of thousands of years; others still over one or several centuries. The causes of these variations are diverse, and the processes that regulate them numerous. Sooner or later, earth will undergo another cold period that may last for thousands of years, but it is difficult to predict when.

At present[476]*, we have no absolute proof that human activities actually influence our climates. The human influence on climatic processes has perhaps been exaggerated, recent political fashions notwithstanding. Some scientists have estimated that termites release during their respiration as much* CO_2 *as all industrial activities combined! The human species may thus play only*

[476] Milankovitch concluded, somewhat prematurely, that the problem was completely solved.

But Milankovitch's theory was abandoned when precise age estimates, made possible by **Willard Libby**'s invention of radiocarbon dating, appeared to show that the timing of the ice ages were in conflict with Milankovitch's detailed calculations. In retrospect, this was not justified. The Milankovitch theory actually explains many of the phenomena that we now see in the data. Do we throw out the astronomical theory of the seasons, simply because the first day of Spring is not always Spring-like? The warm weather of Spring can be delayed by a month, or it can come early by a month; the important fact is that it always comes. With complex phenomena, it is sometimes too much to demand of a theory that it predict all the details in addition to the major behavior.

In fact, it was the observations of the regularity of the ice age cycles that led to the revival of the insolation theory. Scientists developed and promoted the use of isotopes to measure records of past changes in the earth. The technology for obtaining sea floor cores rapidly improved. In 1970, it was shown for the first time that the dominant variation in the ice ages was a repeating cycle of 100,000 years. This was a frequency that appeared in the insolation theory. The use of geomagnetic reversals in sea floor cores allowed a vastly improved time scale. In 1976, it was shown that the presence of both a 41,000 and 23,000 years cycle existed in the data derived from sea floor sediments. The same frequencies were dominant in spectral analysis of the insolation predicted by the theory. Even if the details of the theory were wrong, the presence of the same frequencies as those present in the orbits of the planets was a strong reason to revive the astronomical theory.

But the growing number of problems with the insolation theory is cause for serious concern. It may be the fact that insolation theory predicted the correct values of the frequencies that leads to its tenacity in holding the minds of paleoclimatologists. But there are alternatives now appearing. In 1993, it was discovered that there is another astronomical oscillation (orbital inclination) that could contribute to climate variation; it has a spectrum that is an excellent match to the narrow 100 kyr peak. The theory based on this does not have a causality problem. It does not predict a nonexistent 400 kyr peak, and it accounts in a natural way (no adjustable parameters) for the shift of frequencies that took place about one million years ago, when the dominant frequency of ice age oscillation changed from 41 kyr to the present value of 100 kyr.

a minor role in the history of climate. Furthermore, compared to natural catastrophes and variations, human activities are perhaps minor: our scientific knowledge and technological prowess do not allow us as yet to channel solar winds, to prevent volcanic eruptions, regulate the rotation of the earth, change the size of giant ice-caps, decimate the deserts encroaching upon our meadows, push back the oceans drowning our coastlines, ward off endless droughts or avert hurricanes and torrential rains.

To forecast the climates of coming centuries remains a difficult task because too many poorly known factors have to be dealt with: volcanic eruptions, increase of CO_2 in the atmosphere, jet stream and ocean currents, nebulousity, albedo, changes in polar ice cover, and human activities. Our forecasts therefore remain theoretical, and our working models vague. Much remains to be known before climatic forecasting can become an exact science.

1920–1929 CE **Otto Loewi** (1873–1961, Germany and USA) and **Henry Hallet Dale** (1875–1968, England) independently isolated *acetylcholine*, the substance released by the vagus nerve, thus providing evidence for chemical transmission of nerve impulses across the synapse[477]. Both focused their

[477] *The neuromuscular junction*: Each skeleton muscle fiber is connected to a fiber of a nerve cell. Such a nerve fiber is an extension of a *motor neuron* that passes outward from the brain or spinal cord. Usually a skeleton muscle fiber contracts only when it is stimulated by the action of a motor neuron. The site where the nerve fiber and the muscle meet is called a *neuromuscular junction*. At this junction the muscle fiber membrane is specialized to form a *motor end plate*. The end of the motor nerve fiber is branched, and the ends of these branches project into recesses (synaptic clefts) of the muscle fiber membrane. The cytoplasm at the ends of the nerve fibers is rich in mitochondria and contains many tiny vesicles that store chemicals called *neurotransmitters*. When a nerve impulse traveling from the brain or spinal cord reaches the end of a motor nerve fiber, some of the vesicle release a neurotransmitter into the gap between the nerve and the motor end plate. This action stimulates the muscle fiber to contract.

The *neurotransmitter* is a compound called *acetylcholine*, the general formula of which is

$$CH_3\text{—}\overset{\overset{\displaystyle O}{\|}}{C}\text{—}O\text{—}CH_2CH_2\text{—}N^+(CH_3)_3$$

This substance is synthesized in the cytoplasm at the distal end of the motor work on the physiology and pharmacology of chemicals occurring naturally in animals.

Loewi was born in Frankfurt to a Jewish family and educated at Strasbourg and Munich and appointed professor of pharmacology at Graz (1909–1938). He was forced to leave Nazi Germany (1938) and became research professor at New York University College of Medicine (1940–1961). He demonstrated (1920) the release of stimulating and inhibitory substance (acetylcholine) from terminal branches of nerve fibers. This discovery led to the concept of *nerve impulse transmission* across junctions by means of chemical mediators or neurotransmitters.

Dale was born in London and studied at Trinity College, Cambridge, qualifying in medicine from St. Bartholomew's Hospital (1902). He became director of National Institute for Medical Research, London (1928–1942). Identified *histamine* (1910); Isolated acetylcholine from biological material (1914) and later (1929) showed it to be produced at the ending of parasympathetic nerves. Both shared the Nobel Prize for Physiology or Medicine (1936).

1920–1947 CE **Emil Leon Post** (1897–1954, USA). Mathematical logician. Initiated the modern metamathematical method in logic. Obtained results similar to **Gödel**, **Turing** and **Church** in the 1920's but did not publish them. Modern proof theory, and likewise the modern theory of machine

---

neuron and stored in its vesicles. When a nerve impulse reaches the end of the nerve fiber (it travels at a speed of 91 $\frac{\text{m}}{\text{sec}}$ in man's largest nerves and at a speed of 0.5–1.8 $\frac{\text{m}}{\text{sec}}$ in the smaller fibers of the autonomic nervous system), many of these vesicles discharge their acetylcholine into the gap between the nerve fiber and the motor end plate. The acetylcholine diffuses rapidly across the gap ($\sim 10^{-3}$ sec), combines with certain molecules (receptors) in the muscle fiber membrane, and thus stimulates the membrane. As a result of this stimulus, a *muscle impulse* (action potential), very much like a nerve impulse, passes in all directions over the surface of the muscle fiber membrane and deep into the fiber. In response to the muscle impulse, the membrane becomes more permeable to calcium ions (which are present there). This motion of Calcium ions within the muscle membrane cause, in turn, to the muscle contraction. Due to this very contraction, the calcium concentration is lowered, and within a fraction of a second the muscle fiber relaxes. Meanwhile, the acetylcholine that stimulates the muscle fiber in the first place is rapidly decomposed by the action of an enzyme called *cholinesterase*, which is present at the neuromuscular junction within the membrane of the motor end plate. This action prevents a single nerve impulse from causing a continued stimulation of the muscle fiber. The energy used in muscle fiber contraction comes from ATP molecules, which are supplied by numerous mitochondria positioned within the myofibriles.

computation, hinge on the concept of the *recursive function*. This important number-theoretic concept was discovered independently by four mathematicians, and one of these was Post. Subsequent work by Post was instrumental to the further progress of the theory of recursive functions.

Post was born in Augustow, Poland to Jewish parents. He arrived in New York City (1904), and lived there for the remainder of his life. His life was plagued by tragic problems: he lost his left arm while still a child and was troubled as an adult by recurring episodes of disabling mental illness.

While still an undergraduate at City College, he worked out (1917) a generalization of the differential calculus which later turned out to be of practical importance. In his doctoral dissertation at Columbia University (1920) he proved the *consistency of the propositional calculus* described in Whitehead and Russell's 'Principia Mathematica'. His work marks the beginning of *proof theory*. His researches while a postdoctoral fellow at Princeton (1921–1923) anticipated later work by Gödel and Turing, but remained unpublished until much later, partly because of the lack of a receptive atmosphere for such work at the time. In 1924 Post went to Cornell. Because of recurring bouts of his illness he resumed work as a high school teacher in New York (1929), but in 1935 was appointed a professor of mathematics at City College NY and remained there until his death. In 1936 he proposed what is now known as a *Post machine*, a kind of automaton which predates the notion of a program which von Neumann studied in 1946. Post showed (1947) that the word problem for semigroups was recursive insolvable, a problem posed by Thue in 1914.

His work in computability theory includes the independent discovery of Turing's analysis of the computation process, various important unsolvability results, and the first investigations into degree of unsolvability, which provide a classification of unsolvable problems. He died quite unexpectedly while under medical care.

1920–1951 CE **James Waddell Alexander** (1888–1971, USA). Mathematician. Contributed to algebraic topology. Began his research career by putting the ideas of **Poincare** on a more rigorous foundations. In collaboration with **Veblen** he showed (1920) that topology of manifolds could be extended to polyhedra and that the homology of a simplicial complex is a *topological invariant*. Around that time he also made fundamental contributions to the theory of algebraic surfaces and to the study of *Cremona transformations*.

In his work on the *Jordan-Brower separation theorem* he discovered his *Alexander Duality Theorem* and *Alexander's lemma on the* $n-sphere$. In 1924 he introduced the *Alexander horned space*. In 1928 he discovered the

Alexander polynomial which is much used today in *knot theory* and opened the field of *combinatorial theory of complexes*. In 1935 he discovered *Cohomology theory* (independently discovered by Kolmogorov in 1936).

Alexander was born in Sea Bright, New Jersey. Educated at the universities of *Princeton* (B.S. 1910, M.S. 1911, Ph.D. 1915), *Paris* and *Bologna*. He spent most of his academic career as a member of the Institute for Advanced Study in Princeton (1933–1951). He had become a millionaire through inherited wealth and never drew a salary from the Institute.

1920–1965 CE **Solomon Lefschetz** (1884–1972, USA). Mathematician. Made major contributions to the theories of algebraic topology, differential equations and the stability of nonlinear control systems. Lefschetz had widened the use of topological methods in algebraic geometry as well as in differential equations, and consolidated the use of algebraic methods in topology.

Lefschetz was born in Moscow to Jewish parents. He studied engineering in Paris but later turned to mathematics[478]. He took his doctorate and taught at Kansas University, USA (1913–1925), where he soon made a reputation by his work in algebraic topology. In 1925 he moved to Princeton where he remained until his retirement (1953), when he became a visiting professor at Brown University. Lefschetz was the leading topologist of his generation in the USA and an important theorem on the existence of *fixed points* of mapping bears his name.

His work during WWII roused his interest in differential equations, and he continued to work on their *qualitative theory*. In his 80's he worked on the topology of Feynman Integrals.

1921 CE Development of the *teleprinter* greatly speeded the transmission of long-distance information.

1921–1923 CE **Arthur Holly Compton** (1892–1962, U.S.A.). Physicist. One of the pioneers of high-energy physics. Discovered the '*Compton effect*' through which a high energy photon is scattered by an electron. The electron, initially stationary, recoils with some energy, and the scattered photon, initially with energy $h\nu_0$, is left with a smaller energy $h\nu$, which varies with angle θ. The ensuing change in the photon's wavelength is $\Delta\lambda = \frac{\hbar}{m_0 c}(1 - \cos\theta)$,

---

478 He had the misfortune to lose both his hands in a laboratory accident (1910). This mishap was fortunate for mathematics for at the age of 36 Lefschetz went to the USA and turned to mathematics. He had two artificial hands over which he always wore shiny black gloves. First thing every morning, a graduate student had to push a piece of chalk into his hand and remove it at the end of the day.

where $\frac{\hbar}{m_0 c} = 0.024\ \mathring{A}$ is the electron's *Compton wavelength*. This effect was detected by Compton experimentally, using X-rays scattered from carbon with a Bragg spectrometer (1923). The agreement between theory and experiment indicates that the STR energy-momentum formulation is correct.

The Compton effect has also been detected with protons as the scattering particles. The *probability* of occurrence of the Compton effect (including the probability distribution of the scattering angle θ) must be calculated with the aid of *quantum mechanics*, which was developed in the years immediately after Compton's discovery. In 1921 Compton *speculated* that "the electron is spinning like a tiny gyroscope".

During 1913–1915 Compton devised (at Princeton) an elegant method providing a nonastronomical measurement of latitude and an additional experimental proof of the earth's rotation[479].

Compton was born at Wooster, Ohio, the son of Elias Compton, Professor of Philosophy and Dean of the College of Wooster. He was educated at the college graduating B.Sc. (1913) and spent three years in postgraduate study at Princeton University; M.A (1914); Ph.D. (1916). Professor of Physics at Washington University, St. Louis (1920); University of Chicago (1923); Washington University (1945–1961).

He won the Nobel prize for physics in 1927.

1921–1924 CE **Pavel Samuilovich Uryson** (1898–1924, Russia). Mathematician. Creator of theories of abstract topology that influenced the subsequent development of this field[480]. His main results are the introduction and investigation of a class of so-called *normal spaces*, and metrization theorems, including a theorem on the existence of a topological mapping of any normed space with a countable base into a Hilbert space. The principal tool used in all the recent investigations of normed spaces is the classical *Uryson's Lemma*[481]. In his theory, Uryson presented an inductive definition of *dimensionality* (1921–1922).

---

[479] A.H. Compton, 1913; "A Laboratory Method of Demonstrating the Earth's Rotation", *Science*, 37: 803–806; "A Determination of Latitude, Azimuth, and the Length of the Day Independent of Astronomical Observations", *Phys. Rev.*, 2, 5: 109–117. 1915.

[480] In particular, by **Andrei N. Tikhonov** (1906–1993) and **Juliusz P. Schauder** (1899–1943).

[481] *Uryson's Lemma*: Given two disjoint closed sets in a normal (T_4) topological space, there exists a continuous real-valued function that is 0 on one of the sets and 1 on the other.

Uryson was born in Odessa to Jewish parents. He was educated at the University of Moscow (1915–1919) and in 1921 became an assistant professor there. The reports he delivered at the Mathematical Society of Göttingen in 1923 attracted the attention of Hilbert, and in the summer of 1924, while touring Germany, Holland and France, he met L.E.J. Brouwer and Felix Hausdorff, who praised his works highly. Uryson drowned off the coast of Brittany (*Batz-sur-Mer*, a small town on the Atlantic Ocean) at the age of 26, while on vacation.

Interaction of Radiation with Matter (1860–1921)

One of the greatest achievements of 19^{th} *century physics was the electromagnetic theory of radiation, formulated by* ***Maxwell*** *in the early 1860's. Not only did this theory put physical optics on an entirely new basis, but it suggested a means by which radiation can act and be acted upon by atoms, namely, through the interactions of electric and magnetic fields with charged particles forming part of the atomic structure. The growing body of evidence concerning the existence of such particles led in due course to the classical electron theory of* ***Lorentz****, in which the classical interactions of electrons with the electromagnetic field were fully developed. This theory was able to account for many observed phenomena like dispersion, scattering, and the* ***Zeeman*** *effect.*

However, a detailed theory of atomic interactions must aim to explain the vast amount of spectroscopic data concerning spectral lines emitted by the atoms of different elements. The work of ***Balmer****,* ***Rydberg***[482]*, and others showed that hydrogen and the alkali metals emit discrete spectral lines which form distinct series, but all attempts to account for these series by classical methods failed. It became clear that light possesses certain properties which are not embodied in the electromagnetic theory, despite the successes of that theory in the realms of radio propagation and physical optics.*

[482] **Johannes Robert Rydberg** (1854–1919, Sweden). Physicist. Discovered (1890) the *Rydberg constant*, a spectral parameter that appears in Bohr's atomic theory (1913).

The new properties of radiation were realized in a different context by ***Planck*** *in 1900. His studies of the continuous "blackbody" radiation convinced him that the equipartition theorem of classical statistical mechanics cannot apply to an assembly of electromagnetic waves in an enclosure, and he boldly introduced the quantum hypothesis, according to which radiant energy is emitted and absorbed only in discrete amounts. The provisional quantum theory accounted for the blackbody energy distribution, and was successfully applied by* ***Einstein*** *to the photoelectric effect in metals and the specific heats of solids. Not only did the new theory explain thermal phenomena in which equipartition breaks down, but it also provided the essential clue toward solving the problem of the interaction between atoms and radiation.*

The discovery of X-rays by ***Röntgen*** *in 1895 stimulated research in many fields, but the electromagnetic character of the rays was not established for several years. Indeed, the development of quantum theory raised profound questions concerning the nature of radiation in general.*

As early as 1910 ***W.H. Bragg*** *pointed out that X-rays probably partake in the nature of both electromagnetic waves and corpuscles possessing definite energy and momentum. On the one hand, experiments on polarization and diffraction phenomena demonstrated the wavelike behavior of X-rays; on the other hand, studies of the photoelectric and* ***Compton*** *effects revealed properties similar to those of particles. The introduction of quantum theory therefore meant that models based on Maxwell's theory are incomplete in the realm of optics — a fully developed theory must include within its formalism both the wave and corpuscular aspects of radiation.*

1921–1926 CE **Max Born** (1882–1970, Germany). Distinguished physicist. Gave the probabilistic and statistical interpretation to quantum (*wave*, *matrix*) mechanics. He was first to recognize that the square of the modulus of the complex Schrödinger wave-function can be interpreted as a statistical distribution which describes the behavior of a single subatomic particle in space and time.

The time-independent form of Schrödinger's wave equation in three dimensions is

$$\nabla^2\psi + \frac{8\pi^2 m}{h^2}\left[E - U(\boldsymbol{r})\right]\psi = 0.$$

Here h is Planck's constant, m is the mass of the particle, E is the energy level (discrete or continuous), $U(\boldsymbol{r})$ the potential energy and ψ the wave-function[483]. Although this formalism is successful in determining energy levels in atomic systems, there remains the question of the significance to be attached to the function $\psi(\boldsymbol{r})$. For bound states, or for free (near-continuum) states in a large but finite box, a physically meaningful solution is achieved only when $\psi(\boldsymbol{r})$ is square-integrable over the entire space. Each such solution is a *state function* describing the state of the atomic system. This complex function – also known as a *probability amplitude* – is related to the probability density for a particle being detected at any chosen point, when the system is in the appropriate state.

Born's interpretation of the state function is that the *square* of its modulus at any point,

$$|\psi(\boldsymbol{r})|^2 = \psi^*(\boldsymbol{r})\psi(\boldsymbol{r}) \qquad [* \ = \ \textit{complex conjugate}],$$

is the *probability density function*, that is, the probability per unit volume of the particle being at the point $\boldsymbol{r}$. This principle enables us to impose a normalization condition for the particle, since the total probability is unity if we integrate over all space

$$\int \psi^*(\boldsymbol{r})\psi(\boldsymbol{r})d^3r = 1.$$

This interpretation extends to a time-dependent probability distribution, over space and internal degrees of freedom, for a particle (or system of particles) in a non-stationary state, that is, a superposition of different eigenvectors. The spatial *Fourier transform* of the wave function $\Psi(\boldsymbol{r}, t)$ is yet another kind of probability amplitude; its modulus-squared is the probability density function for values of the particle's *momentum* vector, when measured at time t.

Born's interpretation served to emphasize that a particle cannot in general be precisely located, especially when it is in a well-defined energy state (Heisenberg's *uncertainty principle*). The motion of particles follows probability laws, but probability amplitudes themselves propagate in conformity

---

483 A value of E for which mathematically well-behaved solutions ψ exist, is an *eigenvalue* of the Hamiltonian operator $H = -\frac{\hbar^2}{2m}\nabla^2 + U$ ($\hbar = h/2\pi$ being the reduced Planck constant), and ψ is then the corresponding *eigenvector* (in the sense of functional vector-spaces) or eigenfunction for that energy level. ψ may be an undulatory wave spread over all space (for E in the *continuum* — e.g. for an ionized electron), or a localized wave ('bound state' — e.g. an electron occupying an orbital in an atom).

For *bound* states, E takes discrete values and $E_{\min}$ corresponds to the '*ground state*'; for *continuum* states, E ranges freely over some interval $E_c < E < \infty$.

with the laws of causality. When the particle is free (a 'continuum state'), an initially-localized state function spreads with time over the entire accessible volume. The degree of spread depends, in general, on the mass of the particle, and is greatest for small values of the mass, since the particle's (de Broglie) wavelength is inversely proportional to the momentum[484].

One result of this general principle is that electrons cannot be completely localized by any method inside an atom without completely destroying its original energy state (orbital). On the other hand, atoms themselves are much more massive than electrons and can be located with fair precision in most physical situations, for example, by X-rays in crystal analysis, or individually using tunneling microscopes. Macroscopic or even mesoscopic or nanoscopic objects (DNA nucleotides, Buckeyballs, quantum wires, protein molecules, viruses, cells, magnetic domains, colloidal particles, etc.) possess very short de Broglie wavelengths, so a classical description of the motion of such objects is accurate enough for all ordinary purposes.

Born arrived at his interpretation by analogy with *optics*, where the calculated *intensity* of the light at a given place is taken as a measure of the *probability* of finding a *photon* at that place. He suggested a similar probability interpretation of *matter waves*.

He also introduced a useful technique, known as the *Born approximation*[485], for solving scattering problems in quantum mechanics by perturbations.

Throughout his life Born was a quick and prolific writer, publishing more than 300 scientific papers, about 31 books, as well as numerous articles on nonscientific topics. He had an encyclopedic knowledge of physics and whatever problem one brought to him, he was able to offer a useful insight or suggest a pertinent reference.

Born was born in Breslau[486], Germany, where his father Gustav Jacob Born was a professor of anatomy.

---

484 More generally, one may *superpose* many states (continuum and/or bound) to form localized *wave packets*; the higher the mass, the slower the spread of the packet, and the more accurate it becomes to treat the wave packet as a classical particle.

485 Although Born wrote the basic paper on the subject, he was rather irritated when the *Born approximation* was mentioned. He once said to his collaborator Emil Wolf: "*I developed in that paper the whole perturbation expansion for the scattered field, valid for all orders, yet I am only given credit for the first term in the series*"!

486 *Wroclaw* (Breslau); a city on the Oder River. Founded around 1000 CE. Early in the 11th century it was made the seat of a bishop and its cathedral dates

He became professor of theoretical physics at Göttingen in 1921. Although he had dissociated himself publicly from the Jewish community (baptized, 1913), he was not spared by the Nazis and was ejected from Göttingen in 1933 because of his Jewish origin. He settled in England, lecturing on applied mathematics at Edinburgh University[487] (1936–1953). On his retirement in 1953, he returned to Göttingen and remained there. He shared the Nobel prize for physics in 1954.

Unlike **Einstein**, Born was not proud of his Jewish heritage and did not draw the necessary conclusions from the Nazi holocaust. The establishment of the state of Israel (1948) meant nothing to him, and he never bothered to visit it. He rushed, however, back to Germany at the first opportunity and died in his 'Fatherland'.

1921–1933 CE **Alfred (Habdank Skarbek) Korzybski** (1879–1950, Poland and USA). Scholar and philosopher of language. Originator of a system of *linguistic philosophy* and expression based on man's "time-binding capacity" to transmit ideas from generation to generation. Highly eclectic and in some respects eccentric thinker who nevertheless had considerable influence. He linked a wide range of social, psychological, intellectual and even

---

from the 1100's. After having formed part of Poland, it became the capital of an independent duchy (1163). Destroyed by the Mongols (1241) but soon recovered its former prosperity and received a large influx of Germans. When Henry VI, the last duke of Breslau, died (1335), it was bought by John, king of Bohemia, whose successors retained it until 1460. Austria took over the city (1526) and Prussia seized it in 1741. It was, however recovered by the Austrians (1757) but regained by Frederick the Great in the same year. The French took over (1807) after the battle of Jena, and again (1813) after the battle of Bautzen. It became Prussian through 1814–1870 and then German (1871). Under the new German Empire it turned into one of the most important cultural centers, having some of the best academic institutions in Germany [p. 630,000 (1938)]. The city was almost totally destroyed under the Red Army siege in 1945. It then came under Polish rule. Jews lived in Wroclaw since the end of the 12th century. The entire community was eliminated (1453) by the bloody inquisitor Giovanni di Capistrano, and was Bereft of Jews for the next 200 years. In the 19th century it began to absorb Jews from both Poland and Prussia, but the entire Jewish community was destroyed in the Holocaust [p. 4400 (1817); 20,300 (1900); 20,200 (1933); 0 (1940); 8000 (1962)]. Its community furnished Germany with many distinguished scientists.

[487] One of his best students there was **Klaus Fuchs**. He and his father Emil, a protestant pastor, were German refugees because they were avowed communists. Fuchs later transmitted secrets of the atom bomb to the Soviets.

medical ills to linguistic causes and emphasized the importance of language in the transmission of knowledge.

Author of *Manhood of Humanity* (1921), *Science and Sanity* (1933). Korzybski proposed a system called "*general semantics*"[488], whose basic postulates are:

- words are not to be confused with things,
- words can never say all about anything,
- words about words about words, and so on, can go on indefinitely.

He thought that his philosophy could significantly improve the quality of life of the individual who freed himself from the confusions engendered by language.

Korzybski was born in Warsaw. Educated as an engineer, he served in Russian military intelligence in WWI. Sent to the USA in 1915 on a Russian military mission, he remained there, becoming naturalized American citizen in 1940.

1921–1942 CE **Ronald Aylmer Fisher** (1890–1962, England). Statistician and geneticist. Prominent contributor to the development of both applied and mathematical statistics, especially in the theory of statistical inference, test of significance, estimation and experimental design.

His main contributions:

- Modernized Darwin's theory of evolution through the development of *quantitative* arguments in support of the theory of natural selection[489] (1930–1937). In his book "*The Genetical Theory of Natural Selection*" (1930) he applied his new statistical techniques to genetics in order to show that Mendel's

[488] *Semantics*: the study of the conditions under which signs, symbols and words are meaningful. It is also the study of how human behavior is affected by words (spoken to others or to oneself in thought), In *philology* (the scientific study of languages), semantics is concerned with the historical study of changes in the meaning of words. Semantics deals with the relations between words and the things talked about and with meanings as a factor in human relations. Humans are the only creatures that talk themselves into trouble, and semantics is concerned with how to avoid doing so.

[489] *Fisher's Equation*: Consider a population of individuals carrying an advantageous allele (call it a) of some gene and migrating randomly into a region in which only the allele A is initially present. If p is the frequency of a in the population and $q = 1 - p$ the frequency of A, it can be shown that under the assumption of Hardy-Weinberg genetics, the rate of change of the frequency p

discoveries support Darwin's theory. He thus secured the key biological concept of genetic change by natural selection.

• Introduced the concept of *likelihood* (1921). The likelihood of a parameter involves a function usually having a single maximum value, which he called the *maximum likelihood*.

• Gave a new definition of statistics; It's purpose was the reduction of data and he identified three fundamental problems:

(i) specification of the kind of population that the data came from;

(ii) estimation;

(iii) distribution.

Developed methods suitable for *small samples* (like those of Gosset), discovered the precise distributions of many sample statistics and invented the analysis of variance.

• Evolved statistical rules for *decision making* that are now used universally, and many other methods that have since been extended to virtually every academic field to which statistical analysis can be applied.

---

at a given location is governed by the equation

$$\frac{\partial p}{\partial t} = D\frac{\partial^2 p}{\partial x^2} + \alpha p(1-p),$$

where α is a constant coefficient that represents the intensity of selection. Historically, this model elicited considerable interest and was thoroughly investigated. The equation has a variety of solutions depending on other constraints (such as boundary conditions). Among these are *traveling waves* solutions on an infinite domain. Indeed, putting $z = x - Vt$, $p(x,t) = P(z)$, one obtains the second-order ODE

$$V\frac{dP}{dz} = D\frac{d^2 P}{dz^2} + \alpha P(1-P).$$

It can be converted into a non-linear system of first order ODEs:

$$\frac{dP}{dz} = -S; \quad \frac{dS}{dz} = \frac{\alpha}{D}P(1-P) - \frac{V}{D}S.$$

Kolmogorov (1937) has shown that if suitable initial conditions are assumed, the solution of the Fisher Equation would evolve into a traveling wave that propagates at the minimal speed $V_{\min} = 2\sqrt{\alpha D}$.

- Contributed to the contemporary understanding of genetic dominance

Fisher was born in London, educated at Harrow and graduated in mathematics at Cambridge. In 1919 he became a statistician at the Rothamsted Agricultural Research Institute. There he developed his techniques for the design and analysis of experiments which he expanded in *Statistical Methods for Research Workers* (1925). He also studied the genetics of human groups, elucidating the *Rhesus factor*. He became professor of Eugenics at University College London (1933–1943) and Professor of Genetics at Cambridge (1943–1957).

1921–1944 CE **Emil Artin** (1898–1962, Germany and U.S.A.). Mathematician. Played a major role in the development of the class field theory, abstract algebra and hypercomplex numbers (noncommutative rings). Expanded the theory of algebras of associative rings (*Artin rings*), and the theory of *braids*. He also made contributions to the theory of the Zeta function, algebraic number theory (Artin's conjecture[490]) and Dirichlet series.

Artin was born in Vienna, a son of an art dealer and an opera singer. He grew up in Bohemia and held professorial positions at the Universities of Leipzig and Hamburg (1923–1937). In 1937 he emigrated to the United States and became a professor of mathematics at Princeton University (1946–1958). He returned to Hamburg in 1958.

1921–1947 CE **Ludwig Josef Wittgenstein**[491] (1889–1951, Austria and England). A thinker interested in the limits of meaning, language and thought, whose philosophical perspectives differ radically from that of professional philosophers of the 20^{th} century. Had considerable influence on *linguistic philosophy* and the *philosophy of mathematics*, through which he inspired

---

490 **Artin** (1927) conjectured that if n is not (-1) and not a square, then the set $S(n)$ of all primes for which n is a *primitive root*, must be *infinite*.

Artin further conjectured that if n is not an r^{th} power for any $r > 1$, then, *independently of the choice of* n

$$\prod_{k=1}^{\infty}\left[1-\frac{1}{p_k(p_k-1)}\right] = 0.373\ 955\ 813\ 6\cdots = \text{ Artin's Constant},$$

where the product is restricted to values of k such that p_k are members of the set $S(n)$.

491 For further reading, see:

- Monk, Ray, *Ludwig Wittgenstein*, Penguin Books, 1990, 654 pp.

other thinkers like **Bertrand Russell**, **Alan Turing**, **Moritz Schlick** and **Alfred Whitehead**.

Wittgenstein's philosophy of mathematics is not a contribution to the debate on the foundations of the subject that was fought during the first half of the 20^{th} century by the opposing camps of *logicists* (led by **Frege** and **Russell**), *formalists* (led by **Hilbert**) and *intuitionists* (led by **Brouwer** and **Weyl**). It is, instead, an attempt to undermine the whole basis of this debate — to undermine the idea that mathematics *needs* foundations.

All the branches of mathematics that were inspired by this search for 'foundations' — *Set Theory, Proof Theory, Mathematical Logic, Recursive Function Theory*, etc. — he regarded as based on philosophical confusion[492].

In his book *Tractatus Logico – Philosophicus* (1921) he offered a general means of removing philosophical difficulties by investigating the logical structure of language. He developed the view that all truths of logic are tautological, claiming that the inability to see through the logic of language is the cause of many apparently insoluble problems. He set up a system of *linguistic analysis* by which any statement must satisfy certain logical conditions before being admitted as proper philosophical statement.

Many Western philosophers considered *Tractatus* their 'bible' and much of American and British philosophy in our times has been affected in one way or another by Wittgenstein philosophy of language. It consists of remarks on the

---

492 Hilbert once said: "No one is going to turn us out of the paradise which Cantor has created".

Wittgenstein told his class (1939): "I would try to show you that it is not a paradise — so that you'll leave of your own accord".

Indeed, Wittgenstein's quixotic assault on the status of pure mathematics reached a peak during the academic year 1932–33, at Cambridge. In his lecture "Philosophy for Mathematicians" he would read out extracts from **Hardy**'s *Pure Mathematics* and use them to illustrate the philosophical fog that he believed surrounded the whole discipline of pure mathematics. Since the time of **Plato**, philosophers have traditionally been divided between those who say that mathematical statements are true about the *physical* world and those who say that they are true of the *mathematical* world — Plato's eternal world of ideas or forms. To this division **Kant** added a third view, which is that mathematical statements are true manifestation of the 'form of our intuition' and this was roughly the view of **Brouwer** and the intuitionist school. But for Wittgenstein, the whole idea that mathematics is concerned with the discovery of truths is a mistake that has arisen with the growth of pure mathematics and the separation of mathematics from physical science (in the words of **Willard Gibbs** — "Mathematics is a language").

essence of language, the nature of logic, mathematics, science and philosophy, and ending with comments on ethics, religion and mysticism.

There are many reasons for the wide acceptance of the *Tractatus*. Chief among them are:

- The failure of Einstein's attempts to develop an all-embracing unified field-theory and his futile efforts to crush the subjectivistic 'psychological ghosts' introduced into the scientific interpretation of quantum theory, marked the withdrawal of philosophy from physics and physics from philosophy.
- The collapse of the Austrian Empire and consequently Vienna's loss of political and intellectual leadership, caused members of the 'Vienna Circle' to direct their mind upon themselves rather than face external events.
- The rise of Soviet Communism and dialectical materialism.

The outcome was inevitable: Western thought declined, philosophy was cornered, scientism flourished, and ideology ended up in a dead-end street. The 'inward trend' of the Tractatus seemed the adequate answer.

Wittgenstein was a descendant of a wealthy Jewish family in Vienna. His parental great grandfather, Moses Maier, worked as a land-agent for the princely family of Wittgenstein and after the Napoleonic decree of 1808 (which demanded that Jews adopt a surname), took the name of his employers. Ludwig's grandfather, Hermann, and his family converted to Protestantism (1838), moved to Vienna and were assimilated into the local German elité, shunning any contact with their former fatesakes.

Wittgenstein's father, Karl, became one of the most astute industrialists in the Austro-Hungarian Empire. Because of the Catholic denomination of his half-Jewish spouse, all his offsprings were baptized into the Catholic faith and raised as accepted and proud members of the Austria high-bourgeoisie. The Wittgensteins were thus at the center of Vienneese Germanic cultural life for three generations[493]. [**Johannes Brahms** gave piano lessons to Ludwig's aunts and **Gustav Klimt** was commissioned to paint Ludwig's sister portrait

[493] After the *Anschluss* of Austria by the Nazis (1938), the Wittgensteins discovered, to their horror, that according to the *Nuremburg Laws* they still count as Jews, unless they produced evidence for a second Aryan grandparent! So, some fled to Switzerland, some gave a sworn affidavit that Hermann was known as an antisemite who, in adult life, avoided association with the Jewish community and did not allow his offsprings to marry Jews (the Nazis saw some advantage to themselves in accepting it), while others (like Ludwig's sisters) earned their

(1905); **Mahler** was a frequent visitor to the musical evening at Ludwig's childhood home and young **Casals** played there.]

The *fin de siécle* Vienna of Ludwig's childhood was characterized by a 'nervous splendor': beneath the all-pervading atmosphere of culture and humanity, lay doubt, tension and conflict. Its tensions prefigured those that have dominated the history of Europe during the 20^{th} century. From these tensions sprang many of the intellectual and cultural movements that have shaped that history: It was the birthplace of both Zionism and Nazism, the place where Freud developed psychoanalysis, where Klimt, Schiele and Kokoschka inaugurated the *Jugendstil* movement in art, where Schönberg developed atonal music and Adolf Loos (1870–1933), the pioneer of modern architecture, introduced the starkly functional, unadorned style that characterized the buildings of the modern age.

Wittgenstein came to England in 1911, studying aeronautical engineering until he moved to Cambridge to pursue a philosophical interest in mathematics. Frege, to whom he had written, advised him to seek out Bertrand Russell and the contact was fruitful.

Wittgenstein served in WWI in the Austrian army. He was made an officer, involved in heavy fighting during 1916–1918 and taken prisoner on the Italian front (1918); he thus experienced the dehumanizing results of modern, mechanized combat, the 'grand strategies' of Total War which engineered the slaughter of millions of men in conditions of unimaginable horror.

In 1919 he dedicated himself to a life of simple asceticism (perhaps under the influence of the religious writings of Leo Tolstoy). He gave his money away to his relations and abandoned philosophy. In the following years he worked as an elementary school teacher in the Austrian countryside (until that ended in disaster), an amateur architect and a convent-gardener.

He returned to Cambridge (1929), where he was the center of a small, intensely loyal cult[494]. In 1939 he succeeded G.E. Moore as professor of phi-

---

Aryan papers by handing over all their foreign currency to the Third Reich. Sic transit the Wittgenstein's wealth.

494 "*God has arrived. I met him on the* 5:15 *train*". Thus was Wittgenstein's return to Cambridge announced by one of his disciples.

Soon after his arrival, he was hurriedly awarded a Ph.D. for his thesis, the *Tractatus*, a work that had been in print for seven years and was already regarded by many as a philosophical classic. The examiners were Moore and Russell and the exam was a farce: as Russell walked into the examination room with Moore, he smiled and said: "I have never known anything so absurd in my life". The examination began with a chat between old friends. Then Russell, relishing the absurdity of the situation, said to Moore: "Go on, you've got to ask him some losophy and logic, but he was absent on menial war work soon afterwards and resigned altogether in 1947. Four years later he died from cancer of the prostate after a period of severe illness. For a long time he had meditated suicide[495] fearing that he shared the pronounced strain of insanity in his family (all his three brothers killed themselves).

Wittgenstein was an imposing figure with a fearless independent spirit. People tended to be fascinated or repelled by him, as he was very direct in his approach and impatient of any pretentiousness. The magic of his personality and style was infectious and pupils tended to imitate him. He was a deeply serious man and put his soul into everything he did. He was not learned or widely read, but would only read what he could wholeheartedly assimilate. He was not religious in the conventional sense, but had a deep respect to the Bible and some religious authors (e.g. **Kierkegaard**).

He was an engineer by training and his knowledge was intimately connected with doing. Music was central to his life, and he had no interest in modern music: the music of **Bach**, **Beethoven**, **Schubert** and **Schumann** were amongst his favorites. He intensely disliked academic life, avoided any publicity and regarded the Press as one of the disasters of modern life. Modern times to him were a dark age: the idols of progress and the belief that technology will solve all our problems, he felt were profoundly wrong. He believed that only a change in our way of life would heal the sickness of our age — and this is only to happen when disaster confronts us.

---

questions — you're the professor". There followed a short discussion in which Russell advanced his view that Wittgenstein was inconsistent in claiming to have expressed unassailable truths by means of meaningless propositions. He was, of course, unable to convince Wittgenstein, who brought the proceeding to an end by clapping each of his examiners on the shoulder and remarking consolingly: "Don't worry, I know you'll never understand it".

[495] Some of his biographers believe that his homosexuality provided a key to his tormented personality, and even his philosophy.

Worldview XXXVII: Wittgenstein

* * *

"We could present spatially an atomic fact which contradicted the laws of physics, but not which contradicted the laws of geometry."

* * *

"Whereof one cannot speak, thereof one must be silent."

* * *

"In order to draw a limit to thinking, we should have to think both sides of the limit."

* * *

"Is logic the foundation of mathematics? In my view mathematical logic is simply part of mathematics. Russell's calculus is not fundamental; it is just another calculus. There is nothing wrong with a science before the foundations are laid."

* * *

"The theory he[496] *has constructed, is not metamathematics, but mathematics. It is another calculus, just like any other one. It offers a series of rules and proofs, when what is needed is a clear view. A proof cannot dispel the fog. If I am unclear about the nature of mathematics, no proof can help me and the question about its consistency cannot arise at all."*

---

496 **Hilbert** (1904) endeavored to construct a formalist approach to the foundation of logic and arithmetic. It was a 'meta-theory' of mathematics, seeking to lay a *provably* consistent foundation for arithmetic.

* * *

"The sole remaining task of philosophy is the critique of language."

* * *

"To pray is to think about the meaning of life. To believe in God means to see that life has a meaning; The meaning of life, i.e. the meaning of the world, we can call God."

* * *

"I am my world."

* * *

"Don't try to improve the world. Just improve yourself; that is the only thing you can do to better the world."

* * *

"Philosophy is not a theory but an activity; the purpose of philosophy is the logical clarification of thoughts; a philosophical work consists mainly of elucidations; philosophy should take thoughts that are otherwise turbid and blurred, so to speak, and make them clear and sharp."

* * *

"I never use notes – thoughts become stale that way."

* * *

"I strongly advise you against becoming academic philosophers. The temptation to fake thinking amongst them is very great."

* * *

"Philosophy is a battle against bewitchment of our intelligence by means of language."

* * *

"There is no compulsion making one thing happen because another has happened. The only necessity that exists is logical *necessity. The whole modern conception of the world is founded on the illusion that the so-called laws of nature are the explanations of natural phenomena."*

* * *

"I should not like my writing to spare other people the trouble of thinking. But, if possible, to stimulate someone to thoughts of his own."

* * *

"The riddle does not exist. If a question can be put at all, then it can also be answered."

* * *

"Mathematics is a logical method... Mathematical propositions express no thoughts. In life it is never a mathematical proposition which we need, but we use the mathematical propositions only in order to infer from propositions which do not belong to mathematics to others which equally do not belong to mathematics."

1921–1948 CE **Norbert Wiener**[497] (1894–1964, U.S.A.). Outstanding mathematician and logician. Invented the science of *cybernetics*. He opened up to mathematical analysis many practical areas in physics and engineering which are basically statistical in nature. Wiener's work led to the treatment, solution and interpretation of many physical problems, as well as to the development of computer and communication equipment.

Wiener had a major influence on advances in radar, high-speed electronic computers, control theory, and quantum theory. He contributed in a most significant way to the mathematical analysis of the theory of feedback and automated processes, set theory, group theory, probability and mathematical logic.

Wiener was born in Columbia, MO. His father, Leo Wiener, was a historian of Yiddish culture, who later became a professor of Slavic languages and literature. He made incessant intellectual demands on his son (and did not reveal to him that they were Jews — a fact discovered by Norbert only when he was in his teens).

Wiener was a child prodigy. He could read and write at the age of 3 and read scientific books at 4. He entered Tufts University at 11, and obtained his Ph.D. from Harvard at 18. He then went to Europe and was strongly influenced by **Bertrand Russell**, **G.H. Hardy** and **D. Hilbert**, under whom he studied mathematical logic and pure mathematics.

For five years (1914–1919) he tried various occupations in search of his self realization. Finally, in 1919, he was hired as an instructor by the mathematics department at the Massachusetts Institute of Technology (MIT). Wiener remained at MIT until his retirement in 1960.

His main work started in the early twenties, on the subject of linear spaces and his development of the theory of Banach spaces. In 1930 he published a paper in *Acta Mathematica* on "*Generalized harmonic analysis*"[498], in which he generalized the theory of the Fourier integral to functions whose average

---

[497] For further reading, see:

[498] From about 1900 to 1930, Heaviside's methods dominated the whole of communication engineering, and their rigorous mathematical justification was considered a moot question. Toward the end of this period, rigorous mathematical justifications of the formal Heaviside calculus were found, and with this it came to be appreciated that Heaviside's work belonged together with the theory of the Laplace and Fourier integrals.

power is finite. He defined the autocorrelation, cross correlations, and power spectral density functions and established relations between them (*Wiener-Khinchin theorem*).

He demonstrated convincingly for the first time that the Fourier integral could be used as a link between two distinct branches of mathematics — statistics and analysis. Through 1921–1931, Wiener did highly innovative work on stochastic processes, in particular on the theory of the Brownian motion. During WWII Wiener worked on gunfire control (the problem of pointing a gun at a moving target). The ideas that evolved led to the theory of prediction of stationary time-series. There he introduced certain statistical methods into control and communication engineering, which led him eventually to the formulation of his concept of *cybernetics* [a word coined from the Greek work for "*Navigator*", meaning the study of control. The word is etymologically related to the English "govern" and also appears in Hebrew in the connotation of a *ship captain*].

In his book *Cybernetics* (1948), Wiener opened a new branch of science that deals with control mechanisms and the transmission of information. Wiener noted that the means for internal control and communication in an animal, such as its nervous system, were similar to those in a machine. He also realized that biologists who studied animals, and engineers who designed automatic control equipment, did not usually know each other's fields of work. He proposed that control and communication in both fields be studied together as the science of cybernetics. An important part of cybernetics is the study of *feedback*, where information concerning the error in the operation of a system is fed back to the controlling device, which then acts to correct the error.

Wiener lived up to the stereotype of the absentminded professor. He was worried about the quality of his work and his standing as a mathematician. He was a vegetarian and something of a puritan. He was also an extremely generous man, with a strong sense of social and moral responsibility.

He will be remembered for his marvelously versatile contributions, profoundly original, ranging from pure to applied mathematics, and penetrating boldly into engineering and biological sciences.

Worldview XXXVIII: Norbert Wiener

* * *

"A professor is one who can speak on any subject – for precisely fifty minutes."

* * *

"The modern physicist is a quantum theorist on Monday, Wednesday, and Friday and a student of gravitational relativity theory on Tuesday, Thursday, and Saturday. On Sunday he is neither, but is praying to his God that someone, preferably himself, will find the reconciliation between the two views."

* * *

"Progress imposes not only new possibilities for the future but new restrictions."

* * *

"We are raising a generation of young men who will not look at any scientific project which does not have millions of dollars invested in it... We are for the first time finding a scientific career well paid and attractive to a large number of our best young go-getters. The trouble is that scientific work of the first quality is seldom done by go-getters, and that the dilution of the intellectual milieu makes it progressively harder for the individual worker with any ideas to get a hearing... The degradation of a position of the scientist as an independent worker and thinker to that of a morally irresponsible stooge in a science-factory has proceeded even more rapidly and devastatingly than I had expected."

The Wiener Process (1922–1930)

Whereas from a physical viewpoint Einstein's calculations and Perrin's experiments (1909) had explained Brownian motion quite adequately, from a mathematical viewpoint the subject was still tantalizingly confused. The heart of the difficulty was to make precise mathematical sense out of the notion of a particle moving "at random". Everyone knows what it means to pick between heads and tails at random; it means each alternative has a probability of $\frac{1}{2}$ *(fair toss). The Brownian particle follows a path that is in some sense chosen at random from among all possible paths.*

The set of all possible paths, however, is a very large and complicated one, and it was one of the Wiener's major achievements in pure mathematics to show in what sense one can speak about choosing an element from this set at random. He studied the phenomenon of Brownian motion from a new point of view (1922–1930), expanding the concept of probability further than his predecessors, thereby bringing the term 'Brownian motion' into the language of mathematics.

An intuitive notion of what is involved can be obtained by considering the path traced out in a finite time period (say, an hour) by a one-dimensional motion, which changes direction only at the instances $t =$ *one second,* $t =$ *two seconds and so on. In this case there are only a finite number of possible paths (*2^{3600}*, to be exact), and one could say that the Brownian particle chooses one path at random in the sense each path has a probability of* 2^{-3600}.

In the Wiener process, the distances traveled are distributed according to a Gaussian curve, just as they are in Einstein's physical model of Brownian motion. Moreover, Wiener proved that almost certainly (with a probability 1*) the path is continuous but nowhere smooth.*

When a series of discrete events is taking place at random times [e.g. cosmic rays striking a detector or raindrops falling on a demarked area of ground], the probability that the time interval (between two consecutive events or between a fiducial time and a given event) will fall within the range dt *centered around* t *is* $\rho(t)\,dt$, *where* $\rho(t)$ *is the corresponding probability distribution. We write the probability distribution of* x *as* $\rho(x)$ *if* $\rho(x)\,dx$ *is the probability that the variable lies in the range* dx *about* x. *In two variables, the probability distribution of* x *and* y *is* $\rho(x,y)$, *which means that the probability of finding the variables* x *and* y *in the region* A *of the* xy *plane is given by* $\int_A \rho(x,y)\,dx\,dy$.

Thus Wiener asked:

"What is the probability of the Brownian particle following a certain path in space?" Since in one dimension, the time history of the particle is represented by a continuous function $x(t)$, the question is equivalent to: "What is the probability of obtaining a particular time history $x(t)$?" To this end he considered the space of paths, focusing not on the distribution of a single variable but of complete curves. This entails the construction of functionals[499]*, using mathematical tools provided by the Volterra theory of functionals (1887).*

If $x = 0$ at $t = 0$, then at time t the probability that the particle's position is between a and b is $\int_a^b \rho(x,t)\,dx$. Similarly, the probability that a particle starting at $(0,0)$ is between a_1 and b_1 positions at time t_1, between a_2 and b_2 at time t_2, ..., and between a_N and b_N at time t_N $(a_i < b_i,$ $t_i < t_{i+1})$ is

$$\int_{a_1}^{b_1} dx_1 \ldots \int_{a_N}^{b_N} dx_N \rho(x_1,t_1)\rho(x_2-x_1,t_2-t_1)\ldots\rho(x_N-x_{N-1},t_N-t_{N-1}),$$

where the appearance of the arguments $x_i - x_{i-1}$ and $t_i - t_{i-1}$ reflects the homogeneity in space and in time of this diffusion process and $\rho(x,t)$ is the Gaussian distribution defined above. This distribution fits physical phenomena which are the result of the combination of a large number of independent events occurring randomly. This is the conclusion of the central limit theorem of probability theory.

For us, the quantity of interest is the conditional probability that the path of the particle [starting at $(0,0)$] satisfies

$$a_i < x(t_i) < b_i \qquad \text{at times } t_i, \qquad i = 1,2,\ldots,N-1$$

given that $x(t_N) = x_N$. This conditional probability[500] *density is given by*

[499] *Functional*: A mapping from a space of functions to some set of numbers (such as the real or complex fields). Thus $\rho[f(t)]$ assigns to each function a *number*, in the same way that $\rho(t)$ assigns a number $\rho(t)$ to each value of t. In fact, $\rho(t)$ is a special case of $\rho[f(t)]$ for $f(t) = t$.
Phenomena in which the *probability distribution of a function* is involved may include such diverse cases as the voltage in a resistor, the price of a commodity (both as functions of time), or the shape of the surface of the sea as a function of latitude and longitude.

[500] *Conditional probability* of an event A, given the event B, is

$$P(A \mid B) = \frac{P(A \text{ and } B)}{P(B)}$$

It tells us the probability of an event within a *restricted* set of possible outcomes.

the above multivariable integral without the integral over x_N and divided by $\rho(x_N, t_N)$. It measures the probability that the path of the particle passes through each of the given "portals" at the associated times, given the path's endpoints at times 0 and t_N.

As we increase the density at which a specification of (a_i, b_i) is made as $|a_i - b_i| \to 0$, the path of the particle is pinned down more and more precisely. Substituting the Gaussian distribution for each factor in the integral, we can write the product of the densities for the individual intervals

$$\rho(x_1, t_1) \ldots \rho(x_N - x_{N-1}, t_N - t_{N-1}) = \prod_{j=1}^{N} \frac{1}{\sqrt{\pi(t_j - t_{j-1})}} \exp\Big\{-\frac{(x_j - x_{j-1})^2}{t_j - t_{j-1}}\Big\}.$$

In the limit $N \to \infty$, as the time intervals go to zero, the integration of the above expression defines a measure *on the set of all paths $x = x(t)$, known as the* Wiener measure *which we denote in the abbreviated notation $\int d_W\,[x(t)]$, where*

$$d_W\,[x(t)] = \frac{\rho\,[x(t)]\; Dx(t)}{\int_A \rho\,[x(t)]\; Dx(t)} = \frac{1}{C} e^{-\int_0^1 \dot{x}(\tau)^2\, d\tau} \prod_0^t dx(t).$$

Here, A is the space of allowed paths, $\prod_0^t dx(t)$ is the limit of $\prod_1^N dx_i$ and the integral in the exponent is just twice the time integral of the kinetic energy of the particle with unit mass. C is a constant which normalizes the infinite-dimensional integral under the condition $\int_A d_W\,[x(t)] = 1$.

The concept of measure *underpins the modern interpretation of probability, defined in terms of a measure on the space Ω of elementary events. A general event is a set of elementary events, i.e. a subset of Ω, and its probability is equal to the measure of the corresponding set of events, divided by the measure of the whole space Ω. As a rule, the measure is conveniently chosen such that the measure of the whole Ω is unity. Over the space of elementary events we can construct certain functions whose properties are practically independent of the structure of this space and the detailed definition of probability.*

As an example, we consider the simplest case where the Brownian-motion path is unrestricted: $(a_i, b_i) \to (-\infty, \infty)$. Then the iterated integral (with

$\Delta t = t_j - t_{j-1},$ *fixed)*

$$\lim_{N\to\infty}\Big[\frac{1}{\sqrt{\pi\Delta t}}\Big]^N \int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty} \exp\Big\{-\sum_{j=1}^{N}\frac{(x_j - x_{j-1})^2}{\Delta t}\Big\}\, dx_1 \ldots dx_N$$

can be transformed, with $y_j = x_j - x_{j-1},$ *into the product of ordinary integrals, which all equal* $\frac{1}{\sqrt{\pi\Delta t}}\int_{-\infty}^{\infty}\exp\left\{-\frac{y^2}{\Delta t}\right\}dy = 1.$ *The considered Wiener integral is equal to unity, which equals the total volume of the space of elementary events (particle paths in this case). Thus, the measure of the total space of paths is equal to unity.*

The Wiener measure of an event A is given by the Wiener path integral $\int_A \rho\,[x(t)]\; Dx(t),$ *which weighs each path with a Gaussian probability density functional, and then sums the weighted contribution for all possible paths between two given end-points. This process can, of course, be generalized to probability density functions other than the Gaussian. In fact, we could say that, in general, the integrand has the form* $\rho(x_1, x_2 \ldots x_N)\, dx_1\, dx_2\, \ldots\, dx_N.$ *This, in turn, can be viewed as a discretization of the functional* $\rho\,[x(t)],$ *where* $x_i = x(t_i).$ *Once the path integral has been defined, the analogy to the probability density function of a variable can be stretched further to include the concept of the mean value of any functional* $Q\,[x(t)]$ *on the random path* $x(t).$

Thus, the expectation of the function $Q(x)$ *of the random variable* $x,$ *namely* $\int_{-\infty}^{\infty} Q(x)P(x)\,dx = \langle Q(x)\rangle,$ *with* $P(x)$ *the probability distribution function, takes on an analogous form for the functional* $Q[x(t)]$*:*

$$\begin{aligned}\langle Q\,[x(t)]\rangle &= \int Q\,[x(t)]\; d_W\,[x(t)] \\ &= \frac{\int Q\,[x(t)]\,\rho\,[x(t)]\; Dx(t)}{\int \rho\,[x(t)]\; Dx(t)},\end{aligned}$$

where the functional integrals extend over the allowed histories (paths) of the particles.

Likewise, for the mean-square value of the path function at a particular time, $t = a$*:*

$$\left\langle [x(a)]^2 \right\rangle = \frac{\int [x(a)]^2\,\rho\,[x(t)]\; Dx(t)}{\int \rho\,[x(t)]\; Dx(t)}.$$

Also, the concept of the characteristic function (i.e. the Fourier transform of $p(x)$, *known as the moment-generating function)*

$$\phi(k) = \langle e^{ikx} \rangle = \int_{-\infty}^{\infty} e^{ikx} p(x)\, dx$$

has its analog in the characteristic functional

$$\Phi\,[k(t)] = \frac{\int e^{i \int k(t)x(t)\,dt} \rho\,[x(t)]\; Dx(t)}{\int \rho\,[x(t)]\; Dx(t)},$$

where $e^{i \int k(t)x(t)\,dt}$ *is the limit of the product* $e^{ik_1x_1}e^{ik_2x_2}\ldots$ *for an infinite number of time intervals, with* $k_i = k(t_j)\,\Delta t_i$. *The possibility of performing the inverse transform* $\rho(x) = \int_{-\infty}^{\infty} e^{-ikx}\phi(k)\,dk$, *leads, in principle, to the analogue expression*

$$\rho\,[x(t)] = \int e^{-i \int k(t)x(t)\,dt} \Phi\,[k(t)]\; Dk(t),$$

where the path integral is now carried out over the space of possible k-*functions. In this way Wiener showed the close connection of the Brownian motion to the Fourier transform.*

Returning to the Brownian motion, we assume that $Q\,[x(t)]$ *is some functional of the path* $x(t)$. *Let* $Q(x_1, \ldots, x_n)$ *be the value* Q *takes on the broken (discrete) line path from* $(0,0)$ *to* (t_1, x_1) *to* $\ldots$ (x_{N-1}, t_{N-1}) *to* (x,t), *with* $t_j = j\frac{t}{N}$. *Then, the mean value of* Q *is*

$$\langle Q \rangle = \lim_{N\to\infty} \int_{-\infty}^{\infty} dx_1 \int_{-\infty}^{\infty} dx_2 \ldots \int_{-\infty}^{\infty} dx_{N-1}\, \rho(x_1,t_1)\rho(x_2-x_1,t_2-t_1)\ldots \\ \times \rho(x_N - x_{N-1}, t_N - t_{N-1}) Q(x_1, \ldots, x_{N-1})$$

It can be shown that the special case $W(x,t) = \left\langle e^{\int_0^t U[x(t)]\,dt} \right\rangle$ *obeys the integral equation*

$$W(x,t) = W_0(x,t) + \int_0^t d\tau \int d\xi\, W_0(x-\xi, t-\tau) U(\xi) W(\xi,\tau)$$

with

$$W_0(x,t) = \langle 1 \rangle = (4\pi D t)^{-1/2} e^{-\frac{x^2}{4Dt}} = \rho(x,t).$$

Recalling that $\left(\frac{\partial}{\partial t} - D\frac{\partial^2}{\partial x^2}\right) W_0 = 0$ *and that* $W(x,0) = \delta(x)$, *this integral equation for* W *implies that* W *satisfies the differential equation governing* *diffusion with random coordinate-dependent growth*

$$\frac{\partial W(x,t)}{\partial t} = D\frac{\partial^2 W(x,t)}{\partial x^2} + U(x)W(x,t)$$

For constant $U = U_0 > 0$, *the explicit deterministic solution has two remarkable features:*

(1) *there exists a critical length scale* $L_c = \pi\sqrt{\frac{D}{U_0}}$ *at which gain (amplification) and dissipative loss are in equilibrium.*

(2) *The surface* $\psi(x,t) = \frac{1}{\sqrt{4\pi Dt}}\exp\left[U_0 t - \frac{x^2}{4Dt}\right] = constant$ *propagates with the velocity* $v = 2\sqrt{DU_0}$.

The physical meaning of this result is as follows: in the course of evolution, the field W *is diffusively transported in space and simultaneously changes at a rate* U *which, although constant in this example, generally varies from one position to another; e.g. the evolution of a bacterial population in a medium with randomly distributed food supply and other environmental factors when the population is able to spread via diffusion in space. This model predicts that the bacteria gather in comparatively stable clusters at places where the environment is most favorable for their development. This picture is a surprisingly good description of the distribution of human populations on levels of concentration that range from villages to towns, cities and megalopolises.*

Path integrals are used today in fields ranging from finance to radiophysics and statistical mechanics to quantum field theory.

Although the task of calculating a path integral by superposing an infinite number of paths may seem insurmountable, the Wiener integrals can be calculated numerically, and pioneering results in this direction began to appear in the 1950s as computational mathematics grew in the wake of the advent of electronic computers. The most convenient approach considers the integral as an average over the Wiener measure rather as a limit of an iterated integral.

It is sufficient to consider three dozens typical Wiener paths and calculate the average over them — the central limit theorem guarantees that the result approximates the Wiener integral. There are however certain inherent difficulties here: first, the construction of the Wiener paths requires generators of random numbers which is sometimes accompanied by the onset of chaos.

Another difficulty is that the numerical calculation of Wiener integrals is associated with intermittent[501] *random quantities, and is due to the fact that some of the Wiener integrals are determined by unlikely events (non-typical paths).*

A similar difficulty is also known for ordinary integrals of rapidly oscillating functions. These two kinds of difficulties are actually intrinsically connected: the more exotic the paths that make principal contributions to the Wiener integral, the tougher are the requirements that arise for the reproduction of these paths via random number generators.

Notwithstanding these difficulties, the simplest Wiener integrals are within the reach of modern numerical methods. In this connection we point out a remarkable and surprising peculiarity of computational mathematics: This field of science is generally connected with pure mathematics, the science which exists in the name of rigorous proof.

In modern computational mathematics, however, even if in some cases irreproachable mathematical proofs can be given, they prove to be almost useless after a deeper analysis. As a result, modern computational mathematics is also unexpectedly close to experimental physics in the nature of its heuristic arguments: in both cases, the principal instrument of verification is experimentation, either in a laboratory or numerical.

Let us clarify this by the following example: When computing an ordinary integral, one replaces the integrand by a polygonal line or by using the more precise Simpson's parabolic rule. One should know how many mesh points must be taken in order to reach the desired accuracy. This proof can be made as rigorous as possible for theorems of calculus. However, the result itself is practically useless. At least, nobody thinks of incorporating it into standard software. The reason for this is simple: the desired estimate of the required fineness of the mesh depends on the maximum continuous derivative of the integrand.

For other interpolations, even higher derivatives are involved. The computation of those is much more complicated than the computation of an integral.

Therefore, instead of this rigorously proved estimate, the so-called Runge's empirical estimate is usually applied, which is based on the presumption that the result of the computations is close to the true value of the integral when the doubling of the number of mesh points does not lead to a considerable change in the result. This estimate cannot be proved while the examples that

[501] Similar to a *Gaussian-distributed* random quantity which typically arises as the *sum* of many random numbers, the *intermittent* random quantity is typically a result of the *multiplication* of many random numbers.

directly contradict to it can be given explicitly. Nevertheless, in the hands of a judicious person, this empirical estimate gives excellent results.

1921–1954 CE **Léon Nicolas Brillouin** (1889–1969, France and U.S.A.). Physicist. Made significant contributions to *mathematical physics* (WKBJ, 1926), *electromagnetic wave theory* (signal velocity; diffraction of light by ultrasonic waves, 1921; optics of metals, 1949), and *quantum theory of solid state physics* (Brillouin scattering of light, Brillouin function, Brillouin zones).

He was a professor at College de France (1932–1939), Brown University (1941–1943), Harvard University (1946–1949), and director of research at I.B.M. (1949–1954). His father **Marcel Louis Brillouin** (1854–1948, France) was a physics professor at College de France (1900–1931), and known for his work on structure of crystals, kinetic theory, and the viscosity of liquids and gases.

1921–1994 CE **Leopold Vietoris** (June 04, 1891 – April 09, 2002, Austria). Mathematician. Contributed to general and algebraic topology and other branches of mathematics. Originated the modern *convergence* concepts in topology. The *Mayer-Vietoris sequence* (1927), *Vietoris complex*, the *Vietoris-Begle theorem* and the *Vietoris inequalities*[502] (1958) are named after him.

---

502 *Vietoris inequality*: If $C_{2k} = C_{2k+1} = \frac{1}{2^{2k}}\binom{2k}{k}$, $k \geq 0$, then

$$\sum_{k=1}^{n} C_k \sin kx > 0, \qquad 0 < x < \pi$$
$$\sum_{k=1}^{n} C_k \cos kx > 0, \qquad 0 < x < \pi$$

An *equivalent* theorem states: Let $a_0, a_1, \dots, a_n$ and t be real numbers. If $a_0 \geq a_1 \geq a_2 \geq \cdots \geq a_n > 0$, and $2ka_{2k} \leq (2k-1)a_{2k-1}$ where $1 \leq k \leq \frac{n}{2}$, then

$$\sum_{k=1}^{n} a_k \sin kt > 0, \qquad \text{and} \qquad \sum_{k=1}^{n} a_k \cos kt > 0 \qquad (0 < t < \pi)$$

Putting $a_0 = 1$, $a_k = \frac{1}{k}$ $(k = 1, 2, \dots, n)$ gives the *Fejer-Jackson inequality* $\sum_{k=1}^{n} \frac{\sin kt}{k} > 0$ $(0 < t < \pi)$, and the *W.H. Young inequality* $1 + \sum_{k=1}^{n} \frac{\cos kt}{k} > 0$, $(0 < t < \pi)$.

Vietoris was born in Radkersburg, Austria, and was educated at the Technical University of Vienna (Ph.D. 1919). He was a soldier in WWI (1914–1918). He then worked with **Brouwer** in Amsterdam (1925–1926) and became a full professor at the University of Innsbruck (1930), where he remained for the rest of his life.

He was an avid skier (up to the age of 92!), keen alpinist and an accomplished mountain climber. He also became an expert on the formation of glaciers in his later years, and researched into the physics of blocks of glaciers.

He lived to be 110 years and 309 days old; In his time he was believed to be the oldest living mathematician and the oldest living Austrian. His last paper was written at the age of 94. He died a few weeks after the death of his wife (101), with whom he had been married for 66 years.

History of Meteorology and Weather Prediction[503]

I. Historical Background

Weather phenomena have profoundly affected the social customs, economic activities and personal experiences of human beings everywhere and in every age; weather prophets and 'weather makers' have practiced their arts for thousands of years. In ancient times, weather was often associated with religious cults, and so we have the thunder-God Zeus and the Germanic God Thor. In the old Testament Jehovah spoke to Moses from a cloud (Ex **19***), accompanied by flashes of lightning, and to Job out of the whirlwind (Job* **38***, 1;* **40***, 6)*[504].

[504] When the results of modern meteorological observations are compared with the picture of weather conditions reflected in the Bible, it seems that the climate and weather phenomena of Israel in the first millennium BCE were essentially the same as today. Incidentally, first references to rainfall records had been made in the Old Testament.

In Britain, it was not too long ago that a 16^{th} *century law requiring 'witches and weather prophets to be condemned to death, was struck from the books'. Even today there are primitive tribes to whom weather is still an act of the gods, and many of them are really quite expert at weather forecasting: The inhabitants of the Marshall Islands in the Pacific, for example, can recognize the characteristic high clouds, composed entirely of ice crystals, which precede a hurricane.*

Aristotle *(ca 335 BCE) was first to attribute the global winds to the heating of the sun in his Meteorologica. It was the first systematic study on meteorology. The ancient Greeks knew their* weather signs, *as we know from* ***Theophrastos***[505].

Not much was added to weather lore during the next 2000 *years, and the progress of meteorology has been coincident with the progress of physics and chemistry in general. Exceptions are the works of* ***Alhazen*** *(1050) on* twilight *and* ***Vitelo*** *(1250) on the rainbow. Minor activity is noted during 1300–1600: the first extant record of daily visual weather observations (no instruments yet available!) was due to* ***William Merle***[506] *(d.* 1347, *England) during* 1331–1338. ***Nicolas of Cusa*** *designed in* 1450 *the first Western Hygrometer.*

With the rise of the new physics in the 17^{th} *century, the discipline of meteorology entered its empirical stage. The main stimuli came from the works of* ***Galileo*** *(1607) on the* thermometer, *on the laws of inertia, and on the weight of air, the work of* ***Torricelli*** *(1642) on the* barometer, *the work of* ***Boyle*** *(1659) on fluid pressure, and the work of* ***Newton*** *(1673) on optics.*

The response was immediate: ***Benedetto Castelli*** *(1578–1643, Italy) used, in* 1639, *a cylindrical glass container to measure* rainfall. *It was the first rain-gauge in Western civilization. In* 1657, *the newly founded society Accademia del Cimento (1657–1667) established a network of meteorological observers in Italian cities (later extended to Paris, Warsaw and Innsbruck) for the recording of pressure, humidity, wind direction and the state of the sky.*

Earlier, in 1653, ***Ferdinand II of Tuscany*** *(1616–1670, Italy) organized a local system of stations for daily recording of weather conditions (1655–1670). He provided the observers of the Accademia with thermometers, barometers, hygrometers and other instruments. This effort was discontinued, however, in* 1670.

---

505 **Theophrastos of Eresos** (372–288 BCE, Greece). Philosopher and scientist. The founder of botanical science. Pupil of Plato and Aristotle and successor of the latter as head of the Lyceum (323–288 BCE). Wrote a number of books on many different subjects. Wrote on *winds* and *weather signs*.

506 Rector of Dirby monastery. The records were found in the monastic diary.

In England, **Robert Hooke** *(1663) encouraged the systematic recording of standardized weather observations, including: wind direction and strength, moisture, temperature, pressure, movement of clouds, and precipitation. In response to his call,* **Richard Townely** *(1629–1707, England) recorded detailed rainfall measurements during* 1677–1704.

Edmund Halley *published (1686) the first meteorological chart: a map indicating prevailing winds over the tropical oceans. He outlined a thermal circulation (over a non-rotating earth) with warm air rising in the zone of maximum heating in the low latitudes, producing simple equator-ward flow in the trade winds*[507] *and a poleward flow aloft. This model was improved by* **George Hadley** *(1735). He incorporated the effects of the earth's rotation, deflecting flows to the right in the Northern Hemisphere and to the left in the Southern Hemisphere, with northeasterly and southeasterly trade winds resulting at the surface. Thus, the circulation according to Hadley consisted of convection cells.*

In 1699, **William Dampier** *(1652–1715, England) suggested that major ocean currents are caused by winds.* **James Jurin***, secretary of the Royal Society (England) organized in* 1723 *a system of meteorological observatories in Europe, North America and India. These were equipped with specific instruments for standard daily measurements and recordings. Monthly and yearly averages of these measurements were calculated at each station. In 1728,* **Isaac Greenwood** *(1702–1745, pre-U.S.A.) recommended that the Royal Society extend its meteorology observations to ships on the high seas.*

Jean Jacques d'Ortous de Mairan *(1678–1771, France) suggested in* 1733 *that Northern Lights (Aurora Borealis) are caused by the sun's atmosphere.* **Charles Le Roy** *(1726–1779, France) introduced (1751) the concepts of relative humidity (the actual amount of water in the air relative to*

---

[507] We owe the classification of cloud forms to the English apothecary **Luke Howard** (1803). They were accepted partly because of their simplicity, but also because of the support they received from the German poet **Johann Wolfgang von Goethe** (1749–1832), who was an enthusiastic cloud watcher because of his great sensitivity to weather changes. He mentioned these cloud forms in several of his poems, as well as in a guide to weather watching which he wrote. The first network of weather stations promoted and financed by a government was in the small state of Sachsen-Weimar, where Goethe was a minister responsible for this activity. Unfortunately, however, shortly after his withdrawal from government, financial difficulties forced the dissolution of the organization he had created.

the maximum possible at a given temperature) and Dew point[508]*, and conjectured that the atmospheric moisture is the origin of* precipitation *(rain, hail, snowfall). In the same year,* ***Henry Ellis*** *(1721–1806, England) found that ocean temperature at depth (1630 m;* $25°13'N$, $25°12'W$*) was lower* ($12°C$) *than the surface value* ($29°C$)*.*

In Germany, the meteorological society of the Palatinate in Manheim (Societas Meteorologica Palatine) was founded in 1780 *by* ***Karl Theodor of Bavaria****. The society (disbanded in 1795) established* 57 *observatories in the Northern Hemisphere, each equipped with barometer, thermometer, hygrometer, rain gauge, wind vane and electrometer. In 1784,* ***Benjamin Franklin*** *(1706–1790, U.S.A.) attributed the severe winter of* 1783–1784 *to the volcanic eruption of Laki fissure in Iceland (June 8, 1783), where solar insolation was reduced by the spread of volcanic ash through the atmosphere.*

In 1783, ***Horace Benedict de Saussure*** *(1740–1799, Switzerland) developed a sensitive hair-hygrometer for the measurement of* relative humidity*. In England,* ***John Dalton*** *conducted weather observations during* 1787–1844*. The period* 1752–1783 *is marked by a collective effort to study the nature of the atmosphere and finally establish its character as a simple mixture of gases. This was contributed by* ***Black*** *(1752),* ***Cavendish*** *(1760–1777),* ***D. Rutherford*** *(1772),* ***Priestley*** and ***Scheele*** *(1775), and* ***Lavoisier*** *(1783).*

To obtain a true picture of the seemingly random sequence of diverse weather conditions, it is necessary to record on one chart the observations made simultaneously at many points. This was done for the first time by ***Brandes*** *(1817, Germany) at the University of Leipzig. He based his work on the observations made over many decades by the first international network of weather stations (that of the Meteorological Society of the Palatinate in Manheim, 1781–1795). We call the recording of simultaneous meteorological phenomena '*synoptic meteorology*'. [The invention of the telegraph and all the means of communication based on it – such as radio and teleprinters – , has made it possible for synoptic meteorology to cover vast areas, and nowadays the entire globe.]*

Fourier *suggested in* 1827 *that human activities have an effect on earth's climate.* ***Matthew Fontaine Maury*** *(1806–1876, U.S.A.) was one of the first to treat the oceans and the atmosphere as a unified system: in* 1847 *he published wind and current charts for the North Atlantic, and during* 1850–1857 *he extended his charts to include surface winds over world oceans.*

---

[508] The *Dew point* is that temperature at which the relative humidity becomes 100% (i.e., the air is saturated) and condensation accordingly takes place, invisible water vapor changing into visible water drops. It is the temperature at which an invisible air-stream will breed clouds, and decreases with humidity.

A major advance in the understanding of the motion of air-masses[509] *in the*

---

[509] The Polar Regions can be regarded as the two great '*air-conditioning*' areas for the earth's atmosphere, while the Tropics are the great '*central heating*' areas. Within the Tropics, from Cancer across the equator to Capricorn, day and night are nearly equal throughout the year. The heating by day and the cooling by night are similarly balanced and it is always hot. The daily average temperatures remain steadily high. The path of the rising sun is a steep climb upward in the east. Within an hour it is high enough and strong enough to cancel the heat-loss of the night. Although the downward path of the sun to its setting in the west is as steep as its morning rise, not until several hours after sunset do surface temperatures fall appreciably. (Surprisingly, really intolerable heat is found not on or near the equator but between latitudes 15° and 30° north and south of the equator, and well away from the sea — in the hot desert lands of the world.)

Air masses are huge masses of air with approximately uniform temperature and humidity. They are caused when an area of air, hundreds of kilometers wide, rests on a sea or land mass that has fairly even temperature and humidity. The air takes on the characteristics of the surface below. There are two extreme kinds of air masses — *tropical* ones, which are warm, and *polar* ones, which are cold.

Air moves over the earth's surface, tending to even out the distribution of heat. As air masses leave the place where they formed, they become modified, warming up or cooling down, becoming drier or moister, according to the different surfaces they travel over. Meanwhile, fresh supplies of polar or tropical air are being produced at the Poles and in the Tropics.

Very different air masses do not mix together when they meet. There is a *polar front* in each hemisphere, a boundary between modified polar and tropical air masses. These boundaries are belts of unsettled weather.

On weather maps, air masses are labeled to show where they came from. Air masses from the Poles are labeled P; air masses from the Tropics, T. If they formed over land, they are labeled c; if they formed over sea or ocean, m. So an air mass labeled cP came from a polar land mass, like Alaska, for example, while an air mass labeled mT came from a tropical sea, like the Caribbean.

Air masses play a vital role in the type of weather experienced all over the world. The basic reason for these air masses moving the way they do is *pressure*, the compressive atmospheric force per unit area at any point and upon any surface, and equivalent at *equilibrium* to the weight of a unit-area-base column of air extending upwards from the given point.

This weight varies, depending on *temperature* (warm air lighter than cold air) and *humidity* (wet air lighter than dry air). Barometers react to changes in local pressure by 'rising' when the pressure is high (usually indicating good weather), and falling when low (bad weather).

atmosphere came with the discovery of the Coriolis force[510] *(1835);* ***William Ferrel*** *(1817–1891, U.S.A.) improved on Hadley's model, producing the first reasonably complete model of major wind systems — the first* 3*-cell model. He made a quantitative use of the Coriolis effect to explain the easterly trade winds in low latitudes. Thus, Ferrel included a belt of southwesterly winds in middle latitudes, between the easterlies of high and low latitudes, with subsidence in the subtropical highs and ascent at higher latitudes, at the limit of what is now known as the Ferrel cell.*

He also explained the counterclockwise rotation of cyclons *(low pressure areas) in the Northern Hemisphere and the clockwise rotation of* anticyclones *(high pressure areas) in the Southern Hemisphere. Ferrel also described the effects of the earth's rotation on the distribution of ocean currents caused by the wind, and derived, in* 1874*, the equation relating the barometric gradient of pressure to the velocity of the wind. In the same year* ***M. Leverrier*** *presented a* weather map *of* France*, constructed from observations at* 10 *stations. The modern method of mapping the weather was introduced in* 1863 *by* ***Francis Galton*** *(1822–1911, England). In* 1869*, the meteorologist* ***Cleveland Abbe*** *(1838–1916, U.S.A.) began to send out* weather bulletins *from the Cincinati observatory. In 1885* ***Albert I of Monaco*** *(1848–1922,* Monaco*) provided evidence (through the expedition of his ship Hirondelle) that the Gulf-stream is transatlantic.*

While atmospheric pressure and air density decrease rapidly with altitude, the vertical temperature structure of the atmosphere is not as simple as was once believed. At the end of the 19^{th} *century it seemed reasonable that a decrease in temperature should accompany the lowering of pressure at the outer*

Arctic and sub-tropical areas are normally recognized as being *high pressure zones*, while the temperate latitude area (ca 40 °N–60 °N) and the equatorial belt (ca 15 °N–15 °S) as being *low pressure zones*. High pressure forces air masses towards low pressure: this is a vital clue to all movements of air masses.

510 It is a direct consequence of the conservation of the component of the angular momentum of the air-mass, parallel to the earth's rotation axis: to maintain the constancy of the quantity $\{V_\Theta R \cos\Theta\}$ per unit mass [R = earth's radius, Θ = latitude, V_Θ = linear velocity in west-east direction tangential to latitude circle], V_Θ must increase as $\cos\Theta$ decreases; hence the effect. The magnitude of the *Coriolis force* is shown to be $\{2V\omega\sin\Theta\}$ per unit mass, where $\omega = 7.29 \times 10^{-5}$ rad/sec and V is the wind's speed. Upper-level winds are deflected until the Coriolis force just balances the *pressure gradient force* (normal to isobars). Above 600 meters, where friction is negligible, these winds will flow nearly *parallel to the isobars*, and are called *geostrophic winds*. This was asserted in 1857 by **Christoph Buys Ballot** (1817–1890, Holland).

limits of the atmosphere. The lower temperatures recorded on mountain summits confirmed this assumption. At the turn of the 20^{th} *century* ***Teisserenc de Bort*** *(1855–1913, France), working from an observatory near Versailles, explored the structure of the atmosphere using balloons carrying recording thermometers. His observations during* 1898–1902 *showed that above 11 km, over Europe, temperatures cease to fall and may even increase with height. He had in fact discovered the stratosphere*[511]*, a name which he gave to this region of the atmosphere in* 1908. *In 1918,* ***Vladimir Peter Köppen*** *(1846–1940, Germany) developed an empirical climatic classification based on temperature and precipitation, yielding* 5 *major climate types: tropical, dry, warm temperature, snow, and ice*[512].

The basic features of Atlantic circulation were explained in 1922 *by* ***Alfred Merz*** *(1880–1925, Germany), and* ***Georg Adolf Wüst*** *(1890–1977, Germany), emphasizing cross-equatorial exchange. In the same year,* ***Frederick Alexander Lindemann*** *(1886–1957, England) and* ***G.M.B. Dobson*** *(England) determined atmospheric temperatures at levels above those reached by balloon soundings, by examining meteor trail records, for brightness, height and length of trail. From these they derived air densities, and then calculated temperatures from the density and other variables. They concluded that air is warmer at* 50 *km than at lower levels.*

During 1919–1936, ***Andrew Douglass*** *(1867–1962, U.S.A.) correlated climatic cycles and tree growth, using the tree-rings for dating.*

Alongside with the development of the art of measurement and observation, meteorology benefited from the independent evolution of the sciences of hydrodynamics and thermodynamics developed from the works of ***Newton*** *(1670),* ***Euler*** *(1736),* ***Laplace*** *(1780),* ***Fourier*** *(1785),* ***Poisson*** *(1815), and* ***Stokes*** *(1851).*

[511] Today it is customary to divide the lower part of the atmosphere into two layers: a lower layer called the *troposphere* (from the Greek '*tropos*', meaning 'turn'), which is descriptive of the layer's convective and mixing characteristics. This, the lowest layer of the atmosphere, contains 75% of the total atmospheric mass, and is the most important in terms of weather. It contains virtually all the water vapor and clouds, and the atmospheric pollution. The layer above it is the *stratosphere* (from the Latin '*stratum*' means 'a layer'), which is descriptive of its stratified, non-convective nature. It extends up to about 50 km. It contains the ozone (O_3), which although present in only very small amounts is vital for the existence of life on earth, for it absorbs and filters out the ultraviolet radiation wavelength (0.23–0.32 microns).

[512] **Strabo**, in ca 5 BCE, divided the world into frigid, temperate and tropic zones.

II. The Physical foundations

The theoretical branch of meteorology is based upon the fundamental postulate that the behavior of the atmosphere is capable of being analyzed and understood in terms of the basic laws and concepts of physics. The three fields of physics which are most applicable to the atmosphere are thermodynamics, optics *and* hydrodynamics.

From the field of thermodynamics *we set down three laws:*

- *The equation of state of a perfect gas.*
- *The first law of thermodynamics.*
- *The second law of thermodynamics.*

The relevant laws governing the emission, propagation and absorption of optical radiation *are:*

- *Kirchhoff's law.*
- *Planck's law.*
- *Beer's law.*
- *The equation of radiative transfer.*

In hydrodynamics *we make use of:*

- *Newton's three laws of motion and the law of universal gravitation.*
- *The laws of conservation of mass and energy.*
- *The Navier-Stokes equation incorporating Newtonian viscosity.*

The ultimate aim of theoretical meteorology is to express the above laws and ideas in forms applicable to the atmosphere, and to apply the resultant equations to the modeling and prediction of atmospheric dynamics.

III. The Helmholtz system of equations and its consequences (1858)

For ease of application to meteorological data, it is convenient to choose a Cartesian coordinate system tangent to the earth surface, and co-rotating with the earth: the x-y plane coincides with a hypothetical sea-surface, with the y-axis pointing northward*, the x-axis pointing* eastward *and the z-axis pointing* upward*. If $\boldsymbol{V}$ is the velocity vector relative to this local co-rotating frame, the corresponding acceleration is*

$$\frac{D\boldsymbol{V}}{Dt} = -\frac{1}{\rho}\,\mathrm{grad}\,p - 2[\boldsymbol{\Omega}\times\boldsymbol{V}] - \mathrm{grad}\,\phi + \boldsymbol{F}$$

Here, $\boldsymbol{\Omega}$ is the earth's rotation vector ($|\boldsymbol{\Omega}| = 7.29\times 10^{-5} rad/sec$); ϕ is the geopotential *= sum of the terrestrial Newtonian gravitational potential and the centrifugal potential, and is equal to a constant at standard sea level. Within the first several hundred km above sea level, the surfaces of constant ϕ are sufficiently spherical and $\Delta\phi = \boldsymbol{g} - \boldsymbol{\Omega}\times(\boldsymbol{\Omega}\times\boldsymbol{r})$ is sufficiently uniform that for purposes of atmospheric dynamics the earth may be considered to be a sphere of constant radius a (6370 km) and ϕ can be set equal to gz, where g is constant and z is height above sea-level. Spherical coordinates λ (eastward longitude), Θ (latitude), and $r = a + z$ can thus be used with little error. $\boldsymbol{F}$ represents friction per unit mass (and any additional forces, if needed) that is caused by* molecular viscosity *of the air and* eddy stresses *due to vortex motions.*
The first term on the r.h.s. of the above equation derives from the pressure gradient, where ρ is the density of the air. The second term is the Coriolis acceleration*, which causes only a* change of direction *of the moving air relative to the ground.*
Denoting the local Cartesian components of the air velocity by $\boldsymbol{V}(u,v,w)$, we have

$$-2[\boldsymbol{\Omega}\times\boldsymbol{V}] = 2(v\Omega_z - w\Omega_y)\boldsymbol{e_x} + 2(w\Omega_x - u\Omega_z)\boldsymbol{e_y} + 2(u\Omega_y - v\Omega_x)\boldsymbol{e_z}$$

with

$$\Omega_z = \Omega\sin\Theta, \quad \Omega_y = \Omega\cos\Theta, \quad \Omega_x = 0$$

Therefore, the above Helmholtz equation decomposes into the three scalar equations:

$$\frac{Du}{Dt} = \frac{\partial u}{\partial t} + \left(u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial y} + w\frac{\partial u}{\partial z}\right) = 2\Omega(v\sin\Theta - w\cos\Theta) - \frac{1}{\rho}\frac{\partial p}{\partial x} + F_x$$

$$\frac{Dv}{Dt} = \frac{\partial v}{\partial t} + \left(u\frac{\partial v}{\partial x} + v\frac{\partial v}{\partial y} + w\frac{\partial v}{\partial z}\right) = -2\Omega u\sin\Theta - \frac{1}{\rho}\frac{\partial p}{\partial y} + F_y$$

$$\frac{Dw}{Dt} = \frac{\partial w}{\partial t} + \left(u\frac{\partial w}{\partial x} + v\frac{\partial w}{\partial y} + w\frac{\partial w}{\partial z}\right) = 2\Omega u\cos\Theta - \frac{1}{\rho}\frac{\partial p}{\partial z} - g + F_z$$

In 1858 ***Helmholtz*** *began the study of the complete set of hydrodynamical equations as a possible means of dealing with meteorological problems. It comprised a system of 6 partial differential equations involving the six unknown functions: temperature, pressure, density, and 3 components of particle velocity. The form of these equations is such that their solution is determined* for all time *by the values of all 6 variables at a single* instant *and at every point in the atmosphere.*

For large-scale motions *of the atmosphere* relative to the earth, *various terms in Newton's second law can be neglected. In particular, since* vertical accelerations *are very much less than the gravitational acceleration, the gravitational acceleration is almost exactly balanced by the acceleration due to the atmosphere's buoyancy.*

Thus, for meteorological purposes, it is permissible to treat the atmosphere as if it were always in a state of local vertical hydrostatic equilibrium. *Next, owing to the large horizontal scale of weather disturbances, it turns out that the* horizontal *components of the force of internal viscosity (due to the molecular transfer of momentum) are also negligible, when compared with the Coriolis and horizontal pressure-gradient forces.*

Moreover, although the horizontal accelerations of air are not *negligible, there is a tendency for the Coriolis and horizontal pressure-gradient forces to balance each other. Thus, the approximate form of the equations of motion that are generally employed in the analysis of meteorological problems is*

$$\frac{Du}{Dt} - fv + \frac{1}{\rho}\frac{\partial p}{\partial x} = 0,$$

$$\frac{Dv}{Dt} + fu + \frac{1}{\rho}\frac{\partial p}{\partial x} = 0,$$

$$\frac{\partial p}{\partial z} + g\rho = 0$$

where $\boldsymbol{v}(u, v)$ *is the horizontal velocity field,* $f = 2\Omega \sin \Theta$, Θ *is latitude,* p *is the pressure,* ρ *the density and* Ω *is the angular velocity of the earth's rotation*[513]*. To the above equations, we add the equation of continuity (local conservation of mass):*

$$\frac{\partial \rho}{\partial t} + \mathrm{div}(\rho \boldsymbol{V}) = 0.$$

The last of the physical principles essential to the theory of dynamic weather prediction are the ideal gas law (equation of state) and the first law of thermodynamics for adiabatic non-viscous flow, through which the temperature, pressure and specific volume of a moving air-mass may change without addition of heat energy.

These processes are governed by the two equations

$$p\alpha = RT, \qquad \frac{D}{Dt}\left\{ T \left(\frac{p_0}{p} \right)^k \right\} = 0,$$

where α *is air volume per mole,* R *the universal gas constant,* T *is the absolute temperature (°K),* $k = R/C_p$, C_p = *specific heat at constant pressure, and* p_0 *is some fiducial pressure.*

In all, there are 6 equations in 6 variables. Although the system is complete, it remains to be investigated whether or not it is determinate. If heat is being added to and transported in the atmosphere through physical processes of absorption, radiation, condensation, and eddy heat conduction, the last equation is modified into the general expression for non-adiabatic flow

$$\frac{d\theta}{dt} = \frac{\theta}{C_p T} \frac{dq}{dt},$$

where

$$\theta = T \left(\frac{p_0}{p} \right)^k$$

is known as potential temperature, and $\frac{dq}{dt}$ *is the rate at which heat is added to a unit mass of air.*

In local Cartesian coordinates (x, y, z)*, the horizontal gradient of* $p(x, y, z)$ *for any fixed level* z *is denoted by*

$$\nabla_z p = \boldsymbol{e}_x \left(\frac{\partial p}{\partial x} \right)_z + \boldsymbol{e}_y \left(\frac{\partial p}{\partial y} \right)_z.$$

---

513 Since $\boldsymbol{V} \approx \boldsymbol{e}_z \times \frac{1}{\rho f} \nabla p$, this '*geostrophic wind*' *relationship shows that winds tend to blow parallel to the isobars.*

However, on a given (fixed) isobar, we can define

$$\nabla_p z = \boldsymbol{e}_x \left(\frac{\partial z}{\partial x}\right)_p + \boldsymbol{e}_y \left(\frac{\partial z}{\partial y}\right)_p,$$

where $z = z(x, y; p)$, *for a fixed pressure* p, *is the equation of the isobaric surface itself. Since* $\frac{\partial p}{\partial z} = -g\rho$, *it follows that* $\left(\frac{\partial z}{\partial p}\right)_{x,y} = -\frac{1}{g\rho}$, *and hence*

$$\frac{1}{\rho}\nabla_z p = g\nabla_p z.$$

Consequently, the geostrophic wind relationship takes the form

$$\boldsymbol{e}_z \times f\boldsymbol{V} + g\nabla_p z \approx 0.$$

Differentiating this equation w.r.t. p *and making use of the vertical hydrostatic equation and the ideal-gas equation of state, one obtains*

$$\boldsymbol{e}_z \times f\frac{\partial \boldsymbol{V}}{\partial p} \approx \nabla_p \left(\frac{1}{\rho}\right) = \beta\frac{R}{p}\nabla_p T,$$

where β *is the number of atmospheric-composition moles per unit atmospheric mass.*

This equation, known as the thermal-wind equation, *tells us that* horizontal temperature gradients *induce pressure gradients that in turn produce* change in the local geostrophic wind (with height and across isobars).

This variation of flow 'blows' parallel to the mean isothermals

$$f\frac{\partial \boldsymbol{V}}{\partial p} \approx \beta\frac{R}{p}\nabla_p T \times \boldsymbol{e}_z$$

with low temperatures to the right of the flow variation $\frac{\partial \boldsymbol{V}}{\partial p}$ *(i.e. to the left of* $\frac{\partial \boldsymbol{V}}{\partial z}$*) in the Northern Hemisphere, and its magnitude proportional to the thermal gradient in the layer.*

Thus, high-level isobars depend not only on the pattern of sea-level isobars, but also on the horizontal temperature distribution. This situation will arise when cold and warm air lie alongside each other [as they do in a frontal system, and in general wherever polar and sub-tropical air meet]. The thermal wind must then be added vectorially to the geostrophic wind.

In principle, the above system of equations (including the inertia term deviations from the approximate geostrophic wind relationship) provides the basis for a mathematical system of weather forecasting; *the problem is essentially one of integrating a system of partial differential equations, starting* *with known initial conditions. At this point in the history of science (1858), meteorology was thus finally put on equal footing with astronomy, where the positions of suns, planets, and satellites are predicted from Newton's equations of motion.*

However, the interest in the equations of dynamic meteorology in 1858 *was somewhat premature; in the first place, the equations are too difficult to solve. In mathematical terms, the difficulty is one of solving a general boundary and initial-value problem for a simultaneous system of* 6 *non-linear partial differential equations in* 3 *dimensions. Even today, there are no known methods by which the solution of such equations can be related explicitly to general boundary and initial conditions.*

With exact analytical methods failing, the most satisfactory course would have been to solve the equations by purely numerical methods. These, however, were not fully developed until early in the 20^{th} *century, and in any case, would have required enormous computational power.*

Caught between two complementary difficulties, several generations of dynamical meteorologists were forced to tailor their problems to fit their limited mathematical means — i.e., to introduce such approximations and simplifications into the equations as were necessary to make them amenable to known methods of exact mathematical analysis. It is not surprising that the solutions of the approximate equations reflected little of the actual meteorological behavior of the atmosphere.

The second, and more important, obstacle to early development of dynamical weather prediction was the lack of adequate data; Before the turn of the 20^{th} *century, the main source of meteorological data was a rather loose network of surface observation stations, with only scattered and spasmodic kite and tethered-balloon soundings through the lower troposphere.*

With the advantage of long hindsight, it is easy to see that the dynamical meteorologist of that day did not really know what kind of phenomena he had to explain, *and could not fully test any theory that he might propose to account for the behavior of large-scale weather disturbances (which as we now know, extend through great depths of the atmosphere). He had no direct way of checking his assumptions, either by preliminary estimate or by verification of their mathematical consequences. To some extent, although upper-air observations are now much more frequent, more dense, and more accurate, and extend to higher altitudes, the meteorologist is still confronted by the problem of inadequate data.*

The first concerted attack on the problem of dynamical weather prediction was begun by the Norwegian (Bergen) school of frontal meteorology, led by **Vilhelm Bjerkens** *(1862–1951) and continued by* **Jacob Bjerkens** *(fils;*

1897–1975). Their outstanding achievement was to build a bridge between classical hydrodynamics and thermodynamics, which brought the atmosphere and the oceans within the scope of those two disciplines and opened up the field of applications for the quantitative treatment of motion on various scales in the atmosphere and the oceans.

Building on Helmholtz's theoretical foundations, the Norwegian school addressed the problem of general circulation of the atmosphere and carried out a systematic study of idealized mathematical models, directed toward the classification of atmospheric motions and their identification with the solutions of linearized forms of the hydrodynamic equations. But although their work contributed to our understanding of the kinds *of phenomena occurring in the atmosphere, they still failed to find a satisfactory formulation to the central problem of weather prediction.*

One of the turning points in the development of dynamic weather prediction was the meteorologists' realization that the general hydrodynamical equations could be solved in principle by purely numerical methods. *The form of these equations is such that the* instantaneous local time derivative *of each variable can be expressed in terms of* space derivatives *of variables in the same set.*

Accordingly, if we observe the initial values of all variables *at a network of discrete points,* filling the entire atmosphere, *we can approximate the relevant space derivatives by the method of finite differences and* compute the initial rates of spatial change of each variables. *Knowing the initial value* and *initial spatial rate of change of each variable, we can then extrapolate its value over a very short interval of time at each point in the network. Finally, we regard this very short-range forecast as a new set of initial data and repeat the process. Thus, it is possible (in principle) to build up a prediction scheme over any desired period of time as a series of successive forecasts over very short intervals of time.*

This possibility occurred first to ***Lewis Fry Richardson*** *(1881–1953), a highly original applied mathematician who also had a lively interest in the new finite-difference methods. Richardson's experiment failed, however, for reasons which became clear only in the late* 40*'s. Richardson himself estimated that it would take about* 64,000 *human computers just to predict weather as fast as it happened, let alone gain on nature. This figure was alarming enough that no one had the courage or enthusiasm to repeat his calculations under more closely controlled conditions, and interest in dynamical weather prediction withered and lay dormant for almost* 20 *years.*

The study of the atmospheric sciences has conventionally been divided into two main subject areas: meteorology and climatology.

Meteorology seeks to analyze, explain and ultimately to predict atmospheric processes and their behavior over *time*. It is the science of the atmosphere, and thus the science of the *weather*.

Climatology endeavors to document, analyze and explain the variations of meteorological processes with geography and on a number of time-scales, as related to the human environment. The *climate* of a particular place is an abstraction; it is a statistical generalization for the place rather than an actual reality, for it is misleading in most cases to assume that the climate of a place is simply its 'average weather'.

For many locations, particularly in temperate latitudes, the average weather is rarely the weather that is experienced at any given time. The weather systems which determine the climate of a locality are governed by many interactions and complex feedback processes involving the underlying surface (whether land, sea, snow, ice, mountains, forest or cities), and the overlying atmosphere, with its variable winds and clouds. All these elements and their interactions vary with time; climatic variability about the average state is therefore only to be expected. This variability is the very essence of the climate. It is thus preferable to consider a climate as being the integration of the spectrum of weather, likely to be experienced over time at a particular place.

Traditionally, meteorology has tended to be taught and studied in a university department of physics and mathematics, where students are familiar with the laws of radiation, thermodynamics and hydrodynamics. Because of the spatial and environmental aspects of climatology, the subjects has tended to be taught in university departments of geography, where it is studied as a component of physical environment.

The division between the two branches of the atmospheric sciences is now fading. A climate can only be understood in terms of meteorological mechanisms, no matter what the spatial and temporal scales. Climatology in its modern form can be looked upon perhaps as *spatial long-term meteorology* on a variety of spatial scales (global, regional and local) and time periods..

Moreover, there is a growing interest in the interaction of man and his climatic environment. Climatic extremes such as drought, floods, storms, frosts, fogs and blizzards have economic repercussions for industry, transport, agriculture, tourism and health. Increases in global concentrations of carbon dioxide, sulfur – and nitrogen oxides and methane, depletion of stratospheric *ozone* levels, and the regional problems of *acid rain* may also have serious and fully understood consequences for man's well-being (contributions to global warming, global dimming, etc.), while the nightmare possibility of the *nuclear winter* is one scientific experiment which must never be tested.

Linked to these two developments is the study of climate change. *This may operate on a variety of temporal scales, and the problems of understanding and modeling the meteorological and complex feedback processes in the earth-atmosphere-ocean system, together with the documentation of past climatic changes, represent some of the most important areas of climatological research today.*

The general circulation of the atmosphere manifests itself in the persistent easterly (from the east) wind belt of the trade winds in the tropics, and the prevailing westerly wind belt of temperate latitudes. Apart from long-term fluctuations, this is a constant arrangement, indicating an underlying order in the general pattern of circulation of the global atmosphere. The general circulation can be considered as the long-period average circulation of the atmosphere, free from all but the largest-scale seasonal trends of airflow. It is this which determines the patterns of world climate *and their main characteristics.*

Nevertheless, major climatic anomalies *perturb the world's weather from time to time. One of these is the* El-Niño *syndrome — the largest disturbance oceanographers and meteorologists have recognized in the planet's weather patterns. El-Niño (Spanish for "The Child", because it usually appears off the coast of Peru around Christmas time) is a heat wave in the Pacific, coupled with heavier than usual rainfall in the western portions of the Americas. Some recent occasions were in 1965, 1972, 1982–3, 1986–8. The opposite configuration is termed La-Niña; both seem to have become more frequent as of recent decades.*

Sometimes before the onset of El-Niño, the trade winds stop blowing, or even reverse themselves and blow from west to east.

Then, the warm water piled up off the coast of Asia, sloshes back to the Americas (trade winds, by blowing from east to west, normally heap up surface water on the eastern shores of the Pacific Ocean. Sea level near New Guinea and the Philippines is several feet higher than near Peru.) It spreads out over the Eastern Pacific, creating a ceiling of hot water some 150 *meters thick. When this happens, the cold, nutrient-rich waters from the bottom cannot penetrate the hot layer and are sealed in. The hot surface waters warm the air above them, preventing the trade winds from reasserting themselves. In a long chain reaction, the disruption of the atmosphere above the Pacific sets off a series of storms and droughts elsewhere.*

Thus, the El-Niño of 1982–3 *signaled vast changes in the atmosphere's global circulation, – alterations that made for strange weather around the world; there were torrential storms in parts of Ecuador, Bolivia, Brazil, and Peru — some desert regions got* 4000 *mm of rain. In the United States, there were huge storms and rains along the West Coast, and even in Florida —*

causing more than \$ 1 billion in property damage, and killing at least 100 *people. The tranquil island of Tahiti, which had not seen a single typhoon earlier in the century, was struck by one after another. Meanwhile, in Southern Africa, perturbations of the global weather, coming after two dry years, contributed to the terrible drought that has devastated Botswana, and also led to droughts in Indonesia, India, Sri Lanka, and Australia.*

The underlying causes of the El-Niño are not completely understood yet. It is known, however, that average global temperatures have risen about $0.5\,^\circ C$ *since* 1880. *The year* 1987 *was the warmest, on average, around the globe in the* 100*-year record of instrumentally recorded temperatures. The recent warming surge since* 1965 *is pushing the earth to temperatures that rival the warmest since the last ice age.*

1922, Nov 04 CE Discovery of the tomb of Egyptian Pharaoh **Tutankhamen** in Valley of the Kings near Thebes by archaeologist **Howard Carter** (1873–1939, England). Inside he found an abundance of ancient Egyptian artifacts that have laid untouched since 1342 BCE.

Tutankhamen died at the age of 19 in 1352 BCE.

1922 CE The mathematicians **Oswald Veblen** (1880–1960, U.S.A.) and **Luther Pfahler Eisenhart** (1876–1965, U.S.A.) generalized Levi-Civita's parallelism into *displacement* and the concept of geodesic into *path* in a non-Riemannian geometry, and established the 'geometry of paths'.

1922 CE **Louis Joel Mordell** (1888–1972, England). Pure mathematician. Proved important theorems in number theory. Conjectured[514] (1922)

---

[514] Mordell's conjecture is actually more general: Let K be an algebraic number field and let C be a nonsingular projective curve over K with genus $g \geq 2$. The set of points on C which are K-rational (that is, have coordinates in K) is necessarily finite. If this turns out to be true [taking K = field of rationals and the Fermat curve $x^n + y^n + z^n = 0$, with $n \geq 4$], then there would be only finitely many such solutions in rational numbers, or equivalently, in integers. Since C is projective, (x, y, z) and $(\lambda x, \lambda y, \lambda z)$ are identified $(\lambda \in K)$.
A simple example of a Diophantine equation with finite number of solutions was found by W. Ljunggrens (1942): $x^2 + 1 = 2y^4$ has *exactly* two solutions

$$(x, y) = (1, 1);\ (239, 13).$$

that if, for some $n > 2$, the equation $x^n + y^n = z^n$ has a solution in nonzero integers [with (x, y, z) mutually prime], then it has at *most* finitely many such solutions for that value of n [proved in 1983 by **G. Faltings** (Germany)].

Mordell was born in Philadelphia of Jewish Lithuanian parents who had emigrated to the U.S. in 1881. His father, Phineas Mordell (1861–1934) was a Hebrew grammarian and scholar. In 1906 Louis went to St. John's College, Cambridge, where he graduated in 1912. He was a professor of pure mathematics at the Universities of Manchester (1923–1945) and Cambridge (1945–1958).

1922–1924 CE **Alexandr Alexandrovich Friedmann** (1888–1925, Russia). Applied mathematician and meteorologist. Showed that **Einstein**'s field equations of general relativity admit *non-static* solutions with isotropic and homogeneous matter distributions, corresponding to an expanding universe. His solution was the first to postulate the 'big-bang' cosmology.

Friedmann was born in St. Petersburg to a Jewish family. He entered the university of his native city in 1906 and obtained his master degree in applied mathematics in 1914. He took part in WWI (1914–1918) in an aviation detachment and participated in military flights. During 1918–1922 he did research in the field of theoretical meteorology at the physics laboratory of the U.S.S.R. Academy of Sciences. He died of typhoid fever at the age of 37.

1922–1928 CE **Philo Taylor Farnsworth** (1906–1971, USA). Invented electronic television. Farnsworth was a 16-year-old Mormon boy from Rugby, Idaho, with virtually no knowledge of electronics when he first sketched his idea for electronic video system on a blackboard for his high-school science teacher in 1922. He successfully displayed his first TV picture on Sept 07, 1927, and soon after patented the idea at a tender age of 21. He then successfully fought off the combined might of one of the largest corporations, RCA, and its massive team of lawyers and finally won the battle. The whole of RCA's research effort — at an expense that cost more than $50 million — was intended to circumvent Farnsworth patents[515]. Unfortunately, RCA

---

515 In 1923, Zworykin *applied* for a patent. In 1927, Farnsworth produced the first successful transmission of a television image by wholly electronic means — and Zworykin application was still pending. Farnsworth's patent #1,773,980 was issued in August 1930 — and Zworykin's application was *still* pending. In fact, the 1923 Zworykin application would be all but forgotten — except that a patent was finally issued in 1938 — a long fifteen years after the original application, and then only after many modifications has been made to the original application. Furthermore, the eventual patent on the 1923 application — #2,141,059 was issued by a court, not the patent office. In the end, RCA was forced to pay

managed to maneuver its way around the patents and effectively degraded Farnsworth's status to that of 'just another contributor' in the field.

Born in Beaver, Utah, Farnsworth was educated in the Utah and Idaho public school system. He attended high school at Provo (1923) and enrolled in Brigham Young University (1924) but left it at the end of his second year due to the death of his father. In 1926 he joined the Crocker Research Laboratories in San Francisco. Farnsworth's basic television patents covered scanning, focusing, synchronizing, contrast, controls, and power. When he died at age 64, he held more than 300 U.S. and foreign patents[516].

1922–1932 CE **Stefan Banach** (1892–1945, Poland). Mathematician. One of the founders of modern functional analysis, and among the developers of the theory of topological vector spaces. Utilizing concepts of **Riesz**, he introduced the notion of *complete* normed linear spaces, whose elements need not be defined with respect to the complex number field. These are now called '*Banach spaces*'. The spaces named after **Hilbert** are special

---

royalties to Farnsworth for the Image Dissector.

Zworykin did not have a clue how to create a high-resolution television signal by wholly electronic means until he visited Farnsworth's lab in 1930. As soon as he saw what Farnsworth had achieved, he got busy, not only duplicating Farnsworth's equipment, but using all the might of RCA to claim Farnsworth's achievement for his own. He failed in that effort and RCA was left with no choice but to accept a patent license from Farnsworth in 1939. At the end, however, Zworykin created the standards on which television was based.

[516] One of his patents, known today as the *Farnsworth-Hirsch Fusor*,is a device for producing nuclear fusion reactions which has since become a practical *neutron-source*, and is produced commercially for this role.

In the late 1950's and early 1960's Farnsworth was adapting an earlier device of his, connected with his television work, thus arriving at his fusion reactor. **Robert Hirsch** worked an Farnsworth's development team in the mid 1960's and made significant contributions to the device, which was patented in June 1966.

A deuterium gas is introduced into a high vacuum chamber. An accelerating voltage of several kV is high enough to cause the deuterium (electron orbiting a nucleus containing a proton and a neutron) nuclei to fuse, thus producing free neutrons. Farnsworth and Hirsch could obtain a neutron flux up to 10^{12} neutron/sec. Although hopes were high that it could be developed into a practical power source, later experiments that intended to turn it into a generator have failed.

The resulting neutrons are cheaper and lighter than standard ones and therefore could find applications in material science, nuclear research and medicine.

cases of normed linear spaces whose norm has the parallelogram property $\|x+y\|^2 + \|x-y\|^2 = 2\|x\|^2 + 2\|y\|^2$.

Banach contributed to the theory of orthogonal series and made innovations in the theory of measure and integration. His major publication is his book *Théorie des Opérations linéaires* (1932). His textbook *Mechanics*[517] (1938) is among the best treatises ever written on this subject.

Banach was born at Kraków. He started his academic career as a lecturer in mathematics at the Lwów Polytechnic Institute (1919), and became a full professor in 1927.

1922–1941 CE **Oleg Vladimirovich Losev**[518] (1903–1942, Russia). A self-taught radio engineer and inventor. Pioneer of semiconductor electronics: first to discover (1927) that semiconductor junctions emit light[519] (what we now know as LED) and first to foresee its use in telecommunications[520]. His observations languished for half a century before being recognized in the late 20^{th} and early 21^{th} century. In addition, Losev developed novel kinds of

[520] In February 1907, **Henry J. Round** (1881–1966), one of Marconi's assistants in England, published a 24-line note in *Electrical World* reporting a "bright glow" from a carborundum diode. There was no follow-up publication, and apparently this small note was not known to Losev. It is not appropriate to credit Round with the invention of LED, but he should be recognized as the discoverer of the phenomenon of electroluminescence. In 1962, four research groups in the U.S. simultaneously reported a functioning LED semiconductor laser based on gallium arsenide crystals, thus opening the field of solid-state optoelectronics.

crystal radio sets (with new crystals he fabricated himself) and was the first to study the effects of bias voltage upon the functioning of crystal diodes in circuits, essentially discovering "*negative resistance*" before the tunneling diode, as well as a pre-ATT version of the transistor and associated amplifiers. He then constructed completely solid-state radios that function up to 5 MHz, a quarter century before the transistor (1956).

Losev was born in Nizhniy to a high-ranking family in imperial Russia and served as a captain in the Czarist military. He received no formal education but during the span of his short research career he published 43 papers in leading Russian, British and German research journals and was granted 16 patents, of which he was the sole author.

In the mid 1920s Losev observed light emission from zinc oxide and silicon carbide crystal rectifier used in radio receivers when a current was passed through them. Losev's first paper on the emission of silicon carbide diodes, entitled "Luminous carborundum [silicon carbide] detector and detection with crystals," was published in 1927 by the journal *Telegrafiya i Telefoniya bez Provodov* (*Wireless Telegraphy and Telephony*) in Nizhniy Novgorod, Russia. Important publications in British and German journals soon followed. In his first paper on the LED, Losev established the current threshold for the onset of light emission from the point contact between a metal wire and a silicon carbide crystal, and recorded the spectrum of this light. In the 16 papers published between 1924 and 1930 he provided a comprehensive study of the LED and outlined its applications. Losev understood the 'cold' (non-thermal) nature of the emission, measured its current threshold, recognized that LED emission is related to diode action and measured the current-voltage characteristics of the device in detail. He also studied the temperature dependence of the emission down to the temperature of liquefied air (a predominantly nitrogen-based mixture of gases used at the time) and modulated the LED emission up to the frequency of 78.5 kHz by applying an a.c. current to the contact.

Most remarkably for a young technician with no academic qualifications, Losev was acutely aware of many contemporary developments in physics. He used Einstein's quantum theory to explain the action of the LED and called the emission process the "inverse photo-electric effect." In addition, he proposed a formula relating the voltage drop on the diode contact, V, the electronic charge, e, and the light emission frequency, ν, through Planck's constant, h, that is $\nu = eV/h$. The formula is still in use to this day. Despite the fact that semiconductor band theory had not yet been fully developed, Losev was able to relate the effect in silicon carbide to the diffraction of the electron de Broglie matter waves. According to the prominent Russian physicist Abram Ioffe, Losev wrote to Einstein asking him for help in further developing the theory, but received no reply.

In 1929, Losev published detailed measurements of LED spectra and clearly observed their dependence on current. It is incredibly interesting to see this data now, with the hindsight that the narrowing of the spectrum is evidence of laser action: the 1962 reports of laser action in gallium-arsenide-based diodes were underpinned by such spectral measurements. Did Losev see, without understanding its importance, coherent laser radiation from an LED in 1929? Perhaps not, but remarkably, the first significant blue LEDs reinvented at the start of the 1990s used silicon carbide.

Losev was the first to understand the potential of the LED for telecommunications. In the introduction to his patent entitled 'Light Relay', which was filed in 1927 and granted on 31 December 1929, he wrote: "The proposed invention uses the known phenomenon of luminescence of a carborundum detector and consists of the use of such a detector in an optical relay for the purpose of fast telegraphic and telephone communication, transmission of images and other applications when a light luminescence contact point is used as the light source connected directly to a circuit of modulated current." Unknown and uncelebrated, this should have been the beginning of the photonic telecommunication revolution.

Losev was a lonely scientist who left no disciples and never had a co-author. Being born into the noble family of a Russian Imperial Army officer was not exactly a good starting point in Bolshevik Russia, where people of such descent were banned from the career ladder. A self-made scientist who attended a few university courses but never formally completed his education, Losev was eventually awarded a PhD without a formal thesis by the Ioffe Institute in 1938. The happiest and most productive years of his research work were spent at the Nizhniy Novgorod Radio Laboratory before he moved to Leningrad where, after years of hardship, he eventually found himself a position as a humble technician at the Leningrad Medical Institute. According to Losev's recently discovered autobiography, he was nevertheless able to continue his research in Leningrad. He discovered that "using semiconductors, a tree-terminal system may be constructed analogous to a [vacuum] triode". However, in November 1941 he was unable to pass the finished paper (presumably on an important silicon device) from the besieged city of Leningrad to the evacuated editorial office of the *Soviet Physics JETP* (now *Journal of Experimental and Theoretical Physics*) in Kazan. Was it a paper on what we now know as a transistor? We shall never know for certain unless his manuscript is found. Sadly, after he passed away in Leningrad during World War II, his name was simply forgotten. In the difficult years that followed nobody took the opportunity to propagate his knowledge or follow up the potential revealed by his discoveries.

1922–1942 CE **Enrico Fermi** (1901–1954, Italy and U.S.A.). Distinguished physicist. One of the chief architects of the nuclear age. Developed the correct quantum-mechanical statistics for a class of subatomic particles, discovered neutron-induced radioactivity and directed the first controlled nuclear chain-reaction in the framework of the *Manhattan Project*[521]. He was awarded the 1938 Nobel prize for physics.

In 1922, Fermi generalized and extended the concepts of parallel vector transport and geodetic coordinates. His constructions are known today as 'Fermi transport' and 'Fermi coordinates', respectively.

In 1926 he was first to develop a quantum-mechanical treatment of a gas obeying the Pauli exclusion principle ('*Fermi-Dirac statistics*). The class of particles obeying these statistics are known as 'fermions', in his honor. In 1933, Fermi suggested for the first time the existence of the *weak interactions* in the theory of beta decay, and coined the name '*neutrino*' ("little neutral one").

Bombarding many elements with neutrons, Fermi showed in 1934 that slow thermal neutrons are very effective in producing radioactive elements. He presumed them (erroneously) to be heavier than uranium, not realizing that he had actually split the atom. This work was taken up by **Otto Hahn** at Berlin, who by 1937 had claimed the preparation of several trans-uranic elements with atomic numbers ranging from 93 to 96. However, **Frèdèric Joliot** (1900–1958, France) and **Irène Joliot-Curie** (1897–1956), working in Paris in 1938, pointed out that the radioactive characteristics of the substances produced by bombarding uranium with neutrons resemble those of much lighter radioactive elements. They further showed in 1939 that the fission of uranium produces

[521] Among the many stories told about Fermi, the following is most instructive: Enlisting in the Manhattan nuclear weapon project, the newly arrived immigrant was brought face-to-face with U.S. flag officers. On being told that so-and-so is a great general, Fermi asked for the definition of a 'great general'. "A general who won many battles", he was told. "How many", Fermi continued to ask. They settled on five. "What fraction of American generals are great", asked Fermi again. The officers agreed on a few percent. Fermi was totally unimpressed and explained why: Assume that there is no such thing as a great general, that all armies are equally matched, and that winning a battle is purely a matter of chance, like flipping an unbiased coin. Then the chance of winning five consecutive battles is 1/32 which is about 3 percent. On the other hand, the chance of winning ten consecutive battles is 1/1024, which is about 0.1 percent. So few percent of American generals are *expected* to win five consecutive battles, purely by chance, and that does not make them *great*! Now, has any of them won *ten* consecutive battles..?

neutrons, which under suitable circumstances, could cause further fission in other atoms in their vicinity.

Fermi designed the first atomic piles and produced the first nuclear chain reaction in 1942. He later worked on the atomic bomb project at Los Alamos, NM. After WWII, he pioneered in research on high energy physics.

Fermi was born in Rome. He studied at the University of Rome and received a doctor's degree from the University of Pisa in 1922. He became a professor of theoretical physics at the University of Rome in 1926.

Fermi left Italy in 1938 to escape the Fascist regime, and settled in the United States. He became a professor of physics at Columbia University in 1939. He then moved to the University of Chicago as a professor of physics in 1942. Element number 100 was named after him (fermium).

1922–1964 CE **Leo Szilard**[522] (1898–1964, Hungary, Germany and USA). Physicist, biophysicist, inventor and "scientist of conscience". A most creative, versatile and practical scientist, and politically far-sighted. A key-figure in the birth of the nuclear age — "The man behind the Bomb".

Pioneered in the development of nuclear energy. Szilard's ideas included *modern information theory*[523], *electromagnetic pump* for refrigeration (with Einstein), the *linear accelerator*, *cyclotron*, *electron microscope*, *nuclear chain-reaction*, *isotope separation*, *chemostat*. He was instrumental in establishing the *Manhattan Project*, but at the same time insisted that scientists accept moral responsibility for the consequence of their work.

Born Leo Spitz[524] in Budapest to an assimilated Jewish family. Young Szilard grew up with no personal religious beliefs or traditions. Yet from

[522] For further reading, see:

- Lanouette, W., *Genius in the Shadows*, University of Chicago Press, 1992, 587 pp.

[523] Some 30 years ahead of **Claude E. Shannon**, Szilard (1922) linked the concepts of *information* and *entropy*. In 1947, **John von Neumann** reconsidered Szilard's ideas and later urged Shannon to use the term"entropy" in his work. By the early 1950's, around Columbia University, Szilard also discussed his information-entropy ideas with physicist **Léon Brillouin**. Szilard did not seek to tie his early insights to later commercial developments. Not until the 1970s and 1980s, however, did Szilard's role in information theory gain the attention of a wider scientific community.

[524] In 1900, his father **Louis Spitz**, a prosperous building contractor, changed his name to **Szilard**, yielding to growing government pressure for the magyarization of foreign-sounding names. In Hungarian, Szilard means "solid".

his mother he did acquire a strongly held ethical views, abstract ideals such as honesty and loyalty, independence of mind and defiance of social conventions. He escaped from Hungary (1919) to study engineering at the Technical Institute in Berlin. He transferred (1920) to the physics department of the University of Berlin, where he studied under physicists **Max Planck**, **Max von Laue**, **James Franck** and **Albert Einstein**. His thesis, under von Laue (1922), became a cornerstone of modern information theory. Filed a patent with Einstein (1927) for an electromagnetic pump, which became the basis of cooling systems in "breeder" nuclear reactors in the 1950's and 1960's.

A refugee in England (1933–1938), he turned to nuclear physics, seeking the element which would yield a nuclear chain-reaction and lead to atomic power and bombs. Developed the idea of a nuclear "chain-reaction" (1933; patented 1934) and the concept of "critical mass" to create it.

With **T.A. Chalmers**, developed (1934) first method of separating isotopes of artificial radioactive elements.

Szilard came to the US in 1938 and collaborated with Fermi to design the first nuclear reactor at Columbia University (1939). Early in 1939 (after the discovery of Uranium fission in Germany) prompted, with **Wigner**, Einstein's letter to President Roosevelt warning him of atomic weapons — an alert that led to the creation of the *Manhattan Project* to develop A-bombs.

With Fermi (1942), he put at Chicago into operation the world's first chain-reaction atomic "pile" (reactor) of their design.

Szilard became a central figure in the Manhattan Project, and after WWII became a strong proponent of the peaceful uses of atomic energy. He then turned to biology, developed the chemostat and theories of aging and of memory and recall. He died at La Jolla, California.

Worldview XXXIX: Szilard

* * *

"An expert is a man who knows what cannot be done."

* * *

"If you want to succeed in the world you don't have to be much cleverer than other people; you just have to be one day earlier..."

* * *

"Here in America you are expected to keep busy all the time - it does not matter so much what you are doing as long as you are doing it fast."

* * *

"In our society, there is a market for skills and knowledge. But I have some doubts if there is much of a market for wisdom."

* * *

"A university runs on the happiness of the faculty: see that they are well paid, that their offices are comfortable, their graduate assistants are bright and eager, and that the faculty club food is appetizing. Then you will have a first-rate university."

* * *

"That is not how my brain works. I have no idea where my thought come from and no control over where they go"

(As he refused to sign an agreement that his inventions were 'General Atomic' property)

* * *

"Logical thinking and an analytical ability are necessary attributes to a scientist, but they are far from sufficient for creative work. Those insights in science which have led to a breakthrough were not logically derived from preexisting knowledge; the creative process on which the progress of science is based operate on the level of the subconscious."

* * *

"There were those who would never forgive me for being right."

On Szilard

* * *

"During a long life among scientists, I have met no one with more imagination and originality, with more independence of thought and opinion".

(Eugene Wigner)

* * *

"If the uranium project could have been run on ideas alone, no one but Leo Szilard would have been needed".

(Eugene Wigner)

* * *

"The only secrets then, worth protecting were not in government files but solely in the minds of "enemy aliens" Fermi and Szilard".

(William Lanouette)

[Refereeing to U.S. military security report (1940) on Szilard, recommending to discontinue his work on the A-bomb for being an enemy agent]

* * *

"What he had to say was always of profound and original kind".

(Erwin Schrödinger)

* * *

"Szilard belongs to the group of people who, through their richness of ideas, create an intellectual environment for others".

Albert Einstein

* * *

" Exotically original, versatile, and innovative intellect. A very rare example of a man, because of his combination of great purely scientific acumen and his ability to immerse himself in and solve technical problems".

(Paul Ehrenfest)

* * *

"Szilard was as generous with his ideas as a Maori chief with his wives."

(Jacques Monod)

1923 CE **Johannes Nicolaus Brönsted** (1879–1947, Denmark). Chemist. Professor at Copenhagen (1908–1947). Developed (with **T.M. Lowry**) a theory of acids and bases[525] (1923); suggested that acids give up a hydrogen ion in a solution and that bases accept a hydrogen ion in a solution, virtually the modern concept of acids and bases. It is known as the *donor-acceptor theory* and is especially useful for reactions in aqueous solutions. It is widely used in medicine and the biological sciences.

According to the theory an *acid* is a proton donor, H^+, and a *base* is defined as a proton acceptor. These definitions are sufficiently broad that any hydrogen-containing molecule or ion capable of releasing one or more protons, H^+, is an acid, whereas any molecule or ion that can accept a proton (or several) is a base. An acid-base reaction is the transfer of a proton from an acid to a base.[526]

Brönsted and Lowry presented logical extensions of the **Arrhenius** theory: H^+ ions in water are not bare ions but exist as $H^+(H_2O)_n$ in which n is a small number (due to *hydrogen bonds*). This is because of the attraction of the H^+ ions (protons) to the oxygen end of the water molecule. Indeed, when two water molecules collide, the collision sometimes results in *auto-protolysis*, creating a *hydronium*

$$H_3O^+ \sim H\text{—}\ddot{\underset{\underset{\displaystyle H}{|}}{O}}\text{—}H^+ \sim H^+(H_2O)$$

and a hydroxide:

$$2H_2O \rightleftharpoons H_3O^+ + OH^-.$$

For example, the complete ionization of hydrogen chloride, HCl (a *strong* acid) in water, is an acid-base reaction in which water acts as a base (a proton acceptor):

---

525 The history of this concept goes back to **Robert Boyle** (1680) who noted that acids dissolve many substances, change the colors of some natural dyes and lose their characteristic properties when mixed with alkalis (bases). By 1814, **Gay-Lussac** concluded that acids *neutralize* bases and that the two classes of substances should be defined in terms of their reaction with each other.

In 1844 **Svante Arrhenius** presented his theory of base reactions. In his view *acid* is a substance that contains hydrogen and produces H^+ in aqueous solution. A *base* is a substance that contains the OH group and produces hydroxide ions, OH^-, in aqueous solution. *Neutralization* is defined as a combination of H^+ ions with OH^- ions to form H_2O molecules.

526 However, another definition by **Lewis** holds that a base *donates* electron pairs (*Lewis base*), while an acid accepts electron pairs (*Lewis acid*).

$$\begin{array}{rll} \text{Step 1:} & \text{HCl (aq)} \rightarrow \text{H}^+ \text{ (aq)} + \text{Cl}^- \text{ (aq)} & \text{(Arrhenius description)} \\ \text{Step 2:} & \text{H}^+ + \text{H}_2\text{O} \rightarrow \text{H}_3\text{O}^+ & \\ \hline \text{Overall:} & \text{HCl (aq)} + \text{H}_2\text{O} \rightarrow \text{H}_3\text{O}^+ + \text{Cl}^- \text{ (aq)} & \end{array}$$

Due to this reaction, every liter of pure neutral water at STP has 10^{-7} mol[527] of protons in the form of hydronium, counterbalanced by 10^{-7} mol of OH^-. This is responsible for the *electrical conductivity* of pure water. When the water is not pure it may become more conductive due to the presence of ions.

1923, Sept 01 CE *Earthquake* destroys Yokohama, Japan and much of Tokyo; over 140,000 perish in the quake and its subsequent fire.

The industrial society of the 20th century made earthquakes more hazardous, mainly by gathering more people into cities[528].

1923–1928 CE **Juan de la Cierva Codorniu** (1896–1936, Spain). Aeronautical engineer. Invented the first successful *Autogiro*, forerunner of the helicopter. This aircraft was first flown in 1923. In 1928, Cierva piloted an Autogiro across the English Channel.

Autogiro is a type of heavier-than air craft that is supported in the air by a rotor instead of by fixed wings, as an airplane is. The rotor spins by itself *freely* as it passes through the air. The Autogiro's engine rotates a propeller on the front of the fuselage.

In contradistinction to the *helicopter*, which always has its rotor revolve by an engine, an autogiro must run along the ground before the rotors can revolve fast enough to lift it. While flying, the rotor is disconnected from the engine, but the blades continue to revolve because of the air pressure against them. Thus, while the nose propeller pulls the plane forward, the generated air stream creates a lift force on the rotor blades. The blades are *hinged* at their hubs and made slightly flexible; the advancing blades thus yield to the air pressure and rise, while the retreating blades flap downward against the rise. The tilt of the rotor blades can be controlled, in order to turn the craft in a desired direction.

1923–1929 CE **Vladimir Kosma Zworykin** (1889–1982, Russia and U.S.A.). Physicist, electronic engineer and inventor. Invented the *iconoscope*, the first television transmission tube [an electronic tube that converts

527 We say that the pH of pure water is 7, where $\text{pH} = -\log[\text{H}^+]$.

528 In a sparsely settled rural areas, huge release of energy may harm few. The New Madrid earthquakes of Dec 16, 1811 – Feb 07, 1812 were strong enough to reshape the landscape, alter the course of the Mississippi and cause damage hundreds kilometers away from the epicenter. Yet but a few lives were lost.

light rays into electric signals and acts as a television camera suitable for broadcasting] and the *kinescope* [the picture tube used in television receivers].

He was also largely responsible for developing and perfecting the *electron microscope* (1939).

Zworykin was born in Murom, 320 km east of Moscow. He studied at the St. Petersburg Institute of Technology. There he came under the influence of **Boris Rosing**, a professor who was trying in 1910 to transmit pictures by wire in his own laboratory employing a mechanical disc scanner in the transmitter and the primitive K. F. Braun cathode ray tube in the receiver.

After graduation (1912), Zworykin went to College de France in Paris where he studied X-rays under **Paul Langevin**. With the Russian Revolution, Rosing went into exile and died. Zworykin carried on his work: he left for the United States (1919) and soon joined the staff of the Westinghouse laboratory in Pittsburgh. In 1923 he demonstrated his scanner before officials at Westinghouse, but the company did not find his system worthy of investment.

He continued to perfect it and after using a key idea of **Farnsworth** (1930), demonstrated his *all electronic* television system to the Institute of Radio Engineers. In attendance was **David Sarnoff** who hired Zworykin to develop his commercial television system for RCA. By 1933 a complete electronic system was being employed with a resolution of 240 lines, Zworykin's television system provided the impetus for the development of modern television as an entertainment and educational medium.

He also developed a *color-television* system (1928) and made innovations in the *electron microscope*. His electron image tube, sensitive to infrared light, was the basis for the *sniperscope* and the *snooperscope*, devices first used in WWII for seeing in the dark. His *secondary-emission multiplier* was used in the *scintillation counter*, one of the most sensitive radiation detectors.

In later life Zworykin lamented the way television had been abused to titillate and trivialize subjects rather that being used for the educational and cultural enrichment of audiences.

The Advent of Television

Black-and-white television camera (iconoscope) utilizes the cinematographic projection principle; a picture rate of at least 25 *frames per second* *produces the visual impression of a continuous motion: The image is divided into a large number of "picture elements". This means that the picture is divided into a number of lines (say, 625), and each line must contain several hundred individually identifiable light values. This is known as* scanning. *To obtain a reasonably good picture, the image must be thus analyzed into at least* 200,000 *picture elements.*

In the television camera the image is focused on a plate called the signal plate whose surface is covered with a mosaic of photosensitive elements. Each of these points, corresponding to one picture element, acquires a positive electric charge whose magnitude depends on the strength of the illumination falling on it. An electron beam, forming a scanning spot on the signal plate, zig-zags its way, line by line, across the plate every $\frac{1}{25}$ *second and thus* discharges *each photosensitive point* 25 *times per second. Each point thus gives an electric impulse whose strength corresponds to the strength of illumination at that point at that particular instant. These impulses (forming the picture signal) are amplified and transmitted.*

In the television receiver, *the incoming impulses, after amplification, are fed to the control electrode of the picture tube* (cathode ray tube), *in which an electron beam is zig-zagged across a fluorescent screen synchronously with the beam in the camera tube and with an intensity varying with the strength of the incoming electric impulses. In this way a pattern of luminous points of varying brightness, and formed in rapid succession, is produced on the screen, thus making the picture that the viewer sees.*

The picture signal can be conveyed to the receiver by cable or by wireless broadcasting of high-frequency short waves. These signals are only able to travel in straight paths from the transmitter, so that, because of the earth's curvature the range is limited to the visual horizon. It is for this reason that television transmitters are installed on tall masts or towers, which have to be spaced about 75 km *apart in order to provide good television coverage throughout the region*[529].

1923–1929 CE **Hermann Julius Oberth** (1894–1989, Romania and Germany). Among the three pioneering progenitors of the modern space age.

[529] At the turn of the 21st century, commercial television broadcasts *via satellites* are widely being used.

Published *The Rocket into Interplanetary Space* in 1923. In this book, Oberth discussed many technical problems of space flight. He even described what a spaceship should look like.

Interest in Oberth's book in Germany led to the formation of the *German Society for Space Travel*. The members of this society helped develop the first successful guided missile during WWII. In 1924 Oberth published his second book, *Way to Space Travel* (Wege zur Raumschiffahrt).

Oberth was born in Sibiu, on the northern slopes of the Transylvania Alps (now in Romania). After serving in the German medical corps in WWI, he graduated in physics and astronomy from Heidelberg University. His preoccupation with spaceships and space-travel problems was not appreciated by his peers and he spent most of his scientific career as a university teacher in Romania. During WWII he was distrusted by the Nazis and was not permitted to do serious work in Peenemuenda.

After the war he was arrested by the Americans, together with **Werner von Braun** and **Walter R. Dornberger**. But while the latter were moved to the U.S.A. to help develop American space rockets, Oberth was ignored, despite his potential theoretical capabilities. Yet, when new theoretical problems hindered the development of the big rockets at Huntsville, Alabama, Oberth was rushed there. He returned to West Germany in 1958.

1923–1947 CE **Victor Moritz Goldschmidt** (1888–1947, Norway and England). A pioneer geochemist. Justly called the *father of geochemistry*. Devoted most of his professional life to an attempt to find the laws underlying the frequency and distribution of the various chemical elements in the earth. His discovery of the fundamental relationship between crystal structure and chemical constitution laid the foundation of crystal chemistry. He was first to predict the formation of specific minerals from specific combinations of elements and geological conditions.

Goldschmidt was born in Zürich, a son of a distinguished physical chemist. In 1905 he moved with his family to Oslo. After studying geology, mineralogy and chemistry at Oslo, he was appointed full professor and director of the Minerological Institute (1914). In 1929 he accepted a similar appointment at Göttingen, Germany. As a Jew, he was forced to resign shortly after the Nazis came to power. He was immediately granted a chair at Oslo but became a refugee when the Germans invaded Norway. He escaped to England, where he spent most of the remainder of his life.

1923–1955 CE **Francesco Giacomo Tricomi** (1897–1978, Italy and USA). Applied mathematician. Contributed to the theories of differential and integral equations, *functional transforms*, special functions, probability theory and its applications to number theory. Certain equations[530] and special functions are named after him.

Tricomi studied at the University of Bologna, then at the University of Naples. Prior to WWII he held academic appointments at the universities of Padua, Rome, Florence and Torino.

In 1946 Tricomi joined the *Bateman-project* team (headed by **Arthur Erdelyi** at the California Institute of Technology). He returned to Torino (1950) and continued to work there on various topics of applied mathematics.

1924 CE **Ethel Browne Harvey** (1885–1965, U.S.A.). Biologist and embryologist whose studies of *induction* preceded those of Nobel laureate **Hans Spemann** (1935) by more than 10 years. An investigator at Princeton University for 25 years, she was never made a full professor.

Harvey, working on the mechanics of embryologic development, was first to discover the directive function (embryonic induction) of certain tissues.

1924 CE **Paul Marsh Ramey**[531] (b. 1896, United States). Inventor and electrical engineer. Invented and completely worked out the signal transmission method of *Pulse Code Modulation* (PCM). It is the basics of digital audio and used in voice transmission and reproduction. This ground-breaking work was then apparently forgotten. The idea was reinvented (1939) by **A.H. Reeves** (1902–1971; England), forgotten again and finally resurrected during WWII by the Bell Labs during a research into the method of encoding phone conversation.

Modulation, in communication, is a process in which some characteristic of a wave (the carrier wave) such as: amplitude, frequency or phase, is made to vary in accordance with an information-bearing signal wave (the modulating wave); *demodulation* is the inverse process by which the original signal is recovered from the modulated wave. The original, unmodulated wave may be of any kind, such as sound or, most often, electromagnetic radiation including

---

[530] He studied (1923) the equation $y\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$ now known as the '*Tricomi equation*'. This equation became important in describing an object moving at supersonic speed, but in 1923 there were no supersonic aircraft yet.

[531] The **Ramey** (Remi, Remy) family tree goes back to a tribe in Gaul (Northern France and Belgium). The family was represented in French history by Bishop Saint Remi of Rheims (437–533). A millennium later, Jacques Remy (b. 1547) became a Hugenot and was killed, and so was his son Pierre. Pierre's son, Jacques fled to England and them emigrated to Virginia (1654), establishing the Remy-Ramey branch in North America.

optical waves. When the carrier is a train of regularly recurrent pulses, PCM ensues.

The modulation, in this case, might vary the amplitude (PAM = Pulse Amplitude Modulation), the duration of the pulse (PDM = Pulse Duration Modulation) or the presence of the pulses (PCM). PCM can be used to send digital data[532]; (audio signals on a *compact disc* use pulse code modulation). PCM is the most important form of pulse modulation because it can be used to transmit information over long distances with very little interference or distortion. For this reason it has become increasingly important in the transmission of data in the space program and between computers. Although PCM transmits digital instead of analog signals, the modulating wave-train is continuous.

1924 CE First circumnavigation of the globe by four United States Army airplanes.

1924 CE **Louis Victor de Broglie** (1892–1987, France). Distinguished physicist. Expressed the idea of general *wave-particle dualism* and attributed, for the first time, wave qualities to material particles. This was the final synthesis of the 300-year old debate that started in the days of **Newton** and **Huygens**.

Broglie was led by two trains of thought to this assumption:

(1) An interpretation of Bohr's stationary state of the atom in terms of *standing waves* of discrete vibrational states, like those of a string or a drum but with *azimuthal* sinusoidal variation (for circular orbits).

(2) The application of the basic Planck energy relation $E = h\nu$ to *material particles* as well as to photons. By using special relativity, this becomes the covariant relation $p^\mu = \hbar k^\mu$, where $\hbar = \frac{h}{2\pi}$, $p^\mu = (E, \boldsymbol{p}c)$ is the particle four-momentum, and $k^\mu = (\omega, \boldsymbol{k}c)$ is the wave 4-vector.

[532] The input is sampled periodically at a rate of 8000 times per second for telephone systems (8 bit) and at a rate of 44,000 times a second for audio CD (16 bit). Shannon's sampling criterion (which state that the sampling frequency must at least be double the highest frequency to be transmitted) has been taken into account. Since digitizing assigns a specific (binary) number for any input amplitude, and only a given number of amplitudes are available (e.g. 256 for 8-bit digitizing of phone conversations), chances are that the assigned number will be a little too big or a little too low compared to the actual input. This creates an *error* called *quantization error*, producing *quantization noise* at the output. To partially remedy this situation, digitization values are assigned closer together for long signal levels.

This idea led him to associate with a particle of mass m a wave $\exp\{i(\omega t - \boldsymbol{k}\cdot\boldsymbol{x})\}$, with the *de Broglie wavelength* $\lambda = \frac{h}{p}$, where $p = |\boldsymbol{p}|$ is the particle's momentum. These matter-waves satisfy the uncertainty principle, and *possess a phase velocity* $u = \frac{\omega}{k} = \frac{E}{p}$, where $E = \sqrt{m^2c^4 + p^2c^2}$. Here u exceeds c, but is dispersive; hence (just as in an electromagnetic waveguide), the *group-velocity* of a wave-packet of average momentum p, is $\boldsymbol{V}_g = \frac{d\omega(\boldsymbol{k})}{d\boldsymbol{k}} = \frac{\boldsymbol{p}c^2}{E}$, the correct relativistic *particle* velocity.

Thus, although the crucial Schrödinger equation and *probabilistic interpretation* are still lacking in de Broglie's matter-wave theory, it already contains much of the machinery of the nascent quantum mechanics. For the non-relativistic regime, one obtains

$$\lambda = \frac{h}{p} = \frac{h}{mv}.$$

The theoretical predictions of de Broglie were verified through the first experiments of electron diffraction by **Clinton Joseph Davisson** (1881–1958, U.S.A.), **Lester Halbert Germer** (1896–1971, U.S.A.) and **G.P. Thomson** in 1927. These diffraction patterns are completely analogous to the X-ray diffraction patterns of **von Laue**.

From electron diffraction measurements with crystal lattices of known lattice constants, the wavelength of the material waves corresponding to a beam of electrons may be determined. For electrons having velocity v after being accelerated through a potential difference V, one uses $eV = \frac{1}{2}mv^2$ and $\lambda = \frac{h}{mv}$ to obtain $\lambda_e = \frac{12.3}{\sqrt{V}}\ \mathring{A}$, where V is measured in volts. For example, an electron which has passed through a potential increase of 10,000 volts has a wavelength of 0.12 $\mathring{A}$, corresponding to hard X-rays.

De Broglie was born in Diepp [his grandfather, Albert, was prime minister of France in 1877]. He was educated in Paris, became a professor of theoretical physics at the Sorbonne in 1928 and won the Nobel prize for physics in 1929.

Broglie is the name of a noble French family which emigrated to France from Italy in 1643. The head of the family, Francois Marie (1611–1656), took the title of comte de Broglie. He distinguished himself as a soldier and died as a general at the siege of Valenza. During the next 200 years, members of this family served as marshals of France, statesmen, diplomats and cabinet members.

The development of quantum theory in France was aborted by de Broglie, despite his personal contribution to this theory in its early stages[533].

[533] **S.P. Novikov**, Amer. Math. Soc. Trans. (2) vol. **212**, 2004.

1924 CE **Satyendra Nath Bose** (1894–1974, India). Physicist. First investigated the statistics of identical and indistinguishable particles that are *not* restricted by the exclusion principle[534]. This yielded the quantum theory of the ideal gas (following the classical statistical thermodynamics of **Boltzmann**, with the sole change being the counting rule for microscopic states).

Bose gave a new derivation of Planck's radiation formula, divesting it of all supererogatory elements of electromagnetic theory and basing it on the bare essentials[535]. Together with Einstein[536] he established the new quantum

---

534 A principle unknown to Bose at that time (Pauli, 1925).

535 His derivation rests on replacing the *counting of wave frequencies* by the *counting of cells in one-particle phase space*. Bose's theory assumed a spin value of 1 for the light quanta (photon), at a time when the concept of the photon spin had not yet been established (!). In all, Bose made three bold assumptions (actually, shots in the dark) which later proved to be correct: photon number *nonconservation*, statistical independence of cells (not particles!) and the removal of Boltzmann's axiom of distinguishability.

536 Maxwell-Boltzmann statistics gives the probability distributions for systems of distinguishable particles that are well described by the laws of classical Newtonian physics. However, when the quantum nature of the particles becomes important (such as at high enough densities or low enough temperatures), other types of statistics must be used.

Quantum systems of indistinguishable, identical particles are distributed differently depending on whether only one particle can be put into each state (fermions) or there is no such limitations (bosons). *Bose-Einstein statistics* are derived for indistinguishable, identical particles of *integral spin angular momentum quantum number*, s (particles called *bosons* for which $s = 0, 1, \dots .$) Examples of bosons include photons, ^{4}He atoms and Cooper electron pairs. The *Bose-Einstein distribution function* is $f(E) = \frac{1}{e^{\alpha}e^{E/kT}-1}$, where $\alpha = 0$ if the total number of particles is not conserved within the overall closed system (such as photons in a cavity in blackbody radiation). For systems having a constant total number of particles, α decreases to zero as the temperature is lowered. Near a particular low temperature, this behavior causes the particles to drop rapidly into the ground energy level. This "condensation" of particles is called *Bose-Einstein condensates (BEC)* and is part of the explanation for *superfluidity* (zero viscosity) of liquid helium, for BEC and for *superconductivity*.

Another "particle" that follows the Bose-Einstein statistics is the *phonon*, which is the quantum of energy of the mechanical vibrational mode of a solid-state lattice (actually a *quasiparticle* as it can exist only in solid lattice crystals). Since the total number of phonons is not conserved we have $e^{\alpha} = 1$. It then follows directly from the expression for $f(E)$ that the average number of phonons per lattice vibration mode (energy state), for frequencies that are much less than statistics, known thereafter as the Bose-Einstein statistics. It is one of two known ways in which a collection of indistinguishable particles may occupy a set of available discrete energy states. Aggregation of particles in the same state, characteristic of particles obeying Bose-Einstein statistics, accounts for the coherent streaming of laser light and the frictionless creeping of superfluid helium as well as for the novel optical and acoustical properties of *Bose-Einstein Condensates* (BEC).

Bose was born in Calcutta, India, and was educated there. He sent his 1924 paper to the *Philosophical Magazine*. It was rejected, and Bose sent it to **Einstein**, asking him to consider it. Einstein personally translated it into German and submitted it to the *Zeitschrift für Physik*.

1924–1926 CE **Edward Victor Appleton** (1892–1965, England). Physicist. Explorer of the ionosphere. Discovered that the upper layer of the ionosphere, called the F-region or *Appleton layer*, reflects radio waves. The discovery established the possibility of radio communication over long distances, and was also fundamental to the development of radar. He was awarded the Nobel Prize for physics (1947) for his discovery.

Appleton was born in Branford and matriculated at the University of London at the age of 16. He was trained at St. John's College, Cambridge and studied under J.J. Thomson and Rutherford. Since 1919 he devoted himself to scientific problems in atmospheric physics, using mainly radio waves. In 1924 Appleton began a series of experiments which proved the existence of a reflecting layer in the upper atmosphere. By periodically varying the frequency of the BBC transmitter at Bournemouth and measuring the intensity of the received transmission 100 km away, Appleton found that there was a regular fading in and fading out of the signals at night but that this effect diminished considerable at dawn as the *Kennely – Heaviside layer* broke up.

Radio waves continued to be reflected by the atmosphere during the day but by a higher-level ionized layer. By 1926 this layer (250 km above the earth's surface — the first distance measurement made by means of radio) became generally known as the *Appleton layer*.

Appleton was involved in the initial work on the atom bomb.

$\left(\frac{k}{h}\right)T$, is proportional to the temperature. At the other extreme (low temperatures), the average number of phonons per energy state will be proportional to $e^{-h\nu/kT}$.

1924–1929 CE **Hans Berger** (1873–1941, Germany). Psychiatrist. Recorded the first human electro-encephalogram (EEG). Discoverer of the electric activity of the human brain[537].

Electroencephalography (EEG) uses electrodes (made of lead, zinc, platinum, etc.) attached to the intact skull and connected to an oscillograph. The result is a visual picture of brain wave rhythms. Berger made seventy-three EEG recordings from his fifteen-years-old son, Klaus. The first frequency he encountered was the 10-hertz range, (8 to 12 Hz) which at first was called the Berger rhythm, currently called *Alpha* rhythm brain wave. After five years of investigation and re-examination of his results, he published his findings.

He reported that the brain generates electrical impulses or 'brain waves'. The brain waves changed dramatically if the subject simply shifts from sitting quietly with eyes closed (short or alpha waves) to sitting quietly with eyes opened (long or beta waves). Furthermore, brain waves also changed when the subject sat quietly with eyes closed, "focusing" on solving a math problem (beta waves). That is, the electrical brain wave pattern shifts with attention. The publication of Hans Berger's "On the Electroencephalogram of Man" in 1929 changed neurophysiology forever. Hans Berger thus earned recognition as the "Father of Electroencephalography".

Berger was born in Neuses, Thüringia, Germany. Received his M.D (1897) from the University of Jena and in 1919 was appointed to the chair of psychiatry and neurology. He was rector of the University (1927–1928) and professor (1935–1938). He retired in 1938 and committed suicide in 1941.

After his findings were confirmed, the electroencephalogram was launched into use for the study of normal and abnormal human brain activity. The EEG revolutionized neurological and psychiatric diagnosis and made possible specialized research in the neurological sciences. Today, the EEG is used in

---

[537] In developing electroencephalography, Berger was fully aware that **Richard Caton** (1842–1926), a Liverpool surgeon, had succeeded in 1875 in measuring electrical potentials on the exposed cortex of experimental animals (rabbit and monkey), and that he was thus the discoverer of the electrical activity of the brain. Berger also knew about the further successes along this line achieved by the Polish physiologist **Adolf Beck** (1863–1939) in 1891, and of the findings of Russian workers. In 1912 a paper by the Russian physiologist **Pravdich-Neminski** (1879–1952) for the first time illustrated a photographic record of the electrical activity of the brain. He called it an "electrocerebrogram". Pravdich-Neminski's electrocerebrogram was recorded from dogs with intact skulls by means of the string galvanometer (**Willem Einthoven**, 1860–1927). Having suffered many setbacks in his experiments, Berger's reaction to this demonstration was that he should work harder.

the clinical diagnosis of serious head injuries, brain tumors, cerebral infections, epilepsy, and various degenerative diseases of the nervous system.

1924–1929 CE **Edwin Powell Hubble** (1889–1953, U.S.A.). Astronomer. Provided the first conclusive observational evidence for the expansion of the universe, thus confirming the Friedmann-Lemaître solution of the Einstein field equations of general relativity (1929). Founder of extragalactic astronomy (1924).

Hubble was born in Marshfield, MO. At the University of Chicago he earned undergraduate degrees in mathematics and astronomy, and was inspired by the astronomer **George E. Hale** (1910). However, he turned away from astronomy and athletics (he was a fine boxer too), preferring to continue the study law at Oxford University. In 1913 he joined the Kentucky bar, but soon abandoned his law practice and returned to continue the study of astronomy at the University of Chicago and its Yerkes Observatory. He obtained his Ph.D. in astronomy in 1917, and then served in WWI before settling down to work at the Mount Wilson Observatory.

During 1922–1924 he centered his research on extragalactic phenomena, and discovered that not all nebulae in the sky are part of the Milky Way Galaxy, the vast star system to which the sun belongs. He found that certain nebulae contain stars called Cepheid variables, for which a correlation was already known to exist between periodicity and absolute magnitude.

Using the further relationship among distance, apparent magnitude, and absolute magnitude, Hubble determined that these Cepheids are several hundred thousand light-years away, and thus outside the Milky Way system, and that the nebulae in which they are located are actually galaxies distinct from the Milky Way.

This discovery, announced in 1924, forced astronomers to revise their ideas about the cosmos. He thus settled the *Shapley-Curtis* debate once and for all: the universe was recognized to be far larger and populated with far bigger objects than anyone had seriously imagined — the realm of the galaxies.

Soon after discovering the existence of these external galaxies, Hubble undertook the task of classifying them according to their shapes (1926) and exploring their stellar contents and brightness patterns. In studying the galaxies Hubble made his second remarkable discovery — namely, that these galaxies are apparently receding from ours, and that the further away they are, the faster they are receding (1927).

The implications of this discovery were immense: the universe, long considered static, was expanding. Even more remarkably, Hubble discovered in

1929, from observations of *spectral redshift* of starlight[538], that the universe was expanding in such a way that the ratio of the speed of a galaxy to its distance from us is nearly a constant (*Hubble's law*). This constant is now called

---

[538] A distant galaxy emits light that astronomers later (in today's epoch) detect on Earth. As the light travels through expanding space toward our Galaxy, its wavelengths are steadily stretched. Finally, the light enters a telescope, and the astronomers compare its spectrum with the spectra of other sources of light in the laboratory and within our Galaxy, and in this way they measure the amount of redshift. Invoking the *cosmological principle*, they assume that the light-emitting atoms in the distant galaxy are identical to the corresponding atoms in our Galaxy. The amount of redshift detected depends on how much the universe has expanded between the time of emission and the time of reception. The redshift applies to the whole spectrum, extending from radio waves to visible light to X-rays, and when one wavelength is doubled, all wavelengths are doubled in the spectrum of the source.

The *cosmic redshift* is best interpreted as a result of the expansion of space in the framework of GTR. Although the frequency shifts are in agreement with a Special-Relativistic Big Bang model for low redshifts $\left(z = \frac{\Delta\nu}{\nu} \ll 1\right)$, the frequency of light is also affected by the gravitational field (and attendant spacetime curvature) of the universe, and it is not strictly correct to interpret the frequency shifts of light from very distant sources in terms of a special-relativistic Doppler effect alone (i.e., the frequency shift is not *wholly* the result of a relative motion in Minkowski spacetime that results in an STR Doppler redshift). Distances between locally-comoving galaxies in an expanding homogeneous universe are proportional to the metric scale factor $R(t)$.

The locally-measured wavelength λ of a ray of light traveling in extragalactic space varies as $R(t)$ (in the adiabatic approximation), t being the epoch — the standard cosmological time (i.e. proper time since the Big Bang, as reckoned by a comoving local frame) at the observing creatures' galaxy. If λ_0 is the present (detected) wavelength and $R(t_0) = R_0$ the value of the scaling factor at the present epoch, then $\frac{\lambda}{\lambda_0} = \frac{R(t)}{R(t_0)}$, where t, λ are, respectively, the *epoch* at which the light was emitted and its *wavelength* as reckoned in the locally-Minkowskian coordinate system comoving with its galaxy of origin. *Redshift* is defined by $z = \frac{\lambda_0 - \lambda}{\lambda}$, and hence the cosmic redshift is $z = \frac{R(t_0)}{R(t)} - 1$.

Assuming that $(t_0 - t)$ is small, we may Taylor-expand $R(t)$ to find $R(t) = R_0 - \dot{R}_0(t_0 - t) + \cdots$, where $\dot{R}_0$ denotes the derivative of R w.r.t. time, calculated at $t = t_0$. It then follows that $z = \frac{\dot{R}_0}{R_0}(t_0 - t) + \cdots$. We also have approximately, for the *comoving coordinate of radial distance* r, $R_0 r = c(t_0 - t) + \cdots$. (In this comoving coordinate system $r =$ const. for an average galaxy, ignoring intra-cluster "peculiar" motions.)

Hubble's constant, H. Derived from theoretical considerations and confirmed by observations, most astronomers believe the velocity-distance law has made secure the concept of an expanding universe. (There are nonlinear GTR corrections to the Hubble law at large redshifts.) It is not really a constant, since it varies with the epoch.

Hubble's original value for H in our present epoch was 150 km per second per 1,000,000 light-years. Modern estimates, using more precise distance measurements, place the value of H between 15 and 30 km per second per 1,000,000 light-years. The reciprocal of Hubble's constant thus lies between 10 billion and 20 billion years, and this cosmic time scale serves as an approximate measure of the age of the universe. More precisely, $H = \dot{R}(t)/R(t)$ and as $R(t) \sim t^{2/3}$ in today's nearly flat, matter-dominated universe (it has been thus since $t \approx t_0/10^3$), $H \approx \frac{2}{3t}$; so, the current age of the universe as tallied by a co-moving clock in our local galaxy cluster is estimated at $t \approx \frac{2}{3H}$.

Measurements in the 1990's, utilizing tools such as the Hubble Space Telescope and certain types of well-understood supernova explosions (replacing the old Cepheid-variable stars as a distance yardstick to remote galaxies), have narrowed the range of values considerably, and the age of the universe is now thought to be about 14 billion years.

Whether in its Newtonian, STR or GTR form, Hubble's law implies that, on average, the universe and its evolution are seen to be independent of the galaxy in which the observer happens to reside.

Since for small values of $\frac{v}{c}$ (c is the velocity of light in empty space, v is the velocity of the receding source of light relative to the observer) we can write $z = \frac{\lambda_0}{\lambda} - 1 \approx \frac{v}{c}$ from the known STR Doppler formula, the relation $v = cz = HR_0r$ embodies Hubble's experimental results. Thus, $z \approx \frac{\dot{R}_0}{R_0}(t_0 - t) \approx \frac{\dot{R}_0}{R_0}\frac{R_0 r}{c}$ implies $cz \approx \frac{\dot{R}_0}{R_0} \cdot R_0 r$, which in turn yields $H = \frac{\dot{R}_0}{R_0}$ ($R_0 r$ is the approximate *Euclidean* distance from observer to the location of the emitting object at the time of emission).

These linear relations, *including* Hubble's law, require nonlinear modifications for z of order 1 and higher. Quasars and many known galaxies have such high z values.

The latest astronomical surveys have pushed the largest observable z values to between 2 and 3 for *discrete* objects. The $2.7\,^\circ$K background radiation has undergone a redshift of order 10^3, since that radiation was emitted in the recombination epoch, when the comoving-frame cosmic average temperature was $T \sim 3000\,^\circ$K. ($T(t)$ scales with $\frac{1}{R(t)}$ and $R(t) \sim t^{2/3}$ in the post-recombination, matter-dominate epoch, so $t_0/t_{\text{recomb}} \sim (10^3)^{3/2}$; with $t_0 \sim 1.4 \times 10^{10}\,y$, $t_{\text{recomb}} \sim 400,000\,y$.)

Thus, the prophetic words of cardinal **Nicolas of Cusa** (1401–1464) and **Blaise Pascal** (1623–1662) were vindicated: "*The fabric of nature has its center everywhere and its circumference nowhere*".

How old is the Universe?

The age of the Universe has been a subject of religious, mythological and scientific importance. On the scientific side, ***Newton****'s guess for the age of the Universe was only a few thousand years.* ***Einstein****, the developer of the General Theory of Relativity, preferred to believe that the Universe was ageless and eternal. However, in 1929, observational evidence proved his fantasy was not to be fulfilled by nature.*

In order to understand this evidence, let's think about how a train sounds to a person standing on the platform. An arriving train emits tones that are higher pitched as the train approaches the listener while a departing train emits tones that get lower pitched as the train recedes from the listener. This change in the observed pitch of the train sounds is called a Doppler shift.

The Doppler shift happens with light as well as with sound. A source of light that is approaching the viewer will seem to have a higher frequency than a source of light that is receding from that viewer. In 1929, observations of distant galaxies showed that the light from distant galaxies behaved as if they were going away from us. If all the distant galaxies are receding from us on the average, that means that the Universe as a whole could be expanding. It could be blowing up like a balloon, retaining the relative *distances of its main "landmarks", on average.*

This is what tells us that the Universe probably does have a finite age; it probably is not eternal and ageless as Einstein wanted to believe.

We know from studies of radioactivity of the earth and nuclear reactions in the sun that our solar system probably formed about 4.5 billions years ago, which means that the universe must be at least twice that old, because before our solar system formed, our Milky Way galaxy had to form, and that probably took several billions years by itself (besides which, our galaxy contains older stars than the sun, in some of which the heavier-than-Lithium atoms comprising the sun were formed).

However, we can't do radioactive dating on distant stars and galaxies. The best we can do is balance a lot of different measurements of the brightness and distance of stars and the red shifting of their light to come up with some ballpark figure. The oldest star clusters whose age we can estimate are about 12 to 15 billions years old.

So it seems safe to estimate that the age of the universe is at least about 15 billion years old, but probably not more than 20 billion years old.

As far as we can tell, the expansion of the universe started from a very hot and dense state. From that state, it mushroomed and evolved into the universe we know today. Cosmologists call that process of expansion the Big Bang *because in some phases, especially in the beginning, the process was rather like an explosion.*

Much of our understanding the Big Bang is gleaned by extrapolating between knowledge of particle physics today, projections from the mathematical models of an expanding universe in general relativity, and astronomical and astrophysical data. The Einstein equations give us a mathematical model for describing how fast the universe would be expanding at what size and time, given the energy densities of matter and radiation at that time. Our estimates of the matter and radiation density of the early universe are based on the ancient light reaching us from the past in our night skies, and what we have learned about elementary particle physics, through theory and experiment.

1924–1930 CE **Frank Plumpton Ramsey** (1903–1930, England). Philosopher, mathematician and economist. Made important contributions to the above-named disciplines. In each case the fields of investigation that he opened came to be extensively developed only some thirty years after his death. In mathematics he established a pair of theorems about infinite sets which gave rise to an extensive new field, subsequently called 'Ramsey theory'. He is also known for translating Wittgenstein's *Tractatus* into English (1922).

1924–1935 CE **Pavel Sergeevich Alexandrov** (1896–1982, USSR). Mathematician. Contributed to the development of *algebraic topology* (as founded by Poincaré) and created a homological theory of dimension.

1924–1936 CE *The Vienna Circle* (*Wiener Kreis*): A philosophical movement active during the period between the two World Wars; brought together a group of *Logical Positivists*, led by **Moritz Schlick**[539] (1882–1936). The majority were scientists and mathematicians uninterested in metaphysical problems as such.

Leading figures in the Vienna Circle were: **Otto Neurath** (1882–1945); **Rudolf Carnap** (1891–1970); **Richard von Mises** (1883–1953); **Hans Reichenbach** (1891–1953); **Kurt Gödel** (1906–1978) and others. With the rise of Nazism, many of the Vienna group fled Austria and joined the faculties of British or American universities.

According to the Vienna Circle, *Logical Positivism* (alias *Logical Empirism*, *Neo-Positivism* or *Analytic Philosophy*) dethrones all philosophies, except the philosophy of language. It differs from **Comte**'s positivism in holding that all rational doctrines are meaningless. It claims that the unanswerable questions about causality and determinism are unanswerable just because they are not genuine questions at al; What is left for philosophy is the critique of language. Its result is to show that all genuine knowledge about nature can be expressed in a single language common to all sciences; Emphasis was given to the study of the limitations of the true sentences about nature. Thus, any 'necessary truth' was conceived as derivable from a rule of language or mathematics.

Although Wittgenstein (1889–1951) was not a member of the Vienna Circle, his *Tractatus Logico-Philosophicus* (1921) became one of the foundation treatises of Logical Positivism.

The Chemical Structure of Sex Hormones (1927–1935)

The sex hormones, cortisone, cholesterol and vitamin D — all have a 'bee's honeycomb' structure containing 4 *saturated hydrocarbon rings, known as the steroid ring structure.*

The male sex hormones (androgens) are produced in the testes. Of these, testosterone ($C_{19}H_{28}O_2$) *stimulate the development of the secondary male sexual characteristics, such as a deep voice and facial hair. It is converted in*

[539] Assassinated by a Nazi student on the steps of the Vienna University library on June 22, 1936.

the body into androsterone ($C_{19}H_{30}O_2$)*, which is excreted in the urine. Its principal function is to stimulate the development of the male reproductive organs.*

The female sex hormones are formed in the ovaries, It consists of estrogens [estrone ($C_{18}H_{22}O_2$)*; estradiol* ($C_{18}H_{24}O_2$)*; estriol] and progesterone* ($C_{21}H_{30}O_2$).

Estrogens help to develop the secondary female sexual characteristics that take place at puberty, control the menstrual cycle and are active during pregnancy, e.g. estrone is responsible for the cycle of ovulation. Both estradiol and estrone are found in the urine during pregnancy. Progesterone inhibits the release of ova (eggs) from the ovaries and aids in the maintenance of pregnancy. Relatively small quantities of sex hormones are required to instigate a particular activity. A great deal of effort, however, is required to exhibit even small quantities of sex hormones from animal tissues. Only 16 *mg of estradiol can be obtained from* 20 *tons of hog ovaries.*

The road to chemical identification of the sex hormones was opened in 1927 when ***Selmar Aschheim*** *(1878–1965) and* ***Bernhard Zondek*** *(1891–1966), then in Berlin, discovered that the urine of pregnant women contained amounts of the hormone, sufficient to produce sexual heat in mice or rats.* ***Adolf Windaus***[540] *(1876–1959) was asked by a German chemical firm to explore this substance. Involved at the time in the vitamin D research, he elected to turn over the new problem to his student* ***Adolf Butenandt*** *(1903–1995). The student plunged into the task of isolating the hormone. In the meantime* ***Edward Adelbert Doisy*** *(1893–1986, USA), of the ST. Louis University School of Medicine, also set to identify the active substance. Working independently, both Butenandt and Doisy succeeded to isolate the first known sex hormone — estrone. Soon after, Butenandt deduced the correct structure of estrone.*

The discovery and analysis of the male sex hormone testosterone followed a similar pattern. In 1931 Butenandt isolated from 15,000 *liters of male urine,* 15 *milligrams of a hormonal substance which he named androsterone. From his tiny pile of crystals, hardly enough to cover the tip of a small spatula, Butenandt derived a great deal of information about the nature of the molecule. He tentatively deduced its structure, and his deduction was independently proved correct by* ***Leopold Ruzicka*** *(1887–1976) of Zurich, who produced androsterone by splitting off the eight-carbon side chain from a derivative of cholesterol through oxidation.*

---

540 Received the Nobel Prize for chemistry (1928) for studying *sterols* and their connection with vitamins.

Androsterone was obtainable only in very small amounts, either by synthesis or by extraction from urine, but Butenandt, Ruzicka and others soon succeeded in synthesizing a related substance which could be produced in more plentiful yield. This substance, named hydroepiandrosterone, was made from cholesterol by burning off the side chain, while the essential hydroxyl group attached to the first ring and the double bond at the 5, 6 position in the second ring were protected by stable chemical combinations of those positions. With the more plentiful working material at hand, the investigators were able to synthesize a number of interesting products, some of which proved more potent than androsterone in hormonal activity.

Meanwhile ***Ernst Laqueur*** *extracted pure testosterone from bull's testicles. Shortly thereafter, Butenandt and Ruzicka synthesized testosterone from dehydroepiandrosterone. It became clear that testosterone was the true hormone.*

In 1934, four research groups isolated from the corpus luteum tissue in sow ovaries the pregnancy hormone — progesterone. Butenandt obtained 20 *milligrams of the hormone from the ovaries of* 50,000 *sows. The structure of progesterone, very similar to that of testosterone, was soon inferred from its chemical properties and ultraviolet analysis. Butenandt promptly synthesized progesterone by two methods, one of which was the oxidation of a substance called pregnenolone, a by-product of the production of testosterone from cholesterol.*

At this dramatic point in the development of the chemistry of the sex hormones, and after the establishing of the structure of cholesterol (1932), there came a breakthrough in another field which was to open a more fertile route for production of the hormones — a new surge of intensive research on the extraction of hormones from plants.

1924–1939 CE **Walter Andrew Shewhart** (1891–1967, USA). Statistician. Pioneered modern thinking and developed statistical methods for *quality control* of industrial processes, which were subsequently applied to measurement processes in science. To this end he brought together the disciplines of statistics, engineering and economics. His main idea was to use statistics to distinguish between 'legitimate' statistical fluctuations and sub-performances that are more likely to be due to systematic errors such as a faulty machine, under-qualified workers etc. In the sciences, his methods came handy in distinguishing 'suspect' data sets in empirical work.

Shewhart was born in New Canton, Ill. He studied at the universities of Illinois and California, receiving his Ph.D. in Physics from UC Berkeley (1917). Most of his professional career was spent as an engineer at Western Electric (1918–1924) and at Bell Telephone Laboratories (1925–1956).

Shewhart presented a powerful and convincing case for establishing standards of economic quality using a statistical methodology that recognized the importance of achieving and maintaining stability in the processes of production and supply. And he showed how these standards of quality must be *standards by which the consumer may judge the quality of product, and which in themselves represent the goal of the producer*.

In conclusion, Shewhart observed that the engineer always likes to have a goal to attain, and suggests that he and his superiors must have available quantitative equations based on statistical understanding to define standards of economic quality. Shewhart also noted that in the development of productive science and the meeting of human want there is a balance between economic value to the consumer of a development, and the cost to the producer of such a development.

Quality Control

While studying physics ***Shewhart*** *had become inculcated with the concept of the exactness of physical laws, but when he became a practicing engineer with Western Electric he increasingly realized that another, fresher, concept was needed which matched more closely the real world of production and business.*

In May 1924 he presented his concept of a production control chart *which would "give at a glance the greatest amount of accurate information" about an ongoing process and how to ensure that it is maintained in a state of* economic control.

He was thus the first person to identify the vital importance of removing variation from all processes of production of goods and services, while at the same time recognizing that at the human level *this same understanding would inevitably favor those organization that chose to replace win-lose competition with win-win cooperation.*

In his 1931 book on the subject, Economic Control of Quality of Manufactured Product*, he encouraged his readers to ponder the subjects of psychology, philosophy and logic so as to better understand the mechanism by which the mind, its reasoning, and the practical world all work.*

In May 1932 Shewhart was invited to London to present a series of papers at University College where his work received a warmer welcome than in the United States. The English response to Application of Statistical Methods to Industrial Standardization and Quality Control *(1935) stimulated a reawakening of interest in the subject in the US.*

The win-win cooperation is a better strategy *from the point of view of* game theory*: Indeed, before Shewhart, a great part of the thought and interest of management and workmen in manufacturing establishments has been centered upon the proper division of surplus resulting from their joint efforts. The* management *have been looking for as large a* profit *as possible, and the* workers *have been looking to maximize* wages*: the surplus was the balance of selling* price *and the non-payroll* costs *associated with the manufacture of an article sold. From the surplus would come both the workmen's wages and the management's profit; the division of this surplus has generally been the source of most trouble between management and labor.*

Frequently, when management found the selling price going down they have turned toward a cut in wages — toward reducing the workman's share of the surplus — as their way of preserving their profits intact. Gradually the two sides have come to look upon one another as antagonists, and at times even as enemies — putting their strength against each other bargaining, strikes, layoffs etc.

While profit is clearly a prime measure of success of any organization operating in an open market, it is not the only parameter within the complex equation which defines human happiness and which must guide the thinking of engineers and managers alike. There are other, less tangible parameters by which management's efforts must be gauged, such as quality*, satisfaction etc., but profit is the most broadly accepted and therefore most universally useful.*

Yet profit may be seen in two ways. Firstly, it can be the margin by which the grand total cost of supply differs from the market price. Or it can be seen as the margin between the market price and the lowest possible cost of supply. In the first case profit is the seller's margin; in the second it is the buyer's margin.

It was the early telephone that served to drive managements to discover new levels of reliable performance.

In the early part of the 20th century America was pioneering the widespread use of telephony with transcontinental landlines and improving levels *of reliability. Conventional handsets consisted of a few hundred pieces while the switching arrangements between handsets would account for upward of 100,000 separate, but interdependent, parts — undreamed of complexity! Excessive failures of handsets, switching units and buried amplifiers caused by variations in manufacture could not be tolerated if public demand for reliable and instant communication at a distance was to be met.*

When America entered WWII, the demand for war supplies increased greatly and the need for weapons perfection was of paramount importance.

But with the war ended and a massive redirection of industrial capacity from war to peace, the marketplace of the mid-forties shifted from one of national survival to one of a sellers' paradise. The hard work and discipline of designing quality into controlled production dissipated, and the more laissez faire approach of sorting bad quality out from ad hoc *production, or even shipping products regardless of quality, took over. Quantity was now the issue, moving boxes the preoccupation, easy profits the Pyrrhic prize. In the five postwar years until 1950, when this run-down of quality management took place in the US, precisely the opposite was happening in the Far East.*

There are two ways to accept or reject lots of merchandise in a production line:

- Sampling inspection *is a method for protecting the purchaser against poor quality* after *the product has been manufactured. From a consumer point of view, there is a maximum percentage of defectives that he or she will tolerate. This percentage is expressed by p. Clearly, without a 100 percent inspection, it may be impossible to be certain that the quality is better then the level expresses by p. However, the sampling practice arises from the fact that it is often more economical to tolerate small percentages of defectives than to bear the cost of 100 percent inspection. The sampling inspection procedure ensures the quality of the product* with a certain probability.

- Quality control (QC) *is a method of finding and correcting flaws in the* manufacturing process *to ensure that the product meets the standards of the company. After the bugs are ironed out of a production process, its output is stable and is said to be "in control".* Keeping *it in control is a major statistical and engineering task.*

Statistical theory tells us that the proportion of successes $\frac{x}{n}$ will be approximately normally distributed with mean p and standard deviation $\sigma = \sqrt{\frac{pq}{n}}$ (where $q = 1 - p$), if n is sufficiently large. Now, suppose we want to test whether daily percentages of defectives p may be treated as independent trials of an experiment for which p is constant from trial to trial.

One plots a graph of the observed p *vs time (in units of days) and then draws three parallel lines parallel to the time axis at* $\bar{p}+3\sigma,\ \bar{p},\ \bar{p}-3\sigma$ *where* $\bar{p}$ *is the mean of past daily proportions* $\frac{x}{n}$, *and* $\sigma^2 = \frac{1}{n}\bar{p}(1-\bar{p})$.

Now, if the production process behaves in an idealized manner and if the normal approximation to the binomial distribution may be used, the probability that a daily proportion (when plotted on this chart) will fall outside the control band is approximately equal to the probability that a normally-distributed variable will assume a value more than three standard deviations away from its mean, which is calculated to be 0.03.

Because of this small probability, it is reasonable to assume that the production process is no longer behaving properly when a point falls outside the control band; consequently, the production engineer checks over the various steps in the process when this event occurs. Industrial experience shows that only rarely does a production process behave in this idealized manner when the control-chart technique is first applied. Nevertheless, the technique is highly useful because it enables one to discover causes of a lack of control and thus improve on the production process until gradually statistical control *has been obtained.*

Note that a lot of items is sampled according to a scheme guaranteed to reject a good lot with a certain probability α *(supplier's risk), and to accept a defective lot with a certain probability* β *(consumer's risk). A lot is considered under control if the demerit parameter that characterizes its quality (such as* p*) does not* exceed *a certain limiting value and defective if this parameter has a value not* smaller *than another limiting value.*

1924–1940 CE **Wolfgang Pauli** (1900–1958, Switzerland). One of the most influential physicists of the 20^{th} century. Won the Nobel prize for physics in 1945 for his discoveries in quantum theory. His major achievements are:

(1) In 1924 he was first to propose a fourth *spin* quantum number for the specification of the atomic single–electron energy state[541], which may take

[541] The orbital angular momentum is quantized both in *magnitude* and *direction*. In classical physics, the angular momentum $\boldsymbol{L} = \boldsymbol{r} \times \boldsymbol{p}$ of a system relative to the center of a central or contact force is constant in magnitude and direction. In quantum mechanics the magnitude of the orbital angular momentum

is $|\boldsymbol{L}| = \sqrt{\ell(\ell+1)}\ \hbar$ with the quantum number ℓ a non-negative integer. In a nuclear Coulomb field (or that of a nucleus plus closed inner electron shells), for each value of n specifying a single–electron energy level, there are n distinct values of the orbital angular momentum of each electron, from $\ell = 0$ to $\ell = n-1$. The quantum restriction of $\boldsymbol{L}$ shows that the vector $\boldsymbol{L}$ cannot make arbitrary angles with a given direction (the z-direction, say); allowed values of its observed component in the z direction are quantized, $L_z = m_\ell \hbar$. For each value of ℓ, there are $2\ell+1$ values of m_ℓ $(-\ell, -\ell+1, \dots, \ell)$, or $2\ell+1$ different orientations of $\boldsymbol{L}$. It is *impossible* to know exactly more than one component of the angular momentum; i.e. if we know $|\boldsymbol{L}|$ and L_z, our knowledge of L_x and L_y is at best within the uncertainties ΔL_x and ΔL_y such that $(\Delta L_x)(\Delta L_y) \geq \frac{\hbar}{2}|L_z|$. Thus, for given (ℓ, m_ℓ), $\boldsymbol{L}$ points in an unknown direction along a *cone*. Such uncertainty relations follow from $\boldsymbol{L} = \boldsymbol{r} \times \boldsymbol{p}$ and from the position-momentum uncertainty relation.

The so-called *magnetic quantum number* m_ℓ manifests itself when the electron's motion is disturbed by an applied magnetic field (in the z direction, say). Under a magnetic field, each spectral line in a one-electron atom is observed to split into a number of closely spaced lines [1897; **Pieter Zeeman** (1865–1943, Holland)]. The orbital magnetic dipole moment of the electron is $\boldsymbol{M}_L = -\frac{e}{2m_e}\boldsymbol{L}$, which entails $\{M_L\}_z = -\mu_B m_\ell$ where $\mu_B = \frac{e\hbar}{2m_e}$ is the *Bohr magneton.* Thus, when an atom is placed in a weak magnetic field $\boldsymbol{B}$, the interaction of this field with the magnetic dipole moment of the orbiting electron causes $\boldsymbol{L}$ to precess around $\boldsymbol{B}$, where the tilt of $\boldsymbol{L}$ is quantized. In addition, the electron acquires the energy shift $-(\boldsymbol{M}_L \cdot \boldsymbol{B}) = -\mu_B B m_\ell$ *which is also quantized*, taking $2\ell+1$ distinct values, corresponding to the $2\ell+1$ possible orientations of $\boldsymbol{L}$ relative to $\boldsymbol{B}$ (the application of the external field $\boldsymbol{B}$ automatically selects its direction as the z-axis appropriate for quantization). That is, each energy level $\{n, \ell\}$ splits into $2\ell+1$ levels. This explains the *Zeeman effect*, which thus turns out to provide evidence for (orbital) angular momentum quantization.

A major shortcoming of the Schrödinger theory of hydrogen-like atoms was its failure to account for the *fine structure* of spectral lines, including those of hydrogen. Several lines of evidence converged to indicate that an electron possesses intrinsic angular momentum. In 1925 **Uhlenbeck** and **Goudsmit** suggested that this intrinsic (spin) angular momentum has observable component values $\pm\frac{1}{2}\hbar$. In retrospect, this explained the *Stern-Gerlach* experiment (1921) where the neutral silver atoms could only carry spin angular momentum, due to the single S-orbital $(\ell = 0)$ valence electron in each atom (the other electrons residing in a inner core with zero overall spin and orbital angular momenta). The nonuniform magnetic field in that experiment thus provided a spin-dependent semiclassical force, which split the beam into two components.

The spin angular momentum of the electron $\boldsymbol{S}$ adds another level of complexity to atomic physics. Because the electron is a charged particle, its spin results in an intrinsic magnetic dipole $\boldsymbol{M}_S$, related to $\boldsymbol{S}$ via $\boldsymbol{M}_S = -g_e\frac{e}{2m_e}\boldsymbol{S}$, the numerical values[542] $+\frac{1}{2}$ or $-\frac{1}{2}$ in $\hbar$ units.

(2) In 1925, Pauli introduced his *exclusion principle*, which states that there can be no two electrons in any atom that have the same set of quantum numbers (spin included). With the aid of this principle it was possible to explain the *atomic shell structure and the periodic system of the elements*. In 1940, Pauli generalized the exclusion principle to include all fermions.

(3) In 1927 Pauli proceeded to incorporate the electron spin into the Schrödinger formalism. In his theory the state of the electron was specified by a two–component wave-function, known as the *Pauli spinor*, with a transformation law under rotations given by the general unitary unimodular complex matrix in 2 dimensions. This led to the recognition (by physicists!) that for every unitary unimodular transformation in two complex dimensions there is an orthogonal transformation in three dimensions corresponding to a proper rotation. This fact had been previously known in mathematics, under the guise of the relation between Euler angles and the Cayley-Klein parameters. In this formalism, the three Pauli matrices $(\sigma_1, \sigma_2, \sigma_3)$ act as generators. When multiplied by $(-i)$, these new matrices obey the multiplication laws of *quaternions*.
Van der Waerden later extended Pauli spinors to 4 spacetime dimensions such that the entire Lorentz group $SO(3,1)$ can be represented by them (via the locally-isomorphic $SL(2,C)$ Lie group). However, spin angular momentum does not arise naturally from the solutions of the nonrelativistic Schrödinger wave equation; a better understanding of it thus had to await the advent of the *Dirac equation*, in 1928.
Pauli's theory helped to explain the *Stern-Gerlach experiment* (1921), the

---

where g_e is the *(spin) gyromagnetic ratio* of the electron, with an experimental value of 2.0024. The *total* magnetic dipole moment of an orbiting electron is $\boldsymbol{M} = \boldsymbol{M}_L + \boldsymbol{M}_S = -\frac{e}{2m_\ell}(\boldsymbol{L} + g_s\boldsymbol{S})$. Since the Stern-Gerlach experiment showed that the electron spin may have only two orientations relative to the magnetic field, the solution of the equation $2 = 2s + 1$ yields $s = \frac{1}{2}$, where $m_s = \pm\frac{1}{2}$. The only two permitted values of $S_z = \hbar m_s$ with regard to a selected measurement (z) axis correspond to the two possible orientations of $\boldsymbol{S}$. For brevity, they are referred to as spin up (↑) and spin down (↓), although the spin is never actually directed along the z-axis or opposite to it, due to the uncertainty in S_x and S_y.

[542] Quantum physicists often employ units $\hbar = c = 1$ where mass, energy, momentum, length and time units are all inter-convertible. In $\hbar$ units, Bohr's *orbital* angular momentum takes integer values.

atomic Zeeman effect (1896) and the experiment of **Phipps** and **Taylor** (1927).

(4) In 1931 Pauli proposed a new particle, to account for the apparent violation of the law of conservation of energy in nuclear β decays[543]. It was

[543] Around the year 1930 the skill of experimental physicists had revealed an apparent non-conservation of energy (and momentum) in the radioactive decay of the bismuth nucleus (^{210}Bi), which emits an electron (e^-) and thereupon becomes a polonium nucleus (^{210}Po). The combined total energy of the ^{210}Po and the electron e^- turned out to vary in amount in various such events, but was always *less* than the energy of the initial ^{210}Bi. The angular momentum balance also seemed to be upset by this reaction, because both ^{210}Bi and ^{210}Po nuclei are bosons, possessing integer spin in atomic units, (because they each have the even number 210 of fermionic nucleons, which – like the electron – have spin $S = \frac{1}{2}$); whereas the electron is a fermion possessing half integer ($S = \frac{1}{2}$) spin. Since the orbital angular momentum had never been observed to be anything but an integer number of $\frac{\hbar}{2}$ units, the reaction seemed to violate the conservation of angular momentum as well. The faith in conservation laws drove Pauli to predict the neutrino as the carrier of the "missing" energy, momentum and angular momentum of the reaction.

Strong experimental confirmation of Pauli's hypothesis was gained in 1956, when physicists from Los Alamos succeeded in inducing reactions of a beam of neutrinos from a nuclear reactor with nuclei. It is now known that the neutrinos emitted in the radioactive decay of nuclei consists of two types. The quanta appearing in conjunction with the emission of positive electrons (e^+) always have their angular momentum pointing in a direction opposite the velocity, i.e. their spin aligned opposite to their momentum ("left-handed") and are called neutrinos (ν). The quanta of the neutrino field appearing in conjunction with the emission of negative electrons (e^-) always have their spin aligned *parallel* to their momentum ("righthanded") and are called antineutrinos ($\overline{\nu}$). Thus the all but invisible quantum emitted in the decay of ^{210}Bi is actually an antineutrino. In later decades two more species of ν and $\overline{\nu}$ (*muon* neutrinos – ν_μ, $\overline{\nu}_\mu$ – and τau neutrinos ν_τ and $\overline{\nu}_e$), associated with much heavier (and radioactive) versions of the electron (the μ^-, τ^- leptons and their antiparticles). All the neutrinos have small but finite masses, and slowly *interconvert* (mix coherently) when traveling astronomical distances, or through the earth or sun.

The *helicity* of a particle is defined as the component of its intrinsic angular momentum ($\boldsymbol{S}$) in the direction of its velocity vector ($\boldsymbol{v}$) : $H = \frac{1}{S|\boldsymbol{v}|}(\boldsymbol{S} \cdot \boldsymbol{v})$.

All neutrinos observed in nature are found to have *negative helicity*, while all antineutrinos observed in nature are found to have *positive helicity*. Note that since the neutrino is almost massless (several $\frac{eV}{c^2}$), its speed is almost equal to

> later named '*neutrino*' ("little neutral one") by **E. Fermi**. The neutrino was finally observed in 1956; it is a spin-$\frac{1}{2}$ fermion, like the electron but devoid of electron charge, nearly massless, and interacting only weakly and gravitationally.

Pauli was born in Vienna, son of a Jewish physician whose name was Paschkes before he converted to Christianity. At the age of 21 he wrote a 200-page encyclopedia article on the theory of relativity, which today is still one of the best expositions of this subject. He studied at Münich and was a student of **Sommerfeld**. Later he was an assistant to **Max Born** and **Niels Bohr**.

In 1928 Pauli became professor of theoretical physics at the Federal Institute of Technology, Zürich. In 1940 he was appointed to the chair of theoretical physics at the Institute for Advanced Study, Princeton, NJ. Following WWII he returned to Zürich.

1924–1941 CE **Hendrik Anthony Kramers** (1894–1952, Holland). Physicist. Made significant contributions to mathematical and theoretical physics.

In 1924 he predicted the existence of the *Raman effect* (an inelastic scattering of light off molecules). Discovered, independently of **H. Jeffreys** (1923) **G. Wentzel**[544] and **L.N. Brillouin**, the WKBJ approximation method (1926). Together with **R.L. Kronig**, in their study of optical X-ray dispersion, derived basic relations between the real and imaginary parts of the Fourier transform of a causal function (1927). These are known today as the *Kramers-Kronig dispersion relations*[545] and play an important role in many branches of physics and engineering [they are linked to the Cauchy integral formula and the Hilbert transform].

In 1937 Kramers introduced the quantum–mechanical *charge conjugation operation* (replacing particles by their antiparticles) and the law of invariance

---

the speed of light; in the limit in which it were truly devoid of (rest) mass, it could not be stopped nor reversed by a Lorentz transformation (i.e. there would be no frame in which the neutrino is moving in the opposite direction with *opposite helicity*).

[544] **Gregor Wentzel** (1898–1978; Germany, Switzerland and USA). A student of Sommerfeld in Munich (Ph.D. 1921). Professor of Mathematical physics at Leipzig (1926), Zurich (1928–1947), Chicago (1948–1970).

[545] Originally, they derived relations between absorption and dispersion of EM radiation. In the context of electrical engineering, these causality constraints are known as the *Bode integral theorem*.

(symmetry) under this operation which turned out, like *E. Wigner's parity invariance* (spatial reflection), to be valid for all known interactions except the weak nuclear force. Kramers contributed to the mathematical structure of quantum mechanics, theory of phase transitions in ferromagnetism and the one-dimensional Ising model (1941) [a chain of N spins, each spin interacting with its two nearest neighbors].

Just before he died, he had surgery postponed because he wanted to finish a paper.

1924–1953 CE **Richard Courant** (1888–1972, Germany and USA). Mathematician and educator. Founded the famous Mathematical Institute at Göttingen University and directed it (1920–1933). Founded (1953) and directed the *Courant Institute of Mathematical Sciences* — an applied mathematics research center in New York, based on the Göttingen model.

Courant was born in Lublinitz, Prussia (now Lubliniez, Poland) to Jewish parents. He obtained his doctorate under Hilbert's supervision. He taught mathematics at Göttingen, where he was **Klein**'s successor, until the start of WWI. A few years after the war he returned to Göttingen, becoming a professor (1920). Contributed to various branches in mathematical physics.

In 1924 he published, jointly with **Hilbert**, an important text *Methoden der mathematischen Physik*. When the Nazis purged Göttingen of its Jewish mathematicians (1933), he left for England, and thence to New York (1934).

Although Courant did not originate new ideas or techniques in mathematics, his contribution lies mainly in transplanting the heritage of the German school of mathematics to the United States at a most opportune time on the eve of WWII, thus securing the uninterrupted continuity and growth of mathematical physics in the free Western culture.

1924–1957 CE **Felix Heinrich Wankel** (1902–1988, Germany). Inventor of the *Wankel rotary engine* – a type of internal combustion engine which uses a rotor instead of pistons.

In the Wankel engine, the 4 strokes of a typical Otto cycle occur in the space between a three-sided rotor [having a shape approximating a *Reuleaux Triangle*[546]] and the inside of an oval-like housing (Fig. 5.6).

[546] The *Reuleaux Triangle* (Fig. 5.5) forms the basis of the Wankel rotary internal combustion engine. It is named after the engineer **Franz Reuleaux** (1829–1905, Germany) who did pioneering work on ways that machines translate one type of motion into another (1861–1875).

Reuleaux believed that *machines could be abstracted into chains of ideal elements* constrained in their motions by adjacent parts in the kinematic chain.

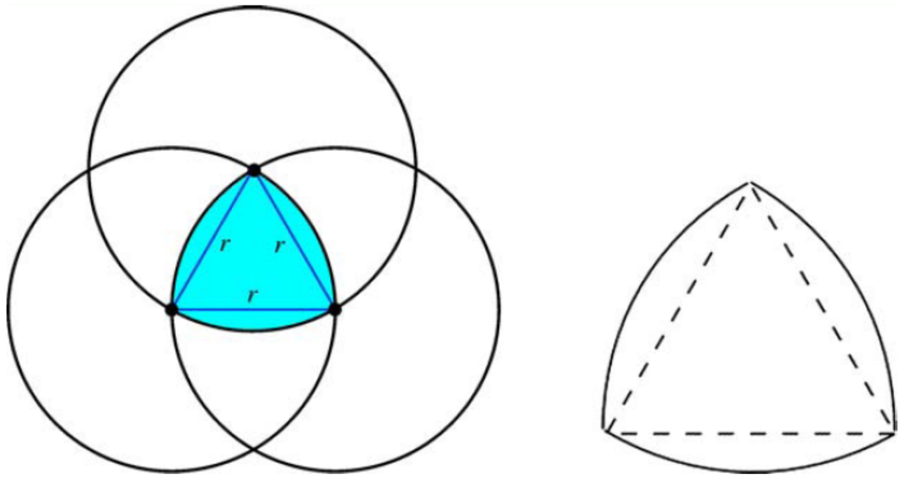

Fig. 5.5: The *Reuleaux triangle* is a constant – width curve based on an equilateral triangle. The distances from any point on a side to the opposite vertex are all equal

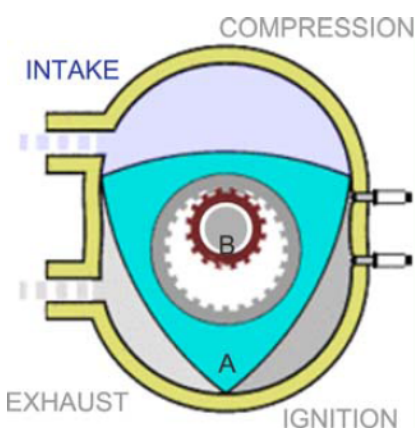

Fig. 5.6: The Wankel cycle. "A" marks one of the three apexes of the rotor. "B" marks the eccentric shaft, and the inner white region – a gear – toothed circular hole bored about the rotor center – is the lobe of the housing– centered eccentric shaft. The shaft turns three times for each clockwise spin of the rotor around the lobe and once for each orbital revolution of the rotor within the housing

The central drive shaft, also called an eccentric shaft or E-shaft, passes through the central borehole (offset lobe) of the rotor; it is half the lobe's radius and engages its boundary via gear teeth, and is supported by bearings. The rotor both rotates about the offset lobe and makes orbital revolutions around the engaged central shaft. Seals at the corners apexes of the rotor seal against the periphery of the housing, dividing it into three moving combustion chambers. Fixed gears mounted on each side of the housing engage with ring gears attached to the rotor to ensure the proper orientation as the rotor moves.

As the rotor rotates and orbitally revolves, each side of the rotor gets periodically closer and farther from the oval walls of the housing, in the process compressing and expanding the combustion chambers similarly to the strokes of a piston in a reciprocating engine. While a four-stroke piston engine makes one combustion stroke per cylinder for every two rotations of the crankshaft (that is, one half power stroke per crankshaft rotation per cylinder), each combustion chamber in the Wankel generates one combustion stroke per each driveshaft rotation, i.e. one power stroke per rotor orbital revolution and three power strokes per rotor rotation. Thus, power output of a Wankel engine is generally higher than that of a four-stroke piston engine of similar engine displacement in a similar state of tune, and also higher than that of a four-stroke piston engine of similar physical dimensions and weight.

He developed a compact symbolic notation to describe the topology of a very wide variety of mechanisms, and showed how it could be used to classify them and even lead to the invention of new useful mechanisms. At the expense of the German government, he directed the design and manufacture of over 300 beautiful models of simple mechanisms, such as the four bar linkage and the crank. These were sold to universities for pedagogical purposes. Today, the most complete set are at Cornell University College of Engineering. Using his notation and methods for systematically varying the elements (e.g. inversions, changing relative sizes of the links, etc.) he showed how the four bar linkage could be mutated into 54 mechanisms, which fall within 12 classes.

Today, he may be best remembered for the *Reuleaux triangle*, a curve of constant width that he helped develop as a useful mechanical form.

To construct the Reuleaux triangle, start with an equilateral triangle. Center a compass at one vertex and sweep out the (minor) arc between the other two vertices. Do the same with the compass centered at each of the other two vertices. Delete the original triangle. The result is a curve of constant width.

The total area of the Reuleaux Triangle is $\frac{1}{2}(\pi - \sqrt{3})r^2$, where r is the circular arc radius. It can be rotated inside a square of side r, covering a fractional area of $2\sqrt{3} + \frac{\pi}{6} - 3 = 0.9877003908\ldots$. By the *Blaschke-Lebesgue theorem*, the Reuleaux Triangle has the least area of any curve of given constant width.

Wankel engines have several major advantages over reciprocating piston designs, in addition to having higher output for similar displacement and physical size. Wankel engines are considerably simpler and contain far fewer moving parts. For instance, because valving is accomplished by simple ports cut into the walls of the rotor housing, they have no valves or complex valve trains; in addition, since the rotor is geared directly to the output shaft, there is no need for connecting rods, a conventional crankshaft, crankshaft balance weights, etc. The elimination of these parts not only makes a Wankel engine much lighter (typically half that of a conventional engine of equivalent power), but it also completely eliminates the reciprocating mass of a piston engine with its internal strain and inherent vibration due to repeated acceleration and deceleration, producing not only a smoother flow of power but also the ability to produce more power by running at higher RPM.

In addition to the enhanced reliability by virtue of the elimination of this reciprocating strain on internal parts, the engine is constructed with an iron rotor within a housing made of aluminum, which has greater thermal expansion coefficient. This ensures that even a severely overheated Wankel engine cannot seize, as would likely occur in an overheated piston engine. This is a substantial safety benefit in aircraft use, since no valves can burn out. A further advantage of the Wankel engine for use in aircraft is the fact that a Wankel engine can have a smaller frontal area than a piston engine of equivalent power. The simplicity of design and smaller size of the Wankel engine also allows for savings in construction costs, compared to piston engines of comparable power output.

As another advantage, the dynamical shape of the Wankel combustion chambers and the turbulence induced by the moving rotor prevent localized hot spots from forming, thereby allowing the use of fuel of very low octane number or very low ignition power requirement without preignition or detonation, a particular advantage for hydrogen cars. Four-stroke reciprocating engines are less suitable for hydrogen. The hydrogen can misfire on hot parts like the exhaust valve and spark plugs. Another problem concerns the hydrogenate attack on the lubricating film in reciprocating engines. In a Wankel engine this problem is circumvented by using a ceramic apex seal against a ceramic surface: no oil film means no hydrogenate attack. Since a piston ring of ceramic material is not possible, a similar fix is unworkable with the reciprocating engine. The piston shell must be lubricated *and* also cooled with oil, which substantially increases the lubricating oil consumption in a four-stroke engine.

Disadvantages

Compared to piston engines, the time available for fuel to be injected into a Wankel engine is significantly shorter, due to the way the three chambers rotate. The fuel-air mixture cannot be pre-stored as there is no intake valve. This means that to get good performance out of a Wankel engine, more complicated fuel injection technologies are required than for regular four-stroke engines. This difference in intake times also causes Wankel engines to be more susceptible to pressure loss at low RPM compared to regular piston engines.

In terms of fuel economy, Wankel engines are generally less efficient than four stroke piston engines. Problems also occur with exhaust gases at the Wankel's peripheral port exhaust, where the concentrations of hydrocarbons can be higher than from the exhausts of regular piston engines.

The reason Wankel-cycle engines have higher fuel consumption and emissions than Otto-cycle engines is that the combustion chambers in a Wankel are quite large at ignition, so the compression ratio is lower. This lowers the thermal efficiency and thus the fuel economy. Additionally, some fuel may get too far from the flame front during combustion to be fully burned. This is why there can be more carbon monoxide and unburnt hydrocarbons in a Wankel's exhausts stream.

Wankel was born in Lahr (upper Rhine Valley), Germany. Although he had no university education, he was able to teach himself technical subjects and conceived the idea of the Wankel engine in 1924. In the 1930s, he was imprisoned by the Nazis for some months.

During World War II, he developed rotary valves for German air force aircraft and navy torpedoes. After the war, he was imprisoned by the Allies for several months; his laboratory was closed, his work confiscated, and he was prohibited from doing further work. In 1951, he began development of this engine, leading to the first running prototype on February 1, 1957. The engine has been successfully used by Mazda in several generations of their RX-series of coupés.

1924–1957 CE **Alexander Ivanovich Oparin** (1894–1980, Russia). Biochemist. A pioneer of modern theories of the origin of life. Put forward the idea that life evolved in random chemical processes in the ocean, which became a '*biochemical soup*' conducive to early life forms. His ideas became the basis of many modern scientific theories of the origin of life.

Oparin's theory of the origin of life rests on the belief that the earth's early atmosphere contained mostly ammonia, hydrogen, methane, and water vapor — not nitrogen and oxygen as it does today. He suggested that the chemicals necessary for life formed spontaneously in such an atmosphere. These molecules combined and formed more complex molecules. These molecules formed still larger compounds and structures, and finally they developed into the first living cells over the course of hundreds of millions of years.

It is, of course, a long leap from an atmosphere containing methane and ammonia to even the simplest living systems, but at least the atmospheric evidence suggests that most of the elements now found in organisms were also abundant on the earth early in its history.

In 1953, **Stanley L. Miller** performed a laboratory experiment on the origin of life. He constructed an apparatus for producing amino acids under primitive earth conditions: steam was passed through a mixtures of gaseous methane (CH_4), ammonia (NH_3), and hydrogen (H_2), and then exposed to a high-energy electric spark before being recondensed as water. After a week of operation of the apparatus, the water was found to contain amino acids, the fundamental building blocks of proteins and organisms.

Miller's simple experiment showed that electrical discharges, such as lightning, in an early reducing atmosphere, could have led to the production of some complex molecules of living systems[547].

Oparin was born in Uglich, near Moscow. He graduated from Moscow State University in 1917. His theory was described in a book *The Origin of Life on Earth* in 1924, long before anything was known about the structure and chemical nature of genes. In the third edition of his book (1957) he proposed that the order of events in the origin of life was: *cells first, enzymes second, genes third*.

The Oparin picture was generally accepted by biologists for half a century, because it seems to be the only alternative to biblical creationism. But since the discovery of the double helix (1953) showed that genes are structurally simpler than enzymes, it became natural to think of the nucleic acids as primary and of the proteins as secondary structures. For that reason, the sequential order of Oparin was changed to: *genes first, enzymes second and cells third* (**Manfred Eigen**, 1981), and Oparin's theory was neglected.

---

[547] Yet, for the next 20 years, scientists could not get close to the next step, which is to produce *proteins*. Simple amino acids are not even proteins, much less life, so the bridge between nonlife and life remained elusive.

In the early 1970s, geochemists realized that the earth's early atmosphere was probably nothing like the gases used in the Miller-Urey experiment. This experiment used an "atmosphere" modeled on what we knew of Jupiter, composed of methane, ammonia, hydrogen, and water. In the 1970s, geochemists discredited this theory of the earth's early atmosphere and concluded that it probably contained more *carbon dioxide*, almost no hydrogen, and possibly some oxygen. Creation of even simple amino acids would have been impossible in such an environment. There is still (2006) no plausible account for the origin of life. Yet, the Miller-Urey experiment is still taught in biology textbooks!

Recently, however, **Freeman Dyson** (1985) chose to base his mathematical model of the origin of life on Oparin's theory, because it allows early evolution to proceed in spite of high transcription-error rates.

Origin and Evolution of Terrestrial Atmospheres

As soon as the solid earth formed, the natural decay of radioactive elements below the surface heated up the crustal rocks, causing the chemical decomposition of some of the minerals present there. In the process water (H_2O), carbon dioxide (CO_2), and other gases were liberated from chemical compounds. These substances outgased to the surface, especially through volcanism. Water was the most plentiful compound to be released from the earth's crust; once it reached the cooler surface, it condensed to form the oceans where most of it remains today.

Next most important was CO_2, with about $\frac{1}{10}$ of the abundance of water. Much of it dissolved in the oceans and some recombined (at surface temperatures) with surface rocks to re-form carbonates, which remain on the ground today. Perhaps only $\frac{1}{5}$ of the abundance of the CO_2 represented nitrogen gas, but nitrogen is relatively inactive chemically, and now remains in the atmosphere as its major constituent (about 78 percent). Another, even more inert gas to be released was argon-40, formed by the radioactive decay of potassium-40. Argon today comprises about 1 percent of the atmosphere.

The early atmosphere of the earth may have been made of nitrogen, CO_2, argon, H_2O, methane (CH_4), ammonia (NH_3), and hydrogen, the last three having originated either from outgassing or from chemical activity at the surface. These would quickly escape or decompose, but their temporary presence, bathed in solar radiation, would create a chemical environment favorable to the formation of more complex molecules.

With energy supplied by sunlight, some water vapor in the upper atmosphere may have broken down to hydrogen and oxygen by a process called photolysis *('breaking by light'). Any oxygen so formed would not have remained free (uncombined) because it is highly reactive and would have quickly combined with gases like methane and carbon monoxide to form water and carbon dioxide. It would have also combined with crustal materials (with metals like iron in olivines and pyroxenes) to form iron oxides like hamatite (Fe_2O_3). The production of significant amounts of* free oxygen, *and its persistence in the atmosphere, probably came about only after life evolved at least to the complexity of green algae*[548].

[548] Although the general course of events described here is based on physical plausibility and extrapolation from experiment, the scenario for the details of each stage is but one of several hypotheses currently extant.

Of all the solar-system's planets, the earth alone has appreciable free oxygen in its atmosphere. It came about because of the development of life. Green plant life, mainly in the oceans, flourished during the first few billion years of the earth's existence. This vegetation removed the CO_2 *from the air by the process of* photosynthesis*, building itself with the carbon and releasing the oxygen into the atmosphere. When the vegetable organisms died, they decayed (or oxidized), removing the oxygen from the air again.*

However, part of the dead vegetation escaped the decay process, by being preserved in the ground in the form of fossil fuels*, where much of it remains today. Thus, most of the oxygen is removed from the air by the decay of dead plant matter (and later by decay of animals, by combustion and by respiration), but a little (somewhere between one part in* 10^4 *and one part in* 10^5*) of that produced by photosynthesis remains in the atmosphere, gradually building up the oxygen concentration. It is estimated that oxygen comprised only about* 1 *percent of the atmosphere* 600 *millions years ago, but since then it has gradually accumulated to about* 21 *percent.*

In recent years man has upset this delicate balance. It is estimated that the amount of oxygen used in the technosphere in relation to the net production of oxygen in the biosphere is about 11 *percent. This arises from our consumption of fossil fuels (coal and oil) extracted from the earth. At the present rate it would still take thousands of years to use up our oxygen (the easily available coal and oil will be used up much sooner than this), but the resulting increase in the concentration of* CO_2 *in the atmosphere could have a profound effect on the climate by increasing the world's average temperature enough to melt the polar caps and flood several countries (the greenhouse effect).*

All life today is protected from deadly doses of the sun's ultraviolet radiation by atmospheric oxygen; under the intense radiation present in the upper atmosphere, this oxygen forms a layer of ozone *(*O_3*) which absorbs most of the sun's ultraviolet rays and prevents them from reaching the lower atmosphere and the earth's surface. Without this ozone screen, life would be possible only under rocks, in deep water, or in other places where direct sunlight could not penetrate. Only after free oxygen, and a consequent ozone screen, began accumulating in the atmosphere was life first possible in shallow waters and, ultimately, on the surface of the land.*

Land life did not become abundant before the time when free atmospheric oxygen and ozone first attained approximately their present-day levels (ca 400 *millions years ago).*

1924–1962 CE **Tibor Radó** (1895–1965, Hungary and U.S.A.). Mathematician. Made important contributions to the calculus of variations, algebraic topology, measure and integration theory and "Turing programs". He proved (1924) that every manifold of dimension 2 can be triangulated. Proved (1930) the existence of a surface of minimal area bounded by a given closed contour in space (*The Plateau Problem*). Discovered (1962) a noncomputable function (Turing Machine).

Radó was born in Budapest, Hungary to Jewish parents. He began his university studies in civil engineering at the Technical University in Budapest. In 1915 he enlisted in the army, was trained and then commissioned as second lieutenant in the infantry. He took part in two major battles on the Russian front before being captured on a scouting mission. His four years in prison camps (1916–1920) read like a scenario of an action movie: prior to the revolution he was imprisoned in Tobolsk, Siberia, where the only books he could obtain happened to be on mathematics. After the revolution he was transported thousands of kilometers under harrowing conditions. During the confusion he and three fellow officers traded names with four private soldiers. As far as his family knew, Radó was dead. He spent the next year working as a laborer in railroad yards. Then, he and a group of prisoners escaped by hijacking a train.

Finally, in 1920 he returned to Budapest on an American-financed boat which was assisting the return of war prisoners. Back at the University of Szeged, he re-enrolled, this time as a mathematics major, and in 1922 he received his Ph.D. under **Frigyes Riesz**. In 1929 he emigrated to the United States and in 1930 moved to Ohio State University as full professor of mathematics. At the end of WWII, he went to Europe to recruit German scientists needed by the United States.

1924–1962 CE **Edward Charles Titchmarsh** (1899–1963, England). Pure mathematician. A dominant figure in Oxford mathematics during 1931–1949. Did important work on Fourier integrals, integral equations, Fourier series, integral functions, the Riemann zeta-function and eigenfunctions of second order differential equations.

Titchmarsh was born in Newbury and educated at Oxford. He served in World War I (1917–1919) and succeeded Hardy as Savilian professor at Oxford.

1924–1968 CE **John Desmond Bernal** (1901–1971, England). Crystallographer and biophysicist. Developed modern crystallography and was a founder of molecular biology. First to take X-ray photographs (1934) of biologically important molecules, plants, viruses, amino acids, proteins, sterols and nucleoproteins. First to determine the structure of graphite (1924).

Bernal was born Nenagh, Tipperary County, Ireland to a Sephardic Jewish family on his father's side. He graduated (1922) from Emmanuel Collage, Cambridge. After graduating he started research under **William Bragg**. He was later a professor of physics at the University of London (1937–1968). It was here that he did the major pioneering work in crystallography. Other prominent scientists who worked or studied with him were **Dorothy Hodgkin**, **Rosalind Franklin**, **Aaron Klug** and **Max Perutz**.

Bernal was convinced that from an understanding of the physical molecular structure of biologically important molecules would come a clearer insight into the way the living processes worked. His researches were dominated by the quest for the *origin of life*.

During his wartime service, he contributed substantially to the scientific underpinning of the invasion of the European Continent.

He joined the Communist Party of Great Britain (1923) during his student days and was awarded the Lenin Peace Prize (1953) for being active in the international peace movement during the Cold War.

White Dwarf — Death of a Small Star

White dwarves are faint stars with absolute magnitudes typically more than 10, making them at least 100 times fainter than the sun. They have temperatures around $10,000\,^{\circ}K$ and appear to be white.

A typical such star is about one solar mass with a density of ca 10^6 g/cm^3. It has exhausted all its thermonuclear fuel and contracted to a size roughly that of the earth. It is slowly cooling as it radiates away its residual thermal energy, and supports itself against gravity by the pressure of degenerate electrons. Its radius is inversely proportional to the cube root of its mass, i.e. the more massive a white dwarf is — the smaller it is.

The first white dwarf was discovered as early as 1844: the motion of the bright, nearby star Sirius had been found to be slightly irregular. Its proper motion of roughly 1 second of arc per year was not along a perfectly straight line across the sky, but rather a slightly wavy path. Astronomers concluded that Sirius was a double star, and that its wavy proper motion is due to an orbital motion around a companion.

This hypothesis was confirmed in 1862 when ***Alvan Graham Clark*** *(1832–1897, U.S.A.) saw it through a new 46 cm refracting telescope at the Dearborn Observatory in Illinois. The star's companion was given the name Sirius B. The strange characteristics of this star were soon discovered: Its effective temperature is* $32,000\,^{\circ}K$*, its radius 5400 km and its mean density* 3×10^6 *g/cm*^{3}*. Astronomers of the late* 19^{th} *century were justifiably skeptical. However, new discoveries of white dwarves soon poured in. A renewed interest in the internal structure of these stars arose after the new theories of matter and gravitation were established during the first quarter of the* 20^{th} *century.*

Walter Sydney Adams *(1876–1956, U.S.A.) measured, in 1925, gravitational red-shifts of several spectral lines from Sirius B, and* ***A.S. Eddington*** *(1926) used GTR to obtain the* M/R *ratio. Since the mass* M *was known from the binary orbit, Eddington could estimate its radius* R *and hence its density. In this way both the validity of GTR and the star's geometry were tested simultaneously.*

In 1926 ***R.H. Fowler*** *applied Fermi-Dirac statistics to explain the puzzling nature of the white dwarves. He identified the pressure, preventing gravitational collapse, with electron degeneracy pressure.*

In 1930 ***S. Chandrasekhar*** *calculated that a white dwarf can exists only if its mass is less than 1.4 solar masses [known as the Chandrasekhar limit].*

The demise of a normal star in that mass range, is thought to proceed as follows: As it grows older, it steadily converts protons into helium nuclei at its center. As the supply of protons there runs low, the star loses its ability to maintain a constant rate of energy liberation. For a time, the star can compensate for its dwindling resources of protons by contracting its central region, thereby raising the temperature to fuse the remaining protons at an ever-increasing rate. This contraction actually increases the rate of energy liberation: part of the extra kinetic energy expands the star's outer layers, cooling them slightly and producing a red-giant star. Its core will eventually contract to the point where helium begins to fuse into carbon. This helium ignition temporarily expands the core, and sets the stage for a period of instability during which the star is likely to pulsate in size and brightness. This is the stage of the Cepheid stars.

When the helium nuclei have fused into carbon, most stars will become degenerate in their centers. At this point, the central regions have such high density that the Pauli exclusion principle (1925) prevents the electrons from packing any tighter. The electrons hold the nuclei by electromagnetic forces, so the exclusion principle supports the entire star against its self-gravitation. After the star's outer layers evaporate, the core remains as a white dwarf.

Quantum Mechanics — The Formative Years[549]

Despite the initial success of the ***Bohr*** *theory, and other developments of the original quantum theory of* ***Planck****, it became increasingly evident in the early* 1920*'s that many features of atomic physics cannot be described in semiclassical terms. The discovery and interpretation of the* ***Compton*** *effect in* 1923 *stressed the photon aspect of radiation, but the necessary connection between the wave and corpuscle treatments remained elusive. Shortly after this discovery* ***de Broglie*** *suggested that beams of particles should exhibit wave properties, the effective wavelength being inversely proportional to the momentum per particle. This idea was widely accepted, but it was not until* 1927 *that full experimental confirmation was obtained, by* **Davisson** *and* **Germer** *and by* **G.P. Thomson**.

The initial development of full-fledged quantum mechanics *stemmed from the problem of calculating the probabilities of transitions between various atomic states. The theory was put in the form of* matrix mechanics *by* ***Heisenberg****,* ***Born****, and* **Jordan**, *whose ideas expressed a new philosophy of physical epistemology and ontology. Briefly, quantum mechanics is connected only with the calculation of observable quantities (including statistical probabilities); detailed mechanical models of observable entities are regarded as misleading and unnecessary.*

An alternative approach, explored by ***Schrödinger*** *in* 1926*, led to a system of* wave mechanics *based on de Broglie's hypothesis, and this system admits of a somewhat different interpretation than matrix mechanics. In wave mechanics an atomic state is described by a function* Ψ*, which is related to (but contains more information than) the probability distribution of the positions of (one or several) electrons in the given atomic state.*

An important consequence of any form of quantum mechanics is the "uncertainty" principle, stated by Heisenberg in 1927*, limiting the accuracy with*

[549] For further reading, see:

- Guillemin, V., *The Story of Quantum Mechanics*, Charles Scribner's Sons: New York, 1968, 332 pp.
- Finkelnburg, W., *Structure of Matter*, Springer-Verlag: Berlin, 1964, 511 pp.

which physical measurements can ever ascertain the point occupied by a physical system in classical phase space. The principle stresses the essentially statistical nature of the new quantum theory, which cannot, in general, predict the exact behavior of any atomic system, but is rather confined to the calculation of probabilities, such as the transition probabilities of Heisenberg's matrix mechanics.

While the quantum mechanical scheme was still being worked out, many difficulties in atomic theory were removed by ***Uhlenbeck*** *and* ***Goudsmit****'s hypothesis that the electron possesses intrinsic angular momentum or "spin". The entire periodic classification of the chemical elements could now be understood with the aid of the spin variables and* ***Pauli****'s exclusion principle. The incorporation of electron spin into a fully relativistic theory of particles was achieved in* 1928 *by* ***Dirac****, whose treatment of the electron was particularly significant in that it predicted the existence of an antiparticle, in this case the positron — discovered soon thereafter.*

Among the many applications of quantum mechanics to systems containing several particles, the most general are the laws governing the statistical behavior of large assemblies. A new form of physical statistics was discovered in 1924 *by* ***Bose*** *and* ***Einstein****, who treated all identical particles in an assembly as strictly indistinguishable (such particles are known as* bosons*; examples are the photon, ^4He, H_2, the graviton, π-mesons). The special properties of particles which are indistinguishable and in addition*[550] *obey Pauli's exclusion principle, were expressed in the* **Fermi-Dirac** *statistics of 1926 (these*

550 Let a system (unit volume, say) consist of a total of N noninteracting fermions distributed among a finite number of energy states, such that there are n_i of them at energy level ϵ_i $[\sum n_i = N;\ \sum n_i\epsilon_i = E =$ total energy of system$]$.
Each energy level ϵ_i has g_i different *quantum states* with the same energy; g_i is known as the *degeneracy* of that level. For free particles of spin $\frac{1}{2}$, not subject to magnetic fields, each particle may have spin up or down, so $g_i = 2$ for all levels. We specialize to this case in what follows; m will denote the fermion mass.
The number n_i/g_i is the *occupancy number* of each degenerate state.
According to the *Fermi-Dirac* distribution law for fermions, the statistical expectation of n_i is $n_i = g_i f_i(\epsilon_i)$, where $f_i(\epsilon_i)$ expresses the probability that a given quantum state of energy ϵ_i is occupied by a fermion $[0 \le f_i \le 1]$. Explicitly, for the *Fermi-Dirac* distribution in equilibrium, one has

$$f_i = \frac{1}{1 + \exp\left(\frac{\epsilon_i - \epsilon_F}{kT}\right)},$$

where k is the Boltzmann constant, T the absolute temperature in °K and ϵ_F is the *Fermi energy*; T and ϵ_F are adjusted to satisfy the two constraints *particles are fermions, e.g.: electron, neutrino, muon, proton, neutron). Two or more bosons, in contradistinction, may occupy the same quantum state. Under suitable almost-classical conditions, both these forms of quantum statistics can be replaced approximately by the classical* ***Boltzmann*** *scheme, but the quantum theory is essential in dealing with problems such as the behavior of photons in an enclosure, atoms in a superfluid or a Bose-Einstein Condensate, electrons in a metal or white dwarf star, nucleons in an atomic nucleus or neutron star, or in atomic and molecular electron orbitals.*

Quantum mechanics provides a method for the theoretical treatment of atomic or subatomic systems, for calculating their energy levels and for predicting the probability of transition from one state to another. When we consider the properties of matter in bulk, new problems arise because of the complicated interactions between atoms.

Even in the gaseous phase, intermolecular forces affect the behavior considerably, although it is usually possible to describe deviations from the gas laws in terms of simple two-body interactions. In the solid or liquid state, the close proximity of atoms gives rise to strong forces affecting many particles.

At the same time, the fundamental rules of quantum statistics become important in dealing with the vibrations of the crystal lattice or with conduction electrons in metals. Despite the mathematical difficulties, condensed-matter physics has made great progress in accounting for many collective (many-body) phenomena which admits of no classical explanation. Moreover, its results have great practical significance and wide implications in many fields of physical research.

As an illustration, consider the study of magnetic effects in solids. The classical statistics of Boltzmann can be applied to assemblies of paramagnetic atoms which are weakly interacting. The basic theory of level splitting in magnetic fields is well known, and can be used directly in such cases to calculate the paramagnetic susceptibility.

However, in the solid state, atoms and ions interact strongly with each other and complex collective phenomena are observed, notably the phenomenon of ferromagnetism. The spontaneous magnetization of metals like iron was treated phenomenologically in Weiss' theory, the prototype of many at-

---

$\sum n_i = N,\ \sum n_i\epsilon_i = E$. At zero temperature and for free electrons, one finds

$$\epsilon_F = \frac{h^2}{8m}\left(\frac{3N}{\pi}\right)^{2/3}.$$

For $T = 0$, all energy states up to $\epsilon = \epsilon_F$ are fully occupied $(n_i = g_i)$ while

all states with $\epsilon > \epsilon_F$ are empty $(n_i = 0)$. In contradistinction, at $T = 0$, in *Maxwell-Boltzmann* statistics, all particles should be at the ground energy level with $T = 0$. In *Fermi-Dirac* statistics, this accumulation at the ground level is prevented by the exclusion principle, and particles at $T = 0$ occupy the lowest energy levels available up to energy ϵ_F. At higher temperatures, the population of the fermions is spread out among the quantum states: electrons with energies within $O(kT)$ of ϵ_F typically absorb thermal energy of the same order, and move to higher levels, in accordance to the distribution $f_i(\epsilon_i)$.
Thus, for temperatures $kT \ll \epsilon_F$, only states with energies close to ϵ_F are affected since the low-energy states are fully occupied and the exclusion principle prevents the addition of further electrons to those states. Consequently, only those fermions with energy close to ϵ_F can move into higher unoccupied states by absorbing a relatively small amount of energy, of order kT.
At sufficiently *high* temperatures, the *Fermi-Dirac* distribution becomes essentially a *Maxwell-Boltzmann* distribution, i.e.

$$n(\epsilon_1)/n(\epsilon_2) = e^{(\epsilon_2-\epsilon_1)/kT}.$$

This occurs in the regime

$$T \gg T_0 = \frac{h^2}{8mk}\left(\frac{3}{\pi}N\right)^{2/3};$$

for electrons when $T_0 = 300\,^\circ\mathrm{K}$ (room temperature), $N \sim 10^{13}$ per cm^3.
In cases where the energy spectrum of the fermions is practically continuous, such as free electrons in a macroscopic box, there are numerous discrete levels (with $g_i = 2$ each) in any reasonable energy interval $\Delta\epsilon$, so we may replace g_i with the continuous distribution $g(\epsilon)d\epsilon$, and n_i by dN. One finds that

$$g(\epsilon) = \frac{8\pi}{h^3}\sqrt{2m^3\epsilon}$$

(again per unit volume) and thus the number of electrons with a kinetic energy between ϵ and $\epsilon + d\epsilon$ is

$$dN = \frac{g(\epsilon)d\epsilon}{1 + e^{(\epsilon-\epsilon_F)/kT}}.$$

This theory can be applied successfully to the problem of finding the energy distribution of a large number of independent nearly free electrons in an enclosure (applicable to conduction electrons in a metal too). Indeed, at low temperatures for $\epsilon \leq \epsilon_F$,

$$N = \sum_{\epsilon=0}^{\epsilon=\epsilon_F} g_i(\epsilon_i) \Rightarrow \frac{8\pi}{h^3}(2m^3)^{1/2}\int_0^{\epsilon_F}\epsilon^{1/2}d\epsilon = \frac{16\pi}{3h^3}(2m^3)^{1/2}\epsilon_F^{3/2},$$

from which the above expression for ϵ_F was derived.

tempts to describe cooperative effects, which include the melting of solids and order-disorder transitions in alloys.

Some success has been achieved in theoretical descriptions of such effects, but it is not always easy to formulate a fundamental account of the interactions responsible for them.

Our Galaxy (1925–1983)[551]

"Poor mankind. We began with the belief that we were the center of the universe. At each step of our growing knowledge, we become less central. Frankly, whenever I think of our insignificant place in the cosmos, and contemplate the fact that we live on one of its hundred billion stars, I become more firm in my belief that we cannot be the only intelligent creatures in the Galaxy".

Robert DeWitt Chapman (1978)

Our sun is located in a stellar system called the Milky Way or simply the Galaxy (on clear dark nights[552] *the cumulative light from the myriad of its faint stars is visible as a luminous band stretching across the sky).*

---

551 For further reading, see:

- Kaufmann, W.J., *III. Universe*, W.H. Freeman, 1985, 594 pp.

552 During WWII cities on the west coast of the United States were routinely blacked out at nights to hamper attacks from the sea. This included Los Angeles, whose city lights normally interfered with observations from Mount Wilson, site of the 2.5 meter *Hooker Telescope*. At the time this was the biggest and best telescope in the world, but the increasingly bright skies due to the development of Los Angeles limited its usefulness. Thus, the war provided excellent opportunities for

The Milky Way, a spiral galaxy, is a dynamic entity with its own structure and evolution governed by complex interactions of stars with each other and with the interstellar gas and dust. It is vastly more complicated than a single star, and its life story is correspondingly more difficult to unravel.

About the turn of the century, following upon the star gauging of ***W. Herschel*** and ***J. Herschel***, *astronomers tried to investigate the structure of the Milky Way system by the methods of stellar statistics. Even if the goal was not attained, the incredible labor of these undertakings has nevertheless proved to be very valuable in other connections.*

H. Shapley*'s method (1918) of photometric distance determinations using cepheids, brought the decisive advance. The period-luminosity relation (i.e. the relation between the period P of the luminosity variation and the absolute magnitude M), made it possible to measure the distance of every cosmic system in which one could detect any sort of cepheids. The distance of the cepheids determined by Shapley implied that these clusters form a slightly flattened system whose center lies at a distance of about* 30,000 *light years in the direction of Sagittarius. The present picture of our Milky Way system developed rapidly from these beginnings.*

Shapley's picture of our Galaxy was not universally accepted among astronomers at first, but when in 1923 ***Hubble****'s observations showed that the Great Andromeda galaxy was similar in size and content to our galaxy, astronomers accepted the hypothesis that the universe is filled with galaxies and turned their attention to studying the detailed structure of our own.*

In 1926, **Bertil Lindblad** *(1895–1965, Sweden) came forward with the hypothesis of* differential rotation *of the Galaxy. The first clues of this rotation came from examining the motions of stars in the sky. Because of differential rotation, the sun is like a car on a circular freeway with the fast lane on one side and the slow lane on the other side; stars on the fast lane are passing the sun and thus appear to be moving in one direction, while stars in the slow*

---

astronomers to observe faint objects. Most American astronomers were unable to take advantage of these opportunities, however, being assigned to war-related duties elsewhere. One exception was **Walter Baade** (1893–1960) (exempted from war duties), who took excellent photographs of the Andromeda galaxy, a spiral much like our own. This allowed him to determine the characteristics of individual stars in that galaxy, something never before possible. From the study of these stellar characteristics emerged the recognition of *stellar populations* and their profound implications for galactic evolution.

After the war the conditions at Mount Wilson became worse and worse due to city lights and pollution, and the 100-inch telescope was closed in 1985.

lane are being overtaken by the sun and therefore appear to be moving in the opposite direction.

However, not all of the stars in the sky move in this orderly pattern. Extra-galactic objects and some components of our galaxy do not seem to participate in the general rotation of the Galaxy; instead they display more-or-less random motions.

Lindblad took the average of these random motions as a background, using Doppler shifts of optical spectral lines to measure the sun's speed w.r.t. the background in various directions. From these measurements, he concluded that sun moves along its orbit about the galactic center at a speed of $250\ \frac{\text{km}}{\text{sec}}$*.*

Observational evidence confirming Lindblad's hypothesis was provided a year later (1927) by ***Jan H. Oort****. The work of Lindblad and Oort thus showed that our galaxy rotates around a point which agrees with the center as determined by Shapley. The agreements of these results established the sun's off-center position in the Galaxy once and for all.*

Toward the 1930's, astronomers gathered sufficient data to be able to quantify the salient geometrical and kinematical features of the Galaxy: the main body of stars forms a flat disc of about 30 kpc in diameter ($\sim 10^{23}$ *cm or* $100,000$ *light years) and about* 2000 *light years-thick. The* galactic center *(nucleus) is surrounded by a spherical distribution of stars called the* galactic bulge *which is hidden from us by clouds of dark interstellar matter. We ourselves are situated far out in the disc, some 10 kpc from its center. The disc is surrounded by the much less flattened* halo *to which the* globular clusters *and certain other classes of stars belong.*

The stars of the disc revolve round the galactic center under the gravitational attraction of the masses that are concentrated there. In particular, the sun describes a circular path of radius about 10 *kpc with a speed of about* $V = 250\ \frac{\text{km}}{\text{sec}}$ *in about* 250 *million years*[553]*. The Galaxy contains about* 10^{11}

[553] The Galaxy must rotate — otherwise all stars would have fallen into the galactic center. Suppose that the sun S moves in a Keplerian circular orbit with radius r_s about C, the galactic center. Draw a line-of-sight to a star P (tangent to the circular orbit of this star about C). The polar coordinates of the star relative to C are (r, θ). Erect a Cartesian coordinate system, with origin at the sun such that the star's motion is in the galactic plane with SC as the x-axis, and the sun's velocity vector along the y-axis. Let ℓ be the angle CSP (galactic longitude). It then follows from elementary plane-geometry considerations that the velocity of approach of P along the line-of-sight is: $U(r, \ell) = \left[\dot{\theta}(r) - \dot{\theta}(r_s)\right] r_s \sin \ell$. Since for a *Keplerian motion* $\frac{d}{dr}\dot{\theta} < 0$, it is evident that $U(r, \ell)$ is positive in quadrants I and III of the Cartesian system

visible stars, gas and dust with a total mass of about 1.5×10^{11} *solar masses* ($1M_\odot = 1.99 \times 10^{33}$ *g*). *Since the gas contains only* $\frac{1}{6}$ *of the total mass, it has little direct influence on the dynamics, but the dense gas clouds are the sites of new star formation and thereby play an important role in the long-term evolution of the Galaxy.*

Since the age of the Galaxy is about 10^{10} *years, a typical disc star has completed over* 30 *revolutions, and hence it is reasonable to assume that the Galaxy is approximately in a steady state at the present time. Simple calculations show that collisions between stars are exceedingly rare and have absolutely no importance to the dynamics of the Galaxy. (This rarity of encounters is fortunate, since the passage of a star within even* 10^9 *km of the sun would cause major perturbations to the earth's orbit and hence have disastrous consequences for life on earth.)*

Because interstellar dust effectively obscures our visual views in the galactic plane, a detailed understanding of the structure of the galactic disc had to await the development of radio astronomy. *Because of their long wavelength, radio waves easily penetrate the interstellar medium without being scattered or absorbed.*

Indeed, radio observations (via Doppler shifted 21*-cm interstellar hydrogen emission*[554], *1951) revealed that our Galaxy has* spiral arms *(concentrations of gas and dust) unwinding from the center in a shape reminiscent of*

---

so that stars and gas in these direction should appear to *approach*, and their spectra should be *blue-shifted*. In quadrants II and IV stellar spectra should appear *red-shifted*. This, in fact, is what Oort observed in 1927. At any given galactic longitude, the highest velocity should be observed at P, where the line-of-sight is tangential. By noting the maximal velocity at given ℓ one can derive the distance of the sun from the galactic center. Present results yield $r_s \sim 9.5$ kpc $\pm$ 1.5 kpc. Using Lindblad's value of $V_s = 250 \ \frac{\text{km}}{\text{sec}}$, and $r_s = 10$ kpc, $G = 6.668 \times 10^{-8}$ dyn cm^2 g^{-2}, Kepler's law $V_s^2 = \frac{GM}{r_s}$ yields the mass of the matter inside the sun's orbit: $M = 2.9 \times 10^{44}$ g $= 1.5 \times 10^{11}$ solar masses. Also $T = \frac{2\pi r_s}{V_s} = 2.3 \times 10^8$ years is the period of the sun's orbit around the galactic center.

554 When the electron and proton spins of a hydrogen atom are parallel, the atom is in a slightly higher energy level than when they are antiparallel. As a result, an atom with parallel spins will eventually flip the electron spin over to reach a lower energy level. This spin flip is accompanied by the emission of a photon that carries away just the energy difference between the two spin states. An average hydrogen atom will spend 10 million years in the parallel spin state before the electron spin flips over, but our Galaxy contains so many hydrogen atoms that about 10^{54} spin flips, and accompanying photon emissions, occur each sec-

a pinwheel. By measuring Doppler shifts, astronomers can determine speeds parallel to our line-of-sight across the Galaxy. These observations clearly indicate that our Galaxy does not rotate like a rigid body but rather exhibits differential rotation.

Thus, the important result of the work of Lindblad and Oort was that the portion of the galaxy in the vicinity of the sun behaves like a fluid, with each star moving in a Keplerian orbit as an independent particle. Near the center of the galaxy this is not true: here the entire system does rotate like a rigid object. The stars in the inner part *of the Galaxy are subject to the combined gravitational pull of all the stars around them (there, speeds of individual stars* increase *with distance from the center, whereas they* decrease *with distance in the outer portion); There is an intermediate distance, just inside the sun's orbit, where a transition between rigid-body and Keplerian orbits occurs, and it is there that stars have the greatest orbital velocities*[555]*.*

---

ond. Collisions among atoms tend to flip some of the antiparallel-spin atoms back into the parallel-spin configuration. At any given time, $\frac{3}{4}$ of the hydrogen atoms have parallel spins, while the remaining ones have antiparallel spins. The parallel-antiparallel spin energy difference amounts to 9.5×10^{-18} erg, and the corresponding frequency is $\frac{\Delta E}{h} = 1420.4058$ megahertz, corresponding to a wavelength $= \frac{hc}{\Delta E} = 21.10611$ centimeters. The astronomer points his radio telescope in a particular direction in the plane of the Galaxy and measures the intensity of the 21-cm hydrogen emission received (proportional to the number of hydrogen atoms in that direction). The receiver is swept in frequency around the 21-cm frequency, and a profile of intensity versus frequency is compiled. The detected emission is not exactly at 21-cm wavelength: The telescope receives 21-cm emission from each segment of spiral arm in that direction, but because of differential rotation, a given arm segment has a distinct velocity from the others that are closer to the center or farther out. Therefore, instead of a single emission peak at 21.1 cm, what we see is a cluster of emission lines near this wavelength but separated from each other by the Doppler effect.

Now, by measuring Doppler shifts away from the standard frequency, astronomers can determine the relative velocity toward or away from us that characterizes a particular group of hydrogen atoms. If we assume that all the atoms move in circular orbits around the galactic center, we can correlate a distance along our line-of-sight to each particular Doppler shift. (The assumption of perfectly circular orbits introduces some imprecision, but the distances derived from this assumption are thought to be rather accurate.)

Using this method, astronomers have mapped the hydrogen distribution in the galactic plane. It showed that hydrogen does concentrate in particular "arms" that exhibit a vaguely spiral pattern.

[555] In the Galaxy, the deviation of a star's motion from a perfect circular orbit is called its *peculiar velocity*. The sun has a velocity of about 20 km/sec w.r.t. a

However, the orbital velocities do not *drop off to lower and lower velocities beyond the sun's orbit, (as it would if all the mass of the galaxy were concentrated at its center). In fact, the orbital velocity of stars and gas is observed to* increase *out to a distance of at least* 60,000 *light years from the galactic center. This indicates that a surprising amount of matter must be scattered around the edges of our Galaxy, raising the total galactic mass to a total of some* $6 \times 10^{11}\ M_{\odot}$. *This outlying matter is dark; it does not show up on photographs. Many astronomers suspect that it is spherically distributed all around the galaxy, along with the globular clusters. Thus our Galaxy halo is more massive than previously expected.*

Almost half the galaxies we know are spiral galaxies like the Milky Way, with a spiral-arm pattern of young, bright stars and interstellar hydrogen gas. When we consider the fact that the inner parts of these spiral galaxies rotate with a higher angular velocity than the outer parts, we would expect that the spiral arms would be wound up after a few revolutions (the farthest regions complete one revolution in 400 *million years, while close to the center it takes only* 100 *million years). Why, then, does the spiral pattern persist? We know that it* does *persist, for we would not otherwise see so many spiral galaxies.*

Bertil Lindblad *was first to argue that the spiral arms of a galaxy are merely a* pattern *(density wave) that propagates among the actual stars. Lindblad struggled with the problem from* 1927 *until his death in* 1965. *He correctly recognized that spiral structure arises through the interaction between the orbits and the gravitational forces of the stars of the disc, and thus should be investigated using stellar dynamics.*

Lindblad recognized that such density waves *would be caused by gravitational perturbations on the circular Keplerian orbit of a star by the motion of other matter in the galaxy. This will cause the star to rotate counterclockwise around an epicycle while the epicycle itself moves clockwise along the undisturbed path. The final path of the star is a* precessing ellipse. *The gravity of this star in turn affects the motions of its neighbors, and thus a wave disturbance, called a* kinematic density wave, *propagates from one stellar orbit to the next.*

The density-wave theory was greatly elaborated and mathematically embellished by the American astronomers ***C.C. Lin*** *and* ***Frank Shu*** *during* 1964–1969. *They made the crucial step that elucidated the theory toward which Lindblad had been groping. They have shown that the spiral structure represents a local increase in density and that this enhanced density spiral*

circular orbit, in a direction about 45° from the galactic center and slightly out of the plane of the disc.

travels around the galaxy like a wave, at a "pattern" velocity different from that of the speed of the stars involved[556].

Stars and gas overtake the spiral pattern, and as they enter it, the gas density increases to 5 *or* 10 *times its density outside. This increase in gas density has an important effect. It triggers the formation and collapse of large gas clouds, which condense into* protostars *within a million years or so — producing clumps of young, bright stars. Thus, within a few million years after the gas enters a dense part of the pattern, some of it becomes incorporated into one of the bright stars that outline spiral arms for a few million years before fading away into obscurity. After a few million (or tens of millions) of years, these stars, known as Blue giants, burn themselves out, because they burn their nuclear fuel so prodigiously.*

By the time the pattern has moved a significant distance around the galaxy relative to the stars, the stars that once outlined the spiral arm will be fading away, while a new group of stars forms the gas that has entered the dense part of the pattern more recently. Thus the density-wave pattern persists even as the individual bright stars perish. It is not known how such a spiral density-wave pattern gets started; one theory suggests that it originates with a close encounter between galaxies. Another theory suggests that spiral galaxies generate their own density-wave pattern.

In 1973, ***A.J. Kalnajs*** *elaborated on the theory of Lin and Shu and showed that each of their precessing elliptical orbit is tilted w.r.t. its neighbor through a specific angle, resulting in a spiral pattern which arises in those locations where the ellipses are bunched together. Thus, in spite of the natural random scatter of the stars in their orbits, the orbits become correlated such that some of the stars happen to get close together along the high arching spiral arms. This in turn enhances the gravitational attraction upon the lightweight atoms and molecules in the interstellar gas and dust, which are readily sucked into the gravitational well along the spiral — forming the crest of the density wave.*

In Kalnajs' spiral pattern process, the density wave moves through the material of the Galaxy at a speed of about 30 *km/sec, slower than the stars themselves. On its own, however, the interstellar gas can transport a compressional disturbance at a speed of only* 10 *km/sec, which is the speed of sound in the interstellar medium. The density wave is therefore* supersonic
