"The genesis of the majority of mathematical theories is obscure and difficult. Often, today's presentation of a classical topic, will be much more accessible and concise than it could even have been when it was developed. Any scientist's work, can only be understood within its contemporary scientific framework".

Walter K. Bühler

Preface

Many books are published every year on the history of science, but I know of no comprehensive treatise that blends the essential historical data (chronology, biographies, major background political and economical events, etc.) *together* with science proper (principles, laws, experiments, observations, theories, equations, etc.). The present encyclopedic treatise does just that; it tells the reader not only *who* did it and *when* it was done but also precisely *what* was done.

The saga of this history of ideas, discovery and invention in the natural and mathematical sciences – spanning about 100 generations of great thinkers from Thales to Feynman – unfolds in all its grandeur before the eyes and mind of the reader. Whether to professional scientists, students, or unassuming curious laymen, the doors of this shrine are open, inviting them to browse, linger and study whatever suits them. I believe that every intelligent person can understand the development of science when properly presented from its beginnings; The historical method is the best for introducing scientific facts and ideas to unprepared minds in a thoroughly understandable manner.

The history of science is more than the arithmetical sum of the histories of all sciences, for it also explains the interrelations of them all. Indeed, our division of science into many branches is largely artificial. Like the branches of a living tree which have no separate existence, but grow together – the progress of each science is dependent upon the progress of all the others.

The main postulate of science is the unity of nature: *nature is one*; and therefore, *science is one*. Finally, the fact that simultaneous discoveries have been made by different groups of workers, in different settings, organizations and nations, demonstrate that *mankind is one*: one mankind through one science is unfolding the mysteries of one nature.

It follows that the only rational way to subdivide this history is not according to the sciences or countries involved, but only according to time; for each period of time we have to consider at once the *whole* of science's historical and intellectual development. This calls for the marshaling of all scientific facts, activities and ideas in a definite order; which means that we must try to assign to each of them a date as precise as possible – not just the date of their birth or their publication, but also that of their *actual incorporation into our knowledge* – often a very difficult thing to do, as the reader will not fail to appreciate. Such work of erudition is the bedrock upon which this history is built.

We have also considered some other departments of life which have bearing on the evolution of science. These are:

- General natural and human history, especially the history of civilization.
- The history of technology.
- The history of philosophy and religions.

To make this general synthesis possible, we found it expedient to write a large number of monographs on various subjects which emphasize the interrelations between environmental, economic, social, cultural, political and scientific 'events' (e.g. the history of epidemics is needed to correctly estimate the evolution of medical ideas).

The history of science is a field of endless complexity and incredible scope. There are many ways to study it and many points of view, none of which is exclusive of the others. The chronological order of discoveries is often very different from their logical sequence. What some people call the logic of scientific discovery is largely a retrospective construction; it is nevertheless useful to bring it out. Discoveries are not always made in logical order but it is worthwhile and helpful to attempt to explain them in such an order: the actual path of progress is not straight but very crooked, although the general direction is clear enough.

We have interspersed our history with a narration of general intellectual climate and of major social, cultural, political, economic and environmental events: science does not develop in a social vacuum and every man of science needs a modicum of food and other amenities in order to do his work; if called to arms and killed in battle his activities come to an end; if he is an empirical scientist, his opportunities will depend upon the laboratory or observatory to which he has been admitted or which he was able to fashion, and his freedom to pursue his work will be limited by the good or bad will of administrators or fellow workers. Yet nobody can completely control his spirit; he may be helped or hindered, but his scientific ideas are not determined by social factors. Honest men of science and mathematics have often continued activities detrimental to their material interests.

In this treatise, I have tried to draw a map of science, technology and great ideas that would be as accurate and complete as possible, yet sufficiently free from unnecessary details and sufficiently condensed so as not to obstruct the general view.

The book was composed through intensive work during 1991–2008. I had planned to present it to my readers just at the turn of the millennium, but unexpected difficulties prevented me from this symbolic gesture.

The diverse sources used in my work are listed in the bibliography and sometimes in the text itself. Whenever possible, the data was cross-checked between different sources.

January 2009 Ari Ben-Menahem

About the Author

Ari Ben-Menahem (Schlanger) was born in Berlin, Germany and came to Israel in 1934.

He earned his M.Sc. degree in physics from the Hebrew University of Jerusalem (1954) and his Ph.D. degree from the California Institute of Technology (1961). He has been a Professor of Mathematics and Geophysics at the Weizmann Institute of Science in Israel since 1964 and a visiting Professor at MIT, Stanford University and the University of Paris. During 1970–1995 he was the incumbent of the Ayala and Sam Zacks Chair of Geophysics at the Weizmann Institute.

Prof. Ben-Menahem also served as Chief Seismologist of the Government of Israel, member of the European Seismological Commission, US National Research Council Fellow and Director of Adolpho Bloch Geophysical Observatory.

Between 1958 and 2008 he published over 150 papers including graduate textbooks (Springer 1981, Dover 2000). He pioneered the birth of modern seismic source elastodynamics based on his observation of wave radiation from

finite rupturing faults with subshear velocity (1960). He introduced the fundamental concepts of Directivity (1959), and Potency (1965) from which the Moment Tensor was derived. He unraveled (1975) the mystery of the Tunguska bolide explosion of 1908.

In this comprehensive tour de force, Prof. Ben-Menahem – a polymath equally versed in pure and applied science, and the humanities – rises to the challenge of tracing the tapestry of human thought and action throughout history and up to our own age, placing it in the context of our niche in the universe.

Alternating between fine details and bird's-eye vistas, this Encyclopedia encompasses man's science and artifice, illuminating his connections with his environmental, economic, sociopolitical and cultural development.

Acknowledgments

I would like to express heartfelt thanks to our family members: Dr. Shahar Ben-Menahem, assisted me in the formulation of essays dealing with modern theoretical physics, contemporary pure mathematics and the nature and evolution of scientific discovery and invention. He is also the text editor of chapters 4 and 5 of this encyclopedia. I am deeply indebted to him for dedicating long time and great efforts to the completeness, accuracy and streamlining of the book.

Dr. Gali Oren-Amit helped me with the formulation of the medical essays. Savyon Amit (LL.B, MBA) assisted me in all legal matters, and helped me keep on track with the publication process. Their children Erel and Ella provided a warm atmosphere of friendly cooperation and fun.

My secretary, Sarah Fliegelman, word-processed the manuscript, until her untimely death in 2002. The camera-ready text was then prepared by Denis Simakov, Ph.D. and Olga Shomron, M.Sc.

The librarians of the Weizmann Institute Wix Library: Miriam Gordon, Libeta Chernobrov and Anna Ilionski rendered constant assistance in search of bibliographic material.

I convey my deep appreciation to professor Max Jammer of Bar-Illan University who heeded the publishers invitation to review the manuscript.

Special thanks go to my editor Dr. Christian Witschel, his assistant Marion Schneider and the Development editor Dr. Sylvia Blago.

My teachers throughout my student years deserve my gratitude for opening to me the doors of the world of science; At the Hebrew University I owe tribute to Profs. G. Racah, A.H. Fraenkel, Y. Levitski, M. Schiffer and C.L. Pekeris; At the California Institute of Technology I had the privilege of being taugth by Profs. F. Press, H. Benioff, O. Taussky, A. Erdelyi and R.P. Feynman.

At the Weizmann Institute I benefited from the friendship of Profs. D. Vofsy, J. Gillis and S. Freier.

But, first and foremost, I am honored to pay my homage to my father Moshe Ben-Menahem (Schlanger): poet, writer and educator, who set me on the course of my scientific career through his imperative maxim: "Always think like a philosopher, see like an artist, and feel like a poet."

He has been a Professor of Mathematics and Geophysics at the Weizmann Institute of Science in Israel since 1964 and a visiting Professor at MIT, Stanford University and the University of Paris. During 1970–1995 he was the incumbent of the Ayala and Sam Zacks Chair of Geophysics at the Weizmann Institute.

Prof. Ben-Menahem also served as Chief Seismologist of the Government of Israel, member of the European Seismological Commission, US National Research Council Fellow and Director of Adolpho Bloch Geophysical Observatory.

Between 1958 and 2008 he published over 150 papers including graduate textbooks (Springer 1981, Dover 2000). He pioneered the birth of modern seismic source elastodynamics based on his observation of wave radiation from

finite rupturing faults with subshear velocity (1960). He introduced the fundamental concepts of Directivity (1959), and Potency (1965) from which the Moment Tensor was derived. He unraveled (1975) the mystery of the Tunguska bolide explosion of 1908.

In this comprehensive tour de force, Prof. Ben-Menahem – a polymath equally versed in pure and applied science, and the humanities – rises to the challenge of tracing the tapestry of human thought and action throughout history and up to our own age, placing it in the context of our niche in the universe.

Alternating between fine details and bird's-eye vistas, this Encyclopedia encompasses man's science and artifice, illuminating his connections with his environmental, economic, sociopolitical and cultural development.

Acknowledgments

I would like to express heartfelt thanks to our family members: Dr. Shahar Ben-Menahem, assisted me in the formulation of essays dealing with modern theoretical physics, contemporary pure mathematics and the nature and evolution of scientific discovery and invention. He is also the text editor of chapters 4 and 5 of this encyclopedia. I am deeply indebted to him for dedicating long time and great efforts to the completeness, accuracy and streamlining of the book.

Dr. Gali Oren-Amit helped me with the formulation of the medical essays. Savyon Amit (LL.B, MBA) assisted me in all legal matters, and helped me keep on track with the publication process. Their children Erel and Ella provided a warm atmosphere of friendly cooperation and fun.

My secretary, Sarah Fliegelman, word-processed the manuscript, until her untimely death in 2002. The camera-ready text was then prepared by Denis Simakov, Ph.D. and Olga Shomron, M.Sc.

The librarians of the Weizmann Institute Wix Library: Miriam Gordon, Libeta Chernobrov and Anna Ilionski rendered constant assistance in search of bibliographic material.

I convey my deep appreciation to professor Max Jammer of Bar-Illan University who heeded the publishers invitation to review the manuscript.

Special thanks go to my editor Dr. Christian Witschel, his assistant Marion Schneider and the Development editor Dr. Sylvia Blago.

My teachers throughout my student years deserve my gratitude for opening to me the doors of the world of science; At the Hebrew University I owe tribute to Profs. G. Racah, A.H. Fraenkel, Y. Levitski, M. Schiffer and C.L. Pekeris; At the California Institute of Technology I had the privilege of being taugth by Profs. F. Press, H. Benioff, O. Taussky, A. Erdelyi and R.P. Feynman.

At the Weizmann Institute I benefited from the friendship of Profs. D. Vofsy, J. Gillis and S. Freier.

But, first and foremost, I am honored to pay my homage to my father Moshe Ben-Menahem (Schlanger): poet, writer and educator, who set me on the course of my scientific career through his imperative maxim: “Always think like a philosopher, see like an artist, and feel like a poet.”

"The genesis of the majority of mathematical theories is obscure and difficult. Often, today's presentation of a classical topic, will be much more accessible and concise than it could even have been when it was developed. Any scientist's work, can only be understood within its contemporary scientific framework".

Walter K. Bühler

Preface

Many books are published every year on the history of science, but I know of no comprehensive treatise that blends the essential historical data (chronology, biographies, major background political and economical events, etc.) *together* with science proper (principles, laws, experiments, observations, theories, equations, etc.). The present encyclopedic treatise does just that; it tells the reader not only *who* did it and *when* it was done but also precisely *what* was done.

The saga of this history of ideas, discovery and invention in the natural and mathematical sciences – spanning about 100 generations of great thinkers from Thales to Feynman – unfolds in all its grandeur before the eyes and mind of the reader. Whether to professional scientists, students, or unassuming curious laymen, the doors of this shrine are open, inviting them to browse, linger and study whatever suits them. I believe that every intelligent person can understand the development of science when properly presented from its beginnings; The historical method is the best for introducing scientific facts and ideas to unprepared minds in a thoroughly understandable manner.

The history of science is more than the arithmetical sum of the histories of all sciences, for it also explains the interrelations of them all. Indeed, our division of science into many branches is largely artificial. Like the branches of a living tree which have no separate existence, but grow together – the progress of each science is dependent upon the progress of all the others.

The main postulate of science is the unity of nature: *nature is one*; and therefore, *science is one*. Finally, the fact that simultaneous discoveries have been made by different groups of workers, in different settings, organizations and nations, demonstrate that *mankind is one*: one mankind through one science is unfolding the mysteries of one nature.

It follows that the only rational way to subdivide this history is not according to the sciences or countries involved, but only according to time; for each period of time we have to consider at once the *whole* of science's historical and intellectual development. This calls for the marshaling of all scientific facts, activities and ideas in a definite order; which means that we must try to assign to each of them a date as precise as possible – not just the date of their birth or their publication, but also that of their *actual incorporation into our knowledge* – often a very difficult thing to do, as the reader will not fail to appreciate. Such work of erudition is the bedrock upon which this history is built.

We have also considered some other departments of life which have bearing on the evolution of science. These are:

- General natural and human history, especially the history of civilization.
- The history of technology.
- The history of philosophy and religions.

To make this general synthesis possible, we found it expedient to write a large number of monographs on various subjects which emphasize the interrelations between environmental, economic, social, cultural, political and scientific 'events' (e.g. the history of epidemics is needed to correctly estimate the evolution of medical ideas).

The history of science is a field of endless complexity and incredible scope. There are many ways to study it and many points of view, none of which is exclusive of the others. The chronological order of discoveries is often very different from their logical sequence. What some people call the logic of scientific discovery is largely a retrospective construction; it is nevertheless useful to bring it out. Discoveries are not always made in logical order but it is worthwhile and helpful to attempt to explain them in such an order: the actual path of progress is not straight but very crooked, although the general direction is clear enough.

We have interspersed our history with a narration of general intellectual climate and of major social, cultural, political, economic and environmental events: science does not develop in a social vacuum and every man of science needs a modicum of food and other amenities in order to do his work; if called to arms and killed in battle his activities come to an end; if he is an empirical scientist, his opportunities will depend upon the laboratory or observatory to which he has been admitted or which he was able to fashion, and his freedom to pursue his work will be limited by the good or bad will of administrators or fellow workers. Yet nobody can completely control his spirit; he may be helped or hindered, but his scientific ideas are not determined by social factors. Honest men of science and mathematics have often continued activities detrimental to their material interests.

In this treatise, I have tried to draw a map of science, technology and great ideas that would be as accurate and complete as possible, yet sufficiently free from unnecessary details and sufficiently condensed so as not to obstruct the general view.

The book was composed through intensive work during 1991–2008. I had planned to present it to my readers just at the turn of the millennium, but unexpected difficulties prevented me from this symbolic gesture.

The diverse sources used in my work are listed in the bibliography and sometimes in the text itself. Whenever possible, the data was cross-checked between different sources.

The main postulate of science is the unity of nature: *nature is one*; and therefore, *science is one*. Finally, the fact that simultaneous discoveries have been made by different groups of workers, in different settings, organizations and nations, demonstrate that *mankind is one*: one mankind through one science is unfolding the mysteries of one nature.

It follows that the only rational way to subdivide this history is not according to the sciences or countries involved, but only according to time; for each period of time we have to consider at once the *whole* of science's historical and intellectual development. This calls for the marshaling of all scientific facts, activities and ideas in a definite order; which means that we must try to assign to each of them a date as precise as possible – not just the date of their birth or their publication, but also that of their *actual incorporation into our knowledge* – often a very difficult thing to do, as the reader will not fail to appreciate. Such work of erudition is the bedrock upon which this history is built.

We have also considered some other departments of life which have bearing on the evolution of science. These are:

- General natural and human history, especially the history of civilization.
- The history of technology.
- The history of philosophy and religions.

To make this general synthesis possible, we found it expedient to write a large number of monographs on various subjects which emphasize the interrelations between environmental, economic, social, cultural, political and scientific 'events' (e.g. the history of epidemics is needed to correctly estimate the evolution of medical ideas).

The history of science is a field of endless complexity and incredible scope. There are many ways to study it and many points of view, none of which is exclusive of the others. The chronological order of discoveries is often very different from their logical sequence. What some people call the logic of scientific discovery is largely a retrospective construction; it is nevertheless useful to bring it out. Discoveries are not always made in logical order but it is worthwhile and helpful to attempt to explain them in such an order: the actual path of progress is not straight but very crooked, although the general direction is clear enough.

We have interspersed our history with a narration of general intellectual climate and of major social, cultural, political, economic and environmental events: science does not develop in a social vacuum and every man of science needs a modicum of food and other amenities in order to do his work; if called to arms and killed in battle his activities come to an end; if he is an empirical scientist, his opportunities will depend upon the laboratory or observatory to which he has been admitted or which he was able to fashion, and his freedom to pursue his work will be limited by the good or bad will of administrators or fellow workers. Yet nobody can completely control his spirit; he may be helped or hindered, but his scientific ideas are not determined by social factors. Honest men of science and mathematics have often continued activities detrimental to their material interests.

In this treatise, I have tried to draw a map of science, technology and great ideas that would be as accurate and complete as possible, yet sufficiently free from unnecessary details and sufficiently condensed so as not to obstruct the general view.

The book was composed through intensive work during 1991–2008. I had planned to present it to my readers just at the turn of the millennium, but unexpected difficulties prevented me from this symbolic gesture.

The diverse sources used in my work are listed in the bibliography and sometimes in the text itself. Whenever possible, the data was cross-checked between different sources.

January 2009 Ari Ben-Menahem

About the Author

Ari Ben-Menahem (Schlanger) was born in Berlin, Germany and came to Israel in 1934.

He earned his M.Sc. degree in physics from the Hebrew University of Jerusalem (1954) and his Ph.D. degree from the California Institute of Technology (1961). He has been a Professor of Mathematics and Geophysics at the Weizmann Institute of Science in Israel since 1964 and a visiting Professor at MIT, Stanford University and the University of Paris. During 1970–1995 he was the incumbent of the Ayala and Sam Zacks Chair of Geophysics at the Weizmann Institute.

Prof. Ben-Menahem also served as Chief Seismologist of the Government of Israel, member of the European Seismological Commission, US National Research Council Fellow and Director of Adolpho Bloch Geophysical Observatory.

Between 1958 and 2008 he published over 150 papers including graduate textbooks (Springer 1981, Dover 2000). He pioneered the birth of modern seismic source elastodynamics based on his observation of wave radiation from

finite rupturing faults with subshear velocity (1960). He introduced the fundamental concepts of Directivity (1959), and Potency (1965) from which the Moment Tensor was derived. He unraveled (1975) the mystery of the Tunguska bolide explosion of 1908.

In this comprehensive tour de force, Prof. Ben-Menahem – a polymath equally versed in pure and applied science, and the humanities – rises to the challenge of tracing the tapestry of human thought and action throughout history and up to our own age, placing it in the context of our niche in the universe.

Alternating between fine details and bird's-eye vistas, this Encyclopedia encompasses man's science and artifice, illuminating his connections with his environmental, economic, sociopolitical and cultural development.

Acknowledgments

I would like to express heartfelt thanks to our family members: Dr. Shahar Ben-Menahem, assisted me in the formulation of essays dealing with modern theoretical physics, contemporary pure mathematics and the nature and evolution of scientific discovery and invention. He is also the text editor of chapters 4 and 5 of this encyclopedia. I am deeply indebted to him for dedicating long time and great efforts to the completeness, accuracy and streamlining of the book.

Dr. Gali Oren-Amit helped me with the formulation of the medical essays. Savyon Amit (LL.B, MBA) assisted me in all legal matters, and helped me keep on track with the publication process. Their children Erel and Ella provided a warm atmosphere of friendly cooperation and fun.

My secretary, Sarah Fliegelman, word-processed the manuscript, until her untimely death in 2002. The camera-ready text was then prepared by Denis Simakov, Ph.D. and Olga Shomron, M.Sc.

The librarians of the Weizmann Institute Wix Library: Miriam Gordon, Libeta Chernobrov and Anna Ilionski rendered constant assistance in search of bibliographic material.

I convey my deep appreciation to professor Max Jammer of Bar-Illan University who heeded the publishers invitation to review the manuscript.

Special thanks go to my editor Dr. Christian Witschel, his assistant Marion Schneider and the Development editor Dr. Sylvia Blago.

My teachers throughout my student years deserve my gratitude for opening to me the doors of the world of science; At the Hebrew University I owe tribute to Profs. G. Racah, A.H. Fraenkel, Y. Levitski, M. Schiffer and C.L. Pekeris; At the California Institute of Technology I had the privilege of being taugth by Profs. F. Press, H. Benioff, O. Taussky, A. Erdelyi and R.P. Feynman.

At the Weizmann Institute I benefited from the friendship of Profs. D. Vofsy, J. Gillis and S. Freier.

But, first and foremost, I am honored to pay my homage to my father Moshe Ben-Menahem (Schlanger): poet, writer and educator, who set me on the course of my scientific career through his imperative maxim: "Always think like a philosopher, see like an artist, and feel like a poet."

Science ‘Progress’ Reports

Worldviews

Why Study the History of Science?

There are a number of compelling reasons for studying the history of science:

1. The story of the development of science can be used as a vehicle for helping *teaching science* to non-scientists. In students, it awakens their critical sense; in working scientists and other thinkers, it tempers the tendency to assume that their original contributions are antecedent-free.

2. From a purely historical perspective, the study of the history of science helps us analyze the development of civilization, to understand man and understand the deeper significance of science. The history of ancient and medieval science is at least as useful as that of modern science. He who knows only one of these histories does not really know the history of science, nor does he know the history of civilization.

3. To project into the future, the present is obviously not enough, and we must depend heavily on historical perspective. This is because the recapitulation of the work of previous generations puts in context the present state of science. Moreover, our civilization in particular is essentially different from earlier ones, because our knowledge of the world and of ourselves is deeper, more precise, and more certain; because we have gradually learned to disentangle the patterns, structures and forces of nature, and because we have contrived, by strict obedience to their governing laws, to capture them and to divert them to the gratification of our own needs. Thus our civilization, more so than previous ones, cannot be understood without proper comprehension of the history of science.

4. Geography and history are two necessary bases of man's education; just as some knowledge of geography removes his provincialism with regard to space – that is, teaches him that things are not necessarily better in his own village, in his own metropolis or in his own country than elsewhere – even so, a knowledge of history is the only way of removing this provincialism with regard to time as well – that is, of making him realize that things are not necessarily better in his day than in earlier or, maybe, in later ones. One has to look at things as they really were perceived in their own time: scientists of the past did *not* think about their own work the way we do; e.g. Kepler did *not* deduce his famous three laws by merely studying the data of Tycho Brahe; much of the spirit of the Middle Ages and the Greek World suffused Kepler's thinking – things that we now no longer associate with planetary motions, were on his mind.

5. As emphasized by physicist Steven Weinberg, the history of science shows us that in their final form the laws of nature are *culture-free*

and permanent, in spite of the fact that many cultural and psychological influences enter into scientific work. In the limit, cultural influences are refined away. Aside from inessentials like the mathematical notation we use, the laws of physics as we understand them now – and thus those of all other sciences, which can be reduced to them in the final analysis – are nothing but a description of reality. When a "revolution" in science replaces one well-verified theory with a better one – e.g. classical mechanics with *relativistic* and/or *quantum* mechanics – the old theory continues to be both (approximately) valid and useful, within its own, more restricted domain.

On this view, physical theories are like fixed points, toward which we are attracted. Starting points may be culturally determined, paths may be affected by personal philosophies, but the fixed point is there nonetheless. It is something toward which any physical theory moves; when we get there we know it, and then we stop. The *final theory* toward which we are moving will be (if reached) a theory of unrestricted validity, a theory applicable to all phenomena throughout the universe - a theory that, when finally attained, will be a permanent part of our knowledge of the world, encompassing all previous successful theories as special limiting cases.

6. The history of science teaches us that it is those ideas that were most successful, of which we should be especially wary, i.e. great heroic ideas of the past can weigh upon us, preventing us from seeing things in a new light and from a fresh perspective. Pioneers are beginners: they cannot be expected to complete their task; it is not their business to complete it. Consider the following example (again due to Weinberg):

   In 1915, Einstein, in the formulation of his theory of gravitation, assumed (in addition to the principle of equivalence) that the equations of the General Theory of Relativity are 2^{nd} order partial differential equations (PDEs); i.e. involve only rates of change in time and space and the rates at which these rates change – but no higher order of change [like the Maxwell equations, the diffusion equation, etc.].

   He could have made them 4^{th} order PDEs – but he did not. Today, this theory of his is regarded a field theory that provides an *approximation valid in the limit of large distances* (much larger than the *Planck length* of 10^{-33} cm). If one supposes that there are terms of higher order derivatives, such terms play no significant role at these large distances, and are thus fairly irrelevant to astronomical (or even most cosmological) observations. We now realize that there must – for many reasons which Einstein could not have foreseen – be such corrections, and that they will be necessary in order to study matter, fields and spacetime at the *Planck scale*.

Guide to the Reader

The main body of this multilateral Encyclopedic History consists of biographies interspersed with essays, articles and events. The biographies are arranged chronologically, within the domains of six consecutive epochal chapters. There are about 2070 detailed biographies of scientists, thinkers, engineers, explorers, inventors and associated creative minds who, in one way or another, left their mark on the history of science and technology in the fields of: *mathematics*, *philosophy*, *logic*, *physical and environmental sciences* (physics, chemistry, astronomy, earth and space sciences, cosmology), *life sciences* (biology, medicine, physiology, botany, zoology, biochemistry), associated engineering disciplines, and *social sciences* (economics, psychology, sociology, anthropology, linguistics etc.).

The total number of scientists, thinkers and other creative individuals featured in the treatise is about 3000.

The book includes the names of some 1700 *inventors* over a period of 2500 years. Of these, 300 belong to the period 350 BCE – 1900 and the rest to the 20^{th} century alone.

The articles (380 in number) summarize the time-evolution of ideas in the above leading fields of science, technology, mathematics and philosophy. In addition, I have included historical environmental events that impacted civilization and also important politico-historical events that affected science, technology and world-order. The reader will also find many useful tables and some 20 'Science Progress Reports' (SPR) dealing with scientific setbacks.

The biographies and articles of this encyclopedia are interspersed with many *quotations*, gathered from the wit and wisdom of sages, savants and scholars throughout the ages from antiquity to modern times.

These quotations are to be found within the text in chapter 6 and under the heading "worldviews" where they are attached to some fifty selected individuals from Socrates to Feynman.

In these quotations, man reflects on himself, his condition, his times and on science proper through the thoughts of scientists, philosophers, humanists, poets, theologists, statesmen, and other miscellaneous mortals.

Our list of biographies is arranged in strict chronology. We must however remember that history is full of uncertitudes. Even when we have managed to arrange our facts in chronological order, we are not sure that the antecedents have influenced the consequents. But at any rate, we are sure that the consequents have not influenced antecedents, and historical certainty is so rare that, when we find it, we must stick to it as closely as possible.

Chapter 6 is dedicated to the second half of the 20^{th} century. Had I included here biographies of contemporary scientists together with proper essays on their respective research achievements (and considering the exponential growth of science during 1950–2005), this chapter alone would have grown into a gigantic size of some 5000 pages. The time needed for the completion of this task would require me to delay the presentation of the encyclopedia by at least five years. To circumvent this difficulty, I have decided to present a general layout of the major research topics and current front-lines, supplemented with tables, timelines and a few key essays.

Credits for Originality of Ideas and Inventions

Observations and measurements provide data that accumulate from epoch to epoch. These form the stuff of hypotheses and theories that in turn suggest new observations. Ultimately we arrive at a major synthesis. These also accumulate, building toward the goal of an ever more inclusive and simple conceptual structure. Connectivity involves the influences of one epoch, one school, one scholar on others, leading to a significant advance in the science. It is a sad but true fact that historical relevance accrues not to the originator of the idea or a fact but to the person providing the connections. e.g. credit for relevance goes not to Aristarchos of Samos, who first proposed, eighteen centuries before Copernicus, that the earth moves around the sun, since that insight was lost. Rather, the connectivity of Copernicus to Galileo, Kepler and Newton was seminal to eventual progress.

It has been said that: "credit in science goes to the man who convinced the world, not to the man to whom the idea first occurs".

My policy in this treatise has been to give credit wherever credit in due, i.e. also to the originator of an idea or a fact, irrespective of whether he made the connection or not. In fact, I made it my business, as much as I was able, to search for the *true originators.*

Credits for Sources of Information

I have borrowed factual information from a vast number of books, articles and encyclopedias, but the creative synthesis of all these sources into a final mold is mine alone, and the responsibility for accuracy and relevance rests on my shoulders. I believe that in presenting the finished material to my readers, I have saved them the trouble and effort of reading libraries of books.

The cited bibliography is sufficient, although no effort was made to make it complete: first, there is a limit to what a single author can reach and read. Then, even from his chosen sources, not everything is suitable nor available to the common reader. However, in this day and age, when the Internet is within reach of many people, all those who wish to, can update their knowledge on a particular subject, person or event. The length of my reviews of a person's life-work was not intended to be a measure of his or her greatness and importance.

Selection of Persons

In a work of this kind, it is not easy to know where to draw the line between inclusions and omissions. While it is relatively easy to determine the most important scientists and thinkers, it is more difficult to agree upon personalities of the second and lower orders. Very often, the inclusion of one scientist entails the admittance of a number of others whose merits were of the same stature. Thus, while it is impossible that I have overlooked any really important personality, it is probable that I have included a few whom it would be better to omit. Clearly, no selection would please everybody. As a rule, however, I have adhered to the following selection criteria:

- Not to mention a person unless there is something special to say of his or her activity (discovery, book, etc.).

- Name people who took the first step in the right direction, however simple it may seem in retrospect.

- Take into consideration the opinion of both contemporaries and later scholars about the contributor.

- Consider the impact and influence of a person's actions, writings and ideas upon the history of science, in both short and long range perspectives.

It was my original intent to deal only with the history of pure science, *but it is often difficult, if not impossible, to draw the line between pure science and the applications.* Sometimes the applications were discovered first and the principles deduced from them; sometimes the converse; but in any case pure and applied science grow together. Yet a line must be drawn somehow, for while the number of pure scientists is relevantly small, that of physicians, teachers, engineers, and other practitioners have always been considerable. My rule is to *speak of a physician, an engineer, or a teacher only if he added something definite to our knowledge*, or if he wrote treatises which were sufficiently original and valuable, or if he did his task in such a masterly way as to introduce new professional standards.

Selection of Data and Evaluation of Scientists

Objective material and scientific facts (equations, laws, rules, discoveries, inventions etc.) are relatively easy to choose, formulate and explain. Human facts are not as clear-cut and are often highly capricious and evanescent. It is thus a difficult mission to choose a few of the achievements amongst a great many.

My account of each personality has been as brief is possible but it is sometimes much easier to indicate a great achievement than a much smaller one, and thus some of the notes devoted to second-rate personalities are much longer than one would expect. This does not matter in itself, *but the reader is warned not to try to measure the importance of a person by the length of the note devoted to him or her; there is no relation between the two.*

I may have made accidental errors in my choice, by omission or commission, but I do not believe that I have made systematic errors. Nevertheless, a certain bias may have been introduced by my *linguistic preferences* (English, French, German, Hebrew), my *scientific specialization* (physics, mathematics, chemistry, geophysics, history, philosophy), *education* (Israel, Sweden, USA) and *origins* (Eastern Europe, Germany and Israel).

I have tried to be as concrete as possible, that is to say, to indicate the specific achievements or contribution in the clearest and briefest manner. That was never easy, often difficult, sometimes impossible. Even as in our own day, there were a number of people in the Middle Ages who attained considerable prestige and rendered undeniable services, yet of whom it can not be said positively who did this or that. In such cases, where the influence was of an indefinite nature, I have been obliged to be vague. In a few other cases I have been reduced to a similar vagueness by my ignorance.

Names of Persons

In the transliteration of names not originally written in the Latin alphabet (e.g. Japanese, Persian, Greek, Chinese) I have followed Sarton whose motto was: 'consistency and simplicity', and who wrote foreign names in such a form that the original written form might be easily reconstructed and found in the dictionary.

Permanent Surnames are of relatively modern origin; they did not exist at all in the Middle Ages. There are many ways of naming a person, and much ambiguity is thus caused. I quoted all the names that each person was known under and selected one of these as the best. When mentioning that person I have always used that name.

The Muslim names are especially difficult. I have given, whenever I could, a large part of their names, not necessarily the whole of them, because this involve a genealogy of indefinite length. In general I have tried to select a name which would be convenient and as characteristic as possible. The case of Chinese and Japanese names poses another difficulty, because, according to their customs, names are not only changed during life, but even after death. and many men are best known under a posthumous name. Hebrew names and words were used in accordance with the 'Jewish Encyclopedia'.

Following George Sarton, I have translated the Greek termination *os* and $o\nu$ by os and on. This has the distinct advantage of distinguishing Greek from Latin writers: Epicuros, Epictetos – Lucretius. Likewise, we write: Miletos, Herodotos, Nicomachos, Eudoxos, Menaichmos, Appolonios, Heironymos, Pappos, Herophilos, Aristarchos, Euhemeros, Aratos, Hipparchos, Ctesibios, Erasistratos, Zenodoros, Diodoros, etc.

Activity Intervals of Scientists

The period of activity is centered in the age of peak creative activity, usually between 30–50 years of age. There are however many exceptions to this rule, especially when the age of greatest prestige is different from that of greatest activity, or because the person's life was cut short. Indeed, it takes a considerable time before the activity of a truly original mind is properly appreciated.

Apart from the class of outstanding persons, whose biographies are known in sufficient detail, the exact period of 'scientific fertility' of most scientists is not accurately known prior to the 17^{th} century. Thus, in the absence of contradictory information, I have considered as a man's prime the year when he became 40 years of age, the nearest to the intellectual climax of most men. It is probable that the greatest scientific discoveries were made, and the most pregnant resolutions taken by men younger than forty, but the accomplishment of their work took considerable time and the maturing of their thought extended over many years.

Classification of Chronology

Every classification has the disadvantage of introducing artificial discontinuities in the flow of life. It must necessarily happen that contemporaries are dealt with in two successive chapters, because one was active at the end of one century and the other at the beginning of the following century; they were flourishing almost at the same time, but at different sides of the cut. This drawback is unavoidable, but is not really objectionable, unless the reader is unaware of it.

The efforts of classification are most disadvantageous in the *Middle Ages*. Not everyone seems to realize that these ages lasted about a 1000 years, and that their development, far from being monotonous, was exceedingly varied. Moreover, brutal political vicissitudes introduced discontinuities in many countries. Under these conditions, any classification of Middle Ages is quiet artificial and no natural classification would be applicable to all sciences and all nations. For that reason the Middle Ages were left undivided and unclassified between 529 CE–1583 CE.

It should be kept in mind that no epoch in history begins or ends sharply at a given year and chronological dividing lines are made mostly for the sake of convenience.

Background Events
(Wars, Revolutions, Social Upheaval and Natural Disasters)

Although our center of interest is the evolution of scientific facts and ideas, general history is always in the background. Not only do the different sciences interact among themselves, but there is also a constant interaction between science and all other intellectual developments, as well as social, natural and economic phenomena. These events often interfere with the accomplishment of science but sometimes stimulate or are even stimulated by it.

Wars and revolutions are not essentially different from natural catastrophes such as earthquakes, volcanic eruptions, floods or epidemics; they are almost as impersonal and uncontrollable. For most men these catastrophes are by far the most important events, and this is natural enough, since their welfare is often radically affected by them. Galileo's or Newton's discoveries did not lower the price of food or shelter, at least not with sufficient suddenness to be perceptible. For us, on the contrary, these discoveries which must sooner or later transform man's outlook and, so to say, magnify both the universe and himself, are the cardinal events of the world's history. All the catastrophes and upheavals, caused either by the untamed forces of nature or by the irrepressible folly of men, are nothing but accidents. They interrupt, upset and sometimes enhance man's essential activity but, however formidable, they do not and cannot dominate it.

* * *

To give our history its full heuristic value, it was not sufficient to retrace the progress of the human mind. It was also necessary to record the regressions, the sudden halts, the mishaps of all kinds that have interrupted its course. The history of errors is extremely useful: for one thing, because it helps us to better appreciate the evolution of truth; also because it enables us to avoid similar mistakes in the future; and lastly, because the errors of science are, to some extent, of a relative nature. Some of the accepted and well-established truths of today will perhaps be considered tomorrow as very incomplete truths; and there are even precedents for the perceived errors of yesterday eventually becoming approximate or partial truths of today. Similar rehabilitations frequently occur en route to be the "fixed points" mentioned above, and the results of historical research often oblige us to admire and honor people who have been misunderstood and despised in their own time.

Thus, although we undertook to explain the progress of scientific thought, it is clear that we cannot properly explain that progress without giving at least a brief account of the intellectual delusions which often delayed our advance or threatened to sidetrack it.

Moreover, to correctly appreciate the scientific ideas of any people, we must consider them not only from our point of view, but also from their own, however wrong the latter may seem. Thus it is necessary to outline the development of some pseudo-sciences, such as astrology, alchemy, and physiognomy.

It should be noted that it is not always easy to distinguish a pseudo-science from one which is sound but imperfect; in some cases it is almost impossible; we can do it now with reference to the past, but it is not certain that we can always do it with regard to the present.

For these reasons I have included in my book a condensed history of astrology, alchemy and other delusions. In addition I have included some 20 articles called '*Science Progress Reports*' in which follies of scientific *regression* are expounded.

I have made no attempt to tell that history with any completeness, for the history of error is, of its very nature, infinite. Besides, as I am bent upon explaining the progressive – not the regressive – tendencies of human civilization, I have kept these fallacies in the background where they belong. Indeed, since they never represented the main current of human endeavor, but were rather like undertows, it would be equally wrong to ignore them altogether or to attach too much importance to them.

As the scope of my field of study is immense, both in time and size, errors are unavoidable; in spite of severe precautions taken by myself and the editors, some errors will regretfully still be present. I hope that in time, we shall be able to weed them out.

בראשית ברא אלהים את השמים ואת הארץ
והארץ היתה תהו ובהו וחשך על פני תהום ורוח
אלהים מרחפת על פני המים ויאמר אלהים יהי
אור ויהי אור

* * *

In principio creavit Deus caelum et terram.
Terra autem erat inanis et vacua;
et tenebrae super faciem abyssi;
Et spiritus Dei ferebatur super aquas.
Dixitque Deus, "fiat lux!", e facta est lux.

(Vulgata)

ca 14,000 Mya

"Give me matter and motion and I will make the world"

(René Descartes, 1637)

Big Bang A model for the history of the universe stating that it began in an infinitely dense and hot state and has been expanding ever since a creation "event", which took place sometime between 13 and 14 billion years ago. The theory is now widely accepted since it explains three of the most significant observations in cosmology: the expanding universe, the cosmic microwave background radiation and the origin and abundancies of the light elements.

A class of models of the early universe that include a thermodynamic phase transition (and subsequent re-heating and a brief exponential expansion) at fraction of second after the Big bang, are known as *inflationary universe* models.

This event, if it happened, released enormous energy, stored until then in the vacuum of space-time. The causal horizon of the universe expanded, temporarily, much faster than the speed of light. This scenario may be able to account satisfactorily for the present spatial flatness of the universe and its uniformity, and some other features.

ca 12,800 Mya Formation of the first stars in the universe.

ca 4700 Mya Our sun is thought to have formed from a small cloud of gas and dust (produced by earlier stars) which, after lingering for billions of years in one of the Milky Way's spiral arms, succumbed to its own gravitational pull and collapsed. Most of the material in this cloud was drawn into a central body. Thus, our sun has a composition nearly identical to that of the original cloud. It contains 99 percent hydrogen and helium, with about 1 percent comprising the remaining elements.

A small amount of the matter in the cloud ended up in a nebular disk around the newly formed sun. This material gravitationally aggregated into planets, moons, asteroids, and comets. The compositions of these objects are very different from that of the sun. This difference is the result of extensive chemical and physical differentiation: those elements contained in dust grains were largely retained through incorporation into the objects making up the planetary system; those elements in gaseous form were largely driven off by the particles and radiation streaming forth from the sun thus, most of the lighter elements (especially hydrogen and helium) not incorporated into the sun, became part of the larger outer planets.

In those parts of the disk close to the hot sun (which formed earth and the terrestrial planets) only the least volatile of the chemical compounds were in solid form. What little primordial hydrogen survived was locked inside chemical compounds (most notably water and organics). In the more distant reaches of the disk, the abundance of elements heavier than helium was low.

Because of this, the comets and planets of the outer solar system have a chemical composition quite different from that of the asteroids and planets of the inner solar system.

ca 4600 Mya Earth[1] was formed by the accretion of rocky masses. As this mass increased, the temperature rose dramatically and the rocky solid material melted and separated. Eventually the dense material, mostly iron and nickel, sank to form the central core while the lighter, mostly silicate material rose to the surface to form the planet's crust.

As earth cooled, it was bombarded by objects from space.[2] Perhaps the

---

[1] The third planet from the sun is one of the most geologically active planets in the solar system, with large volcanoes and great mountain chains. Water is abundant, as vapor in the atmosphere and as liquid and ice on the surface (and subterranean liquid as well). Earth is the only planet in the solar system with an average temperature between the freezing and boiling points of water. Its most unique characteristic is that it supports an amazing diversity of life.

Oceans cover 70 percent of earth's surface. It they were spread out evenly, earth would be under 4 km of water. More than 80 percent of all *photosynthesis* (the process by which plants convert sunlight into chemical energy) takes place in the oceans, making them the principal habitat of life on earth. Ocean water contains many minerals leached or dissolved out from rocks and soil and carried to the oceans by rivers. Sodium chloride, or common table salt, composes 3.5 percent of ocean water.

Fresh water, containing almost no salt, is essential for most living things not found in the oceans. The sources of fresh water is rain, which comes from pure water vapor evaporated from the oceans. The proportion of fresh water to ocean water is small. Only a little over 2 percent of the total amount of water on or near earth's surface is fresh water. Of this fresh water, about 80 percent is frozen in glaciers at the poles.

[2] On July 4, 2005, NASA's spacecraft *Deep Impact* (launched Jan 12, 2005) plunged a self-guided copper slug (having a mass of 370 kilograms) into Comet Temple 1, thus delivering to its nucleus' surface the equivalent of 4.5 tons of TNT. Just minutes after the impact the flyby probe passed the nucleus at a close distance of 500 km, taking pictures of the crater position, the ejecta plume, and the entire cometary nucleus. The entire event was photographed by earth-based telescopes and orbital observatories, such as the *Hubble*, *Chandra*, *Spitzer* and

largest of these objects was the size of Mars, blasting a cloud of debris into orbit that would eventually become the moon. Before the bombardment ceased, about 3.8 billion years ago, 35 impact basins larger than 300 km across were formed on the moon. The larger and more massive earth probably experienced hundreds of comparable impacts. Some would have formed gigantic impact basins with diameters equal to half the width of the continental United States.

Earth is the only inner planet that has liquid water on its surface, although Mars and Venus may have surface ice particles now. As earth cooled, a primitive atmosphere was formed through a volcanic process known as outgassing. This is the release of gases from the interior, including water vapor, hydrogen, nitrogen, and carbon dioxide. As the water vapor in the atmosphere increased, it condensed and fell as rain. Eventually, enough water collected to form our oceans.

ca 3960 Mya Oldest rocks (discovered 1989 CE).

ca 3900 Mya Advent of life; oldest fossils of primitive cells (simple algae and other single-celled organisms) have been found in rocks in Greenland, South Africa and Australia.

ca 3500 Mya Organic carbon compounds; primitive virusoid cells.

ca 3300 Mya Sedimentary rocks already teaming with life.

ca 3000 Mya Organisms capable of *photosynthesis*.

ca 2600 Mya Evidence for the existence of the geomagnetic field, at that epoch.

ca 2500 Mya Tectonic plates clash in India (studied by 1989 CE).

XMM-Newton. In addition, the impact was observed by *cameras* and *spectroscopes* on board Europe's *Rosetta* spacecraft, which was about 80 million km from the comet at the time of impact. Rosetta could then determine the composition of the gas and dust cloud kicked up by the impact.

Analysis of data from this mission disclosed that comets (formed about 4.5 billion years ago) probably carried to earth *water* and *organic* compounds (the two necessary ingredients of life) early in the planet's history, when strikes by asteroids, meteors and comets were common.

Table 0.1: Geological Time

	Millions of years ago
Precambrian Time	
Archean Era	4600–2500
Proterosoic Era	2500–570
Phanerozoic Time	
Paleozoic Era	
Cambrian Period	570–505
Ordovician Period	505–438
Silurian Period	438–408
Devonian Period	408–360
Carboniferous Period	360–286
Permian Period	286–245
Mesozoic Era	
Triassic Period	245–208
Jurassic Period	208–144
Cretaceous Period	144–66.4
Cenozoic Era	
Tertiary Period	
Paleocene Epoch	66.4–57.8
Eocene Epoch	57.8–38.6
Oligocene Epoch	38.6–23.7
Miocene Epoch	23.7–5.3
Pliocene Epoch	5.3–1.6
Quarternary Period	
Pleistocene Epoch	1.6–0.01
Holocene Epoch	0.01–0

ca 2000 Mya *Free oxygen*[3], a by-product of photosynthesis by algae[4], began

[3] Much of earth's initial atmosphere, and its water were probably outgassed early in the planet's history. Carbon dioxide, nitrogen, hydrogen, water vapor, and other *volatile* gases (i.e. that evaporate at relatively low temperatures) comprised earth's early atmosphere. These elements may have come both from the rocky material on earth and from the volatiles-rich material from the outer solar system.

For the first billion years, oxygen was only a small component of earth's atmosphere. Oxygen accumulated in the atmosphere only after photosynthesis began producing it faster than it was lost by chemical combination with other gases and metals. Most of the carbon dioxide in earth's early atmosphere was removed not by plant life but by chemical combinations with calcium, hydrogen, and oxygen, forming limestone (calcium carbonate) in the oceans and other compounds.

to accumulate in the atmosphere.

ca 1600 Mya Primitive plant life.

ca 1300 Mya *Eukaryotes* cells with nuclei, e.g. amoeba; tremendous proliferation and diversification of life.

ca 1000 Mya First *multicellular* animal phylum: e.g sponges (no nervous system nor muscle fiber).

ca 750 Mya First '*Snow-ball earth*' episode. One of four climatic reversals that ended in ca 580 Mya. (The theory was first suggested in 1964 and accepted in 1997).

ca 700 Mya Advent of the cycle of disruption and unification of the earth's crust known as *continental drift*; Remains of the earliest known large-bodied animals in rocks, most belonging to corals and jelly-fish phylum.

The interaction among the plates of the lithosphere is called *plate tectonics*. Much of earth's landscape has been shaped by plate tectonics. As oceanic plates have been created and subducted and the continents have collided and broken apart, mountains have been built, rift valleys formed, ocean ridges and trenches created, and volcanoes constructed.

Most activity occurred along the edges of the plates as they move in relation to one another. Plate tectonics began with plate recycling and was driven by convective cooling of earth's interior. The continental lithosphere was made largely of rocks such as granite that are less dense than the mantle. So, while oceanic plates were forced back into the mantle, the continents stayed afloat and remained at the surface, although they have drifted together and broken apart many times. By 80 million years ago, most of the continents we know today were isolated and had begun moving toward their current positions.

In recent times humans have been generating carbon dioxide faster than plants or the oceans can take it up. At the same time, we are cutting down forests that use carbon dioxide and burning the wood, releasing more carbon dioxide. Earth's atmosphere is now about (by volume) 78 percent nitrogen, 20 percent oxygen, 1 percent argon, and 1 percent water vapor, with CO_2 making up only 385 ppm (seasonally averaged). The average atmospheric surface pressure is about 15 pounds per square inch (1 kg/sq cm).

[4] *The web of life*: In the single-celled algae *Emaliana huxlexi*, the shield-like structures on its surface are composed of calcium carbonate, which goes to form chalk when the cell dies. Blooms of *Emaliana* cover large areas of the ocean. They perform a vital role by removing carbon dioxide from the air and producing dimethyl sulphide, which acts to nucleate clouds.

The term "continental collision" conjures up visions of high-speed crashes, but the continents move only up to 10 cm per year, and it takes millions of years to build a mountain range. Around 250 million years ago, when North America collided with Africa, the ensuing large-scale crustal shortening generated the Appalachian Mountains. Erosion has worn them down, but they were once comparable to the present-day Himalayas. The Himalayas, however, were formed only about 35 million years ago when India plowed into Southern Asia. The large-scale horizontal shortening that resulted built up the highest mountains on today's earth.

ca 660 Mya Hard-shelled animals in the sea: organisms large enough to leave clear *fossil* evidence started to evolve at this time. Oldest known multicellular animal fossils.

Collision Events and Geological History

After the earth formed, its bombardment by 'cosmic bullets' such as comets and asteroids (protoplanets) did not cease. Accretion, the process of planetary building, continued, and to a tiny extent it continues to this day.

The accretion by the early earth of comets *through collisions played a key role in the history of life on earth. The comets brought the water of the oceans and the carbon-enriched materials that would someday form the biomass of the planet. Indeed, trillions of comets in the* Oort cloud*, billions of objects in the* Kuiper belt*, and millions in the asteroid belt are reservoirs for potential earth-crossing objects.*

Of all the terrain on earth that underwent the period of heavy bombardment, none has survived the effects of erosion, plate recycling, and plate tectonics. Yet, evidence remained that the earth has been hit by asteroids and comets: In the last 100 million years, earth has been hit by well near a 1000 objects capable of producing craters with diameters in the range 10–150 km. About a 100 known impact structures *on earth range in diameter from 2 to over 150 km. Only a few of the largest impact structures are older than 500 million years.*

The earth's history is divided into periods of time based on the types of fossils present in sedimentary rocks formed during those times. The time before 570 million years ago, the Pre-Cambrian era, *lacked life-forms with hard parts that formed fossils easily. All large organisms were soft-bodied and lived in the ocean. Fossils of primitive cells have been found inside rocks in South Africa and Australia that are 3500 million years old.*

However, organisms large enough to leave clear fossil evidence did not evolve until about 600 million years ago. During the Paleozoic era, *from 570 to 245 million years ago, hard-bodied plants and animals exploded in abundance, and colonized the land. The first amphibians arose, and ferns and conifers dominated the forests. The* Mesozoic era, *from 245 to 65 million years ago, was the time when dinosaurs were abundant land animals. Mammals also existed, but were of lesser importance. Later in this era, the first flowering plants occurred.*

The Mesozoic era of the dinosaurs is in turn divided into three periods based on the dominance of different species: the Triassic *(245–180 million years ago), the* Jurassic *(180–144 million years ago), and the* Cretaceous *(144–66 million years ago). The earth's continents began to assume a recognizable configuration only during the Cretaceous period. The continuing processes of erosion, plate-tectonics, volcanism and cratering created changes in the surface of the earth.*

The fossil record testifies to global mass extinction *of species in the oceans and on land. Such events occurred about 11 million, 35 million, 66 million, 91 million and 250 million years ago, correlating with sedimentary layers that contain the element iridium, which is 10,000 more abundant in most meteorites than in the earth's crust. The iridium could have come either from volcanic eruption from deep in the mantle or from an impact of an asteroid.*

Other evidence suggests that large impacts threw enormous amounts of dust into the atmosphere, thus blocking out much of the sunlight for a few months or even years, and possibly igniting great forest fires.

In the mass extinction about 65 million years ago, 75 percent of the existing plant and animal species disappeared in less than a few million years, ending the age of the dinosaurs and ushering in the age of the mammals. The Cenozoic era, *since the extinction of the dinosaurs 65 million years ago, is the age dominated by mammals. The first grasses developed, and the landscape took on its present appearance. In comparison, human civilizations have developed only during the last six thousand years.*

Some believe that this extinction was triggered by the impact that formed the Chicxulub Crater[5]*, releasing energy of the order of* 10^8 *megatons of TNT [1 MT* $= 4.2 \times 10^{22} erg$*]. Others point to the outgassing that accompanied the formation of the Deccan Plateau about 66 million years ago as the cause of that mass extinction.*

ca 543 Mya The *Cambrian evolutionary explosion*:

Sudden appearance of *complex life*[6]; most of the animal groups now on earth appeared in the fossil record (and can also be genomically traced today) a relatively short time; possible causes:

- Level of atmospheric oxygen rose to a critical point so that oxygen dissolved in sea-water, finally achieved sufficient levels to support large arrays of active animal life.

---

[5] It is hidden under the sediments on the coast of the Yucatan Peninsula. The crater was detected when instruments measuring variations in the earth's gravitational and magnetic fields showed a circular structure about 180 km wide and possibly a larger concentric structure 300 km wide. The asteroid that made the crater is estimated to have been about 10 km across, having an estimated mass of 10^{18} g and hitting the earth with geocentric velocity of 40 $\frac{\text{km}}{\text{sec}}$. Its radius of total destruction was about 5000 km.

[6] Until recently, scientists had thought that the so-called "*Cambrian explosion*" lasted for 20–30 million years. A new study (1994), however, revealed that the period probably lasted only about 5 million years, telling us that evolution can operate extraordinarily rapidly when conditions are right.
The researchers determined the new time scale for the Cambrian explosion by analyzing volcanic rock from the early Cambrian period; by dating *zircon crystals* within these rocks, they were able to determine that the *Cambrian period began* about 543 million years ago and the *Cambrian explosion began* about 530 million years ago, and terminated about 525 million years ago. The body plans that evolved in the Cambrian served as blueprints for those seen today. Few new major body plans have appeared since that time. All the evolutionary changes since the Cambrian period have been mere variations on those basic themes. Are these blueprints truly the optimal solutions to the problems of survival and reproduction (reached through an early fast bout of natural selection before development congealed)? Or are they just random combinations of characters assembled by accidents of history? And just how random is biological evolution? – Science, at this point, has no answer to these questions.

- Sunlight radiation on earth reached a critical level, increasing the transparency in oceans and atmosphere.
- It is during this period that the *eye* evolved: the primitive Cambrian life-forms were able to process visual imagery for the first time.

ca 420 Mya Earliest life on the land. Life probably originated in the seas, to which the majority of invertebrate groups are still restricted. Life on land involved major adaptations for these creatures that originated and lived in the oceans. The modifications included changes necessary for protection against dessication, new methods of support in air as opposed to the more buoyant water, breathing oxygen as opposed to extracting it from the water, new sources of food and water, and new reproductive mechanisms to ensure fertilization in the absence of water. Colonization of rivers and lakes was only slightly less formidable, for it involved development of mechanisms to prevent dilution of body fluids that, in all animals, contain dissolved salts precisely adjusted to the osmotic balance of sea water.

Land dwelling, in spite of its problems, offered all the advantages of an empty environment. Because of the delicate interdependence of all living things, it is not surprising that both plants and animals seem to have colonized the land at about the same time during the Silurian and Devonian. The invasion of the land almost certainly involved the earlier invasion of fresh waters. Many living groups, which are essentially marine, contain a few freshwater colonists (clams and crustaceans, for example), but only the plants and three major groups of animals (snails, arthropods, and vertebrates) have become fully established on the land.

ca 250 Mya A volcanic[7] eruption in Hawaii that lasted for a million years. Some evidence for encounter with a large bolide, which caused mass extinction of life on earth.

ca 230 Mya Mammal fossils.

ca 200 Mya Breakup of Pangea; opening of the Atlantic.

ca 180 Mya Separation of African and South American continents.

[7] Volcanism occurs when magma, or melted rock, beneath the surface of a planet or satellite breaks through the surface. On earth, an example of a volcanic land-form is a stratovolcano, a cone-shaped mountain built up by alternating layers of lava and volcanic ash.

ca 65 Mya A large object from outer space rammed into the earth. Extinction of dinosaurs may alternatively be linked to megavolcanic eruptions.

ca 40 Mya Primitive apes.

ca 22 Mya *Hominoid primates* split from Old-World monkeys to a line eventually leading to humans.

ca 6–4.5 Mya Our ancestral ape diverged from chimps and gorillas (we share 98.4 % of our DNA with chimps and 97.7 % with gorillas). Thus, a full 6 million years of evolution separate the minds of modern humans and chimpanzees. We know nothing about the environment in which the ancestral ape lived, as it appears to have left no stone tools.

4.8–4.5 Mya Appearance of the *upright bi-pedal* hominids, known as *Australopithecus (A.) ramidus* (4.5 Mya), *A. anamensis* (4.2 Mya), *A. afarensis* (3.5 Mya), *A. africanus* (2.5 Mya), *A. robustus* (2.2 Mya) and *Homo habilis*[8] (2 Mya).

ca 2 Mya Volcanic eruption (VEI = 8, Energy $\simeq 2 \times 10^6$ MT) shaped the Yellowstone landscape. The lava covered more than 2600 km^2.

ca 1.8–0.4 Mya *Homo erectus* – The first large-brained proto-humans (900–1200 ml); spread out of Africa to explore the Near East and Asia ('*Peking man*', '*Java man*'); begins to develop *local* characteristics. By 500,000 ya the descendants of homo erectus reach Europe and *fire* is tamed. *Ice age* (Pleistocene) began around 1.75 Mya with formation of ice sheets in high latitudes. Glaciation began about 1.2 Mya.

ca 700,000 ya Latest Geomagnetic field reversal.

---

8 Modern anthropology has confirmed their existence in Africa through the discoveries of the Leaky family. In 1959 **Louis Leaky** (1903–1972, USA) discovered the skull of *Australopithecus Robustus* in Tanzania and the remains of *Homo Habilis* (1964). His wife **Mary Leaky** (1913–1996, USA) found (1976) fossil footprints of one of our upright ancestors. Homo habilis was confined to East Africa. His larger brain (700 ml), fueled by eating more meat, may have made room for the feature known as "Broca's area" – a region connected with *speech perception*; speech enables complex information, history and legends, to be passed and lies to be told. It encouraged invention of words - an important social tool; enabled group *decisions* to be made, intentions to be communicated, memories shared and passed on.

For further reading, see: Mithen, S.: *The Prehistory of the Mind*. Phoenix, Thames and Hudson, 1996. 357 pp.

ca 400,000–40,000 ya *Homo Sapiens*: Wooden tools, artifacts and weapons give evidence of a hunting-gathering life style. This is the earliest form of our own species.

By 150,000 years ago a new actor had appeared in Europe and the Near East, *Homo neanderthalensis*, popularly known as Neanderthal man. He had the propensity to use tools, and could hunt large game. Like the other characters of this act, the Neanderthals had to cope with frequent and dramatic changes of scenery: their's was a period of the ice ages witnessing ice sheets repeatedly advanced and then retreated across Europe, and with them vegetation changed from tundra to forest and back. Yet even with such changes, the action seems rather monotonous. His tools seem to be very finely crafted, they are all made of either stone or wood. Although unmodified pieces of bone and antler were used, no carving of these materials took place.

At first glance, Neanderthal remains appear primitive and crude, rather like *Homo erectus* and quite different from modem humans. Their arm and leg bones were, in fact, approximately twice as thick as ours, suggesting their immense strength and the rugged conditions of their existence. Otherwise, their bodies were strikingly modern. They had prominent noses, long faces with sloping foreheads and big skulls. Their average brain capacity (1400–1500 cc) actually exceeded that of modem humans – although the configuration of parts of the brain was different. The speech areas of the Neanderthal brain were not as developed as ours and the forebrain was smaller.

The Neanderthals were the first humans to live in Ice Age conditions, surviving by hunting the largest and most formidable Pleistocene mammals – the mammoth, woolly rhinoceros, and wild cattle. They competed with large wolves and lions in an extremely harsh Ice Age environment.

Neanderthals lived in caves, forming large family groups, and used stone axes, bone tools, bows and arrows; pregnancy lasted one year; they took care of their sick and aged.

Climatic Changes[9] *in the Earth's History*

The earth has gone through alternate periods of cold and warm climates. Some changes extended over millions of years, others through a couple of centuries. The causes of these changes were diverse, the leading phenomena being:

- *Changes in volcanic activity (with diminution of activity leading to rise of global temperature) modulating the amounts of infrared-trapping of CO_2 and albedo-decreasing volcanic dust in the atmosphere.*
- *Variation of solar output and activity*

  Contrast between the zones of low and high pressure is apparently controlled to some extent by variations of solar activity. When sunspots become more numerous, pressure increases in the areas where it is already high, and decreases in those where it is already low. In the temperate storm belts, a high sunspot number tends to be associated with low pressure, great storminess, and heavy rainfall.

  Since in the interior of the continents and in tropical regions a good deal of rain is associated with thunderstorms, this suggests that rainfall maxima should coincide with maxima of sunspots, and there is other evidence that on the whole the total rainfall over the land area is greatest when sunspots are most numerous[10]*. Additionally, the sun overall light output has varied over its history. Thus it is thought that during the Cambrian bio-evolutionary explosion, the sun was significantly dimmer than it is today, and 'greenhouse gases' such as CO_2, played an important role in maitaining life-friendly temperatures on our planet.*

---

- Lamb, H.H., *Climate: Present, Past and Future*, Methuen: London, 1977.

[10] The short record of the low-level stage of the Nile can only be relied upon between 640 and 1400 CE, but during this period it presents considerable similarity to the sunspot curve (which can be read off ancient tree-rings). Thus we have

Sunspot maxima	620	840	1077	1200	1370	CE
Nile low-level stage	645	880	1100	1225	1375	CE

The maxima of water levels in the low-water stage of the Nile apparently follow sunspot maxima by intervals of from five to forty years.

- *Bolide impacts (collisions with objects on earth-crossing orbits).*
- *Astronomical* causes (changes in *eccentricity* of the earth's orbit, *obliquity* of the ecliptic, *precession* of the equinoxes etc.). These may have caused the succession of glacial and interglacial periods.

  Seasonal weather changes on earth are largely a matter of *geometry.* Earth follows a nearly circular orbit. The tiny difference of three percent between its greatest and smallest distance from the sun does not account for the range of temperatures between the seasons. The explanation lies in earth's axis, which is tipped 23.5 degrees off the perpendicular to the plane of its orbit. When the northern hemisphere tips toward the sun, the north pole is continuously lighted and days are longer everywhere north of the equator. There is also more radiative heat generated by insolation in the hemisphere. The sun's rays reach the northern hemisphere at less of an angle, with less filtering by the atmosphere, so on average the surface absorbs more heat each hour. For part of the year more heat is gained each day than is lost at night through re-radiation.

  Seasons change each time earth moves a quarter of the way around its orbit. The longest day, on about June 21, is called the *summer solstice* in the northern hemisphere. Three months later, on about September 23, day and night are of the same length. This is the *autumnal equinox.*

  The obliquity of the ecliptic appears to have reached a maximum et about 8150 BCE and to have decreased steadily since that date. Also, about 8500 BCE the earth was farthest from the sun (aphelion) in the northern winter, whereas it is now farthest from the sun in the northern summer. Both these factors would cause an appreciably greater seasonal range of insolation in the ninth millennium BCE than at present.

  Variations in earth's orbital *eccentricity* (the degree to which an orbit deviates from a circle) and in the *obliquity* of its axis (tilt of the axis with respect to the plane of orbit) vary on time scales of 10,000 and 40,000 years, respectively. Changes in the orientation of earth's axis, called precession, occur over a 25,800-year period.

  One of the most dramatic effects of these changes is ice ages. Quasi-periodic ice ages, during which the polar ice caps advanced halfway to the equator, occurred over the past million years and dramatically reshaped landscapes.

  Climate changes caused by earth's orbital and axial characteristics have also influenced the formation of deserts. Climate models that adjust for the precession and nutation of the axis suggest that about 10,000 years ago the Sahara Desert of Africa had ample rainfall, rich vegetation, and monsoons. But there may be other influences. While earth's climate *has been stable since the last ice age 10,000 years ago, analysis of ice core samples from Greenland shows that some earlier abrupt changes in climate lasted only decades or centuries: At one time, the average temperature plunged 14° C in a decade, and the cold snap lasted for 70 years.*

- *Short-range variations [especially variations in rainfall] are due to changes in the general circulation in the atmosphere which may have no external cause. They result from the interaction of winds, ocean currents, and floating ice fields.*

  The atmosphere, oceans, continents, and glaciers are the principal motors of the climatic system. They have a stabilizing effect on the temperatures at the surface of the earth: a slightly different distribution of heat can modify these effects.

  Because of the nonlinear nature of these interactions, under favorable conditions comparably small causes may have disproportionately large effects.

  Climatic changes tend to be synchronized globally, but not generally in the same sense or magnitude in all places. So there can be damp weather in Western Europe, but drought in North America.

  When warm interglacial climate changes into cold glacial climate, the precipitation of large areas change from rain to snow. The latter does not return back to the water of the oceans but stays on the land locked up in ice sheets. This results in lowered sea levels. In general, any change in climate that alters the amount of ice on the land will effect the level of the oceans correspondingly (so called eustatic changes in sea-level).

  During the peak of the last glaciation, much water was stored in the form of ice on Greenland, northern Canada, Antarctica, and high mountain ranges. As a result, sea levels were far below what they were today.

  A rise of sea level may be due to one and more of three causes:

  - *A decrease in depth of part of the sea floor, compensated by the decrease in the elevation of part of the land area.*
  - *An increase in the volume of sea water without change of mass, owning to a decrease in density.*
  - *The actual addition of water to the oceans.*

The mean depth of the oceans is approximately 4000 meters. Taking the coefficient of thermal expansion of water as 0.00015 for one degree centigrade, we find that an increase of temperature by 1° would raise the mean level of the ocean's surface by 0.55 meters. Thus, a rise of the *mean temperature of the whole mass of the oceans by 3° would raise the general level about 1.7 meters.*

The main way in which water can be added to the oceans is through the melting of the ice sheets in Greenland and the Antarctic. Their area is about (1.55×10^7) *km*^{2} *and the average thickness of the ice is nearly 1500 meters. If all this ice were melted it would raise the general level of the ocean by between 43 and 58 meters. The area occupied by the ocean is about* $(3.62 \times 10^8$ *km*$^2)$*, or 23 times the area occupied by ice, so that in order to raise the sea level by 3 meters, it would be necessary to melt off some 70 meters of ice. Because of the difference of density between glacier-ice and water, we may put the actual figure at 76 meters.*

Now, we know that even in the much less intense warm period of the high Middle Ages, the boundaries of the Greenland ice sheet retreated appreciably, which implies a corresponding diminution of thickness, so that in the prolonged warm period of the Climatic Optimum a lowering of the average level of the ice sheets by 76 m is quite possible. These two factors, increase of ocean temperature *and* increase in the mass of water*, appear to be quite competent between them to raise the general level of the oceans by 3 m, the greater part of this being due to the melting of ice.*

We have evidence that sea levels rose at a rate of 1 meter per century and reached its maximum during the Climatic Optimum *between 5500 and 3000 BCE, after which the rate gradually diminished and by 500 BCE it had reached nearly its present level.*

At present, the level of the world oceans is rising by 1 millimeter/year (= one meter per millennium). Scientists have calculated that a complete melting of ice caps would cause sea level to rise 60 meters.

Even if only the ice in the Antarctic will melt $(20 \times 10^6$ *km*$^3)$ *it will cause a sea-level rise of 6 meters. Under these conditions, all large coastal cities will disappear into the ocean, one third of France would be covered by water, and so would much of England. All these catastrophes could become a reality if the content of* CO_2 *in the air were to double*[11]*.*

[11] Indeed, a UN panel of climatologists has recently (2006) warned the world scientific community and world governments that a global warming by more than 3 deg is expected within the next century, and they adduced evidence that greenhouse gas emission — including human-caused CO_2 — were strongly implicated. The consequent melting of Antarctic ice sheets may then raise the ocean level by 5–10 m, causing a global flooding catastrophe of unpredictable proportions. However, these conclusions remain quite controvertial and politicized.

The Gaia[12] Hypothesis[13]

It often seems obvious that life on earth is at the mercy of powerful non-biological forces like volcanic eruptions, storms, climatic changes and earthquakes. On the other hand, much of the earth's surface is covered by a layer of life, and everywhere on earth the influence of living organisms had an effect.

Recently there has emerged a theory, known as the Gaia Hypothesis. *It is based on the idea that, over the long run of geological time, life may control the powerful physical forces on which it depends for its own good.*

The essential idea of the Gaia Hypothesis is analogous to the concept governing the thermostat in one's home, or the thermostat in one's brain. One's thermostat at home may be set to $18.5°C$ in order to keep a comfortable living environment. When the temperature falls below this, the furnace is switched on. When the temperature in the house reaches the target, the furnace is switched off. Something more complicated, but with similar effect, goes on in our bodies. If our body temperature deviates very far from a narrow range, we die. The human body has a number of self-regulatory, or homeostatic, mechanisms, which monitor and stabilize such quantities as: temperature, acidity, and concentrations of hormones.

The conditions for life as we know it to exist also require a relatively narrow range of circumstances in our terrestrial environment. How does life modify the physical and chemical conditions of the earth? Some examples of regulations of the environment, according to Gaia are:

- *Where does the oxygen come from? Small amounts emanate from volcanic activity, but usually it is combined with other elements, e.g., the compounds as CO_2 and H_2O. The earth's original atmosphere contained almost no oxygen, it was the advent of photosynthesis some 2.5 billion years ago that was responsible for the presence of abundant oxygen in the atmosphere (presently 20%, by volume). Initially it was the liberated oxygen combined with oxidizable minerals such as iron, leaving a sedimentary record of red bands that tells us that a new atmospheric chemistry was being brought about by life. Other geological evidence suggests that oxygen levels on earth have been, within a factor of roughly*

[12] Gaia = Greek Goddess of the earth.

[13] Originated in the 1970's by James Lovelock and Lynn Margulis. For further reading, see: Lovelock, J.E., *Gaia: A New Look at Life on Earth*, Oxford University Press: Oxford, 1987, 157 pp.

two, at near-present values for the past billion years, during which complex multi-cellular life arose.

If oxygen were to reach a level of 35% of atmospheric gas composition, fires would occur whenever a lightening bolt hit humid vegetation. The planet would be in serious danger of burning up. What has kept oxygen from building up to dangerous levels? Why has it gone from nearly zero to 20%, and then stopped? One possible answer is the biological production of methane by bacteria. A short-lived molecule, methane can combine with oxygen to produce CO_2 *and water, thus stabilizing oxygen concentrations.*

- *We know that climate has changed a great deal in the past, producing episodes of glaciation as well as short-term warming and cooling episodes. However, climate change might have been much more extreme. At least for the past billion years it is unlikely that the earth's mean temperature was more than 15 degrees warmer or 5 degrees colder than it is today. Earlier temperatures are very uncertain.*

  Astrophysicists calculations suggest that the sun emitted perhaps 25% less radiant energy some 4 billion years ago, than it does today. Calculations also suggest that under this faint early sun, the earth should have been a frozen ball. However, life arose under these conditions, and there is geological evidence of flowing water from this time. It has been suggested that a kind of greenhouse warming was in effect at that time, involving such gases as methane, ammonia, and carbon dioxide, and that this is evidence of a kind of Gaian planetary temperature control mechanism.

  And why hasn't the planet overheated, since the sun has increased in luminosity over the past 4 billion years? ***Lovelock*** *and* ***Margulis*** *argue that life solved this problem too. A warming earth stimulated greater plankton production, removing* CO_2 *from the atmosphere. When the plankton died they sank to the ocean floor, forming sediments, and thus removed* CO_2 *from the system.*

  Moreover, a warmer planet has more rain, which means more erosion and more nutrient runoff to the oceans. This also stimulates phytoplankton growth, again removing CO_2 *from the atmosphere. Thus, Gaia maintains a fairly constant climate as the sun heats up.*

  Life exerts other influences over the chemistry of the planet: methane and ammonia exist in their present abundances because bacteria continually regenerate them by decomposing organic matter. Perhaps life regulates the physical and chemical environment of the planet so as to maintain suitable planetary conditions for the good of life itself. If so, then the planet can be thought of as a single, integrated, living entity with self-regulating abilities.

The adherents of Gaia have offered the following alternative formulations to their hypothesis:

"The Gaia hypothesis says that the temperature, oxidation state, acidity, and certain aspects of the rocks and waters are kept constant, and that this homeostasis is maintained by active feedback processes operated automatically and unconsciously by the biota."

(James Lovelock 1979)

"The Gaia hypothesis states that the lower atmosphere of the earth is an integral, regulated and necessary part of life itself. For hundreds of millions of years, life has controlled the temperature, the chemical composition, the oxidizing ability, and the acidity of the earth's atmosphere."

(L. Margulis and J. Lovelock 1976)

"The biota have effected profound changes on the environment of the surface of the earth. At the same time, that environment has imposed constraints on the biota, so that life and the environment may be considered as two parts of a coupled system."

(Watson and Lovelock 1983)

"The Gaia hypothesis states that the temperature and composition of the earth's atmosphere are actively regulated by the sum of life on the planet."

(Sagan and Margulis 1983)

But perhaps the most succinct observation was made by James Lovelock:

"People have the attitude that 'Gaia will look after us'. But that is wrong. Gaia will look after herself. And the best way for her to do so might be to get rid of us."

ca 300,000 ya First appearance of the *Neanderthal man*.

ca 130,000–11,000 ya *Homo Sapiens Sapiens*; First seen in South Africa and the Near East[14] and joined a cast that continued to include the Neanderthals and archaic Homo Sapiens. He grinded pieces of bones to make harpoons and made tools from materials other than wood or stone. Around 60,000 ya, Homo Sapiens Sapiens built *boats* and then made the very first crossing to Australia. He entered Europe at about 40,000 ya, bringing with him a host of new tools made of new materials, including bone end ivory. During the interval 40,000–30,000 ya the Neanderthals of Europe were trying to mimic the new type of blade tools that Homo Sapiens Sapiens was making, but the Neanderthals soon faded away, leaving Homo Sapiens Sapiens alone on the world stage. Modern man (known as *Cro-Magnon*) immigrated to Siberia and North America (ca 11,000 BCE) and domesticated the *dog* (descendant of the Asian Wolf) at about 9000 BCE.

ca 100,000 ya Homo Sapiens Sapiens developed symbolic thinking manifested in linguistic speech capacity.

ca 75,000 ya *Tuba volcano eruption* (Indonesia); VEI = 8 (Energy $\simeq 6 \times 10^5 MT$).

ca 50,000 ya An iron-nickel *asteroid* about 50 m in diameter hit flat-lying sedimentary rocks and blasted out a crater about 1200 m wide and about 450 m deep in Arizona USA; known as the *Barringer Crater*. (Energy ca 20 MT.)

- Oil lamps, made from carved stone and using animal fat as fuel, found in Mesopotamia and Europe.

- Cave painting made with manganese oxide paints found in Europe, Middle East and Africa.

[14] His traces were discovered in Israel (1988).

ca 40,000–10,000 BCE Preagricultural Cro-Magnon man lived by hunting and gathering. He was an excellent artist and craftsman in stone, bone, wood, and antler. His application of new and innovative technology allowed him to spread throughout the world.

His achievements were: First blade tools (34,000 BCE); early engravings (32,000 BCE); Asian hunters cross the Bering Strait land bridge to populate the Americas (30,000 BCE); first tent-like structure constructed with mammoth bones and tusks; first man-made sculpture (26,000 BCE); first known spear thrown (20,000 BCE); first sewing needle (20,000 BCE); cave paintings in France and Spain (18,000 BCE); Dogs (descendants of the Asian Wolf) domesticated in the Middle East. People inhabiting caves in what are now Israel and Jordan used notches in bones to record *sequences of numbers.*

ca 35,000–20,000 ya *Emergence of Proto-Mathematics in Africa.* Mathematics initially arose from a need to count and record numbers. Proto-Mathematics existed when no written record was available. It is believed that there has never been a society without some form of *counting* or *tallying* (i.e. matching a collection of objects with some easily-handled set of marking like stones, knots or notches on wood or bone).

The earliest evidence of a numerical recording device was found in a cave in the Lebembo Mountains, on the border of Swaziland in South Africa (ca 35,000 ya). It was a baboon bone with 29 clearly visible tally-mark notches, used to record the passage of time. Then, archaeological excavations (1962) on the Shores of Lake Edward (one of the farthest sources of the Nile, on the borders of Uganda and Zaire) unearthed a bone, ca 20,000 years old known as the *Ishango Bone*. The markings on it consist of a series of notches arranged in three distinct columns. Certain underlying numerical patterns may be observed in each column. It seems to have been devised by people who had a number system based on 10, as well as a knowledge of multiplication and of *prime numbers.*

It is conjectured that the bone markings represent of a system of sequential notation – a record of different *phases of the moon.* This they apparently needed to maintain their regular lake-shore lifestyle as a hunter-gatherer neolithic society: migration between dry and rainy seasons, festivities, religious rituals and other activities dictated by their special economic and religious needs.

It is now believed that the creation of a complicated system of sequential notation was well within the inherent capacity of early man to reason and conceptualize. Moreover, the close link between mathematics and astronomy was enhanced by the need felt by early man to record the passage of time, out of curiosity as well as for practical needs. This, in turn, was translated by him into *observations* of the changing aspects of the moon.

From the existing evidence of the transmission of Ishango tools (notably harpoon heads) northward up to the frontiers of *Egypt*, the Ishango numeration system may have traveled as far as Egypt and influenced the development of its own number system – the earliest decimal-based system in the world.

Table 0.2: Classification and nomenclature of periods in the evolutionary track of earth and man; Categories: *Geological* (G); *Climatical* (C); *Historical* (H); *Archaeological-Anthropological* (A)

Pleistocene (G):	the last 2 million years (up to 10,000 ya)
Holocene (G):	the past 10,000 years
Paleolithic (A):	1,000,000 ya → 8000 BCE
Mesolithic and Neolithic (A):	8000 → 4500 BCE
Chalcholithic (A):	4500 → 3200 BCE
Bronze Age (A):	ca 3100 → 1200 BCE (in Middle East)
Iron Age (A):	ca 1200 → 500 BCE (in Middle East)
Israelite period (H):	ca 1200 → 587 BCE (in Middle East)
Climatic Optimum (C):	ca 5500 → 3000 BCE (in Europe)
Ice Ages (C):	1,750,000 ya → 10,000 ya

Post-glacial world – the dawn of civilization

ca 10,000 BCE End of most recent *Ice Age* (*Pleistocene*) and beginning of the *Holocene* age: glaciers melted and retreated and climate was stabilizing. Vegetation began to dry up and water became scarce in the high grasslands, taking with it the herds on whose survival the hunting nomads depended. People were moving to the river valleys, planting crops and domesticating animals. Consequently they created towns and cities. In North Africa, for example, people were moving to the Nile Valley where African peoples mixed with people from the East. Thus, these post-glacial climatic changes impacted the decline and rise of civilizations throughout the Holocene[15].

With the rapid development of the postglacial warming, rivers were swollen enormously, particularly in spring and summer, by the melting ice; gravel and sand were deposited in great quantities along the river courses, lakes formed and sometimes quickly burst or rapidly silted up. The landscape was changing rapidly. But the greatest change for the human population and the animals they hunted was the disappearance of the open plains, as the forest advanced north in Europe. Man seems to have adapted himself more successfully than the animals. The ranges of both moved northward in Europe, Asia and North America, but some species among the animals were lost, probably due to their reduction by Man.

Other significant changes in the landscape were brought about by *the rise of sea levels, proceeding over some thousands of years at the rate of about 1 m a century.*

ca 9000 BCE Earliest beginnings of *agriculture*; domestication of the *dog.* Beginning of rapid rise in sea levels. Floods.

ca 9000–8000 BCE Urban culture in the Anatolian highlands founded by refugees from the flooded lowlands.

ca 8000–7700 BCE Final break up of the Scandinavian Ice Sheet. Highly organized Neolithic civilizations gradually begin to develop in a number of river valleys and alluvial plains in latitudes 20° to 40° N, where irrigation could be most easily arranged and provided seemingly reliable intensive crops.

[15] **F. Hoyle** and **N.C. Wickramasinge** speculated that sometime between 9000 and 8000 BCE, a cometary mass of ca 10^{10} tons impacted the Tasman and China Seas, causing a sudden global warming of 10 °C. This, they said, abruptly ended the Ice Age and created the necessary conditions for an advanced human culture.

Thus Neolithic man changed from food-hunter and food-gatherer into food-producer, domesticating animals and plants. This agrarian revolution centered mainly in the Middle East and the lower hills and adjacent plains of the Zagros Mountains.

- Agriculture in Mesopotamia (Northern Iraq) with farming of *wheat* and *barley*
- *Potatoes* and *beans* cultivated in Peru; *rice* in Indochina.
- Polynesians in the East Indies and Australia begin to spread out over islands of the South Pacific.
- First city-states appear in Mesopotamia and the Near East, including *Jericho* in Israel (population ca 2000, area $\simeq$ 40,000 m^2).
- *Clay tokens* in Mesopotamia used to tally shipments of grain and animals – the basis of a forthcoming first system of numerals and writing.
- The *Maya* make *astronomical* inscriptions and constructions in Central America.
- Sheep domesticated in Persia (Iran).
- Domestication of the bee.

ca 7000–6000 BCE Rise of temperatures continued and moisture increased. By 6000 BCE all of Western Europe was occupied by a rich forest of oak, cedar and elm. With the stabilization of the seas and coastlines, mankind dared to venture forth and seek the fertile valleys. First settlers in *Greece* (ca 7000 BCE).

The *pig* and *water buffalo* domesticated in China and East Asia; the *chicken* domesticated in South Asia; *Sugarcane* cultivated in New Guinea; *Flax* was grown in Southwest Asia; *Maize*, *squash* and *beans* were grown in Mexico; *Mortar* was used with *sun-dried bricks* in Jericho; invention of the *potter's wheel* in Asia Minor (ca 6500 BCE) heralded the production of clay pottery; use of *Woven cloth* was invented in Anatolia; *Cattle* was domesticated in Asia Minor (from a wild ox called auroch, now extinct). This ended the age of the *hoe* (began 8000–7000 BCE) in agriculture [*Genesis*, **3**, 19]. The earliest direct evidence for water craft (ca 6500 BCE) is a wooden paddle found at Star Carr, England.

ca 6300 BCE The llama and alpaca domesticated in Peru. Advent of picture-writing; Copper knives used in the Middle East. An *alcoholic drink* was made from grain.

ca 6000–3000 BCE *Age of revolutionary inventions*: With the availability of cheap tools the way was clear for a rapid expansion of agriculture and technology. The plow was devised; the wheeled cart was in use on land and the sailboat on water; the inclined plane and lever were common implements.

Copper ores were smelted; bronze was alloyed; bricks and pottery were fired. Canals and ditches were dug; grains were fermented; orchards were planted.

At the same time a systematic urban life became clearly outlined. There was an accurate solar calendar; eclipses were predicted. There were adequate methods of accounting and measuring. There was a definite recording of information and transmission of knowledge from one individual to another and from one generation to the next. Discoveries of that period are unrivaled in their impact on human progress. Even today's science cannot match them in fundamental importance to the basic well-being of man.

ca 5600 BCE The great *Mesopotamia flood* (Deluge); an uncertain date for the earliest documented natural catastrophe in the annals of mankind. It first echoed in the Sumerian story about **Ziusudra**, who by building an ark saved himself from the great flood sent by the gods. The narrative (which derived from folk memories of a giant cataclysm, actually experienced in recent geological times) evolved down the millennia and passed from nation to nation. Ziusudra became **Ut-Napishtim** of the Assyrian Gilgamesh Epic[16], **Noah** of the Hebrew Bible, and eventually the **Deukalion** of the Greeks. The most remarkable parallels between the Bible and the entire corpus of cuneiform inscriptions from Mesopotamia are found in the deluge accounts of the Babylonians and Assyrians on one hand, and the Hebrews on the other. It seems that these two versions are independent and refer to an actual event of some kind. According to the *Gilgamesh Epic* and the Sumerian source, the flood was accompanied by a storm of extraordinary magnitude probably issuing from the Persian Gulf, that ravaged for a week or so. The *Biblical* version[17], on the other hand, tells about simultaneous torrential downpour

---

[16] Fragments from the Gilgamesh Epic were discovered in the Nineveh library of King Ashurbanipal and date from ca 700 BCE. However, other examples of tablets of this epic date from about 1700 BCE. The story was probably composed at about 2000 BCE. Yet many of the episodes included in the epic have prototypes in the *Sumerian* language which are much older than 2000 BCE.

[17] The total number of flood legends has been estimated at ca 100. They are found in India, southern Asia, the East Indies, Mesopotamia, Polynesia, New Guinea, Australia, China, Europe and North and South America. These widespread legends of a great flood reflect dim folk-memory of the inundation of former coastal plains with the rise of world sea-level in the post-glacial period as the ice age glaciers melted.

from heaven *and* a flow of subterranean waters, the whole occurrence lasting for about a year.

The specific cause of the great flood is uncertain; two competing scenarios were recently[18] suggested:

- Large fragments of a *comet* crashed into seas around the world. The resulting impact triggered violent earthquakes and severe flooding of surrounding coastlines.
- The melting of the Eurasian Ice Sheet (began at ca. 12,500 BCE) raised the level of the ocean some 115 m above the shoreline of the Black Sea, eventually causing the sea water to burst through the narrow Bosporus valley into the lake, racing over beaches and up rivers, destroying or chasing all life before it[19].

  The flood rapidly created a human diaspora[20] that spread as far as Western Europe, Central Asia, China, Egypt and the Persian Gulf. These Black-Sea people could well have been the *proto Sumerians*, who developed civilization in Mesopotamia. These people could be responsible for the spread of farming into Europe, and the advances in agriculture and irrigation in Anatolia and Mesopotamia.

  Associated with the Mesopotamian flood is the biblical account of an Ark, constructed of gofer wood, or cypress, smeared without and within with pitch, or bitumen, to render it water-tight. Today's biblical scholars and shipbuilders agree that the Ark was a very suitable device for shipping heavy cargoes and floating upon the waves without rolling or pitching.[21] It was thus admirably suited for riding out the tremendous storms in the year of the flood.

---

[18] The astronomer **Edmond Halley** suggested (1688) that the biblical flood might have been due to a shock of a *comet*. Newton's successor, **William Whiston** (1696) supposed that flood was due to the close earth approach of a comet that broke the earth's crust via tidal forces and released subterranean waters. With the help of water released from the comet's tail and the atmosphere, an enormous tide was created.

[19] **W. Ryan** and **W. Pitman**: "*Noah's Flood*", Simon and Schuster N.Y., 1998, 319 pp.

[20] *Genesis* **11**, 8: "So the Lord scattered them abroad from thence upon the face of all the earth: and they left off to built the *city*" – the advent of *civilization*!

[21] Assuming the *cubit* to be 45.7 cm long, the Ark would have been 137.2 m long, 22.8 m wide and 13.7 m high. Noah's Ark was said to have been the largest seagoing vessel ever built until the late 19^{th} century, when giant metal ships were first constructed. Its length to width ratio of 6 : 1 provided *excellent stability* on the high seas.

ca 5000 BCE Animal domestication and land cultivation in South-East China. It spread from there to all of South-East Asia, but stopped short of Australia where the aborigines continued to be gatherers and hunters. Rice had a major impact on the mode of living of the peoples of Asia and was a direct cause of their fast rate of reproduction.

ca 5000 BCE *Irrigation* invented in Mesopotamia and China; nuggets of metals (gold, silver, copper) were used as ornaments or for trade; first alphabet began to develop; *Sumerians* enter Mesopotamia after the flood.

ca 4895 BCE Crater Lake formed in North America by a volcanic eruption ($VEI = 7, \quad E \simeq 5 \times 10^4$ MT).

ca 4800 BCE Sailing boats in Eridu, Sumer.

ca 4400–4200 BCE Neoglaciations and severe climatic depressions on *a global scale*. Several episodes of climatic deterioration were manifested through glacial advance, increased rainfall, decline of average temperatures, rise of sea level and major flooding.

Science 'Progress Reports'

Worldviews

Environmental Events that Impacted Civilization

ca 5600 BCE	The Great Mesopotamian Flood
2500–2000 BCE	Major climatic changes in Afro-Eurasia linked to encounter of Taurid meteor stream with earth; Megalithic constructions around the world
ca 2180–2130 BCE	Prolonged drought over the Eastern Mediterranean and adjacent lands
ca 1800 BCE	Ecological collapse of the irrigation system in Mesopotamia
ca 1628 BCE	Paroxysmal eruption of Tera Volcano near Crete
ca 1200–850 BCE	Major climatic changes in Eurasia; Drought disrupted agriculture in lands of the Eastern Mediterranean. The resulting Indo-European migration caused the collapse of the Hittite kingdom
ca 400 BCE	Malaria epidemic in Greece
79 CE	Eruption of Mount Vesuvius
ca 250–550 CE	Prolonged drought and epidemics (malaria) hastened the decline and fall of the Roman Empire. Simultaneous drought on the steppes of Central Asia drove barbarians to seek new lands

Political and Religious Events that Impacted Science, Philosophy and World Order

ca 1800 BCE	Hebrews conceive the idea of *Monoteism*
1286 BCE	Hittite-Egyptian Battle of *Kadesh* on the Orontes River
1230 BCE	Emergence of the *Hebrew Mosaic laws* – mankind first 'bill of rights'
1200–200 BCE	Creation of the *Hebrew Bible*
853 BCE	Battle of *Karkar* on the Orontes River
583–331 BCE	Rise and fall of the Persian Empire
508 BCE	*Democracy* born in Athens
490–479 BCE	*The Persian Wars* – a decisive and permanent influence upon development of Western culture and civilization
431–404 BCE	*Peloponnesian Wars*
390–220 BCE	*Celtic-Roman Wars*
339 BCE	*Battle* of *Amphissa*: Greek becomes a Macedonian protectorate
331 BCE	The Greco-Persian battle of *Arbela*
213 BCE	*'Burning of the books'* in China; construction of the Great *Wall of China* (214 BCE)
202 BCE	The Scipio-Hannibal *Battle of Zama*
146 BCE	Greece made a Roman province
52 BCE	*Battle of Alesia*, birth of Gallicio-Roman civilization
48 BCE	The Roman burn the *Alexandrian Library*

63 CE	Israel comes under Roman rule
391 CE	Christian Emperor Theodosas I ordered the burning of the remnants of the Alexandrian Library
325 CE	*Council of Nicaea* marks the rise to power of the *Christian Church* in the Mediterranean World
ca 400–500 CE	End of compilation and canonization of the *Talmud*
451 CE	The *Hun Invasion*
476 CE	'Official' end of the Roman Empire
529 CE	Emperor Justinian closed the *Athenian Academy*

"*Chemistry emerged from alchemy as astronomy from astrology and physics from philosophy*".

(George Sarton, 1950)

The Beginning of Science[1]

"Our forefathers had no other books but the score and the tally".

William Shakespeare, 'Henry 6', pt. 2, **iv***, 7 (1591)*

We shall perhaps never have any adequate information on the most critical period of man's history, when he was slowly emerging out of the darkness.

Science began thousands of years before man learned to write. There certainly was science before there were scientists but no one knows who first kindled a fire, who invented the earliest stone implements, who invented the wheel, developed the bow and the arrow, or tried to explain the rising and setting of the sun. Without articulate language man would have remained an animal. Without writing, the transmission and preservation of knowledge were impossible. It is probable that the above-mentioned breakthroughs involved collaboration; thousand of men, each big step forward being finally secured by exceptional genius. The evolutions leading to each of these fundamental discoveries were exceedingly slow – so slow that the people who took part in them were utterly unaware of them. Genius was then required only from time to time to clinch the results obtained by the unconscious accumulation of infinitesimal efforts, to secure what was gained and prepare another slow movement in the same general direction.

These major advances were among man's first attempts to understand and control the things he saw around him.

Through careful observations of recurring relationships in their environment they began to know nature, and because of nature's dependability, they found they could make predictions that would give them some control over their surroundings.

---

[1] Derived from the Latin verb *scire* = to know, to discern, to distinguish. The word *scientist* was coined by **William Whewell** of Cambridge in 1840. For further reading, see:

- Sarton, G., *Ancient Science and Modern Civilization*, University of Nebraska Press, 1954, 111 pp.
- Clark, G., *Space, Time and Man*, A Prehistoric Review, Cambridge University Press, Canto edition, 1994, 165 pp.

When our own particular subspecies, Homo sapiens sapiens, emerged some 40,000 year ago he was already a rather advanced user of tools: spears for hunting, axes for killing animals and for fashioning wood, knives and scrapers for working with materials — these were some of man's earliest tools. He soon devised tools to help him make tools, something no animal before him had done.

These first tools, man's earlies technology, had a great impact on his way of life; weapons enabled him to change his diet from a mostly vegetable one to a reasonably steady diet of animal flesh supplemented with fruits and vegetables. His tools enabled him to fashion cloths and dwellings, so that he was able to live in cold climates. Dwelling gave him another alternative to living in caves or in the open.

Man's bodily evolution reached its present form about twenty-five thousand years ago. Since then there has been a continuous unfolding of his mental capacities. Even at that time the Cro-Magnons in France were already paying attention to life far beyond the bare necessities of food. Spirited inscriptions of women and animals were being made on the walls of their caves. Expressive creativity was an early human trait.

For all but the most recent 10,000 years of his existence, man was a hunter-gatherer; he did not raise plants or animals for his own use, but went out and got them from the wild, when he needed them. Then — about 10,000 years ago — came man's most significant technological discovery: the cultivation of plants[2]*. In terms of its impact on society, agriculture is undoubtedly the most far-reaching of all man's technological innovations. A number of other technological innovations accompanied agriculture, the domestication and raising of animals, the making of pottery, and the weaving of cloth.*

The elaborate civilizations of Mesopotamia and Egypt depended for their birth and development on a settled agriculture practiced by Neolithic people in these regions since 8000 BCE. Without it, they could not have sustained either the increased population or the specialization of urban life. Once secured, these societies spawned a remarkable series of technological advances. The 4th *millennium BCE saw the invention of the plow, the wheel, the sailing boat, and methods of writing. Stone tools gave way to those of copper and bronze, that came into use ca 2500 BCE.*

Although yet devoid of the scientific method as we know it, the technical knowledge of these early societies was rather sophisticated; the pyramids remain one of the finest engineering feats of all time and the mathematics used

[2] The biblical narrative about man's *expulsion from Paradise* (*Gen* **3**, 23) may hint to his transition from food-gathering to food-producing at the beginning of the Holocene.

by priests provided for the development of other sciences. Trade and warfare were the main stimuli of technological advance in the second millennium BCE. The greatest technological event was the mastery of iron by Hittite smiths.

After centuries of experience, the annual nature of the river flood created the need to match human agricultural activity to the natural cycle – irrigation and ploughing came to pass. This most fundamental innovation in the history of man brought civilization into being because if was the instrument of surplus*. Communities were capable of supporting those who are not food producers.*

In order for early man to change from the primitive hunting and gathering way of life to a settled agricultural existence he needed to learn the concept of time*: settled farmers needed to understand the movement of the moon and the sun in order to regulate their agricultural production. Settled farming means trade, trade means communities (villages or towns) which in turn mean the specialization of trades, craftsmanship and art, language, laws and a primitive writing are not far away.*

Science, therefore, began with the conquest of time and distance. That is to say, with the quest of the knowledge needed to keep track of the seasons and to find man's whereabouts in the world he inhabited.

We now know that the social achievements of mankind before the beginning of the written record include far more important things than the perfection of axes and arrowheads. Several discoveries into which he blundered many millennia before the dawn of civilization in Egypt and Sumer, are especially significant: he learned to herd instead of to hunt, he learned to store grain to consume when there were no fruits to gather and he collected bits of meteoric iron. The sheep is an animal with seasonal fertility and cereal crops are largely annual. The recognition of the passage of time now became a primary necessity of social life.

In learning to record the passage of time, man learned to measure things. He learned to keep account of past events. He made structures on a much vaster scale than any of which he employed for purely domestic use.

The arts of writing[3]*, architecture, numbering, and in particular geometry, which was the offspring of star lore and shadow reckoning, were all by-products of man's first organized achievement – the construction of the* calendar*.*

Science began when man started to plan ahead for the seasons, because this demanded an organized body of continuous observations and a permanent record of their recurrence.

---

[3] In fact, a symbolic system of notation (primitive writing) seems to have been in use by prehistoric cave-painters! Ergo, necessary elements of civilized cultures were in place by 35,000 BCE.

In the age of satellite communication, atomic clocks, and cheap almanacs, we take time for granted. Before there were any clocks or even simpler devices like the hour-glass or the clepsydra for recording the passage of time, mankind had to depend on the direction of the heavenly bodies (sun by day and stars by night). He learned to associate changes in vegetation, the mating habits of animals, and the recurrence of drought or floods, with the rising and setting of bright stars and star clusters immediately before sunrise or in evening twilight.

When the agrarian revolution reached its climax in the dawn of city-life (ca 8000 BCE), a technique of timekeeping emerged as its pivotal achievement. What chiefly remain to record the beginnings of an orderly routine of settled life in cities are the vast structures which bear eloquent witness to the primary social function of the priesthood as custodians of the calendar: The temple *with its corridor and portal placed to greet the transit of its guardian star or to trap thin shaft of light from the rising of setting sun; the* obelisk *or shadow clock; the* Pyramids *facing equinoctial sunrise or sunset, the pole and the southings of the bright stars in the zodiac; the great stone circle of* Stonehenge *with its sight-line pointing to the rising sun of the summer soltice – all these are first and foremost almanacs in architecture.*

Nascent science and ceremonial religion had a common focus of social necessity in the observatory-temple of the astronomer – priest. That we still divide the circle into 360 *degrees, that we reckon fractions of a degree in minutes and seconds, remind us that men learned to measure angles before they had settled standards of length or area. Angular measurement was the necessary foundation of time keeping. The social necessity of recording the passage of time forced mankind to map out the heavens. How to map the earth came later as unforeseen result.*

Science rests on the painstaking recognition of uniformities in nature. In no branch of science is this more evidence than in astronomy, the oldest of the sciences, and the parent of the mathematical arts. Between the beginning of city life and the time when human beings first began to sow corn or to herd sheep, ten of twenty thousand years – perhaps more – may have been occupied in scanning the night skies and watching the sun's shadow throughout the seasons. Mankind was learning the uniformities which signalize the passage of the seasons, becoming aware of an external order, grasping slowly that it could only be commanded by being obeyed, and not as yet realizing that it could not be bribed. There is no hard and sharp line between the beginnings of science and what we now call magic. Magic is the discarded science of yesterday. The first priests were also the first scientists and the first civil servants.

The Sumerian Heritage (ca 4000–1800 BCE)

The first civilizations[4] *grew up when nomadic hunters and seed-gatherers began to farm the land, and so were able to form settled communities. Where the soil was rich, they could grow enough food to support non-producers like craftsmen and administrators. Probably the earliest civilization grew up in the fertile region between the rivers Tigris and Euphrates — in the lower part of an area known as Mesopotamia*[5].

The first settlers came here about 4000 *BCE, soon after the soil deposited by the rivers had dried enough for farming. The* Sumerians *were among the earliest invaders who probably came from the highlands at present day Turkey and Iran (scholars, however, do not know the exact origin of their racial or language group). They learned to drain the swamps, and to make bricks from mud. They farmed, dug canals, and raised livestock. On an agriculture economy they developed a true city life, so they must have understood the technique of specialization or division of labor.*

Their small settlements grew into cities and city-states. The more powerful city-states conquered their neighbors and created small kingdoms, including Kish*,* Lagash*,* Nippur*,* Umma*,* Uruk *and* Ur*. Each of these had fine buildings, streets, temples, palaces, fortifications, public water supplies and drainage over an average area of one square kilometer. They built a great network of irrigation canals, domesticated animals and their society included priests, soldiers, tradesmen and engineers. To this end they developed a government that handled both secular and religious matters, a trained army with armor, weapons of war, and carts for transportation.*

The Sumerian cities were united in a loose league. They shared a common culture, they spoke similar languages, and they worshiped the same gods. A typical Sumerian city-state consisted of the city proper and as much of the surrounding population as the city walls could accommodate in times of crisis. The focal point of each city was a great platform raised above the surrounding residential areas. On it were erected the many-storied temples (ziggurates) which became a hallmark of Babylonian monumental architecture[6].

---

[4] From the Latin: *civitas* for "city-state".

[5] From the Greek: "between the rivers".

[6] Many Sumerian traditions lie behind Bible legends: the *Tower of Babel* was almost certainly one of the ziggurates (its height could reach 100 m). The *Flood* is described in the Sumerian *Epic* of *Gilgamesh*. Archaeologists have shown that a great flood overwhelmed the area thousands of years ago. For further reading,

Writing, in the strict sense of the term, was first invented and employed in Mesopotamia about 3100 BCE. If it was not actually originated by the Sumerians, it was at any rate very soon taken over by them to represent their language, and it became one of the most important ancient writing systems.

The Sumerian wrote by pressing a split bamboo reed (stylus) on wet clay which was then baked until it was hard. The end used was triangular in shape. The writer did not scratch the lines of his picture, but in making a single line he impressed one corner of the tip of the stylus into the soft clay, and then raised it again to impress another line in the same way. Owing to the oblique tilt of the stylus, as well as its shape, each line thus made was wider at one end than at the other, and hence appeared triangular or wedge-shaped. Finally, every picture or sign written with such a stylus came to be made up of a group of wedge-shaped lines. We therefore call the system cuneiform[7] *(from the Latin* cuneus *= wedge) writing. Pictures made up of these wedge lines became more and more difficult to recognize, especially as speed of writing increased. All resemblance to earlier pictures finally disappeared.*

Most of the earliest examples of Sumerian writing that we have found are business records. But school texts appeared almost at once as means of educating specialists in the new technique. Literary texts and historical records followed in due course.

The transition from the picture stage to the phonetic *stage was early made. Sumerian writing finally possessed over 560 signs, but each of these signs represented a syllable or a word, that is a* group *of sounds; the Sumerian system never developed an* alphabet of letters *which made up the syllables. That is, there were signs for syllables, but no signs for the letters which made up such syllables.*

The Sumerian clay tablets reveal the sophistication of the Sumerian civilization as well as their degree of knowledge of mathematics, astronomy and medicine. The clay records show us that in measuring time the Sumerian scribe began a new month with every new moon, and he made his year of 12 of these moon-months. Since 12 such months fall short of making up a year, the scribe slipped an extra month whenever he found that he had reached the end of his calendar-year a month or so ahead of the seasons. As in Egypt,

see: Kramer, S.N., *History Begins at Summer*, Doubleday Anchor Books: New York, 1959, 247 pp.

[7] The decipherment of the cuneiform was pioneered in 1802 by **Georg Friedrich Grotefend** (1775–1853, Germany). His work was continued by **Henry Creswicke Rawlinson** (1810–1895, England), and by the mid-1800's the cuneiform code was broken. Since 1802, several hundred thousands cuneiform tablets have been recovered and placed in museums.

the years themselves were not numbered, but each year was named after some important event occurring in the course of the year.

The Sumerian system of numerals was not based on tens, but had the unit 60 *as a basis. The leading unit of weight which they used was the mina, divided into 60 shekels (the* mina *had the weight of a pound).*

The Sumerian writing spread to Elam (Iran) and Egypt by 3000 *BCE, to Crete (2200 BCE), India (2000 BCE) and to the Hittites (1500 BCE). [China invented writing independently by* 1300 *BCE and the Mayans by* 700 *CE].*

The Sumerian age of small, independent city-states which began at about 3000 *BCE, lasted until* 2500 *BCE. Such cities as Ur, Uruk, and Lagash waged local wars. Each city ruled its neighboring areas at various times. But the advantages of civilization could not be contained within the confines of the Sumerian city-states. By about* 2500 *BCE, cities on the Sumerian model had appeared throughout the area from the Tigris-Euphrates Valley to the eastern coast of the Mediterranean. The people of these newer cities were not Sumerian but Semitic. The Semites, a number of different people speaking similar languages, seem to have originated from the Arabian peninsula where they had been nomads who lived by breeding animals. As Arabia turned desert, Semites moved in several waves into the eastern Mediterranean and the parts of Mesopotamia north of the Sumerians. By* 2300 *BCE, the old Sumerian cities were merely the core of a much larger civilization that embraced the entire Fertile Crescent and whose population was primarily Semitic. The region first occupied by the Semites north of Sumer was finally called* Akkad *and the leading Semitic settlers there bore the name of* Akkadians*. Akkad occupied a very strong commercial portion on the main road from the Two Rivers to the eastern mountains and its trade brought it prosperity.*

The Semitic King Sargon I (ca 2300 BCE) was first to unite the city-states of Mesopotamia into a single empire, and the Sumerian civilization was gradually absorbed by the Semitic people. By 1800 BCE the Sumerians lost all political power, but the union of Sumerians and Semites furnished the base on which the Babylonian civilization developed[8].

[8] Recent archaeological evidence disclosed that by 1800 BCE the accumulated *salinization* of the soil due to irrigation reached a level where food production was insufficient for the growing population. This man-made ecological disaster was probably one of the major factors in the demise of the Sumerian civilization.

Climate and Civilization

Climate has been subject to change since the earliest times known to geologists. Because geology is a relatively young science, however, this fact has been recognized for only about a century; and at first only the larger fluctuations, the extremes of Ice Ages and Interglacial, were recognized. But soon geologists found evidence that ice sheets, both in their expansion and recession, were subject to interruption — that is, neither advances nor retreats proceeded smoothly and linearly, but each of them from time to time interrupted by a reversal of the primary trend. Thus, paleo-ecological, geological and archaeological evidence has been accumulated in favor of climatic fluctuations in Europe, in the form of damped oscillations, of gradually diminishing amplitude and duration, over the past 10 *to* 15 *thousand years.*

In the Mediterranean Basin, the Near East and northern and central Africa the evidence is more subtle and difficult to detect. However, the relation in time between the subtropical and European climate changes were clarified due to intensive research in the past four decades. A synchronism was established between the period of advance and growth of glaciers in Europe to glacier advance in central-east African mountains and the pluvial period in the Mediterranean Basin. It was also found that fluctuations that were too small to leave clear geological evidence, could still be large enough to produce highly significant ecological effects, which may be reflected in archaeological evidence.

The 8000 *years between the end of the last ice-age (breakdown of the Scandinavian ice-sheet) and the time of Christ saw a sequence of substantial changes, including some thousands of years that were warmer, and in low latitudes, moister than now. Such shifts in climate may have been manifested through long summer drought, repeated rains and river floods, damaging gales and long severe frost. Glaciers may have melted or expanded, blocking mountain passages previously used for traffic. World sea-level rose and fell with the gain or loss of water from the world's glaciers. In primitive economies such effects could be disastrous and may have affected the course of history.*

A particularly sharp change seems to have occurred in the interval 1200–500 BCE. This history overlaps the rise and fall of various civilizations and migrations of the so-called 'barbarian' cultures of Northern and Central Europe and Asia. The driving forces behind many historical upheavals could well have been famine, epidemics and wars caused by droughts and floods and the arrest of naval commerce lines caused by stormy seas.

At the present time we have more or less a complete record of human history in South-Western Asia since about 5200 BCE for which we have the following data sources:

- *Instrumental records and old weather journals going back at most for 300 years.*
- *Literary records: accounts of floods, droughts, severe winters, and great storms.*
- *Traditions (such as that of the Deluge which can sometimes be correlated with other data.*
- *Fluctuations of lakes and rivers, glaciers and other natural indices of climate, which can often be connected with historical events or dated by laminated clays.*
- *Arguments from migration of people, for which climatic reasons may be assigned with some determined probability. To this we may add the waxing and waning of civilizations.*
- *The rate of growth of trees, as shown by annual rings of tree-growth, which can be correlated with the annual rainfall.*
- *Geological evidence — great advances or retreats of glaciers, growth of peat-bogs, succession of floras, etc., which can sometimes be approximately dated.*

The evidence afforded by racial migrations depends on the principle that during a period of increased rainfall there is a movement of peoples from regions which are naturally moist to regions which are naturally dry, while during the drier periods the direction of movement is reversed.

It has been shown, for example, that emigration from Europe to the United States depended on the rainfall. In order that this principle may be used to determine the course of climatic variations, certain conditions are necessary. First, there must be large areas which are on the borderline between aridity and complete desert; these areas must be mostly too dry for extensive agriculture, but with sufficient resources to support under average conditions a large nomadic population, while a succession of dry years renders them almost uninhabitable.

In close proximity to this arid region there must be a fertile well-watered plain, with a long and accurately dated history. During dry periods the nomads are driven from their homes by lack of water, but they find little difficulty in moving from point to point, and the sedentary agriculturists of the neighboring plain generally find them irresistible. It is only in Asia that these conditions are fulfilled in perfection, the rich plains of the Tigris and Euphrates, the site of a long succession of civilized states, having on the one *side the semi-deserts of Arabia and Syria, on the other side a great dry region extending eastwards and north-eastwards as far as China. We should expect a period of decreased rainfall to initiate a series of great migrations spreading out from the dry regions and recorded in the history of the Mesopotamian states as the invasions of barbarians.*

The history of Egypt does not provide such a complete a record, because the desert on either side of the Nile valley is too dry, even under favorable conditions, to support a nomadic population sufficiently large to have made any impression on the might of ancient Egypt. The Hyksos conquest of about 1800 *BCE is the main exception, but the Hyksos themselves probably came out of Asia. The invasions of China from the west provide some evidence of climatic fluctuations in the east of Asia.*

Man's awareness of the fickleness of climate can be traced back to the dawn of history and may have existed long before that in tales carefully transmitted from generation to generation, which even now survive enshrined in myth and legend. In contrast, the view, regarded as scientific, which was widely taught in the earlier part of this century, that climate was essentially constant apart from random fluctuations from year to year, was at variance with the attitudes and experience of most earlier generations. It has also had to be abandoned in face of the significant changes that occurred in many parts of the world.

Among the earliest written reports of climatic fluctuations are the inscriptions recording the yearly levels of the Nile flood, some of them from around 3000 BCE. Other inscribed tablets, or steles, show a reasoned awareness of the liability of the Nile to fluctuations lasting some years.

In numerous ancient writings and legends we may distinguish knowledge of certain climatic catastrophes, which changed the face of the world and from which recovery was either long delayed or never fully established. The commonest of these accounts, usually of the distant past, are those that relate to a great flood, of which NOAH's flood is perhaps the best known example.

Climatic oscillations lasting up to 100 years or so, may be due in part to changes in the general circulation of the atmosphere and in part due to interaction of ocean currents and floating ice-fields.

Because of the nonlinear nature of these interactions, under favorable conditions, comparatively small causes may have disproportionally large effects.

One must also remember that while major climatic changes tend to be nearly synchronous globally, they are not generally in the same sense or magnitude in all places: so there can be damp weather in Western Europe, and simultaneous drought in North America.

One of the consequences of a short term climatic change which affected and afflicted mankind during its entire history is the drought condition resulting from a significant shortage in water storage due to lack of precipitation.

4226 BCE Time-reckoning may have began in Egypt with the institutioning of the first calendar with a 365-day year, broken into 12 thirty-day months plus 5 days for festivals.

4000–3200 BCE *Chalcolithic Age*: The copper-stone age, just before the dawn of history, during which man first learned to create metal tools and ceremonial objects. Emergence of houses, towns and geometric designs on pottery. This transition from the Prehistoric to the Historic Age was everywhere a slow and gradual one. *Civilization* slowly appeared in the *Near East* while the men of the Late Stone Age in *Europe* continued to live without metal, government, writing, large ships and many other creations of civilization. Beginning at about 2000 BCE, civilization gradually and slowly diffused toward Europe via the Aegean world as it received all the above benefits from the nations of the Near East.

ca 4000 BCE Advent of *horseback riding* in the uplands between the Dnieper River and the Carpathian Mountains, first *sail-propelled boats*; bricks are fired in kilns in Mesopotamia; first recording of *star-constellations*. Invention of the plough. Sea-level rise began to slow down, but the slow rise will continue to ca 2000 BCE.

4000–3000 BCE First urban civilization in the world appeared in the region between the Mediterranean and India during the so-called post-glacial optimum[9].

ca 4000 BCE Early metallurgists in the foothills and semiarid plains of Anatolia[10] and Iran discovered sources of copper other than the native metal. None of these ores superficially resembles copper itself and cover a

[9] Caused by cessation of volcanic activity and slight increase in solar radiation in the middle and high latitudes.

[10] Neolithic man was acquainted with various *minerals*: In the cave painting in France and Spain, he employed *ocher* (hydrated Fe_2O_3) and *pyrolusite* (MnO_2) as pigments. Women used *rouge* (Fe_2O_3) and *eye shadow* (PbS) before the 6^{th} millennium BCE. Beads of malachite [$Cu_2(OH)_2CO_3$] and other minerals and

wide range of colors: green malachite, blue azurite [$Cu_3(OH)_2(CO_3)_2$], red cuprite (Cu_2O), gray chalcocite (Cu_2S) yellow chalcopyrite ($CuFeS_2$), and purple bornite (Cu_2FeS_2). The first reduction of malachite to metal must have been an accidental discovery, probably in a pottery oven. The propagation of copper from sulfide ores was a still more extraordinary discovery, because a much more sophisticated technique is required.

3784, Oct 20 BCE First record of a solar eclipse was made in India (according to the **Rig Veda**). The next four records of solar eclipses in human history were: 2136, Oct 10 BCE (China); 1375, May 13 BCE (Ugarit); 1178, April 16, BCE (Homer's *Odyssey*, Greece).

ca 3580 BCE Great eruption of mount *Vesuvius* (VEI=6).

ca 3500 BCE The introduction of the *wheel*[11] in Mesopotamia during the period of establishment of the city-states. It took two forms: a stone potter's wheel and a cartwheel made from a solid piece of wood[12]. A simple picture of a solid-wheeled vehicle was found at *Uruk*. The royal standard of Ur, dating from 2750 BCE, shows carts with solid wooden wheels.

ca 3500 BCE *Indo-European proto language*, spread by nomadic *horseback* herders from the Eurasian steppes, reached the Near-East. Their language will give rise to the Indo-European languages, including the branches called *Germanic* (English, German), *Italic* (Latin, French), *Slavic* (Russian), *Indo-Iranian* (Sanskrit), *Baltic* (Lithuanian), *Celtic* (Gaelic), and Greek, Albanian, Armenian, and Anatolian (Hittite). Linguists and anthropologists tend to

pieces of copper and gold were among their items of personal adornment. In the region from the Anatolian plain to the edge of the Iranian desert, neolithic man could find nuggets of gold and copper in stream beds, where the native metal was concentrated by the flowing water. In northern Iraq, copper beads have been found that date from 8500 BCE. By 6000 BCE, neolithic people in the region of the Fertile Crescent had abandoned their nomadic life as hunters to become grain growers and stock raisers. They had also mastered some of the secrets of fire and clay, for pottery makes its first appearance at this time and the skills of potter were indispensable to the first metallurgists.

[11] Was the invention of the wheel a result of man's keen observation of the ease with which the dung-beetle (scarab) was maneuvering the dung ball? We know that this beetle was once held sacred by the ancient Egyptians.

[12] First literary mention in the biblical story of Joseph (*Genesis* **45**, 21, 27), relating to ca 1650 BCE.

believe that this *mother tongue*[13] spread into Europe by farmers. Even if a farmer's offsprings had moved only 15 km from the family farm to set up farms of their own, the resulting move of agriculture could have diffused throughout Europe from Anatolia in about 1500 years, carrying the Indo-European language with it.

Moreover, cultural anthropologists[14] are now able to trace *the migration of people* throughout the world in the last 10,000 years as having started with the growth of population in a location between the Black Sea and the Caspian Sea.

ca 3500 BCE Earliest known use of *Bronze*[15] in Sumer. The period in history between the *Stone Age* and the *Iron Age* (ca 1100 BCE) became known as the *Bronze Age*[16]. The origin of bronze had been different in different places, but it is reasonable to suppose that it was first discovered by the accidental smelting of mixed ores of copper and tin, such as known to occur.

Bronze Age flourished in the *Aegean world* during 2900–2000 and continued during 2000–1100 in the *Cretan*, *Minoan* and *Mycenaean* civilizations.

ca 3500–3000 BCE Mesopotamia springs into *history* with the *city-states* of Sumer and Akkad; advent of pictographic *writing*; emergence of societies in the Great Valleys with social and material benefits (Egypt, China, India,

---

[13] The Bible (*Genesis* **11**) associates the story of the *Tower of Babel* with the confusion of languages and the *dispersion of the races throughout the world*. Clay tablets written in Sumerian indicate that Sumerians believed that there was a time when all mankind spoke one and the same language, and that it was *Enki*, the Sumerian god of wisdom, who confounded their speech.

[14] **Luigi Luca Cavalli-Sforza** and **Francesco Cavalli-Sforza**, *The Great Human Diasporas*, Addison-Wesley, 1995.

[15] *Bronze*: an alloy of *copper and tin*. The oldest alloy known to man. It replaced stone and soft copper and was used as the primary material for weapons and cutting tools. It was commonly used to cast containers such as cups, urns, and vases. Men also shaped bronze into battle-axes, helmets, knives, shields, swords, and ornaments. In contradistinction, *Brass* is an alloy of *copper and zinc* and was probably discovered later by melting copper ore that also contained a small amount of zinc.

[16] The bronze age is not a particular period of time; some areas had their bronze age early, others had it late, and some skipped it altogether. The Bronze Age in any region usually overlapped on earlier Stone Age and a later Iron Age, because people did not stop using one material all at once. The Biblical reference to *Tuval-cain* as a master forger of bronze tools (*Genesis* **4**, 22) is probably associated with the early Bronze Age III in the Near East (ca 2400 BCE).

Mesopotamia); introduction of the *wheel* in Mesopotamia and its use in hauling carts and making pottery (ca 3300 BCE).

Glacier advances around 3000–2800 BCE severely disturbed Neolithic agricultural economy in central Europe and Asia, causing the spread of people to Western Europe. Climate deteriorated on a global scale and glacier's movement caused major flooding in Mesopotamia and Egypt.

ca 3400 BCE Development of *hieroglyphic writing*. Egyptians developed their *number system*[17] to the point where they could record numbers as large as 100,000,000. Thus, written numbers preceded any known form of written

[17] The invention of hieroglyphics took many years, maybe even centuries. Hieroglyphs were carved or "printed." The *hieratic* was the first cursive form of hieroglyphics, developed much later. It was a quicker and more convenient way of recording an agreement, conveying a message, or making a calculation with numbers than by drawing hieroglyphs.
As the need for keeping track of large numbers arose, the Egyptians developed a grouping system in order to perform more complex operations. In this system some number n is selected for the base and symbols are adopted for $1, n, n^2, n^3$, and so on. Then any number was expressed by adding these numbers.
Their grouping system had a base of ten. Their symbols were powers of ten:

- 1: The symbol for a staff or rod.
- 10: A heel bone or arc.
- 100: A rope coil or scroll symbol.
- 1,000: The lotus flower.
- 10,000: A pointing finger.
- 100,000: A burbot (fish).
- 1,000,000: An astonished man.
- 10,000,000: A sun on the horizon.

They had no mathematical notation, except the symbol for total. There were no plus, minus, multiplication, or division signs. No square root signs, zeros, or decimal points were used. If they wanted to indicate a sign, they had to write it out in hieroglyphics. Although they didn't have mathematical notation, theretwice-times table and two-thirds-table enabled them to do a significant amount of mathematical problems for their time.

words. Numerals probably preceded words in the Orient and in the Americas as well.

ca 3200 BCE Metal-molding were practiced at Sumer to make copper and bronze axes. Egyptians used papyrus to write on. Sailing ships were used in Egypt. A *ziggurat* in Ur (Mesopotamia), 12 m high, shows that the Sumerians were familiar with columns, domes, arches and vaults.

3200 BCE Earliest evidence of *political structuring* in Egypt: administrators are appointed to ensure a regular water supply to the fields. Egypt is developing into a sophisticated centralized civilization. Astronomy, picture-writing and mathematics evolve and develop as necessities from the demands of canal-building, regular harvesting, granary building, taxation system and security (metal weapons).

3300 BCE Evidence for *copper industry* in the Alps found in 1991 with the discovery of the Austrian Alps 'Iceman' buried in snow. This pushes back the copper age by some 1000 years.

ca 3200 BCE Egyptians made the earliest recorded sea voyage during the reign of Pharaoh **Sneferu**. It was commemorated in a hieroglyphic inscription which recorded the "bringing of 40 ships of one hundred cubits with cedar wood from Byblos". It was the need for timber, for their temples, palaces and ships, that occasioned the voyage to Byblos, the port for timber hewn in the great cedar groves of the Lebanon mountains.

ca 3000 BCE The first glass was made by man in the form of a glaze on ceramic vessels.

ca 3000 BCE Breakup of a large comet produced a *zodiacal light*[18] so prominent that it was confused with the *Milky Way*. It is mentioned repeatedly in ancient literature.

ca 3000 BCE *First large-scale irrigation system* in Egypt and Mesopotamia. It began with the discovery of farmers that they could exploit the natural irrigation afforded by rains and floods in order to raise crops during most of

[18] *Zodiacal light*: sunlight reflected off dust that lies in the ecliptic plane (zodiac). This dust is believed to be fine debris from long-lost comets and is studied by astronomers using space-borne telescopes sensitive to infrared (heat) radiation. Sometimes, when an active comet sheds a great deal of material, the zodiacal light becomes very bright. Such was the case e.g. on the night of 07 June 1843 in South Africa, when it resulted from debris of comet *Encke*. It is currently so faint that it barely even merits mention in textbooks.

the year. By this means the same patches of land were cultivated repeatedly. Farmers were then led to invent the *plow* that oxen could pull. This in turn helped farmers produce much more food than they needed for their families. The food surpluses enabled more and more people to give up farming and more to the cities. Classes of builders, craftsman, merchants priests, clerks, miners, smelters, transporters and officials began to appear – and systems of writing were invented.

ca 3000 BCE Earliest written reports of *climatic fluctuations* in Egyptian inscriptions, on tablets or steles, recording the yearly levels of the Nile flood.

ca 3000 BCE The Chinese used the binary system in their arithmetic calculations. Hieroglyphic numerals in Egypt.

ca 2900 BCE Earliest archaeological evidence for the existence of the city of *Yafo*[19], on the Mediterranean coast of Israel. It was the scene of the ancient legend of Andromache and Perseus. The part of Yafo is mentioned in Old Testament (*Josh* **19**, 46; *Jonah* **1**, 3; *Ezra* **3**, 7; *Chron.* II. **16**). The name is also mentioned in the tribute lists of the Egyptian king Tethmosis III in the 15^{th} century BCE.

Yafo was probably under the control of the Phoenicians until the Persian period. It was brought under Israeli control by the Maccabees (164 BCE). Pompey made it a free city (63 BCE), but Caesar restored it to the Israelis (47 BCE).

As the only harbor in the Israeli coast between Egypt and Carmel, Yafo was of great commercial importance throughout history. The modern *Tel Aviv-Yafo* with a population of ca 360,000 is the largest city in Israel.

ca 2800 BCE The earliest known book of medicine, the *Great Herbal* of Emperor **Shen Lung**. There is a Babylonian physicians seal of about the same date.

[19] Other names are *Joppa* (Greek) and *Jaffa* (Arabic). The Hebrew name could have originated from the Hebrew word *Yafé* (= beautiful) or *Japeth* (= son of Noah).

Origins of the Egyptian Civilization

Egyptian civilization did not emerge spontaneously as a full-grown discipline. It had its note in former African civilizations: Carbon dating of the remains of barley and einkorn wheat found at Kubbaniya, near Aswan in Upper Egypt, shows the beginning of agriculture that existed around 16,000 BCE, and this evidence is supported by the large concentrations of agricultural implements from around 13,000 BCE.

Moreover, the discovery of recent archaeological artifacts of neolithic communities in Egypt, indicate that they may have belonged to groups from the once fertile Sahara region who were forced to migrate eastward as the desert spread. So, the culture and people of Egypt initially originated in the heartlands of Africa. This is borne out by the historian **Diodorus**, *who wrote (ca 50 BCE) that the Egyptians "are colonists sent out by the Ethiopians... And the large part of the customs of the Egyptians are Ethiopian".*

Egyptian mathematics[20] (3100–1250 BCE)

Due to the more advanced economic development of Babylonia, the mathematics of ancient Egypt never reached the level attained by Babylonian mathematics: Babylonia was located on a number of great caravan routes, while Egypt stood in semi-isolation. Nor did the relatively peaceful Nile demand such extensive engineering and administrational efforts as did the more erratic Tigris and Euphrates. But the veneration that the Egyptians had for their dead and the unusually dry climate of the region, led to the preservation of many papyri and objects that would otherwise have perished.

The origins of the urban revolution that transformed Egypt into one of the great ancient civilizations are the gradual development of effective methods of flood control, irrigation and marsh drainage which contributed to a significant increase in agricultural yield. Clearly, a prerequisite for such innovations required organization that sprang out of cooperation among preexisting scattered settlements. Thus, prior to the emergence of the highly centralized government of Pharaonic Egypt, a form of communal village nucleations may

have come into existence as an institutional back-up for these agricultural innovations.

Between 3500 and 3000 BCE, the separate agricultural communities along the banks of the Nile were gradually united, first to form two kingdoms – Upper and Lower Egypt – which were brought together (ca 3100 BCE), as a single unit by ***Menes****, who came from Nubia (part of present-day Sudan). Menes forced a long line of Pharaohs, 32 dynasties in all, who ruled over a stable society for the next 3000 years.*

Up to 1350 BCE, the territory of Egypt covered not only the Nile valley but also parts of Israel and Syria. Control over such a wide expanse of land required an efficient and extensive administrative system. Censuses had to be taken, taxes collected, and large armies maintained. Agricultural requirements included not only drainage, irrigation and flood control, but also the parceling out of scarce arable land among the peasantry and the construction of silos for storing grain and other produce.

As Egyptian civilization matured, there evolved other pursuits requiring practical arithmetics and mensuration: financial and commercial practices demanded numerical facility. This evolving numerate culture, serviced by a growing class of scribes and clerks led, in turn, to the construction of calendars and the creation of a standard system of weights and measures. Finally, this practical mathematical culture culminated in the construction of ancient Egypt's longest lasting legacy – the Pyramids.

It is possible to distinguish three different notational schemes of numeration used in ancient Egypt: hieroglyphic *(pictorial),* hieratic *(symbolic) and* demotic *(popular). The hieratic notation was employed in both the Moscow and Rhind papyri . The demotic variant was a popular adaptation of the hieratic notation and became important during the Greek and Roman periods of Egyptian history.*

The hieroglyphic *system of writing was a pictorial script where each character represented an object. Special symbols were used to represent each power of 10 from 1 to 10^7. With these symbols, numbers were expressed in the decimal system e.g.* $17509 = 1(10^4) + 7(10^3) + 5(10^2) + 0(10^1) + 9(10^0)$. *No difficulties arose from not having a symbol for zero or place-holder in this number system. Addition and subtraction posed few problems: In adding two numbers, one made a collection of each set of symbols that appeared in both numbers, replacing them with the next higher symbol as necessary. Subtraction is merely the reversal of the process of addition, with decomposition achieved by replacing a larger hieroglyph with ten of the next lower symbol.*

The hieratic *representation was similar in that it was additive and based on powers of ten, but it was far more economical (fewer symbols). While this* *notation was more taxing on memory, its economy, speed and greater suitability for writing with pen and ink (for writing on paper in contradistinction to hieroglyphs carved on stone or metal) caused the gradual replacement of hieroglyphs.*

These papyri reveal the state of mathematics in Egypt from about 3100 BCE to about 1100 BCE.

One consequence of their numerical system is the additive character of the dependent arithmetics. Multiplication and division were usually performed by a succession of doubling operations depending on the fact that any number can be represented as a sum of powers of 2.

This Egyptian process of multiplication and division eliminated the necessity of learning a multiplication table. It is also so convenient on the abacus that it persisted as long as that instrument was in use.

Thus, this method required prior knowledge of only addition and "two-time" table.

In a modern variation of this method, still popular among rural community in Russia, Ethiopia and the Near East, there are no multiplication tables and the ability to double and halve numbers (and to distinguish odd from even) is all that is required.

Whether the Egyptians knew it or not, their method is based on the unique binary representation of every number.

In modern notation, if N *is a positive integer, it can be written as*

$$N = a_r 2^r + a_{r-1} 2^{r-1} + \cdots + a_1 2^1 + a_0,$$

where $a_k = 0$ *or* 1. *Suppose that* N *and* M, *whole numbers, are to be multiplied; then* $NM = \sum_i 2^i M$, *where the sum includes only these terms for which* $a_i = 1$. *Then to calculate* $2^i M$, *just double* M, *then double the result and continue to double until* $2^i M$ *is reached. Therefore, if we can add and double numbers, we can also multiply them. The Egyptians (lacking computers) still faced one little problem: how to find, quickly, the non-zero coefficients in the binary representation of* N. *Their ingenious trick was to half the multiplicand* N *(to the nearest integer* $[\frac{N}{2}]$*) and keep halving the result until unity is obtained. Then, consider only the odd number in this sequence!*

This ancient method of multiplication provides the foundation of Egyptian arithmetic. It was widely used, with some modifications, by the Greeks and continued well into the Middle Ages in Europe.

In the inverse process of division, fractions had to be introduced whenever the quotient was not an integer. But since their method of writing numerals did not allow any unambiguous way of expressing fractions, they tackled the problem in a quite ingenious way.

Modern historians and mathematicians have tried to discover the rules that the Egyptians actually followed in performing calculations with fractions. From all cases available in the table of the Papyrus Rhind (ca 2000–1800 BCE), ***Neugebauer*** *recorded that the Egyptians actually used simple algebraic rules such as (in modern notation)*

$$\frac{2}{n} = \frac{1}{2}\frac{1}{n} + \frac{3}{2}\frac{1}{n} \qquad \textit{or} \qquad \frac{2}{n} = \frac{1}{3}\frac{1}{n} + \frac{5}{3}\frac{1}{n}$$

to obtain results such as

$$\frac{2}{3} = \frac{1}{6} + \frac{1}{2}, \qquad \frac{2}{5} = \frac{1}{15} + \frac{1}{3}.$$

In general, they were concerned with the representation of a rational numbers as the sum of unit fractions, i.e.

$$\frac{m}{n} = \frac{1}{x_1} + \frac{1}{x_2} + \cdots + \frac{1}{x_k}.$$

This has suggested numerous problems, many of which are still unsolved, and continue to suggest new problems, so that interest in Egyptian fractions is as great as it has ever been. One such problem suggested by ***Paul Erdös*** *concerns the Diophantine-like equation*

$$\frac{4}{n} = \frac{1}{x} + \frac{1}{y} + \frac{1}{z}, \qquad n > 1,$$

where $x,\ y,\ z$ and n are positive integers [e.g. $n = 4,\ x = 2,\ y = 3,\ z = 6$]. Examples of other fractions are

$$\frac{2}{7} = \frac{1}{5} + \frac{1}{13} + \frac{1}{115} + \frac{1}{10465},$$

$$1 = \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \frac{1}{9} + \frac{1}{15} + \frac{1}{21} + \frac{1}{27} + \frac{1}{35} + \frac{1}{63} + \frac{1}{105} + \frac{1}{135}.$$

A well-known riddle associated with Egyptian fractions is the following: A dying rich man, who owned 11 cars, willed 1/2 of them to his oldest daughter, 1/4 to his middle daughter, and 1/6 to his youngest daughter. But the *problem arose how to divide his 11 cars in strict accordance with the will. A car-dealer offered his help by* lending *the heirs a brand-new identical vehicle so that each daughter could now receive a whole car: the oldest 6, the middle 3 and the youngest 2. After the heirs had driven off, one car remained for the dealer to reclaim!*

The problem really solved here was to express $\frac{n}{n+1}$ *as a sum of three Egyptian fractions:*

$$\frac{n}{n+1} = \frac{1}{a} + \frac{1}{b} + \frac{1}{c}.$$

In the above story $n = 11,\ a = 2,\ b = 4,\ c = 6$. *Interestingly, for* $n = 11$, *there is another solution (and story) with* $a = 2,\ b = 3,\ c = 12$ *because* two *subsets of the divisors of 12 (1, 2, 3, 4, 6, 12) add to 11 (2+3+6=1+4+6=11). The inheritance problem is related to* pseudo perfect *numbers, defined as numbers equal to a sum of a subset of their divisors.*

Thus, the main Egyptian mathematical accomplishment was the invention of a system of notation that made it possible to express the result of an arbitrary division of integers. However, this process was cumbersome and did not result in a unique expression for a fraction, which in turn made it difficult to compare the size of numbers. They used $17/12$ *for* $\sqrt{2}$ *and symbols for plus, minus, equality and unknowns appeared in their arithmetic.*

With this limitation of their calculational capabilities, the Egyptians could not have solved quadratic equations. Clearly, advances in algebra are dependent on an efficient notation for numbers and on systematic methods for computing with them.

As opposed to continued fractions, *unit fractions are of relatively little use. In fact, they probably set back the development of Egyptian mathematics. However, they do provide fertile ground for numerous unsolved problem in* Diophantine analysis.

Operating with unit fractions is a singular feature of Egyptian mathematics, and is absent from almost every other mathematical tradition.

*Egyptian algebra is referred to as '*rhetorical algebra*': the rules devised by mathematicians for solving problem about numbers were expressed* verbally *and consisted of detailed instructions about what was to be done to obtain the solution to a problem.*

In time, the prose form of rhetorical algebra gave way to the use of syncopated algebra *where abbreviations for recurring quantities and operations* *were introduced. Traces of such algebra are to be found in the works of* **Diophantos***(ca 250 CE), but it achieved its fullest development in the work of Hindu and Arab mathematicians during the first millennium CE.*

During the past five centuries there has developed 'symbolic algebra' where, with the aid of letters and signs of operation and relation ($+, -, \times, \div, =$)*, problems are stated in such a form that the rules of solution may be applied consistently. This evolution had to await the development of a positional number system which allowed numbers to be expressed concisely and with which operations could be carried out efficiently.*

An ancient mathematical document dated ca 1850 BCE and known as the "Moscow Papyrus" reveals the state of knowledge of ancient Egyptian mathematicians.

The papyrus was discovered in 1890 in the Necropolis of Dra Abul Negga in Egypt and it was acquired in 1912 by the Moscow Museum of Fine Arts. It consists of 25 mathematical problems and their solutions. The solutions of the geometrical problems are basically arithmetical, offering no trace of a proof in the Euclidean sense.

A second document from the same time is the "Rhind Papyrus", now in the British Museum. It reveals a highly original procedure for operating with fractions. The Egyptians used a decimal system of notation, but had no procedure which was in the nature of a general proof. The geometrical problems were mensurational. The document was found at Thebes and purchased in 1858 by the English archaeologist Alexander Henry Rhind.

The above sources reveal that Egyptian algebra did not go far beyond linear equations in one unknown and pure quadratic equations in one unknown. Their algebra had some symbolism such a symbols for plus, minus and equals.

In geometry they advanced only as far as was required for computing simple land areas and granary volumes. Thus, the area of a circle was taken equal to that of a square of side 8/9 of the diameter (leading to the value $\pi \sim 3.16$*). The volume of a right cylinder was obtained as a product of the base area by the length of the altitude. They also knew that the area of any triangle is given by half the product of the base and altitude.*

An army of some 100,000 laborers working for a period of 30 years built for them the great pyramid of Gizeh at about 2700 BCE. It undoubtedly involved some mathematical and engineering problems. Indeed, problem 14 of the Moscow Papyrus reveals that they knew the general formula

$$V = \frac{1}{3}h(a^2 + ab + b^2),$$

giving the volume of a frustum of a square pyramid of the height h and the sides a and b of the bases.

The geometry of the Egyptians was merely an applied arithmetic in the sense that areas and volumes were determined according to certain approximate calculational rules[21]*. However, nowhere does a systematic derivation of these rules occur. Looking at Egyptian mathematics as a whole, one sees only rules for calculation without any motivation, but calculation is not the same as mathematics.*

Astrology was, in Egypt, the prelude to astronomy*. The stars were observed that they might be duly worshiped. The importance of their first visible appearances at dawn (for the purposes of both practical life and ritual observance) caused them to be systematically noted. The length of the year was accurately fixed in connection with the annually recurring Nile flood, while the curiously precise orientation of the Pyramids afforded a lasting demonstration of the high degree of technical skill in watching the heavens attained in the 3^{rd} millennium BCE. The constellational system, in vogue among the Egyptians, appeared to have been of native origin, but they contributed little or nothing to the genuine progress of astronomy.*

The ancient Egyptians bequeathed to us the idea which is at the heart of our calendar*. Unlike the Babylonians, Greeks and early Romans, they based their calendar upon the* sun *alone. As the earliest great farming civilization, Egypt was dependent upon the annual flood of the Nile which brought water and rich silt to the river's flood plain. Life in Egypt was controlled by the seasons, and hence by the sun. The moon played no part in the calendar.*

The Egyptian year had 12 months, each of 30 days, plus an extra 5 days at the end of the year. These 5 days were associated with the birthday of the greatest gods of the Egyptian Pantheon and were given over to celebrations. Thus the year was 365 days long. The Egyptians made no attempt to force their calendar to keep step with the actual seasons (as we do by adding leap-days, or a leap-month). Instead, they accepted that the seasons would gradually become later and later w.r.t. the calendar, in a cycle that would take 1460 years to complete. The Egyptian checked the relation of their calendar to the natural year not by observing the equinoxes and solstices but

[21] The two major achievements of Egyptian geometry were the approximation to the area of the circle, and the derivation of the rule for calculating the volume of a truncated pyramid. Some historian claimed that they also found the correct formula for the surface area of a hemisphere.

by the heliacal rising of Sirius, the Dog-star. This was the first sighting each year of Sirius in the morning sky just before sunrise.

ca 2770 BCE Egyptian introduced the *calendar* based on a year of 365 days. The Egyptians recognized that the point on their horizon where the sun rises or sets moves from day to day; in the spring the sunrise and sunset points move north along the horizon until they reach a northern limit at the time when daylight last longest. Then they move south until they arrive at a southern limit when the period of daylight is shortest. By counting the number of sunrises or sunsets from either one of these points until that point is next reached they found the number to be about 365. They noted independently that the Dog star, Sirius, reappeared in the eastern sky just before sunrise after several months of invisibility.

They also discovered that the annual flood of the Nile river came soon after Sirius reappeared; again they counted 365 days between two such consecutive events. So at some point[22] they began using this event to fix their calendar and came to recognize a year of 365 days made up of 12 months, each 30 days long and an extra 5 days added at the end for festivals. But the year length is actually 365 days, 5 hours, 48 minutes and 46 seconds (about a quarter of a day) and so, their calendar slowly drifted into error.

Important observations of the sky were also made by people in other parts of the ancient world, especially in India, China and Mesopotamia. These early observers realized that it was easier to describe the location of a particular object in the night sky if the stars were divided into recognizable groups, called *constellations*.

2750 BCE **Gilgamesh**, legendary king of Uruk, Sumer.

2700–2500 BCE Building of the early big Pyramids[23] during the 3^{rd} and 4^{th} Old Kingdom Dynasties in Egypt.

[22] The Egyptian calendar is known to have accurately matched the seasons with dates in 139 CE. Their calendar gradually went into and out of alignment with the seasons with a period of about 1455 years. Knowing this, astronomers have speculated that the year of 365 days was institutioned at ca 4226 BCE.

[23] The word *Pyramid* appears for the first time in the *Ahmes Papyrus* (ca 1630 BCE) and is believed to have originated either from the Egyptian *piromi* or *pyros* = grain, as in "granary". The Greeks obtained it from the Egyptians.

At the beginning of the 3^{rd} Dynasty, **Imhotep**[24] (ca 2700 BCE) designed for King Djoser the first great stone structure built by man – the Step-Pyramid at Saqqarah [h. 60 m; base: 121×109 m^2]. This was an experiment, using a new architectural form and new building materials and construction technique with dressed stone.

The first smooth-sided Pyramid was built at Meidum at about 2600 BCE [h. 92 m; base: 144×144 m^2; inclination: $51°51'$].

The *Pyramid of Cheops*, the largest and most massive of the Pyramids, stands at Gizah (west bank of the Nile river, outside Cairo). Built by Prince **Hemon**, a son of King Sneferu and cousin to Cheops (Khufu), sometimes during 2600–2500 BCE [originally 146.5 m tall and base of 230.4 m with inclination $51°51'$. Some 2.5 million stones were used for its construction.][25]. According to Herodotos, some 100,000 workers[26] were engaged in the construction at any given time over a period of 30 years.

The great Pyramids were constructed on a common geometrical plan: the perimeter of the four sides, which face exactly to the north, south, east and

---

Because of the pyramidal form of a flame, the word was thought by medieval and Renaissance writers to come from the Greek word pyr for fire (as in "pyrotechnic"). However, the word *prism* is from the Greek *prizein* = to saw, hence something sawed off.

[24] According to **Manetho** (ca 280 BCE). **Imhotep**, architect, engineer, writer, statesman and physician, is honored in medicine as the first physician known by name. He served as *vizier* (prime minister), and after his death was elevated to the status of a god. He was worshiped for his healing powers, the only scientist ever to have become a god. The Greeks identified him with their own god of healing, Asclepius: temples were built to Imhotep, and bronze statuettes of him have been preserved. A statue of him stands today in the Hall of Immortals in the International College of Surgeons in Chicago.

Imhotep is the first figure of a *universal man* to stand out clearly from the mists of antiquity; probably of the caliber of **Archimedes** and **Leonardo da Vinci**, to be produced by nature only once in some 2000 years.

Apart from Manetho's book there is no real history of Imhotep and his royal master Djoser. However, a papyrus of Ptolemaic times relate how the kingdom was afflicted by famine for several years because the Nile failed to rise. Djoser accordingly took counsel with Imehotep, who explained that Khnum, the god of the Cataracts, was wrath. So the king deeded lands for temples to the god, and all was well. This story provides the kernel of the biblical story of Joseph and the seven lean years.

[25] Relative error in the right angle at corners not exceeding 1/27,000.

[26] Replaced every 3 months.

west, has the same ratio to the height as the ratio of the circumference to the radius of a circle, i.e. $2 \times 3\frac{1}{7}$ or 2π. This was *no* coincidence: The symbol of the sun-god Ra was a circle. So, when Ra rose every morning over the land of Egypt, he was greeted by a shining golden image of himself. The squareness and level of the base have an average error that is less than 10^{-4} of a side.

The rays of Sirius (whose rising announced the Egyptian New Year and the flooding of the Nile river), were perpendicular to the south face at transit, and shone down the ventilating shaft into the royal chamber while building was in progress. The Pyramids, built when α-Draconis was the pole-star[27], had interior passages aligned in the direction of that star as it passed the meridian of the Pyramid. Thus, the ancients, believing that the motion of the heavenly bodies held the secret of man's fate, spared no effort to unlock this secret by a systematic study of the heavens.

ca 2679 BCE Chinese astronomers record an observation of a Nova.

ca 2600 BCE Egyptians build the first *stone-paved* highway – a 60 km long road which carried the materials for the pyramids. At about the same time they invented the *wooden saw* to cut granite.

First recorded seagoing voyage. Egyptian sailors travel to Byblos in Phoenicia (today's *Lebanon*) in search of cedarwood.

---

[27] During 4480–2330 BCE the sun rose on the spring equinox in the constellation *Taurus* and during 10,970–8810 BCE in the constellation *Leo*. This led some scholars to speculate that the *Sphinx* (Lion-faced!) was built during the age of Leo. Geological studies of the *Sphinx* (1991) by a team of American geologists from Boston University, headed by **Robert Schoch**, concluded that the Sphinx would seem to date from around 7000 to 5000 BCE, during the Neolithic rainy period. This is a direct challenge to Egyptologists who maintain that the Sphinx was excavated out of solid rock around 2500 BCE at the time of Pharaoh Khafre. It means that social organization and technology needed to create this Sphinx had to exist prior to the 1^{st} Dynasty kingdoms – a revolutionary idea unaccepted by most Egyptologists today.
It is believed that the Gizah-complex pyramids (Khufu, Khafre, Menkaura) were oriented according to the stars, i.e. the three pyramids were apparently deliberately related to each other in a unified geometric design, forming an integral part of the ritual basis behind the Egyptian understanding of death and the afterlife. For example, if a line is drawn linking the center points of the two larger pyramids then the third and smaller pyramid is off set. The three then seem to create a pattern on the ground corresponding to the three stars of *Orion's Belt* in the sky.

ca 2500 BCE Early Minoan civilization in Crete. Indus Valley civilization founded in India.

Egyptian priests began to develop and codify medical practice, including primitive surgical procedures. They gain their understanding of the human body by preparing *mummies*. Papyri from that time tell how to set bones, the pumping function of the heart, the pulse and the prescription of medications and diets. Mummies were in part produced by *saponifying* the flesh of the corpse with *natron* (a mixture of Na_2CO_3, $NaHCO_3$, NaCl and Na_2SO_4). *Chinese* probably developed practice of acupuncture by this time.

2500 BCE Egyptians and Mesopotamians had developed a sophisticated society operating with essential tools: civil engineering, astronomical measurement, water lifting machineries, writing and mathematics, primitive metallurgy, and the *wheel*.

ca 2500 BCE The knowledge of agriculture, of the potter's art, and of the use of copper reached northern China, by way of Central Asia, either from Russian Turkestan or from Persia. Thus the initial (Neolithic) civilization of China came indirectly from the ancient centers in Western Asia – from either the lower Indus lands or from lower Mesopotamia.

From these areas cultural currents equally passed into Europe. Subsequently to this remote phase, however, Chinese civilization seems to have developed in almost complete independence of influence from the West. Europe and China developed along independent lines because of geographical conditions (distance, mountain and desert barriers). Both Europe and China stood at the terminals of a steep-desert belt where rainfall was sufficient for cultivation; hence they were geographically equipped to support relatively dense populations.

ca 2500–2000 BCE Hugh climatic changes in the Aegean, Anatolia, Near and Middle-East, Egypt, North Africa and large parts of Asia. May be linked to the encounter of the *Taurid meteor stream* (including asteroids and active comets) with earth. This is the age of *megalithic constructions* around the world such as the Pyramids of Egypt and the Stonehenge[28] in England.

[28] For further reading, see:

- Hoyle, Fred, *On Stonehenge.* W.H. Freeman, 1977, 157 pp.
- Niel, F., *The Mysteries of Stonehenge.* Avon, 1975, 208 pp.

ca 2500 BCE *The Egyptian sea-expedition to Punt*[29] (in the reign of the *Pharaoh Sahure*) in quest of incenses and cosmetics ingredients.

As the power and luxury of Egypt increased, so did its need for rare, costly and exotic materials. From the mines on the Sinai peninsula Egyptian ships brought turquoise, malachite and copper. From equatorial Africa they brought the incenses frankincense and myrrh, and antimony – an ingredient of rouge, one of the most highly prized cosmetics of the day.

These products became so prodigiously expensive as they traveled slowly up the continent, passing through the hands of one entrepreneur after another, that the Egyptians were eventually impelled to send their own fleets through the Red Sea to the sources of these goods, in order to trade directly with the inhabitants.

ca 2500 BCE The final disappearance of the elephant, giraffe and rhinoceros from Egyptian territory. Elephants continued to exist in Syria and Mesopotamia up to ca 1000 BCE.

ca 2500 BCE Coastal Indians at Chicama (Peru) engaged in agriculture.

ca 2400 BCE Sumerians develop positional notation for numbers with base 60.

ca 2400 BCE *Bitumen*, a form of oil that seeps from the ground, was used in Mesopotamia to make boats watertight. This is reflected in the Biblical story of Noah and the Deluge [*Gen* **6**, 14].

ca 2316 BCE Chinese record an observation of a comet.

ca 2300 BCE The earliest surviving *map* is one inscribed on a baked clay tablet from *Mesopotamia*. It is a map of the city-state *Lagash*.

ca 2300 BCE The observational work of the Chinese resulted in an accurate calendar in which the year was $365\frac{1}{4}$ days long.

---

[29] The Land of Punt, "The Sacred". Various locations have been suggested: Perhaps on the borders of Somalia and Ethiopia; could be identical with the Biblical *Ophir* (*I Kings* **9**, 28; **10**, 11; **22**, 49; *II Chron* **8**, 18; **9**, 10). Equatorial Africa was the source of ebony and other rare woods, ivory, gold and silver. Prized above all were the incenses, *frankincense* and *myrrh*. The latter, a gum resin burned in vast quantities in the temples, and also widely used as an unguent, perfume and embalming agent. The tree which exudes the myrrh resin, *Commiphora myrrha*, grows extensively inland from the port of Zeila.

ca 2200 BCE The custom of *horseback riding* finally diffused to the Middle-East from its origin in the forested uplands between the Dnieper River and the Carpathian Mountains[30].

2180–2130 BCE A Dark Age in the history of ancient Egypt. Earliest known great famine in Upper Egypt, due to drought caused by a severe failure of the annual floods of the Nile. A second famine, less severe, occurred between 2002 and 1991 BCE.

This prolonged drought occurred more or less simultaneously over the entire Eastern Mediterranean and adjacent lands. The dire famine was caused by failure of the rains over the central and eastern African sources of the Nile[31]. The crisis shattered a weakened central government utterly unable to

---

30 *Horseback riding* began at ca 4000 BCE in the Cucuteni-Tripolye culture, which flourished from about 4500 to 3500 BCE in the forested uplands between the Dnieper River and the Carpathian Mountains.

Horseback riding, by bringing distant cultures into contact, seems to have stimulated both trade and war, and provided a possible mechanism for the dispersal of early Indo-European dialects.

An eastward dispersion by the first riders would have encountered only small and scattered human resistance. Dispersal to the west would have been much more complex because it would have encountered the well-established agricultural societies of Copper Age Europe.

Archaeological data and theoretical models of migration tend to support the theory that such movements took place, first to the east, and then to the west, between 3500 and 3000 BCE. In all these developments the horse played a critical role.

It took a very long time for the custom of riding to diffuse southward into the Middle East. When horses finally did appear there around 2200 to 2000 BCE, they were used first as draft animals attached to battle carts, and eventually, to drive the war chariots. It was as a chariot animal that the horse trotted onto the pages of history, two millennia after it had first been broken to the bridle.

31 The volume of water in the Nile depend on the rainfall over Central Africa (*White Nile*) and the summer monsoon rains over East-African Highlands (*Blue Nile*). Thus the most important source of information as to the variations of rainfall in Africa is provided by the levels of the River Nile.

As is well known, the Nile commences in *Lake Victoria*, in Central Africa, and flows to *Lake Albert* as the Victoria Nile. From there it continues as the Bahr-el-Jebel, becoming known as the White Nile after the junction of the Sobat River. At Khartoum it receives the Blue Nile, and near Berber the Atbara River, both of which originate in the mountains of Abyssinia. From the junction of the Blue Nile to the Mediterranean, a distance of 2900 km, it receives no appreciable accession of water. The level of the Nile passes through an extremely regular cope with the problem, decimated the Egyptian people and brought about a general decline in material culture[32].

Outside Egypt, the drought affected civilization throughout the Eastern Mediterranean Basin: it contributed to the destruction of the Akkadian Empire. The second drought (2002–1991 BCE) contributed to the downfall of the Third Dynasty of Ur.

2159 BCE According to accounts of the time, the court astronomers in China, Hi and Ho were beheaded when they failed to predict on eclipse.

2100 BCE Egyptians record star configurations and base upon it a 24-hour day.

---

annual variation; the water is at its lowest in April or May, it rises slowly and irregularly in June and the first half of July, but rapidly and steadily in the latter half of July and the first half of August, remaining high during September and commencing to fall rapidly in October.

[Herodotos tells us: "*When the Nile overflows, the country is converted into a sea, and nothing appears but the cities, which look like islands in the Aegean*".]

The regular annual flood is the source of fertility of Egypt, without it the whole land would be a barren desert, and hence the levels of the flood have been recorded annually, probably for some thousands of years.

The significance of both high and low levels of the Nile is as follows: The *White Nile* drains a large area of equatorial Africa which has a considerable annual rainfall distributed fairly evenly throughout the year; moreover, it passes through two large lakes, Victoria and Albert, which further regulate the flow. Hence the *White Nile*, above its junction with the Sobat River, *discharges an almost constant volume of water throughout the year*.

The *Blue Nile*, the *Atbara*, and the *Sobat River*, on the other hand, originate in Abyssinia, which receives the greater part of its monsoonal rainfall in the summer months. It is these rivers which *supply most of the waters of the annual flood*. For this reason the level of the Nile during the stage of low water reflects the general rainfall of equatorial Africa, while the flood levels represent the monsoon rainfall of the eastern highlands. Since the rainfall in the equatorial belt is associated with *low pressure* (which is very closely connected with the intensity of the *general circulation of the atmosphere*) it shows a closer relation to the rainfall of Europe than the monsoon rainfall in the eastern highland (governing the floods).

32 When a similar situation arose in the middle of the 2^{nd} millennium BCE, it was met by a stronger and more experienced government which succeeded to manage the economy through a sequence of 7 years of abundance and 7 lean years that followed (*Gen* **41**, 29–57).

2000 BCE Babylonian arithmetic evolved into *rhetorical algebra*: quadratic equations are solved and cubic and biquadratic equations were discussed.

ca 2000 BCE *Ziggurates* in Mesopotamia serve as platforms for astronomical observations. The *shaduf*, a device for astronomical observations raising water from one level to another with a bucket, appears in Mesopotamia.

The palace of *Minos in Crete* has light and air shafts and interior bathrooms with their own water supply.

Mesopotamian traders journey as far east as India. Egyptians trade with Nubia, Ethiopia, and Crete.

Mathematics and Astronomy in Mesopotamia[33]

(ca 3200–300 BCE)

"In Babylon, in Babylon
They baked their tablets of the clay;
And year by year, inscribed thereon
The dark eclipses of their day;

They saw the moving finger write
Its 'Mene, Mene', on their sun
A mightier shadow cloaks their light,
And clay is clay in Babylon".

Alfred Noyes (1922)

The Babylonians[34] *played a large part in laying the foundations of our science. From the beginning of the* 2^{nd} *millennium BCE they catalogued and classified with meticulous care everything that came under their observation, and this body of information was passed on to be recognized or revised by the generations following.*

Archaeological excavations of the ruins of the ancient cities of Babylonia during 1840–1940, *revealed a complex civilization which flourished more than* 4000 *years ago in the fertile land watered by the Tigris and Euphrates rivers. It was a civilization characterized by prospering agricultural settlements, crisscrossed by a network of canals, whose purpose was to reclaim swamps and feed parched areas. Numerous individuals were occupied with law, religion, science, art, architecture, trading, teaching and engineering. Large palaces, sculptures, metal bass-reliefs, copper and bronze figures, painted pottery and other artifacts of great antiquity were recovered.*

---

33 The data used in this article was assembled form the groundbreaking works of the Assyriologist **Otto Neugebauer** (1899–1990) [*The Exact Sciences in Antiquity*, Dover 1969] and **B.L. Van der Waerden** (1903–1996) [*Science Awakening*, Kluwer 1988]. We have also consulted the works of the mathematicians **Morris Kline** (1908–1992) [*Mathematical Thought from Ancient to Modern Times*, Oxford Univ. Press 1990] and H.L. Resnikof and R.O. Wells [*Mathematics in Civilization*, Dover 1984].

34 "Babylonian" refers to all cultures of the cuneiform users in Mesopotamia, after the city that was the center of many of the empires that occupied the region between the Tigris and the Euphrates rivers.

Most significant of all the finds, however, were the thousands upon thousands of clay tablets unearthed at Nineveh, Assur, Nippur and other cities, bearing the written records of the economic, juridical, educational and scientific phases of daily life, previously known to us only through Biblical allusions.

Lacking papyrus and having little access to suitable stone, they resorted to clay as a writing medium. The inscription was pressed into a wet clay tablet by stylus. The finished tablet was then baked in an oven or sun-dried to a time-resisting hardness that resulted in a permanent record. The cuneiform writings incised on the tablets include among a whole gamut of subjects, astronomical observations that were used principally for the timing of religious festivals.

Underlying the commercial, monetary and astronomical systems employed by the Babylonians, were their achievements in mathematics, made known to us through the continuing study and decipherment of the cuneiform inscriptions on the ancient tablets.

Their numerical system was a mixed one: numbers below 60 were written in the decimal system, but number above 60 were written according to the sexagesimal system. Thus

$$1\cdot 60^2 + 0\cdot 60 + 1\cdot 60^0 = 101 \quad (sexagesimal),$$

$$= 3\cdot 10^3 + 6\cdot 10^2 + 0\cdot 10^1 + 1\cdot 10^0 = 3601 \quad (decimal).$$

Likewise

$$524,549(decimal) = 2\cdot 60^3 + 25\cdot 60^2 + 42\cdot 60 + 29 = (2\cdot 25\cdot 42\cdot 29).$$

Fractions could also be represented in this system, e.g.

$$\frac{1}{2} = (30)60^{-1} = 0;\ 30$$

$$\frac{1}{8} = (7)60^{-1} + (30)60^{-2} = 0;\ 7,30$$

$$532\frac{3}{4} = (8)60 + (52)60^0 + (45)60^{-1} = 8,52;\ 45$$

$$\frac{1}{64} = (56)60^{-2} + (15)60^{-3} = 0;\ 0,56,15$$

$$1029 = (17)60^1 + (9)60^0 = 17,9.$$

To divide, say, 1029 by 64 the Babylonians evaluated the product $1029\times\frac{1}{64}$. *The answer* $16;4,41,15$ *can be converted to the decimal base*

$$16 + 4(60)^{-1} + (41)60^{-2} + (15)60^{-3} = 16.078125.$$

As used by the early Babylonians, the sexagesimal number system lacked two basic features of our modern decimal system: there was no zero and there was no "sexagesimal point". The resulting ambiguity (on existing clay tablets) due to the lack of the zero can often be resolved only by a careful study of the context. After 300 BCE a special symbol was introduced to denote the unfilled position. However, the lack of the sexagesimal point did not impede their computational ability, and this is why their astronomy and algebra were far superior to that of their Egyptian contemporaries.

Most of the mathematical tablets have been classified either as 'table texts' or as 'problem texts'. The latter appear in many cases to have been school texts illustrating rules for the solution of problems. The table texts were ever-present aids both for instructional problems and for practical use. They include tables of reciprocals, squares, square roots, cubes, cube roots *and multiplication tables. With these tables at their disposal for the numerical calculations involved, the Babylonians developed many ingenious rules and methods for the solution of a wide variety of mathematical problems. These tablets are cogent evidence of a high degree of skill and originality on the part of the Babylonian mathematicians.*

Their tablets reveal that they knew the Pythagorean theorem *more than a thousand years before the Greeks. Indeed, the Pythagorean triplet*

$$(3456)^2 + (3367)^2 = (4825)^2$$

was incised on Plimpton 322 (1500–1600 BCE). This example leads us to believe that they were familiar with the general solution *of $a^2 + b^2 = c^2$ in integers:*

$$a = 2pq, \quad b = p^2 - q^2, \quad c = p^2 + q^2$$

for which the above triplet is obtained with $p = 64, \quad q = 27$. They also prepared numerical tables for c^n with

$$n = 1, 2 \;...\; 10, \qquad c = 9, 16, 10, 225.$$

The Babylonians could solve linear and nonlinear equations with one unknown [e.g. $ax = b, \;\; x^2 = a, \;\; x^2 \pm ax = b, \;\; x^3 = a, \;\; x^2(x+1) = a$], and systems of equations with 2 unknowns such as

$$x \pm y = a, \quad xy = b;$$

$$x \pm y = a, \quad x^2 + y^2 = b.$$

Furthermore, the following formulae were known to them by 300 BCE:

$$(a+b)^2 = a^2 + 2ab + b^2,$$
$$(a+b)(a-b) = a^2 - b^2,$$
$$1 + 2 + 4 + \cdots + 2^{n-1} = 2^n - 1,$$
$$1^2 + 2^2 + 3^2 + \cdots + n^2 = \frac{1}{3}(1+2n)(1+2+3+\cdots+n).$$

The Babylonians were able to solve different types of quadratic equations, e.g. (in today's notation)

$$x^2 + bx = c, \quad b > 0, \quad c > 0 \quad \therefore \quad x = \sqrt{\left(\frac{b}{2}\right)^2 + c} - \frac{b}{2},$$

$$x^2 - bx = c, \ b > 0, \ c > 0 \quad \therefore \quad x = \sqrt{\left(\frac{b}{2}\right)^2 + c} + \frac{b}{2}.$$

To handle the more general case $ax^2 - bx = c$, *they multiplied throughout by* a *to get* $(ax)^2 - b(ax) = ac$ *and then substituted* $y = ax,\ e = ac$ *to obtain their standard form* $y^2 - by = e, \quad e > 0$. *They also solved higher order equations such as* $ax^4 - bx^2 = c$ *and* $ax^8 - bx^4 = c$ *by treating them as if they were 'hidden' quadratics in* x^2 *and* x^4, *respectively.*

Babylonian handled cubic equation of the form $x^3 = c$ *with the help of cube root tables, and equations of the form* $x^2(x+1) = c$ *with help of* $(n^3 + n^2)$ *tables. There are even a few examples in Babylonian algebra of the solution of a set of equations in three unknowns*

$$x^2 + y^2 + z^2 = 1400, \quad x - y = 10, \quad y - z = 10 \qquad (x, y, z) = (30, 20, 10).$$

Babylonian geometry is intimately related to practical mensuration, though their geometry was chiefly of algebraic character.

They were familiar with proportionalities arising from parallel lines, the Theorem of Pythagoras, the area of a triangle and of a trapezoid, volumes of a prism and of a cylinder. They used the poor approximations $3r^2$, $6r$ *for the respective area and perimeter of a circle of radius* r, *and wrong formulae for volumes of cone and pyramid frustums.*

Of special interest is the value that the Babylonians have assigned to $\sqrt{2}$ *in their sexagesimal system, that is equivalent to* 1.414 213 562, *to 10 decimal* *figures. This again, could not have been achieved without the availability of some algorithm, probably the same one known to the Greeks*[35].

The Babylonians could also calculate areas of triangles and quadrilaterals and volumes of prismatically-shaped canals. Finally, the Babylonians knew the laws of similarity of triangles and the ensuing rules of proportion, ergo – they knew the fundamentals of trigonometry.

In ancient times, astronomy was the sole means of regulating the calendar and thereby determining the proper time for annual agricultural activities such as crop planting and land irrigation. In addition, stars and other celestial bodies were worshiped as gods, and the study of their motion formed

---

[35] Babylonians gave approximations to square roots of nonsquare numbers such as $\frac{17}{12}$ for $\sqrt{2}$ and $\frac{17}{24}$ for $\frac{1}{\sqrt{2}}$. Apparently they were aware of the approximation formula

$$a + \frac{h}{2a+1} < \sqrt{a^2+h} < a + \frac{h}{2a}, \qquad 0 < h < a$$

(used later by Archimedes for his calculation of π). Historians of mathematics now believe that the Babylonians had an *algorithm* through which they could extract square roots accurate to 10 decimal digits. Take 27, for instance. Since $5^2 = 25 < 27$ and $6^2 = 36 > 27$, it is expected that $\sqrt{27}$ will lie somewhere between 5 and 6. They then noticed that since $5 < \sqrt{27}$, $\frac{27}{5}$ must be *greater* then $\sqrt{27}$. They then guessed that a better approximation to $\sqrt{27}$ than either 5 or $\frac{27}{5}$ would be the average

$$\sqrt{27} \approx \frac{1}{2}\left(5 + \frac{27}{5}\right) = 5.2,$$

which yields $5.2 \times 5.2 = 27.04$. This process can now be repeated, with the next step giving

$$\sqrt{27} = \frac{1}{2}\left[5.2 + \frac{27}{5.2}\right] = 5.19615,$$

where now $(5.19615)^2 = 26.99997$. Thus, two application of their method yields a result of better than six-figure accuracy.

With a method as powerful as this, the Babylonians had no fear of square roots. Nowadays, digital computers use this iterative process (Hero's algorithm) $y_{n+1} = \frac{1}{2}\left(y_n + \frac{x}{y_n}\right)$ for a successive approximation of the solution $y = \sqrt{x}$ of $y^2 - x = 0$. The Babylonians could have arrived at the same result through the following reasoning: Let the positive number a_1 be a guess that is too small, $a_1 < \sqrt{x}$. It then follows that $a_1\sqrt{x} < x$ and consequently $a_1 < \sqrt{x} < \frac{x}{a_1}$. The *mean* of these estimates, namely $a_2 = \frac{1}{2}\left(a_1 + \frac{x}{a_1}\right)$ can be shown to be closer to $\sqrt{x}$ than either a_1 or $\frac{x}{a_1}$. Therefore, a_2 can be taken as a *new* estimate of $\sqrt{x}$. With $a_1 = 1$, the process has to be repeated just 4 times in the sexagesimal system to obtain the value for $\sqrt{2}$ found in the Babylonian texts!

part of the religious duties owed them. In this sense astronomy was initially a technical branch of religion that served as one of several channels of communication between the priestly hierarchy and the god they served. Therefore, the astronomical study of these deified objects was virtually identical with the study and prediction of their paths of motion through the heavens. Astronomy was therefore exclusively mathematical, and mathematics thereby became the servant of religion which in return fostered its development and ensured its prestige for thousands of years.

The practical component of religion which applied the achievements of mathematical astronomy to the welfare of mankind was astrology, the ancient art of divining the fate of human beings from the configurations and motions of the planets and stars.

Already in 3200 BCE Sumerian priests made astronomical observations on watch towers and prepared maps and time tables of star-motions.

In 3000 BCE, astrology was already well developed in Babylonia. It was founded on the Babylonian's identification of personal deities with the planets[36] *Mercury (Nebo), Venus (Ishtar), Mars (Nergal), Jupiter (Marduk), Saturn (Ninib), as well as moon (Sin) and the sun (Shamash). The movements of these heavenly bodies, were regarded as representing the activity of the corresponding gods. If one could correctly 'read' the heavenly motion of these divinities, one would know what they were aiming to bring about on earth.*

Their astrology was based on the fundamental assumption that all events on earth are influenced by the stars. In particular we can trace back to them, by way of the Hebrews, the origin of our present seven-day week associated with the Sun, Moon and the five planets[37] *Mars, Mercury, Jupiter, Venus,*

---

[36] Before the regular movement of *planets* about the sun was known, they seemed to the ancients as stars wandering the heavens. Hence the name (Greek) *planan*, to wander. Latin used *planetae* to mean wandering stars.

We know today that to be called a planet, an object must have a mass less than about $\frac{1}{10}$ of its sun.

[37] If at that time there had been any knowledge of the planets *Uranus*, *Neptune* and *Pluto*, discovered in 1781, 1846 and 1930 respectively, our week might today consist of 10 days instead of seven!

The planetary week presents a strange combination of ideas from different cultures. From Babylon came the doctrine of the influence of the stars on man's destiny, from the Alexandrian Greeks came the mathematical astronomy that placed the planets in a certain order of distance from the earth, and then on these foundations the late Hellenistic astrologers, who were familiar with the ancient cult of the magical number seven, constructed a purely Pagan week. By the *and Saturn that they discovered. Indeed, the separation of these planets from the so-called 'fixed stars', was one of their greatest achievements. Many believe that the week had its origin in the above seven "stars" visible to the naked eye which traverse the celestial zodiac. (Of these seven, only the sun, of course, is actually a* star *in the modern scientific meaning of the word.)*

The motion of the bodies in the solar system is viewed against the background of the fixed stars. From the earliest times the various star formations were identified with familiar creatures and objects whose forms appeared to be similar to the patterns traced by the stars. Of principal importance were those constellations that lie, when viewed from earth, behind the path of motion of the planets, moon and sun. Since all these bodies move in nearly the same plane – the plane of the ecliptic[38] *– their motion against the background of the stars appears to take place in a relatively narrow band. This imaginary zone of the heavens, bounded by two circles equidistant from the ecliptic plane and separated by about 18°, is the* zodiac[39]*. The zodiac is partitioned into 12* equal signs[40] *each comprising 30° in the ecliptic plane. Each sign*

---

end of the third century CE, the Christians, who had previously adhered to the Jewish seven-day week in which the days simply had numbers and not names, began to be influenced by the astrological beliefs of converts from Paganism and changed over to the planetary week. The stars were no longer regarded as deities but as demons capable of affecting the fate of man. At the same time, the oriental worship of the Sun-god Mithra was extremely influential in the Roman world. This led to the substitution by pagans of the *dies Solis* (the Sun-day) for the *dies Saturnis* (the Saturn-day) as the first day of the week. This change appealed to the Christians, who had long observed Sunday as the first day of the week. All the names of the days can be traced back to the Roman (or equivalent Norse) planetary gods: Monday (Moon = Luna); Tuesday (Tiw = Mars, god of war); Wednesday (Odin = Mercury); Thursday (Thor = Jupiter, god of thunder); Friday (Frigga = Venus); Saturday (Saturn); Sunday (Sun).

In 1901, the following inscription was found scratched on the wall of a dining-room in Pompei (79 CE): SATVRNI, SOLIS, LVNAE, MARTIS, IOVIS, VENERIS. This gives the days of the week in the order still adopted at the present time, with the omission of Wednesday, which is no doubt an accidental error.

[38] Ecliptic – the sun's apparent path in the heavens, so-called because eclipses can occur only when the moon crosses it.

[39] From the Greek *zoon* = a living thing.

[40] The *duodecimal* system, based on 12, allows thirds, quarters and sixths to be expressed very simply, in contradistinction to the decimal system where a third cannot be represented exactly, but only as a repeating decimal fraction. It is no coincidence that we have 12 hours of day, 12 hours of night, 12 months in the

is associated with a constellation that lies in the zodiacal band from which the sign draws its name. These signs are: Capricorn (Goat), Saggitarius (Archer), Scorpio (Scorpion), Libra (Balance), Virgo (Virgin), Leo (Lion), Cancer (Crab), Gemini (Twins), Taurus (Bull), Aries (Ram), Pisces (Fish), Aquarius (Water bearer).

No one could deny that the Babylonians were the fathers of astronomy. The little rainfall in Mesopotamia and its clear unpolluted sky enabled almost continual watch of the motion of the planets by the naked eye over many centuries on end[41]*. Their astronomers noted every single phenomenon with such great care that they were able to notice even the changes caused by the precession of the equinoxes*[42]*. Eclipses of the sun, moon, and stars were so carefully described that part of the ancient chronology has now been unambiguously determined by just such occurrences.*
In fact, the basis for predicting eclipses, which rests on a period of 6585 *days (known as the Saros*[43]*), was discovered by the Babylonians.*

Through their continuing astronomical observations, the Babylonians knew that the apparent slow rotation of the heavens (due to the precession of the earth's axis), gave rise to an equally slow change in the position at which the sun appears to rise each year on the vernal equinox relative to the

---

year and 12 tribes of Israel. Also, the 12 signs of the zodiac divide into 4 groups of signs associated with fire, air, earth and water respectively. It is as easy to test a number for divisibility by 2, 3, 4, 6, 8, 12, 16, 24 in base 12 as it is to test for divisibility in base 10 by 2, 5, 10, 20 etc. These were important advantages when calculation itself was a subtle art and difficult to learn.

The sexagesimal system, based on 60, has been used for scientific calculations. Because $60 = 5 \times 12 = 6 \times 10$ it has the advantages of bases 10 and 12 combined. In 1944, *the Duodecimal Society* was established in New York State as a voluntary non-profit organization. Its aims were "to conduct research and education of the public in mathematical science, with particular relation to the use of *base twelve* in numeration, mathematics, weights and measures, and other branches of pure and applied science". This society proposed to add the letter X to represent 10 and E to represent 11.

41 It is an extraordinary fact that modern astronomers have not yet been able to accumulate a series of astronomical observations as long as the Babylonians'. The longest known series of modern observations – those at Greenwich – was begun in 1750.

42 Although it has not been established that the Babylonian astronomers were aware of precession as a regular phenomenon.

43 After the lapse of this period, eclipses of the sun and the moon recur under almost identical circumstances except that they are displaced about 120° westward on the earth.

zodiacal constellations. This phenomenon, the precession of the equinoxes[44], *was viewed as responsible for the catastrophic fall and subsequent rise of successive "ages" of the world. When the vernal equinoctial sun passed from one zodiacal constellation to the next, an Age ended and a new one began. At this time, (so they believed) violent and cataclysmic events are to be expected as the transcendental power guiding our world passes from one constellation to the next.*

In the period before 4000 *BCE the sun rose in Gemini, during* 4000–1800 *BCE it remained in Taurus, then in Aries (*1800 *BCE*–400 *CE). It will remain in Pisces until* 2740 *and then move into Aquarius*[45].

[44] The proximate reason for it and the estimate of nearly 26,000 years for this great rotation of the heavens was first given by the Greek astronomer **Hipparchos of Nicaea** (180–135 BCE). The *physical mechanism* that actually causes this precession is due to *tidal torques* applied upon the earth's equatorial bulge by the solar and lunar gravitational fields. This insight, along with a theoretical explanation of the 26,000 year period, had to await modern science and the age of Newton.

[45] The image of the Bull (Taurus) is repeated in ancient myths and religions, from the Bull worship of Apis-Osiris in Egypt and Zeus the Bull carrying off Europe, to Hercules' defeat of the Cretan bull and Jason's triumphal capture of the Golden (ram's) Fleece. The Hebrew calendar starts at 3760 BCE, the year of the world's creation according to the Hebrew tradition. This date was moved by James Ussher (1650) to the transition zone between the ages of Taurus and Gemini.

The Scribes

The difficulty of writing on clay necessitated a long period of schooling. The regular schools were attached to the temples and were therefore at some distance from one another. However, scribes who could be depended upon to teach were scattered everywhere, even in the small towns. Just as in the Middle Ages an expert craftsman would take under his protection some young boy as an apprentice to whom he taught his trade, so most of the scribes had some youths who were ambitious to enter the profession. The scribe "adopted" his apprentice as his own son, and the relationship lasted until the young man was able to enter the profession as a regular member. Such private tutoring would be quite sufficient to prepare scribes for a business life. But only schools that were located in the vicinity of great temples had facilities for the study of the sciences and literature, and prepare one to become a priest or a 'scientist' (kings usually kept scribes at court to copy manuscripts and write official letters).

Besides taking dictation, all students in the temple schools had a certain amount of arithmetic (the four operations). It was follows by instruction in the higher branches qualifying for the different professions.

In addition to temple libraries, used mainly for instruction, kings kept their own royal libraries. We see them sending their own scribes throughout the land for the purpose of collecting all the important works gathered in the temples. Thus, Assyrian kings collected clay tablets in huge libraries.

The library of Ashurbanipal (reigned 668–627 BCE), discovered at Nineveh *in* 1864*, contained tablets dealing with religion, literature, medicine, history and other subjects. Indeed, these kings did more than merely collect, index and recopy the material found in ancient libraries. After their scribes had copied texts written in the Sumerian language, they* retranslated *this whole mass of material into the vernacular and adopted it to the needs of the time. It must have required an immense amount of time and a great number of learned scholars to bring this work to completion.*

The royal courts at this time must have been centers of culture as notable as those of the patrons of science during the Renaissance. Notwithstanding their great array of learning, the translators *must have had trouble of interpreting the old texts, for the language had been dead more than a thousand years. It is an achievement of modern science that we can now correct some of the translations made in those days. Moreover, scholars put in possession of such a large number of bilingual texts could immediately tackle the decipherment of Sumerian.*

2nd Millennium BCE Renewed predominance of warm summers in temperature latitudes. Drier climate; fair sailing weather around the coasts of Europe even in latitudes $50^\circ - 65^\circ N$, making possible the trading exploits of the Bronze Age people and later the Phoenicians.

Ships underwent improvement and *sea battles* took place toward the end of the millennium.

Glass bottles appeared in Egypt. Chinese bronze urns and vases appeared under the Shang dynasty. The earliest form of *steel* appeared in Asia Minor under the rule of the Hittites.

Water-clocks were invented in Egypt in about 1400 BCE. Around 1200 BCE, the know-how of Hittite iron-smiths (scattered with the destruction of the Hittite empire, and kept secret by them for hundreds of years) began to diffuse into Eastern Europe. By 1100 BCE this lore was absorbed by the Assyrian iron-smiths who developed a technology for mass production of iron tools, especially *iron blades*. The subsequent production of effective swords, axes and *iron plowshares* led to greater crop yields and boosted the Assyrian military potential.

Early *food technology*, including the preservation of fish by drying was developed by the Phoenicians and the Greeks around 1100 BCE.

2000–1650 BCE *The Cretan Age*. The peak of the Aegean civilization centered on the island of Crete.

The Hittites[46] (ca 1900–700 BCE)

There have been many vast movements of populations across and within Asia Minor. Numerous invasions from East, West and North, made its territory the scene of incessant conflicts, and the blending place of diverse cultures, races, and religions. Arian, Mongolian and Semitic masses were either attracted to Asia Minor by its wealth or driven there by the pressure of stronger hordes behind.

During 12 centuries the history of Asia Minor was practically the history of the rise and decline of the powerful Hittites. They left their impressive monuments from Smyrna to the Euphrates and from Boghaz-Keui to Aleppo. For centuries they contended on equality with the powers of the Nile and the Euphrates, and for a thousand years Asia Minor under their leadership held the balance of power in antiquity. They saved Asia Minor from being completely Asiaticized so that as a result its history has throughout been bound up with that of Europe as much as with Asia. They carried oriental (especially Mesopotamian) culture, technology and art Westward. They overthrew the Amorite empire of Babylon; they annihilated the Egyptian power in Asia; they held the dreaded Assyrians in check far centuries; they exercised an important economic influence by their control of the rich mineral resources of Asia Minor.

In the 15th century BCE they engaged the attention of the Pharaohs in several military expeditions. In the 14th century BCE they attained the zenith of their power in an empire of federated states under their leadership. For two centuries they were the dominant power in West Asia.

However, these exhaustive wars led to the eclipse of the Hittite Empire: by the 9th century, a renewed pressure of the Phrygians and the renewal of the struggle with Assyria rendered the decline of the Hittites irrevocable: they vanished, scattered by wakes of migrations from Europe.

---

[46] The Hittites mentioned in the Old Testament were probably an offshoot or remnant of the Anatolian Hittites who became separated from the main body and had remained in ancient Israel. **Abimelech** (*Sam I*, **26**, 6) and **Uriah** (*Sam II*, **11**) belonged to these Israeli Hittites, and **Ezekiel 16**; 3, 45 is to be explained in the same way. The origin of the Hittites is obscure, but their kingdom was mentioned already in 1900 BCE by a colony of merchants in Capadocia (on the Anatolian plateau) who meticulously recorded their business transactions in cuneiform writings on clay tablets. The Hittites language, found on clay tablets, was deciphered only in the 1960's.

The Hittites were possibly the first people to make iron *of superior quality. Other kingdoms came to the Hittites as supplicants of their proficiency in iron making (ca 1300 BCE). Nevertheless, the use of iron in the old world was on a very small and restricted scale until after the downfall of the Hittite Empire, as their metal craftsmen dispersed throughout the Middle East. Consequently, metal-smiths began to make technical discoveries that led to the transformation of iron, from a metal inferior to bronze, to one which was destined to become a universal replacement for it.*

ca 1800 BCE Ecological collapse of the *irrigation system* in southern Mesopotamia due to salinization of cultivated soils: food supply to the growing population of the city-states was hampered gradually, leading eventually to malnutrition, epidemics and mass-migration. This man-made ecological disaster was probably one of the major factors in the demise of the Sumerian civilization.

ca 1800 BCE The *Hebrews* conceive the idea of *monotheism*: evolutionary universe of *one* origin, *one* and only *one* supreme cause.

ca 1765 BCE Severe prolonged drought in China.

ca 1750 BCE Invention the *war-chariot* in China; Due to its *shaft* and *balance-point*, the new chariot gained speed and mobility, thus increasing its military power. This new weapon revolutionized the art of war with an effect similar to the appearance of the tank and war-plane in Europe in the first half of the 20^{th} century. From China, the war-chariot arrived in the 'Fertile Crescent' to become a decisive weapon in the armies of Egypt and Mesopotamia.

ca 1750–1650 BCE Age of the Biblical Patriarchs and Matriarchs: Abraham and Sarah, Isaac and Rebecca, Jacob, Leah and Rachel.

ca 1700 BCE A form of printing with movable type was invented by an unnamed printer of ancient Crete in the Minoan age: a single baked-clay disk 15 cm in diameter was found buried deep in the ruins of a palace at Phaistos on Crete; the disk is covered on both sides with spiraling arrays of 241 symbols constituting 45 different syllabic signs. A decipherment identified the signs' language as an ancient form of Greek that predates even Homer. The symbols were printed by a set of punches, one for each of the 45 signs (and *not* scratched into the clay by hand, as was true of most ancient writing on clay). The Minoan printing, however, died out because it was syllabary rather than alphabetic and therefore clumsy and ambiguous; it could be read by few people and used for only very particular kind of texts, perhaps only tax lists and royal propaganda. To make if efficient would have required technological advances that did not occur until later, like the creation of paper, an alphabet, improved ink, metals and presses.

ca 1700 BCE The neolithic astronomical analog computer that is *Stonehenge*, was completed[47]. It was built from stones weighing as much as 35 tons each, to keep track of the progress of lunar eclipses. The position of a stone marked the day of the summer solstice when the sun rises farthest north along the eastern boundary of the horizon. In contradistinction to the sidereal or Pyramid year, the Stonehenge year was solar, and corresponds to what is now called the *tropical year*. Because of the *Precession of the Equinoxes*, the average solar year is not exactly the same as the sidereal year.

By the time Stonehenge was erected, stoneage people had observed the sky for more than 10,000 years. No doubt they recognized the constellations and the paths of the sun and the moon. If the religion of these people was concerned with the worship of the sun and the moon as divinities, eclipses would be events of great importance. Successful predictions ahead of time would confer power and prestige to those who understood how the predictions might be made. Perhaps this is why paleolithic people dragged 35 ton stones over 300 km to erect this mysterious monument.

The people who built Stonehenge are known today as the *Beaker People*; their remains have been found all over Europe and the British Isles. The earliest remains from north-west France date from 5500 BCE. They left thousands of stones in shapes of lines, circles, spirals and ovals covering the Atlantic coast of Brittany and most of Britain and Ireland. Most of the stones are large, some gigantic ranging up to 300 tons or more (*megaliths*). Stonehenge differs from the stone alignments and circles because it has stones placed on top of two supports to form 3-stone arches called *trilithons*. I was discovered in 1974 that the axis of the trilithons points to the first rays of the midsummer sun in 2045 BCE!

ca 1630 BCE The first phase of the decline and eventual demise of the Minoan civilization due to the paroxysmal eruption of the Thera volcano

[47] Construction began at ca 2500 BCE.

(Santorini)[48], which lies some 100 km north of Crete. It may have been the site of Plato's Atlantis as told in the 'Critias'. This, in turn, is based on documents passed on to Solon by priests in Egypt on his visit there ca 500 BCE.

This natural disaster changed the whole course of civilization in the Eastern Mediterranean. The Minoan language and culture and the power of Crete, which was dominant until then, thereafter gave way to Mycanean civilization of the Greek mainland.

ca 1630 BCE **Ahmes** (ca 1680–1620 BCE, Egypt). A scribe who wrote the *Rhind*[49] *Papyrus*. Ahmes claims not to be the author of the work, but only a scribe. He says that the material comes from an earlier work of about

---

[48] The Greek archaeologist **Spyridon Nikolaou Marinatos** (1900–1974) excavated (1967) an ancient port city on the Island of Thera. Under the pumice he brought to light a settlement which had close links the Minoan culture. His findings place Thera alongside with Mycenae and Knossos for our understanding of the prehistoric people of the Aegean.

The severe drought in Egypt, managed by Joseph (*Gen* **41**, 29-57) may be linked to the aftereffects of the Thera event. Some historians and Biblical scholars link the Thera event to the '*plagues of Egypt*' and the *Exodus* of the Hebrews (led by Moses), which they place at ca 1500 BCE during the reign of Ahmose I (18^{th} dynasty). Biblical allusions can be found in *Exodus* **10**, 21–22; **13**, 21; *Psalm* **46**, 1–8; *Jeremiah* **47**, 2–4.

According to archaeological dating, the Thera explosion ($36.25°N$ $25.25°E$) occurred sometime between 1450–1500 BCE, whereas dendrochronology and radiocarbon dating support the earlier time window 1600–1650 BCE for the eruption. On account of its great intensity (VEI=6), the effects of Thera could have affected the Nile delta at a distance of almost 1000 km. Plume height could have reached 36 km and the displacement volume is estimated at 30 km^3, forming a caldera of 480 m deep and with an overall area of 83 km^2.

After the Thera explosion came a great displacement of the surviving population in search of arable land. Their exodus took them to Greece, Italy, Sicily, North Africa, Egypt and the Levant. A remnant of this 'diaspora' settled on the southern coastal strip of the Mediterranean and were known as the Philistines. The Hebrew prophet **Amos** (fl. 765–750 BCE) refers to this remote migration (*Amos* **9**, 5–7) and links the event with a description of volcanism and inundations (tsunami).

[49] **Alexander Henry Rhind** (1833–1863, Scotland). Egyptologist, went to Thebes for health reasons. He then became interested in excavating and purchased the papyrus in Egypt (1858), donating it later to the British Museum (1863). He died of tuberculosis in the same year.

The papyrus was published in 1927. It is about 6 m long and about 30 cm wide.

2000 BCE. The papyrus is one of our chief sources of information on Egyptian mathematics; it contains 87 problems of the four operations, solution of equations, progressions, volume of granaries and more. Nothing is known of Ahmes except for his own comments in the papyrus.

Some of the problems that appear in the Rhind did not apply to the real life in Egypt. This shows a genuine interest in mathematic for mathematics sake, characteristic of a society made of mathematics oriented minds.

ca 1600 BCE **Hammurabi** promulgated his famous code in Babylonia. It includes regulations on medical fees and penalties for malpractice.

ca 1600 BCE A primitive form of the *Greek language* was inscribed on fire-baked clay tablets found at *Pylos*, on mainland Greece, and at *Knossos*, on Crete. No other European language comes close to claiming such longevity.

1600–1550 BCE Unknown Egyptian physicians completed the oldest known medical document: *Smith Papyrus* contains 48 clinical descriptions of surgical cases, including injuries to head, spine, and chest.

Egyptian physicians wrote *Ebers Papyrus*: encyclopedic work that lists remedies for many diseases, including deformative arthritis, and conjunctivitis.

1600–1100 BCE *The Mycenaean Age*: As the fleets of Egypt and Crete pushed their commerce with the mainland of Greece, they naturally entered the southern bays, and especially the Gulf of Argos. Here, in the plain of Argos, behind the sheltered harbor, the Cretan nobles, migrating to the mainland, established their settlements.

1500 BCE The Egyptians invented the well-sweep with counterpoise (shadoof)[50] for irrigating the fields. Introduced later into Assyria.

ca 1500 BCE The first vessels entirely of *glass* were made in Egypt and Mesopotamia. Oldest *sundial*.

---

[50] Usually made by erecting two pillars, some 2 m high, joined near the top by a short beam. Over this, a long pole is balanced, which has at one end a vessel to hold water and at the other end a counterpoise. A man standing at the water edge fills the receptable by dipping, raises it, and empties it into an irrigation channel. With this device, a man can raise about 2400 liter to a height of 2 m in a day.

ca 1500 BCE Appearance of *gold ingots* in Egypt. Their *weight* was certified by the government of the kingdom and represented the maximum exchange values[51].

1500–1100 BCE Origins of the oldest *phonetic alphabet* in the Sinai peninsula[52]. The Semites who lived in the Land of Israel developed from it an alphabet writing. They used signs to show the consonants of syllables, just as the Egyptian did, and invented their own set of characters to stand for consonants in their language. No direct links with the Egyptian writing were found.

Egyptian voyagers, at behest of Queen Hatshepsut (d. 1481 BCE), journeyed down Red Sea to Punt (probably present-day Somaliland) in search of myrrh-trees.

1479 BCE *Battle of Megiddo*, the first major battle in history. Thutmosis III conquers the Land of Israel, Phoenicia and Syria.

1375 BCE, May 03 Literary evidence from Ras Shamra Ugaritic Tablets of a total eclipse of the sun observed in Ugarit city-state. This may be the earliest record of a solar eclipse that we posses.

ca 1350 BCE Emergence of a system of mathematical notation in China (Shang dynasty) which used nine numerals and the place-value principle. This was about a 1000 years before the Hindu number system, and was the earliest instance of the use of the place-value principle, after Babylon.

1350 BCE Multiplication tables appeared in Mesopotamia. (Its development lasted some 400 years.) Decimal numerals were used in China.

ca 1350 BCE Great emigration from Arabia due to extended drought.

---

[51] Material *symbols* of goods exchanged in transactions between individuals or from an individual to a group, have existed since very early in prehistory. They are attested by the bronze and iron *arrowheads* which the inhabitants of Gaul used for this purpose 5000 years BCE. It was called *obeliskos*. Other forms of non-metallic money were found in Africa, Oceania and South America (e.g. feathers and beaks of birds, shells, etc.).

[52] According to *Hebrew* tradition [as revealed in the book of **Ex.**: *16*, 14; *24*, 4; *32*, 15–16; *34*, 28, and the book of **Deut.**: *10*, 4; *27*, 3; *31*, 9, 22, 34], the protosinaic version of the Hebrew alphabet was invented by **Moses** in Sinai. The phonetic alphabet was based on symbols for sounds, not things or syllables and is the ancestor of all modern Western alphabets.

ca 1300 BCE Great eruption of Bronze age people from the Hungarian plain due to floods.

1286 BCE The Hittite under **Muwatallish** defeated Egypt under Rameses II in the decisive battle of *Kadesh* on the Orontes. The following peace treaty (1271 BCE) determined the final borders of the Land of Israel (*Num.* **34**, 1–12).

ca 1240 BCE Egyptians under Rameses II (1301–1235) dug a proto-Suez canal from Lake Timsah (the Nile) to the Red Sea.

The first canal at Suez to link the Mediterranean and the Red Sea may be a case in which climate played a part; it was done approximately when the world sea-level[53] reached its highest post-glacial stand, and the project may therefore have suggested itself just because it then, for the first time, looked feasible. It is believed to be during the reign of **Sestoris I** (ca 1980 BCE) that a fresh water canal was dug from the Nile delta to the Red Sea near where Suez now stands. The fact that **Rameses II** was able to build his canal (or perhaps put the earlier canal in order again), fits the concept of sea-level being specially high in the latter end of the very long warm epoch.

The canal fell into decay and was restored for the first time by Pharaoh **Necho II** (ca 600 BCE), and completed a century later by the Persian conqueror **Darius**. It was reopened around 100 BCE by the Roman emperor Trajan, and again for the last time in 7^{th} century CE. A century later it was finally abandoned after being blocked for military reasons.

ca 1230 BCE *Exodus* of the Hebrews from Egypt under the leadership of Moses (Hebrew: **Moshe**). According to biblical tradition Moses gave the Israeli nation a written code of law[54] that spelled out the new relationship of man to man, man to state, and man to God.

The laws of the Torah (the five books of Moses) regarding man's relation to man constitute mankind's first "*bill of rights*". These laws boldly assert that man's freedom is his supreme right. He has the right to personal liberty,

---

[53] The rise of the sea-level, proceeded over some thousands of years at a rate of 1 *meter per century*. It continued until about 2000 BCE.
The account of the exodus of the Israelites from ancient Egypt (ca 1230 BCE; *Exodus* **13**, 17–**14**, 31) indicates that the isthmus of Suez was narrowed at that time by an area penetrated by a tongue of the Red Sea, in which the sand of the desert was awash, sometimes as tidal shallows but sometimes rather more deeply.

[54] The Greeks had no written laws until the time of **Lycurgos** (ca 700 BCE). A written judicial code was totally unknown to the Egyptians until 300 BCE.

free speech, and private property. Charges against him must be made in open court where he has a right to defend himself. The Torah recognizes no class distinction before the law. Slaves in ancient Israel were treated more humanely than slaves in the United States in 1800 CE. Slave-trading, as practiced by Christians until the 19^{th} century CE was unthinkable to the Jews a millennium before Jesus.

Although the Mosaic laws pertaining to man's relations to man and man's relations to the state provided the Hebrews with a workable framework to govern themselves, it was the ideas in the Torah pertaining to man's relations to God which assisted the Hebrews most in carrying out their mission; by making God spiritual instead of material, they were free to speculate of the nature of God himself. This permitted them to attain a higher concept of deity than was possible for the Pagan Greeks.

In the history of all other people, first comes the state, and then comes the law; this held true for the Babylonians, the Greeks and the Romans. With the Jews – first came the Torah, the law to shape the future state, and 200 years later came the state. This Mosaic Magna Carta saved the Jews from straying into detours and oblivion, and prepared them for their special destiny in the history of mankind.

ca 1220 BCE **Bezalel ben Uri**. Master craftsman and chief artificer of the Sanctuary tent and its furnishings. Constructed and built the *tabernacle*, *ark*, *altars*, and the *ephod* [*Ex* **31–39**, I *Chron* **2**, 20, II *Chron* **1**, 5]. His *brasen altar* survived onto the days of King Solomon[55] (ca 950 BCE).

1201–1198 BCE **Joshua** in Jericho and Gibeon; singular astronomical and geophysical events over the ancient Near-East[56] during the Israeli conquest of Canaan:

[55] There is little in the biblical data itself to suggest that ancient Israel has a class of professional architects. The construction of buildings and monuments appears to have been the responsibility of craftsmen or master masons. Even these seem to be of non-Israelian origin, such as *Hiram*, the Phoenician master craftsman from Tyre who was in charge of Solomon's Temple in Jerusalem (*I Kings* **7**, 13; *2 Chron* **2**, 13-14).

[56] Hasegawa, I. (1980) Catalogue of ancient and naked-eye comets, *Vistas in Astronomy* **24**, 59–102.

Ben-Menahem, A. (1992), Cross-dating of Biblical history via singular astronomical and geophysical events over the ancient Near-East, *Q. J. Roy. Astr. Soc.* **33**, 175–190.

(1) Comet Halley apparition 1198 BCE, May 11, or the apparition of another comet brighter than the 6^{th} magnitude in 1201 BCE (**Josh** *5*, 13). It may have been seen by **Joshua bin-Nun** prior to the assault of the Israelites on Jericho (**Josh** *5*, 13). Described as bearing the shape of a flaming sword.

(2) Long day with extra light hours due to "bright nights" phenomenon following a close encounter of Apollo-type asteroid with the earth. This could explain: "*And the sun stood still, and the moon stayed...*" (**Josh** *10*, 13).

ca 1200 BCE The Hittite kingdom (began ca 1750 BCE) came to an end as a result of the great *Aegean migration*, of which the *Homeric War* against Troy was an incident.

ca 1200 BCE *Indo-European Invasion* was disturbing the entire Eastern Mediterranean world[57]. The whole of Asia Minor had been overrun by another wave of new Indo-European, who came behind the Greeks and crossed the Hellespont from Europe. The most important of these were the *Phrygiens* and the *Armenians*.

The *Hittite Empire*, lying directly in their path, was completely crushed and disappeared. Many of its communities peregrinated beyond the Mediterranean.

The Egyptian monuments of this time reveal these sea-wanderers very vividly. Besides the *Philistines*, who were fleeing from Crete, the monuments show us the sea-roving *Achaeans* who combined with the other displaced people to invade Egypt in the last declining days of the Egyptian Empire. This was apparently a second group of Achaeans, who had remained in Asia Minor after the invasion of Greece by their earlier kindred. Forced out by the Indo-European invasion, this second group of Achaeans joined with other fleeing

---

[57] Modern scholars link this mass-migration to sharp *climatic changes* during 1200–850 BCE. A northward displacement of the arid zone in Europe and Asia caused the rise and fall of civilizations and southward migration of people in Northern and Central Europe and Asia, even as late as 500 BCE. The ensuing extended drought was sufficiently severe to disrupt agriculture in Crete, Greece and the whole Eastern Mediterranean. The Greek countryside was apparently depopulated for a time before the Dorians moved in from the north. Refugees wandered from the drought-stricken land to Egypt and southwest coasts of Asia Minor.

The *atmospheric circulation patterns* which caused this drought may have continued rather prominent until about 850 BCE, e.g., a drought lasting $3\frac{1}{2}$ years occurred in the days of Ahab (King) (reigned 874–853 BCE; *I Kings*, 17–18).

Asia Minor peoples to seek a new home in Egypt. Among these were the *Sardinians* and the *Etruscans*. The Cretan Philistines and the Sardinians had in their possession, for the first time in the ancient world, a long two-edged bronze-made dagger, to be known henceforth as the *sword*[58]. The main body of the "*sea-people*", as the Egyptian monuments call them, kept together for the purpose of invading and conquering Egypt.

All the great powers of the Ancient Near East were threatened by this vast Indo-European movement[59], which stretched from the Balkan Peninsula eastward to the upper Euphrates. Its front had set in motion before it a wave of fleeing Aegeans and Asia Minor people, who were mostly pre-Indo-Europeans. It was this wave of refugees that crossed the sea and began to break upon the shores of the eastern and southeastern Mediterranean, from the Nile Delta to the harbors of Phoenicia. The onset of these sword bearing northerners shook the Egyptian Empire to its foundations. Eventually, however, this wave was driven back by Rameses III.

Consequently, the *Cretan Philistines* settled on the coast of Israel, some of the *Achaenas* migrated to Greece, while the *Etruscans* sailed far westward around the heel of Italy. The *Sardinians* settled in Sicily. Thus the Indo-European invasion of the Eastern Mediterranean ushered a new age in the *Western Mediterranean*.

The Iron Age

Metal forms a large part of the earth on which we live. The earth's crust is made up of about 8 per cent aluminum, 5 per cent iron, and 4 per cent calcium. Potassium sodium and magnesium also occur in large amounts.

---

[58] This elongation of the Egyptian bronze dagger into a heavier weapon took place in the north after the discovery of tin in *Bohemia*.

[59] *The Table of Nations* (*Genesis* **10**) provides a schematic arrangement of the major cultural divisions of mankind, specifying ancient nations and their great cities. It derives from Mesopotamian sources reflecting the Near-East population toward ca 1100 BCE. The figure behind the hero **Nimrod** is the Assyrian Emperor **Tukulti-Ninurta I** (reigned 1234–1200 BCE), known for his conquest of Babylon and his building projects. The genealogical lists actually reflect political and economical filiation, as well as cultural affinities.

Ancient man knew and used many native metals. Some metals, such as gold, silver, copper and tin[60]*, occur naturally and are easy to work. They have been used to make object for ornaments, plates, and utensils as early as 3500 BCE. Thus, gold objects showing a high degree of culture have been excavated at the ruins of the ancient city of Ur in Mesopotamia. The attached evolutional timetable reflects the order by which metals were discovered since the end of the stone age.*

As early as the beginning of the Bronze Age (ca 3000 BCE), some people in the Middle East began to make tools by beating and hammering iron from meteors. They decorated many of these skillfully made implements. The oldest pieces of such iron in existence are Egyptian sickle blades and crosscut saw, thousands of years old. During the Bronze Age, however, most craftsmen continued to use primitive tools of the late stone age, because metal was expensive. Only kings and warriors could afford if. Indeed, a dagger, resurrected (1926) from the tomb of Tutankhamun (ca 2000 BCE) has an iron blade almost untarnished.

How could Egyptian craftsman, 3000 ears ago, achieve such a startling feat? Iron was a metal which at that time was hardly used. It was considered inferior to other metals: it was soft and would not harden. It was also easily oxidable by the atmosphere. There were few iron objects that survived these 3000 years and those left show severe deformation.

Around 1400 BCE wrought iron was first produced by the Hittites in Northern Anatolia: they burned iron ore with wood and removed most impurities by repeated hammering. Hittite dominated Asia Minor from ca 1900–1200 BCE, establishing a great empire.

---

[60] Human history reflects the activity of metals; the fact that metals were discovered in the order: gold, silver, copper, tin, iron is strongly tied to the chemical properties of metals. One such property is their *tendency to loose electrons*; This tendency is greatest for the metals on the lower left side of the periodic table. Very active metals, such as sodium, lose their electrons easily; they are unlikely to be found free in nature. In contrast, noble metals, such as gold, are often found free in nature. The larger pieces of free gold near the surface of the earth may have been found during "gold rushes". When heated, compounds of inactive metals yield the free metal. We may imagine, therefore, prehistoric people discovering free metals when building fires in areas rich in metal ores. Since it is easier to extract less active elements from ores (oxides of metals) than it is to extract more active elements, we can see why less active metals were discovered first. Iron is more active than copper, lead and tin. We have been able to make *stainless steel* (80% iron, 12% chromium, 8% nickel) since 1790 CE, when the even more active metal *chromium* was discovered. In the early 1800's very active metals such as *potassium* and *lithium*, were discovered.

Events were however to confer about iron a new and almost everlasting life: At the eastern end of the Mediterranean, in the 2^{nd} *millennium BCE, trade in metals thrived between ports like Tyre and Sidon and the ancient Aradus (Arwad) port on the coast of Syria. Copper and other metals were being mined in quantities in Cyprus and Anatolia and supplied to metal workers in the cities of Egypt, Crete and Mesopotamia. But this established order was suddenly disrupted.*

Historically, the Eastern Mediterranean has always been a linking passage from Europe to India, Central Asia and Afghanistan, through which the circulation of metals had come to have increasing importance. In ca 1200 BCE, it was invaded by the Sea People-waves of migrating masses from the north – who disrupted the established trade routes which followed the supplies of tin from their distant sources.

And without tin there is no bronze! An age which lasted for 2000 years was strangled and it never revived.

The whole material balance tipped: bronze became scarce and iron, which had been used until then mainly for ornaments, begun to appear with increasing regularity in the archaeological record.

Out of the ashes of the bronze age cultures there slowly emerged the cultures of the iron age.

Nevertheless, the use of iron in the old world was on a very small and restricted scale until after the downfall of the Hittite Empire under the heavy blows inflicted upon it by the Sea-People. Its iron craftsmen dispersed through the entire Middle-East and interacted with metal-smiths of other nations. New technical discoveries were made which led to the transformation of iron, from a metal inferior to bronze, to one which was destined to become a universal replacement for it.

The basic technology, successful for a thousand of years in smelting copper, failed when applied to iron; the melting point of iron is much higher, more than $1500\,^{\circ}C$*. Such temperatures were unobtainable. At the temperatures which were possible, iron was reduced from its ore without ever becoming liquid, or separated from the slag. The result was a spongy mess of slag, embedded with grains of iron called the bloom. By hammering the bloom and driving out the slag, a blacksmith could actually obtain a bar of almost pure wrought iron. To keep the iron meltable enough to work, the smith kept reheating it in his forge. This produced a subtle but important change – the repeated contact with white hot charcoal caused small amounts of carbon to combine with a surface layer of iron. This blend of carbon iron was much harder then pure wrought iron – it is steel.*

Having discovered the method of steeling (carburizing) iron, the early smiths made a further advance – they found that if steeled iron was cooled suddenly like quenching, it became even harder, or quite brittle. Finally they found that if this hardened steel was reheated, it lost its brittleness but retained its hardness – this process came to be called tampering.

These three vital discoveries transformed the properties and potential of iron. About 1100 BCE true iron working began in the Middle East and from there spread over much of Asia, Africa and Europe. Iron ores were much more plentiful than copper and with the diffusion of the techniques of steeling iron in the first millennium BCE the Iron Age gained momentum. Craftsmen abandoned the crude tools of the Bronze Age and made wider use of iron, including plows and weapons. This age continues to the present day.

In Europe the Iron Age began at about 600 BCE at Noricum in the East Alps: In the village of Halstad in the Austrian Alps, excavations (1864) unveiled a cemetery. Buried with the dead was a whole culture of metal, including weapons and ornaments made of iron. This iron metallurgy had spread to Noricum from the Hittite empire. After about 400 years the center moved to the Celtic lands, and especially to Spain, where the Celtic smiths developed the Catalan iron furnace[61]*. Soon all of Western Europe was put under the anvil. In the energetic hands of these creative people, the iron technology laid the political and economical foundation of European civilization.*

Iron is a symbol of the confident positive commitment by man everywhere to a new metal and to a new age. It is a milepost of that time by which the making of iron has become a central preoccupation, a determinant of success or failure of national survival[62]*, and became something not just to*

---

[61] The new metal was first used for weapons; then for the *hoe* and the axe and pick of the farm and mine; lastly, for improved tools; the iron of early classical Greece was not suitable for ploughshares, and was evidently a very inferior metal compared with the properly hardened and tempered material that served the *Roman legions* about the beginning of the Christian era.

The best steel known to the Romans was the so-called '*Seric iron*'. It was a high-carbon crucible steel, made in round cakes, about 10 cm in diameter, which reached Rome via Abyssinia from Southern India.

The defensive armor and shield of the Greek hoplite were made of bronze, but his main weapons were a 3 m spear tipped with iron and a short, straight iron sword.

[62] E.g. the word iron is mentioned in the Old Testament 76 times, and duly represents the impact of this metal in the world of the Hebrews during 1200–500 BCE. Israel became acquainted with it through the *Philistines*, who had long known to work the metal. The raw material was brought in by Tyrians, mainly from Spain, though it was found also in the Lebanon range (*Jer* **11**, 4; *Deut* **4**,

make but to emulate. It entered all languages as a synonym for strength and resolution: before the iron age, man was as strong as an oak, now they seek to become iron-willed! That change in metaphor signalized a further step away from agriculture and towards industry, and iron changed the quality if not the form of a vast number of things in both.

It means better tools and better weapons, sharper axes, cut down more trees to make more fuel. It cleared more forest for more cultivation to support larger populations and when it came to blood and iron – superior sword won decisive wars.

Without it there would be no bridges, no engines, no skyscrapers: iron is the top root of our material civilization.

20; **8**, 9; *I Kings* **8**, 51). Out of iron, the blacksmiths made axes, hatches, sickles knives, swords, spears, bars, chairs, fetters, nails, hoes, pens, plows and sledges.

Iron metallurgy – signposts of Progress
(4000 BCE–1600 CE)

ca 4000 BCE First reduction of *copper* in Anatolia and Iran, Egyptians mine copper ores and smelt them. End of Stone Age and begin of the *Copper Age*.

ca 4000–3500 BCE Egyptian and Sumerians smelt *silver and gold*; Egyptians mine and process *iron*, used mainly for utensils. Metal mirrors in Egypt. Egyptians and Babylonians make extensive use of *bronze*.

ca 3500 BCE Discovery of *lead*.

ca 3000 BCE End of the Copper Age. Begin of Bronze Age.

ca 2500 BCE Chaldeans in Ur (Mesopotamia) join sheets of *gold* by soldering.

ca 2000 BCE *Copper* bar from Nippur (weight 41.5 kg, length 110.35 cm) is the earliest standard measure.

ca 1500 BCE *Gold* nuggets in Egypt serve as weight standards.

ca 1400 BCE Hittites of Anatolia first produced *wrought iron*: they burned iron ore with wood and removed most impurities by repeated hammering.

ca 1100–800 BCE Begin of Iron Age.

ca 1000 BCE *Steel* was being made in the Middle-East and India: bars of iron were steeled by hand labor with hammer and anvil or by roasting with charcoal. In this way the iron was mixed with small amounts of carbon that made it harder and stronger.

ca 600 BCE Iron-Age began in Europe at *Noricum*.

ca 315 BCE The earliest existing treatise on *minerals* written by the Greek philosopher **Theophrastos**.

ca 300 BCE Chinese first produced *cast-iron*. Better furnaces produced higher temperatures which could melt the iron completely. The product was stronger than wrought iron. Their technique was, however, unknown in Europe until 1380 CE.

ca 200 BCE Chinese develop form of cast iron.

ca 77 CE **Pliny the Elder** (Rome) writes about ores in his *Historia Naturalis*.

ca 450 CE Chinese learn to make *steel* by forging together cast and *wrought iron*.

ca 800 CE Blast furnaces for making *cast iron* are built in *Scandinavia*.

ca 1000 CE *Celtic* iron technology in Spain; the Catalan iron furnaces.

ca 1262 CE **Albertus Magnus** (Germany) wrote about minerals in his treatise *De Mineralibus*.

1380–1389 CE *Cast iron* becomes generally available in Europe: Tall furnaces were built and water-power was harnessed to produce stronger blast of air than that achieved by hand-operated bellows. Furnaces could now be operated at temperatures high enough to produce molten iron.

ca 1540 CE **Vannocio Biringuccio** of Siena (Italy) issued his treatise *Pirotechnica*, describing production techniques of brass and bronze in Europe.

1556 CE **Georgius Agricola** (Germany) published *De re metalica*, a systematic treatise on mines and metallurgy.

ca 1200 BCE The quest of *Jason and the Argonauts* for for the *Golden fleece* describes an expedition out beyond the Golden Horn over the Euxine Sea to present-day Armenia to seize the source of gold. It was extracted by the laborious process of washing the river sands through the fleece of sheep, with gold nuggets left clinging to the oily fibers.

ca 1200 BCE *The Phoenicians*[63], who lived along the coast of the Mediterranean Sea, developed a system of 22 signs to form an alphabet that was structurally related to Semitic and Egyptian. It has signs for consonant sounds, but not vowel sounds. Early Phoenician writing consists partly of pictographic forms and partly of geometric or diagrammatic signs. Possibly, the Phoenicians based their alphabet on the earlier Semitic alphabet. The Phoenician alphabet spread throughout Western Asia along the caravan routes. It passed down the Euphrates to Persia, and, penetrating to the frontiers of India, even furnished the East Indian people with their Sanskrit alphabet.

ca 1200–400 BCE *Chavin de Huantar*. Pre-Inca culture in the central Andes. Pottery, weavings and impressive stone buildings.

1122 BCE Severe drought in China.

ca 1100 BCE **Chou Kung**. Chinese statesman and mathematician. He is accepted as the author of the first dialogue contained in the Chou-Pi, one of the oldest of the ancient Chinese scientific treatises. It deals principally with calendrical problems and thus with astronomy and mathematics. We have evidence here of knowledge of mensurational geometry, the *Pythagorean theorem*, *elements of trigonometry* and some instruments for astronomical measurements.

Chinese astronomers determined the obliquity of the ecliptic (the angle between the earth's orbit and its equatorial plane) to a few minutes of arc.

ca 1000 BCE The Chinese developed the *counting board*, the forerunner of the *abacus*.

ca 1000 BCE Legendary *Thule* civilization in the Gobi region destroyed by a *natural catastrophe* of unknown origin. Survivors migrate to Agarthi and Shamballah.

ca 1000–700 BCE Beginning of the *Iron Age*[64]. Iron was already known to man in prehistoric days, but it remained a rarity until the *Hittites* discovered

---

63 The origin of this alphabet is attributed to the Phoenician **Cadmus** (son of Agenor, king of Tyre), who is said to have brought 18 letters to Boetia (ca 1313 BCE).

64 The three ages of metals:
The *Copper Age*: from the 4^{th} millennium to about 2000 BCE;
The *Bronze Age*: from about 2000 to 1000 BCE;
The *Iron Age*: from about 1000 BCE to the modern *Age of Steel*.

it in northeastern Asia Minor. From the 13^{th} century onward, the Hittite kings distributed iron throughout the Near East. It was therefore in the first centuries of the Age of Iron that the *Assyrians* were preparing for Western conquests, and their success was largely due to the use of this metal in warfare. Thus, the Assyrian forces were the first large armies completely equipped with weapons of iron. The bulk of the Assyrian army was composed of archers, supported by heavy-armed spearmen and shield bearers.

Assyria had without doubt learned much from the skillful horsemen of *Mitani*. The famous horsemen and chariotry of Nineveh became the scourge of the East. For the first time, too, the Assyrians employed the battering-ram and formidable siege machinery. The sun-dried brick walls of the Asiatic cities could thus be battered down or pierced, and no fortified place could long repulse the assaults of the fierce Assyrian infantry.

Under the influence from the Hittite art, the sculptors of Assyria learned to tell the story of the king's valiant exploits in elaborate *stone pictures* cut in flat relief on great slabs of *alabaster*.

The Assyrian armies had marched westward and had crossed the Euphrates by 1300 BCE. They had looked upon the Mediterranean by 1100 BCE, but for more than 350 years after this the kings of Assyria were unable to conquer and hold this western region against the strong alliance of Arameans, Hebrew and Phoenician kingdoms.

986 BCE, Dec. Perihelion passage apparition of comet Halley. May have been witnessed by King David in Jerusalem. [*Chron I* **21**, 16; *Psa* **18**, 13–15].

950 BCE The valued $\pi = 3$ was used by the Israelites in constructions associated with King's Solomon Temple in Jerusalem. [*I Kings* **7**, 23; *Chronicles II* **4**, 2].

Chinese chariots had wheels with spokes. Iron mines in Italy.

ca 950 BCE The Queen of Sheba arrives in Jerusalem to visit King Solomon (ca 984–928 BCE) and establish commercial relations with the Hebrew Kingdom.

ca 900 BCE *The Etruscans* settled on the western coast of Italy, north of the Tiber. The earliest of them had arrived in consequence of the breakdown of the Hittite Empire[65] and brought with them an *oriental* civilization. They introduced the chariot, the arch in building and an alphabet, and were

[65] The eastern origin of the *Etruscans* has been proved (1926) by the discovery of an Etruscan cemetery on the Greek island of Lemnos.

therefore not illiterate like their predecessors in Italy. The Etruscans brought also from the East much skill as craftsmen. In Italy they found copper, and in the course of time they developed the finest bronze industry in the ancient world of that period. Their goldsmiths too were unrivaled by any in the older countries.

The Etruscans invented gladiatorial games, drained the marshes, plied the seas with commerce, traversed the heartland of Europe with goods, and founded a religion built on fornication, death and hellfire. The senior trinity of their gods consisted of a holy father, a virgin mother, and an immaculately begotten daughter. In Etruscan theology, the dead went first to purgatory, for judgment, where, if found guilty, their souls were damned to various degrees of torment, the ultimate punishment being eternal hellfire. [In the 13^{th} century CE, these concepts seeped into Christianity via the *Divina Commedia* of Dante, who was steeped in Etruscan mythology.]

When the Greeks arrived in Italy to plunder, trade, and colonize, those Etruscans who survived the encounter acquired Greek culture. The Roman Kingdom founded by Romulus in the 8^{th} century BCE, was conquered by the Etruscans in the 6^{th}. Though their rule was brief, the Etruscans did nevertheless influence Roman culture more profoundly than the Sumerians influenced the Babylonian; two and a half centuries of Etruscan rule (ca 750–500 BCE) left their mark on Rome, always afterwards discernible in architecture, religion, organization, city planning and roads. Many Etruscans continued to live in Rome and Latium, and in the days of Roman splendor, some of the greatest families of Rome were of Etruscan descent and were proud of it.

After their expulsion from Rome, the Etruscan continued as a powerful and highly civilized federation, although surrounded by dangerous enemies. They finally lost their territories to Gauls, Samnites and the Romans.

876 BCE A symbol for zero was used in India. The first known reference to this symbol.

853 BCE The *Battle of Karkar*; one of the biggest iron-battles of the ancient world through which a grand alliance of Aramean, Hebrew and Phoenician kingdoms stemmed the advance of the Assyrians along the Eastern Mediterranean coast to Egypt. The historic military encounter at Karkar (ca 100 km NNW of Hamah, on the Orontes River; today's Qarqur) involved some 200,000 men and 6000 chariots on either side.

After the fall of *Mitani*, *Egypt* and the *Hittite* empires, there still remained the powerful mercantile civilizations of the Western Semites – the line of harbor towns on the Phoenician coast, the Aramean city of Damascus under

Ben Hadad II, and the Israeli kingdom of Ahab[66], which blocked their way to Egypt. When Assyria, under **Shalmaneser III** were ready to strike, Ahab and Ben Hadad II were ready and the might of Assyria clashed with the massed strength of twelve buffer states. When all was over, the Assyrians were dealt a stunning defeat that set their timetable for conquest back a hundred years. This battle "bought" Israel an extra century until the kingdom was finally dissolved and the *Ten Tribes* dispersed and lost by the Assyrian deportations of 740–700 BCE.

842–771 BCE Great drought in China.

831 BCE, Aug. 15 A total eclipse of the sun in Southern Judea at *midday*. The Hebrew prophet **Amos of Tekoa** (fl. 765–750 BCE) rendered a vivid account of this event[67] (*Amos* **8**, 9; **5**, 8).

ca 800 BCE Egyptians used techniques of *tanning* hides to make leather and *hardening* of leather with alum. They were using *sundials* with six time divisions to tell time. The sundial was introduced in Greece by the 6^{th} century BCE.

ca 800 BCE Phoenicians established trade routes to *Gadir*, on the Atlantic coast of Spain. By this time, Phoenician refused to allow ships other than their own to sail through the strait of Gibraltar to Atlantic coasts of Europe or Africa.

ca 800 BCE The Greeks borrowed Phoenician symbols and modified them to form the *Greek alphabet*. They came into contact with Phoenician traders and learned from them the idea of writing individual sounds of the language. Since the Phoenician alphabet included more consonants than the Greek needed for their language, they used the extra consonants for vowel sounds: thus the Phoenician *aleph* (meaning *Ox*) became *alpha*, the Phoenician *beth* (meaning *house*) became *beta*, etc. The Greeks later modified the

---

66 During the reign of King Ahab (874–853), there occurred a drought in Israel which lasted for $3\frac{1}{2}$ years (*I Kings* **17–18**).

67 The zone of totality fell within the southern boundaries of Judea. The moment of greatest darkness was almost exactly at midday. Such phenomena are very rare at any given locality. The partial eclipse of June 15, 763 BCE was not as impressive in Judea, since it was not total within the borders of Israel and greatest darkness occurred in the early morning hours.
Amos may have witnessed the 831 BCE event in his early youth or could have been told of it. [*Solar and Lunar Eclipses of Ancient Near East From* 3000 BCE *to* 0 *with Maps* Kudlek, M. and E.H. Mickler (eds.), Verlag, Butzon and Bercker Kevelaer, 1971].

shapes of these letters, adding and dropping some letters to form the 24-letter Greek alphabet of today.

8^{th} century BCE Chinese astronomy reaches its peak with outstanding quality and quantity of observations[68]. The earliest reliable observation report a total solar eclipse on July 8, 709 BCE.

776 BCE The first *Olympiad* celebrated in Olympia, Greece. The Olympic games took place 292 times, the last occasion being in 393 CE. Their importance was such that Olympiads were the basis of *Greek chronology* and their organization and development were subject to an established and unchanging ritual and continued for almost 1200 years.

767 BCE First recorded worldwide plague (*Amos* **4**, 10).

ca 720 BCE The *Latin alphabet* was borrowed by the Romans from that of the Greeks, probably through the Etruscans (who moved to central Italy from somewhere in the Eastern Mediterranean sometimes after 1000 BCE, carrying the Greek alphabet with them). The Romans learned the alphabet from the Etruscans, and gave it much the same form we use today. The early Roman alphabet had about 20 letters, and gradually gained 3 more. The letters J, U and W of the English alphabet were not added until the Middle Ages.

Capital letters were the only forms used for hundred of years, and were finally perfected by 114 CE when *sculptors* carved the inscriptions on a memorial column built in honor of the emperor Trajan. Lower-case letters gradually developed from capitals by *scribes* who copied books, using rounded letters (*uncials*) that were easier to form than some capitals.

711 BCE, Mar. 14 A partial eclipse of the sun, visible in Jerusalem. The prophet **Isaiah I** (fl. 740–685 BCE) and the Judean king **Hezekiah** (reigned 715–687 BCE) are linked to this event in the unique biblical story that is threaded in three books [*Kings II* **20**, 8–11; *II Chron* **32**, 31; *Isa* **13**, 10; **38**].

Hezekiah, king of Judea, was a patron of learning and caused great public works to be undertaken; he fortified Jerusalem and improved its water-supply.

---

[68] About 800 BCE (Homer's time), the Greeks believed that the mass of the earth, surrounded by the river *Okeanos*, filled up the lower half of the sphere of the universe, while the upper half was out above it, and that *Helios* (the sun) extinguished its flames each evening by bathing in the deep waters of the ocean and lit them again in the morning.

To this effect, the Shiloa tunnel[69] was chiseled in ca 700 BCE [*Chron II* **32**, 3–4, 30; *Kings II* **20**, 20; *Isa* **22**, 9–11].

700 BCE The Assyrians introduce the *aqueduct*. Carved bone or ivory dentures with gold braces worn by Etruscans of Northern Italy.

668 BCE **Ashurbanipal**, king of Assyria, established a *library* at his capital *Nineveh* (destroyed ca 612 BCE).

ca 650 BCE The Lydians of Asia Minor introduced the *first standard coinage* of the Western world.

It has been the custom for centuries in the Egyptian and Babylonian empires to *stamp* ingots with some mark giving authority of the value of the metal. This however did not ensure a standard quality to the precious metal, and therefore did not make the ingots more freely exchangeable. However, some time in the 8^{th} century BCE someone discovered the *touchstone*, a flinty river stone (schist), used to assay the quality of the gold ingot.

Herodotos tells us that the Lydians cut the top surface of the stone flat, leading it matt. If gold were rubbed on this matt surface it would make scratch marks. Pure gold would leave yellow marks, gold mixed with silver, white ones, and gold mixed with copper, red marks. It gave the rulers of Lydia, starting with **King Gyges** (685 BCE), the ability to ensure a standard quality to their money by easily detecting forgery. The mark of the King's mint was now evidence of purity, weight and acceptability.

In the 6^{th} century BCE a smaller unit of exchange, the Lydian *stater* was produced. It was made of a gold-silver alloy called *electrum* and punch-marked by the issuing mint. Within a century a set of coins, each one a

---

[69] An underground *S*-shaped aqueduct, 513 meters long. The rock was pierced simultaneously at both ends and the workmen met in the middle – a triumph of precision engineering.
Herodotos tells us of a similar water project undertaken in Samos by the Greek engineer **Eupalinos of Megara** (fl. 520 BCE). He built water conduits during the rule of Polycrates (ca 530–522 BCE). The remains of the tunnel were found in 1882; it is about 1000 m long and 1.75 m high and wide, at the bottom of the tunnel there is a trench, about 60 cm wide and reaching at the south end a depth of 8.3 m, wherein the clay pipes were embedded.
The Hezekiah and the Eupalinos tunnels were *started at both ends*. How did the engineers solve the mathematical problems involved? We may guess that they had instruments to measure azimuths and difference of levels. The problem involved was solved *theoretically* for the first time by **Hero** in his treatise on *dioptra* (ca 50 BCE).

fraction of the stater, had been issued. When *Croesus of Lydia* introduced the first standard imperial coinage (550 BCE), Lydian money was already known for its high and unchanging standard. When **Cyrus** conquered Lydia (546 BCE) he issued the first Persian coins.

The economic revolution following the development of coinage was enormous. Before this, the only money was the bullion weighted out at the time of a transaction. Small farmers and artisans were forced to barter. The introduction of coins that petty producers could use brought the mass of the population the benefits of money, since the craftsman was no longer condemned to "eat his wages". He could buy products with his earnings, opening up new markets for fellow artisans. The small farmer was free to follow the aristocrats into specialized farming for an export market.

Money is perhaps man's most useful discovery, next to fire and the wheel. As the use of coinage spread, it had two fundamental effects. The first was *political*: money issued by a central mint had a unifying effect on the users. The mark of the government on the coin was present in every transaction. Its presence defined the boundaries of governmental authority, and its value mirrored the health of the economy and political stability of the country. The second was *cultural*: with the growth of international trade grew the exchange of technological innovations and scientific ideas.

But money was a mixed blessing, and in its wake followed usury, mortgages, and *debt slavery*. Money was power. Anything could be reduced to *abstract numbers*: the value of a pot, a jar of oil, a plot of land, a slave, could all be expressed by exact number of coins, as could the wealth and worth of any citizen. Numbers seemed to have magical powers. Money invested at interest could even multiply itself without any effort on the part of the lender.

As the money economy developed, so did chattel *slavery*. Such an institution, based on the sale of slaves, is impossible without the free exchange of money. Slavery threatened either to enchain the small producers themselves or to undercut their livelihood, and so devalued productive activity. To Greek slaveholders, work was something done by slaves, thus in itself degrading. Only detached thought is worthy. As slavery separated thought from action, so did a new trend in Greek philosophy glorify abstract reason while denigrating physical observation. Slavery also undercut the development of technology that required and fed observation: slave-owners did not need labor-saving devices.

The Greek philosophers in the 6^{th} century witnessed the effects of money on the Greek states, and some of them extrapolated from the power of numbers in society to the idea that numbers rule the universe as well.

650 BCE Assyrians compile Mesopotamian medical knowledge in collection of *clay tablets* at the Royal Library in Nineveh. Over 300 medications and such diseases as paralytic stroke and rheumatism are described. The diseases of tuberculosis, gonorrhea and leprosy first described with accuracy.

The Greeks[70]

"The isles of Greece, the isles of Greece!
Where burning Sappho loved and sung,
Where grew the arts of war and peace,
Where Delos rose, and Phoebus sprung!

Eternal summer gilds them yet,
But all, except their sun, is set".

George Gordon Byron (1788–1824)

Originally a shepherd people, the Greeks had migrated to the Greek peninsula in about 1900 *BCE out of central Europe, possibly from the Danube. They were one of several peoples speaking Indo-European languages who migrated southward at this time. These include, among others, the Germanic, Celtic, Latin and Iranian peoples, and the Aryans who in the same millennium invaded and conquered Northern India. The Greeks found their new home too arid to satisfy their needs and soon turned to the sea for their livelihood, learning the secrets of navigation, and their metal working skills, from the Minoans.*

By about 1600 *BCE, the Greeks were established throughout the Aegean area in independent city-states and the* Mycenaean civilization *had begun to take shape.*

Imaginative, curious, with an innate appreciation of the beautiful and a genuine love of adventure they became fishermen, pirates and merchants, trading with the nearby island of Crete, where the Minoan civilization was just reaching its peak.

With the decline of the Minoans, following the Thera natural catastrophe, the westward migration of the Phoenicians and the comeback of the New Kingdom in Egypt, Mycenaean traders sought new markets in the Black Sea. During 1150–900 *BCE, the Dorians moved into the Greek Peninsula in a series of destructive waves and wiped out the Mycenaean ruling classes together with their entire civilization. The centuries preceding and following* 1000 *BCE witnessed in that part of the world a tremendous upheaval caused by the introduction of iron, complicated migrations, and widespread turbulence. This was the Dark Age that preceded the dawn of Greek culture. (In this respect that Dark Age resembles the Christian Middle Ages; both were periods of unconscious assimilation and preparation.)*

By 800 *BCE a new urban society was formed, and during* 800–600 *BCE, more than* 100 *colonies were founded, from the Black Sea, virtually a Greek lake, to Marseille (Massillia). They controlled the coast of Thrace and the entire littoral of Asia Minor, where they took over the trade previously enjoyed by the Phoenicians.*

They made Miletos, on the Aegean shore, the richest of their cities, and a port of departure for expeditions to the Black Sea. They colonized the eastern sea-board of the Adriatic, southern Italy, Sicily and Cyrene on the coast of Libya[71].

By the middle of the 7^{th} *century, they have established themselves in Egypt, founding the port of Naucratis at one of the now extinct mouths of the Nile. To this port, which later became the city of Alexandria, they brought merchandise which was paid for by Egyptians with gold from Sudan.*

During this period of trade and colonization, the small Greek villages of the Aegean evolved into strong self-sufficient city-states which transformed from monarchies to aristocracies. It is in these Greek cities of Asia Minor, particularly Miletos, that western philosophy was born.

Indeed, between 600–400 *BCE, there occurred a unique phenomenon in the annals of mankind: People with Greek names, living in the Greek colonies on islands and inlets of the Eastern Aegean Sea (Ionia) suddenly decoupled themselves from the bondage of myths and became aware that the universe*

71 In ca 650 BCE, **Colaeos**, Greek merchant, discovered the Straits of Gibraltar for Greece. *Massillia* was founded by Greeks from the Ionian city of *Phocaea*.

around them is knowable and exhibits an internal order ("cosmos"). They began to look for regularities, laws, rules, predictions – science was born.

And they found that everything is made of 'atoms', that the earth is only a 'planet' going around the sun, that stars are far away, that light travels with finite speed, that the earth was a sphere, and more.

Why did this happen in Samos, Miletos, Ephesos, Elea, Abdera and Cnidos and not in India, Egypt, or in the Maya and Aztec societies?

They lived in an open, free, decentralized, mercantile, pluralistic island society, situated on the cross roads of Africa, Asia and Europe, under the influence of the great cultures of Egypt and Mesopotamia. Not far to the east, roamed the voices of the Hebrew prophets, poets and sages in praise of unity, law and order in the universe.

Moreover, widespread literacy and writing and the free communication of thoughts through debates made inquiry and accumulation of knowledge feasible.

And finally, the umbilical cord to mainland Greece, where art, architecture and literature have been flourishing since 800 *BCE. It is this Greek connection that finally brought the decline of the Ionian awakening. The complex amalgam of city-states was inherently unstable: rivalry between individual states and alliances made each of them vulnerable. With the emergence of the powerful Macedonian kingdom, the majority of independent city-states disappeared. Greek culture was carried away to Italy (Tarentum, Syracuse), Africa (Cyrene) and as far east as the Oxus and Indus rivers, and a new imperial age, the Hellenistic period, begun.*

The Romans (300 BCE–476 CE) did not develop a civilization of seaboard city-states like the Greek. Rome was a warrior-agricultural community, like Sparta (the least intellectual of the Greek states). Commerce was forbidden to the senators of Rome, whilst the merchants submitted to the values of their society, aspiring to become the owners of farming land.

The Romans therefore lacked the quantitative and spatial thinking of the merchant-traveler, rendering them weakest in the mathematical sciences. The spirit of pragmatism and utilitarianism which pervaded the Roman world was alien to the air of disinterested and free creativity so essential to all developments of science and art. Thus they did not add a great deal to science. Their contribution lay in the fields of organization: public medical service, buildings, roads and aqueducts, Julian calendar, Roman Law, etc. They had no mathematicians and astronomers of note, and consequently science declined during their sojourn in history.

Notwithstanding the surpassing brilliance of the Greeks, there occurred earlier (ca 1800 BCE) a historical event which had a direct bearing on the *development of science, albeit* 3000 *years later. It was the* intellectual revolution *born with the introduction of the concept of monotheism by the ancient Hebrews.*

It freed men from a fearful subordination to the forces of nature by positing a supernatural cosmic power; the idea of one God emancipated men from their terror of many evil demons, apparitions and fiendish hobgoblins.

Apart from fusing religion and morality, monotheism ultimately became a stimulus to science*, because it suggested a unitary, consistent pattern within which everything in nature functioned. It promoted the idea of order, consistency, and meaning in the universe – all waiting for man to explore and understand.*

The idea of One God contained within itself the concept of a central cause, a prime reason for things, and the search for that reason in the analyses of sacred writings, or experimental ventures, or the detached observation of physical phenomena. For once cosmic unity is accepted, universal consistencies, regularities, and interrelations follow.

Another major contribution of the ancient Hebrews concerns their apprehension of time as a linear cosmic trend; history is presented as a unified process confirming a master plan of divine significance, which began with the creation. Prior to the rise of Christianity, with the exception of Philo and Seneca, only the Hebrews and the Zoroastrian Iranians have thought of history, man's fate included, as progressive rather than cyclic. This is made clear in every Book of the Old Testament (with the exception of Ecclesiastes) and is rather strongly emphasized in the Book of Daniel.

In contradistinction, all *other ancient civilizations, and especially the Greek scholars Plato, Aristotle, Pythagoras, the Stoics and certain Neoplatonic philosophers, believed in the doctrine of eternal recurrence and cyclic time, in which the world was destined to be destroyed and created anew in a cyclic pattern. The linear concept of time had a profound effects on western thought. Without it, it would be difficult to conceive of the ideas of* progress *or* evolution.

Curiously enough, both Judaism and Christianity, each in its own way, and for different reasons, did not encourage their believers to develop science for its own sake, and the world had to wait for the late Renaissance *and Spinoza to continue the intellectual revolution of the Hebrews.*

The same source that kindled the spirit of the great natural philosophers during 600–400 *BCE, has earlier endowed humanity with equally great poetry. As happened thousands of years later, during the European Renaissance, art preceded science by some* 200 *years: In Ionia, perhaps on the island of Khios,* **Homer** *sang his great epics, the* Iliad *and the* Odyssey*, at ca 750 BCE. [Not* *far away, in Judea, the contemporary Hebrew prophet,* **Isaiah**, *was reciting his Biblical visions*[72]*.]*

These two great epics bring European literature into existence with a bang; its echoes are still reverberating. However, there must have been a long history behind the Homeric poems, since works of such massive scale and great sophistication do not come out of nothing. The common origins of Greek science, philosophy and literature are to be sought in the heritage of the Indo-European family of peoples which later created the corresponding separate cultures.

Moreover, in the Homeric epics themselves, we can already discern the buds of later philosophical apprehension of nature and of man: the Greek people stand before us alive with all their skills, cunning and above all, their inquisitiveness and ingenuity which later developed into a keen sense for detailed physical observation. The Greek culture, through all of its transformations, is the manifestation of one and the same spirit.

In Greece, humanity approached for the first time the riddles of nature and man as problems that can be rationally solved.

We can feel the harmonious equilibrium of these two elements in the following lines from the conclusion of book VIII of the Illiad [in the translation of **Alexander Pope** *(1688–1741, England), during 1715–1720].*

[72] Greek literature reflects the vital impact of the stars on the life of an agricultural and seafaring people. **Homer** noted the Bears, Bootes, the Pleiads and Hyades, and the star Sirius, all by the names we use today. [These are also mentioned in the Bible: Sirius = *Hadre Theman*; Orion = *Kesil*; Venus = *Mazzaroth*; Hyades = *Ayish*; Pleiads = *Kimah*.] The Greeks in Homer's time used Ursa Major to navigate by.

"The troops exulting sat in order round,
And beaming fires illumined all the ground.

As when the moon, refulgent lamp of night,
O'er heaven's pure azure spreads her sacred light,
When not a breath disturbs the deep serene,
And not a cloud o'ercasts the solemn scene,
Around her throne the vivid planets roll,
And stars unnumber'd gild the glowing pole,
O'er the dark trees a yellower verdure shed,
And tip with silver every mountain's head:
Then shine the vales, the rocks in prospect rise,
A flood of glory bursts from all the skies:
The conscious swains, rejoicing in the sight,
Eye the blue vault, and bless the useful light.
So many flames before proud Ilion blaze,
And lighten glimmering Xanthus with their rays.
The long reflections of the distant fires
Gleam on the walls, and tremble on the spires.
A thousand piles the dusky horrors gild,
And shoot a shady lustre o'er the field.
Full fifty guards each flaming pile attend,
Whose umber'd arms, by fits, thick flashes send,
Loud neigh the coursers o'er their heaps of corn,
And ardent warriors wait the rising morn".

The Greeks themselves declared that they found in Egypt and in Babylonia the material for their geometry and astronomy[73]*. Thales and Pythagoras, Democritos and Eudoxos: all of them are reported to have traveled to Egypt and to Babylonia, in search of elements of value in alien cultures.*

From the Egyptians, the Greeks learned their multiplication and their computations with fractions, which they then developed further. The Greeks may also have taken from the Egyptians the rules for the determination of areas and volumes [for the Greeks such rules did not constitute mathematics, it merely led them to ask: how does one prove this?]

It is, however, on Babylonian science and mathematics that the Greeks based their own. The two cultures met around 604 BCE, at the beginning

[73] In his posthumous dialogue *Epinomis*, **Plato** says of the relation of the Greeks to the old cultures of the Orient: "*Whatever Greeks acquired from foreigners is finally turned by them into something nobler*".

of the reign of the Chaldean Nebuchadnezzar, when cultural and commercial communications were opened in both directions. In addition to the mathematical heritage, the Greeks received the sun-dial and the 12 *hours of the day.*

The political equilibrium was disturbed in 540 *BCE, when Cyrus II, the Great, subjected the entire Orient to Persian domination. The Ionian cities, which had come to the aid of his opponent Croesus, had to pay heavy tributes. Many Ionians left the country: the Phocaens, for example, established the town of Elea, in Italy, which was destined to play an important part in the history of philosophy. It was also at this time that Pythagoras migrated from Samos to Croton. The center of gravity of the world of mathematics and philosophy moved from Ionia to Italy.*

But it was not long before the Persian empire reestablished economic and cultural links with the Greeks. Ionian artisans and artists took part in the construction of the palace of Darius. The sculptor ***Telephanes of Phocia*** *worked for Darius and for Xerxes. The Greek physician* ***Democedes of Croton*** *lived at the court of Darius.*

The great Persian kings Cyrus and Darius were very tolerant. They did not interfere with the cultures and the religions of subject peoples (a reference to the Bible is in order here). Babylonian stellar rituals continued to exist. The observation of the moon and the planets by the Babylonian priest-astronomers, were continued systematically during the Persian regime. Without these carefully dated observations, the later flowering of Babylonian theoretical astronomy during the era of the Seleucids, the successors of Alexander the Great, would have been impossible. The Greeks also showed interest in these observations.

Callisthenes*, who accompanied Alexander the Great to Babylon, sent his uncle Aristotle, upon his request, Babylonian observations.* ***Hypsicles****, a Greek astronomer of the* 3^{th} *century, calculated the times of rising and setting of the Zodiacs in the Babylonian manner, because Greek geometry of the sphere was not yet able to solve this problem.* ***Hipparchos*** *(150 BCE) made use of Babylonian observations and periods of the moon, which Ptolemy could use* 300 *years later – practically without corrections.*

From all this it is apparent that even during the period of flowering of their own astronomy, the Greek were glad to learn from the Babylonians in any respect in which the latter had advanced beyond them. This certainly applied as well to the initial period of Greek mathematics, when the Babylonians were already in possession of a highly developed algebra and geometry, which the Greek had not yet acquired.

The natural point at which fruitful contacts between East and West could take place at the beginning of the 6^{th} *century BCE, was the flourishing commercial town of Miletos on the coast of Asia Minor, the most important center of Ionian culture.*

The Greeks invented democracy *more than* 2000 *years before any modern Western nation took the first steps toward it; they invented* philosophy *and the* theater *and organized competitive athletics; they invented* political theory, biology, zoology, *and* atomic theory[74].

The Greeks created philosophy; *without philosophy we would have no science, and the attempt to arrive at truth of any sort would remain largely a matter of fantasy and whim.*

Chinese *civilization invented the movable type, gunpowder, the rocket, the magnetic compass, the seismoscope, and made systematic observations and chronicles of the heavens.* Hindu *mathematicians invented the zero – the key to comfortable arithmetic and therefore to quantitative science.* Aztec *civilization developed a far better calendar than that of the European civilization; they were better able, and for longer periods into the future, to predict where the planets would be.*

But non of these civilizations had developed the skeptical and inquiring method of science. All that came from ancient Greek. The development of objective thinking *by the Greek appears to have required a number of specific cultural factors. First was the assembly, where men first learned to persuade one another by means of rational debate. Second was a maritime economy that prevented isolations and parochialism. Third was the existence of a wide spread Greek-speaking world around which travelers and scholars could wander. Fourth was the existence of an independent merchant class that could hire its own teachers. Fifth was a literary religion not dominated by priests, and sixth was the persistence of these factors for a thousand years.*

Greek mathematics was a brilliant step forward. Greek science, on the other hand was riddled with error:

---

[74] Yet, in spite of their great achievements in science, art and literature, their *technology* stood still through the entire millennium of their creative existence (the inventions of Archimedes were never applied to the needs of daily life)! Why?

The answer is quite simple: almost all their manual work was done by *slaves*. The Greeks despised work of any kind and therefore lacked the motivation for the invention and applications of labor-saving tools.

- *Believed that* vision *depends on a kind of radar that emanates from the eye, bounces off what we are seeing, and returns to the eye (Ignoring the fact that we cannot see in pitch darkness!).*
- *Believed that* heredity *was carried by semen alone, the woman being a more passive receptacle (Ignoring the fact children resemble their mothers!).*
- *Believed that the* horizontal motion *of a thrown rock somehow lifts it up, so that it takes longer to reach the ground than a rock dropped from the same height at the same moment.*
- *Believed that* planetary orbits *are exactly circular.*
- *Did not believe in interrogating nature by doing* experiments*, (Exceptions:* ***Eratosthene****'s measurement of the earth's diameter or* ***Empedocles****' experiment demonstrating the material nature of air). In a society is which manual labor was thought fit only for slaves, the experimental method did not thrive.*

What Ionia and ancient Greece provided is not so much inventions or technology or engineering, but the idea of systematic inquiry, the notion that nature, rather than capricious gods, govern the world. Water, air, earth, and fire – all had their turn as candidate "explanations" of the nature and origin of the world. Each such explanation was deeply flawed in its details. But the mode of explanation, an alternative to divine intervention, was productive and new[75].

Indeed, in contrast to the static civilizations of the great Eastern river valleys – Tigris, Euphrates and Nile – the Greeks created in the restless turbulence of their tiny city-states that impatient rhythm of competition and innovation that has been the distinguishing characteristic of Western civilization ever since.

[75] This approach of the *pre-Socratics* was (beginning in about 4^{th} century BCE) quenched by Plato, Aristotle, and then Christian theologians. If the brilliant guesses of the atomists about the nature of matter, the plurality of worlds, the vastness of space and time – had been treasured and built upon, if the innovation technology of Archimedes had been taught and emulated, if the notion of invariable laws of nature that humans must seek out and understand had been widely propagated – we would perhaps be living by now in a different world.

The Hebrews and their Bible[76]

Whereas the Greeks were interested chiefly in positive knowledge, the Hebrew's main concern were morality and apocalypses, though they were also keen observers of nature. The Hebrews had freed man's mind from magic by tying him with ethics to a moral God; the Greeks had freed man's mind from magic by tethering him with reason to a relative truth[77].

The Hebrews introduced the notion of monotheism, which may be considered as a scientific hypothesis. The earliest known Hebrew prophet after Moses, to expound monotheism to the people of Israel in their own land, was ***Amos*** *(fl. 765 BCE). The ethical theory of the world and the conception of a God, unique, conscientious, and just are published under his name in the Book of Amos. The ethical side of Hebrew monotheism was reinforced by the prophets* ***Hoshea*** *(fl. 740 BCE),* ***Isaiah*** *(fl. 720 BCE),* ***Micha*** *(fl. 720 BCE),* ***Zephaniah*** *(fl. ca 630 BCE),* ***Jeremiah*** *(fl. 626–586 BCE),* ***Nahum*** *(fl. 620 BCE),* ***Habakkuk*** *(fl. 615 BCE),* ***Ezekiel*** *(fl. 610–580 BCE),* ***Haggai*** *(fl. 520 BCE),* ***Zachariah*** *(fl. 520 BCE)* and ***Joel*** *(fl. 370–340 BCE).*

The Bible is also the main source-book on Hebrew law and history. The only part of the Pentateuch which can be dated with any precision is the 5^{th} *and last book called Deuteronomy. The kernel of this book was discovered in Solomon's Temple in Jerusalem in* 621 *BCE. It inspired King Joshia's revolutionary decision to centralize all formal worship in one place, Jerusalem. The book of* ***Samuel*** *was probably composed around* 600 *BCE. It deals with*

[77] Jewish law became tied to religious thought, and Greek law became tied to philosophical precepts. The Romans went a step beyond the Jews and the Greeks by totally separating their civil law from both religion and philosophy.

the history of the early kings Saul and David (fl. 980 BCE). The Books of ***Judges*** *and* ***Kings*** *are the product of the* 6^{th} *century, but were based upon early manuscripts.*

The Jews had two unique characteristics as ancient writers; They were the first to create consequential, substantial and interpretive history: They were fascinated by their past from very early times. They believed that they were a special people who had not simply evolved from an unrecorded past but had been brought into existence, for certain definite purposes, by a specific series of divine acts. They saw it as their collective business to determine, record, comment and reflect upon these acts.

No other people has ever shown so strong a compulsion to explore their origins. This passion for aetiology, the quest for explanations, broadened into a more general habit of seeing the present and future in terms of the past. The Jews wanted to know about themselves and their destiny. They wanted to know about God and his intention and wishes. Since God, in their theology, was the sole cause of all events, and thus the author of history, and since they were the chosen actors in his vest dramas – the record and study of historical events was the key to the understanding of both God and man.

The Jews developed the power to write terse and dramatic historical narrative 500 years before the Greeks, and because they constantly added to their historical records they developed a deep sense of historical perspective which the Greeks never attained. In the portrayal of character, too, the Biblical historians achieved a degree of perception and portraiture which even the best Greek and Roman historians could never reach. The Jews were not interested and did not believe in impersonal forces. They were less curious about the physics of creation *than any other literate race of antiquity. They turned their back on nature and discounted its manifestations except in so far as they reflected the divine-human drama. The notion of vast geographic or economic forces determining history was quite alien to them. There is much natural description in the Bible, some of astonishing beauty, but it is stage-scenery for the historical play.*

The second unique characteristic of ancient Jewish literature is the verbal presentation of human personality and its full range of complexity. The Jews were the first race to find words to express the deepest human emotions, especially the feeling produced by bodily or mental suffering, anxiety, spiritual despair and desolation, and the remedies for these evils produced by human ingenuity – hope, resolution, confidence in divine assistance the consciousness of innocence or righteousness, pertinence sorrow and humility [e.g. Psalms: *22, 23, 39, 51, 90, 91, 103, 104, 130, 137, 139]. Wisdom texts produced by the Jews are more observant of human nature and more ethically consistent than their precursors and models in the entire ancient Near East. Thus* Ecclesiastes, *is quite without equal in the ancient world, with which the Greeks alone could complete.*

This book is counted among the four great skeptical dramas of history along with Prometheus vinctus (Aeschylos); Hamlet (Shakespeare), and Faust (Goethe). Yet not even the Greeks produced a document so mysterious and harrowing as the book of Job, written in Israel in 5^{th} *century BCE. This great essay in theodicy and the problem of evil has fascinated and baffled both scholars and ordinary people for more than two millennia*[78]*, and of all the books of the Bible it has most influenced other writers.*

Job is a formidable work of Hebrew literature, written in a sustained level of powerful eloquence. Its burden is to show that suffering is not necessarily retributive and that the justice of God is impenetrable. It is crammed with natural history in poetic form, presenting a fascinating catalogue of organic, cosmic and meteorological phenomena. In chapter 28, for instance there is an extraordinary description of mining in the ancient world. Through this image, a view is presented of the almost unlimited scientific and technological potentials of the human race, and this is then contrasted with man's incorrigibly weak moral capacities[79]*.*

The Bible opens to us a window in time that extends from ca 2000 *BCE to ca* 300 *BCE*[80]*. It abounds with detailed descriptions as well as terse allusions to eclipses, comet apparitions, bolide impacts, paroxysmal volcano eruptions, major earthquakes, tsunamis, floods, and a host of meteorological*[81]*, botanical,*

---

78 **Thomas Carlyle** called it "one of the grandest things ever written with pen".

79 The author of Job delivers the following message: There are two orders in creation – the *physical* and the *moral* order. To understand and master the physical order of the world is not enough: man must come to accept and abide by the moral order, and to do so must acquire the secret of Wisdom, and this knowledge is something of an altogether different kind from, say, mining technology. Wisdom came to man, as Job dimly perceived, not by trying to penetrate God's reasoning and motives in inflicting pain, but only through obedience, the true foundation of moral order: "And he said to man: "Behold, the fear of the Lord, that is wisdom: and to depart from evil is understanding" [*Job* **28**, 28].

80 The Old Testament was canonized *gradually*, book by book, over a period of ca 1000 years. However, the final stages of canonization of the *Pentateuch* and most of the books of the *Prophets* began at the time of the scribe **Ezra** (fl. 458 BCE) and ended ca 200 BCE. The time of canonization of the *Writings* is uncertain, but believed to end by the first century BCE. A standard text of the Hebrew Bible appeared by about 150 CE.

81 Earth's *weather patterns* and the *hydrological cycle* were known to the Hebrews [*Job* **26**, 8; **28**, 23–26; *Eccl* **1**, 6; *Psalms* **146**, 16–17]. *Job* [**38**, 19–20] wonders

zoological, medical[82]*, geological, geographical, astronomical and other data*

on the nature of light and states that it is an element in a state of *motion*(!). The *earth* is floating in space, surrounded by a thin form-fitted layer – our atmosphere [*Job*, **26**, 7].

82 Ancient peoples regarded *disease* as something aside from the regular working of nature. To them disease was the expression of disfavor or hostility on the part of the god, and in the nature of *punishment*. As a consequence, the treatment of disease in the early days lay in the hand of the *priests* (*Lev* **13**), whose concern was to appease the angry Jehovah; diagnosis could be disregarded and medication naturally played a minor part. Diseases might be averted by repentance, e.g. Jeroboam's paralysis cured [*I Kings* **13**, 4–6], Hezekiah's illness cured [*II Kings* **20**, 5], Miriam's leprosy healed [*Nu* **12**, 14], plague checked by Aaron's use of incense [*Nu* **16**, 47].

Anatomy known to Biblical writers was a thing of shreds and patches – only very few parts of the body are mentioned in the Bible, and these references are vague and general. Something, however, was learned of comparative anatomy by the examination of animals slaughtered in sacrifice [*Deut* **18**, 3; *Lev* **3**, 10; **8**, 17; *Ezek* **21**, 21]. More accurate knowledge of the anatomy of the human body to be obtained by dissection was totally forbidden [*Nu* **18** 16].

Physicians were recognized as a distinct class [*II Chron* **16**, 12; *Job* **13**, 4], but their intervention met with the disapproval of the priests. There are several allusions to medical matters in *Proverbs* [**17**, 22; **20**, 30].

Preventive medicine: The Mosaic laws enforcing public and personal cleanliness were of great hygienic value [e.g. circumcision, ban upon sexual perversions (*Lev* **15**), sexual inversion (*Lev*, **18**), sanitation of camp life (*Deut* **23**, 13) etc.] These rules invested the figure of a good and virtuous woman with that peculiar halo of respect which has been preserved by all highly civilized nations down to the present time. The institution of the *Sabbath day of rest* was perhaps the most distinctive and beneficial of all the Mosaic provisions for the physical and moral well-being of the Hebrew people.

Medicines were largely used [*Prov* **17**, 22; *Jer* **30**, 13; **46**, 11; *Ezek* **47**, 12]. Moses was learned in all the wisdom of the Egyptians, and among the other branches of this lore, medicine was largely cultivated. Assyria and Babylon were learned in the medical science of that day. Thus, King Asa had medical treatment for his feet [*II Chron* **16**, 12], King Joram went back to be healed of his wounds [*II Kings* **8**, 29]. Of details of treatment and *materia medica* we have:

- *Balm* used for the treatment of wounds [*Jer* **8**, 22].
- *Caperberry* and *Mandrake* [*Ec* **12**, 5; *Gen* **30**, 14] used as aphrodisiac.
- *Ointments*: *Oil* was used in dressing wounds, and in anointing the sick [*Isaiah* **1**, 6]. *Wine* was used as a stimulant for gastric disturbances [*Pro* **31**, 6]. A *poultice of figs* [*II Kings* **20**, 7].
- *Antidotes*: An indication to the knowledge of the use of antidotes for poison

concerning the natural history of the ancient Near East.

No archaeological discovery has ever been made that contradicts or controverts historical statements in the scriptures, and most of the narratives relating to geophysical and astronomical events, are found today to bear a

---

is given in *II Kings* **4**, 38–41. Here the bitter fruit of the poisonous *colocynth* has been mixed in the pot with the stew. **Elisha** neutralized its effects by *meal* thrown into the pot. In modern times chemists have been able to show the neutralizing effect of the protein of the meal, when cooked, upon the poisonous alkaloid of colocynth.

There is no mention in the Bible of any anesthetics or analgesic drug treatment.

Diseases and *epidemics* are repeatedly mentioned. The great epidemic of the East are cholera, bubonic plague, small pox, typhoid, typhus, measles, and venereal diseases [*Ex* **9**, 9; *Deut* **28**, 27; *Nu* **11**, 33; **14**, 37; **16**, 47; **21**, 27; **25**, 1–9]. The plague that followed the capture of the Ark by the Philistines [*I Sam* **5**, 6–**6**, 21] killed 50,070 of the Hebrews; it would seem that contagion from the Ark was still possible and it was not without reason that the Ark was quarantined for 20 years.

Of the Assyrian army against Ethiopia 185,000 died in one night [*II Kings* **19**, 35]. Such sudden mortality suggests either cholera or plague. A pestilence of 70,000 mortality is recorded in *I Chron* **21**, 14 and *Ps* **91**, 5–10. *Leprosy* is abundantly mentioned [*Lev* **13**, 1–17; *Ex* **4**, 7; *Num* **12**, 10; *II Kings* **5**, 27; **7**, 3; **15**, 5].

Individual cases of disease cited: *Infantile paralysis* [*II Sam* **4**, 4]; *Dysentery* [*II Chron* **21**, 18]; *Homicidal melancholia* [*I Sam* **16**, 14; **18**, 10–11; **19**, 9–24; **20**, 33; **22**, 17]; *Inscaity* [*Dan* **4**, 33]; *Dwarfism* [*Lev* **21**, 29]; *Gigantism* [*Deut* **4**, 11; *I Sam* **17**, 1; *II Sam* **21**, 16–20]; *Alcoholism* [*Gen* **9**, 20; **19**, 33; *II Sam* **11**, 13; *I Kings* **20**, 16 etc.]. *Heart disease* [*Deut* **28**, 65]; *Sunstroke* or *meningitis* or *pernicious malaria* [*II Kings* **4**, 18; *Ps* **121**, 6]; *Pneumonia* [*II Sam* **12**, 15–18].

Circumcision is the only surgical procedure mentioned in the Bible. There is a reference to the *roller bandage* in the treatment of fractures [*Ezek* **30**, 22].

Diseases of the eye were common and numerous in the East. This is largely due to the presence of *trachoma* and of gonorrheal ophthalmia [*Gen* **27**, 1; *I Sam* **4**; *I Kings* **14**, 4]. Thus, Leah was tender-eyed, probably the result of *trachoma* [*Gen* **29**, 17].

Woman's diseases are mentioned [*Lev* **15**, 19–24; **15**, 25–30]. Sterility was regarded as a great calamity [*Gen* **18**, 11; **20**, 17; **25**, 21; *I Sam* **1**, 5; *II Sam* **6**, 23; *II Kings* **4**, 4].

Obstetrics: The suffering of child-birth is the penalty for the sin of **Eve** [*Gen* **3**, 16]. Midwives in the Near East from the earliest times have conducted deliveries upon the obstetric chair [*Ex* **1**, 16]. The obstetric chair is mentioned by ancient Greek authors. Rachel offers the use of her knees in lieu of an obstetric chair, as a symbol that the child borne by her maid is her own [*Gen* **30**, 3].

rather exact account of real natural phenomena. Several examples are:

- *Volcanism [Ex.* **19**, *16;* **20**, *18; Deut* **4**, *11; Jud* **5**, *5; Micha* **1**, *3–4; Psa* **97**, *3–5]. It is the oldest known description of a volcanic eruption based on a very careful observation. In addition to the pillars of cloud and fire, the account contains no fewer than seven features, each characteristic of a volcanic explosive eruption: noise, flames, smoke, quaking, summit cloud, electrical discharges and darkness.*
- *Eclipses. The events:* **Sept. 30, 1131 BCE** *[Jud* **5**, *20],* **Aug. 15, 831 BCE** *[Amos* **8**, *9],* **June 15, 763 BCE** *[Amos* **5**, *8; Isa* **24**, *19–23],* **May 09, 594 BCE** *[Ezek* **8**, *14–16],* **Sept. 21, 582 BCE** *[Ezek* **30**, *18;* **32**, *7–8],* **Mar. 28, 517 BCE***[Zach* **14**, *6],* **Mar. 01, 357 BCE** *[Joel* **3**, *3–4],* **July 04, 336 BCE** *[Joel* **3**, *3–4], are among he earliest documented descriptions.*
- *Comet apparitions.* **1230 BCE** *[Exod* **13**, *21],* **May 11, 1198 BCE** *[Josh* **5**, *13],* **Dec. 02, 986 BCE** *[I Chron* **21**, *16],* **July 28, 616 BCE** *[Ezek* **1**, *4; Hab* **3**, *4–12].*
- *Earthquakes.* **2100 BCE**, *the destruction of Sodom and Gomorrah [Gen* **19**], **ca 1210 BCE**, *the fall of the walls of Jericho [Psa* **114**, *3–8],* **759 BCE** *[Amos* **1**, *1; Zach* **14**, *4–5; II Chron* **26**, *16–23].*
- *Severe climatic changes* causing *floods, drought* (famine), *epidemics* and *mass-migration [Gen* **6–9**; *I Kings* **17**–**18**; *Gen* **41**, *29–57; Jer*[83] **18**, *14; Proverbs* **25**, *13].*

The creation of the universe ex nihilo *(from nothing) is described in the first chapter of Genesis. Genesis tells how God created the universe by organizing a preexisting chaos, "the waters": Genesis* is *silent about where the initial chaos came from since the priests who wrote the account had no interest in the question. Their concern was how God created* order *in the universe.*

Next to cosmogony, treated in the first chapter of Genesis, (Table 1.2) *the following two chapters relate to anthropology – the origin of human civiliza-*

[83] A careful reading of the Bible reveal around 600 BCE more frequent snow than now and that it lay longer into the summer on the heights of the Lebanon, possibly throughout the year.

tion. The story of man's expulsion from paradise alludes to the transition from food-gathering to food-producing society[84] *(ca 10,000–8000 BCE).*

The outburst of intellectual energy that characterizes the extraordinary phenomenon of Hebrew prophecy during 750–350 *BCE, had its counterpart in an akin occurrence in the East: the foundation of new philosophies of religions by* ***Confucius***, ***Buddha***, ***Lao Tsu*** *and* ***Zoroaster***, *all of whom flourished during the* 6^{th} *century BCE. These spiritual leaders had the capacity to persuade their fellow-men to adopt new conception of the universe and of themselves; they thus radically transformed the intellectual atmosphere of their time.*

[84] When the glaciers still covered parts of Northern Europe, the whole area extending from the Atlantic Ocean to Iran was virtually a gigantic garden, providing ample food for animals and man ('Paradise'). As climate became drier, abundance of edible plants diminished and man was forced to produce a great part of his food: domesticate animals and use the plough to cultivate the land in the valleys of the great rivers.

Table 1.2: Dating of key events in the Book of *Genesis*, consistent with discoveries of modern science up to 2000 CE

Event	Thousands of years ago	Reference
Origin of the universe	ca 14,000,000	"In the beginning..." (**1**, 1)
Undecoupled matter and radiation; light was continually emitted and screened		"...darkness was on the face of the deep" (**1**, 2)
Light – transparent universe; Decoupling of matter from radiation; recombination of plasma to neutral hydrogen atoms	ca 13,999,700	"Let there be light."(**1**, 3) "...divided light from darkness."(**1**, 4)
Formation of primitive stars	ca 13,100,000	"Let there be light in the firmament of the heaven" (**1**, 14)
Primitive plant-life on earth	ca 1,600,000	"Let the earth bring fourth grass." (**1**, 11)
Primitive life at sea	ca 1,000,000	"Let the waters bring forth abundantly the moving creature that hath life." (**1**, 20)
Evolutionary explosion of life an earth	ca 540,000	"Let the earth bring forth the living creature..." (**1**, 24)
Appearance of hominides	ca 4,500	"Let us make man..." (**1**, 26)
Branching off of Homo Sapiens from the Neanderthals; The biblical *Eve*	ca 200	"And Adam knew Eve his wife; and she conceived..." (**4**, 1)
Man's expulsion from "Paradise" – past glacial warming; advent of agriculture	ca 11	"...sent him forth from the garden of Eden, to till the ground..." (**3**, 23)
The Mesopotamia Flood	ca 7.6	"...the water of the flood were upon the earth" (**7**, 10)
Advent of civilization	ca 6.2	"...scattered them abroad upon the face of all the earth" (**11**, 8)

648 BCE, Apr. 06 **Archilochos of Pharos**. A Greek poet. Described a solar eclipse on that date, which he may have watched in Pharos on Thasos (Cycledes Islands).

644 BCE Windmills in Neh, Persia.

630 BCE **Zoroaster** (Zarathustra, ca 660–583 BCE, Persia). Philosopher and prophet. Preached ethical monotheism, insisting on moral values, especially truth, justice and agricultural labor. Founded the Zoroastrian religion. Cyrus the Great and Darius the Great, spread his religion throughout their empire. After Alexander the Great conquered Persia, Zoroastrianism began to die out.

Zoroaster was born in the vicinity of Lake Urmiyah in Azerbaijan, in northern Persia. At the age of 30 he came out of the wilderness to preach his new religion.

626–574 BCE **Jeremiah** (Yirmiahu, 644–574 BCE). The last pre-exilic Hebrew prophet. Historian and biblical author and editor. Lived at the time of the decline and fall of the Hebrew monarchy[85]. He came of a priestly family descendant from Moses (the *Shiloh* line).

After the discovery of the Deutronomic Code in the days of King Josiah (622 BCE), Jeremiah (perhaps with the assistance of his scribe Baruch ben Neriyah) set forth to compile the final version of Deutronomy on the basis of ancient texts. It is believed[86] that he compiled the books of Joshua, Judges, Samuel and Kings, and the Book of Lamentations. Jeremiah died in Egypt.

ca 600 BCE *Phoenicians* sent by the Egyptian King Necho II (d. 593 BCE) sailed around Africa. These voyages took about two years each, going

---

[85] He witnessed six major political events in the Near East; which deeply impacted his ideology:

- 625 BCE; Scythians overrun Western Asia; Judah escaped serious damage;
- 612 BCE; *Nineveh* fell to the Babylonians; end of Assyrian Empire;
- 609 BCE; King Josiah killed at Megiddo while attempting to oppose the northward march of Egypt;
- 605 BCE; Egypt defeated by Babylon in the battle of Carcemish; Judah comes under Babylonian rule;
- 597 BCE; Babylonian captured Jerusalem and deported King Yehoiachin to Babylon;
- 587 BCE; Babylonian destroyed Solomon's Temple, sacked Jerusalem and deported many Judeans to Babylon; end of Hebrew monarchy in Israel.

[86] Freedman, R.E., *Who Wrote the Bible*, 1987.

through the Red Sea, around Africa, and back to Mediterranean by way of Strait of Gibraltar.

600–500 BCE Cooler weather, increase of rainfall and flooding in Europe and Middle-East. Confirmed by Herodotos' description of the climate of the Northern Black Sea. Evidence in the Old Testament.

ca 600 BCE Completion of the *Etemenanki Ziggurate Tower*[87] in the ancient city of Babylon[88] in honor of Marduk, the Babylonian Jupiter. After several destructions and rebuilding, it reached its final form under Nebuchadnezzar II. Then it towered skyward for nearly 100 meters with seven stages, pinnacling with a brilliant blue-glazed temple for Marduk. It was covered with Enameled bricks in colorful patterns, as if it was clothed in the scaly skin of some monstrous reptile. Some anthropologists believe that the tower was meant as a landing platform to facilitate the gods' descent to earth from the heaven to which they have vanished. Thus the Tower of Babel was built for communication with the gods.

ca 600 BCE According to Herodotos, Phoenician seamen circumnavigated Africa from east to west. Their enterprise, however, bore no results; the opening-up of the oceanic route from Europe to India, the East Indies and China, awaited the discoveries of Portuguese navigators about 2100 years later.

600–300 BCE (**Thales to Euclid**) Development of postulational thinking and the foundation of systematic logical structures in mathematics.

Mathematics, as we understand it today encompasses any activity that arises out of, or directly generates, concepts relating to numbers or spatial configurations together with some logic.

In trying to understand things of the physical universe, the ancients repeatedly encountered certain basic *patterns*; these were patterns of *form* (such as the shapes and paths of the astronomical bodies), patterns of *arrangements* (such as the symmetrical arrangements of the limbs of living creatures), or patterns of *relation*. To this last group belong the orderings in man's minds of sound, which we call *music*, the ordering in man's minds of forms and color,

---

[87] Some Biblical scholars connect it to the *Tower of Babel* (*Genesis* **11**) and the *Confusion of Tongues* which may have echoed the labor troubles during the building of Etemenanki. We know that when Alexander the Great set out to rebuild the tower, he put 20,000 men to work. It stands to reason that the original tower must have required many more laborers than that.

[88] 80 km south of today's Baghdad.

which we call *art*, the ordering in man's minds of words, which we call *poetry*, or the ordering in man's minds of thought, which we call *philosophy*. To the study of these and all other such pattern the Greek called *Ta mathémata*, which means: '*what is learnable*' (*manthanein means to learn*) *and also from the word mathésis, which means* '*the teaching*'. *Thus* '*mathematics*' *essentially stands for those things that can be learned and at the same time also taught. The idea that the Greeks wished to convey by the choice of this word is that only he who can truly learn can truly teach, i.e. the genuine teacher differs from the pupil only in that he can learn better and that he more genuinely wants to learn. In the last analysis, in all teaching, the teacher learns the most.*

6^{th} century BCE an important epoch in the history of humanity. It was an age when **Buddha** was searching for a path to enlightenment in *India*, **Confucius** was teaching new rules for society in *China*, *Ionian* philosophers were initiating a tradition of scientific thinking in *Greece*, and when the exiled *Hebrews* in Babylon were collecting the messages of their prophets in a holy scripture. On the other flank of Mesopotamia another religious movement was initiated by an *Iranian* prophet, **Zoroaster**, who preached his message of cosmic strife between the God of Light and the principle of evil.

ca 585 BCE **Thales of Miletos** (624–548 BCE). The first known Greek philosopher, scientist and mathematician. Was the first to attempt an explanation of the world in terms of its observable nature rather than by mythology. This meant that his conclusions could be subjected to rational arguments about whether they were right or wrong.

None of his writing survived, so it is difficult to determine his views and to be certain about his mathematical discoveries. With him began the study of geometry and scientific geography and astronomy in Greece. The invention of geometry as an abstract mathematical theory supported by rigorous deductive proofs was one of the turning points of scientific thinking. It led to the creation of mathematical models for physical phenomena.

Thales taught the *sphericity of the earth*, the *obliquity of the ecliptic* and the *causes of eclipses*. His visit to Egypt and his exposure there to the heritage of Babylonian astronomy may have aroused his interest in these subjects.

Thales was an Ionian, but possibly had some Phoenician blood in his veins. During middle life Thales engaged in commercial pursuits, which took him to Egypt. He resided there and studied the physical sciences with the Egyptian priests, and upon his return founded the Ionian School of Astronomy and Philosophy. Thales is credited with the prediction of the *year* of the solar eclipse of May 28, 585 BCE. Estimated the height of an Egyptian pyramid by measuring its shadow when his own shadow was equal to his height.

Thales noticed that matter comes in three forms – liquid, solid and gas. He investigated the phenomenon that amber, when rubbed, gained the property of attracting light objects. He also knew about the power of *lodestone* to attract iron[89].

His great contribution to mathematics is in fitting the Babylonian and Egyptian empirical geometrical rules in a logically connected abstract system through which one advances by means of demonstration from theorem to theorem. Specifically, he is credited with five theorems of elementary geometry:

(1) A circle is divided into two equal parts by its diameter;

(2) The base angles of an isosceles triangle are equal.

(3) The angles between two intersecting straight lines are equal.

(4) Two triangles are congruent if they have two angles and one side equal[90].

(5) An inscribed angle in a semicircle is a right angle.

Some idea of the advancement in astronomy made by the Greeks can be gleaned from the fact that Thales taught the *sphericity of the earth*, the obliquity of the ecliptic, and the causes of eclipses. According to **Diogenes Laertius**[91] (fl. 222–235 CE) he was first to determine the length of the year. It is fair to assume that he borrowed much of his information from Egypt, though the basis for predicting eclipses rests on a period of 6585 days, known as the *saros*, discovered by the Chaldeans. Thales thought that all things are derived from the single element *water* and that the solid earth was afloat on the world-encircling flat ocean.

---

89 This appears to have been familiar to the Greeks as early as 800 BCE, and is mentioned by Homer. However, the property of orientation, in virtue of which a freely suspended magnet points approximately to the geographical north and south, is not referred to by any. European writers before the 12^{th} century, thought it is said to have been known to the Chinese at a much earlier period. The oxide Fe_3O_4 occurred plentifully in the district of *Magnesia* near the Aegean Coast; hence the name *magnes* or the *Magnesian stone* given to if by Greeks.

90 He applied this theorem to determine the distance between two ships at sea through measurements made on board one of them: In general, to find the distance from A to the inaccessible point B, one erects in the plane a normal AC to AB, of arbitrary length, and determines the midpoint D. In C one constructs a line CE perpendicular to CA, in a direction *opposite* to that of AB, and one extends it to a point E, collinear with D and B. Then CE has the same length as AB.

91 Biographer of the Greek philosophers, from the town of Laerte in Cilicia (or the Roman family of Laertii). Flourished during the reign of Alexander Severus and his successors. He was an Epicurean.

His conclusion that water is the original substance may seem fantastic on the surface, but it becomes far more plausible if one examines it more closely. Water is the only substance that is known to man without difficulty in the three states, solid, liquid and gaseous; it is not difficult to connect clouds, fogs, dew, rain, hail with the ice and snow found in the mountains and the water of the sea and rivers. Water seems to occur everywhere in one state or another; would it be overbold to imagine that it may occur also in hidden forms? Moreover, without water no life is possible, but as soon as water appears, there may be life.

While the Jews were postulating the moral unity of the cosmos, Ionian philosophers, of whom Thales was the first, were postulating its material unity.

While giving the honor of being effectively the first scientist to Thales, one recognizes that Thales was heir to an intellectual tradition whose origins are obscure. Strangely enough, his fame rests mainly on an achievement that we are now obliged to discredit, though its genuineness was accepted as a cast-iron belief until our own day.

Nevertheless, Thales is the father of a new breed of thinkers who have taken upon themselves the task of trying to understand the nature of the physical universe. This endeavor and the various activities arising from it are collectively labeled as *science*.

After Thales, philosophy rapidly began to flourish. More philosophers appeared, with a succession of different explanations of the world. The philosophers who belong to this period (ca 550–450 BCE) are generally known as *pre-socratists*.

ca 580–320 BCE At Laureion (modern Lávrion) in Southern Attica, galena rich in *silver* was mined by the Athenian. The lumps of rock from the mine were picked over by hand and worthless pieces discarded. The ore was then crushed in mortars to facilitate further parting of galena from gangue, and it was washed on sloping trays to effect some separation of placer action. Only after these preliminary concentration steps was the galena reduced to metal by heating it with *charcoal*.

The lead so produced contained 850 g silver per ton and was parted by *cupellation* – air blown over the molten metal converted the lead to litharge (PbO), which was absorbed by a bone ash hearth, leaving a residue of pure silver.

In the 5^{th} century BCE, the annual yield of silver from Laureion was about 2.5 tons. Following the battle of Marathon, Themistocles persuaded the Athenians to use this revenue to build ships for defense against Xerxes. The mines later provided the silver for the Golden Age of Pericles. Against these splendid achievements the balance sheet of history must set the abominable mistreatment of slaves who worked the mine and smelter.

Origins of Philosophy and Metaphysics

The word 'philosophy'[92] *comes from the Greek, philos = love, sophia = science or wisdom. One may loosely define philosophy as a rational method of examining a body of knowledge that provides us with a reasoned framework within which to think. "An unusually stubborn attempt to think clearly" (William James). Plato defined philosophers as those who "are able to grasp the ethernal and immutable, setting their affections on that which in each case really exist."*

The fundamental problem of philosophy is that of the relation between existence and thought. All philosophical tendencies divide up into materialists and idealists.

Philosophy started as a criticism of religious beliefs, by seeking reasons for natural phenomena. Two opposed camps sprang up which still persist to his day: religion on one hand and science on the other. Eventually religion had to invent some kind of 'science' for itself (theology) to justify its existence. Philosophical ideas are of two kinds: Materialism considers that there is noting beyond natural things and seeks to explain them on the basis of science (including even religion). Early form of materialism sought to explain all natural phenomena by mechanical laws.

IDEALISM *starts by assuming the existence of supernatural and divine forces. Idealists imagine things and presuppose the existence of 'spirits'.*

RELIGION *is a combination of beliefs and cult-practices which subordinates human life to a divine super-order. Alternatively it can be defined as a body of knowledge (dogma or revelation) imposed from without (e.g. Bible,*

[92] The sages of Greece used to be called *sophoi* ("wise men"), but Pythagoras thought the word too arrogant and adopted the compound *philosophoi* ("lovers of wisdom"), whence "philosopher", one who courts or loves wisdom.

Koran, Gita etc.). The believer is expected to accept this revelation without question.[93]

The pseudo-science which seeks to give foundation to religion by borrowing from philosophical argumentation is known as Theology.

Syncretism – *The interworking of two or more cultural perspectives into one system.*

Eclectism – *Choosing according to taste, without internal framework of a genuine understanding of function.*

Rationalism *is a philosophical theory which tends to recognize reason as the* unique *source of true knowledge; contrary to* empiricism *which makes perception this source of knowledge.*

Other related concepts are:

Metaphysics *A branch of philosophy that seeks to understand reality beyond what we know from our sense perception, i.e. to seek answers to the question of* why *there are patterns in nature any* why *they are describable in mathematical schemes. It lies outside the scope of physics.*

Fundamental questions of metaphysics:

- *What is real?*
- *How is knowledge possible?*
- *How are the mind and body related?*
- *How can we find truth?*
- *What is the nature of the universe?*
- *How can we reconcile personal freedom and scientific determinism?*

93 There are *exoteric* religions (Judaism, Christianity, Islam, Baha'ism, etc.), *esoteric* religions (Sufism, Lurianic Kabbalah, Gnosticism, etc.) and even *secular* religions (Marxism). *Western* religions are more concerned with the "Manifest" (creation, nature, ultimate purpose of the cosmos and of men). *Eastern* religions are more concerned with the "Unmanifest" (transcendental) and how to attain it.

Teleology*: The study of the evidence of design or* purpose *in nature based on the* belief *that such characteristics exist and are indeed apparent.*

Epistemology*: The theory of knowledge. A philosophical discipline that investigates origin, nature, methods, and limits of human knowledge.*

The two great founders of modern physics, Albert Einstein and Max Planck produced by their contributions to epistemology a revolution in the theories of knowledge that is almost as profound in its impact on philosophy.

System*: a set of interrelated structures that may consist of an hierarchic arrangement of subsets or subsystems.*

Essentialism*: a "realistic" philosophical position that dates back to the idealism of Plato and Aristotle, was then placed into religious scholastic argument by Thomas Aquinas, and finally put into modern methodological form by Karl Popper (1957). Essentialism is concerned with understanding the potential, or universal, meaning of the descriptors of a class or set; it takes an opposite view of that of* nominalism*, which believes that such descriptors are only labels of characteristics. The concept of essentialism, as first proposed, argued that those properties which are common to the many individuals of a set, a class, a group, have a reality exceeding that of their mere occurrence as parts of the individual members of such sets, classes, and so on.*

This position, then, allows one to search within natural groupings for common plans, designs, and patterns, with the expectancy that such patterns will be understandable by analogy. In recent years, essentialism has been considered somewhat sterile, at least in the natural sciences, because it focused on universals of meaningless generality. Plato, on the other hand, used this position to search within nature for order, regularity, and perfection.

Historicism: the approach to science – particularly to science that is historical, as is geology in large part – which assumes that historical prediction (or retrodiction) is a principal aim, attainable by discovering the patterns, laws, and trends that underlie the evolution of history.

570 BCE **Lao Tsu** (604–510 BCE, China). Philosopher. The reputed founder of the religion called *Taoism*. In his *Book of Tao* he preaches non-assertion, the being without desire, and submission to the universal Tao (the way). The Tao represents the characteristic or behavior that makes each thing in the universe what it is. The word is also used to mean reality as a whole, which consists of all the individual "ways". The ideas of Tao were partly a reaction against *Confucianism*. According to Confucianism, people can live a good life only in a well-disciplined society that stresses attention to ceremony, duty, and public service. The Tao ideal, on the other hand, is a person who avoids conventional social obligations and leads a simple, spontaneous, and meditative life close to nature. The Taoist search for knowledge of nature has led many believers to pursue various sciences, such as astronomy and medicine.

Lao Tsu was born in Honan and flourished at Lo-Yang, capital of the Chou dynasty. He died at an unknown place.

ca 563–483 BCE **Buddha (Siddhartha Gautama)**. Founder of Buddhism. Born in southern Nepal to a rich and powerful royal family. At age 29 he became overwhelmed with the conviction that life was filled with suffering and unhappiness and he abandoned his wife and infant son to seek religious enlightenment as a wandering monk.

After traveling throughout northeastern India for about six years, Gautama experienced enlightenment. He believed he had discovered a way for man to escape his unhappy existence. His disciples called him Buddha, which means *Enlightened One*.

To break the eternal cycle of death and rebirth, Buddha preached to follow a code of ethics composed of the Middle Way and the '*Eightfold Way*', the latter consisting of 8 'commandments'.

ca 560 BCE **Anaximander of Miletos** (611–547 BCE). Ionian astronomer[94], geographer and philosopher. One of the first to give a naturalistic rather than a mythological explanation of natural phenomena. He anticipated the theory of evolution by stating that animals came originally from a moist environment, and man evolved from aquatic animals. Anaximander taught (and may have discovered) *the obliquity of the ecliptic*, and is believed to have produced the first map of the known world (although he claimed the earth to be *cylindrical in shape*).

Anaximander introduced into Greece the *gnomon* (for determining the soltices) and the *sundial*.

He was a citizen of Miletos and a companion or pupil of Thales, both of them being pioneers of the exact sciences among the Greeks. His pupil, **Anaximenes of Miletos** (585–525 BCE) was first to suggest that the moon

[94] From the Greek $\alpha\sigma\tau\rho o\nu$ = star; $\nu\epsilon\mu\epsilon\iota\nu$ = to classify or arrange.

receives its light from the sun, and correctly understood (ca 550 BCE) *eclipses* of the moon as being caused by the shadow of the earth, cast by the sun. From this he inferred that the earth is roughly *circular* in section (a disc). He went further than his teacher in completely ignoring the mythical elements in the natural laws. He taught that, with age, the earth broke down by its own weight, thus causing the motion of earthquakes.

ca 551–479 BCE **Confucius (Kung Chiu)**. The most influential philosopher in Chinese history. The name Confucius is a Latin form of his title Kung-fu-tzu, which means Great Master Kung. At his death he was largely unknown throughout China. His disciples spread his teachings. In a work referred to as the *Annals of Lu*, his native state, Confucius has sketched a history of 242 years from 722 to 481 BCE. Therein he recorded 36 eclipses of the sun. His description of the 720 BCE eclipse is one of the earliest astronomical publications on record.

Ancient Eastern Philosophy (ca 1500 BCE–500 CE)

Philosophy is the search for knowledge and for the means to express it, and Eastern philosophy has many forms of both.

Eastern philosophy is a vast collection of philosophical and religious ideas that derive from the ancient cultures of India, China, Persia, Japan, Korea, Tibet, etc, and from many different traditions and forms of thought that shaped the development of the East from earliest recorded times; it is a multifaceted set of ideas that reflect the complex societies they grew out of.

Unlike Western philosophy, the Eastern tradition does not attempt to distinguish clearly between philosophy and religion. While Western philosophy has always been more concerned with truth, logic, reason and independence, the search for knowledge in Eastern philosophy has always been more holistic, and less scientific; where Western science has sought absolute truth in rationality, Eastern philosophy has sought-complete enlightenment via reflection.

Western philosophy has always tended to over-emphasize the individual and individual things. In contradistinction, Eastern thought resolutely believes in the interconnectedness of all things and of the need to escape from the limits of individualism, which is connected to materialism and bodily pleasures. In contrast to the Western idealization of power, money and science, Eastern traditions have honored the thinker, the sage, the poet and the mystic. They declare the reality of the unseen world and venerate the call of spiritual life.

In *India*, history, myth, religion and philosophy interacted within a very long tradition, dating back to ca 3000 BCE. There are two main schools, *Hinduism* and *Buddhism*. Hinduism derived from ancient Vedic religions brought to India by people who called themselves *Aryans*. They arrived in India in waves between 2000 and 1000 BCE.

Since there was no written language in India before the 11^{th} century BCE, the Vedas were transmitted by word of mouth in the form of cryptic poetry. The *Rig-Veda*, the oldest of them all, was created during 1500–900 BCE. The invading Aryans created the cast system.

The main thing about Hinduism and Hindu philosophy is that they do not claim one master, one truth and one revealed wisdom, but many. This diversity is due to the very mixed ethnic groups and invasions of India throughout its history, and to its varied climate, geography and customs.

India has been at the crossroads of trade, culture and religion for thousands of years, continually absorbing, adapting and redefining its own beliefs. As in other regions of the world, the great spiritual upheaval in India during the Golden Age 800–200 BCE (see Table 1.1), derived from the fusion of national cultures with foreign influences.

Developing over many centuries through hymns and texts, the Vedas (meaning "knowledge") became a living, unified and complex religion and philosophy. The fullest philosophical expression of the most dominant strand within Hinduism are the *Upanishads* (800–300 BCE). This philosophy was not a philosophy of the mind but a philosophy of life in which the individual had to live the problem of trying to find deliverance. It is concerned with seeking self-enlightenment through the search for identity and salvation through a higher ultimate reality which lies behind wordly appearances.

Buddhism is opposed to the philosophy of the Vedas. It is less strictly philosophical, being more concerned with practical liberation from suffering. Buddhism avoided the ritual and elitism of the Vedic approaches, teaching in the common languages of the day and supporting an egalitarian approach to Enlightenment. It is not interested in questions about the ultimate nature of reality, but simply in the down-to-earth business of achieving *nirvana*, or the escape from suffering.

Unlike Hinduism, Buddhism asserts that there is no unique individual self[95]*: the 'self' is an illusion created by the combination of mental and physical activities:* meditation *is a way of approaching the mind as pure mind to get past the illusion of self.* Consciousness *is the combination of the many forms and states of being which are like a stream of impressions, ideas and sensations.* Mind *links these states that are thought of as the* 'person'*, but only mind exist through* rebirth*.*

Buddhism did not fare well in India itself, but became a very important force in many parts of Asia and the East, particularly China[96] *and Japan. However, Chinese culture, although Eastern, is markedly different from Hindu. What fundamentally distinguishes Chinese culture is its sense of harmony, interconnectedness, language and continuity. China has a cult of the Old in which* tradition *is everything. Also, the Chinese* language *is much more allusive and dependent on context than Romance languages and is not easily amenable to logical philosophy.*

Chinese culture is one of the most ancient and self-contained we know of, and its longevity is one of the key features that mark it out as unique. Its philosophy, rather like Hindu philosophies, shows a complexity and unity which incorporates many diverse veins and philosophical strategies that stretch over thousands of years. In philosophical terms, there is a period known as the time of the hundred Schools (400–200 BCE) *in which many different philosophical positions were advanced, but they almost all relied on tradition and past ideas for authority.*

Chinese culture does not depend on the idea of God to whom everyone is answerable, nor do its original myths talk about a supernatural creation. Chinese culture is secular and philosophical in the broadest sense.

From the earliest days of Chinese civilization, traditional ways of thinking were passed from generation to generation. Traditional ideas were treated with the kind of respect that is often accorded to religion. Also, the language of ancient China remained unchanged throughout the centuries, so that Confucius can be understood today in much the same way as 2500 years ago.

To sum up, the characteristics of Chinese civilization are these:

---

95 Western *postmodern* philosophy often seems to claim that the self is fiction [e.g. **Jacques Lacan**, 1901–1981].

96 Buddhism was brought to China by various Hindu missionaries traveling along the silk route and the channels of trade. The influence of Buddhism began during the reign of *Emperor Ming* (58–75 CE).

- *The oldest continuous culture in the world (ca 5000 years old), and fundamentally a product of an agricultural society.*
- *Secular and multi-religious civilization.*
- *Its language is an important unifying factor, and expresses a particular way of thinking.*
- *Confucian philosophy, or ethics, underpins most of later Chinese civilization and culture.*
- *Religion and philosophy are closely interwoven and therefore difficult to separate out.*
- *Much Chinese philosophy extolled the virtues of wise rulers and a well-governed people.*
- *The family, and familial relations, are the basis of Chinese society, with women at the bottom of the pile.*

The three over-arching philosophies are: Confucianism, Taoism *and* Buddhism, *but they all interact with one other. Chinese philosophy is not about accumulating facts, but about elevating human nature. It was basically humanistic – it thought of man as being the center of the universe. It is not divorced from daily ordinary activities, yet it is very concerned with leaving this world behind in achieving nirvana (Buddhism).*

Confucians seem to believe in a predetermined fate. Next to the Confucian Analects, *the Tao Te Ching (the 'way of the Power', supposedly by* ***Lao Tsu****), is the most famous work of Chinese philosophy.*

Tao (the 'way') means the Universal Path. It is the force that governs the universe, the ultimate reality which cannot be described, but which is the origin of all things. The Taoists did not think much of Confucius trying to make the world a better place. Because of their position on the forces of nature and the ultimately unchanging reality *that lay behind all change, the Taoists generally did not believe in progress and science. Holding that the conquest of the world, comes invariably from doing nothing, they wanted to escape from the world, rather than challenging it. Thus Taoists aimed at a life of simplicity and harmony with Tao, not being ruled by intellect, but by a natural power, the Te. However, the Confucians held that the paradoxical sayings of the Taoists did not add up to anything other than the avoidance of complex realities.*

Although Buddhism ideas of no-self, withdrawal from the world and self-liberation seem to be the very opposite of Confucian social thinking, it managed to implant itself in China, in a culture that was practical, secular and not very fond of foreign things.

Perhaps the condition of the Chinese peasantry was seriously grim and something that promised definite release would seem attractive. Whatever the reasons, the introduction of Buddhism to China was a cultural revolution with a long-term impact.

***Bodhidharma** (ca 460–534 CE) brought Chán (Zen)*[97] *which later became important in Japan. Chán emphasized meditation and study. The introduction of Buddhism to Japan in the* 6^{th} *century CE, was the crucial step in the development of Japanese philosophy. This led eventually to the formation of the Japanese form of* Zen Buddhism*, which epitomizes the special character of the Japanese Way.*

Japanese Ways of thinking about the world are concerned with the clarity and precision of images, rather than with formal logic. Japanese philosophy can be seen in its art, its calligraphy, its ritual, in the order and interconnectedness of its culture. The key ideas of Zen are:

- *Genuine Enlightenment is* instantaneous*. Preparation may be necessary, but true realization is a total experience.*
- *Zen involves action through non-action, working towards a result in which no-self in exercised.*
- *Enlightenment and ordinary experience are related, but scriptures, texts and theory do not provide the path to nirvana. One does not have to retreat to the mountain to find Enlightenment.*
- *Zen enters into everything, calling for a* mastery between mind and body*, a sense of being through doing which transcends the act.*
- Meditation *leads to the intuitive experience which transcends ordinary reality. It can be described as finding one's true nature. One aims for the losing of 'body-mind' to achieve a non-conceptual awareness.*
- *The enlightened nature of the whole world is that '*nothingness*' that we must recognize as the essential emptiness of all things. Things do not have a meaning in themselves, but only in relation to other things.*

[97] *Zen*, the Sanskrit for *meditation*.

ca 550 BCE *The Temple of Artemis at Ephesos* was one of the largest and most complicated temples built in ancient times. Designed by the architect **Cherisphron** and his son, **Metagenes** in the Greek city of Ephesos (on the Aegean coast of Asia Minor), and dedicated to the Greek goddess Artemis. It was entirely marble, except for its tile-covered wooden roof, and its foundation measured 115×55 m^2. It had 106 columns, about 12 meters high, in a double row around an inner space. Cherisphron invented a new method to transport the huge columns. His son improved the method of transportation of columns and of putting them into place.

The temple was burned down in 356 BCE, and another one like it was built on the same foundation by **Deinocrates of Rhodes**, the Greek architect of the age of Alexander the Great. Goths burned down the second temple in 262 CE. Only the foundation and parts of the second temple remain.

The earliest clues, indicating to the existence of *Ephesos* are found in the 14^{th} century BCE Hittite documents. There, they were mentioning the city of *Apasas* around the Miletos region, where some artifacts belonging to the *Mycenaean* era were found. The city was colonized by the Ionians in the 11^{th} century BCE. Its ruins lay today about 80 km south of Izmir. During the 6^{th} centuries BCE, the city came under control of **Croisos**, king of Lydia and later under the rule of the Persian king **Cyros**.

Artemis, the most sacred goddess in Anatolia, had a long history of evolution going back thousands of years. The earliest forms of Artemis statue were found in Catalhoyuk and Hacilar, Central Anatolia, where its earlier name was Kybele. Then, the same goddess earned a wide respect and acceptance from Rome to Mesopotamia and even Arabia. Arabs named her *Lat*, Egyptians – *Iris*, Romans – *Diana* and Ionians – *Artemis*.

Artemis descended from the primitive Sumerian goddess of nature. She always remained the *virgin-mother of all life* and an embodiment of fertility and production power of the earth. The cult of Artemis survived till the edict of **Theodosius I** (394 CE) closed the pagan temples. Consequently, the material of the Temple of Artemis was quarried extensively for the construction of the nearby Cathedral of St. John Theologos. The Ecumenical Council of Ephesus (431 CE), headed by Emperor **Theodosius II**, officially replaced the cult of Artemis by the cult of the Virgin Mary. It was thus elevated from the rank of mother of the Mesiah to that of god's mother; thus closing the cycle of the ancient Sumerian virgin cult one full circle.

During 1866–1874, Ephesos was first excavated for the British Museum by the British Architect **John Turtle Wood** in an effort to locate the Temple of Artemis. After many explorations, Wood struck the actual pavement of the temple on Dec 31, 1869.

In 1904–1906 another British mission, directed by **David George Hogarth** (1862–1927) renewed the excavation. He established the chronology of its famous shrine from remnants, and on reaching deep levels, found some significant treasure dating from 650–550 BCE. The ivory and gold objects showed that Ionian Helenism, from its beginning, had borrowed freely from oriental traditions.

Of the Temple of Artemis even ruins were not found: there is absolutely nothing remaining above the ground. When the Byzantic emperors prohibited Pagan cults, the goddess was dethroned and the temple itself was taken to pieces. Vestiges from it can be found in the city buildings erected during the Christian epoch or in St. Sophia in Constantinople, to where many columns were taken.

The apostle Paul stayed in Ephesos but was driven away by the supporters of the cult of Arthemis. The apostle John stayed and died there. Alexander the Great was received by the Ephesonians in 334 BCE and established a democratic government in the city. During the summer of 33 BCE, Mark Antony was at Ephesos with Cleopatra, assembling the forces used against Octavians.

538–331 BCE *Rise and fall of the Persian Empire*. **Cyrus the Great**[98] (ca 580–530 BCE), a Zoroastrian, conquered Babylonia (539) and founded the ancient Persian Empire, which extended from the Indus to the Mediterranean, and from the Caucasus to the Indian Ocean. Good roads, with stations for royal messengers, made possible regular communications within the empire. A canal was dug from the Nile to the Red Sea by **Darius I, the Great** (reigned 521–486 BCE). A revolt of the Ionion Greeks in Asia ended in the fall of Miletos (494), but the war against the European Greeks was unsuccessful (battle of *Marathon*, 490 BCE). The son of Darius I, **Xerxes I** (ca 519–465 BCE) ascended to the throne in 485 BCE. In 483 BCE he collected the largest army that was even known before him, over 180,000 men drawn from all parts of the empire, with an immense fleet that the Phoenicians had assembled for him. He used a double line of ships to form two bridges across the Hellenspont, and cut a canal through the isthmus of Mount Athos Peninsula.

In 480 BCE Xerxes sent his warriors across the Hellenspont and invaded Greece. He won a victory at *Thermopylae*, entered Athens and burned all houses and temples. But his fleet was crushed at the sea battle of *Salamis*

[98] He permitted the Jews to return to Jerusalem (538 BCE) from their captivity in Babylonia (586 BCE), and rebuild the Solomon Temple. The first wave of ca 50,000 people returned in 537 BCE and the next in 458 BCE (Ezra), and 445 BCE (Nehemiah). The Second Temple in Jerusalem was built during 519–516 BCE.

(480). A Greek offensive began in 465 BCE, and after the peace treaty of 446 BCE, Persia was on the decline.

In 401 BCE, **Cyrus the Younger** employed 10,000 Greek mercenaries in a civil war against his brother. But Cyrus and the Greek commanders were killed, and the 'ten thousand' were stranded in a strange country without a leader. They chose **Xenophon** (430–355 BCE) who lead them during a five month's retreat (401–400 BCE) from Cunaxa on the Euphrates through Kurdistan and the highlands of Armenia and Georgia to Trapezus (Trebizond) on the Black Sea, a trek of 2410 kilometers. Xenophon described this march in his *Anabasis*. Although a soldier and a man of action, Xenophon is best known as an historian and a disciple of Socrates.

ca 535 BCE **Pythagoras of Samos** (ca 580–500 BCE). A Greek philosopher and mathematician who clothed his wisdom in a mysterious oracular form, and made momentous and lasting contributions to mathematical knowledge. In particular, he introduced the notions of *axiom* and *proof* into geometry: the very terms *mathematics*, *theory*[99] and *philosophy*, as they are known today, were originated by the Pythagoreans.

Pythagoras, the second person (after Thales) to be mentioned by name in the history of mathematics, was the founder of the semimystical Pythagorean brotherhood. First to furnish a logical demonstration to the theorem that was named after him, although he did not in fact discover it himself. Pythagoras discerned the role played by numbers in music i.e. that harmony depends upon numerical ratios.

To Pythagoras the pure relations of *numbers* in arithmetic and geometry were the changeless reality behind the shifting appearances of the sensible world. In contrast to the Ionians, he taught that reality can be known not

---

[99] From the Greek *theoria* = a viewing, from *theoros*, from *thearos* (spectator), from *theasthai* (to behold) – whence also *thea-tron* = place for beholding things (the *theater*). It then diffused into Latin as *theoria*, French: *théorie* (1496), Spanish: *teoria* (1580), English: *theory* (1597), German: *theorie* (1700), and Russian: *teoriya* (1720).

Pythagoras proclaimed that the pursuit of disinterested knowledge is the greatest purification, and that the highest kind of life is the *theoretical* or contemplative. It is noted that in Greek, *theorein* is used for the contemplation of a spectacle such as the olympic games or the contemplation of truth; *theorema* may mean a spectacle but also speculations; *theoria* is a viewing or a theory. However, our words: theorem, theory, theoretical, have lost the early concrete senses and preserved only the abstract ones.

through sensory observation, but only through *pure reason*, which can investigate the abstract mathematical forms that rule the world.

Pythagoras was born on the Aegean Island of Samos, not far from Miletos. According to an old tradition recorded by Aristotle and his pupil Aristoxenes, Pythagoras had made extensive journeys to practically all Oriental countries, probably going as far as India. He remained in Babylon for a few years, during which time he learned from the Magi the theory of numbers, the theory of music and astronomy, and was initiated by the priests into oriental mysticism. This lore and wisdom served later as the basis for the teaching and learning of the Pythagorean school.

Returning home after years of wandering, he found Samos under the tyranny of Polycrates and much of Ionia under Persian dominion, and accordingly migrated to the Greek port of Crotona, located in the boot of southern Italy. There he founded a brotherhood of believers among the aristocrats of that city. In addition to being an academy for the study of philosophy, mathematics and natural science, it developed into a closely knit brotherhood with secret rites and observances[100]. This order later spread from Croton to a number of Greek cities in Italy and seemed to have played an important role in the political life of these cities.

In time, the political power and aristocratic tendencies of the brotherhood became so great that the democratic forces of southern Italy destroyed the buildings of the school and caused the society to disperse. Pythagoras fled to Metapontum, Lucania, where he died, maybe through murder by his pursuers. The brotherhood, although scattered, continued to exist for at least two more centuries.

What distinguished the Pythagoreans from other mystery rites is that mathematics formed a part of their religion. Their doctrine proclaimed that number was the essence of all things and that God has ordered the universe by means of numbers. God is unity, the world is plurality and it consists of contrasting elements. It is harmony which restores unity to the contrasting parts and which moulds them into a cosmos. Harmony is divine, it consists of numerical ratios. Whosoever acquires full understanding of this number-harmony, becomes himself divine and immortal.

[100] He preached the immortality and the transmigration of the soul (it is still the belief of many sects in India). After a testing period and after rigorous selection, the initiates of this order were allowed to hear the voice of the Master behind a curtain, but only after some years, when their souls had been further purified by music and by living in purity in accordance with their regulations, were they allowed to see him.

Music, harmony and numbers – these three are indissolubly united, according to the doctrine of the Pythagoreans. All three are among the essential elements of the Pythagorean system of education and of its path for the elevation of the soul. It was from this mystical doctrine that the exact science of the later Pythagoreans developed.

Not much is known about the true achievements of Pythagoras in theory of numbers, geometry and astronomy. Our sources are mainly secondary: the Neo-Pythagoreans **Nicomachos of Gerasa** (ca 100 CE), **Iambilichus** (300 CE) and the 3 arithmetical books of **Euclid**. It is also impossible to separate the contributions of Pythagoras himself from those of his followers.

The Pythagoreans introduced the *perfect numbers* [equal to the sum of their true divisors, e.g. 6, 28, 496, 8128][101], *amicable numbers* [each of which equals the sum of the proper divisors of the other, e.g. 284 and 220], *figurative numbers* [sequences of numbers, each of which is a partial sum of a certain arithmetical progression[102]]. Pythagoreans have been given credit for a rule for determining numerical solutions of the indeterminate equation $x^2 + y^2 = z^2$. Apparently Pythagoras adapted from the Babylonians various remarkable ideas about numbers and about their mystical significance. His disciples continued the investigations in a more systematic manner and built them into a logically consistent form[103].

---

101 The general rule of their formation was proved by **Euclid**: when the sum $1 + 2^1 + 2^2 + \cdots + 2^{n-1} = p$ is a prime number, then $2^{n-1}p$ is a perfect number. Thus, $2^{n-1}(2^n - 1)$ is an *even* perfect number if 2^{n-1} is a prime (*Mersenne Prime*). **Euler** proved that this formula gives *all* even perfects.

Euclid's formula leads to all kind of weired and beautiful properties of perfect numbers [e.g. the sum of the reciprocal of all divisors of any perfect number always equals 2]. It is not known if there is an odd perfect number nor if their number is infinite. The 30^{th} perfect number was discovered in 1985, with $n = 216,091$, having 130,099 digits.

As for *amicable numbers*, the Pythagorean brotherhood regarded 220 and 284 as symbols of friendship. Indeed, we find in *Gen* (**32**, 14) that Jacob gave Esau a gift of 220 goats as a token of friendship! More than 1000 amicable pairs are now known, the largest of which has 152 digits in each pair.

102 Triangular numbers $1, 3, 6, 10, 15, \ldots$, $a_n = 1 + 2 + 3 + \cdots + n = \frac{1}{2}n(n + 1)$;
Square numbers $1, 4, 9, 16, 25, \ldots$, $a_n = 1 + 3 + 5 + \cdots + (2n - 1) = n^2$;
Rectangular numbers $2, 6, 12, 20, \ldots$, $a_n = 2 + 4 + 6 + \cdots + 2n = n(n + 1)$;
Pentagonal numbers $1, 5, 12, 22, \ldots$, $a_n = 1+4+7+\cdots+(3n-2) = \frac{1}{2}n(3n-1)$.
The names of these sequences stem from the fact that they can be arranged in arrays with the corresponding geometrical shapes.

103 It is believed that Pythagoras knew the identity $n^2 + \left(\frac{n^2-1}{2}\right)^2 = \left(\frac{n^2+1}{2}\right)^2$. From the writings of later Greek mathematicians we gather that Plato (ca 380

In geometry, the Pythagoreans were acquainted with the cube, the tetrahedron and the dodecahedron. The faces of a dodecahedron are regular pentagons. The diagonals of such a pentagon form a star-pentagon, the pentagramma, which served as a distinctive mark among the Pythagoreans. The construction of the star-pentagon led to the quadratic equation $x^2 = a(a-x)$, associated with the '*golden section*', which the Pythagoreans knew how to solve (as did the Babylonians).

However, the greatest contribution of the Pythagoreans to mathematics was the '*Pythagoras theorem*'[104], the first truly great theorem in mathematics. It occupies a central position in Euclidean geometry, since it governs the metric of the Euclidean space. This theorem led Pythagoras to the establishment of the concept of the *irrational numbers* $\sqrt{2}, \sqrt{3}, \ldots$ etc. and *their incommensurability* with the integers[105].

BCE) was familiar with $(2n)^2 + (n^2-1)^2 = (n^2+1)^2$ and Proclos (ca 460 CE) with

$$(2n+1)^2 + \left[\frac{(2n+1)^2-1}{2}\right]^2 = \left[\frac{(2n+1)^2-1}{2}+1\right]^2.$$

104 The origins of this theorem are obscure. It is, however, established that the Egyptians and the Babylonians were familiar with the Pythagorean theorem as early as 2000 BCE, and were also acquainted with the general parametric representation for primitive Pythagorean triplets (**Plimpton** *322*). They used $3\frac{1}{8}$ for π [Egyptians used $\pi = 4\left(\frac{8}{9}\right)^2$]. The Pythagorean triplet $(3,4,5)$ was known to the Egyptians and the Chinese. Moreover, it has recently been claimed that the Chinese had a *geometrical proof* of the theorem as far back as 1100 BCE! Did *Pythagoras prove the Theorem*? (For further reading, see: Swetz, F.J. and T.I. Kao, *Was Pythagoras Chinese*? The Pennsylvania State University Press: Pennsylvania, 1977, 75 pp.) Although it was attributed to him by various writers [**Proclos** (ca 460 CE), **Plutarch** (1^{th} century CE), **Cicero** (ca 50 BCE), **Diogenes Laertius** (2^{nd} century CE), and **Athenaeus** (ca 300 CE), no one of them lived within, say, 5 centuries of Pythagoras. Not only are we not positive that the proof is due to Pythagoras at all, but we are still more in doubt as to the line of demonstration that he may have followed.

105 The Pythagoreans had an analytic proof by contradiction that $\sqrt{2}$ is irrational. This proof appears in Aristotle's *Prior Analytics*. It goes as follows: Suppose $\sqrt{2}$ is rational; then it can be expressed as a fraction in lowest terms, say $\frac{n}{m} = \sqrt{2}$, where n and m are integers which have no common factor except 1. Then $n = m\sqrt{2}$, or if we square both sides of this equation $n^2 = 2m^2$. Thus n is an integer whose square is even and by the identity $(2k+1)^2 = 4k(k+1)+1$, n is also even. Setting $n = 2r$ and substituting in the above equation we find $(2r)^2 = 2m^2$, or $2r^2 = m^2$. But this shows that m is an integer whose square

The appearance of the *Pythagorean Theorem* marks the first known intellectual leap from the confines of empirical speculation to the limitless bounds of deductive reasoning. This is a milestone of mathematical accomplishment in the early history of the human race. In fact, it is actually the most profound such accomplishment, judged by its level of intellectual achievement and its eventual consequences for mankind.

From the earliest times, man has perceived his environment in terms of vertical and horizontal – a tree grows vertically to the horizontal plane of the earth, a person stands vertical to the surface that supports him. These vertical-horizontal relations were manifestations of the action of gravity on terrestrial objects. No doubt, man rapidly learned to use this relationship to his advantage; thus for maximum efficiency and security, the supporting pole for a shelter should be placed vertically to the ground. While nature supplied the prime example of perpendicularity, man must have soon realized that elements of the vertical realm always met with elements of the horizontal realm in the same visual pattern, forming what we know as a *right angle*. Once this concept was grasped, the potential of this union could be utilized in a wider variety of human endeavors, such as a stringing of an arrow to a bow or erecting permanent structures of wood and stone.
Perpendicularity could now be translated from the fixed vertical-horizontal constraints of nature and used to human benefit. Some of the first '*scientific instruments*' incorporated in their functioning the use of right angles. With an understanding of perpendicularity, a pole fixed in the ground could become a gnomon. The Pyramids of Egypt stand in mute testimony to the surveying applications of the right angle. Both the construction of the Egyptian plumb bed level and the rope loop square were based on an understanding of the right angle and the right triangle.
Eventually, an empirically based formulation of the *relationship of perpendicularity* emerged in the form of a rule that related the three sides of a right triangle – the Pythagorean theorem.

Numbers were thought of as made up of units, which was a suitable measure as long as they were integers. But numbers like $\sqrt{2}$ could not be accounted for in this way and were called irrational, which in Greek meant measureless rather than bereft of reason. In order to overcome this difficulty, the Pythagoreans invented a method of finding these elusive numbers through a sequence of approximations where the irrational number aimed at

is even; hence m is even, which contradicts the statement that n and m have no common factor except one.

is the limit of the process. This is the construction of continued fractions[106] through which we can reach rational approximation as close as we like to the *limit*. This feature is indeed the same as that involved in the modern conception of limit. Pythagoras was probably the first to represent number by length and produce geometric processes to prove identities and solve quadratic equations. Despite their theoretical disdain for the senses, the Pythagoreans did in practice make accurate observations of nature. Thus, in astronomy, Pythagoras himself taught that the earth is spherical, rotates on its axis and revolves around a central fire. He also believed that the motion of celestial bodies obey certain quantitative laws. His fantastic theories of the heavens were based on his very real discoveries of the laws of musical harmonies and of the regular polyhedra.

Myth and Number – Our Pythagorean Heritage

Greek philosophers, and in particular Pythagoras, endowed natural numbers with an almost magical character. They actually believed that the formal statement of facts expressed in terms of natural numbers are natural laws. Pythagoras singled out the triangular array of 10 points which he called tetraktys. This pattern is encoded in the 4^{th} *in a series of triangular numbers (Fig. 1.1)* $a_{n+1} = a_n + n + 1 \quad (a_0 = 0)$

---

[106] $1+\frac{1}{1}=2; \qquad 1+\cfrac{1}{1+\frac{1}{1}}=1\tfrac{1}{2}; \qquad 1+\cfrac{1}{1+\cfrac{1}{1+\frac{1}{1}}}=1\tfrac{2}{3};$

$$1+\cfrac{1}{1+\cfrac{1}{1+\cfrac{1}{1+\frac{1}{1}}}}=1\tfrac{3}{5};$$

$$1+\cfrac{1}{1+\cfrac{1}{+\cfrac{1}{1+\cfrac{1}{1+\frac{1}{1+\cdots}}}}}=\tfrac{1+\sqrt{5}}{2}=\sqrt{1+\sqrt{1+\sqrt{1+\sqrt{1+\cdots}}}}.$$

(a)

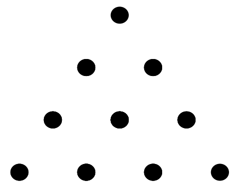

Fig. 1.1: Triangular numbers

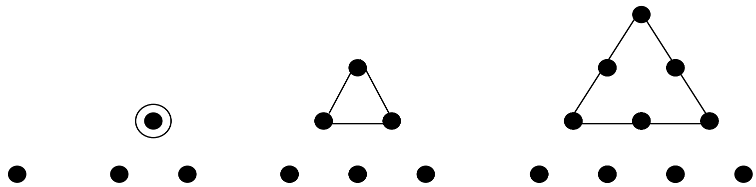
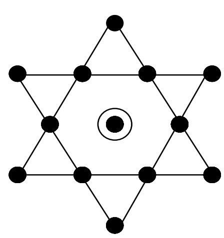
Thus, $a_n = 1, 3, 6, 10, ..., \frac{1}{2}n(n + 1)$ *are pictured as*

(b)



In mythical lore, the natural numbers 1 was called monad, the origin of all numbers. The dyad 2 was the first feminine number and represented the first stage of creation. The number 3, the first masculine number, represented the second stage of creation. The sum of the first feminine and the first masculine number, 5, represented man, microcosm, harmony, love, and health. Inanimate life was represented by the number 6. The tetraktys 10, represented the cosmos and macrocosmos. Two interlocking tetraktys created the "Star of David" in which 12 evenly spaced dots, representing the signs of the zodiac, surround a 13th *representing the "source of all being",*

(c)



In retrospect, we can deduce that the prescientific mind found, in the mystical mode of expression, a concise way to convey the kernel of meaning in *a mass of observations about the natural world. For example, the number 6 does seem to arise most frequently in inanimate forms such as snowflakes and other crystals. One the other hand, the number 5 characterizes living forms such as the starfish and certain forms of radiolaria.*

Number and geometry also lies at the basis of many sacred structures such as Stonehenge *and the* Pyramids. *In the latter case the "Egyptian triangle" 3, 4, 5 had sacred significance used in some of the key proportions of the Pyramid of Cheops. The significance of this triangle arose from the fact that the celestial sphere can be represented as a circle divided into 12 equal segments. The line can then be folded up to a 3, 4, 5 right triangle with a perimeter of 12 units.*

In ancient tradition, the square, *by its axial geometry symbolizing the directions of the compass, represented the earth and the dimensions of space while the circle, symbolizing the celestial sphere, represented the realm of the heavens and the dimension of time. Thus, ancient* mathematics, architecture, astronomy *and* music *may have been entwined to form a holistic view of the cosmos.*

It can be said that an attempt was made to bring heaven down to earth and replicate it at all scales and to synchronize space and time. The extant mathematics of the ancient world and the surviving artifacts and structures that comprise the archaeological record, serve as evidence for the number myth of those ancient cultures.

The Pythagorean philosophy, however, went beyond the link of number and geometry. They studied four subjects which they believed to be different aspects of one unifying entity: arithmetica *(the theory of numbers),* geometry, music, *and* spherics *(mathematical astronomy). The unifying theme was Number, namely* positive integers. *The relationship between number and musical intervals was one of their first discoveries.*

If a stretched string of length, say, 12, sounds a certain note, the tonic, *then it sounds the* octave *if the length is reduced to 6. If sounds the fifth (do to sol) if the length is reduced to 8, and the fourth (do to fa) if reduced to 9. So Harmony is Number.*

There follows a study of means. *The fourth is the* arithmetic *mean of the tonic and octave,* $9 = \frac{1}{2}(12 + 6)$, *while the fifth is their* harmonic *mean,* $\frac{1}{8} = \frac{1}{2}(\frac{1}{12} + \frac{1}{6})$, *since its pitch is half-way between theirs.*

There also follows a study of proportion. *The fifth is to the tonic as the octave is to the fourth, and the criterion of such proportionality is found in* $8 \cdot 9 = 12 \cdot 6$. *Since we may write this as* $9 \cdot 8 = 12 \cdot 6$, *we also have that the fourth is to the tonic as the octave is to the fifth, etc. The study of means and proportion was an important ingredient of Pythagoreanism.*

The Pythagorean relationship between music and spherics is less convincing. The intervals between the seven "planets" – the Moon, the Sun, Venus, Mercury, Mars, Jupiter and Saturn – correspond to the seven intervals in the musical scale. This explains the Celestial Harmony, and shows that the Heavens too are essentially Number. However, this mystic nonsense played a most important role in the history of science, *as we shall soon see.*

The direct relation between number and spherics, without music as a middleman, was also known to Pythagoras from his travels in Egypt. The simple gnomon *instrument, which he saw there, exemplifies the Pythagorean synthesis of spherics, geometry and arithmetica.*

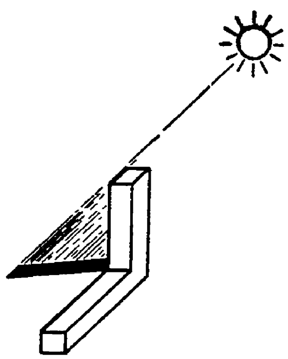


Fig. 1.2: The gnomon sundial

The gnomon (Fig. 1.2) is an L-shaped movable sundial used for scientific studies. It rests on one leg; the other is vertical. The length and direction of the shadow is measured at different times of the day and year. If the shadow falls directly on the horizontal leg at noon (when the shadow is shortest), that leg points north. The noon shadow changes length with the seasons – minimum at summer solstice and maximum at winter solstice. The sunrise shadow is perpendicular to the horizontal leg during the vernal or autumnal equinox. Thus the gnomon is a calendar, a compass and a clock.

Pythagoras knew the world was a sphere – the gnomon measures latitude, it measures the obliquity of the ecliptic, etc. Here we have Solar Astronomy with Number (measurements) as the basis.

In all such shadow measurements the geometry of similar triangles *and of right triangles is essential. A generation before Pythagoras, Thales of Miletos (a commercial center near Samos) also went to Egypt, studied mathematics* *and started a school of philosophy. It is sometimes said that Pythagoras was one of his students. Plutarch tells the story that Thales determined the height of the Great Pyramid by comparing the length of the shadows cast by the Pyramid and by a vertical stick of known length.*

The Pythagoreans used the word gnomon *also in another connection: while the triangular numbers were important as the sums of consecutive numbers, the Pythagoreans also loved the* squares *1, 4, 9, 16,... being the sum of successive* odd *numbers:*

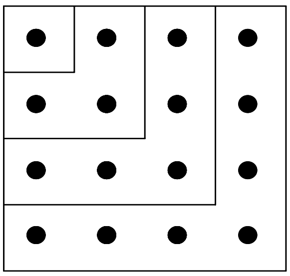

Fig. 1.3: Gnomons

16=1+3+5+7 etc. The odd numbers the Pythagoreans called gnomons. *It follows at once that if m is odd, and if m^2 is thought of as a gnomon of side $\frac{1}{2}(m^2+1)$, then*

$$m^2 + \left[\frac{1}{2}(m^2-1)\right]^2 = \left[\frac{1}{2}(m^2+1)\right]^2$$

which links number and the gnomon geometry *through the Pythagorean Theorem.*

It is irrelevant whether or not Pythagoras "discovered" the Pythagorean Theorem. He may have actually learnt it from Egyptian "rope stretchers" who used it in their construction of the Great Pyramid (2700 BCE). It is believed, however, that he was first to prove *it, using the fact that the altitude from the right-angle vertex divides the hypotenuse into two triangles that are similar to the original triangle.*

Thus, to the Pythagoreans, the right-handed triangle, the squares built upon its sides, the square numbers and the 'astronomical shadow' were all aspects of the same thing.

But not all was wine and roses in the kingdom of the Pythagoreans: when they discovered that $2a^2 = c^2$ has no solution in positive integers[107]*, or equivalently that the hypotenuse and side of a 45° right-triangle are incommensurable, it undermined their entire philosophy. For if number (i.e. positive integers) cannot even explain a 45° triangle, what becomes of much more far reaching claims.*

At a late date a new embarrassment arose: the Pythagoreans knew of 4 regular polyhedra, and they associated these with 4 "elements". The tetrahedron was fire, the cube was earth, the octahedron was air, and the icosahedron, was water. But ***Hippasos***[108] *(ca 500 BCE), a member of the society, discovered the* 5^{th} *regular polyhedron, the dodecahedron.*

The "$\sqrt{2}$*-crisis" of Greek mathematics lead to paradoxes and contradictions, but it also served as a strong motivation for the transition from naive mathematics to rigorous mathematics*[109]*. The task was left to* ***Eudoxos*** *(ca 370 BCE) and* ***Euclid*** *(ca 300 BCE), who expelled Number from geometry*[110] *placing integers were they belong – in the theory of numbers.*

The Pythagorean said that number is everything, but, aside from the analysis of music, they did not make a good case for this assertion.

If we ask whether modern physical scientists believe that the world can be best understood numerically, the answer is in the affirmative. But here "numbers" are no longer confined to integers; they also include real numbers, vectors, complex numbers, and other generalizations.

The founders of modern physical science at the dawn of the 17^{th} *century,* ***Galileo*** *and* ***Kepler*** *did not have a rigorous theory of real numbers, but they had the practical equivalent, namely, decimal fractions which the Greek did not have. The formulation of the laws of nature in terms of ordinary differential equations [***Newton***], and in terms of partial differential equations [***Euler***;* ***D'Alambert***;* ***Fourier***;* **Cauchy**; **Poisson**; **Navier**; ***Maxwell***], appeared to further weaken the role of integers in nature and to strengthen that of real numbers. But even here we may note that while the variables in an equation are continuous, the order of the equation, and the number of variables in it are integers! Furthermore, the case for Old Pythagoreanism,*

---

107 From a modern point of view, $\sqrt{2}$ is a *Dedekind Cut* – a class of ordered pairs of rational numbers. It is totally "man-made" according to **L.Kronecker** (1861).

108 Supposed to have been drowned for divulging this "secret" of the Pythagorean brotherhood.

109 A similar situation arose in the 19^{th} century, where the paradoxes of the Fourier Series motivated a rigorous functional analysis.

110 Restored back to geometry by **Fermat** (1629) and **Descartes** (1637).

namely – the fundamentality of integers (not only mathematically) in nature is even stronger as the following examples will show:

- ***Galileo*** *(1590) found that during successive seconds from the time of which it starts falling, a body falls through distances proportional to the odd integers and that the total distance fallen is proportional to the square of time. Here we have square numbers arising as sums of the odd Pythagorean gnomons.*

- ***Kepler*** *(an avid Pythagorean who really believed in the Harmony of the Spheres) sought for years to find accurate numerical laws for astronomy. He finally discovered (1618 CE) his important* Third Law*, stating that the squares of the periods of the planets are proportional to the cubes of their mean distances from the sum.*

- *Even before* Newton's Principia *(1687) it was known to* ***Robert Hooke****,* ***Christopher Wren****, and others that the kinematic laws of Galileo and Kepler imply that each planet has an acceleration toward the sun which is inversely proportional to the square of distance from the sun. Hence the power of (-2) in the universal Law of Gravitation.*

- *Inspired by Newton's Law of Gravitation,* ***Coulomb***[111] *(1785) determined, with a torsion balance, that electrostatic forces were also inverse square. Many years later it was shown by* ***Maxwell*** *that mathematically, the only law of force which would behave in this way is one whose divergence in zero – that is, one that falls radially in such a way as to just compensate for the increase in the area of a spherical shell with its radius; this area increases with the square of the radius because we live in a space of three dimensions.*

- *From a similar inverse-square law due to* ***Ampere*** *(1822), and from other experimental results,* ***Maxwell*** *(1865) was led to the electromagnetic wave equations. While the dependent and independent variables here are both continuous, the number of independent variables (4), and the number of dependent variables (6) is fundamental, as became clear from the Einstein-Minkowski space-time structure (1905-1908).*

---

[111] **Henry Cavendish** (1773) had already observed the same law by another method. The experiment was repeated by **Maxwell** a hundred years later. They showed that the field inside a charged hollow conductor is zero. The Cavendish-Maxwell experiment not only suggested that the exponent(-2) is *exact*, but that the reason for this is that the dimensionality of space is an integer.

- **Proust**'s *Law of Definite Proportions (1799)* and **Dalton**'s *Law of Multiple Proportions (1808) in chemistry directly imply an Atomic Theory of matter. The integral rations in the second law exclude any other interpretation. Further, it appears that chemical affinity involves integers directly.*

- *In exact analogy, the* **Romé de l'Isle** *(1772) Law of Constant Angles* and **Haüy**'s *Law of Rational Indices (1784) for crystals, directly imply that a crystal consists of an integral number of layers of atoms. Again, the integral ratios in the second law exclude any other interpretation. Further, there is a direct relationship between number and form, e.g., the six-sided symmetry of frozen H_2O.*

- *The ratio of the two specific heats of air is 7/5 and of Helium is 5/3. While phenomenological theory (thermodynamics) cannot explain these integral ratios at all, the atomic theory explains them easily (***Boltzmann***). By a similar argument Boltzmann explained the Dulong-Petit Law for the specific heat of solids.*

- ***Faraday's*** *Law of Electrolysis (1834) states that the weight of the chemical deposited during electrolysis is proportional to the current and time. If chemical weight is atomic, then this law implies that electricity is also atomic. Such electric particles were called electrons by Stoney (1891).*

- *In 1814* ***Joseph von Fraunhofer*** *invented the diffraction grating. A glass plate is scratched with a large number of parallel, uniformly spaced fine lines. This produces an optical spectrum: since parallel beams of a given wavelength, shining through the successive apertures on the glass, will be diffracted only into those directions where the successive beams have path lengths that differ by an integral number of wavelengths.*

- *The simplest spectrum is that of hydrogen. The wavelengths of its lines have been accurately determined. In 1885* **Balmer** *found that these wavelengths are expressible by a simple formula involving integers.*

- ***Pieter Zeeman*** *(1896) discovered that the lines of a spectrum are altered by a magnetic field, and* **H. A.** ***Lorentz*** *at once devised an appropriate theory. The radiating atoms contain electrons whose oscillations produce the spectrum by electromagnetic radiation. The frequency of the oscillations (and therefore also their wavelength) is changed by the action of the magnetic field upon the electrons.*

- *From Maxwell's Equations and thermodynamics,* ***Ludwig Boltzmann*** *(1884) derived Stefan's Law of Radiation (1879). This states that a blackbody radiates energy at a rate proportional to the fourth power of its absolute temperature. Although electromagnetism and thermodynamics are both theories of continua, the real point of the law is the* exponent. *Here again the exponent 4 is said to be exact and, in fact, even a casual examination of Boltzmann's derivation shows that this exponent equals the number of independent variables in the wave equation – the three of space and one of time. Just as* $2 = 3 - 1$ *so does* $4 = 3 + 1$ *here.*

- ***Max Planck*** *(1900) found it necessary to assume that energy is radiated discretely in* quanta and ***Albert Einstein*** *(1905) used them to explain photoelectricity. Thus* discrete matter (atom) implies both *discrete electricity* (electron) and *discrete energy* (quantum).

- *Emergence of the 4-dimensional space-time continuum of* ***Albert Einstein*** and ***Minkowski*** *(1905-1908). In this theory, particular importance is attached to vectors with four components. One such vector is a space-time displacement. Another is the momentum-energy vector, three components of momentum and one of energy. A skew-symmetric tensor in this four-dimensional world has six components – four things taken two at a time. The most important example is the electromagnetic field – three components of electric field, and three of the magnetic field.*

Note that the Pythagoreans also considered 4 to be especially important because it was related both to properties of the tetrahedron and fire. Tetrahedron has two special properties: it is the smallest polyhedron, and it has the same number of vertices and faces (i.e. it is self-dual). Both of the properties follow from the fact than its number of vertices is one more than the dimensionality of space. If Pythagoras could be alive today and deeply versed in modern physics, he could argue "I told you so" on two counts:

(1) *The number 4 is as important to me for the same simple reason that it is important to Albert Einstein, Minkowski, Stefan and Boltzmann:* $4 = 3 + 1$.

(2) *Fire is radiation heat and light, and that is electromagnetic: your 6 components of this fields are obtained by taking the 4 dimensions of space-time, 2 at a time. So likewise, my 6 edges of the tetrahedron join the 4 vertices 2 at a time, and also are the intersections of the 4 faces, 2 at a time.*

- ***Mendeleev's*** *Periodic Table of the chemical elements (1869). If the elements are listed in order of their atomic weights, then chemical, spectroscopic, and some other physical properties recur periodically. But there were many imperfections and many questions arose. Tellurium weighs more than iodine. But if placed in the table in that order these elements clearly fall into the wrong groups. Again, the position of the rare earths and the numerous radioactive decay products were not clear. The rare gases were entirely unanticipated.*

  Further, the table is not strictly periodic but has periods of length 2, 8, 18, and 32. Why these periods should all be of the form $2n^2$ *was not clear. Indeed, how could it be – for what can mere* weight *have to do with these other properties?*

  But the experiments of **C.G. Barkla** *(1877-1944, England) by X-ray scattering (1911) and the experiments of* ***E. Rutherford****, in the same year, by alpha particles, lead to an atomic model – a miniature "solar" system with the light, negatively charged electrons bound to a heavy, positively charged nucleus by inverse-square Coulomb forces.*

  In 1913 **Niels Bohr** *assumed that the hydrogen atom had this (simplest) Rutherford structure – one proton as a nucleus and one electron as a satellite. With the use of Planck's* $E = h\nu$*, he deduced the Balmer formula with great precision. However, he had to assume that the electron could have a stable orbit only if its angular momentum were an integral multiple of* $h/2\pi$*. That is,*

  $$mvr = nh/2\pi$$

  with m *the electron's mass,* r *the orbit's radius,* v *the electron's velocity, and* h *Planck's constant. The integer* n*, the* principal quantum number*, made no sense in the theories then in vogue, but its acceptance was forced by the remarkable accuracy of the theory's predictions.*

  Thus, 1913 was a good year for Old Pythagoreanism. ***Soddy*** *and* ***Fajans*** *found that after radioactive emission of an alpha particle (charge +2) the resulting element is two places to the left in the periodic table, whereas emission of a beta particle (charge -1) results in a daughter element one place to the right. Together with the earlier results this Displacement Law makes it clear that* atomic number*, not atomic weight, is the important factor. This integer is the positive charge on a nucleus, the equal number of electrons in that atom, and the true place in the table of elements.*

  In 1912 **von Laue** *made the suggestion that a crystal would act like a diffraction grating for radiation of a very short wavelength.*

Henry Moseley *(1913) used von Laue's suggestion to measure the (very short) wavelengths of X-rays. Optical spectra, like chemical behavior, are due to the outer electrons in an atom, and thus have a periodic character. But X-ray spectra are due to the inner electrons, and these electrons are influenced almost solely by the charge on the nucleus. Moseley's photographs show a most striking monotonic variation of the X-ray wavelengths with atomic number.*

Atomic number at once cleared up most of the difficulties. But what about $2n^2$*?*

In 1923, **L. *de Broglie*** *combined relativistic invariance of four-vectors with Planck's* $E = h\nu$*. The energy* E *and the time associated with the frequency* ν *are merely single components of two four-vectors. The remaining three components of momentum and of space, respectively, must be similarly related. Thus a particle of momentum* mv *should have a wavelength* λ *given by*

$$\lambda = \frac{h}{mv}.$$

When this is applied to Bohr's

$$mvr = nh/2\pi$$

one obtains

$$n\lambda = 2\pi r.$$

Thus the matter wave has exactly n *periods around the circumference of the orbit and the interpretation of the stability of the electron's discrete orbitals (quantum orbits) is that it constitutes an azimuthal standing wave.*

This conception was refined in the ***Schroedinger****'s Wave Equation (1926). Here there are three quantum numbers* n*,* l*, and* m *corresponding to the dimensionality of space. In polar coordinates the wave functions corresponding to given* l *and* m *are spherical harmonics (not quite "Harmony of the Spheres" – but very close to it). It further develops that the integer* l *can equal* $0, 1, 2, ..., n-1$ *while* m *can equal* $-l, -l+1, ..., l-1, l$.

For n = 4, for example, we have 16 possible 'Gnomon-like' states (Fig. 1.4):

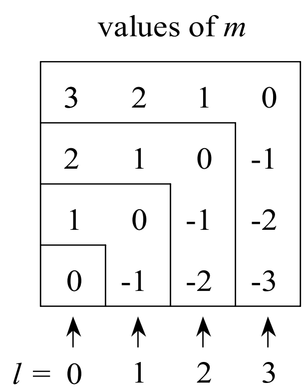

Fig. 1.4: Quantum ‘Gnomon-like’ states

But a fourth quantum number was already waiting in the wings. In 1925 ***Uhlenbeck*** *and* ***Goudsmit*** *discovered the spin of the electron. This gives rise to a fourth quantum number m_s which can take on two possible values. When this fourth "integer coordinate" is added, we obtain the $2n^2$ states which correlate with the periods in the periodic table of the elements. But we must distinguish two different types of "harmonies" here. In one atom an electron can transition from state to state; thus giving rise to the spectrum. This is the first "harmony." On the other hand, as we go through the periodic table, adding one new electron each time, the new electrons will also fill successively available distinct quantum states according to the* Pauli Exclusion Principle *(1925) combined with Coulomb energetics criteria resulting from inter-electron repulsion. This gives rise to the periodic table – the higher-level "harmony."*

*Pythagoras, if living today, would be delighted with nuclear "magic" numbers (**Mayer**), "strangeness" (**Gell-Mann**) of quarks, charmed quarks, the "eightfold way," all the numerology associated with the elementary particle Zoo and the strong links of string theory with number theory.*

The Earth as a Sphere (550–530 BCE)

One may wonder: how did Thales and Pythagoras reach the bold conclusion that the earth is a sphere? They may have observed that the surface of the sea is not flat but curved, for as a distant ship approaches one first sees the top of its mast and sail and the rest appears gradually. The circular edge of the shadow cast in an eclipse of the moon would also suggest a spherical (or disk) shape of the earth, yet this observation implies an understanding of eclipses that had not yet been attained in the 6^{th} century BCE.

It is more probable that as soon as the Babylonian hypothesis of a flat earth (common in the Old Testament) had been rejected, the sphericity of the earth was postulated*, on insufficient experimental grounds. This fundamental Pythagorean idea was an act of faith rather than a scientific calculation, but it made the theory of eclipses possible. In turn, the development of that theory and the observations that suggested it, repeatedly confirmed the initial assumption. Does not every scientific hypothesis start that way?*

The dogma of spherical perfection and its cosmological consequences may be considered the kernel of early Pythagorean science. It was postulated that the celestial bodies are of spherical shape and that they move along circular path in uniform motion.

532 BCE **Theodoros of Samos**. Greek architect and engineer, to whom many inventions are ascribed: level, square rule, key. He is said to have introduced bronze casting from Egypt into Greece. When the foundations of the Temple of Ephesos were laid down, he used various means to solidify the marshy ground.

ca 530 BCE **Xenophanes of Colophon** (ca 580–485 BCE). Greek poet and philosopher. The first thinker of Greek culture to advance the idea of one, true, eternal, supreme God (in opposition to the ideas of the gods of the poets and the popular cults), to whom he attributed the shape of a *sphere*. A contemporary of Pythagoras, he relied principally on the Miletian school and his main concern was in studying the phenomena of nature.

Xenophanes was the first of the early philosophers to focus upon the geological time scale, recognizing the significance of fossils as remnants of former life and correctly inferring that sedimentary rocks originated as sediments deposited on the sea bottom. Moreover, he concluded that such rocks and fossils must be of great age, considering them as witnesses of periodical submergences of the dry land. Xenophanes was not particularly loved by some of the erudite establishment of Greek philosophers, most of whom had deduced that there was no beginning and no end to the earth.

Born in Ionia (Asia Minor), his religious rigor caused him to leave his native country and lead a migratory life: he resided for a time in Sicily, at Zancle and Catana and afterwards established himself in southern Italy, at Elea, where he founded the Elean school of philosophy.

The idea of God's sphericity was later echoed in the words of **Aristotle** (354 BCE): "*...there can only be God, the same from all sides... Otherwise the various parts would be superior and inferior to each other, and this is impossible. Hence such a universal homogeneity of God implies that he has the shape of a sphere...*".

530–520 BCE **Eupalinos of Megara** (c. 570–510, Greece). Architect and engineer. Built an aqueduct and a water-supply system for Megara. Constructed a tunnel of 1100 m under 300 m high Mount Castro on the island of Samos to supply water. The tunneling was started from the opposite sides and driven into the center[112].

512 BCE **Mandrocles of Samos**. Greek civil engineer. The first known bridgemaker.

When Darius I (king of Persia, 550–486 BCE) made his expedition against the Scythians (ca 514 BCE), he ordered Mandrocles to build a bridge across the Bosporos to enable his immense army to pass into Europe. Mandrocles was able to satisfy him by building a *floating bridge of boats*. The Greek borrowed ideas from the Egyptians, the Babylonians, and the Phoenicians, much as these people in their time had borrowed ideas from each other.

510–507 BCE **Darius I** conquered northwestern India. He then sent the Greek **Scylax of Caryanda** on exploratory voyage down the Indus. Scylax sailed to its mount and then followed the coast to the Red Sea.

---

[112] As in the case of the *Hezekiah Siloam Tunnel* in Jerusalem, dug ca 710 BCE by Hebrew engineers. The tunnel was about 533 m long. An inscription commemorating its completion was discovered in 1880 CE, and provides the information that it was dug from both ends simultaneously [see *II Kings* **20**, 20; *2 Chron* **32**, 3-4; *Neh* **3**, 16].

ca 510 BCE **Hecataeos of Miletos** (ca 550–475 BCE). Greek traveler, map-maker and historian. Drew the first recognizable map of the Mediterranean world. Wrote *Periegesis* (tour round the world), widely used by Herodotos and other writers.

Opposed Ionian revolt (500 BCE) against Persia and, after the Ionians were defeated (494), was appointed Ionean ambassador to negotiate terms of peace with Artaphenes.

508 BCE *Democracy in the form of isonomia (equality before the law) was born in Athens.* To break the power of the noble clans, which were connected with the old hereditary tribes, **Cleisthenes** reformed the constitution of Athens; a new system of government was created, called *demokratia* (the people in power). With the economic boom that followed the *Persian wars* (490–479 BCE), the nature of the Athenian system of government changed from conservative democracy based on agriculture into full popular sovereignty based on commerce.

ca 500 BCE A toy regular dodecahedron of Etruscan origin found in 1885 near Padua.

ca 500 BCE **Nabu-rimannu** (Naburimanus). Leading Babylonian astronomer. Employed a special sign for a true *zero* in his astronomical tables for the calculation of a new moon and eclipses. Known to the Greeks and mentioned by Pliny and Strabo.

ca 500 BCE Quill pens were introduced in Europe and the Middle East.

ca 500 BCE **Heraclitos of Ephesos** (ca 540–475 BCE). Ionian philosopher, first to discover the concept of *Natural law*. To sum his philosophical system in one sentence is to say that universal law and order, manifests itself through a state of perpetual change. His philosophy has three main themes:

(1) Nothing is permanent except change. All phenomena are in a state of continuous transition from non-existence to existence and vice versa. Where there is no strife, there is decay. Things lack identity and possess only the attributes of *becoming* but not *being*. In his own words and letters: "πάντα ρεῖ καῖ ούδὲν μὲνεῖ" (all things flow, nothing abides). One can discern here a crude form of the principle of Relativity.

(2) The process of change takes place in accordance with a deep Universal Reason (λογ́ος = Logos), i.e. a rational principle that dominates nature. This law is the only constant thing amidst the cosmic motion. This law was and will be forever: cosmic motion is the eternal reality.

(3) Cosmic history runs in repeating cycles, each beginning and ending in fire: from chaos to cosmos and vice versa. Contemporary Buddhist philosophy taught that the universe is periodically created and destroyed.

ca 500 BCE **Alcmaeon of Crotona**. Greek Pythagorean philosopher and writer on medical subjects. A pupil of Pythagoras. He was concerned with the internal causes of diseases. He divided these causes into disorders of environment, of nutrition and of lifestyle. His book is lost and only a few fragments of his writings have remained. He is the first person known to have dissected human cadavers for scientific purposes. Discovered the *optical nerve*, the *Eustachian tube*[113] [two millennia before **Bartolomeo Eustachi** (1564)], the origin of *sperm*, and gave explanations of *sleep*. He performed physiological experiments and knew that the *brain* is the central controlling organ of the body and the seat of the intellect.

Alcmaeon held that health and disease are respectively an equilibrium and a rupture of equilibrium of the organism, and that everything in nature is a conflict between opposites.

490–479 BCE *The Persian Wars*: A series of military conflicts which had a decisive and permanent influence upon the development of Western culture and civilization.

- 490 BCE, Sept. 12. *Battle of Marathon*: Army of Militiades (11,000 Athenians and Palataeans) defeated much larger Persian force under Darius I (549–486 BCE), turning back Persia's second invasion of Greece.
- 480 BCE. *Battle of Thermopylae*: Small force of 300 Spartans and 700 Thespians led by King Leonides bravely held strategic pass against invading Persian army, 180,000 men strong, under King Xerxes I (519–465 BCE). The Persians burned Athens to the ground, but its citizens fled to Salamis and the Peloponnese.

– *Battle of Salamis*: The greatest naval encounter of the ancient world. Celebrated Greek naval victory in which Themistocle's (525–460 BCE) fleet sinked about 200–300 Persian ships in the narrow straits of the Island of Salamis.

[113] Auditory passage (3.8 cm long) made of bone and cartilage, and lined with mucous membrane. The tube connects the middle-ear to the throat: it allows air to pass through it. Swallowing helps open the tube and thus equalize the air pressure on the inner side of the eardrum to the air pressure on the outside. The tube also allows mucous formed in the middle ear cavity to escape into the throat.

- 479 BCE. *Battle of Plataea*: The Spartan general **Pausanios** won a decisive victory over Persian forces led by **Mardonias**.
- *Battle of Cape Mycale*: Greeks won a naval victory against Persian fleet. This ended any further threat of invasion by Persia.

These events, some of the most momentous in the history of the world, marked the victory of Europe over Asia and enabled Greece to become that which it had to be.

As soon as the Persian retreated, the Athenian rebuilt their city on an even grander scale. They used their large navy to bring former Milesian trading positions (on the Black Sea, in Syria and in Egypt) under their own control and gradually established a prosperous economic empire. Athenians of the 5^{th} century, not only dominated the Aegean but produced one of the richest eras in the history of Western civilization. This era is known as the *Golden Age of Greece*.

In addition to its most sublime resources of the human intellect, the Greek civilization also drew its strength from more mundane endorsements. *Silver* financed the city-state of Athens, its trade and its commerce. From the mines at *Laureion*, at the southern tip of Attica, a stream of silver flew through the Athenian treasury. The raising up of a commercial power in Greece, able to throw back the advancing tide of barbarism that threatened to extinguish its arts, literature and science, was due in some indispensable measure to the silver mines at *Laureion*.

ca 480 BCE "Optical telegraph"[114] operating in Greece; Using two torches (one in each hand), letters of the alphabet were simulated by various positions to code plain-language messages transmitted from one hilltop to another in succession.

---

[114] During the French Revolution (1794 CE), **Claude Chappe**(1763–1805 CE) converted this old idea into a reality by establishing a nation-wide *semaphore* (a word devised by Chappe from the Greek for "bearing a sign") visual telegraph. With the National Assembly's backing he built a series of 22 towers over the distance of 240 km between Lille and Paris. Each tower was equipped with a pair of telescopes, one pointing in each direction, and with a two-arm semaphore. Each arm could assume 7 clearly visible angular positions, making 49 combinations that were assigned to the alphabet, numerals and other symbols. It only took 2 to 6 minutes to transfer a message over 240 km whereas riding couriers would have needed 6 hours. Depressed by illness and by mounting claims of Plagiarism, Chappe committed suicide by throwing himself down the well in his hotel.

Greeks also used sound signals (trumpets, drums, shouting), smoke signals, mirror reflections and beacon fires. At about the same time Persia had a form of Pony express.

ca 480 BCE **Panini** (ca 520–460 BCE, India). A Sanskrit grammarian who gave a comprehensive and scientific theory of phonetics, phonology, and morphology. In his treatise called *Astadhyayi*, Panini distinguished between the language of sacred texts and the usual language of communication. Panini gave formal production rules and definitions to describe Sanskrit grammar. The construction of sentences, compound nouns etc. is explained as ordered rules operating on underlying structures in a manner similar to modern theory.

Panini should be thought as the forerunner of modern formal language theory used to specify *computer languages*.

ca 470 BCE **Parmenides of Elea** (ca 504–456 BCE, southern Italy). Greek philosopher. Founder of the Elean school and one of the great pre-Socratic thinkers. Down to recent times, philosophy has accepted fundamental concepts from Parmenides, notwithstanding considerable modifications and combinations with other ideas.

He was the originator of the doctrine of *being*, which he developed in opposition to the doctrine of *becoming* of **Heraclitos**. He also initiated the distinction between the sensible world (the world known by the senses) and the intelligible world (the world known by the mind). It was he who first assumed an indestructible *substance* and used it as a basis for his speculations (although he did not formulate its concept). He was among the first to distinguish between scientific truth and popular opinion. In this way Parmenides influenced **Empedocles**, **Leucippos** and **Democritos**, the Sophists and **Plato**. **Hegel** was not the last philosopher who followed Parmenides by founding metaphysics upon logic.

Parmenides shaped a principal characteristic of the Greek mind, which is significant in Greek philosophy, science and art – his preference for *unity, composure, and the comprehension of limits and contours*. His longing for unity made him suspicious of the senses; his emphasis on composure made him deny change, and the need of limits made him conceive of the unchanging world as a *spherical* form and repudiate the idea of infinite, or empty space. Specifically he asserted that *void* was unnecessary for the description of the world.

Parmenides was born in *Elea*, a Greek colony in southern Italy; probably a disciple of **Xenophanes** and **Ameinias**, a Pythagorean. He resided for some years in Athens (ca 450 BCE) where **Socrates** met him and learned much from the aged philosopher. He was one of the first Greek philosophers to express his thoughts in poetry.

ca 460 BCE **Leucippos of Miletos** (ca 490–430 BCE). Greek philosopher and founder of the Abderan school. One of the early mathematicians to investigate the squaring of the circle. He was founder of the doctrine of *atomism*, and all modern physicists may be regarded as the followers of his way of thinking that led to immense results in science and practical life. His theory that the Universe is composed of an infinite number of small indivisible particles (which he called *atoms*) remained a philosophical idea until 1808 CE. It has undergone many and important modifications, but has maintained its validity even after the "indivisible" atoms could be split.

Leucippos maintained that atoms are separated and distinguished from one another by *Non-beings* (empty space). He stated that atoms are *imperceptible*, *individual particles that differ only in shape and position*. Things come into existence by virtue of motion of these atoms in space and their accidental coming together.

All Leucippos' works, among which the books *Megas Diacosmos* (the Great Order of the Universe) and *Peri Nou* (On Mind), were most famous, are lost. He was a contemporary of Zeno, Empedocles and Anaxagoras. His fame was so completely overshadowed by that of Democritos (who subsequently developed the theory into a system) that his very existence was denied by Epicuros, but Aristotle expressly credits him with the invention of atomism.

Nothing is known of his life, and even his birthplace is uncertain.

ca 460 BCE **Anaxagoras of Clazomenae** (500–428 BCE). The last philosopher of the Ionian school. Maintained that nature is a work of design and order, driven by reason. He assumed that things are made up of an immense number of tiny "*seeds*" of different kind of matter. These seeds (today's atoms) never change, but they exist mixed together in different combinations; apparent changes in matter are simply recombinations of the changeless seeds. For these recombinations to occur, *motion* is needed. He thus paved the way for atomic theory. In astronomical history, Anaxagoras is remembered for correctly explaining eclipses and for his cosmology.

Anaxagoras was first in attempting to give scientific account of celestial objects and events such as eclipses, meteors, rainbows and the sun which he described as a mass of blazing metal. The heavenly bodies, according to him, were masses of stone, formed from the earth and ignited by rapid rotation. He is known to have made the first attempts to square the circle[115].

[115] It is thought that Anaxagoras worked on solving it while he was in prison for having claimed that the sun is a giant red-hot metal rather than a deity, and that the moon shines by its reflected light.

Anaxagoras was born at Clazomenae (30 km west of today's Izmir). He came to Athens from Ionia in 480 BCE and brought with him the spirit of scientific inquiry. But the ignorant polytheism of the time could not tolerate such explanations, and he was imprisoned (450 BCE) on the charge of contravening the established dogmas of religion. It required all the eloquence of **Pericles** to secure his acquittal. Even so he was forced to leave Athens in 434 BCE. He died in Lampsacos.

Anaxagoras was a contemporary of **Euripides** and **Socrates**. The concept of reason in nature was taken up again by **Aristotle**, on whose scientific work he exerted much influence.

ca 460 BCE **Zeno of Elea** (ca 490–430, southern Italy). Philosopher. Pupil of Parmenides. Expressed eight paradoxes contrasting continuity in space and time with discreteness. These paradoxes had a profound influence on the later development of the notion of infinitesimals, and assert that motion is impossible. The Greeks could not break away from their intuitive notion that the sum of an infinite number of positive quantities is infinitely large, even if the quantities become infinitely small, and that the sum of an infinite numbers of quantities of zero measure is zero. Thus infinitesimals were excluded from Greek mathematics, and science had to wait another 2000 years to resolve these paradoxes.

The *first paradox* is that of the runner of the race track. He can never reach the end of his course, Zeno tells us, since he must first cover half the remaining distance, and then after he has done so, half of the remaining distance, and then half of that, and so on. Each new distance to be covered is half of the distance just covered, and is therefore a finite distance, and yet there are an infinite number of these (finite) half-distances. Hence, Zeno concludes, an infinite time would be required to reach the goal.

The *second paradox* is the one about Achilles and the tortoise. Achilles is trying to catch up with the slowly moving tortoise, which he trails by a short distance. But he can never reach the tortoise, because whenever he comes to the point where the tortoise was, he will find that the tortoise has moved ahead some small distance. It will always take Achilles some time to cover the distance between himself and the tortoise, and the tortoise will always move some distance ahead during that time, Zeno argued[116].

[116] Essential fallacies in Zeno's arguments were exposed by Aristotle in his *Physics*. In modern times, an acceptable treatment of the paradoxes has been given along lines similar to Aristotle's, but with the benefits of the precision of the mathematical theory of continuity and infinite sums.

It is clear to us today, thanks to well-established mathematical principles, that the first two paradoxes are based on the misconception by Zeno regarding

In the *third paradox*, Zeno claims to prove the impossibility of any motion whatsoever. He states that if what is moving is always in the *now* – is always in the instantaneous present – then motion is impossible. As an example, Zeno uses an arrow in flight. At a given instant the arrow is in a fixed position and occupies just the space which corresponds to its physical volume. It occupied a different region of space in its past, and will occupy a different space in the future. Hence, at any given instant the arrow is motionless and therefore indistinguishable from a motionless arrow in the same position. How then do we know that it is moving? Since any period of time is a sum (albeit infinite) of its component instants, the arrow is motionless throughout the period. Zeno concludes from the paradox that all motion is impossible[117].

---

the value of an infinite sum of terms. It can be readily shown that the sum $\sum_{n=0}^{n=\infty} q^n$, where q is a positive number less than one and n takes the integral values from zero to infinity, is equal to $\frac{1}{1-q}$. In the first paradox, Zeno asserted that the runner must first go $\frac{1}{2}$ the remaining distance, then $\frac{1}{2}$ of that distance, which is $\frac{1}{4}$, then $\frac{1}{2}$ of that, which is $\frac{1}{8}$, and so on, giving a total distance of $\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+\cdots=\sum_{n=1}^{n=\infty}\left(\frac{1}{2}\right)^n$. This sum is equal to 1 by the above formula, since q is $\frac{1}{2}$ in this case, and the first term, $\frac{1}{2}$ to the zeroth power, which is equal to one, is not included in the series. Hence, in this case the sum of an infinite number of terms is finite, and not infinite as Zeno supposed.

The solution of the problem of Achilles and the tortoise is similar to that of the runner. Suppose that Achilles' and the tortoise's running speeds are such that while Achilles runs a given distance the tortoise runs only q times that distance, and that Achilles is X meters behind the tortoise when we first consider the two. While Achilles advances X meters, the tortoise advances qX meters. Then while Achilles covers this distance between them of qX meters, the tortoise moves $q(qX)$, or Xq^2 meters, and so on. In order to catch up with the tortoise, Achilles will have to run through an infinite number of intervals; i.e., he will have to run $X+Xq+Xq^2+Xq^3+Xq^4+\cdots$ meters, which is equal to $X\cdot\sum_{n=0}^{n=\infty} q^n=\frac{X}{1-q}$ meters. Thus, if X is 25, and q is $\frac{1}{10}$, Achilles will have to run $25\left(\frac{1}{1-\frac{1}{10}}\right)=25\left(\frac{10}{9}\right)$ meters in catching up with the tortoise. Of course, if q is 1, Achilles is running only as fast as the tortoise, and will never catch up with him. This is indicated by the fact that $\frac{1}{1-q}\to\infty$ as $q\to 1$. Incidentally, when $q=\frac{1}{10}$ it is easy to see why the sum of an infinite number of terms, $\sum_{n=0}^{n=\infty}\left(\frac{1}{10}\right)^n$, may be finite in value. Each new term that we add gives a digit 1, one more decimal place further to the right than its predecessor, giving us a sum of the form 1.11111. . . . No matter how many terms are added, we never increase the digit from 1 to 2 in any decimal position.

117 The concept of the continuity of a line, which was introduced into mathematics by Dedekind in 1872, gives us a solution of the third paradox. According to this concept a straight line, or generally any continuous region, contains as many

The argument of the arrow paradox can be further amplified in the following manner. The moving arrow occupies different sets of spatial points at different instants. Yet, since it must be stationary at any instant, how can it ever move to the set of points which it occupies at some other instant?

458–428 BCE **Ezra ben Seraya ha-Kohen** the scribe[118]. Founder of the postexilic viable Judaism. Edited and canonized the Five Books of Moses

---

points in any finite interval as we wish to denumerate. By giving a line this property of consisting of as many points as desired, it is found that the line will consistently have the properties of being continuous. In contrast, a discrete line is one which has a finite number of points between any two given points. Thus, we ask, if the arrow is at rest *now* at one point (instant) on the time-axis line, how does it ever get to the next instant?. The answer is that such a question is ill-defined, since there is no "next" point. For between the point in question, and any point that is designated as the "next point", there can be any desired number of intervening points. To quote Bertrand Russell's discussion of the problem (1929): "*The solution lies in the theory of continuous series: we find it hard to avoid supposing that, when the arrow is in flight, there is a next position occupied at the next moment; but in fact there is no next position and no next moment, and when once this is imaginatively realized, the difficulty is seen to disappear*".

118 At the beginning of the Persian period (538 BCE) the Jewish exiles in Babylon were free to return to their own land and there was the first exodus of Babylonian exiles in the days of Cyrus (538–529 BCE). These people built the second Temple in Jerusalem (ca 515 BCE). The Persian rule lasted until 332 BCE, when it was overthrown by Alexander the Great. During the two centuries of Persian domination, the Jewish community in Israel, with its center at Jerusalem, in spite of varied hindrances, gained new life; the Law was codified, the Temple-worship fully organized, and the work of collecting and arranging the sacred books of the Old Testament well begun.

Under the long reign of Artaxerxes I (465–424 BCE), the 'second return' of the Jews (458 BCE) under the aegis of Ezra and **Nehemiah** during their two visits to Jerusalem (445 and 432 BCE) took place.

If not for the actions of Ezra and Nehemiah, Judah would have disintegrated, Jerusalem faded out of Jewish consciousness, and there would be no motivation for exilic Jews to exist as Jews. Dying memories and tempting assimilation would hurl them out of Jewish history.

Ezra and Nehemiah created a new age for the Jews; now that the era of prophecy was over, the time has come to transubstantiate prophetic ideology into practical policies. Where the function of the prophets has been to universalize the Hebrew concept of God and give mankind a universal ethic, the function of Ezra and Nehamiah was to formulate ideas that would preserve the Jews as Jews.

(Pentateuch), thus fusing the most important of the then-extant Mosaic documents into what is now known as the Torah. This act of canonization cleared the way for the compilation of the Old Testament. His exegesis on the Torah and the major reforms he instituted in Judaic practice may be seen as the beginning of classical Judaism.

Ezra was a scribe in the court of the Persian King Artaxerxes in his summer capital city of Susa. It is there that he heard of the plight of the Jews and the sad state of Judaism in Jerusalem. He successfully petitioned the king to let him organize a second Zionade, which proved successful beyond all expectations.

Ezra and Nehemiah introduced three innovations to strengthen the Jewish identity of the returnees from Babylon: a ban on intermarriage with any Gentile, a stress on nationalism, and a canonization of scripture. These were destined to shape the character of the Jews and chart their course through the next two millennia.

450 BCE **Empedocles of Acragas** (ca 490–435 BCE). Greek philosopher, statesman, and physician. A scientific thinker, precursor of the physical scientists. First to try to identify principles of motion. He believed that light moves in space with a finite velocity.

Empedocles was born in Acragas (Agrigentum) on the south coast of Sicily of a distinguished family, then at the height of its glory. His grandfather was victorious in the Olympian chariot race in 496 BCE. Like his teacher Parmenides, he was steeped in Pythagorean tradition. He tried to combine this with the more naturalistic philosophy and science of the Milesians. Fragments of two treatises, one entitled *On Nature* and the other *Purification*, are extant.

The doctrine of the four elements: water, fire, air and earth, which dominated the popular thinking about nature for more than 2000 years, was probably originated by Empedocles. He is credited with founding the first great medical school. His legendary death is supposed to have taken place by falling into the crater of Mount Etna (this has been a source of inspiration for many poets, among them: Mattew Arnold and Friedrich Hölderlin). He has been celebrated by followers of Mazzini as the democrat of antiquity par excellence.

Empedocles tried to reconcile the doctrine of the permanence of being (Eleatics) with the doctrine of change and motion (Heraclitos). His four elements are eternally brought into union and eternally part from each other. The different proportions in which these four indestructible and unchangeable matters are combined with each other determine the different organic structures produced. It is in the aggregation and segregation of elements thus arising that Empedocles, like the atomists, finds the real process which corresponds to what is popularly termed growth or decay. Nothing new comes or can come into being; the only change that can occur is a change in juxtaposition of element with element.

Empedocles believed that light travels very fast, but not infinitely fast. Demonstrated that nature does not allow the creation of a macroscopic vacuum ("horror vacui").

450 BCE **Herodotos** (ca 484–425 BCE). Greek historian[119], called the *Father of History*. He undertook to write the history of the world up to his own time, yet he limited his 9 books to the rise of the Persian Empire, the Persian invasions of Greece in 490 and 480 BCE, the heroic fight of the Greeks against the invaders, and the final Greek victory. He wholly omitted the histories of Phoenicia, Carthage and Etruria, three of the most important states existing in his day. Even the Trojan war is not mentioned in his writings.

Herodotos included many stories which he did not believe[120], because they made his account more interesting. Historians even now cannot disentangle fact from legend in his work. Yet some of his keen observations are remarkable: while traveling through the lower Nile River valley, his observations led him to reason that the Nile delta must have been made from a series of floods. It then quickly followed, by his reasoning, that if a single flood were to lay down only a thin layer of sediment, it must have taken many thousands of years to build up the Nile delta.

He was born at *Halicarnassos*, today *Bodrum*, in Asia Minor. During his youth he traveled widely in Greece, the Middle East and North Africa. The things he learned in his travels formed the materials of his histories. In about 447 BCE he visited Athens, and three years later settled in the colony of Thurii which Pericles was then founding in southern Italy. Nothing is known of the rest of Herodotos' life.

His visits to the cultural centers of Persia, Babylon, Egypt and Greece, and his attempts to describe the whole evolution of the non-Greek peoples of the Persian Empire (including the Egyptian and the Babylonians) make his books a valuable source of information on the state of science and technology in the ancient world.

In Herodotos' writings, the existence of *China* is recorded for the first time in the European literature: According to him, a Greek named **Aristeas** (ca

[119] His history was written about 450 BCE; first printed in Latin translation in 1474; the Greek text first printed in 1502; first translated into English in 1709.

[120] In Egypt, for example, he was shown a temple in which the priests put out food for the god every night. The food was always gone in the morning, a fact which they presented to Herodotos as proof of the god's existence. "*I saw no god*", he commented, "*but I saw many rats around the base of the statute*".

6^{th} or 7^{th} century BCE) claimed to have journeyed across Central Asia as far as the Djungarian Basin and the Altai mountains. There he heard of the Chinese as a settled and prosperous people who dwelt by a never-frozen sea[121].

ca 450 BCE **Bryson of Heraclea**[122] Mathematician. Discovered that the area of a circle is a limit to the increasing areas of inscribed polygons and to the decreasing areas of the circumscribed polygons, and as the number of sides of those two series of polygons is increased, their areas approach closer to the area of the circle on both sides of it. The method was actually applied by Archimedes, who measured the areas of two inscribed and circumscribed polygons of 96 sides each and reached the conclusion that

$$3.141 \approx 3\frac{10}{71} < \pi < 3\frac{1}{7} \approx 3.142.$$

ca 450 BCE **Philolaos of Tarentum** (*or Croton*). Greek mathematician and philosopher of the Pythagorean school. The first to propound the doctrine of the *motion of the earth*. He arrived at this conclusion on the basis of the

121 When Alexander the Great overthrew the Persian Empire (329 BCE) he did not venture beyond Bukhara and Southern Turkestan and did not attempt further conquests in Central Asia. The first efforts of China itself to establish relations with the West were made by the Emperior Wu Ti (of the Han dynasty) in 128 BCE. He sent an embassy to the Yuer-Chi (nomadic people) whose court lay near Bukhara; it provided China with the *geographic knowledge* on which it based the imperialistic policy in Central Asia. It let also to the introduction into China of the *vine* which the Greek brought into Bukhara and Samarkand. The Chinese exchanged this for gold and *silk*, then unknown in the Greco-Roman world during the first century BCE. In the second century CE, some Roman sailors actually reached China directly by sea, by rounding Cape Comorin in Southern India and passing through the Strait of Malacca.

122 In his book *"Ancient Science Through the Golden Age of Greece"* (1952), **George Sarton** made the observation that the mathematical genius of Greece manifested itself through the ideas of men who were not mathematicians in the restricted sense of today; they were philosophers and sophists who realized the fundamental importance of mathematics and tried to understand it as well as possible. They came from many parts of the Greek world, widely distributed across Hellas as was the artistic or literary genius: **Zenon** hailed from Magna Grecia, **Hippocrates** from Ionia, **Democritos** from Thrace, **Hippias** from Peloponnesos, **Theodoros** from Cyrenaica, **Bryson** from the Black Sea, **Antiphon** from Athens (the only one from that city) and **Archytas** from Sicily. This burst of mathematical creativity was not restricted to any locality – it was the genius of Greece.

following observations: the Sun, Moon, Venus, Mercury, Mars, Jupiter, Saturn – all travel slowly *across the stars* from West to East. On the other hand, the star pattern carries the whole lot daily from East to West.

This reversal, which spoils simplicity, could be removed if the view of the earth as the static center of the universe is abandoned. The new scheme of Philolaos was based on two elements:

(1) The earth is revolving around a central fire, making a small circle once every 24 hours. This accounted for the daily motion of the stars, sun, moon and planets without the need to assume that the earth was spinning about its axis (to explain why the fire was not seen from earth, it was necessary to assume further that its inhabited part was always facing outward, away from the fire).

(2) Seven spheres, carrying the sun, moon and 5 planets respectively, rotate *slowly* in the same direction as the earth around the central fire; the outermost crystal sphere of the stars is fixed.

This fantastic scheme was revolutionary in the sense that it treated the earth as a planet.

Philolaos was perhaps the first to suggest the earth's spherical shape. He inferred this from the circular shape of the earth's shadow cast on the moon during lunar eclipse. Philolaos and the Pythagoreans described the motion of the heavenly bodies by a rough but simple scheme that could be called a *theory*, in contrast with the more accurate working *rules* that were developed in Babylon. As a machine for making predictions, this first Greek system of uniform revolutions was hopelessly inaccurate; but as a frame of knowledge it was indeed superior: it gave a feeling that the heavenly scheme of things makes sense.

ca 450 BCE Development of the 12 constellations of the zodiac in Mesopotamia, recognizing the importance of the *plane of the ecliptic*.

ca 450 BCE **Hanno the Carthaginian**. Phoenician navigator and explorer. Made exploring and colonizing voyage down African west coast, reaching Gambia, Sierra Leone and perhaps Cameroon, or even Gabon. Hanno had no real successors until the Portuguese in the Middle Ages. They were to take over 40 years to accomplish what Hanno had achieved in a single voyage of only a few months.

Hanno described, among other things, the gorilla. Phoenician navigators are believed to have reached the Atlantic Ocean, sailing as far as Cornwall, England to the north where they established tin mines. They also circumnavigated Africa, to the south.

About the same time, another Carthagenian, **Himilco**, sailed out out Massalia (Marseille). In his voyage, which lasted four months, Himilco sailed northward round Spain. He reached the coasts of Brittany and Cornwall and thus firmly established a Phoenician monopoly of the flourishing trade in Cornish tin between Brittany and the Mediterranean[123].

450 BCE **Hippocrates of Chios** (ca 470–410 BCE). Greek mathematician and excellent geometer. Among the inventors of the method of 'reductio ad absurdum'. Was first to use letters in geometrical figures. Devised a method for the quadrature of certain lunes. He was the author of the first systematic treatise in geometry, and proved numerous geometrical theorems[124]. Though his work is now lost, it must have contained much of what **Euclid** later included in Books 1 and 2 of the *Elements*. Hippocrates' book also included geometrical solutions to quadratic equations and early methods of integration.

ca 445 BCE **Melissos of Samos** (ca 480–415 BCE). Philosopher and statesman. Disciple of *Parmenides* and a contemporary of Zeno. Commanded the fleet of Samos in victory over Athens, but after defeating Pericles was himself defeated (442–440 BCE).

The last member of the Eleatic school of philosophy, differing from Parmenides in maintaining the spatial infinity of the universe.

The extant fragments of his work defend Eleaticism against **Empedocles**' doctrine of the four elements, against the Atomists' belief in a void, against **Anaximenes**' derivation of the world from its original matter by rarefaction

[123] The *Phoenicians* emerged as a significant maritime power after the collapse of the Mycenaens in the 12^{th} century BCE, although by this date they had long been involved in trade between Mesopotamia and Egypt. In the civilized East Mediterranean they established extensive commercial contacts, but no colonies, with the possible exception of Kition (Larnaka) in Cyprus.
Indeed, it was only in the central and West Mediterranean outside the areas directly controlled by the Greeks, that the Phoenicians founded a network of colonies. The most powerful western colony was Carthage, founded in 814 BCE. The Phoenicians were the most adventurous merchants and explorers of the ancient world (*Ezechiel* **27**); in the early 6^{th} century BCE a Phoenician fleet reputedly circumnavigated Africa.

[124] Contributed to the old problem of the *duplication of the cube*, by reducing it to the finding of two mean proportionals between one straight line and another twice as long. In modern language we would say that Hippocrates has reduced the solution of a cubic equation to that of two quadratic equations.

and condensation, and against **Anaxagoras**' assumption of the reality of heat and cold.

The Sophists

* * *

"Man is the measure of all things, of those which are – that they are, of those which are not – that they are not".

* * *

"As to the gods, I cannot say whether they exist or not. Many things prevent us from knowing, in the first place the obscurity of matter, then the brevity of human life".

(Protagoras of Abdera)

The political and economical unrest in the interim period between the Persian wars (490–478 BCE) and the Peloponnesian wars (431–404 BCE) created a social climate of skepticism, disillusionment, uncertainty and despair. Intellectuals were perplexed by the conflicting doctrines of **Heraclitos**, **Parmenides**, **Anaxagoras** *and* ***Empedocles***. *Where could the truth be found? Is there any truth? And if there is any, can mortal man attain it?*

The most perplexing question of all was this one – to whom should one entrust the education of ones growing sons? The need for teachers was felt acutely, and it was now satisfied by a new class of them who were called

Sophists[125]*: professional teachers of grammar, rhetoric, dialectics, and eloquence who taught young men to behave themselves, to be wise and happy; the first to require students to pay for instructions.*

For nearly a century the sophists held almost a monopoly of liberal education and contributed much to advancement of learning and popularization of science. They practiced their mission in introducing the common man to a higher standard of culture – imparting to him the values and skills of sophisticated philosophical inquiry and communication and tasks enabling him to live more useful and better life.

The sophists build their philosophy on the doctrine of the relativity of truth. At first they where influenced mainly by ***Heraclitos*** *and his followers who rejected the idea of absolute truth and interpreted reality as a process of constant change. The leading sophist philosopher,* **Protagoras** *applied the idea of change to epistemology (the study of what knowledge is and how it is obtained). He concluded that knowledge and truth are both dependent on judgment by the individual.*

The Pythagorean concept of unchanging, mathematical relationships as the essence of reality and the Eleatic principle that nature obeys laws of permanent Being, that the laws of physics are fixed and permanent[126]*, were propositions analyzed critically by the Sophists. They inquired whether such*

---

[125] From Greek $\sigma o \phi \iota \sigma \tau \eta' \varsigma$ = man of wisdom; the name given by the Greeks about the middle of the 5^{th} century BCE to certain teachers of a superior grade who, distinguishing themselves from philosophers on one hand and from artists and craftsmen on the other, claimed to prepare their pupils, not for any particular study or profession, but for civil life. Most of the Sophists were good men, yet other more conspicuous were moneymakers and hypocrites. As time went by, the number of bad teachers increased in numbers and the name Sophist acquired gradually a negative connotation.

For about 2300 years the Sophists have been despised and unjustly discredited as unscrupulous distorters of facts. It was **Friedrich Nietzsche** (1883–1887 CE) who rehabilitated them, and since then their contribution to philosophy can no longer be disregarded. Their foremost critic and adversary, **Socrates**, condemned their practice of accepting financial remuneration for teaching philosophy, stating that the search for scientific knowledge should never be debased in this way. **Plato** and **Aristotle** followed suite and induced posterity to condemn them as dishonest thinkers whose practices degenerated into hair-splitting of words, frivolous argumentativeness, and heuristic discussions designed to confuse the issue. Consequently the name *Sophist* which had earlier been applied to all philosophers (including even Socrates and Plato) became an opprobrious term.

[126] The Greek word for *physics* means unchanging nature.

unchanging laws of nature could be accepted as the basis for laws governing man. In other words: are there genuine moral laws, norms for evaluating human behavior, comparable to the laws which govern physical nature?

On the basis of their premise that knowledge was at best relative, they concluded that truth was unattainable. Because of his belief in the unavailability of absolute truth, the sophists turned his concern to the art of debate, to technique of convincing or converting ones opponent. Instead of trying to make truth prevail, the Sophist was interested only in winning an argument. Thus the Sophist's deep interest in grammar was motivated by the desire to manipulate it to serve his personal ends.

ca 450–410 BCE **Protagoras of Abdera**[127] (ca 485–410 BCE) Greek philosopher. Known as the first of the *Sophists*. One of the creators of Greek *rhetoric* and the *science* of *language*. He is credited with being first grammarian, distinguishing parts of speech, tenses and modes. He wrote numerous books, of which only four small fragments survived. Protagoras based his entire philosophy on the concept of *relativity of truth*. His doctrine can be summarized as follows: "Man is measure of all things..."[128]

- Sensation is the only source of knowledge. Man is capable of knowing what his sense tell him about what he perceives, not the thing itself perceived. Thus, sense knowledge is incomplete and not to be trusted, and man is wiser to be skeptic about everything.

- The subjectivity of sensation implies not only the *relativity of truth* (what is true for you is true only for you and what is true for me is true only for me) but also the *relativity of morals* (what is right for me may be wrong for you). From this follows, a most remarkable corollary, the

[127] *Abdera*, at the northern end of the Aegean Sea, was an ancient flourishing city. It gave birth to Democritos, Anaxarchos and Protagoras; it was the cradle of *atomic theory*.

[128] Some philosophers have interpreted this dictum as referring to man as an *individual*, while others have interpreted it as referring to a man in the *generic sense*, hence that ethical conduct and justice depend upon the moral codes of groups instead of the moral practices of individuals. In any case, either point of view had an enduring impact on the history of philosophy down to contemporary times.

doctrine of *equal rights* for all mankind, including women and slaves: the doctrine that each individual must decide for himself as to the validity of any proposition, leads to a principle of *social reform*, for it places all persons on an equal footing as judges of the truth. Protagoras therefore demanded that sweeping social and political reforms be instituted by democratic means.

- Human character can be improved by *education*, especially during childhood years. This capability is implied by the doctrine of the relativity of truth.

- God existed for those who wanted to believe in God.

Protagoras was born in Abdera, and when he reached the age of thirty he set out on his travels all over Greece as well as Sicily, lecturing and teaching. He lived and taught in Athens and became a friend of **Pericles** (495–429 BCE). In 411 BCE Protagoras was forced to flee Athens under sentence of death after having been accused of impiety. His books were publicly burned[129] (411 BCE). The ship that was carrying him to freedom was wrecked and he perished.

Another leader of the sophist school was **Gorgias** (ca 483–375). Born in Sicily, he settled in Athens (427 BCE) and supported himself by the practice of oratory and teaching rhetoric. He died at Larissa in Thessaly. He was the author of a lost work *On Nature or the Non-Existent*. Gorgias is the central figure in the platonic dialogue *Gorgias*.

440–410 BCE **Antiphon the Sophist** (480–411 BCE). An Athenian orator, who flourished at the same time as Socrates. He was a sophist, interested in many sciences. He made an early attempt to square the circle and invented a new method for the solution of that old problem – the *method of exhaustion*: Antiphon suggested that a simple regular polygon, say a square, be inscribed in a given circle: Then an isosceles triangle could be built on each side, its vertex being on the circumference. A regular octagon would thus be constructed, and continuing in the same manner one would easily construct regular polygon of $16, 32, 64, \ldots$ sides. Now it is obvious that the areas of each of those regular polygons approaches in the limit the area of the circle,

[129] This is the first recorded example of book burning. It suggests that there was already an established book trade in Athens at that time. The last event of this kind is the one ordered by Hitler on May 10, 1933 in the Third German Reich.

thus *exhausting* the area of the circle[130]. Since the area of each polygon can be exactly expressed in terms of repeated square roots of integers (i.e., the polygon can be "squared"), and since these areas increase in such a way that they are bounded by the said limit, the Sophists claimed that the limit itself is also squareable.

Antiphon was involved in an anti-democratic revolution which failed and, despite his profession as a writer of defense speeches, his brilliant speech failed to save his life when he was tried for treason, and he was executed.

440–399 BCE **Socrates** (469–399 BCE, Greece). Philosopher; One of the great Greeks who fashioned the traditional Western thinking system. Teacher of Plato. He embodied the revolt of Greek common sense against the intellectual extravagances of the early philosophers. Although he distrusted science, few men have contributed more to its development. His method of investigation prepared the elaboration of the method of inductive science. It was characterized by: insistence upon *clear definition*, use of *induction*, incessant war against vagueness of thought, deep sense of duty, *reasoned skepticism* (the very skepticism of the scientist who refuses to believe a thing until it has been proved to him).

Socrates held that scientific knowledge about the external world is not enough since it provides us only with universals, principles which hold true for us all in common. What is needed is self-knowledge, gained through self-examination; the principal value of scientific knowledge is simply to gain better understanding of oneself to enable one to live a better life. His question "who am I?" led him to the secret of self-control "Know thyself" (*gnothi-seauton*).

He was concerned with putting ethics on a firm basis so that the persuasive skills of the *Sophists* could no longer sway society. **Plato**, with his strong totalitarian tendencies, developed the notion of 'ideal forms' which was imposed on the world of his thinking. Later, **Aristotle** tightened up the system and showed its application to science. Plato took over Socrates' ideas and methods, reshaped them, added some of his own, and then gave them back to Socrates in the dialogues: what we call the 'Socratic method' is as expressed in Plato's writing, when the method is put into the mouth of Socrates by Plato.

---

[130] In modern notation we would write for a unit circle: $S_{2^n} = 2^n \sin\left(\frac{\pi}{2^n}\right)$, $n = 2, 3, 4, \ldots$, with $\lim_{n\to\infty} S_{2^n} = \pi$. This method was criticized by **Aristotle** on the grounds that no matter how many times the number of sides of each polygon is doubled, the area of the circle can never be completely used up. The method of exhaustion was later perfected by Archimedes and led to an early determination of an approximation for π.

It consists of the '*endless search for truth through asking questions*'. To this we attribute the immense progress of *science*. This obsession with 'search' means that the quest may be more important than the destination itself, which is why Socrates was not at all bothered when his discourses reached no conclusion. The '*endless search*' has a great merit because it means the sort of divine dissatisfaction which is the *essence of progress*. The apparent advance of Western Civilization compared to some others have been due to this 'search' component of intellectual effort.

Socrates wrote nothing of his own. Most of our information about his life and teachings comes from the writings of **Xenophon**, **Plato** and **Aristotle**.

Socrates was born in a village on the slopes of Mount Lycabettus (20 minutes walk from Athens) and lived in Athens. Upon the outbreak of the Peloponnesian War (431), Socrates, then 38 years of age, was called to service as a haplite (private, with shield and sword), and distinguished himself in battle. He had an enthusiastic following among the young men of Athens, but the general public mistrusted him because of his unorthodox views on religion and his disregard of public opinion. Inevitably, Socrates made enemies among influential Athenians. He was brought to trial, charged with corrupting the young and showing disrespect for religious traditions.[131] Sentenced to death, he refused several opportunities to escape from prison, and carried out the sentence by drinking a cup of hemlock poison.

During his youth Socrates said to have met the aging **Parmenides** and learned much from him. According to Parmenides, the world as we know it is merely an illusion; the ever changing multiplicity we observe is merely the *appearance* of a static, all-embracing Being. Why them bother with the working of the world (i.e. science) when they are nothing but an illusion?

Socrates accepted this antiscientific attitude: Reality was an illusion. This had negative effects on him and his successor Plato. During their lifetime a few significant advances were made in mathematics, but, only because this was considered timeless and abstract, and thus thought to be in some way connected with the ultimate reality of Being. Fortunately their successor Aristotle drew philosophy back toward reality.

[131] The modern political philosopher **Leo Strauss** (1899–1973) in his book *Socrates and Aristophanes* (1966) shockingly admits (contrary to generations of liberal professors who have taught him as a martyr to the First Amendment) that the prosecution of Socrates was not entirely without point. Strauss argues that philosophy cannot really construct a rational basis for ethics and therefore has a tendency to promote *nihilism* in mediocre minds and they must be prevented from being exposed to it. Thus, philosophy (contrary to mythology) — matters.

It is most ironic that, although Socrates and his followers disdained science as pointless and considered it a waste of time, the most beneficial effects of his legacy have in fact been in the field of science. But Socrates, himself, sought to make ethics, politics and other social matters the subject of his scientific inquiry. He hoped to discover universal laws and truths (as in mathematics) which would put these subjects on an absolute basis and so rescue them from the manipulations of people like the Sophists.

The antiscientific attitude that developed with Socrates was to cast a blight on philosophy for centuries to come. Largely as a result of Socrates' antiscientific attitude, the few great scientific mind of the ancient Greek world worked *outside* philosophy. **Archimedes** (in physics), **Hippocrates** (in medicine), and to a certain extent **Euclid** (in geometry) were isolated from philosophy and thus from any developing tradition of knowledge and argument.

Ancient Greek scientists knew the earth went round the sun, knew it was round, and even calculated its circumference. They observed electricity and were aware that the earth had a magnetic field. Outside the "universal wisdom" of philosophy, such factual bits of knowledge were isolated oddities. The fact that philosophy came of age under the aegis of an antiscientist must count as one of the great misfortunes of human learning. The mental energy expended in the Middle Ages calculating the number of angels who could stand an the head of a pin might instead have been directed toward the solution of real-world problems.

Worldview I: Socrates

* * *

"The unexamined life is not worth living".

* * *

"Only those who have lived an evil life hope that death is the end of everything for them".

* * *

"Knowing nothing, what could I write down?"

* * *

"Do as you please, since whatever you do you will regret it".

(When someone asked him whether he should be married or not)

"The body is forever wasting our time with its demands".

* * *

"I know that I don't know".

* * *

"We go our separate ways I to die and you to live. Which one is better God alone knows".

* * *

"This discovery of yours will create forgetfulness in the learner's souls, because they will not use their memories; they will trust to the external written characters and not remember of themselves. The specific which you have discovered is an aid not to memory, but to reminiscence, and you give disciples not truth, but only the resemblance of truth; they will be hearers of many things and will have learned nothing...; they will have the show of wisdom without the reality".

(Lamenting the effects of writing
on the memory and the soul of the learner)

* * *

437 BCE Hospital, possibly earliest, was build in Sri Lanka (Ceylon).

ca 435 BCE The sculpture **Pheidias**[132] (ca 500-430 BCE, Greece) completed the *statue of Zeus* at *Olympia*, Greece, the most famous statue in the ancient world and one of the *seven wonders* of the world. The statue, 12 meters high, showed Zeus on his throne. Zeus' robe and ornaments were made of *gold*, and his flesh of *ivory*; he had a wreath around his head and held a figure of victory in his right and a scepter with an eagle in his left. Thousands who came to Olympia for the *Olympian Games* admired this gold and ivory figure.

The statue was toppled during the great earthquake of July 21, 365 CE, some 800 years after its erection. It was later removed to Constantinople (ca 429 CE) where it still could be seen for another century until its final demolition by the Christian authorities.

432 BCE **Meton of Athens**. Greek astronomer. Discovered 19-year *Metonic cycle* of solar years and synodic months.

In 432 BCE, Meton and **Euctemon** in Athens, made the first accurate solstitial observations. These observations enabled them to determine the length of the seasons with greater precision. They introduced in that same year a new cycle, called the *Metonic cycle*[133], a period of 19 solar years, equivalent to 235 lunar months; this implied a year of ca $365\frac{5}{19}$ days, that is $365^d 6^h 18^m 56^s$. (It is just $30^m 10^s$ longer than the Mean tropical year of $365^d 5^h 48^m 46^s$.) In the next 300 years the margin of error was steadily reduced, until Hipparchos (130 BCE) arrived at the figure $365^d 5^h 55^m 12^s$. Thus the accuracy of Meton was of the order of approximately 1:17,000, and that of Hipparchos 1:100,000.

431–404 BCE *Peloponnesian War*. A series of three wars fought between the city-states of Athens and Sparta.

---

[132] **Pheidias** son of Charmides, universally regarded as the greatest of Greek sculptures. Born in Athens and studied under Agelades of Argos. According to Plutarch he was made an object of attack by the political enemies of Pericles, and died in prison at Athens. Pheidias was commissioned by Pericles to execute the greatest of the city's monuments. Among his notable works were sculptures on the *Parthenon* and the *Propylaea*, statue of *Athene Parthenos*, and statue of an *Amazon at Ephesos*.

[133] Our knowledge of this observation is obtained from a papyrus (now in the Louvre) called the *papyrus of Eudoxos*. It is probably a notebook of a student who flourished in Alexandria in ca 193–190 BCE.

The Peloponnesian league, consisting of Sparta and its allies, attacked the Athenian empire because it feared the growing power of Athens. The war ended in victory for Sparta which gained the support of Persia, helped subjects of Athens to revolt and forced the city to surrender.

Sparta was a military nation with good army but no fleet; Athens was a maritime power with a strong navy and a week army. Since her land defenses were almost invulnerable and ample supplies could be imported by sea, Athens could neither be brought to battle by land nor starved into submission. Fighting a defensive battle on land and offensive war at sea, she should have been able to defeat Sparta without great difficulty. During the first year of war Athens was successful both on land and sea, but her defensive policy necessarily led to the Athenians being crowded and besieged within their city walls.

Disaster struck in 430 BCE: A plague epidemic, starting in Ethiopia and traveling to Egypt, was carried across Mediterranean by ships to the Piraeus and Athens. It ravaged the city, killing as much as $\frac{2}{3}$ of the population and breaking the morale. The plague then broke out in the ships, decimating the naval expedition force and killing **Pericles** (429 BCE).

The plague of Athens undoubtedly contributed to the downfall of the Athenian empire. By killing so large a number, by demoralizing the capital and, above all, by destroying the fighting power of the navy, the plague prevented Athens from striking a decisive blow at Sparta. It thus provides a striking example of the effect of disease upon history.

431–400 BCE **Thucydides of Athens** (460–395 BCE, Greece). One of the greatest historians of all times. The father of scientific historiology. His history of the Peloponnesian War (of which he had been a witness, 431–404 BCE), is a literary and scientific classic. His description of the annular solar eclipse of Athens on August 3, 431 BCE, is the first *detailed* description of an eclipse (solar crescent, visibility of certain stars). In his history he described also the plague which lay waste to Athens in 430–425 BCE.

Thucydides was born in Athens. During the Peloponnesian War he commanded part of the Athenian fleet. He failed to relieve the siege of Amphipolis, and was exiled for 20 years. During his exile, he visited all parts of the Greek world.

430–420 BCE **Hippias of Elis** (460–ca 400 BCE). Greek sophist. Younger contemporary of Socrates. Introduced the first curve beyond the circle and the straight line later termed *quadratrix of Deinostratos*. It can be used to trisect an angle[134] and to square the circle (although Hippias probably did not know it). The quadratrix is the first curve known that cannot be constructed with straightedge and compass.

Hippias lectured in Athens on mathematics, music, astronomy, history, poetry and politics. He traveled all over Greece, giving public lectures and teaching, being a kind of a wandering sophist whose activities were dominated by love of fame and money. He was ready to discuss any subject but was especially interested in mathematics and science. His aim was not to give knowledge, but to provide his pupils with the weapons of argument in discussions on all subjects alike.

430–380 BCE **Hippocrates of Cos** (460–377 BCE, Greece). The father of medicine; one of the greatest clinical physicians of all times. His writings later provided scientific and ethical basis for modern Western medicine. He emancipated medicine from superstition, systematized the empirical knowledge which had accumulated in Egypt and in the schools of Cnidos and Cos, and founded inductive and positive medicine.

Hippocrates introduced the elements of the *scientific method*: he argued careful and meticulous observation: "Leave nothing to chance. Overlook nothing. Combine contradictory observations. Allow yourself enough time".

His principles of medical science formed the basis for the medical theory developed in the 19^{th} century. The *Hippocratic oath*, named for him, gave the medical profession a sense of duty to mankind which it never lost. Hipparchos maintained that the laws of nature could be discovered by studying facts and applying reason to them. He showed that disease had only natural causes,

---

[134] The function is $r = \frac{2a}{\pi}\frac{\phi}{\sin\phi}$, where $r(\phi)$ is the polar equation for a curve with polar coordinates $\{r, \phi\}$. Consider a Cartesian x–y system, with a circle of radius a about its origin, and let ϕ be measured from the positive x-axis counterclockwise. From a general point $\{r, \phi\}$ in the first quadrant draw a line normal to the x-axis; divide the line in the ratio 2:1, with the larger section toward the curve. Draw a parallel to the x-axis through the point of division of the line. Connect the origin with the point of intersection of that parallel with the curve. The angle between this new radius-vector and the x-axis is $\frac{\phi}{3}$. **Deinostratos** was the brother of **Menaichmos**.

The impossibility of trisecting a general angle with straightedge and compass tended to direct attention away from problems involving the trisectors of angles. This helps account for the late appearance of the following delightful theorem: "*The adjacent pairs of the trisectors of the angles of a triangle meet at the vertices of an equilateral triangle*".

This was discovered only in 1904 by the Anglo-American geometer **Frank Morley** (1860–1937) and the theorem now bears his name.

and took treatment of disease out of the hands of religion. He treated his patients with proper diet, fresh air, change in climate, and attention to habits and living conditions.

Before the invention of the thermometer, he charted the temperature courses of many diseases. He recommended that physicians be able to tell, from present symptoms alone, the probable past and future course of each illness. He stressed honestly the limitations of the physician's knowledge, (confiding to posterity that more than half of his partners were killed by the diseases he was treating). His options of course were limited; the drugs available to him were chiefly laxatives, emetics, and narcotics. He objected to the use of strong drugs without careful tests of their curative values.

Hippocrates also used surgery, but only as a last resort. His period was one of great intellectual development, and he certainly brought to bear upon medicine the same influences which were at work in other sciences by such contemporaries as **Socrates**, **Herodotos**, **Democritos**, and **Plato**[135].

He was born on the island of Cos of a family of priest-physicians. Democritos of Abdera was one of his masters. Hippocrates began his medical studies at Cos and Cnidos[136]. He traveled extensively, and taught and prac-

[135] Considerable further advances were made in classical times through the fall of Rome. While the medicine in the Islamic world flourished, what followed in Europe was truly a dark age. Much knowledge of anatomy and surgery was lost. Reliance on prayer and miraculous healing abounded. Secular physicians became extinct. Chants, potions, horoscopes, and amulets were widely used. Dissection of cadavers was restricted or outlawed, so those who practiced medicine were prevented from acquiring firsthand knowledge of the human body. Medical research came to a standstill.

[136] The great doctors recognized the spiritual side of healing; when all else failed, they were quite happy for their patients to attend one of the many *asclepieia* – temples to the patron god of physicians, *Asclepios* (*Aesculapis* to the Romans and realy the Egyptian **Imhotep** in a Greek dress), and his daughters **Hygeia** (health) and **Panacea** (healing). [Asclepios would often be accompanied by a snake, the *dracon* – hence the medical symbol of a snake rounding a staff.]

Pilgrims to the temples relaxed among beautiful surroundings and read inscriptions on marble pillars that told of the miraculous cures performed by god. Then they would bed down for the night in the sacred hall, where Asclepios would supposedly appear as they slept, to give them a 'dream drug' or even perform 'dream surgery'. These rites were derived from Egyptian models. Thanks to them, a large number of clinical observations were concentrated in the temples, especially in Cos and Cnidos.

Without those abundant clinical cases such as were afforded by the Asclepieia, ticed his profession at Athens, Thrace, Thessaly, Delos and his native island. He died at Larissa in Thessaly.

ca 425 BCE **Theodoros of Cyrene**. (ca 465–399 BCE) Mathematician and philosopher. Showed that the noninteger roots $\sqrt{3}$ up to $\sqrt{17}$ were irrational. The proof of the irrationality of $\sqrt{2}$ is quoted by **Aristotle** (384–322 BCE), but its originator is unknown. It is possible that $\frac{1}{2}(\sqrt{5}-1)$, which is the ratio of a side to a diagonal of a regular *pentagon*, was the first known irrational.

Theodoros was born in Cyrene, which was then a flourishing Greek colony just south of Greece on the North African coast. He was the teacher of both Plato and **Theaitetos**, starting his life as a philosopher and then switching to mathematics.

Plato stated in *Theaitetos* that Theodoros discussed the irrationality of $\sqrt{2}$, $\sqrt{3}$ ... and stopped at $\sqrt{17}$.

ca 420 BCE **Democritos of Abdera** (ca 460–370 BCE). A Greek physical philosopher and mathematician. The father of *Materialism* . Synthesized the ideas of Parmenides and Heraclitos and is the intellectual forerunner of the modern philosophers Locke and Descartes. Archimedes claimed that Democritos (ca 410 BCE) stated that the volume of pyramid on any polygonal base is 1/3 that of a prism with the same base and altitude[137].

---

the progress of medicine would have been considerably slower. Thus, the Asclepieia were the cradles of Greek medicine, and they help to account for the extraordinary richness of the Hippocratic collection, which themselves inherited and continued Egyptian tradition.

The Greek believed in the existence of 4 fluids, or humors, within the body, the *balance* of which was vital for health. The humors correspond to the 4 elements, and had the same qualities. They were also associated with particular parts of the body: Air $\leftrightarrow$ blood; Water $\leftrightarrow$ brain; Fire $\leftrightarrow$ liver; Earth $\leftrightarrow$ spleen; the corresponding humors were: blood, phlegm, yellow bile; black bile.

[137] Although Democritos could have hardly render a rigorous demonstration of this theorem, he still have *guessed* the result following two logical steps:

1. A prism can be dissected into a sum of prisms all having triangular bases, and, in turn, a prism of this latter sort can be dissected into 3 triangular pyramids having, in pairs, equivalent bases and equal altitudes. It follows that the crux of Democritos' problem is to show that two pyramids of the *same* height and *equivalent bases* have equal volumes (this was later demonstrated by Eudoxos of Cnidos, using the method of exhaustion).

2. If two pyramids with equal heights and equivalent bases (same area but not necessarily same form) are cut by planes parallel to the bases and dividing the

A pupil of Anaxagoras and Leucippos, a friend of Philolaos, and an admirer of the Pythagoreans. Studied in Egypt the mathematical and physical systems of the ancient schools. Diodoros Siculus tells us that he lived to be ninety years old.

Taught that mechanical relationships (arrangements of atoms) account for various characteristics of nature i.e. mechanistic causes account for all phenomena. Even morality, the soul, and all mental life are reducible to mechanistic terms with physical imperceptible atoms as their basic structure.

Spiritual reality does not exist: mechanistic Materialism is complete, self-sufficient and self-contained.

Atoms, owing to their non-sensory nature and small size, can only be thought, not directly observed. Nevertheless, these imperceptible atoms account for all observable phenomena of nature which are manifest to the senses. But sense experiment produces multiplicity of options because people receive and interpret sensory phenomena from different perspectives. Knowledge derived from the senses is therefore *relative to the person from whose experience it originates*. Therefore one can never use the senses to attain *truth* (knowledge of metaphysical reality[138]).

In his own words: "*Opinions say hot and cold, but the reality is atoms and empty space*". He believed that at every moment stars are colliding and new worlds are rising out of 'Chaos' by the selective aggregation of atoms, that there is no design and that the universe is a machine. He vaguely anticipated the notions of conservation of matter and energy and was first to discover the correct formulae for the volumes of a pyramid and a cone.

Democritos thus stated that all material is built out of indivisible atoms moving about in the microvacuum. He also believed that space is infinite, having always existed, and that the number of atoms is infinite. Records state that Democritos ranked intellectually equal if not superior to Plato and that his works, now vanished, were as comprehensive as those of Aristotle.

After Democritos, his school rapidly passed into near oblivion and its followers diverted in into *Sophism*.

---

height in the same ratio, then the corresponding sections formed are equivalent. Therefore the pyramids contain the same infinite number of equivalent plane sections, and hence must be equal in volume.

[138] Thus, 2300 years before Planck, Albert Einstein, Bohr, Born and Feynman, Democritos already foreshadowed the ontological difficulties that *quantum physics* posed to 20^{th} century physics.

ca 400 BCE Magnetic needles were used on Chinese ships. The mariner's compass is said to have been known to the Chinese as early as 1100 BCE, though it was not introduced into Europe until ca 1000 CE. Prior to 1600 CE nobody knew the true reason for the orientation of the needle.

ca 400 BCE The diseases of malaria and gout first identified or described with accuracy.

400 BCE Diminished rainfall caused endemic malaria in ancient Greece, undermining people's vitality.

400 BCE Oil was drilled on one of the Greek islands.

390 BCE **Theaitetos of Athens** (ca 415–369 BCE). A mathematician of great stature of the time of Plato. Studied with Theodoros of Cyrene and at the Academy. First to study the *octahedron* and the *icosahedron*. He fell on the battlefield (369 BCE) in a war between the Athens-Sparta alliance against the Theban army. One of Plato's dialogues is dedicated to his memory.

Theaitetos introduced the exact concept of *commensurability in length* and proposed that line segments, which produce a square whose area is an integer, but not a square number, are incommensurable with the unit of length. He was the first to write on the 5 *regular polyhedra* and the first to construct them, and finally, he formulated the theory of proportions. Since Euclid's Book X contains a detailed mathematical development of matters briefly indicated in Plato's dialogue, it is believed that a number of Euclid's propositions on the subjects of commensurability and proportion were originated by Theaitetos.

390–220 BCE *The Celtic-Roman Wars*. By about 400 BCE, Etruscan power had already started to wane, largely as a result of the occupation of most of Northern Europe by the *Celts* (ancestors of the Bretons, Welsh, Scots, Irish and the French). One group of Celts, the *Gauls*[139], crossed the Alps into Italy and pushed the Etruscans out of the Po Valley. From here they attacked Etruscan cities further south. The presence of the Celts in Northern Italy blocked the north-south trade routes and slowly choked the Etruscan economy. In 391 BCE, the Etruscan asked Rome for help and a military encounter between the two archenemies of the Etruscans became inevitable.

On July 18, 390 BCE, 70,000 Celts under Brennus defeated the Roman army at Allia and captured Rome. They sacked and burned the city and held all of it except the capitol. The Celts could have, there and then, destroyed the city-state, changing at one fell swoop the course of worlds history, but

[139] The origin of the district names of *Galicia* in Spain, Turkey and Poland derived from *Gaul*.

they sold their victory for ransom gold and withdrew after seven months. This they would dearly regret 65 years later. Indeed, during that time-interval, the Romans improved their weapons, military skill, discipline and administration.

In 225 BCE, a grand army of 70,000 Celts was crushed by an equal-sized Roman army under Marcellus at Telamon. *The Battle of Clastidium* (220 BCE) finally removed the Celtic treat on Rome and eventually caused the Celts to leave Italy.

387–360 BCE **Archytas of Tarentum** (ca 428–347 BCE). Greek philosopher, scientist, mathematician and distinguished in the administration of civic affairs. Occupies a high place among the versatile savants of the ancient Greek world. An intimate friend of Plato who quoted him as an example of the perfect ruler, the philosopher-king who combines practical sagacity with high character and philosophic insight. It was through him that Plato received his initiation in the exact sciences and Pythagorean philosophy. Aristotle wrote a special treatise '*On the Philosophy of Archytas*'.

He is described as the 8^{th} leader of the Pythagorean school, and was a pupil of Philolaos.

He was elected seven times to command the army. Under his leadership, Tarentum fought with unvarying success against the Messapii, Lucania, and even Syracuse. After a life of high intellectual achievement and uninterrupted public service, he drowned while on a voyage across the Adriatic.

In mathematics, he was the first to draw up a methodical treatment of *mechanics* with the aid of geometry and for that reason he is sometimes called the *founder of mechanics*. He first distinguished *harmonic* progression from *arithmetical* and *geometrical* progressions. He contributed many original theorems to geometry and new ideas to the study of music and acoustics. For, besides computing the numerical ratios for the new musical scales by means of systematic applications of the arithmetic and the harmonic means, he also laid the number-theoretical foundations for the theory of music which is found in Euclid's "*Sectio Canonics*".

Archytas is said to have been the inventor of a kind of *flying machine*, a wooden pigeon, balanced by a weight suspended from a pulley, and set in motion by compressed air escaping from a valve.

387–347 BCE **Plato** (427–347 BCE). One of the most influential thinkers in Western culture. Regarded as a father of traditional Western philosophy, who gave civilization a powerful thinking method. Philosopher and mathematician. Rejected the experimental method with ardor and contempt. In his view, no precise study of the ever changing phenomena in the natural universe was possible, and it was only in the philosophic theory of forms and in the science of pure mathematics that absolute knowledge could be attained. These contemplative disciplines of the intellect dealt with objects *timeless* and *invariant*, known independently of experience and existing logically prior to the material world, which could at most be merely an approximation to eternal forms or ideas.

Plato posed the three most basic questions of philosophy:

- How can man discover the truth?
- What is the origin of the Universe?
- What is the purpose of human life?

The answers Plato gave to these questions laid the foundation to a system of philosophy called 'Objective Idealism', according to which all things are the mere shadows of *ideas*[140]. Ideas are eternal, while things are transitory: true knowledge comes neither through perception nor reason but only via 'inspiration' arriving from beyond. We must look on this world as only the image, the shadow of an invisible system; the universe we see is based on ideal forms, which are imperfectly embodied in various objects. Since these ideal forms are ideas, they cannot be perceived by the senses, but only uncovered by the use of reason, guided by critical use of logic.

In his dialogue *Timaeus* Plato gave an account of his ideas about the creation of the universe; he maintained that every theory was of necessity based on ideas originated by the scorching intellect, *Science* is never able to reach any conclusion with absolute certainty. All the phenomena that we can perceive with our senses, the objects of physical science, provide only a picture of transcendental world of ideas , which represented for Plato the *real* world. Whereas the physical world is subject to continuous changes and consists of passing phenomena, the actual reality of the world of ideas is permanent. *Plato thus refused to accept the absolute character of science.*

Plato admitted in *Timaeus* that science may have a certain amount of precision. But in that case it must use *mathematics*, which was for him the natural language of science. Deeply influenced by the Pythagorean school, Plato realized the powerful creative force of mathematical formalism. Mathematics is somehow in the middle between the world of ideas and the observable

[140] One of Plato's strong opponents was **Antisthenes of Athens** (c. 444-365 BCE), founder of the *Cynic* school of Greek philosophy. He was a faithful student of Socrates and was present at the latter's death. Ridiculing Plato's doctrine of Ideas he said: "I am able to see the horse, but I cannot see his horse-ness".

world. His emphasis on the paramount importance of mathematics for science is widely considered one of the most important and far-reaching contributions to the development of human thought.[141]

In the *Timaeus* Plato formulates a cosmology and creation story consistent with this concept of human knowledge. At the beginning of time, a beneficent creator used the eternal ideas or forms to mold *preexisting, chaotic matter*[142] (like Pythagoras, Plato believed that the ultimate basis of these forms was mathematical[143] and geometrical). The creator molded matter into approximations of these ideal shapes, creating a universe ruled by eternal mathematical laws, laws which humans can deduce through reason. *These eternal mathematical laws are the true reality*, while the changeable universe we see is mere appearance – the observation of nature is thus unreliable. Ergo men cannot know truth by means of science.

Plato emphasizes the *ethical* implication of this distinction: the ideal forms are the source of all good, while base, earthy matter is the source of the world's evil. The mundane, changeable world of everyday life cannot be used to understand the eternal, perfect, and unchangeable heavens. The most perfect motion, circular motion, occurs only in heaven, not on earth. Plato thus developed a new mode of thinking about the universe and creation. Against the traditional appeal to authority, Plato counterposes the power of human reason. But he *attacks observation as a route to knowledge* and strictly separates the worlds of thinking and doing, the spirit and the flesh, the heavens and earth. He thereby created a mathematical myth, a formidable barrier to the development of science.

---

141 The views of Democritos on the atom were generally accepted as a dogma by 19^{th} century scientists. But Planck's observations on thermal radiation (1900 CE) where difficult to reconcile with the prevailing notion of the atomic structure of matter, thereby reviving Plato's notion in science, with strong emphasis on the belief that *mathematical laws* underline the structure of matter.

142 In this sense, Plato's creation story holds important similarities with the story of *Genesis* **1**.

143 In Book 5 of his *Laws*, Plato gives $7! = 5040$ as the population of an ideal city: it has 58 proper divisors (without 1 and 5040), which makes for efficient division of the population for purposes of taxes, land distribution, war and so on. (Plato was not aware that 7560 and 9240 have 62 proper divisors each – the maximum possible number of 4 and fewer digits). In Book 12, Plato cites 3 and 18 as the most difficult sums to roll with three dice: they are the only sums that can be made in only one way, 1–1–1 and 6–6–6. Since there are $6^3 = 216$ equally probable ways of rolling three dice, the probability of making 3 or 18 is $\frac{1}{216}$.

Plato conceived his view of the universe as consistent with, and reinforcement for, his concept of the ideal society. In that society, outlined in the dialogue of *The Republic*[144], all thought is to be done by philosopher-kings, aided by a small elite of guardians. No one else has political or social rights. As ideas and matter, heaven and earth, are separated at creation, so guardians and philosopher-kings must be separated from those who work: slaves are to work without thinking, and philosopher-kings are to think without working. As the creator gave eternal mathematical laws to the universe, so the philosopher-king give laws to society[145].

His real name was **Aristocles** and Plato was a nickname (broad-shouldered). After the death of **Socrates** (399 BCE) he left Athens and

[144] From the vantage-point of the turn of the 21^{th} century Plato can be regarded as *centralist*, *totalitarian* and *authoritarian*. His rigid rules, harsh judgments, high degree of righteousness and category boxes remind us of the symptoms of certain totalitarian regimes in our own times.

In his *Republic*, Plato suggested that society is to be ruled by a special class called *Guardians*. These are originally to be soldiers who take over government. They, in turn, are divided into *Rulers*, who make policy decisions and the *Auxiliaries* (police etc.) who carry out the policies. Ordinary people are to have no say in government whatsoever. The Guardians are a sort of hereditary caste who are to be bred on strictly scientific lines. Families and private wealth are distractions and are to be abolished. The *State* is to come first. There is to be *censorship* in the arts and in the materials allowed into education. Nothing that might threaten the State is to be permitted. The whole purpose of education is to produce a small 'elite of Guardians'. *Breeding* is to be arranged through special marriage festivals. It is thus not surprising that there are strong echoes of Plato in the Marxists approach to state and government and that the Nazi party in Germany had as one of its official aims the production of 'Guardians of the highest Platonic ideals'. But this is where the similarity ends. Plato was a good philosopher who meant well and did not seek power for himself. Moreover, he was *not* advocating bully-boy fascism and was against the rule of wealth. What he wanted was competence.

[145] Plato's *Republic*, a rejection of Athenian democracy, was modeled on Sparta, where a small body of landlords ruled over a mass of rightless serfs, or helots. Sparta had defeated Athens in the 30-year long Peloponnesian War, begun in the year of Plato's birth, 428 BCE. Deprived of its colonies in the wake of defeat, Athens erupted in social conflict as rich landholders battled freeholders and artisans. To protect themselves from the growing demands for abolition of debts and land distribution, the landholders sought to combat political democracy and to erect a hierarchical society. Plato became the theoretician of this new society, rationalized in *The Republic* and justified by the cosmology expounded in *Timaeus*.

traveled widely for several years through the ancient world. In 387 BCE he returned to Athens and founded there a school of philosophy and science known as the *Academy* (after the Greek hero Academus) which lasted under various forms until 529 CE. It can be considered as the first university. Subjects such as astronomy, biological sciences, mathematics and political science were investigated at the Academy. While the influence of **Socrates**[146] (ca 469–399) in the development of mathematics was negligible (if not actually negative) that of Plato was substantial, since the Academy became the mathematical center of the world. His '*Theory of Forms*' [147] is a remarkable precursor of modern *physical* theories on two counts: (1) the notion that everything can be reduced to geometry, a view held by Descartes and in a different way by Einstein; (2) the notion that the elements (atoms of Democritos) are made of still smaller basic entities ('triangles' in his language, which are evidently what in modern physics are called nuclear or elementary particles or even quarks). Plato believed that the planets move in circular orbits around a stationary earth.

In addition, Plato accepted the Pythagorean doctrine that the world is ultimately intelligible in terms of numbers. Altogether therefore, his method is that of mathematical modeling of the physical world, which is the aim of mathematical physics today. In mathematics proper, Plato introduced rigorous definitions (straight line; plane surface) and began the study of the *golden section*. He gave a new rule to find square numbers which are the sum of two squares $\left[(2n)^2 + (n^2-1)^2 = (n^2+1)^2\right]$ and the five regular solids are named after him.

It must be remembered, however, that the Pythagorean school and Plato fostered the idea that rational order and harmony lie at the base of all things – quite independently of the human mind. This and similar thoughts were organized in a systematic philosophical edifice.

Plato's concept of eternal mathematical laws is two-sided. The belief in such laws and the search for them has been immensely important to science.

---

[146] This great philosopher championed clear thinking with careful definitions, and condemned the astronomers for their wild conjectures. Thus he probably helped astronomy towards becoming an inductive science that extracts its data from observations.

[147] Before Plato, Philosophers like **Parmenides** and **Heraclitos** had been wrestling with the problem of *change*. Heraclitos believed that all was change: you can never stem into the same river twice. Parmenides believed that there was an unchanging inner core. Plato put both of these views together with his theory of 'inner forms' or 'essence'. Those were absolute and fixed while the surficial matter could change.

But scientists have had two contrasting views about what these laws are: One view follows Plato and believes that the laws truly rule the universe, that the universe is the embodiment of abstract mathematics. The other, quite different view, is that mathematical laws are *descriptions* of physical processes and patterns of nature – the reality is a process *described* by mathematics, the language of exact science.

It took mankind another 1600 years to liberate itself from Plato's total reliance on the regularity and perfection of the material universe and advocate systematic observations, experimentation and the reliance on mathematical rigor.

Plato Versus Democritos

The concept of the atom was first proposed by Democritos and Leucippos (ca 460–420) BCE. They considered their hypothetical atom the smallest indivisible unit of matter, eternal and indestructible. The atoms of Democritos were all of the same substance, but had different sizes and different shapes.

Plato finally rejected the idea of the atom proposed by Democritos and Leucippos. For him the smallest parts were geometrical forms: *Those of the earth he compared with cubes, of fire with tetrahedra, of air with octahedra, and of water with icosahedra. Moreover, he did* not *consider these smallest part indivisible. The elements can be transformed*[148] *into each other, they*

[148] Anaximander (ca 560 BCE) was the first to envisage the possibility of the *transformation* of one primary substance into another. **Heraclitos** (ca 500 BCE) assumed that *fire* is the basic element, which is both matter and moving force. **Werner Heisenberg** (1954) pointed out that if the word *fire* is replaced by *energy*, modern atomic physics is in some way extremely close to the doctrine of Heraclitos: Energy – or more precisely, quantum fields – is in fact the substance from which all things, and even the vacuum itself, are considered to be made in modern physics; energy is what moves (the famous $\pi'\alpha\nu\tau\alpha \quad \chi\omega\rho\epsilon\iota$), and even in classical (pre-quantum) physics energy is transmutable into motion, heat, light and tension. Einstein's Special Relativity, of course, taught us that *energy* and *mass* (the latter quantifying *inertia* – the tendency *opposing* motion) are, in a deep sense, inter-convertible.

can be taken apart and new regular solids can be formed by them; for Plato, the form *was more fundamental than the* substance *of which it was the form.*

The ideas of Democritos prevailed in physics and chemistry until the turn of the 20th century, soon to be modified through the advent of quantum physics: **Planck**, ***Heisenberg***, **Pauli** *and other leading atomic physicists were greatly influenced and inspired in their philosophy of science by Plato and Neoplatonism. They considered themselves to be much nearer to Plato and the Pythagoreans then to the materialistic view of Democritos. The elementary particles (such as* protons, neutrons, electrons, mesons, quarks *and the like) are not eternal and indestructible units of matter, but rather, interconvertible (in certain allowed combinations) via absorption and release of motion-energy. Furthermore, one of these particles is the photon – a particle of light ("pure energy").*

As modern physics has indeed shown, these particles can be transformed into each other (in the laboratory or in natural radioactive processes) through collisions or instability. Such events support the idea that all particles are made from the same substance, namely dynamical quantum fields, of which a particle is but one manifestation. These modern views resemble in a remarkable way those of Plato as expressed in Timaeus. *In the last analysis, the basic building blocks of matter a-la-Plato are not substance but* mathematical forms.

In modern atomic physics elementary particles are also considered as forms, albeit of a much more complicated nature. In Greek philosophy these forms were considered as static; *modern physics stresses their* dynamic *nature. There are in few fields so many strikingly similar ideas, despite basic differences, as are encountered when comparing Greek philosophy with modern theories of the atom.*

384–100 BCE The concept of 'parallelogram of velocities' was known to **Aristotle** (384–322 BCE), **Archimedes** (287–212 BCE) and **Hero of Alexandria** (ca 100 CE, author of '*Automata*', first book on robots).

373 BCE A major earthquake followed by a devastating sea wave emanated from the Corinthian Gulf (38.3 °N, 22.1 °E).

ca 370–355 BCE **Eudoxos of Cnidos** (ca 408–355 BCE, Asia Minor). A distinguished Greek mathematician, astronomer, orator, legislator, philosopher, geographer, and medical man. The method of Exhaustion, credited to him, is a mathematical scheme similar to the integral calculus, although formally quite different. It is the Platonic school's answer to the paradoxes of Zeno. The method assumes the infinite divisibility of magnitudes and has, as a basis, the proposition: "*If from any magnitude there be subtracted a part not less than its half, from the remainder another part not less than its half, and so on, there will at length remain a magnitude less than any preassigned magnitude of the same kind*".

The method is rigorous but sterile, because it does not enable one to calculate the result. Archimedes however, discovered a procedure which he established by the method of exhaustion. His idea was to cut up his area, or volume, into a very large number of parallel plane strips, or thin parallel layers and (mentally) hang these pieces at one end of a given lever in such a way as to be in *equilibrium* with a figure whose content and centroid are known. With our modern method of limits this method can be made perfectly rigorous, and is identical with present day integration.

Eudoxos was the founder of scientific astronomy. He constructed a mathematical model of motions of heavenly bodies, with 33 concentric spheres rotating around a stationary earth. The combination of these motions succeeded in imitating the actual motions of the sun, moon and even planets across the fixed stars. His work was the first astronomy which broke away from philosophical speculations and sought to build a mathematical model to fit observations.

Eudoxos studied mathematics with Archytas in Tarentum, and medicine with Philistrium on the island of Sicily. When he was 23 years old, he went to Athens to learn philosophy and rhetoric. He was so poor that he had to live in the harbor-town Piraeus, a walk of two hours each way from Plato's Academy. Some years later his friends enabled him to undertake a journey to Egypt. From Agesilaos, King of Sparta, he received a letter of recommendation to the Pharaoh Nectanebus. In Egypt he learned astronomy from the priests of Heliopolis and he made observations himself in an observatory, situated between Heliopolis and Cyzicus on the sea of Marmara, which attracted a large number of pupils.

Around 365 BCE Eudoxos came once more to Athens with his pupils. He held discussions on philosophical questions with Plato who did not agree with some of his views and ideas. He died in his native town of Cnidos on the Black Sea, highly renowned and honored.

The story of Greek Infinitasphobia

The Pythagoreans could not accept $\sqrt{2}$ *as a number, but no one could deny that it was the diagonal of the unit square. Consequently, they believed that geometrical quantities must be treated separately from numbers or, rather, without mentioning any numbers except rationals. Greek geometers thus developed ingenious techniques for precise handling of arbitrary lengths in terms of rationals, known as the* theory of proportions *and the* method of exhaustion.[149] *The rejection of irrational number by the Greeks was just part of a general rejection of infinite processes.*

Aristotle *said that infinity exists only potentially, not in actuality. In fact, until the late 19*th *century*[150] *most mathematicians were reluctant to accept infinity as more than 'potential'. The infinitude of a process was understood as the possibility of its indefinite continuation without its eventual completion. (e.g. the paradoxes of Zeno; ca 450 BCE)*

Thus, the Greek accepted that the sequence of natural numbers 1,2,3,... is a potential infinity. They also understood, that one can generate a sequence of rational numbers according to a definite rule that approaches $\sqrt{2}$ *in the limit*[151]*, yet they were afraid to draw the final logical conclusion even in the face of the* geometrical *evidence that such limits do indeed exist.*

Nevertheless, the fear of infinity forced the Greek mathematicians to seek the infinite in the finite*, that is, devise a calculus devoid of infinitesimals, through which they could successfully compute areas, volumes and lengths of arcs. This was perhaps the Platonic school's answer to the paradoxes of Zeno. The names of the persons who achieved this feat were* **Antiphon** *(480–411*

149 When theses techniques where reconsidered in the 19^{th} century by **Dedekind**, he realized that they provided an *arithmetical* interpretation of irrational quantities after all. It was then possible to reconcile the apparent conflict between arithmetic and geometry.

150 With the exception of the 18^{th} century, the great age of the infinitesimals; then, no barrier between mathematics and physics was recognized, since the leading physicists and the leading mathematicians were the same people.

151 The first mathematical process we would recognize as infinite was devised by the Pythagoreans via the recurrence relations $x_{n+1} = x_n + 2y_n$; $y_{n+1} = x_n + y_n$, for generating integer solutions of the equations $x^2 - 2y^2 = \pm 1$. It is likely that those relations arose from an attempt to understand $\sqrt{2}$ and it is easy to see that $\lim_{n\to\infty}(\frac{x_n}{y_n}) \to \sqrt{2}$.

BCE), **Eudoxos** *(ca 408–355 BCE) and* **Archimedes** *(287–212 BCE) The method was advanced in two stages:*

- *Theory of proportions: enables length to be treated as precisely as numbers while only admitting rational numbers. The objectives of* ***Eudoxos*** *was to be able to compare two ratios to determine whether they are equal, and if they are not, which is larger in a way that is equally valid for ratios of commensurable and incommensurable magnitudes. This resulted in the statement: "The ratio $\frac{a}{b}$ exists when whole numbers m and n can be found such that $ma > b$ and $nb > a$". [i.e. $\frac{1}{m} < \frac{a}{b} < n$].* ***Euclid*** *included this statement among his 'definitions' in book V.* **Archimedes***, who used it extensively, regarded it as an axiom. He attributed it to* ***Eudoxos****, and it is now known as the Eudoxos-Archimedes axiom. Its virtue is that it excludes not only zero but any idea of infinity – either the infinitely large or the infinitely small.*

  Eudoxos went on to state a criterion for two ratios to be equal (in modern terminology): "If a, b, c, d" are four given magnitudes, then $\frac{a}{b} = \frac{c}{d}$ iff, given any two positive integer, then:

  $$\begin{array}{l}(1)\ ma > nb \text{ implies } mc > nd\\ (2)\ ma = nb \text{ implies } mc = nd\\ (3)\ ma < nb \text{ implies } mc < nd\end{array}$$

  If the magnitudes are commensurate, (2) is sufficient, both ratios being equal to the rational number $\frac{n}{m}$. The subtlety of the theory lies in (1) and (3), because (2) never holds for incommensurable magnitudes. Out of two inequalities the condition for equality somehow emerges. Eudoxos goes on to deal with unequal ratios by asserting that if two numbers m and n exist such that $ma > nb$ and $mc < nd$ then $\frac{a}{b} > \frac{c}{d}$.

  The above three Eudoxian assertions (or axioms) provided a firm foundation from which to extend the Pythagorean treatment of the ratios of whole numbers to deal with incommensurable magnitudes, while avoiding the notion of irrational numbers on the one hand and providing the basis for a generalization into the method of exhaustion, on the other.

  The theory of proportions was so successful that it delayed the development of the theory of real numbers for 2000 years! This was ironic, because the theory of proportions can be used to define irrational numbers just as well as can lengths[152].

[152] Any *arithmetic* approach to $\sqrt{2}$, whether by sequences, decimals, or continued fractions, is infinite and therefore less intuitive. Until the 19^{th} century this seemed a good reason for considering geometry to be a better foundation

For the measurement of the circle, Archimedes needed to calculate the value of $\sqrt{3}$*. He did it by a clever uses of the method of proportions in the following way (modern notation):*

$$2^2 = 3 \times 1^2 + 1 \qquad \therefore \quad \left(\frac{2}{1}\right)^2 = 3 + \frac{1}{1^2}$$

$$7^2 = 3 \times 4^2 + 1 \qquad \therefore \quad \left(\frac{7}{4}\right)^2 = 3 + \left(\frac{1}{4}\right)^2$$

$$26^2 = 3 \times 15^2 + 1 \qquad \therefore \quad \left(\frac{26}{15}\right)^2 = 3 + \left(\frac{1}{15}\right)^2$$

$$97^2 = 3 \times 56^2 + 1 \qquad \therefore \quad \left(\frac{97}{56}\right)^2 = 3 + \left(\frac{1}{56}\right)^2$$

$$362^2 = 3 \times 209^2 + 1 \qquad \therefore \quad \left(\frac{362}{209}\right)^2 = 3 + \left(\frac{1}{209}\right)^2$$

$$1351^2 = 3 \times 780^2 + 1 \qquad \therefore \quad \left(\frac{1351}{780}\right)^2 = 3 + \left(\frac{1}{780}\right)^2$$

Therefore

$$\frac{2}{1} > \frac{7}{4} > \frac{26}{15} > \frac{97}{56} > \frac{362}{209} > \frac{1351}{780} = 1.7320510... > \sqrt{3}$$

Likewise, the numerical identities

$$5^2 = 3 \times 3^2 - 2 \qquad \therefore \quad \left(\frac{5}{3}\right)^2 = 3 - \frac{2}{3^2}$$

---

for mathematics than arithmetic. Then the problems of geometry came to a head, and mathematicians began to fear geometric intuition as much as they previously feared infinity. There was a purge of geometric reasoning from the textbooks and an industrious reconstruction of mathematics on the basis of numbers and sets of numbers.

Indeed, **Dedekind**(1872) introduced a partition of the positive ratios into sets L, U such that a member of L is less than any member of U. This definition of a positive real number, now known as *Dedekind cut* [e.g. $L(\sqrt{2}) = \{r|r^2 \leq 2\}$; $U(\sqrt{2}) = \{r|r^2 > 2\}$ with r rational], gives a complete and uniform construction of all real numbers as points on a line, using just the rationals. This is an explanation of the *continuous* in terms of the *discrete*, finally resolving the fundamental conflict in Greek mathematics.

$$19^2 = 3 \times 11^2 - 2 \qquad \therefore \quad \left(\frac{19}{11}\right)^2 = 3 - \frac{2}{11^2}$$

$$71^2 = 3 \times 41^2 - 2 \qquad \therefore \quad \left(\frac{71}{41}\right)^2 = 3 - \frac{2}{41^2}$$

$$265^2 = 3 \times 153^2 - 2 \qquad \therefore \quad \left(\frac{265}{153}\right)^2 = 3 - \frac{2}{153^2}$$

$$989^2 = 3 \times 571^2 - 2 \qquad \therefore \quad \left(\frac{989}{571}\right)^2 = 3 - \frac{2}{571^2}$$

$$3691^2 = 3 \times 2131^2 - 2 \qquad \therefore \quad \left(\frac{3691}{2131}\right)^2 = 3 - \frac{2}{2131^2}$$

lead to the inequalities

$$\frac{5}{3} < \frac{19}{11} < \frac{71}{41} < \frac{265}{153} < \frac{989}{571} < \frac{3691}{2131} = 1.7320506... < \sqrt{3}$$

To 6 significant figures, we therefore find by Archimedes' method

$$\sqrt{3} = 1.732050...$$

To calculate the ratio of the circumference of a circle to its diameter, Archimedes began by trapping the circle between an exterior hexagon and an interior hexagon. His result, in terms of $\sqrt{3}$, is

$$3 < \frac{\text{circumference}}{\text{diameter}} < 2\sqrt{3} = 3.461...$$

Successively halving the angle subtended by the polygon side at its center, there appear regular figures having 12, 24, 48, 96 ... sides[153]*. Using no more than proportions and the Pythagorean theorem, Archimedes obtained with a 96-gon his best value*[154] *for π*

$$3.1408 = 3\frac{10}{71} < \frac{\text{circumference}}{\text{diameter}} < 3\frac{1}{7} = 3.1428.$$

[153] Today we would have written:

$$2^k n \sin\left(\frac{\theta}{2^k}\right) < \pi < 2^k n \tan\left(\frac{\theta}{2^k}\right), \qquad \theta = \frac{\pi}{n}$$

when n is the original number of sides, doubled k times. (Archimedes took $n = 6$, $k = 4$).

[154] This *may* have been known to the ancient Egyptians who built the Great Pyramid of Gizah: the ratio of the perimeter of this pyramid to its height was 2×3.142 which falls right in between Archimedes' two limits.

It correctly compares to $\pi \approx 3.14159$ *to 5 figures. The value of* $3\frac{1}{7}$ *was used by most European mathematicians until 1573, when Valentinus Otho used* $\pi = \frac{355}{113} = 3.141592...$ *That Archimedes arrived at his result without trigonometry, and without decimal (or other positional) notation is an illustration of his tenacity.*

- *The* method of exhaustion *is a generalization of the theory of proportions. Just as an irrational* length *is determined by the rational lengths on either side of it, more general unknown quantities (such as arcs, for example) become determined by arbitrary close approximation using known elements. Examples (as expounded in book XII of Euclid's elements) are an approximation of the* circle *by inner and outer polygons and an approximation of the* pyramid *by stacks of prisms.*

  In both cases the approximating figures are known quantities, on the basis of the theory of proportions and the theorem that the area of a triangle $= \frac{1}{2}$ *base* $\times$ *height.*

  "Exhaustion" does not mean using an infinite sequence of steps to show (in the case of the circle) that area is proportional to the square of the radius. Rather, one shows that any disproportionality can be refuted in a finite *number of steps. This is typical of the way in which exhaustion arguments avoid mention of limits and infinity.*[155] *In the case of the pyramid, one uses elementary geometry to show that stacks of prisms approximate the pyramid arbitrarily closely. Then exhaustion shows that the volume of a pyramid, like that of a prism, is proportional to base* $\times$ *height. Finally there is an argument to show that the constant of proportionality is* $\frac{1}{3}$.

  Archimedes used the method of exhaustion to calculate the area of a circle. He was able to show that $S = \lambda r^2$ *(*S *= area;* r *= radius), with*

$$\lambda = 32\sqrt{2 - \sqrt{2 + \sqrt{2 + \sqrt{2 + \sqrt{2}}}}} = 3.140...$$

In Euclid, both the infinite and the infinitesimal are deliberately excluded[156].

155 **Euclid** (330–260 BCE) avoided even the method of exhaustion itself in his derivation of the area of a polygon, using clever *dissection* arguments.

156 Had the Greeks accepted the concept of infinity, they would have had to accept the notion that the whole is no greater than some of it's parts, since infinity, plus whatever number you please, or plus or times or minus infinity, can still be infinity. This Aristotle was *not* ready to accept.

Archimedes, *working in the tradition of Aristotle and Euclid , asserted that an infinitesimal, if it existed, would be a number greater than zero, which nevertheless remained less then 1, say, no matter how (finitely) many times it was added to itself. But such a number* could not exist *since even a very small non-zero number becomes arbitrary large if it is added to itself enough times. So, on the one hand Archimedes rejected infinitesimals, but on the other hand, being also an engineer and physicist, he* used infinitesimals *to solve problems in the geometry of parabolas. Then, since infinitesimals "do not exist", he gave "rigorous" proofs of his results using the method of exhaustion, relying on indirect arguments and purely finite constructions.*

The method of exhaustion, is a rigorous but sterile method: once a formula is known, the method may furnish an elegant tool for establishing it. How then, did Archimedes discoverer the formulas which he so neatly established by the method of exhaustion?

*The above question was finally answered in 1906, with the discovery by Heiberg, in Constantinople, of a copy of Archimedes' long lost treatise '*Method, addressed to Eratosthenes*'. In it, Archimedes reveals that his deepest results were found using dubious infinitary arguments, and only later proved rigorously. Because, as he says, "It is of course easier to supply the proof when we have previously acquired some knowledge of the questions by the method, than it is to find it without any previous knowledge".*

Archimedes, nevertheless, made the most elegant application of the method of exhaustion, coming nearest to actual integration, in his quadrature of a parabola*. In a letter to his fried* ***Dositheos****, he mentioned that he had shown that 'any segment bounded by a straight line and a section of a right-handed cone is $\frac{3}{4}$ of a triangle, which has the same base with the section and equal height.' We now call the section of right-angled cone a* parabola[157]*.*

The concepts that Archimedes needed for proofs in geometry – the theory of proportions and the method of exhaustion – had already been supplied by Eudoxos. It was, however, Archimedes' phenomenal insight and technique that lifted him head and shoulders above his contemporaries. Indeed, even

157 A canonical parabola $y = \lambda x^2$ is cut by the line $y = b$; the area of the triangle is $b\sqrt{\frac{b}{\lambda}}$; the area of the parabolic sector is

$$2\int_0^{\sqrt{\frac{b}{\lambda}}} (b - \lambda x^2)dx = \frac{4}{3}b\sqrt{\frac{b}{\lambda}} = \frac{4}{3} \times (\text{area of triangle}),$$

as calculated by Archimedes.

with the limitations imposed on him through Aristotle's fear of the infinitesimals, he was not to be surpassed for the next 1900 years.

370–350 BCE **Thymaridas** (ca 400–350 BCE). Phytagorean mathematician known for his solution of the special system of linear equations

$$\begin{aligned} x + x_1 + x_2 + \ldots + x_{n-1} &= S \\ x + x_1 \qquad\qquad\qquad &= a_1 \\ x + \quad x_2 \qquad\qquad &= a_2 \\ x + \qquad x_3 \qquad &= a_3 \\ \vdots \qquad\qquad\qquad\qquad &\vdots \\ x + \qquad\qquad x_{n-1} &= a_{n-1} \end{aligned}$$

The solution $x = \frac{(a_1+a_2+\ldots+a_{n-1})-S}{n-2}$, is known by the name "*flower of Thymaridas*". In this line of development, the Phytagoreans carried forward the development of Babylonian algebra and transformed it into geometrical algebra. Thymaridas also wrote on prime numbers. Little is known about his life except for the fact that he was apparently a rich man, who for some unknown reason, fell into poverty.

367 BCE **Kiddinu** (Cidenas). A Babylonian astronomer from the city of Sippar, known for its school of astronomy. His name is mentioned by Greek and Roman historians and appeared also on clay tablets. He may have been the originator of lunar theory, some 200 years before Hipparchos[158].

---

[158] Cidenas is mentioned by **Strabo** and **Pliny**. He was rescued from a long obscurity, to take his place as one of the greatest ancient astronomers: The Jesuits **Epping** and **Kugler** deciphered in 1881 a Babylonian tablet of about 100 BCE, entitled '*The Lunar Computation-Table of Kiddinu*'. They found in it just the same length of the lunar (synodic) month from New Moon to New Moon, that Ptolemy afterwards attributed to **Hipparchos**.
In 1920 it was discovered that Kiddinu had recognized the *tropical and the sidereal years*. Thus he was acquainted with, and was probably the discoverer of, the *precession of the equinoxes*, on which Hipparchos' fame had mainly

357–336 BCE Astronomical evidence for the date of the prophecy of **Joel**.

Joel is one of the few biblical writers who clearly alludes to *total lunar and solar eclipses*. His statement in **2**, 31, "*The sun shall be turned into darkness and the moon into blood*" – is unique in the Old Testament.

Total eclipses of the sun, because of their extreme rarity in any one region, are very useful for chronological dating. The sudden and intense *darkness* which occurs when the whole sun is obscured by the moon is an awe-inspiring sight, not easily forgotten. Joel's reference to the moon is more direct; the association of a total eclipse of the moon with *blood* is often mentioned in early literature; the moon often glows a deep red color during totality of a lunar eclipse on account of sunlight scattered in the earth's atmosphere.

The originality of Joel's prophecy suggests that Joel himself witnessed total eclipses of moon and sun.

As lunar obscurations of this type are frequent (on the average about one every three years at any given place), it is not improbable that Joel saw several of these in his lifetime. Consequently, he would not need to draw on the experience of others.

Astronomical calculations show that from 1130 BCE until almost 310 BCE only two obscurations of the sun could have been complete anywhere in Israel.

The dates of these events in terms of the Julian Calendar are 357 BCE, March 01 and 336 BCE, July 04. Both eclipses would be very striking in Judah; the 357 eclipse would be total at about 1:15 p.m. with the sun at altitude of about 45 degrees. The later eclipse (336) would be even more impressive: it would reach totality within a few minutes of noon and the sun would be at an altitude of 80 degrees (almost at zenith), duration of totality of each event being about three minutes. Total lunar eclipses visible through Israel occurred within two years of each event. It would therefore appear that the astronomical evidence favors a time window 357–356 BCE for the prophecy of Joel.

354–322 BCE **Aristotle** (384–322 BCE). A Greek philosopher, educator, encyclopedic scientist and a mastermind in all fields of human inquiry: he wrote on physics, metaphysics, ethics, logic, politics, art, biology, zoology

---

rested!

The astronomical data which Kiddinu determined (or at least employed) are incredibly accurate: for the sun's motion relative to the moon he erred by a single second; for a certain other motion of the sun from the node, his value is 0.5 second too great, and is actually better than that on which our principal modern tables of eclipses are based. Kiddinu had at his disposal the records of every eclipse of the moon visible in Babylon for at least 300 years.

and astronomy. He formalized the gathering of scientific knowledge. While it is difficult to point to one particular theory, the *total* result of his compilation of knowledge was to provide the fundamental basis of science for a thousand years. Tightened up the *Socratic method* and showed its application to science. Made important contributions by systematizing deductive logic.

His conception of nature stood in marked contrast to those of Pythagoras and Plato in that it grossly underestimated the importance of mathematics. Logic, on the other hand, was overrated.

Aristotle found Plato 'ideas' ridiculous and considered the *senses* as the only sources of truth. His teachings about ethics was that the goal of life was happiness. He was a student and disciple of Plato in the Academy (and later an educator and protegé of Alexander the Great).

Established in 334 BCE the Lyceum of Athens[159]. He was perhaps the world's first great biologist, but his views on physics and astronomy were rather confused[160]. In his book *Physics* (stemming from the Greek word 'nature') he defined philosophy of nature as a study of things that change. But although Aristotelian physics was wrong, it was an essential precursor of modern physics.

Aristotle was primarily a philosopher and biologist, but he was thoroughly au courant with activities of the mathematicians. He made no lasting impact on the field, although like his teacher, he contributed indirectly to the development of mathematics.

Aristotle was among the first to rightly describe the heart as the center of a system of blood vessels. However, he thought that the heart was both the seat of intellect (the brain was not identified as a seat of intellect until over a century later) and a furnace that heated the blood. He considered this warmth to be the vital force of life because the body cools quickly at death. Aristotle also erroneously theorized that the "furnace" was ventilated

---

159 A member of Aristotle's school or a follower of Aristotle (Aristotelian) is known as *peripatetic*; it is an adjective pertaining to the philosophy or method of teaching of Aristotle, who conducted discussions while walking about in the Lyceum (from the Greek *peri* = around and *patein* = walk). The Lyceum was a school of philosophy and rhetoric near the temple dedicated to the god of shepherds, **Apollo Lyceus**.

160 In a letter to his friend Solovine, Albert Einstein said (1948): "*Certain things from the philosophical writings of* **Aristotle** *were actually deceptive. If they had not been so obscure and so confusing, this kind of philosophy would not have held its own very long. But most men revere words that they cannot understand and consider a writer whom they can understand to be superficial*".

by breathing. Moreover, he did not think that there was a direct connections between arteries and veins.

Aristotle supported the view that vacuum could not exist ("*horror Vacui*" – nature abhors vacuum). He believed that object would travel with infinite speed in vacuum, but did not believe that actual infinity could exist. He did believe, however, that all of space is filled with the four elements (fire, earth, water, air) and with "ether". The terms 'ether' and 'vacuum' would be largely viewed as synonymous for the next 2200 years.

Aristotle set out to construct an actual physical model of the universe. All motion, according to Aristotle, is either rectilinear, circular, or a combination of the two, because these are the only "simple movements". Upward motion is motion toward the center, downward motion leads away from it, while circular motion is movement around the center. Celestial bodies revolve in circles. He devised a scheme that allowed the concentric spheres of Eudoxos to rotate in practice as well as in theory. His cosmology required a large number of spheres for its elaborate machinery to operate.

Aristotle had a strong sense of religion and placed much of his belief in the existence of God on the glorious sight of the starry heavens. He delighted in astronomy and gave much thought to it. In supporting the scheme of concentric spinning spheres, he gave a dogmatic reason: *the sphere is the perfect solid shape*; and this prejudiced astronomical thinking about orbits for centuries. The heavens then, are the region of perfection, of unchangeable order and circular motions.

For ages Aristotle's writings were the only attempt to systematize the whole of nature[161]. They were translated from language to language, carried from Greece to Rome to Arabia, and back to Europe centuries later, to be copied and printed and studied and quoted as the authority. Long after the crystal spheres were discredited and replaced by eccentrics, those circles were spoken of as spheres; and the medieval schoolmen returned to crystal spheres in their short-sighted arguments, and believed them real.

The distinction between the perfect heavens and the corruptible earth remained so strong that Galileo, 2000 years later, caused great annoyance by showing mountains on the moon and claiming the moon was earthly; and even he, with his understanding of motion, found it hard to extend the mechanics of downward fall to the circular motion of the heavenly bodies.

Aristotle did much to set science on its feet. His whole teaching was a remarkable life's work of vast scope and enormous influence. At one extreme

---

[161] As **Renan** observed, "*It is largely by the titles of his books that Aristotle has dominated the human mind; the labels of his books remained for two thousand years the divisions of knowledge itself*".

he catalogued scientific information and listed stimulating questions; at the other extreme he emphasized the basic problems of scientific philosophy, distinguishing between the *true physical causes* and *imaginary schemes to save the phenomena*.

He was first to realize that the economic set-up gives rise to social inequalities and hence to social conflicts. *Slavery*, however, seemed justified to him because it was 'necessary' to society.

Aristotle was born at Stagira in Chalcidice and grew up at the Macedonian court, where his father was the king's physician. In 367 BCE, at the age of 18, he went to the academy at Athens to study with Plato and remained there until the latter's death 20 years later. In 343 BCE Aristotle returned to Macedonia as tutor of Alexander the Great, then a lad of 13. When Alexander died at the age of 33, his conquests had spread Greek culture and learning throughout most of the known world. Thus Aristotle's association with the young prince, which lasted four years, was to have far-reaching effects on history in general and his own life in particular.

Aristotle was identified with the Macedonian rulers of Athens and their supporters, and upon Alexander's death in 323 BCE, he fled the city to Chalcis, on the Aegean Island of Euboea, to escape the outbreak of anti-Macedonian sentiment. He died a few months later, leaving a body of writings whose importance in the history of Western thought cannot be overestimated[162].

The works of Aristotle fall under three headings:

(1) dialogues and other works of popular character;

(2) Collection of facts and material from scientific research;

(3) systematic works.

The works on the second group include 200 titles, most in fragments collected by Aristotle's school and used as research. Some may have been done at the time of Aristotle's successor **Theophrastos**. The systematic treatises

[162] It is reported that Aristotle writings were held by his student **Theophrastos**, who succeeded Aristotle in leadership of the Peripatetic School. Theophrastos' library passed to his pupil **Neleos**. To protect the books from theft, Neleos' heirs concealed them in a vault, where they were damaged somewhat by dampness, moths and worms. In this hiding place they were discovered about 100 BCE by **Apellicon**, a rich book lover, and brought to Athens. They were later taken to Rome after the capture of Athens by Sulla in 86 BCE. In Rome they soon attracted the attention of scholars, and the new edition of them gave fresh impetus to the study of Aristotle and of philosophy in general. This collection is the basis of the works of Aristotle that we have today.

of the third part were not, in most cases, edited and published after his death from unfinished manuscript. Aristotle's systematic treatises may be grouped as follows:

- *Logic*

  The heart of his logic is the *syllogism* (e.g.: All men are mortal; Socrates is a man; therefore Socrates is mortal). The syllogistic form of logical argumentation dominated logic for 2000 years.

- *Physical works*

  1. Physics (explains change, motion, void, time)
  2. On the Heavens (structure of heaven, earth, elements)
  3. On Generation (through combining material constituents)
  4. Meteorology (origin of comets, weather, disasters)

  Empty space is an impossibility. *Elements* are not composed of geometrical figures (as taught by Plato and Pythagoras). *Time* depends for its existence upon motion and on man's counting mind if there were no mind to count, there could be no time.

- Psychological works

  1. On the Soul (explains faculties, sciences, mind, imagination)
  2. On Memory, Reminiscence, Dreams, and Prophesying.

- *Works on natural history* (mostly on animals)

- *Philosophical works*

  1. Metaphysics (substance, cause, form, potentiality)
  2. Nicomachean Ethics (soul, happiness, virtue, friendship)
  3. Eudemain Ethics
  4. Magna Moralia
  5. Politics (best states, utopias, constitutions, revolutions)
  6. Rhetoric (elements of forensic and political debate)
  7. Poetics (tragedy, epic poetry)

The prodigious activity of Aristotle marks the climax of the golden age of Greece. The very existence of his works not only reflects his encyclopedic genius, but is also testimony that a large amount of scientific research had already been accomplished by his time. He had a deep mathematical knowledge, but that knowledge was happily balanced by a very extensive acquaintance with every branch of natural history. Thus, his philosophy was naturally more experimental, more inductive, than that of Plato[163].

Aristotle is one of the founders of the inductive method. He was first to conceive the idea of *organized research*, and himself contributed considerably to the organization of science by his systematic survey and classification of knowledge of his time[164]. He classified the sciences into two broad categories: *theoretical* (knowledge and speculation) and *practical* (action) sciences. The first group was in turn divided into three subgroups: philosophy, physics and mathematics. He took pains to elucidate the fundamental principles of each science in particular and of science in general.

Aristotle's theories were *physical*, not metaphysical, in nature. Superstition and astrological predictions were noticeably absent. Although his cosmology of concentric spheres and circular, geocentric, heavenly motions was quickly superseded by Ptolemy's epicyclic motions, Aristotle's views on natural phenomena were mostly unchallenged for the next 2000 years and his influence lasted until the beginning of the 18^{th} century.

---

163 In a detail of Raphael's fresco *The School of Athens*, **Plato** and **Aristotle** are depicted in a way which symbolizes their approach to knowledge. Aristotle gestures toward the earth; Plato points his finger to the heavens. Aristotle looked to nature for answers; Plato searched for the ideal.

164 The Aristotelian method of problem-solving hinges on the Socrates doctrine of 'endless search for the truth'. The notion that there *is* an ultimate truth and that we can seek to get nearer and nearer to that truth, is what has driven science along. We look at a complex phenomenon in the belief that at the end there will be the simplest of 'ultimate truths'. In practice, the problem is first subjected to *analysis*; the *cause* is identified. When the cause is removed, the problem is solved. The method presupposes that the cause (or causes) can be identified, and then, when eventually found – can be removed.

Worldview II: Aristotle

* * *

"To live alone one must be either a beast or a god".

* * *

"Wisdom is not a wisdom at all, if it comes too late."

* * *

"Plato and truth are both clear to us; but it is a sacred duty to prefer truth."

* * *

"The mathematical sciences particularly exhibit order, symmetry, and limitation; and these are the greatest forms of the beautiful."

* * *

"Inferiors revolt in order that they may be equal, and equals that they may be superior."

* * *

"Injustice arises when equals are treated unequally and when unequals are treated equally."

* * *

"Wicked men obey from fear; good men from love."

* * *

"Philosophy is the science which considers truth."

* * *

"The whole is more than the sum of its parts."

* * *

"It was through the feeling of wonder that men now and at first began to philosophize."

* * *

"Art not only imitates nature, but also completes its deficiencies."

* * *

"Dignity does not consists in possessing honors, but in deserving them."

* * *

353 BCE *The Mausoleum at Halicarnassos*: A great marble tomb erected by Queen Artemisia in memory of her husband King Mausolos. The Greek architects **Satyros** and **Pythios** designed the tomb and the sculptors **Bryaxis**, **Leochares**, **Scopas**, and **Timotheos** carved the decorated band on the building. The tomb was about 41 meters high. It has a rectangular basement beneath a colonnade formed by 36 columns. A stepped pyramid rested on the colonnade, and a statue of Mausolos in a chariot stood on top of the pyramid. Only pieces of the building and its decorations remain.

350 BCE **Menaichmos** (ca 380–320 BCE). Mathematician. Pupil of Eudoxos. Geometry teacher of Alexander the Great. Is reputed to have discovered the conic sections, later to be known as the *ellipse*, *parabola* and *hyperbola*. He derived some of their properties. The names were supplied by **Apollonios of Perga** (262–200 BCE). Menaichmos lived mostly in Alexandria, and made a fundamental study of the conic sections.

Menaichmos was especially interested in the old problem of the duplication of the cube[165]. He found two ways of solving the reduced quadratic equations

---

[165] Three classic problems emerged in the 5^{th} century BCE:

- the squaring of the circle;
- the trisection of an angle;
- the duplication of a cube (the *Delian* problem).

Hippocrates of Chios and Menaichmos were especially interested in the third of these problems; Hippias of Elis found an ingenious solution of the second by means of the curve invented by him, the *quadratrix*. Deinostratos applied it to the solution of the first problem.

The origin of the third problem is associated with a story: In 430 BCE a great plague struck Athens, killing **Pericles** (429 BCE). The Athenians appealed to the oracle at Delos to provide a remedy. The oracle said that Apollo was angry because his cubical altar was too small. If it were doubled, the plague would end. The Athenians had a new altar built that was twice the original in length, breadth, and height. The plague became worse because the god wanted the *volume* of the cube doubled, and the Athenians has octupled it. The plague went on until 423 BCE. The Delian problem went on until the 19^{th} century.

Around 320 CE, **Pappos** declared that it was impossible to solve any of the classic problems under the Platonic restrictions (straightedge and compass only), although he did not offer a proof of this assertion. In the 19^{th} century, each problem was shown incapable of any solution that met the Platonic requirement:

- **Pierre Wentzel** (1837) supplied a rigorous proof that an angle cannot be trisected with an unmarked straightedge and collapsing compass.
- **Ferdinand Lindemann** (1882) showed that π is a transcendental number, implying that the circle cannot be squared.

of Hippocrates of Chios by determining the intersection of two conics – two parabolas in the first case, a parabola and a rectangular hyperbola in the second.

ca 350 BCE *Mayan arithmetic and numerical notation.* In order to escape rapidly mounting calendric chaos, the Mayan priests devised a simple numerical system, including the concept of *zero*, which even today stands as one of the brilliant achievements of the human mind. Numbers were denoted by bar-and-dot glyphs; the dot · has a numerical value of 1 and the bar – a numerical value of 5, and by varying combinations of these two symbols, the numbers from 1 to 19 were written. The glyph for *zero* was a symbol that looks roughly like a half-closed eye,

$$\begin{array}{ccccc}
 & \dot{1} & \ddot{2} & \dddot{3} & \ddddot{4} \\
\overline{5} & \dot{\overline{6}} & \ddot{\overline{7}} & \dddot{\overline{8}} & \ddddot{\overline{9}} \\
\overline{\overline{10}} & \dot{\overline{\overline{11}}} & \ddot{\overline{\overline{12}}} & \dddot{\overline{\overline{13}}} & \ddddot{\overline{\overline{14}}} \\
\overline{\overline{\overline{15}}} & \dot{\overline{\overline{\overline{16}}}} & \ddot{\overline{\overline{\overline{17}}}} & \dddot{\overline{\overline{\overline{18}}}} & \ddddot{\overline{\overline{\overline{19}}}}
\end{array}$$

Mayan bar-and-dot notation was simpler than Roman notation: to write the numbers from 1 to 19 in Roman notation, it is necessary to employ the symbols I, V and X, and the processes of addition and subtraction (VI is V plus I, but IV is V minus I). In the Mayan system there is only one arithmetic process, that of addition.

The Maya employed a second notation comparable to our Arabic notation in which different types of *human heads* represented the numbers from 1 to 13, and zero.

In writing bar-and-dot numbers above 19 the Maya used a positional system of numeration. In our decimal system, the positions to the left of the decimal point increase by tens. In the Mayan vigesimal system the values of the positions increase by *twenties* from bottom up. (An exception is made in counting *time*, when, the third position is 18 instead of 20 times the second.)

- It was shown that the Delian problem required the construction of a line whose length is the *cube* root of 2. (With a straightedge and a compass, it is only possible to construct square roots.).

Thus, for example, the numbers $10,951 = 11 \cdot 20^0 + 7 \cdot 20^1 + 7 \cdot 20^2 + 1 \cdot 20^3$ (right) and $806 = 6 \cdot 20^0 + 0 \cdot 20^1 + 2 \cdot 20^2$ (left), where written as:

		$\cdot$	1×20^3
$\cdot\cdot$	2×20^2	$\overset{\cdot\cdot}{-}$	7×20^2
(figure of an 'eye')	0×20^1	$\overset{\cdot\cdot}{-}$	7×20^1
$\overset{\cdot\cdot}{-}$	6×20^0	$\overset{\cdot}{=}$	11×20^0

The largest number found in the codices is 12,489,781.

ca 350 BCE **Heracleides of Pontos** (ca 388–315 BCE). Greek philosopher and versatile and prolific writer on mathematics, music and physics. Made a step toward the heliocentric idea: "*The stars of Mercury and Venus, make their retrograde motions and retardations about the rays of the sun, forming by their courses a wreath or crown about the sun itself as center*". He clearly recognized that the earth rotates on its axis.

Heracleides was born at Heraclea in Pontos. Studied philosophy at Athens under Speusippos, Plato and Aristotle (Plato, on his departure for Sicily, left his pupils in charge of Heracleides). The latter part of his life was spent at Heraclea.

339–314 BCE **Xenocrates of Chalcedon** (ca 385–314 BCE). Mathematician and philosopher. Disciple of Plato. Head of the Athenian Academy for 25 years. Continued Plato's policy of excluding from the Academy the applicants who lacked geometric knowledge. Saying to one of them: "*Go thy way for thou haste not the means of getting a grip of philosophy*".

Xenocrates wrote a great many treatises, all of which are lost. It is known that he tried to solve the earliest problem of combinatorial analysis: calculating the number of syllables that could be formed with the letters of the alphabet (According to **Plutarch** that number was 1,002,000,000,000).

At the time of Plato's death, his sister's son **Speusippos**, succeeded him as the head of the school (347–338). **Aristotle** and his friend Xenocrates decided to leave, accepting the invitation of a fellow student, Hermeias, ruler of Atarneus (opposite Lesbos). Aristotle then married Pythias, who was Hermeias niece and adopted daughter. Hermeias also recommended Aristotle to Philip as a tutor to his son, Alexander (the Great).

Xenocrates advanced the idea of *indivisible atoms of time*. The idea of temporal atomicity does not necessarily imply that there must be gaps between successive instants. The essential criterion for atomicity is that there is a limit to the division of any duration into constituent parts. In other words, time would be like a line which can be divided into a finite number of adjacent segments with no intervals between them. It would mean that, from the temporal aspect, there are minimal-time processes in nature, no process occurring in less than some shortest unit of time, or *chronon*[166].

339 BCE *The Fourth Sacred War*: Philip II of Macedonia defeated an alliance of Greece with Thebes near Amphissa. Philip conquered Greece and turned the Greek peninsula into a Macedonian protectorate.

The Macedonian army used the *phalanx* offensive battle formation. It was made up of heavily armed infantry troops formed in tight ranks for the attack. The troops carried long spears and protected themselves with overlapping shields. The depth of each formation ranked from 8 to 12 ranks. The phalanx had great striking power, but no flexibility. It needed support from lighter troops and cavalry.

338 BCE, August The decisive *battle of Chaeronea* where Philip of Macedonia crushed the allied Greek citizen armies. Athens finally lost its independence, as foreseen by **Demosthenes** (384–322 BCE). End of the classical period of Greece[167].

---

[166] *Modern* speculations concerning the chronon have often been related to the idea of a smallest natural length. One suggestion was that this is given by the effective diameter of the proton and electron, that is to say about 10^{-15} meters. If this were a shortest natural length and we divided it by the fastest possible speed, that of light in *vacuo* (3×10^8 meters per second), the resulting interval of time would be about 10^{-23} – 10^{-24} seconds. A time of this order characterizes the normal decay processes of nucleons, i.e. processes involving the so-called 'strong interactions' between protons and neutrons, and also the lifetime of the most transient elementary particles. It is therefore possible that if the chronon exists it is of this order of magnitude. A purely theoretical unit of length much shorter than 10^{-15} meters can, however, be constructed from the three fundamental constants, G, h and c (constant of gravitation, Planck's constant, and velocity of light). It is $\sqrt{(Gh/c^3)}$, and is of the order of 10^{-34} meters. If this is divided by the velocity of light, it gives a time of the order of 10^{-43} seconds. It is possible that this time, sometimes called the 'Planck time', might be the chronon.

[167] Athens made peace, but Demosthenes kept up his opposition. Later he defended his policy in his speech *On the Crown*, considered as the most nearly perfect speech in history. He poisoned himself (322 BCE), when the last Greek effort to win freedom was a failure.

334 BCE **Alexander the Great** (356–323 BCE). One of the greatest conquerors in the annals of history. Hellenized Western Asia and orientalized Eastern Europe. Pupil of Aristotle. Attacked the Persian empire with an army of Macedonians and Greeks. Within 12 years he conquered an area almost the size of the United States, founding Greek cities and establishing Greek garrisons everywhere he went.

By spreading Greek civilization, ideas and language into the very heart of Asia, Alexander profoundly affected the history of the world, and Greek culture rapidly became world culture. Moreover, the cultural intercourse among ancient peoples was so stimulated by his conquests, that the various cultures of the ancient world began to congeal into a universal culture to which all contributed but in which the Greek element predominated. This was the first large scale contact between East and West.

Alexander's scientific curiosity was apparently great, and his and Aristotle's initiative are probably responsible for the first *scientific expeditions* and the first attempts to organize science on a large scale. In 332 BCE Alexander founded in Egypt the city of Alexandria, which was to become one of the greatest centers of learning and of cultural diffusion between the East and the West.

334–ca 146 BCE *The Hellenistic Era*. Marks the culmination of Greek science and its influence on the civilized ancient world, mainly from its center in Alexandria.

The word 'Hellenism' signifies that culture which drew its vitality from the classical Hellenic culture. It spread over the entire empire of Alexander the Great and coated with a thin layer the original ancient cultures of the conquered nations. The Hellenic influence penetrated by means of the Greek *language*, *religion*, *art*, *literature*, *philosophy*, *science*, *architecture*, and *political* ideas. Hellenism spread to Rome in the beginning of the 2^{nd} century BCE and challenged Judaism as of the 3^{rd} century BCE.

But Jewish culture in Israel was firmer and more consolidated than other cultures and was thus capable of arresting the advance of Hellenism. In fact, the rigorous encounter of the two rivals at the time of the Maccabees (164 BCE) marks the first sign of the Hellenistic retreat in the east.

Hellenism, though, was more successful in the Jewish diaspora in the east and in the Aegean world, where the Bible was translated into Greek (*septuaginta*) and where Greek became the spoken language even in the synagogue. Eventually, the Hellenization of diaspora Jewry expedited the spread of Christianity among the Jewish masses in Asia Minor and elsewhere. The Sassanic Kingdom that rose in Persia in the 3^{rd} century CE, finally put an end to Hellenism in the entire Orient.

The roots and fruits of Hellenistic philosophy

1. Historical background

Throughout history, philosophy and religion both influenced and were influenced by economical, political and social conditions. This is true in particular for the transition era between the downfall of the Hellenic city-state regime and the rise of Christianity. We list below the main political events in this time-window:

339 BCE *Greece becomes a Macedonian protectorate.*

323 BCE *Death of* **Alexander the Great***; Beginning of Hellenistic age.*

275 BCE *Alexander's Empire finally divided under the rule of three dynasties: Antigonides (Macedonia), Ptolemies (Egypt) and the Seleucides (East).*

188 BCE *Peace of Apamea: Greek cities lose their independence.*

148 BCE *Macedonia becomes a Roman province.*

133–27 BCE *Decline of the Roman Republic. A century of incessant violence and confusion. Fall of the Hellenistic states.*

27 BCE *Beginning of the Roman Empire under* **Augustus***. End of the Hellenistic age; order and stability are restored.*

180 CE *Death of* **Marcus Aurelius***; Beginning of the decline of the Roman Empire.*

325 CE *The Council of Nicaea: rigidification of the Christian Church.*

415 CE *End of the Alexandrian School.*

451 CE *The Hun Invasion of Europe.*

476 CE *End of the Western Roman Empire.*

529 CE **Justinian** *closes the Athenian schools of Philosophy.*

During 322–148 BCE, Greece was subject, not only to political decline and the confusion of the wars, but also to very serious social stress. Consequently, the condition of the majority grew steadily worse. In all parts of Greece, and in the Aegean islands, many people were living at the very edge of a subsistence level, and the impression of personal insecurity was very general. Sparta, in particular, underwent three successive violent social revolution during 250–200 BCE.

Thus, in spite of their wealth and almost unlimited opportunities, the Hellenistic states eventually wasted their resources in a series of inconclusive wars among themselves. As a result, between 200 BCE and 31 BCE all the Hellenistic world except Macedonia and Persia was annexed piecemeal by Rome, a new militaristic power that had risen, at first almost unnoticed, in the Western Mediterranean.

But the Greek culture that had been forged in the classical era and that had spread in Hellenistic times to most of the rest of the civilized world was not suppressed by the Romans. It survived and spread to the West. Although Latin was spoken in Rome itself and in the western provinces, Greek remained the language of the educated classes of the East. Throughout the life of the Roman Empire, Rome itself was never more than the political capital. Alexandria remained the most active commercial city of the empire and Athens the center for scholars, yet most of the scientific work was done in Alexandria. After the western half of the Roman Empire, including Rome itself, fell to barbarian invaders in the fifth century CE, the Hellenistic world survived for more than 1,000 years as the Byzantine Empire, with its new capital in the Greek city of Constantinople.

How did philosophy fare in this era of great political changes?

The earlier Milesian Greek philosophers, had called attention to cosmic order and the beauty of nature. Later, the monist ***Parmenides of Elea*** *stressed the power of reason and thought, whereas* ***Heraclitos of Ephesos****, precursor of the philosophy of becoming, had alluded to the constancy of change and the omnipresence of divine fire, which illuminates all things.*

A deeper understanding of man *himself came with* **Socrates** *(469–399 BCE), symbol of the philosophical man, who personified* Sophia *and* Sapientia *(Greek and Latin: "wisdom"). From Socrates emanated the philosophical system of the* Cynics *and the* Skeptics[168]*. Thus, although Socrates did not found any philosophical school, and in fact had no intention of doing so, his*

[168] **Socrates** said that the only thing he knew was that he did not know anything. However, he did at least believe that knowledge was possible, and, he was bent on acquiring some. He took a positive attitude towards inquiry and the possibility of learning.

teaching were indirectly responsible for the systems of thought sponsored by groups of his disciples. His heritage lasted for many centuries and left its mark upon the medieval and modern philosophies of the Western World.

In spite of its political downfall and its poverty, Athens was still the focus of philosophical teaching. The four main schools were: the Academy *(*Plato*), the* Lyceum *(*Aristotle*), the* Garden *(*Epicuros*), and the* Porch *(*Stoa*). To these must be added the unorganized efforts of the* Cynics *and the* Skeptics*.*

The successors of ***Plato*** *(427–347 BCE) as heads of the Academy were:* ***Speusippos*** *(347–339 BCE),* ***Xenocrates*** *(339–315 BCE),* ***Polemon*** *(315–270 BCE),* ***Crates of Athens*** *(270–264 BCE),* ***Arcesilaos*** *(264–240 BCE),* ***Lacydes of Cyrene*** *(241–224 BCE),* ***Teleclos*** *(224–216 BCE),* ***Erandros the Phocian*** *and* ***Hegesinos of Pergamum****.*

The love of philosophy was so diffuse in the Greek population that the Athenian schools were not enough to satisfy it. Provincial schools were needed in Megara*,* Eretria*,* Cyrene*, and probably other places.*

Aristotle's leadership of the Lyceum *lasted only thirteen years (335–323 BCE). It was then headed in succession by* ***Theophrastos of Eresos*** *(328–286 BCE),* ***Straton of Lampsacos*** *(286–268 BCE),* ***Lycon of Troas*** *(268–225 BCE),* ***Ariston of Iulis****. The golden age of the Lyceum lasted less that 70 years (335–268 BCE).*

The death of ***Alexander the Great*** *(323 BCE) and* ***Aristotle*** *(322 BCE) marked the beginning of a period of extreme social and political disturbances, the character of which Aristotle failed to foresee, and which radically affected the course of philosophical thought. From this time onwards, the political importance of the Greek city-states rapidly declined.*

With Athens no longer the center of worldly attraction, its claim to cultural prominence passed on to other cities – to Rome, to Alexandria, and to Pergamum. The Greek polis gave way to larger political units; local rule was replaced by that of distant governors. The earlier distinction between Greek and Barbarian was destroyed; provincial and tribal loyalties were broken apart, first by Alexander and then by Roman legions.

The loss of freedom by subject peoples further encouraged a deterioration of the concept of the freeman and resulted in the rendering of obligation and service to a ruler whose moral force held little meaning. The early intimacy of order, cosmic and civic, was now replaced by social and political disorder and traditional mores gave way to transient values. Amid so much uncertainly and confusion, many felt the need to preserve some firm foundation. At that time no religion *had power or prestige enough to satisfy such a demand, and the result was an enormous popular interest in* philosophy*.*

Hellenistic philosophy and religion reflected the great problem of the age: What part could an individual play in a society in which individual effort seemed useless? In a small city-state during the Golden Age the individual played an important role in his community; he could find meaning and purpose in his life and his work. But in the busy and cosmopolitan Hellenistic world a man was lost in a community as large as civilization itself. Often he lived in a massive city with a population of hundreds of thousands where the highest endeavors of an individual might pass unnoticed, or still worse, serve no purpose. In such a society the values of an earlier time – such as duty to the state, honesty, justice, piety, and personal honor – often seemed to have little meaning.

It was inevitable that, under these conditions, there should occur an almost immediate movement away from the recent tradition of Plato and Aristotle. Those philosophers were certainly too difficult, and in a sense too conventional, to satisfy the new popular demands. Their work was too full of intricate logical argument, it demanded too high a devotion to abstract thought, to provide a possible basis for any popular creed.

***Aristotle** in particular, in his writing on ethics and politics, had tended to take for granted as the background of his argument just those political conditions and conventions of conduct which, so soon after his death, had ceased to exist.*

He addressed himself to the ordinary well-educated citizen of the (now) old-fashioned Greek city-state; he had not, and probably would not have wished to claim that he had, any moral message for mankind at large in a period of chaos. He and Plato were philosophers for intellectuals; and for this reason, though their prestige and their fame remained unassailable, the philosophy of the new period was provided by others, and was quite different from theirs.

Perhaps the clearest indication of the changed atmosphere of philosophy can be found in the changing conception of "happiness," the goal of life, and consequently of the means proposed for achieving it. For one thing, this question came to be the dominant concern of philosophy, at the expense of those epistemological and metaphysical inquiries which, for Plato and Aristotle at least, had been no less important and absorbing. But also the topic itself was very differently treated.

Aristotle, in his Nicomachean Ethics, had taken the conventional – one would almost like to say, the sensible – view that the well-being of the individual was determined in large part by the circumstances in which he lived, by the activities in which he engaged, by the achievements which could be counted to his credit. He would certainly have recommended an active, indeed a masterful, part in the public affairs of one's community. But it is clear that, if so, the well-being of the individual is dependent in part upon external affairs; and in the precarious post-Aristotelian world, it seems to have been felt that individual happiness, thus conceived, was itself intolerably precarious. Accordingly, almost every later school agreed in the attempt to maintain that happiness, rightly conceived, must lie in the sole power of the individual himself. The attempt to maintain this, however understandable, led at times to an extremity of paradox.

Even so, it seems to have been tacitly agreed that some conception of happiness must be worked out which would ensure that, at least in theory, it could be attained quite independently of shifting, perilous and uncontrollable circumstances. The resulting tendency was, strongly and persistently, towards some sort of philosophy of "non-attachment" – towards a kind of strategic withdrawal, as it were, from a world which no one now could believe, as Aristotle did, to be manageable by careful and enlightened individual effort.

Out of this new reality there arose four systems of philosophy: Epicureanism, Stoicism, Cynism and Skepticism. The first three were primarily moral doctrines, philosophies of life, far more earnestly occupied with the actual predicament of man than with any merely theoretical questions and they were concerned in particular to teach, in a world that was too often dangerous and deceptive, the secret of individual well-being. And even the Skeptics were apt to recommend their skepticism as offering a relief from anxiety – as a kind of restful acquiescence in the single conviction that no exclusive faith or doctrine whatever would ever be proved, so that all intellectual struggles must be ultimately vain.

The pursuit of knowledge passed from Aristotle to the distinguished scientists of the Hellenistic age. The philosophers took up instead the pursuit of virtue, of happiness, or – in this at least they were all agreed – of security.

Table 1.3 lists most of the important persons that were active in the various philosophical schools in the Greco-Roman world in the millennium prior to the close of the Athenian schools by Justinian.

Table 1.3: Greek Schools of philosophy and their post - Aristotelian cults and creeds *(470 BCE–530 CE)*

PHILOSOPHER	*LIFE-SPAN BCE*	*FLOURISHED BCE*	*SCHOOL*
Xenocrates of Chalcedon	—	*339–314*	*Platonic*
Theophrastos of Ephesos	*373–286*		*Peripatetic*
Eudemos of Rhodes		*325*	"
Antisthenes of Athens	*444–365*		*Cynic*
Diogenes of Sinope	*412–323*		"
Crates of Thebes	*365–285*		"
Demetrius		*40–75 CE*	"
Theodoros of Cyrene	*465–399*		*Hedonist*
Aristippos of Cyrene	*435–355*		"

2. The Cynics (ca 400 BCE–200 CE)

* * *

"I am a citizen of the world".

"There is no need to rebel because everyone is already free".

(Diogenes, ca 350 BCE)

* * *

"Truly, if I were not Alexander I would wish to be Diogenes".

*(**Alexander the Great**, ca 330 BCE)*

The Cynics rejected all social conventions and believed in individual self-sufficiency, independence and self-control, virtue as the only good and withdrawal from the corrupt world.

It is especially desirable to understand the essentials of cynicism because that school of thought developed into Stoicism, the major philosophy of the Stoics which lasted for centuries and left its mark upon the medieval and modern philosophies of the Western world.

The Cynic school of Greek Philosophy can be traced back to **Socrates** *and* **Antisthenes***(c. 444–365 BCE), who was one of Socrates' immediate pupils and is generally considered the founder of the sect. The word cynic means 'doglike' in Greek, because Antisthenes accentuated Socrates' tendency to live in the simplest fashion and to disregard many of the social conventions and amenities.*

Antisthenes' most famous disciple was ***Diogenes of Sinope*** *(c. 412–323 BCE), on the Black Sea, whose excesses of austerity have become proverbial.*

Diogenes, an anarchist who lived in great poverty, proclaimed the necessity of self-sufficiency, austerity, and shamelessness and made an aggressive display of his contempt of conventions; But he did not add anything new to Antisthenes' teachings, just dramatized and advertised them. From a popular conception of the intellectual characteristics of the school comes the modern *sense of "cynic", implying a sneering disposition to disbelieve in the goodness of human motives and a contemptuous feeling of superiority.*

What are then the general principles of this school in its internal and external relations as forming a definite philosophical unit? The importance of these principles lies not only in their intrinsic value as an ethical system, but also in the fact that they form the link between Socrates and the Stoics, between the essentially Greek philosophy of the 4^{th} century BCE, and a system of thought which has exercised a profound and a far-reaching influence an medieval and modern ethics.

Antisthenes imbibed from Socrates the fundamental ethical precept that virtue, not pleasure, is the end of existence. He was, therefore, in the forefront of that intellectual revolution *in the course of which speculation ceased to move in the realm of the physical and focused itself upon human reason in its application to the practical conduct of life.*

"Virtue," says Socrates, "is knowledge"; in the ultimate harmony of morality with reason is to be found the only true existence of man. Antisthenes adopted this principle in its most literal sense, and proceeded to explain "knowledge" in the narrowest terms of practical action and decision, excluding from the conception everything except the problem of individual will realizing itself in the sphere of ordinary existence.

Just as in logic the inevitable result was the purest nominalism, so in ethics he was driven to individualism, to the denial of social and national relations, to the exclusion of scientific study and of almost all that the Greeks understood by education; This individualism he and his followers carried to its logical conclusion. The ordinary pleasures of life were for them not merely negligible but positively harmful inasmuch as they interrupted the operation of the will. Wealth, popularity and power tend to dethrone the authority of reason and to pervert the soul from the natural to the artificial. Man exists for and in himself alone; *his highest end is self-knowledge and self-realization in conformity with the dictates of his reason, apart altogether from the state and society. For this end, disrepute and poverty are advantageous, in so far as they drive the man back upon himself, increasing his self-control and purifying his intellect from the dross of the external. The good man (i.e. the wise man) wants nothing: like the gods, he is self-sufficing; "let men gain wisdom – or buy a rope"; he is a citizen of the world, not of a particular country.*

With all its defective psychology, its barren logic, its immature technique, cynicism emphasized two great and necessary truths: firstly, the absolute responsibility of the individual as the moral unit, and, secondly, the autocracy of the will. These two principles are sufficient ground for our gratitude to these "athletes of righteousness" (as Epictetos calls them). Furthermore they are profoundly important as the precursors of Stoicism.

Finally it is necessary to point out two flaws in the Cynic philosophy. In the first place,the content of the word "knowledge" is never properly developed. "Virtue is knowledge"; knowledge of what? and how is that knowledge related to the will? These questions were never properly answered by them.

Secondly they fell into the natural error of emphasizing the purely animal side of the "nature," which was their ethical criterion. Avoiding the artificial restraints of civilization, they were prone to fall back into animalism pure and simple. Many of them upheld the principle of community of wives; some of them are said to have outraged the dictates of public decency.

It was left to the Stoics to separate the wheat from the chaff, and to assign to the words "knowledge" and "nature" a saner and more comprehensive meaning.

3. The Skeptics (330 BCE–200 CE)

* * *

"Every man of science is somewhat of a Cynic*, because he does not accept words and conventions at their fare value, and of a* skeptic*, because he refuses to believe anything without adequate proof".*

(George Sarton, 1955)

* * *

*"*Skepticism *produces happiness, because by having no dogmatic beliefs you become free from worry".*

"By Skepticism *we arrive first at suspension of judgment, and second at freedom from disturbance".*

(Sextus Empiricus, c. 200 CE)

Skepticism was a philosophical movement in ancient Greece that elevated doubt into an overall thought-principle claiming that it is impossible ever to arrive at the knowledge of truth, either through the senses or by the mind.

The skeptics tried to weaken man's confidence in observation and reason as trustworthy guides to understanding the world. They believed that man can be certain of the nature of his observations, but he cannot be sure that these observations reflect the real world. Therefore, man must withhold judgment if he wants happiness and mental peace.

According to them, the best thing to do was to believe in nothing, to give nothing away, and to feel as little emotion as possible; the only way to live a virtuous life was to dispense with philosophy altogether and avoid asking such questions, since there were no any answers to them. All knowledge is untrustworthy and nothing can ultimately ever be proven. No two views are alike because no two men are alike. Hence – there can be no single truth understood by man.

The philosophical school of Skepticism was a direct result of the competition between the conflicting views of the diverse schools of thought. The Skeptics believed that by suspending judgment, they could avoid a feeling of insecurity arising from possible error. Their most potent rivals were the Stoics who claimed that Skepticism was self-contradictory, since, if nothing can be known, how could this alleged fact itself be known?

The origins of Skepticism can be traced to the earliest days of Greek philosophy when the inclination towards bold assertion was accompanied by a contrary tendency towards questioning, doubt, and sometimes despair. Among the pre-Socratics ***Xenophanes of Colophon*** *(560–478 BCE) and* ***Empedocles*** *(490–430 BCE) expressed occasionally the gloomy feeling that, in the welter of conflicting doctrines, it was really impossible to find any assertion deserving of full belief.*

A basis for skepticism may be found in Socratic irony, a technique devised by Socrates (he started from the assumption that he knew nothing about the truth); a similar approach is evident during the Socratic period in ***Plato****'s dialogues, which arrive at no definite conclusions, in accordance with the Socratic method.*

Eventually however, skepticism itself became a doctrine in the hands of ***Pyrrhon of Elis****, who died at nearly ninety years of age in about 275 BCE. Pyrrhon had served as a soldier with Alexander the Great, and had campaigned with him as far as India.*

Another philosopher present on that occasion was ***Anaxarchos of Abdera*** *(fl ca 320 BCE), a follower of* **Democritos** *(460–370 BCE). Democritos' view of the insufficiency of mere sense perception had been given a definitely* *skeptical emphasis by his followers, and it may thus be that Pyrrhon derived from Anaxarchos the first impulse towards general questioning and doubt.*

Distinguished among later leaders of the Academy, and also a skeptic, was **Carneades** *(214–128 BCE) who made a great stir on a visit to Rome (156 BCE) by giving a series of public lectures, in the first of which he forcefully expounded the views of Plato and Aristotle on Justice, while in the second lecture refuted everything he had said in the first.*

The skeptics apparently differed over the proper guide to personal conduct. Some believed that a man can best decide how to act by calculating the most practical course of action. Others believed he should follow local laws and customs. Under ***Arcesilaos*** *and* **Carneades** *the skeptics philosophy spread through the Athenian Academy. No writings of Skeptics survived. Summaries of Skeptic doctrines were presented in the writings of* **Cicero** *and* ***Sextus Empiricus****, a Roman physician of the 200's CE.*

4. The Epicureans (300 BCE–500 CE)

* * *

"Live unknown".

"Death is nothing to us: for that which is dissolved is without sensation, and that which lacks sensation is nothing to us".

"It is not possible to live pleasantly without living prudently and honorably and justly, nor again to live a life of prudence, honor, and justice without living pleasantly".

"Self-sufficiency is the greatest of all riches".

"The ultimate purpose of philosophy is to lead man to the good life of true happiness".

"If God listened to the prayers of men, all men would quickly have perished".

(Epicuros, ca 306 BCE)

* * *

"Epicuros questions are yet unanswered: Is God willing to prevent evil, but not able? Then he is impotent. Is he able but not willing? Then he is malevolent. Is he both able and willing? Whence then is evil?"

(David Hume, 1765)

Epicureans believed that man could attain the 'good life' by seeking moderate pleasures and avoiding pain. Pleasure can best be gained by living in accordance with prudence, moderation, courage, and justice, and by cultivating friendship. Death should not be feared because good and evil lie in sensation, and death deprives man of sensation.

Epicureanism can be traced back to discussions of the Epicurean Society at Athens in 306 BCE. There had been a few temporary meetings of these philosophers in Mitylene and Lampsacos. Thereafter the society met in the gardens of Epicuros, and were therefore known as "Philosophers of the Garden."[169]

[169] The *Garden* was like the Porch in many respects; their resemblance was perhaps due to common Oriental origins and even more so to the similarity of their functions. As far as can be judged from the fragments relative to it and to its founder, the *Garden was more informal and simpler than the other schools*; life was generally frugal but animated and quickened with regular feast days which brought the fellows more closely together; women were admitted to the fellowship.

Epicuros, who regarded philosophy as medicine for the soul, wrote three hundred books to set forth his views. The basic principles of his philosophy were derived chiefly from two sources: Cyrenaic Hedonism, and the physics, metaphysics, and psychology of Democritos. From the Cyrenaics he accepted the theory that pleasure is the sole good. He agreed with Aristippos that pleasure consists of a gentle motion (the modern equivalent of pleasant emotion), and with Theodoros that the goal of life is an optimistic disposition. From Anniceris came the concept of the great value of friendship, and from Hegesias the conclusion that life's principal objective is to avoid or escape from suffering.

Among post-medieval thinkers, the following were influenced, in one way or another, by the ethics, physics or the metaphysical philosophy of Epicuros' during the past four centuries: **Michel de Montaigne** *(1533–1592);* ***Pierre Gassendi*** *(1592–1655);* ***Isaac Newton*** *(1642–1727);* ***La Mettrie*** *(1709–1751);* ***Helvetius*** *(1715–1771);* ***Immanuel Kant*** *(1724–1804);* ***Jeremy Bentham*** *(1748–1832);* ***James Mill*** *(1773–1836);* ***John Stuart Mill*** *(1806–1873);* ***Herbert Spencer*** *(1820–1903);* **Ernest Renan** *(1823–1892);* ***Karl Marx*** *(1818–1883);* ***Niels Bohr*** *(1885–1963);* ***Werner Heisenberg*** *(1901–1976).*

5. Cyrenaic Hedonism

Hedonism is the belief that pleasure is the highest good in life. The name hedonism comes from a Greek word meaning pleasure. In contradistinction, the Epicureans believed that men should seek pleasures of the mind rather than pleasures of the body, in direct antithesis to everything that the Cynic stood for.

Both philosophical systems developed out of the teachings of Socrates; while the Cynics emphasized the Socratic concept of virtue, the Cyrenaics stressed the Socratic principle that happiness results from the practice of virtue. Whereas the former argued that virtue itself is happiness, the latter taught that the virtuous man is he who knows how to achieve happiness or has the talent necessary for achieving it. Although both philosophies agreed that happiness is a state of mind, for the Cynic the term meant the serenity and mental security which a self-sufficient man experiences, whereas for the Cyrenaic it referred to that satisfaction which follows upon the fulfillment of physical appetite.

Both schools derived their basic concepts from Socratic philosophy and their leaders have been included among the Lesser Socratics. Moreover, both schools developed into more sophisticated thought – the Cynics into Stoicism, and Cyrenaic Hedonism into Epicurean Hedonism.

Just as basic concepts of Stoicism have been perpetuated in Christian doctrine, and in the philosophies of Kant, Spinoza, and other leading philosophers, so the fundamental views of Hedonism have been incorporated in the philosophies of the Utilitarians, Freudians, and some Darwinians.

The founder of Cyrenaic Hedonism, **Aristippos of Cyrene** (435–355 BCE) was influenced by the teaching the Sophist **Protagoras** and subsequently became a disciple of Socrates. His philosophy reflects both sources, particularly the Protagorean doctrine of relativism and the Socratic belief that virtue is a sine qua non of happiness. Since the Cyrenaics equated pleasure with happiness, they concluded that pleasure is man's highest attainable good.

Moreover, according to the Cyrenaic Hedonists, since pleasures are of a single kind, namely, physical satisfactions, there should be no attempt to designate any of them as inferior or superior to the others, the only discernible difference among them being their intensity or duration. The Cyrenaics' theory that pleasures lack qualitative distinction, that they differ only quantitatively from one another, is known as 'quantitative Hedonism'. A corollary of this doctrine is the conclusion that pleasure itself is never evil, that only the laws and customs of the community designate some as good, others as morally bad – the central thesis of ethical relativism.

How did the Cyrenaic Hedonists define this experience of pleasure, which they accepted as man's highest good? Aristippos described it as a sensation of gentle motion in contrast to the violent motion of painful experience – but it must be understood that the Cyrenaics did not use the term motion in the sense of merely physical movement. Their interpretation came much closer to the modern conception of emotion.

They held that there are two basic emotions, the emotions of pleasure and of pain. The emotion of pleasure, or the sensation of gentle motion, resembles the pleasant feeling of the hungry person immediately after he has satisfied his appetite. The Cyrenaics ascribed no significance to the state of apathy, the absence of emotion, which the Cynics regarded as a worthy goal.

Since the Cyrenaic Hedonists believed pleasure to be the only good, they ignored all scientific, mathematical, and cultural pursuits except those with useful applications. In this sense they could be classified as Utilitarians, for they devoted themselves to the study of logic because of its practical utility.

The Utilitarian view of epistemology (the study of how man obtains knowledge) colored their entire philosophy. Accepting the doctrine of Protagoras, they agreed that human knowledge is limited to sensations and does not extend to the real objects to which the sensations correspond – a basic thesis of Protagorean relativism.

Consequently, man is aware of nothing but his own subjective states of feeling; for Aristippos, therefore, feeling is the only valid criterion of truth. The feelings which we experience are the essence of our existence. During our span of life, we should experience as much pleasure as possible; therefore, Aristippos insisted that we must pursue the pleasures of the moment, for tomorrow we shall die. We must enjoy immediate experience inasmuch as the future does not lie in our hand.

Virtue, then, is the means whereby we can achieve pleasure and increase our capacity for enjoyment. But the indiscriminate gratification of pleasure is to be eschewed; at this point in the philosophy of Aristippos, the influence of Socrates is discernible. The sage, or wise man, while enjoying pleasure, remains in control of it. Aristippos claimed that the Cynics erred in seeking independence by abstaining altogether from pleasure, for "not he who abstains, but he who enjoys without being carried away, is master of his pleasures."

***Diogenes Laertius**, discussing the Cyrenaic philosophers, emphasized their view that man's proper goal is to control pleasure and never to be controlled by pleasure. In order to achieve the highest ends of life, man must retain mastery over his experience by means of adaptation to circumstances, self-control, wisdom, the curbing of momentary desires, and an optimistic outlook and temperament.*

*Other leading Cyrenaic Hedonists included Aristippos' son, **Aristippos the Younger**, and daughter, **Arete**; **Theodoros**, the atheist; **Anniceris**; **Euhemeros**; and **Hegesias**.*

Theodoros contended that the specific momentary gratification of pleasure is an inconsequential matter and that, consequently, the primary objective should be to develop an optimistic cheerful attitude toward life. In other words, the wise man knows that true happiness can be found only within the mind of the individual – as a result of an appropriate inner mental disposition.

Anniceris raised Cyrenaic Hedonism to a higher level by designating friendship, gratitude, piety, and aid to others as the true sources of pleasure. Euhemeros contributed the theory that men who had achieved distinction in their lifetime became divine beings in the hereafter. Finally, Hegesias, "the death-counselor," introduced the doctrine of eudaemonistic pessimism, the theory justifying suicide as a way out of the pain and suffering which dominate the lives of the vast majority of human beings.

According to Hegesias, since the frustration of human desires is a universal experience, man should prefer death as a happy, pain-free alternative. Thus, ironically, the philosophy which set out to promote the pursuit of pleasure became a self-defeating philosophy as a consequence of critical deficiencies in its rationale.

6. The Stoics (ca 300 BCE–200 CE)

* * *

"Of all existing things – some are in our power, and other are not. In our power are: thought, desire, will to chose and will to avoid, and, in a word, everything which is our own doing. Things not in our power include the body, property, reputation, office, and, in a word, everything which is not our own doing. Things in our power are by nature free, unhindered, untrammeled; things not in our power are weak, servile, subject to hindrance, dependent on others".

"It is not death or hardship that is fearful, but the fear of hardship and death".

"Death, the most dreaded of evils, is therefore of no concern to us; for while we exist, death is not present, and when death is present, we no longer exist".

(Epictetos, ca 100 CE)

* * *

"Death, as birth, *is a mystery of nature: a composition out of the same elements, and a decomposition into the same. You shall disappear in that which*

produces you, be received back into its seminal principle by transmutation".

"Think of the universal substance, *of which you have a very small portion; and of the* universal time, *of which a short interval has been assigned to you".*

"Constantly regard the universe *as one living being, having one substance and one soul; and observe how all things have reference to one perception, the perception of this one living being, and how all things are the cooperating causes of all things which exist".*

"What then is that which is able to conduct a man? One thing and only one, philosophy*".*

"My city and my country, so far as I am Antoninus, is Rome, but so far as I am a man, it is the world".

"It is one of the acts of life, this act by which we die".

(Marcus Aurelius Antoninus, ca 170 CE)

Stoicism is composed of three parts: Ethical, social and metaphysical, with ethics being by far the most important part of the doctrine. The core of Stoic Philosophy lies in the view that there can be no authority higher than reason. *Its overriding objective was the* attainment of peace, *through an attitude of self-control of one's passions, self-sufficiency and utter indifference both to pleasure and pain.* Virtue *(which the stoics equated with* wisdom *and obedience to* reason*) is the only necessary prerequisite to* happiness.

The stoic view was that all that occurs should be accepted *without any stirring whatever of emotion or appetite. The only good is virtue, the only evil is* vice *(which the stoics equated with failure to control one's passions). Virtue and vice were held to consist, respectively, primarily in right and wrong* *disposition of the will. But the will (it was assumed) was wholly and unalterable under the control of the individual. Everything that did not fall within the sphere of his absolute control, was to be regarded with indifference – pain and pleasure along with the rest.*

According to Stoic philosophy, since passions are a disease of the soul, the individual must expel them completely from his personality; he must never allow his feelings to deteriorate into passions, which are both unnatural and irrational. Man conquers the world only by overcoming his own impulses. External things cannot control him unless he, by an act of his own will, permits them to do so. A person must maintain an unconquerable will, which surrenders to no man. Man should act in accordance with nature because nature is reason – the same reason which every man recognized as the highest part of himself. Everything that occurs has its place in nature's grand design. Their essential worldview can succinctly be described as follows[170]*:*

"The world as our reason presents it to us, that is to say the world of nature, is all the reality there is. There is nothing "higher." And nature itself is governed by rationally intelligible principles. We ourselves are part of nature. The spirit of rationality that imbues us and it (and that is to say, everything) is what is meant by God. As thus conceived, God is not outside the world and separate from it, he is all-pervadingly in the world – he is, as it were, the mind of the world, the self-awareness of the world.

Because we are at one with nature, and because there is no higher realm, there can be no question of our going anywhere "else" when we die – there is nowhere else to go. We dissolve back into nature. It is through the ethics evolved from this belief that Stoicism achieved its greatest fame and influence.

Because nature is governed by rational principles there are reasons why everything is as it is. We cannot change it, nor should we desire to. Therefore our attitude in the face of our own mortality, or what may seem to us personal tragedy, should be one of unruffled acceptance. In so far as our emotions rebel against this, our emotions are in the wrong. The Stoics believed that emotions are judgments, and therefore cognitive: they are forms of "knowledge", whether true or false. Greed, for instance, is the judgment that money is a pre-eminent good and to be acquired by every available means – a false judgment. If all our emotions are made subject to our reason they will embody none but true judgments, and we shall then be at one with things as they actually are."

---

[170] Brayan Magee, "The Story of Philosophy", DK Publishing Book, 1998, New York.

The social *component of Stoicism is based on the recognition that* friendship *is natural, hence good. Although Stoics were indifferent to nationalistic loyalties, they had faith in the social value of friendship between individuals. Common brotherhood and common legal prescriptions were prized as natural laws, two of which – justice and brotherly love – are innate in human nature. Marriage is an accepted institution insofar as it is infused with moral spirit. The Stoics viewed man as a citizen of the world. Their cosmopolitan spirit was reflected also in their defense of the natural rights of slaves. The Stoic social philosophy harmonized with Christian ideals and its point of view was buttressed by the rise of Christianity.*

Stoic metaphysics and philosophy of religion was closely allied with ethical naturalism; piety was identified with knowledge, and religious obedience with universal laws of nature. Stoic religious naturalism acquired pantheistic characteristics, emphasizing the belief that God and nature are one, although it differentiated the essential nature of God from the world of nature. Their metaphysics, which was decidedly Heraclitean, posited fire as the fundamental principle in things. It was their view that man's fate is determined by the mechanistic laws governing all natural phenomena. They linked religion closely with philosophy. Although they permitted recourse to polytheistic spirits as media for the worship of God, they held steadfast to a monotheistic doctrine and made their belief in one supreme, universal Deity (as creator and sustainer of the universe) the foundation of their moral philosophy.

Three types of Stoics were common, each emanating from its respective source: (1) philosophers, (2) statesmen, and (3) poets. Consequently, the Stoics remained sympathetic to the central themes of their religion. Their point of view was optimistic about nature, but pessimistic about man's moral insight. Stoic pessimism was vividly reflected in their acceptance of suicide (taedium vitae) *as a permissible solution to extreme exigencies of life. This practice seemed to them a symbol of moral strength, evidence that they could choose to be indifferent to life itself.*

Accordingly, they felt justified in ending life whenever the natural course of events made such a course appear to be an appropriate way of dealing with insufferable problems. Zeno committed suicide, as did Cleanthes, who deliberately starved himself to death. It may be noted that the Stoics were not always consistent in their ideology. Thus they adhered to the doctrine of self-preservation as the most fundamental law of nature, yet this doctrine was precisely contrary to their belief in suicide as a rational solution.

The Greek name for Stoicism, Stoa Poikile *(Painted Porch), referred to the portico in Athens where the early adherents held their meetings. The movement was founded by* ***Zeno of Citium*** *(c. 340–265 BCE), who was a disciple of the Cynic* **Crates***, and taught the first Stoic groups in that center.*

Among his eminent contemporary Stoics were two heads of the Stoic school: ***Cleanthes of Assos*** *in Troas (c. 303–232 BCE), who had also been a student of Crates and was the purported author of a monotheistic hymn (Hymn to the Most High) to Zeus; and* ***Chrysippos of Soli*** *(280–206 BCE), who integrated many of the Stoic doctrines and classified their terminology. Two students of Chrysippos, namely,* ***Zeno of Tarsos*** *and* ***Diogenes of Babylon****, succeeded him as leaders of Stoic philosophy in the third century BCE.*

The Stoics of the middle period (second and first centuries BCE) modified the doctrines of early Stoa to take into account the doctrines of the Platonic philosophers of the Academy and the Aristotelian Peripatetics. The founder of this form of Stoicism was ***Panaetios of Rhodes*** *(c. 180–110 BCE) who was greatly influenced by some of the views of Plato even though he disagreed with the fundamental Platonic principles expounded by Carneades, head of the Academy. Subsequent leaders of the Stoics during this middle period were* ***Antipater of Tarsos*** *and* ***Boethos of Sidon*** *(d. 119 BCE).*

Later Stoa, which prevailed during the first two centuries of the Christian era, was dominated by two groups of Roman philosophers, one concerned chiefly with Stoic interpretations of reality, the other with applied morality, that is, a religious belief in God's relationship to and interest in mankind and the universe. To this period belonged ***Arios Didymos of Alexandria*** *(63 BCE–10 CE), author of commentaries on Greek philosophical works;* ***Lucius Annaeus Seneca****, tutor and for some years an advisor to Nero, who condemned him to death in 65 CE;* **C. Musonius** ***Rufus of Volsinii****;* ***Epictetos of Hierapolis*** *(c. 50–138 CE), the most articulate Stoic exponent of moral philosophy; and the Roman emperor* **Marcus Aurelius Antoninus** *(121–180 CE).*

During the period when Christian institutions were developing (230–1450 CE), elements of Stoic moral theory were known and used in the formulation of Christian and Muslim philosophical doctrines of man and nature, of the state and society, and of law and sanctions – e.g. in the works of **Boethius** *(524–525 CE),* ***Isidore of Seville*** *(ca 560–636 CE), and* ***John of Salisbury*** *(1120–1180 CE).*

If the influence of Stoic doctrines during the Middle Ages was largely restricted to the resolution of problems of social and political significance, it remained for the Renaissance*, in its passion for the rediscovery of Greek and Roman antiquity, to provide a basis for the rebirth of Stoic views in logic, epistemology, and metaphysics, as well as the documentation of the more familiar Stoic doctrines in ethics and politics. The thinkers associated with this revival are:* ***Pietro Pompanazzi*** *(1462–1525 CE);* ***Desiderius Erasmus*** *(1466–1536);* ***Thomas More*** *(1478–1535);* ***Huldrych Zwingli***

(1484–1531); ***Philipp Melanchton*** *(1497–1560);* **Michel de Montaigne** *(1533–1592);* ***Pierre Charron*** *(1541–1603);* ***Justus Lipius*** *(1547–1606).*

The leading thinkers of the seventeenth century were predominantly rationalistic. Reason was the faculty that distinguished man from the beast, and the triumphs of seventeenth century science proved that reason could be trusted. And so the conclusion was drawn that the man of reason could know and understand the world into which he was born if he made the right use of his mind.

This optimistic attitude was reflected in the growing belief in "natural law." The idea of a law of nature that served as a standard of moral behavior for all men at all times in all places originated with the Stoics and was developed by the medieval Schoolmen. During the Renaissance and the Reformation this idea went into eclipse, but the discovery of "laws of nature" like Kepler's laws of planetary motion helped to revive it in the seventeenth century.

Cicero had given the idea classic formulation: "There is in fact a true law – namely, right reason – which is in accordance with nature, applies to all men, and is unchangeable and eternal. By its commands this law summons men to the performance of their duties; by its prohibitions it restrains them from doing wrong."

This law was implanted in the minds of men by God himself. Its content was hazy, but it was understood to include respect for life and property, good faith and fair dealing, giving each man his due. These principles could always be discovered by reason, just as reason could discover the proof of a geometrical proposition.

The influence of Stoic philosophy on 17^{th} and 18^{th} centuries thinkers is reflected through the works of: ***Francis Bacon*** *(1561–1626);* ***Hugo Grotius*** *(1583–1645);* **Rene Descartes** *(1596–1650);* ***Blaise Pascal*** *(1623–1662);* ***Baruch Spinoza*** *(1632–1677) and* ***Montesqieu*** *(1689–1755).*

Along with its rivals, Stoicism enabled the individual to better order his own life and to avoid the excesses of human nature that promote disquietude and anxiety. It was easily the most influential of the schools from the time of its founding through the first two centuries CE, and it continued to have a marked effect on later thought.

Unfortunately, the Stoics paid little, if any, attention to science and favored divination (manteia) and astrology; on the ethical plane their doctrines were too abstract, cold, impersonal; this explains the ultimate victory of Christianity over Stoicism, for the Christians put a new emphasis on love, charity, and mercy.

Christianity in general, in spite of striking contrasts with Stoicism, has found elements within it that parallel its own position. As the Stoic, for example, feels safe and protected in the rational care of some immanent Providence, so the Christian senses that a transcendent though incarnate and loving God is looking after him. And in general, Stoicism has played a great part throughout the ages in the theological formulation of Christian thought as well as in the actual realization of the Christian ideals.

Contemporary philosophy has borrowed from Stoicism, at least in part, its conviction that man must be conceived as being closely and essentially connected with the whole universe. And contemporary Humanism still contains some obviously Stoic elements, such as its belief in the solidarity of all peoples based upon their common nature, and in the primacy of reason. It is perhaps just because Stoicism has never become a full-fledged philosophic system that, many centuries after the dissolution of the Stoic school, fundamental themes of its philosophy have emerged again and again, and many have become incorporated into modern thinking.

Stoic ethics have always been widely found to be impressive and admirable, even by people who do not wholly go along with them. They are not easy to practice – but perhaps it is bound to be a characteristic of any ethics worthy of the name that they are difficult to put into practice. They had an unmistakable influence on Christian ethics, which were beginning to spread at the time when Seneca, Epictetos, and Marcus Aurelius were writing. And, of course, to this very day the words "stoic" and "stoicism" are in familiar use in our language, with perhaps grudgingly admiring overtones, to mean "withstanding adversity without complaint".

There must be many people now living who – even if they have never consciously formulated this fact to themselves – subscribe to an ideal in ethics which is essentially the same as that of the Stoics.

The fact that in recent centuries the best available school education in many European countries was based on the study of Latin literature had, as one of its side-effects, that many generations of well educated European males absorbed some of the values of Stoicism.

7. The Eclectics (100 BCE–200 CE)

* * *

“Truth itself is hidden in obscurity; I only wish I could discover the truth as easily as I can expose falsehood”.

“Frivolity is inborn, conceit acquired by education”.

“Any man is liable to err, only a fool persists in error”.

“To be ignorant of what occurred before you were born is to remain always a child. For what is the worth of human life, unless it is woven into the life of our ancestors by records of history?”

“Law is the highest reason implanted in Nature, which commands what ought to be done and forbids the opposite”.

“We must conceive of this whole universe as one commonwealth of which both gods and men are members”.

“Mankind must pray to God for fortune but obtain wisdom for themselves”.

“Men are sprung from the earth, not as its inhabitants and denizens, but to be as it were the spectators of things supernal and heavenly, in the contemplation whereof no other animal participates”.

"The study and knowledge of the universe *would somehow be lame and defective, were no practical results to follow".*

"That long time to come when I shall not exist has more effect on me than this short present time".

(Marcus Tullius Cicero, ca 50 BCE)

The Eclectics advocated a philosophical system which would bring together and integrate the best ideas of all the philosophers. Like their predecessors, both the Skeptics and the Eclectics regarded philosophy as a practical inquiry, for they were concerned primarily with ethics, the philosophy of life, *a philosophy which can be implemented. This system which amalgamated the best doctrines available, was established mostly by Roman philosophers, including particularly* **Cicero** *(106–43 BCE) and* **Seneca** *(4 BCE–65 CE).*

The Eclectics did not take refuge in Skeptical defenses to maintain a formidable philosophical position. Yet, like the Skeptics, they too developed a reactionary view seeking to establish acceptable doctrines to cope with the conflicting philosophical situation which prevailed at that time.

The following four leading schools of philosophy in Athens competed for adherents: (1) the Stoa *group of the Stoics; (2) the* Epicurean *"Philosophers of the Garden"; (3) the* Academy *(Platonists); and (4) the* Lyceum, *consisting of the Peripatetic philosophers accepting the views of Aristotle. The Skeptics supported none of these schools; in contrast the Eclectics sought truths in all of them and attempted to unify them into a single integrated philosophical system.*

It will be recalled that the Skeptics of the Middle Academy regarded probability *as the best criterion of truth. The Stoics preferred* consensus gentium, *that is, the universal opinion of mankind derived from the laws of nature, such as the law of self-preservation. Cicero and other Roman philosophers joined these two criteria with the concept of innate ideas (a concept which the modern philosopher Descartes later used as a foundation stone of his philosophy). In ethics,* **Cicero** *vacillated between the* Stoic *virtue of self-control and the* Peripatetic *view of happiness as the product of satisfying purposive activity. In the field of physical science, he showed no interest. In political philosophy, he blended the ideas of Platonism, Aristotelianism, and Stoicism. (The Eclectics had revived and emphasized ancient ideas which had been neglected and* *underemphasized, but they did not actually contribute any important original ideas to philosophy.)*

8. Gnostic and Gnosticism (100 CE–500 CE)

Alexander the Great's military campaigns were instrumental in expanding Greek cultural influence into what is now Egypt, the Middle East, and out into India. Almost inevitably this brought Greek culture into contact with many other cultures that adhered to very different religious and philosophical traditions.

Following Alexander's death in 323 BCE, the Greek empire collapsed and political power in the Mediterranean shifted from the east to the west, from Greece to Rome. In 146 BCE, Greece became a Roman colony and Rome was about to begin the cultural dominion over Europe and beyond that was to last until the barbarian invasions some 500 years later.

The status of the Land of Israel as a Roman colony was a source of resentment among certain members of the many radical Jewish sects that existed at this time. It was also the place where Greek, Judaic, and Persian philosophers met each other. From this cultural melting pot there arose a number of spiritual movements.

Gnosticism *is a blanket term used to embrace various dualistic esoteric cosmologies and spiritual teachings which developed in the syncretic Hellenistic civilization in the centuries immediately after Christ. The name designates a wide assortment of sects that promised salvation through an occult knowledge that they claimed was revealed to them alone. Scholars trace these salvation religions back to such diverse sources as* Jewish *mysticism,* Hellenistic *mystery cults,* Iranian *religious dualism (*Zoroastrianism[171]*),* Babylonian *and* Egyptian *mythologies, astrology and pagan religions. The definition of* Gnosis[172] *was already present in earlier Greek philosophy.*

---

171 Zoroastrianism — ancient Persian religion that viewed the universe as an eternal struggle between forces of light and darkness. (Still has many adherers today. The German philosopher Nietzsche have been sympathetic to some of its doctrines.)

172 *Gnosis*, from the Greek $\gamma\nu\omega\sigma\iota\zeta$ = knowledge, insight, enlightenment (it is pronounced with a silent "G", No-sis). The essential knowledge that comes from *within.* A gnostic may be part of a tradition (Sufi, Kabbalistic, Christian, etc.), but each person always interprets that tradition in an individual way;
Complete comprehension which comes from both rational and intuitive means.

Gnosticism, Religion and Philosophy

Gnosticism is the teaching based on Gnosis, the knowledge of transcendence arrived at by way of interior, intuitive means, as opposed to episteme, which is knowledge in the more mundane sense. The Gnostics believed that knowledge, not blind faith, held the key to the mysteries of life, but they thought that knowledge came from spiritual insight, rather than from scientific study.

This knowledge is hidden (esoteric) and only a few may possess it. In other words, Gnostics claimed to have secret knowledge about God, humanity and the rest of the universe of which the general population was unaware.

Gnosticism thus rests upon specific personal religious experience, an experience that does not lend itself to the language of theology or philosophy, but which is instead closely affinitized to, and expresses itself through, the medium of myth. The truths embodied in these myths are of a different order from the dogmas of theology or the statements of philosophy.

The Gnostics taught that:

(1) *The physical world is ruled by evil Archons, led by a lesser "god" (known as Demiurge, after Plato), the deity of the Old Testament, who hold captive the spirit of humanity. But human bodies, although their matter is evil, contain within them a divine spark (pneuma) that fell from the Source, or Nothingness from which all things came. Knowledge (gnosis) enables the divine spark to return to the Source from whence it came. Thus, salvation is achieved through knowledge.*

    Gnosticism held that human beings consist of flesh, soul, and spirit (the divine spark), and that humanity is divided into classes representing each of these elements. The purely corporeal (hylic) lacked spirit and could never be salved; the Gnostics proper (pneumatic) bore knowingly the divine spark and their salvation was certain; and those, like the Christians, who stood in between (psychic), might attain a lesser salvation through faith. Such a doctrine may have inspired extreme asceticism (as in the Valentinian school) or extreme licentiousness (as in the sect of Caprocrates and the Ophites). The influence of Gnosticism on the later development of the Jewish Kabbalah and heterodox Islamic sects such as the Ismailis is much debated.

(2) *The Good God is a transcendental spiritual being, who is utterly alien to this world, and had nothing to do with its creation.*

Experience based not in concepts and percepts, but in the sensibility of the heart; The idea that there is a special hidden knowledge that only a few may possess.

(3) *The Savior – whether Christ, Seth, the Thought (Ennoia) of God, or some other figure – is an emissary of the transcendental God who has descended into this lower world to confer gnosis on those able to receive it (the gnostic race).*

In stark difference to many orthodox religions or secular worldviews, Gnosis holds that human's "natural" state in this world is that of contingency, dissatisfaction, bondage and exile. At best, human beings, confined and enclosed within gnostic "box" of the empirical natural world, can live lives of temporary relief and fleeting pleasures. True peace and fulfillment evade them. Salvation can be achieved only by contemplation (theoria), not by faith (orthodox Christianity).

Christian ideas were quickly incorporated into these syncretic systems by ***Simon Magus*** *(fl. 30 CE),* ***Marcion of Sinope*** *(85–160 CE),* ***Capocrates*** *(fl. 140 CE),* ***Ptolemaeus*** *(fl. 140 CE),* ***Valentinus*** *(ca 100–175 CE) and* ***Basiliades of Alexandria*** *(fl. 135 CE). The largest of them, organized by Valentinus and Basiliades, were a significant rival to Christianity. Other known early Gnostics were* ***Numenius of Apamea*** *(fl. 150 CE), a Platonic philosopher, and* ***Mani*** *(216–276 CE) who founded the syncretic religion of Manichaeism with roots in Zoroastrianism, Jewish Christianity and Buddhism. Much of early Christian doctrine was formulated in reaction to this movement by* ***Irenaeus*** *(ca 130–200 CE),* ***Clement of Alexandria*** *(ca 145–213 CE),* ***Tertullian*** *(160–225 CE),* ***Hippolytus*** *(170–230 CE) and* ***Plotinos*** *(fl. 255 CE).*

By the second century CE, many very different Christian-Gnostic sects had formed within the Roman Empire at the eastern end of the Mediterranean. Some Gnostics worked within Jewish Christian and mainline Christian groups, and greatly influenced their beliefs from within. Others formed separate communities. Still others were solitary practitioners.

There does not seem to have been much formal organization among the Gnostics during the early centuries of the Christian movement. As mainline Christianity grew in strength and organization, Gnostic sects came under increasing pressure, oppression and persecution. They almost disappeared by the 6^{th} *century. The only group to have survived continuously from the* 1^{st} *century CE into modern times is the Mandaean sect of Iraq and Iran who can trace their history continuously back to the original Gnostic movement.*

Many new emerging religions in the West have adopted some ancient Gnostic beliefs and practices. By far, the most successful of these is the Church of Jesus Christ of Latter-day Saints– the LDS or Mormon church, centered in Salt Lake City, UT.

Gnosticism began with the same basic, pre-philosophical intuition that guided the development of Greek philosophy — that there is a dichotomy between the realm of true, unchanging being, and ever-changing becoming. However, unlike the Greeks, who strived to find the connection between the overall unity of these two 'realms', the Gnostics amplified the difference, and developed a mytho-logical doctrine of humankind's origin in the realm of Being, and eventual fall into the realm of darkness or matter, i.e. Becoming.

This general Gnostic myth came to exercise an influence on emerging Christianity, as well as upon Platonic philosophy[173]*, and even, in the East, developed into a world religion (Manichaeism) that spread across the known world, surviving until the Middle Ages.*

Gnosticism, in its turn, was influenced by:

1. Hellenistic-Jewish *speculation regarding the figure of Sophia (in Hebrew,* Hokmah*) or divine Wisdom, a personified female creator deity — midrashic (rabbinic) interpretation of the first few chapters of Genesis (specifically, Gen* ***2***–*6)*

2. *A particular form of baptismal ritual. Baptism was a common practice at this time (the biblical John the Baptist being by no means unique), but the Sethians believed their baptismal water to be of a celestial nature, a Living Water identical with the spiritual Light, and enabling the ascent of the soul; and so were critical of the ordinary water baptism*

3. *The developing* Christ-doctrine *(Christology) of the early church, especially the identification of Christ with the pre-existent Logos (the creative power or emanation of God)*

4. Neopythagorean *and* Middle Platonic metaphysics*, such as the emanation of divine beings from a single transcendent Absolute, and the understanding of the cosmos as the reflection of the spiritual world.*

[173] Long before the advent of Gnosticism, **Plato** had posited two contrary World Souls: one "which does good" and one which has the opposite capacity. It meant to him that this cosmos, like the human soul, possesses a rational and an irrational part, and that it is the task of the rational part to govern the irrational. Clearly, this conjecture flew in the face of everything that the ancient thinkers believed about the cosmos — i.e., that it was divine, orderly, and perfect. A common solution, among both Platonists and Pythagoreans, was to interpret the "evil" soul as Matter, which is the opposite of the truly divine and unchanging Forms. Then, the purpose of the "god" soul is to bring this "disorder" under the control of reason, and thereby maintain an everlasting (but not *eternal*) cosmos.

5. *Babylonian and Chaldean Astrology; the identification of the planets with deities, and the postulation of a number of a celestial heaven pertaining to each; all of which determines human destiny and induces a sort of fatalism.*

6. *The Pythagorean tradition with its pairs of opposites (light and dark, good and evil, spirit and matter, etc.)*

7. *Zoroastrian dualism*

8. *Ancient Egyptian thought, specifically Memphite and Heliopolitan theologies*

In the 20th century, there began a renewed interest in Gnostic ideas; Gnosticism has been treated by several modern authors, philosophers and psychologists:

- ***Carl Jung*** *(1875–1961, Switzerland), drew upon Gnostic motifs in his theoretical work and explained the Gnostic faith from psychological viewpoint.*

- ***Hans Jonas*** *(1903–1993, Germany and USA) interpreted it from an existential viewpoint. Indeed Gnosticism, as an intellectual product, is grounded firmly in the general human act of reflecting upon existence. The Gnostics were concerned with the basic questions of existence or "being-in-the-world" (Dasein) – that is: who we are (as human beings), where we have come from, and where we are heading, historically and spiritually. These questions lie at the very root of philosophical thinking; but the answers provided by the Gnostics go beyond philosophical speculations toward the realm of religious doctrine and mysticism.*

- ***Eric Voegelin*** *(1901–1985, Germany and USA) held the view that totalitarian ideologies were caused by Gnostic impulses, including Communism and Nazism.*

331 BCE, Sept. 20 Eleven days before the great *battle of Arbela*[174] (Oct. 01, 331 BCE, the last of the Greco-Persian wars and the end of Darius' Persian

[174] **Pliny** implies that at Arbela the moon was eclipsed two hours after sunset, while at Sicily the full moon was at sunset. **Ptolemy** also cites this eclipse and uses Pliny's data to calculate the distance between Carthage and Arabela.

Empire), there occurred a lunar eclipse[175] just as **Alexander**'s army crossed the Tigris. Greek astronomers used it to determine the difference in *longitude*[176] of two cities from the different *times* read in clocks when the eclipse began. One of the cities was *Carthage* (36°54′N, 10°16′E; now Tunisia) and the other *Arbela* (36°12′N, 44°01′E; now Arbil, Iraq). Sadly, the clocks were wrong, the difference in longitude was overestimated, and maps of the region were severely distorted.

ca 330 BCE **Praxagoras of Cos** (ca 360–290 BCE). Greek physician; the first to study the *pulse* and the first to point out the distinction between *arteries* and *veins*, although he thought that arteries are hollow tubes that carry *air* throughout the body. Indeed, the word artery is derived from the Greek *arteria* = windpipe [since it was noticed that no blood is in them after death, it was assumed the arteries carried air].

---

[175] In modern times, astronomical determination of longitude at an observing station is done by fixing the exact instant of a star's meridian passage. To determine the longitude of the station, one needs to determine only the *Greenwich-time* of the transit of the star over the local meridian. The difference in time between the star's meridian passage at the said station and its meridian passage at Greenwich is converted into the difference in longitude of the two stations by using the knowledge that the earth rotates at a rate of 15° in each hour of sidereal time. In practice, radio signals are used, where any reference longitude (not necessarily Greenwich) can serve.

[176] The plane of the earth's orbit and the plane of the moon orbit intersect along a line called the *line of nodes*. The line of nodes passes through the earth and is pointed in a particular direction in space. Lunar eclipses can occur only when both the sun and the moon are in or very near the line of nodes, because only then do the sun, earth, and moon lie along a straight line at a full moon.

When the moon is full and near one of its *nodes*, the *umbra* of the earth will cover its face completely, producing a *total lunar eclipse*. Somewhat further from the node, only part of the umbra will fall on the moon – a *partial lunar eclipse*. Still further from the node, only the *penumbra* may fall on the moon. If the moon is more than about 10° from the node, there is no eclipse. As the moon and sun will be near the nodes only twice a year, usually not more than two lunar eclipses occur in one year.

The moon's hourly motion in the sky is a little greater than its own diameter. As the width of the earth's shadow at the moon's distance is more than two and a half times the moon's diameter, the whole moon may be in shadow (totality) for over an hour; shadow may cover part of the moon for about two hours. Lunar eclipses are visible at the same moment from every part of the earth's surface, wherever the moon is above the horizon at the time.

330–310 BCE **Callippos** (ca 370–310 BCE). Astronomer. Made accurate determinations of the length of the seasons and constructed a 76 year cycle to harmonize the solar and lunar years, which was used by all later astronomers.

330–290 BCE **Deinocrates of Rhodes**. Greek architect. Designed for Alexander the Great the new city of Alexandria and for Ptolemy I Soter the library and museum.

Deinocrates designed the *new* temple of Artemis at Ephesos and constructed the vast funeral pyre at Hephaestion.

325 BCE **Antimenes** (Greece) devised the first system of insurance mentioned in history. With a premium of 8 percent per annum he guaranteed owners against the loss of their slaves.

ca 325 BCE **Eudemos of Rhodes**. The first historian of mathematics on record. A pupil of Aristotle, a friend of Theophrastos and a member of the Lyceum. Among the writing ascribed to him (but lost), were histories of arithmetic, geometry, and astronomy. Only fragments have come to us, yet his work was the main source out of which whatever knowledge we possess of pre-Euclidean mathematics has trickled down. The appearance at this time of a historian of mathematics and astronomy proves that so much work had already been accomplished in these fields that a historical survey had become necessary.

ca 320 BCE **Aristaios the Elder**. Mathematician. Marks the transition between the age of Aristotle and the Age of Euclid . Wrote a treatise on Conics regarded as *loci*, anticipating Euclid's book on the same subject. He defined the different kind of conics as sections of cones with acute, right, and obtuse angles. In a second book entitled *Comparison of the five figures* (regular solids) he proved the remarkable proposition that "*the same circle circumscribes both the pentagon of the dodecahedron and the triangle of the icosahedron when both solids are inscribed in the same sphere*"[177].

ca 320 BCE **Pytheas of Massilia**. A Greek explorer-mariner, geographer, and astronomer. The first Southern European to visit the northern seas. He was also the first person to work out the position of the true North (realizing that the North Star is not directly above the North Pole), to *link the alternation of tides with the phases of the moon* and to invent an accurate

[177] This is truly on unexpected result! For who could have foreseen that the faces of two different regular solids are equally distant from the center of the sphere enveloping them? Thus the icosahedron and dodecahedron have a special relation not shared by the other three solids.

method of determining latitude with a calibrated sundial. At the time when Alexander the Great had carved himself an empire as big as the United States – territory stretching from the eastern Mediterranean to the banks of the Indus – the Greeks, astonishingly, had given no more than a passing glance to the North and West. It was not until some years after Alexander's death in 323 BCE that a Greek first ventured into the chill waters of the Arctic Circle.

Sometime near 320 BCE, Pytheas set out from his native city, Marseilles, slipped by a blockade set up by the Carthaginian navy at Gibraltar and headed northward to Britain and beyond on an extensive voyage of the order of 11,000 km. He visited the Cornish tin mines and circumnavigated Britain, which he described as triangular in shape with three unequal sides (its perimeter he reckoned at about 4000 km). Thus he had occasion to observe the considerable tides on its coasts, and the daily regression of the times of high water, parallel to that of the time of the moon's transit. He then went to make a 6-day crossing of the North Sea to 'Thule' (Norway). Turning back to a further commercial objective, Pytheas sailed along the coast of Europe to the estuary of the Vistula on the Baltic coast.

His writings have been lost, and are known only through quotations and allusions by later authors. Also, since Pytheas was acting as a commercial spy, his mission was cloaked in a certain amount of secrecy. Greek and Roman geographers, among them **Eratosthenes**, **Polybius** and **Strabo**, were incredulous about his geographical discoveries, and scoffed at them [they found it hard to believe that lands in the latitude of Britain could be habitable – knowing nothing of the Gulf Stream and its effect on the climate of western Britain].

However, geographers would depend for centuries on Pytheas' data about northern countries. Later discoveries showed that he was telling the truth about what he had seen. The countries visited by Pytheas were not visited by any subsequent authority during more than 200 years. Pytheas' accurate determinations of latitude were adopted by Ptolemy, and became the basis of the Ptolemaic map of the Western Mediterranean.

312 BCE *Via Appia* (Appian way). The most famous of Roman roads. A high-road leading from Rome to Campania and lower Italy, whose construction began in 312 BCE by the censor **Appius Claudius Caecus**. It originally ran only as far as Capua (200 km), but was successively prolonged to Beneventum (268 BCE), Venusia (190 BCE), Tarentum, and Brundisium. Initially covered by gravel and later by stone; altogether, the road was made of multiple layers of durable materials, the top layer composed of a mixture of concrete, rubble and stones set in mortar.

Not only was the road usable by troops in all weather, it was crucial to building commercial interests and sustaining cultured links and political control over the provinces. The road was administered under the empire by a curator of praetorian rank, as were the other important roads in Italy.

Over time, several roads were built to link Rome with other cities and colonies, including the *Via Flaminia*, which headed north to link Italy with the Latin colony of Ariminum. In all, the Roman road system covered 80,000 km and crossed through 30 countries.

The Via Appia was the world's first all-weather road system built to facilitate warfare. Following their defeat in the *Samnite Wars*, particularly their humiliation at the Battle of the *Caudine Forks* along the rocky Apennines (321 BCE), the Roman military began to develop more effective attack formations and better transportation routes through uneven terrain.

A large number of milestones and other inscriptions relating to its repair at various times are known.

The first aqueduct brought pure water into Rome.

ca 310 BCE **Zeno of Citium** (336–264 BCE). Philosopher of Phoenician descent. Founded the *Stoic*[178] school of philosophy in Athens. Most of its early representatives were not Greeks but Asians. Stoicism began in Greece and then spread to Rome and flourished for more than 500 years until it was finally harmonized with the spirit of Christianity by some Fathers of the Church.

The early Stoics were interested in logic and natural philosophy as well as ethics. The later Stoics, especially **Seneca** (4 BCE–65 CE), **Marcus Aurelius** (121–180) and **Epictetos** (ca 60–135) emphasized ethics.

Zeno was born in Citium on the Island of Cyprus. The commercial activities of his family first took the young man to Athens (314 BCE) and there he developed an interest in philosophy. He abandoned trade and eventually set up a school of his own.

Fragments of 26 books written by him are extant, but most of his works have been lost.

According to Zeno, nature is strictly ruled by law; the laws in conformity with which the world runs its course emanate from some supreme authority that governs history in all its details. Everything happens for some reason in a pre-ordained manner. The supreme or divine agency is thought of not as something outside the world, but running through it, like moisture seeping

[178] Derived from *Stoa*, a painted roofed colonnade (portico) on the north side of the market place of Athens, which the celebrated painter Polygnotos had adorned with frescoes representing scenes from the Trojan war. There Zeno taught his disciples.

through sand. God is thus immanent power, part of which lives within each human being. (This kind of view has become famous in modern times through the philosophical writings of **Spinoza**, who was influenced by the Stoic tradition.) Men's lives are guided by Provident Reason, against which it is futile to resist and to which the wise man willingly submits with indifference to life's vicissitudes.

It was Stoicism, not Platonism, that filled men's imaginations and exerted the wider and more active influence upon the ancient world at some of the busiest and most important times in all history. And this was chiefly because it was above all a practical philosophy, a rallying point for strong and noble spirits contending against odds. Its concepts, values, and codes of honor have infiltrated Western Culture more deeply than we commonly recognize.

Although Stoicism was by no means dormant through the Middle Ages, the great period of its revival began with the Renaissance and lasted until the beginning of the 19^{th} century. Stoic morality inspired **Shakespeare**, **Schiller**, **Spinoza**, **Kant** and many leaders of the French Revolution.

Stoicism is symptomatic of the subtle infusion of the Asian soul into the wearied civilization of the Greeks overlords during the decay of Greece after the death of **Alexander the Great** (323 BCE). While this boy-emperor dreamed of spreading the Greek culture through the Orient, he ended up importing into Europe oriental cults and faiths along the new lines of communication opened up in the wake of his victorious armies. He had underrated the inertia and resistance of the Oriental mind, and depth of the Oriental culture.

The Oriental spirit of apathy and resignation found a ready soil in decadent and despondent Greece. The introduction of the Stoic philosophy into Athens by the Phoenician merchant Zeno was but one of a multitude of Oriental influences.

Both Stoicism and Epicureanism – the apathetic acceptance of defeat, and the effort to forget defeat in the arms of pleasure – were theories as to how one might yet be happy though subjugated or enslaved. When the glory had departed from Athens, she was ripe for Zeno and Epicuros.

The Romans, coming to despoil Hellas in 146 BCE, found the rival schools of Stoicism and Epicureanism dividing the philosophical field. Having neither leisure nor subtlety for speculation themselves, they brought back these philosophies with their other spoils to Rome.

Stoics agreed that space has no edge and rejected the Aristotelean outer boundary of the universe. They proposed instead a system consisting of a star-filled cosmos surrounded by a starless extracosmic void extending to infinity. The Stoic astronomical scheme endured in various guises for more than 2000 years until the first quarter of the 20^{th} century, when the existence of the galaxies beyond the Milky Way was established beyond dispute.

Cleanthes (310–232 BCE), a devoted disciple of Zeno, studied under his master for 19 years. Upon Zeno's death, he assumed the directorship of the school for 31 years. **Chrysippos** (ca 280–207 BCE) succeeded Cleanthes as director of the Stoic school. He was born in Soli, Cilicia, Asia Minor, and went to Athens in 260 BCE.

310–301 BCE **Epicuros of Samos** (341–270 BCE). Greek philosopher. Promoted the concept of Democritos that matter is made of atoms and adopted the principle of *conservation* of *matter*. Established in Athens a freethinking school that embraced much of the atomistic philosophy. He rejected the gods as the controlling forces of the natural world, invoked physical causes whenever possible, and taught that sense perceptions form the basis of all knowledge. Epicuros also outfitted the atomistic world with a comprehensive theory of ethics, claiming the highest good to be pleasure taken wisely and in moderation, leading to life of maximum freedom from physical and mental pain. The atomistic system, taught in this practical form – unfortunately easily misunderstood as a hedonistic doctrine – gained the acceptance of multitudes throughout the known world.

Educated Romans, skeptical of the mythological religion, turned to the teachings of Epicuros. For more than seven centuries, three before and four after Christ, Epicureanism flourished. Others – first the Platonists, then the Stoics, and finally the Christians – reviled Epicuros as an atheist and attacked his doctrine with bitter hostility.

Epicuros was born on the Island of Samos, seven years after the death of Plato. At the age of 18 he went to Athens, where the Platonic school was flourishing under the lead of Xenocrates, and stayed there for a year. Stimulated by the perusal of some writings of Democritos, he began to formulate a doctrine. In 307 he returned to Athens and established there a philosophy school. He lived there for the rest of his life.

The arena for his teaching was a garden which he purchased. There he passed his days as the loved and venerated head of a remarkable and unique society of men.

310–272 BCE **Hieronymos of Cardia** (ca 350–246 BCE). Greek historian and general. Took active parts in the wars that followed the death of Alexander the Great. He served successively Eumenes of Cardia, Antigonos and Demetrios in various administrative and diplomatic posts, including that of governor of Boeotia and superintendent of the asphalt beds of the Dead Sea.

Hieronymos wrote a history of the *Wars of the Successors* from the death of Alexander (323 BCE) to the death of Pyrrhos (272 BCE). His work was used by **Arrian**, **Diodoros** and **Plutarch**. In the last part of his work he made an attempt to acquaint the Greeks with the character and early history of the Romans.

ca 310 BCE **Autolycos of Pitane**[179] (ca 340–280 BCE). Astronomer and mathematician. An older contemporary of Euclid, representing the transition period between the Hellenic school of mathematics and the Alexandrian Age. Author of the earliest Greek mathematical text-book that has come to us entire. His first treatise, entitled *On the moving sphere*, deals with the geometry of the sphere (poles, great circles, etc) and many of its prepositions are used by Euclid in his *Phaenomena*.

Another work of Autolycos, in two books, *on the rising and settings* (of stars) is more astronomic and implies observations. In these books, propositions follow one another in logical order; each proposition is clearly enumerated with reference to lettered figures, then proved[180] – a Euclidean form, before Euclid!

In a third book (now lost) Autoclycos criticized Eudoxos' hypothesis of concentric spheres on the grounds that it did not account for the planets being at different distances from the earth at different times. He wondered how the theory could be reconciled with the changes of the relative size of the sun and the moon and with the variations of brightness of the planets, especially Mars and Venus. Autolycos, however, could not resolve the difficulty[181].

The practical value of his books was immediately realized by mathematical astronomers, who transmitted them from generation to generation with special care. Their preservation was facilitated and insured by the fact that they were eventually included in a collection called "Little Astronomy" (in

---

179 A harbor facing Lesbos, near Assos (where Aristotle taught).

180 Some propositions, however, are not proved; that is, they are taken for granted. This suggests that Autolycos' books had been preceded by at least one other book, now lost. Indeed, in his *Sphaerics*, **Theodosios of Bithynia** (ca 100 BCE) gives the proof of theorem unproved by Autolycos.

181 He assumed that all the stars were supposed to be on a single sphere. Any three stars are vertices of a spherical triangle, the sides of which are great circles. Measuring the distance between two stars on that sphere is equivalent to measuring the angle which that side of the triangle subtends at the center of the earth. All such problems are solved now by means of spherical trigonometry, but trigonometry had not yet been invented in Autolycos' time and he tried to obtain geometric solutions.

contradistinction to Ptolemy's *Almagest*, the "Great collection"). "Little Astronomy" was transmitted in its integrity to the Arabic astronomers, and became in Arabic translation, parts of homogeneous collections, each helping the other to survive.

300–291 BCE **Ptolemy I (Soter)** (called **Soter**, i.e., preserver) built the *library and Museum of Alexandria* and made it a haven for scholars. The library may have contained 700,000 'volumes' (rolls) and its Museum ('home of the muses') was a publicly funded research institute.

Soter (366–282 BCE, king 323–285 BCE) was a general in the army of Alexander the Great and one of his successors. He made Alexandria his capital and the foremost city of the world.

His son, **Ptolemy II** (called **Philadelphus**, 308–246 BCE, king 285–246 BCE) built a canal from the Red Sea to the Nile and made Alexandria the center of Hellenistic culture. Built a lighthouse on Pharos.

His son, **Ptolemy III** (called **Euergetes**, i.e., benefactor, king 246–221 BCE) replaced the Macedonian calendar with Egyptian solar year. He was a liberal patron of the arts and added many books to the library of Alexandria.

The Alexandrian School[182] (300 BCE–415 CE)

Alexandria was founded by Alexander the Great about the time (332 BCE) when Greece, in losing her national independence, lost also her intellectual supremacy. The city was in every way admirably adapted for becoming the new center of the world's activity and thought. Its situation brought it into commercial relations with all the nations lying around the Mediterranean, and at the same time rendered it as the main communication link with the wealth and civilization of the East. These natural advantages were augmented to a great extent by the care of the sovereigns of Egypt.

In 304 *BCE* ***Ptolemy I Soter*** *began to draw around him from various parts of Greece a circle of men eminent in literature, art and science. To these he gave every facility for the prosecution of their learned researches. Under the inspiration of his friend* **Demetrios of Phaleron** *(350–283 BCE), the Athenian orator, statesman and philosopher, this Ptolemy laid the foundations of the great Alexandrian library and originated the keen search for all written works, which resulted in the formation of a collection such as the world has seldom seen.*

He also built, for the convenience of his men of letters, the Museum, in which they resided, studied and taught. This museum, or academy of science, was in many respects not unlike a modern university. It probably included dormitories for the men of science, their assistants and disciples, assembly rooms, roofed colonnades and open-air study for discussion, laboratories, an observatory, botanical and zoological gardens. Its scientific development owed much to its royal patrons and even more so to ***Straton***[183] ***of Lampascos*** *(Latin: Strato Physicus, ca 340–268 BCE) who was called to Alexandria by*

[182] For further readings, see:

- Sarton, G., *Hellenistic Science and Culture*, Dover: New York, 1993, 554 p.
- Sarton, G., *Ancient Science Through the Golden Age of Greece*, Dover: New York, 1993, 646 pp.

[183] Greek Peripatetic philosopher; known for his doctrine that all substances contain void; tempered Aristotle's interpretation of nature by insisting on *causality* and materialism and denial of supernatural forces at work in nature. Pupil and successor of the botanist **Theophrastos** (372–288) as head of the Peripatos (ca 288 BCE). He also expanded on Aristotle's *Physics*, noticing that falling objects (e.g. rainwater off a roof) *accelerate* as they reach the ground rather than falling at a steady rate as Aristotle foretold.

Ptolemy. Straton was indeed the real founder of the Museum for he brought to it the intellectual atmosphere of the Lyceum, and it was thanks to him that it became not a school of poetry and eloquence, but an institute of scientific research. He was deeply interested in the study of nature and thus was nicknamed hoi physicos (the physicist). Under the distant influence of Aristotle and his own master, Theophrastos, he realized that no progress is possible except on a scientific basis and stressed the physical tendencies of the Lyceum. He remained in Egypt about 15 years, being finally recalled to Athens in 288.

The patronage of the Museum was passed on to the son and grandson of Ptolemy I Soter.

***Ptolemy II Philadelphus** [whose librarian was the celebrated **Callimachos** (305–240 BCE)] bought up all Aristotle's collection of books, and also introduced a number of Jewish and Egyptian works. Among these appears to have been a portion of the Septuagint.*

***Ptolemy III Euergetos** largely increased the library by seizing on the original editions of the dramatics laid up in the Athenian archives, and by compelling all travelers who arrived in Alexandria to leave behind a copy of any work they possessed.*

The Alexandrian Renaissance was mainly accomplished by these three kings within the first half of the third century. It was a magnificent attempt to continue and develop, under new conditions, the old Hellenic culture.

*Much was done at the Museum during the first century of its existence. Mathematical investigations were led by **Euclid**, **Eratosthenes** (who was first to measure the size of the earth with remarkable precision), and **Apollonios** (who composed the first book on conics). **Archimedes** flourished in Syracuse, but may have visited Alexandria and was certainly influenced by its mathematical school.*

*Alexandria was an ideal place for astronomical syncretism; Greek, Egyptian and Babylonian ideas could mix freely – there were no established traditions and representatives of various races and creeds could and did actually meet. Astronomical observations were made by **Aristarchos** and **Timocharis**, and a little later by **Conon of Samos** (ca 245 BCE).*

*The anatomical investigations carried out in the Museum by **Herophilos** resulted in an elaborate survey of the human body on the basis of dissections.*

*During 250–150 BCE, the scholars and critics of the Alexandrian library set to work to establish the texts of the classical Greek authors, equip them with commentaries and select the list of the principal figures in each literary genre. **Homer** and **Hesiod** were singled out from the immense body of early epic poetry as the great masters.*

Among the lyric poets nine were nominated for immortality – ***Pindar***, ***Bacchylides***, ***Sappho***, ***Anacreon***, ***Stesichoros***, ***Ibycos***, ***Alcman***, ***Alaeos***, *and* ***Simonides***. *The crowned heads of the tragic stage were* ***Aeschylos***, ***Sophocles***, *and* ***Euripides***. *Of the comic stage they chose* ***Aristophanes***, ***Eupolis***, *and* ***Caritanos***. *There were lists of best historians and philosophers, and also a list of ten greatest Attic orators,* ***Demosthenes*** *prominent among them. The Alexandrian term for the canonized authors was hoi enkrithentes (the admitted). The Roman later expressed the idea with the word classicus, meaning: "belonging to the highest class of citizens".*

The period of creative activity of the library lasted only about 150 *years; this period was also that of greatest commercial prosperity. After the* 2^{nd} *century BCE, the library declined and fell into somnolence. At the time of its climax it may have contained* 700,000 *"rolls". It was by far the largest one of antiquity and found no equal perhaps until the* 10^{th} *century, when very large collection of books became available in the Muslim world, both East in Baghdad and West in Cordova. Decadence was rapid during the* 2^{nd} *century CE and there is good reason for believing that many books were taken to Rome. Under Aurelian (Emperor 270–275 CE) the Museum and the mother library ceased to exist.*

Yet, the scientific tradition was carried on by ***Hero*** *(ca 100 CE),* ***Menelaos*** *(ca 100 CE),* ***Ptolemy*** *(ca 150 CE),* ***Diophantos*** *(ca 250 CE),* ***Pappos*** *(ca 300 CE), and* ***Hypatia*** *(ca 415 CE).*

Alexandrian science, however, did not have the same significance to the Hellenistic world as it does to ours; true, the above-mentioned scholars developed theories and performed some remarkable experiments that foreshadowed the scientific achievements of the 17^{th} *and* 18^{th} *centuries. Yet, experimentation with physical phenomena was to them only an aspect of philosophy, a speculative pastime not intended to impact day to day life.*

The principle of the steam engine, for instance, was understood but used only for tricks of magic. The astronomer ***Aristarchos*** *demonstrated that the earth was round and that the planets revolved around the sun.* ***Eratosthenes*** *measured the circumference of the earth and came within* 300 *km of modern measurements. But neither was interested in publicizing the discoveries. Most of the Hellenistic world, including scholars, continued to believe that the world was flat and that it was the center of the universe.*

The Hebrew Torah (5 books of Moses) was translated[184] *into Greek during the* 3^{rd} *century BCE, in the reign of Ptolemy II Philadelphus. Other books*

184 The ancient Greeks hardly paid any attention to the nearby Hebrews and vice versa. In Hellenistic times, this situation was reversed, because Jews and Greeks were sharing the same environment in Egypt. However, the large and influential Jewish colony of Alexandria was losing its command of the Jewish language. Ac-

of the Old Testament were translated later, many of them in the 2^{nd} *century BCE — the last one, Koheleth (Ecclesiastes), not until about* 100 *CE (the original was produced in the period 250–168 BCE).*

While important contributions to optics, mechanics, and medicine are to be credited to the Alexandrian culture, its supreme achievements are all related directly or indirectly to the discovery of a scientific basis for earth survey. Alexandria was a center of maritime trade. It was also a cosmopolitan product of Greek imperialism, and thereafter a cultural center of the Roman Empire. The art of navigation grew out of the mariner's practice of steering his course by the heavenly bodies. Thus, for example, knowledge of latitude arose from noticing the changing elevation of the Pole star in coastal sailing northward and southward across the Mediterranean or beyond the Pillars of Hercules.

Knowledge of longitude came from the arts of war, where estimates of long east-west distances depended on information from campaigns. Scientific geography was in part a by-product of imperial expansion. Brilliant innovation in mathematics arose in close relation to the same group of problems: the trigonometry of Archimedes and Hipparchos, the algebra of Theon and Diophantos can be traced to the inadequacies of Platonic geometry and Greek arithmetic for handling the large-scale measurements which Alexandrian geodesy and astronomy entailed.

The principal discoveries which form the basis of the Ptolemaic system may be arranged under 4 *headings:*

- *Measurements of the size of the earth.*
- *Construction of universal star maps with latitude and longitude as 'coordinates'.*
- *Introduction of latitude and longitude for terrestrial cartography.*
- *First estimates of the distances of the moon and sun from the earth.*

300–250 BCE Irrigation by means of the *sakya* was introduced by Greek engineers into Egypt. It is a rude water-wheel, with earthen pots on an endless chain running round it, worked by one or two bullocks. [In Northern India

cording to the story told in Greek by the Jew **Aristeas**, the librarian Demetrios of Phaleron explained to King Ptolemy II the need for translating the Torah into Greek. This allegedly resulted in the *septuagint*.

it is termed the *harat*, or *Persian wheel*]. With one such water-wheel a pair of oxen can raise water up to 6 m, and keep from 5 to 12 acres irrigated throughout an Egyptian summer. This primitive contrivance is still in use today in Egypt and India.

Archimedes is credited with the invention of the *Archimedes screw* (ca 250 BCE) which raises water as the handle is turned: the water flows from one spiral of the inclined screw to the next and finally come out of the upper end of the screw. The devise is still used today; except that a Diesel engine turns the screw.

300 BCE–100 CE The former cities of *Palmyra* and *Petra* (now in the deserts of Syria and Jordan) flourished, cultivating the vine and olive without much recourse to artificial irrigation. This seems to imply not only a higher water table than now but a climate that supplied more dependable rain. The cities were abandoned at ca 100 CE.

304–291 BCE **Herophilos of Chalcedon** (ca 335–280 BCE, Alexandria). Greek physician and surgeon. First scientific anatomist. Founder of the Alexandrian school of anatomy. One of the first to conduct post-mortem examinations and public dissections[185].

Discovered: prostate gland, duodenum, ovaries, fallopian tubes. Made the first methodical study of the brain (describing its ventricles), the liver, the spleen, the retina. First to time the pulse, to distinguish between arteries and veins and between sensory and motor nerves. Determined that the seat of *reasoning* is in the brain, not the heart.

The Alexandrian doctors also discovered *Ligature*, the tying off of blood vessels. This enabled them to perform operations that had before been impossible. They removed bladder stones, repaired hernia and performed amputations.

Herophilos was born in Chalcedon (Asia Minor) and flourished under Ptolemy Soter (366–282 BCE). His bold anatomical investigations were carried through in the *Museum*. Through his ambitious program of anatomical research, he conducted an elaborate survey of the human body on the basis of dissections. As this was done *systematically* for the first time, the men in charge were bound to make many discoveries.

---

185 The Ptolemaic rulers allowed the dissection of human corpses, a *taboo* among the Greeks.

It was claimed by the Roman encyclopedist Celsus (1^{st} century CE) and by Church fathers (who were eager to discredit Pagan science) that the Alexandrian anatomists obtained permission to dissect the bodies of living men, in order to have a better understanding of the functions of the organs.

His pupil **Philinos of Cos** (fl. 250 BCE) founded the so-called *Empirical School of Medicine* that rejected dogma and based its practice on experience, clinical cases and analogy.

ca 300 BCE **Euclid**[186] **of Alexandria** (ca 330–260 BCE). Greek mathematician who founded the mathematical school of Alexandria. The university opened ca 300 BCE and Euclid may have been invited from Athens, to head its school of mathematics.

Euclid is the most prominent mathematician of antiquity best known for his treatise on geometry *The Elements* (13 books). The long lasting nature of *The Elements* makes Euclid the leading mathematics teacher of all times. Indeed, the treatise became the center of mathematical teaching for 2000 years.

We are ignorant of the dates of his birth and death, of his parentage, teachers and the residence of his early years. **Proclos** (412–485 CE), the authority for most of our information regarding Euclid, states in his commentary on the first book of the 'Elements' that Euclid lived at the time of Ptolemy I (**Soter**), King of Egypt, who reigned from 323 to 285 BCE, that he was younger than the associates of Plato, but older than **Eratosthenes** (276–196 BCE) and **Archimedes** (287–212 BCE).

The question has often been raised as to the extent to which Euclid, in *The Elements*, is a compiler rather than a discoverer. To this question no satisfactory answer can be given. The general agreement is that Euclid must have made great advances beyond his predecessors both in geometry and number theory.

Five propositions in the Elements are of special interest:

(1) Propositions 12 and 13 of Book II are recognized as the *law of cosines* for plane triangles. They adumbrate the concern with trigonometry that was shortly to blossom in Greece.

(2) *Euclid's algorithm*, which gives a very simple and efficient method for the determination of the greatest common divisor (g.c.d.) of two numbers – a basic method of elementary number theory. This is found in the seventh book of 'Elements'. This method is essentially that of converting a fraction into a *continued fraction*. It therefore constitutes the earliest important step in the development of the concept of a continued fraction.

(3) The idea of the *prime-factorization theorem* as well as the lemma used in proving it – are found in 'Elements' Books VII and IX.

[186] His name reads *Eucleides*.

(4) The proof of the *infinity of primes* is found in Proposition 20, Book IX.

(5) $2^{n-1}\,(2^n - 1)$ is perfect if $(2^n - 1)$ is prime. [Final proposition, Book IX].

If we take Egyptian and Babylonian efforts into account, Euclid's *Elements* is the climax of more than a thousand years of research. Granted that many discoveries were made before him, he was the first to build a synthesis of all the knowledge obtained by others and himself and to put all the known propositions in strict logical order. Thus, although he was seldom a complete innovator, he did much better and on a larger scale what other geometers had done before him. Those propositions which cannot be ascribed to others were probably discovered by Euclid himself and their number is considerable. The arrangement is to a large extent Euclid's own; he created a monument which is marvelous in its inner beauty, clearness and durability.

Consider Book I, explaining first principles, definitions, postulates, axioms, theorems and problems. It is possible to do better at present, but it is almost unbelievable that anybody could have done as well 2300 years ago. The most amazing part of Book I is Euclid's choice of *postulates*. In particular, the choice of postulates 5 is, perhaps, his greatest achievement, the one which has done more than any other to immortalize the word "*Euclidean*": "*... if a straight line falling on two straight lines makes the interior angles on the same side less than two right angles, the two straight lines, if produced indefinitely, meet on that side on which the angles are less than two right angles*".

The first consequence of Euclid's decision to accept this as a postulate[187], was the admirable concatenation of his *Elements*. The second was the endless attempts which mathematicians through the ages made to correct him.

The third consequence is illustrated by the list of alternatives to the 5^{th} postulate. Some bright men thought that they could rid themselves of the postulate and succeeded in doing so, but at the cost of introducing another one (explicit or implicit) equivalent to it[188]. Thanks to his genius, Euclid

---

187 **George Sarton**'s remark concerning the greatness of this postulate is adequate here: "*A person of average intelligence would say that the proposition is evident and needs no proof; a better mathematician would realize the need of a proof and attempt to give it. It requires extraordinary genius to realize that a proof was needed yet impossible. There was no way out, then, from Euclid's point of view, but to accept it as a postulate and go ahead*".

188 "*If a straight line intersects one of two parallels, it will intersect the other also*". (Proclos)

"*Given any figure there exists a figure similar to it of any size*". (John Wallis)

"*Through a given point only one parallel can be drawn to a given straight line*" (John Playfair) saw the necessity of this postulate and selected intuitively the simplest form of it.

The 4^{th} consequence, and the most remarkable, was the eventual creation of non-Euclidean geometries.

Euclid flourished in Alexandria under the first Ptolemy and possibly under the second. Two anecdotes help to reveal his personality. It is said that the King (Ptolemy I) asked him "*if there was in geometry any shorter way*

"*There exists a triangle in which the sum of the three angles is equal to two right angles*". (Legendre)

"*Given any three points not in a straight line there exists a circle passing through them*". (Legendre)

All these men proved that the 5^{th} postulate is not necessary if one accepts another postulate rendering the same service. The acceptance of any of those alternatives would, however, increase the difficulty of geometrical teaching. It is clear that a simple exposition is preferable to one which is more difficult.

On the other hand, mathematicians like **Saccheri**, **Lambert** and **Gauss** argued that inasmuch as the 5^{th} postulate cannot be proved, there is no obligation to accept it, and if so, it can deliberately be rejected.

The first to build a new geometry on an opposite postulate was **Nicolai Ivanovitch Lobachevsky** (1793–1850), who assumed that through a given point more than one parallel can be drawn to a given straight line or that the sum of the angles of a triangle is less than two right angles. The discovery of a non-Euclidean geometry was made at about the same time by **Janos Bolyai** (1802–1860). Sometime later, another geometry was outlined by **Bernhard Riemann** (1826–1866), who was not acquainted with the writings of Lobachevsky and Bolyai and made radically new assumptions. In Riemann's geometry, there are no parallel lines and the sum of the angles of a triangle is greater than two right angles. The mathematical teacher **Felix Klein** (1847–1925) showed the relationship of those geometries: Euclid's geometry refers to a surface of zero curvature, in between Riemann's geometry on a surface of positive curvature (like the sphere) and Lobachevsky's applying to a surface of negative curvature. To put it more briefly, he called the Euclidean geometry parabolic, because it is the limit of elliptic (Riemann's) geometry on one side and of the hyperbolic (Lobachevsky's) geometry on the other.

It would be foolish to give credit to Euclid for pan-geometrical conceptions; the idea of a geometry different from the common-sense one never occurred to his mind. Yet, when he stated the fifth postulate, he stood at the parting of the ways. His subconscious prescience is astounding; there is nothing comparable to it in the whole history of science.

than that of the Elements, and he answered that there was no royal road to geometry". The other anecdote is equally good. "*Someone who had began to read geometry with Euclid when he had learned the first theorem asked him*, '*But what shall I get by learning these things*?' *Euclid called his slave and said*: '*Give him an obol* (*silver coin*), *since he must gain out of what he learns*' ".

A Brief History of Geometry[189] (3000 BCE–1900 CE)

Geometry Before the Greeks

The beginnings of geometry are shrouded in the mists of pre-history. This stage is sometimes called "subconscious geometry." Later, humans came to recognize certain principles, such as the fact that the circumference and diameter of circles are always in the same ratio. This stage is the "scientific geometry."

Geometry as a science may have begun in Egypt, where the rulers had need to measure the areas of fields in order to assess taxes on them. (The word "geometry" means "earth measurement.") The Moscow papyrus *(19th cen. BCE) and the* Rhind papyrus *(17th cen. BCE) make it clear that the Egyptians had a significant amount of geometrical knowledge at least 4000 years ago, and perhaps much earlier than that. (The great Pyramid of Gizah*

was built nearly 5000 years ago.) Many of the methods used to calculate areas and volumes were only approximately correct. One of the most remarkable results in the Moscow papyrus is a correct procedure for calculating the volume of a truncated pyramid.

Wherever it may have appeared first, it is clear that some significant geometry was developed – probably independently – in Egypt, Mesopotamia (Babylonia), China, India, and perhaps in other places and cultures as well. Wherever it developed it seems likely that this development came about to meet the practical needs of surveying, engineering, and agriculture. Geometry remained empirical and utilitarian until the Greeks made it into a science which could be, and was, studied independently of its practical applications.

Geometry in Greece

The Greeks of the Classical Period (600–300 BCE) not only increased the quantity of geometric knowledge, they changed the very nature of the subject, and of mathematics in general. Some Greek mathematicians traveled to Egypt and Babylonia and learned what was known of geometry in those places. They "transformed the subject into something vastly different from the set of empirical conclusions worked out by their predecessors. The Greeks insisted that geometric fact must be established, not by empirical procedures, but by deductive reasoning; geometrical truth was to be obtained in the study room rather than in the laboratory." They created what we may call "demonstrative geometry," whose truths are supported by (deductive) proofs rather than only by inductive evidence.

This work began with **Thales** *in the first part of the 6th century BCE. Thales, who had traveled in Egypt, is the first known individual with whom the use of deductive methods in geometry is associated. This axiomatic-deductive method is the cornerstone of modern mathematics, which thus may be truly said to have begun with the classical Greeks.*

The next important name is that of **Pythagoras**, *who may have studied under Thales. He founded the celebrated Pythagorean school, a brotherhood knit together with secret and kabbalistic rites and observances and committed to the study of philosophy, mathematics, and natural science. The Pythagorean belief that everything is explainable by numbers may be regarded as one of the origins of the quantitative emphasis in modern science. Pythagoras may have been the first to provide a proof of the theorem named* *for him, but the result had been understood by many peoples for many centuries. Demonstrative geometry was considerably advanced by Pythagoras and his followers.*

Several attempts were made to unite all of the truths of mathematics into a single chain which could be deduced from explicitly-stated "self-evident" assumptions (or axioms). And then, about 300 BCE, **Euclid** *produced his epoch-making effort, the Elements, a single deductive chain of 465 propositions neatly and beautifully comprising plane and solid geometry, number theory, and Greek geometrical algebra. From its very first appearance this work was accorded the highest respect, and it so quickly and so completely superseded all previous efforts of the same nature that now no trace remains of the earlier efforts. The impact of this single work on the future development of geometry has been enormous and is difficult to overstate. Euclid's Elements remained the standard textbook in geometry until the early years of the 20th century.*

After Euclid the most exceptional of the Greek mathematicians were **Archimedes** *and* **Apollonios**. *Archimedes (287–212 BCE), universally acclaimed as the greatest mathematician of antiquity and among the greatest of all time, wrote extensively on geometry. He proved that the value of π must lie between $3\frac{10}{71}$ and $3\frac{1}{7}$. He discovered and established the relationship between π and the area of a circle. He found and proved formulas for the volume and surface area of a sphere (using methods which anticipated the development of integral calculus).*

Apollonios (262–190 BCE) wrote a number of works, most of which have been lost. We do have his monumental work on parabolas, hyperbolas, and ellipses, The Conic Sections, which has been called one of the greatest scientific works of antiquity.

Arabic and Hindu Contributions

The five or six centuries following the fall of Rome (in the 5th century CE) is often referred to as the Dark Ages of Europe. Leadership in the world of mathematics during this period passed to the Arabs and the Hindus. It has been said that the greatest mathematical contribution of the Arabs was the preservation and transmission of Greek achievements to the modern period. But it is important to note that the Arabs and Hindus made many important contributions of their own. The most important of these are in the areas of numeration, computation, algebra, and trigonometry.

Noteworthy geometrical achievements include the work of ***Brahmagupta*** *(fl. 630 CE) on cyclic quadrilaterals,* ***Abu al-Wafa*** *on constructions,* ***Omar Khayyam*** *on geometric solutions of cubic equations, and the work of* **Nasir al-Din al Tusi** *on Euclid's parallel postulate.*

The Modern Period

The modem period has seen much activity in geometry, including the creation of a range of new kinds of geometry, namely: Projective Geometry, Coordinate Geometry, Differential Geometry, Non-Euclidean Geometry, and Topology. The first three of these arose in the 17th century. Projective geometry results from the application of the concept of a "projection" to geometry. Coordinate geometry results from the application of algebra to geometry. Differential geometry results from the application of calculus to geometry. The previously existing geometry is sometimes called "synthetic geometry" to distinguish it from these newer branches of the subject.

Projective geometry grew out of the efforts of Italian artists in the 15th century who created a geometrical theory called "mathematical perspective" to aid them in the production of realistic paintings. Later this theory was taken into mathematics and considerably expanded by several, led by ***Girard Desargues*** *and* **Pascal**. *Descriptive geometry, which is related to projective geometry, was created and extended by several mathematicians:* ***Gaspard Monge***, ***Jean Victor Poncelet***, *and others in the 18th and 19th centuries.*

Analytic geometry, also called coordinate geometry or Cartesian geometry, was one of the great mathematical achievements of the 17th century – a century which also saw the creation of calculus and foundations laid in the theory of probability. Created independently by **Rene Descartes** *and* ***Pierre de Fermat***, *coordinate geometry is the fruitful marriage of algebra and geometry. It made possible the use of algebra as a tool for solving geometric problems (and vice versa).*

Differential geometry is that geometry which uses calculus as a tool to investigate the properties of curves and surfaces. The most prominent names in the history of differential geometry are ***Gaspard Monge*** *(1746–1818),* ***Gauss*** *(1777–1855), and* **Bernhard Riemann** *(1826–1866).*

Non-Euclidean Geometry was created by ***Gauss***, ***Nicolai Ivanovitch Lobachevsky*** *(1793–1856), and* ***Janos Bolyai*** *(1802–1860).* **Bernhard Riemann** *extended their researches. Non-Euclidean geometry is obtained* *by replacing Euclid's parallels postulate by one of its contradictory forms, and deducing theorems from this new set of axioms.*

It took unusual imagination to entertain the possibility of a geometry different from Euclid's, for the human mind had for two millennia been bound by the prejudice of tradition to the firm belief that Euclid's system was most certainly the only way to geometrically describe physical space, and that any contrary geometric system simply could not be consistent. One result beyond the world of mathematics was the doubt which the discovery of non-Euclidean geometries cast upon human ability to know the truth about anything.

Topology, sometimes described as "rubber-sheet geometry," is the study of those properties of objects which are not altered by stretching or bending (or more generally, by "continuous deformation"). It began in the 19th century as a branch of geometry. It has been a major area of mathematical research in the 20th century and has come to be regarded as a fourth division of mathematics, along with algebra, geometry, and analysis. Among the many important contributors to topology are **Riemann** *and* ***Henri Poincare*** *(1854–1912).*

Other recent developments in geometry include "The Erlangen Programm" of ***Felix Christian Klein****, the abstract spaces of* ***Maurice Frechet****, and the "Grundlagen" of* **David Hilbert**.

The 19th century also saw the serious investigation of spaces of dimension greater than three. **Cayley**, ***Grassmann***, *and* ***Riemann*** *were important contributors.*

Perfect and Amicable Numbers

The ancients considered numbers with the property $\sigma(n) - n = n$, *or* $\sigma(n) = 2n$, *where* σ *is the sum of all divisors (including* 1 *and* n*). The first two examples* $6 = 1+2+3$ *and* $28 = 1+2+4+7+14$ *were noticed already by the Pythagoreans and had a strong appeal for mystics, since the creation took*

6 days, and there are about 28 days in a lunar month. For this reason they were named perfect numbers by the Pythagoreans. Two other perfect numbers known to the Greeks were 496 and 8128. ***Euclid*** *proved that* $2^{p-1}(2^p-1)$ *is perfect whenever* 2^p-1 *is prime.*

If we denote $M = 2^p - 1$, $n = \frac{1}{2}M(M+1)$, *then* $\sigma(n) = 2n$. *To see this, list all the possible factors of* n. *Certainly each of* $1, 2, 2^2, ...2^{p-1}$ *is a factor. It is a hypothesis of the theorem that the factor* $2^p - 1$ *is prime, but as many more factors again can be obtained by multiplying it by each factor in the above list of powers of 2. This exhausts the possibilities:* n *has no further factors. We have then two sets to add:*

$$S_1 = 1 + 2 + 2^2 + \cdots + 2^{p-1} \equiv 2^p - 1$$

$$S_2 = (1 + 2 + 2^2 + \cdots + 2^{p-1})(2^p - 1) = S_1(2^p - 1)$$

$$\therefore \quad S_1 + S_2 = (2^p - 1) + (2^p - 1)(2^p - 1) = 2^p(2^p - 1) = 2n$$

This is the sum of the factors. Why did it come out $2n$ *instead of* n*? Because we neglected to delete* n *itself as one of the factors when we formed* S_2. *Thus the sum of the proper factors, including* 1 *but not including* n, *is* n, *and* n *is therefore a perfect number.*

The fact that $2^p - 1$ *was prime had to be used in the proof, which brings us back to the problem of the primality of the Mersenne numbers. We know already that for* $2^p - 1$ *to be prime it is necessary that* p *be prime, but not sufficient;* $2^{11} - 1$ *is composite* $(= 23 \cdot 89)$ *and therefore* $2^{10}(2^{11} - 1)$ *is not perfect.*

Euler *proved*[190] *the inverse: all even perfect numbers have the Euclid form. That is, an even number is perfect if and only if it is of the form*

$$N = 2^{p-1}(2^p - 1),$$

where $2^p - 1$ *is prime. Thus, the knowledge of even perfect numbers is equivalent to the knowledge of Mersenne primes.*

As for odd perfect numbers, not even one has ever been found. If one exists (as it well might) it is fairly large, at any rate greater than 10^{300}.

The only perfect numbers known to the Greeks were

$$N_2 = 2(2^2 - 1) = 6$$

---

190 Let $2^n q$ be perfect, where q is odd and $n > 0$. Then $2^{n+1}q = (2^{n+1} - 1)s$, where s is the sum of all the divisors of q. Thus $s = q + d$, where $d = q/(2^{n+1} - 1)$. Hence d is a divisor of q, so that q and d are the only divisors of q. Hence $d = 1$ and $q = 2^{n+1} - 1$ is a prime.

$$N_3 = 2^2(2^3 - 1) = 28$$

$$N_5 = 2^4(2^5 - 1) = 496$$

$$N_7 = 2^6(2^7 - 1) = 8128 = 1^3 + 3^3 + 5^3 + 7^3 + 9^3 + 11^3 + 13^3 + 15^3$$

Four additional perfect numbers were discovered by the end of the 18^{th} century:

$$N_{13} = 33,550,336$$

$$N_{17} = 8,589,869,056$$

$$N_{19} = 137,438,691,328$$

$$N_{31} = 2,305,843,008,139,952,128 \quad (Euler,\ 1772)$$

Perfect numbers have the following remarkable properties

- *The last digit of every even perfect number*[191] *is always 6 or 8.*
- *Except 6, the sum of digits* $\equiv 1(mod \quad 9)$.
- *The sum of the reciprocal of all divisors is 2.*
- *Every even perfect number* $2^{p-1}(2^p - 1)$ *is a sum of cubes of* 2^k *odd numbers, when* $k = \frac{p-1}{2}$, *except for* $n = 2$. *Indeed, let*

$$S_1 = 1 + 2 + 3 + \cdots + m = \frac{m(m+1)}{2},$$

$$S_2 = 1^2 + 2^2 + 3^2 + \cdots + m^2 = \frac{m(m+1)(2m+1)}{6},$$

$$S_3 = 1^3 + 2^3 + 3^3 + \cdots + m^3 = \frac{m^2(m+1)^2}{4} = S_1^2.$$

[191] For $p = 2$ we have the number 6. If $p > 2$, then p is a prime of the form $4k+1$ or $4k+3$. If $p = 4k+1$, then $2^{p-1} = 2^{4k} = 16^k$, and the last digit of 2^{p-1} is obviously 6, while $2^p - 1 = 2^{4k+1} - 1 = 2 \cdot 16^k - 1$ and the last digit is obviously 1. Thus, the last digit of the product $2^{p-1}(2^p - 1)$ is 6. If $p = 4k+3$, then the number $2^{p-1} = 2^{4k+2} = 4 \cdot 16^k$ has the last digit 4, while the last digit of 2^p is 8, hence the last digit of the number $2^p - 1$ is 7, and, consequently, the number $2^{p-1}(2^p - 1)$ (as the product of two numbers, one with the last digit 4, and the other with the last digit 7) has the last digit 8.

Then

$$\begin{aligned} S &= 1^3 + 3^3 + 5^3 + \cdots + (2m-1)^3 = \sum_{i=1}^{m} (2m-1)^3 \\ &= \sum_{i=1}^{m} (8m^3 - 12m^2 + 6m - 1) \\ &= 8 \cdot \frac{m^2(m+1)^2}{4} - 12 \cdot \frac{m(m+1)(2m+1)}{6} + 6 \cdot \frac{m(m+1)}{2} - m \\ &= m^2(2m^2 - 1). \end{aligned}$$

If $m = 2^k$, $S = 2^{2k}(2^{2k+1} - 1)$. *The even perfect numbers are of this form for* $n = 2k + 1$.

Amicable Numbers

The ancients, with their quest for the mystic interpretation of numbers, came across number pairs *related by the property that the sum of the aliquot divisors of either number equals the other number,*

$$\sigma(m) - m = n, \quad \sigma(n) - n = m$$

or

$$\sigma(m) = \sigma(n) = n + m.$$

Pythagoras, for example, knew of the smallest pair[192] *(220; 284), since*

$$\sigma(220) - 220 = 1 + 2 + 4 + 5 + 11 + 20 + 22 + 44 + 55 + 110 = 284$$

$$\sigma(284) - 284 = 1 + 2 + 4 + 71 + 142 = 220.$$

[192] So may have **Jacob** (*Genesis* **32**, 14) when he presented Esau with 200 she-goats plus 20 he-goats, to secure his friendship.

The Pythagoreans named such numbers amicable. Other pairs are (1184; 1210), (17,296; 18,416).

Amicable numbers intrigued the Greeks, Arabs and many other since antiquity[193]*. The mathematician* ***Thabit Ibn Qurra al-Harrani*** *(ca 855 CE) found that prime numbers of the form*

$$p = 3 \cdot 2^m - 1; \qquad q = 3 \cdot 2^{m-1} - 1; \qquad r = 9 \cdot 2^{2m-1} - 1$$

generate the amicable pairs $2^m pq$, $2^m r$. *Clearly, the permissible values of* m *(such that* p, q, r *are prime) follow from the relations*

$$\sigma(2^m pq) = (2^{m+1} - 1)(p+1)(q+1) = 2^m(pq + r)$$

$$\sigma(2^m r) = (2^{m+1} - 1)(r+1) = 2^m(pq + r).$$

It is thus required that for any prime of the form $q = 3 \cdot 2^{m-1} - 1$, *also* $p = 2q+1$ *and* $r = 2(q+1)^2 - 1$ *be primes. Consequently, beyond the small values of* m

$m = 2$	$p = 11$	$q = 5$	$r = 71$
$m = 4$	$p = 47$	$q = 23$	$r = 1,151$
$m = 7$	$p = 383$	$q = 191$	$r = 73,727,$

these amicable numbers become vary large, following the exponential growth of permissible values of m. *Many other amicable numbers, generated by different algorithms, are also known.*

Whether or not there are infinitely many amicable pairs is unknown, although it was proved (1977) that $\sum(\frac{1}{m})$ *is convergent if* m *runs over all members of amicable pairs.*

[193] One can ask for numbers such that $\sigma(n) = kn$. Although k seems to be as large as we wish, it was conjectured that $k = O(\log \log n)$.

The Ancient Maya[194] (1200–300 BCE)

About 1000 *BCE a strange civilization emerged in the lowland jungles of the Yucatan area in Central America. The people who created it, the Maya, were not city dwellers like most early civilized people; they lived in small farming villages. But they built great ceremonial centers – complexes of pyramid-like temples and palaces which were the focus of their religion and political life.*

Some time during the fourth or third centuries BCE, their priests devised a vigesimal (base 20) positional numerical system, which embodied the concept of zero – a notable abstract intellectual achievement. Elsewhere, this mathematical concept is known to have been developed only in the late Babylonian civilization. The Mayan calendar was more sophisticated and complicated than either the Gregorian or the Julian calendar. Apparently, the Maya did not attempt to correlate their calendar accurately with the length of the solar year or lunar months. Rather, their calendar was a system for keeping track of the passage of days and for counting time into the past or future. Among other purposes, their calendar was useful for predicting astronomical events, for example, the position of Venus in the sky[195].

---

[194] For further reading, see:

- Von Hagen, V.W., *The World of the Maya*, Mentor Books: New York, 1962, 224 pp.
- Morley, S.G., *The Ancient Maya*, Stanford University Press: Stanford, CA, 1956, 507 pp.

[195] Using the simplest equipment, the Mayas calculated the length of the solar year with an accuracy equal to that of modern astronomy, and devised correction formulae to adjust the discrepancy between the true year and the calendar year which is handled by our leap-year correction. They worked out an accurate lunar calendar and calculated the synodical revolution of Venus, in each case devising means for correcting the accumulated error.

The ancient civilizations of Mesopotamia employed a positional system of arithmetic, but it seems to have been in existence for centuries before the concept of zero diffused to them from the Hindu world. The ancient civilizations of the Mediterranean arena derived many of their cultural features from the civilizations of the Middle East, but they did not take over the well-developed system of computation. This sort of mathematical complex did not penetrate Western Europe until the time of the Arab invasion in the Early Middle Ages, several centuries after the Maya had developed their own accurate and flexible system.

To specify completely a particular date, the Maya made use of what is called the 'long count', a perpetual tally of the days that had elapsed since a particular date about 3000 *years ago in the past. This system is analogous to that of the 'Julian day', but the starting date was not meant to be that of "the beginning" – it was merely a fiducial, from which days could be counted. The significant point of the 'long count' is that it employed a* vigesimal *number system (i.e.* based on 20*) which included a zero and consequently simplified their arithmetic (at that time the zero was unknown in Europe).*

Mayan astronomers could predict eclipses of the sun*. This was achieved without the instruments upon which modern astronomers depend (Mayan temples were sufficiently high to obtain clear lines of sight from their summits to distant points on the horizon: a pair of crossed sticks was set up on top of a pyramid. From this fixed observation point, the places where the sun, moon or planets rise or set was noted with reference to some natural fiducial feature on the horizon. When the heavenly body under observation rose or set behind this same point for the second time, it had made one complete synodical revolution).*

It must be noticed that the Mayan precise predictions of eclipses, the position of the moon in the sky and the position of Venus, were all done by arithmetic*: they counted a certain number and subtracted some numbers, and so on. There was no discussion of what the moon was, or even of the idea that it revolved. They just calculated the time when there would be an eclipse, or when the moon would rise at the full, and nothing more.*

In about 1200 *CE, the Maya deserted their centers and the old stable way collapsed*[196]*; the Spaniards who came in the* 1500*'s met little resistance from*

The basis for the Maya calendric system was the 260-day *tzolkin*, with its named and numbered days, and the 365-day *haab*, with its named months and numbered positions within each month. These two meshed calendars repeated cyclically, and could return to a given starting point only after a lapse of 52 years. The inscriptions for longer time periods were based on the vigesimal (base 20) system. Using these longer periods, the Maya counted the elapsed time since the hypothetical starting date of their chronology. They also reordered in the inscription the fact that the stela was erected on a certain *numbered and named* day of the tzolkin which occupied a certain position in a particular month of the haab; the accompanying supplementary series recorded lunar information for the date.

196 It is now believed that over-exploitation of farming land ruined the agrarian resources of the Maya. The ravishes of famine finally put an end to the Maya civilization. A steadily growing population and limited fertile corn-growing land around the royal centers, forced the Maya peasants to intensify food production by disregarding *fallow* (resting periods which the land needs to regain its fertil-

the decadent remnant, weakened by internecine fighting.

ca 300 BCE **Euhemeros of Messina**. Greek philosopher and mythographer from Sicily. The author of *Hiera anagraphe* (Sacred History). First to try to link mythical beings and events with historical fact, explaining the gods as distorted representation of ancient warriors and heroes. His name lives on in the term *Euhemerism*.

Flourished at the court of Cassandros (358–297 BCE; Regent of Macedonia 316–306 BCE, King 306–297). He was said to have sailed down the Red Sea and across the Arabian sea and to have reached an Indian Island called Panchaia, where he found sacred inscriptions which he described in his book. Therein he emphasized the historical origins of myths – an attempt to rationalize mythology (i.e. Greek religion).

283 BCE The sculptor **Chares of Lindos** completed the *Colossos of Rhodes* – a huge bronze statue built near the harbor of Rhodes on the Aegean Sea, in honor of the sun god Helias to commemorate the survival of the people of Rhodes after a year-long siege by the Macedonians (303 BCE). The statue stood 37 meters tall (about as high as the Statue of Liberty) and Chares worked on it 12 years, using stone blocks and 6.8 ton of iron to support the hollow statue. Its cost was defrayed by selling the siege machines left behind by Demetrius I Poliorcetes.

The Colossos was thrown down by the great earthquake of 227 BCE, but its remains lay on the spot for centuries, until they were sold for scrap by the Arabs in 653 CE.

ca 280–240 BCE **Aristarchos of Samos** (310–230 BCE). Alexandrian Greek mathematician and astronomer. The exponent of a sun-centered universe who made pioneering efforts to determine the sizes and distances of the sun and the moon. Appeared to have been the first to combine *trigonometrical theory* and a mathematical model of the heavens, with some simple

---

ity) and also causing massive *soil erosion* by farming the hillsides around the royal centers. Thus, the Maya could not grow enough food to meet the needs of the population, which dwindled from 3 million (ca 800 CE) to about 50,000 (ca 950 CE). Malnutrition finally caused iron-deficiency anemia (discovered in skulls exhumed from graves). This is an example of human-induced ecological disaster – a punishment for living in disharmony with nature.

physical measurements, to investigate the metrical relationships of the earth, moon and sun. In these calculations, trigonometry is used for the first time as a *basic tool*. In his study he assumes certain properties of the *trigonometric functions* ($\sin\alpha/\sin\beta < \alpha/\beta < \tan\alpha/\tan\beta$ for $0 < \beta < \alpha < \frac{\pi}{2}$), which must have been known in his time. This indicates a rather advanced state of knowledge in this branch of mathematics.

Aristarchos proposed an improved scheme of motion for the celestial bodies by making two simplifying suggestions:

(1) The earth spins – and that accounts for the apparent daily motion of the stars (others had made this suggestion before).

(2) The earth moves round the sun[197] in a yearly circular orbit, and the other planets do likewise – that accounts for the apparent motions of the sun and the planets across the fixed stars.

His book on the subject has not come down to us, but his idea was quoted by Archimedes and referred to by Plutarch.

This simple scheme failed to catch on[198]. Tradition was against it and the Alexandrian school was reluctant to accept such a radical alternative: earth

[197] Although it was merely an idea, not backed up by observational evidence, Aristarchos anticipated the great discovery of Copernicus in 1514. Copernicus could not have known of Aristarchos' doctrine, since Aristarchos' work was not published till after Copernicus' death.

On this account, Aristarchos was accused of impiety by the Stoics, just as Galileo, in later years, was accused by the theologians. His heliocentric scheme was abandoned and was not revived until 1800 years later.

[198] Instead of the bold suggestion of making the earth spin and move round a central sun, the school of Alexandria devised the new theories of *Eccentrics* and *Epicycles*:

A stationary central earth remained the popular basis, but spinning concentric spheres made the model too difficult. Instead, the slightly uneven motion of the sun around its "orbit" could be accounted for by a single eccentric circle. According to this model, the sun is carried around a circular path by a radius that rotates at constant speed. *The observer on earth is off-center*, so that he sees the sun moves unevenly – as it does – faster in December, slower in June. The eccentric scheme for a planet was somewhat more elaborate: each planet is carried at the end of a radius that rotates at constant speed, but this whole circle – center, radius and planet – revolves once a year round the eccentric earth. This added a small circular motion to the large main one, producing the planet's epicycloidal track. The daily motion with the whole star pattern was superimposed on this.

An alternative scheme to produce the same effect assumed that the earth remained fixed at the center of the main circle. The planet, while going around moving around an orbit raised *mechanical* objections that seemed even more serious in later ages, and it immediately raised a great astronomical difficulty. If the earth moves in a vast orbit, the pattern of fixed stars should show parallax changes during the year. None was observed, and Aristarchos could only reply that the stars must be almost infinitely far off compared with the diameter of the earth's orbit. Thus he pushed the stars away to far greater distances and released them from being all on one great sphere!

Aristarchos also made the hypothesis that the moon receives its light from the sun.

In his only surviving short treatise, *On the Magnitudes and Distances of the Sun and the Moon* (with a commentary by Pappos), he devised most ingenious schemes for determining distances to the sun and the moon and the relative sizes of the earth, moon and sun. His method of estimating the relative lunar and solar distances is geometrically correct, though the instrumental means at his command rendered his data erroneous.

These methods were refined in ca 140 BCE by **Hipparchos of Nicaea** (180–110 BCE) who obtained an *earth-moon* distance of 385,000 km and a *sun-earth* distance of about 8 million km.

276 BCE **Aratos of Soli** (315–245 BCE). Greek poet of the Alexandrian school, who in his poem *Phenomena* (= $\phi\alpha\iota\nu o\mu\epsilon\nu\alpha$) gives a systematic account of the stars, including the early fruits of Greek observation since Thales.

Aratos described 43 constellations: 19 in the north, the 12 of the zodiac, and 12 in the south. He also named 5 individual stars: Arcturus, Stachys (Spica), Protrugater (Vendemiatrix in Virgo), Sirius and Procyon. He described the Pleiads and his account of the polar star sheds an interesting light on the state of astronomical understanding in the 3^{rd} century BCE.

Aratos recognized the earth as the center of the heavens, which turn about two poles – one visible, the other hidden. His mention of a slight shifting of

---

this circle, was simultaneously rotating with a small radius-arm around an instantaneous center on the circumference of the main circle. The motion around the small sub-circle (epicycle) was at a steady rate, once in 365 days. To an observer in space, the two circular motions combine to produce an epicycloidal pattern.

Though these schemes use *circles*, they were described more grandly in terms of spinning spheres and sub-spheres. For many centuries, astronomers thought in terms of such *motions of the heavenly spheres* – the spheres growing more and more real as Greek delight in pure theory gave place to naive insistence on authoritative truth.

the axis suggests a suspicion of precession, which was not actually discovered (except perhaps by Kiddinu) until a century later.

Aratos was born in Cilicia. He was invited (ca 276 BCE) to the court of Antigonos Gonatas of Macedonia, where he wrote the *Phenomena*. He then spent some time with Antiochos I of Syria, but subsequently returned to Macedonia, where he died. Although Aratos was ignorant of astronomy, his poem attracted the attention of **Hipparchos**, who wrote commentaries upon it. Amongst the Romans it enjoyed a high reputation; **Cicero** translated it, **Ovid** mentioned him, **Virgil** imitated it, and **Paul** quoted from it (**Acts** *17*, 28).

270 BCE *The Pharos lighthouse of Alexandria.* A landmark in the development of both navigation and architecture. One of the seven wonders of the ancient world. Designed by the Greek architect **Sostratos**; it rose to the height of 134 meters and stood on the island of Pharos off the coast of Alexandria, guiding ships into the city's harbor. The structure rose from a stone platform in 3 sections: the bottom section was square, the middle eight-sided and the top circular. A fire on top provided light.

It stood for over 1000 years before being toppled by the great earthquakes of April 07, 796 and Aug. 08, 1303.

250–550 BCE Decline and fall of the Roman Empire. Decreased rainfall in Rome. Condition of warmth and drought undermined the agriculture and favored epidemic diseases (such as malaria) that gradually weakened the population of the Roman Empire. Simultaneously, increasing drought on the steppes of Central Asia drove the barbarians to seek new lands, tending to cut the trade caravans route between Rome and China.

ca 250 BCE **Erasistratos of Ceos** (Iulis) (ca 304–2 BCE). Greek physician and anatomist of the Alexandrian school. Founder of physiology and comparative anatomical pathology. His main anatomical discoveries concern the brain, the heart, and the nervous and vascular systems. Credited with being the first to distinguish between motor and sensory nerves. Distinguished between cerebrum and cerebellum, traced cranial nerves in the brain itself and investigated the relation of muscles to motion. Traced veins and arteries to the heart and named the trachea and tricuspid valve of the heart. Was close to the discovery of the circulation of the blood[199]. Conducted post-mortem dissections.

[199] Erasistratos proposed that the liver used food to make blood, which was delivered to the other organs by the veins. He believed that the arteries contained air, not blood. This air (*pneuma*), a living force, was taken in by the lungs, which transferred it to the heart. The heart transformed the air into a "vital

Erasistratos was born at Iulis, the main city of Ceos, one of the Cyclades, close to the mainland of Attica (todays Zia). Was educated at Athens and began his career as assistant of Herophilos. He continued the latter's investigations, but was more interested in physiology and the applications of physical ideas to the understanding of life.

ca 250 BCE **Ctesibios**. Greek inventor. The 'Edison' of Ptolemaic Alexandria. He built the first *pump*; it consisted basically of a cylinder with a plunger (valve) inside. As the plunger was moved up and down, it created a pressure that could be used to pump water. Invented the *water clock* or *clepsydra*; it has water dropping like tears into a funnel from the eyes of a statue. A float mechanism raised another human figure with a pointer which indicated the hours on a vertical cylinder. Once in 24 hours the figure descended to the bottom of the column by a siphon mechanism. The siphon outflow worked a water wheel which very slowly rotated the cylinder dial, making a complete rotation in a year. The graduation of the cylinder was adapted to the varying lengths of the hours throughout the seasons.

Ctesibios also built musical instruments worked by pneumatic machinery, a hydraulic pipe organ, the musical keyboard and the *metal spring*, made from bronze plates and used in a catapult.

ca 250 BCE – The earliest preserved examples of our present number symbols 1, 2, 3, 4, 5, 6, 7, 8, 9, are found in some stone columns erected in India by King Aśoka. These early specimens do not employ positional notation.

ca 250 BCE **Archimedes of Syracuse**[200] (ca 287–212 BCE). Mathe-

---

spirit" that was carried by the arteries to the other organs. George Sarton, in his "*Hellenistic Science and Culture*" (1959) warns against modern interpretation of *physiological* facts: "*... one may easily misinterpret Erasistratos' ideas, which we know to be his only through Galen, and Galen's phrasing may suggest to us some ideas that did not exist in his mind, let alone in the mind of Erasistratos. It is almost impossible for us to put ourselves back in their situation, and relatively easy to interpret their ideas in terms of our knowledge*".

matician, physicist, astronomer, engineer and inventor, the greatest universal intellect of ancient times. The creator of statics, hydrodynamics and mathematical physics. Impressed his contemporaries and the bulk of posterity by his practical inventions. Considered for almost two thousand years to be the archetype of the inventor and of the mechanical wizard.

His methods anticipated the *integral calculus* 2000 years before Newton and Leibniz. Discovered the mathematical law of the lever, screw[201] and pulley and the basic laws of hydrostatics. Invented ballistic machines, a hydraulic organ, cranes, burning mirrors, compound pulleys, fulcrums[202], and the like.

He showed[203] that the value of π is between $3\frac{1}{7}$ and $3\frac{10}{71}$. This discovery made it possible for him to solve many problems involving the area of circles

[201] Although Archimedes discovered the *principle of the screw*, ordinary wood screws, as a small fixing device, originated only in the 16^{th} century!
Saws, hammers, nails, chisels and drills all date from the Bronze and early Iron Ages. Many types of modern tools originated even earlier, in the Neolithic period, about 8000 years ago. In fact, there is only one tool that would puzzle a Roman and a medieval carpenter – a *screwdriver*! Ancient screws were large wood contraptions, used for raising water. One of the earliest devices that used a screw to apply pressure was a Roman clothes press; presses were also used to make olive oil and wine. The Middle Ages applied the same principle to the printing press and to that fiendish torturing devices, the *thumbscrew*. The inventor of the hand-held screwdriver remains unknown, but the familiar tool does not appear in carpenters' toolboxes until after 1800. There was not a great call for screwdrivers, because screws were expensive. They had to be painstakingly made by hand and were used in luxury articles like clocks. It was only after 1850 that wood screws were available in large quantities.

[202] He allegedly said: "Give me a fulcrum on which to rest and I will move the earth; give me a place to stand on, and I will move the world".

[203] His method for calculating π is based on the observation that the circumference of a circle is greater than the perimeter of the inner regular n-polygon and less than the perimeter of the outer regular polygon. In modern notation: $n \sin \frac{180}{n} < \pi < n \tan \frac{180}{n}$. For $n = 6$ (hexagon), $3 < \pi < 2\sqrt{3} = 3.46\ldots$. For $n = 96$, calculations yield values which are close to the Archimedean bounds.

and the volume of cylinders, cones and spheres[204]. He also proved that the area of the *spherical cap* is equal to the area of a circle, the radius of which is equal to the cord connecting the 'pole' of the cap to its rim.

Archimedes invented an enumeration system that was more workable with large numbers than were the Greek and the Roman systems. Using this, he calculated the number of grains of sand he thought it would take to fill the universe[205]. He also used methods which, in essence, are used now in modern calculus ("Method of Equilibrium"). He was probably the greatest mechanical genius until Leonardo da Vinci (1452–1519, Italy). Since he made some of man's basic scientific discoveries, some historians call him "the father of experimental science". In his own time he was best known for his many inventions, but he looked upon his inventions as play, and considered mathematics his real work.

The work of Archimedes is characterized by extreme originality and directness as compared with the work of Euclid and Apollonios. The geometry of Archimedes is chiefly a geometry of measurements, while that of Apollonios is rather a study of forms and situations. He realized quadratures of curvilinear plane figures and quadratures and cubatures of curved surfaces by a method more general than the method of exhaustion, and which can be regarded as an anticipation of the integral calculus. He studied paraboloids, hyperboloids, ellipsoids and polyhedra[206]. He summed $\sum n^2 = \frac{1}{6}n(n+1)(2n+1)$, and

---

204 Archimedes stated that the volume of any sphere is 4 times that of a cone with base equal to a great circle of the sphere and with height equal to the radius of the sphere – a statement that amounts to saying that $V = \frac{4}{3}\pi r^3$. He also stated that a cylinder with base equal to a great circle of the sphere and with height equal to the diameter of the sphere is equal to $1\frac{1}{2}$ times the sphere – a statement that amounts to the same thing. These facts are stated in yet another form, known as *Archimedes' theorem*: the ratios of the volume of a cone, half-sphere and a cylinder, all of the same height and radius are 1:2:3 (i.e. $\frac{1}{3}\pi r^2 h$, $\frac{2}{3}\pi r^2 h$ and $\pi r^2 h$ respectively).

205 The largest number given a name by the Greeks was a *myriad*, which we call 'ten thousand' (10^4). Archimedes began by thinking of *myriad of myriads*, and he referred to numbers from 1 to 10^8 as *numbers of the first order*, numbers from 10^8 to 10^{16} as *numbers of the second order*, etc. He continued in this way until he got to the *numbers of order* 10^8. Archimedes then estimated that 10^{63} grains of sand were needed to fill the entire universe. Current estimates of the size of the observable universe in terms of Archimedes' grain-size units, require no more than 10^{93}.

206 *Archimedean polyhedra*: According to Pappos, Archimedes invented a class of *semi-regular* polyhedra, known also as 'facially' regular. This means that every face is a regular polygon, though the faces are not all of the same kind. How-

solved cubic equations by means of the intersection of two conics. [His problem, to cut a sphere by a plane so that the two segments shall be in a given ratio, leads to a cubic equation $x^3 + c^2 b = cx^2$.]

To Archimedes is credited the famous 'Cattle Problem'[207] (*Problema Bowinum*). He must have known about the Pell Equation $u^2 - Nv^2 = 1$ since

---

ever, the faces must be arranged in the same order around each vertex, and all the solid angles of the polyhedron are equal. Thirteen such solids exist. One of them, the *truncated icosahedron*, is formed by truncating the vertices of an icosahedron such as to leave the original faces hexagons. It is therefore enclosed by 20 *hexagonal* faces belonging to the icosahedron, and 12 *pentagonal* faces belonging to the coaxial dodecahedron. It has altogether 32 faces, 60 vertices and 90 edges. The dihedral angles are $138°11'(6–6)$, $142°37'(6–5)$. All Archimedean solids are inscribable in a sphere.

Chemists assumed they knew everything about pure carbon and its manifestations as graphite and diamond. But in 1985 they discovered that 60 carbon atoms can arrange themselves at the vertices of a truncated icosahedron to form the most symmetric molecule possible in 3-dimensional space. This molecule was given the name *buckminsterfullerine*, in honor of Richard Buckminster Fuller's geodesic dome.

207 *The sun god had a herd of cattle consisting of bulls and cows, one part of which was white, a second black, a third spotted, and a fourth brown.*

Among the bulls, the number of white ones was one half plus one third the number of the black greater than the brown; the number of the black, one quarter plus one fifth the number of the spotted greater than the brown; the number of the spotted, one sixth and one seventh the number of the white greater than the brown.

Among the cows, the number of white ones was one third plus one quarter of the total black cattle; the number of the black, one quarter plus one fifth the total of the spotted cattle; the number of spotted, one fifth plus one sixth the total of the brown cattle; the number of the brown, one sixth plus one seventh the total of the white cattle.

What was the composition of the herd?

If we use the letters X, Y, Z, T to designate the respective number of the white, black, spotted, and brown bulls and x, y, z, t to designate the white, black, spotted, and brown cows, we obtain the following *seven* equations for these *eight* unknowns:

$$\begin{aligned} X - T &= \tfrac{5}{6}Y, & x &= \tfrac{7}{12}(Y + y), \\ Y - T &= \tfrac{9}{20}Z, & y &= \tfrac{9}{20}(Z + z), \\ Z - T &= \tfrac{13}{42}X, & z &= \tfrac{11}{30}(T + t), \\ & & t &= \tfrac{13}{42}(X + x). \end{aligned}$$

After some algebraic manipulations, one is led to so-called *Pell equation* $u^2 - 4729494\,v^2 = 1$, where v must be divisible by 9314. Stupendous feats he used it to obtain a very good approximation to $\sqrt{3}$. Indeed,

$$1351^2 - 3 \cdot 780^2 = 1, \qquad \text{so } \left(\frac{1351}{780}\right)^2 - 3 = \frac{1}{780^2}.$$

Therefore

$$\sqrt{3} \approx \frac{1351}{780} = 1.732,051,282\ldots,$$

whereas

$$\sqrt{3} = 1.732,050,805\ldots.$$

Archimedes was born in Syracuse, then a Greek colony. He went to school in Alexandria, Egypt, then the center of Greek learning. He spent the rest of his life back in Syracuse, Sicily.

When Syracuse was attacked by the Roman forces under Marcellus, The Romans met an enemy in the form of a 75-years-old mathematician, supplied with unexpected and powerful weapons. Archimedes actively participated in the defense of the city. He directed the use of systems of pulleys, levers, cranes and other devices which he had invented long before, as practical demonstrations of his theories. The approaching Roman were knocked down by a very effective artillery, which discharged long-range projectiles. The ships of the Roman fleet were sunk by huge cranes. Finally the ships were incinerated by "burning mirrors"[208]. Thus Archimedes forced the withdrawal of the Romans and was the principal factor in the 3-year delay of the fall of Syracuse.

Details of his death are variously told, but all accounts agree that he was killed at the age of 75 by a blundering soldier of the invading Roman army. Marcellus, overwhelmed with grief at the news of his death, attempted to make amends by protecting and even honoring any who could claim relationship to Archimedes. **Cicero** informs us that when he was quaestor in Sicily (75 BCE), he saw Archimedes' tombstone which, though neglected, still showed the incised figure of a sphere inscribed in a cylinder. The theory epitomized by this figure was considered by Archimedes to be his greatest achievement. His greatness can be measured by the fact that the scholars of the 17^{th} century,

of calculation have been performed throughout the ages to obtain integer solution to this equation. Finally, H. Williams, R. German and C. Zarnke obtained the first exact solution in 1965, using an IBM 7040 electronic computer. For a good discussion of the problem, see Vardi (1998): *Archimedes' cattle problem*, Amer. Math. Monthly **105**, no. 4, pp. 305-319; or http://www.jstor.org/.

208 The feasibility of this last contrivance has been demonstrated experimentally (1747) by the naturalist **George Buffon** and again (1973) by the Greek engineer **Ioannis Sakkas**.

living almost 2000 years after him were the first to perceive the subtleties of his computational methods. In their hands, Archimedes' writings were of prime influence in the evolution of the calculus.

On Archimedes

* * *

"The works of Archimedes are without exception, monuments of mathematical exposition; the gradual revelation of the plan of attack, the masterly ordering of the propositions, the stern elimination of everything not immediately relevant to the purpose, the finish of the whole, are so impressive in their perfection as to create a feeling akin to awe in the mind of the reader."

(Thomas Heath, 1921)

* * *

"One cannot read Archimedes' complicated accounts of his quadratures and cubatures without saying to oneself, "How on earth did he imagine those expedients and reach those conclusions?"

(George Sarton, 1952)

'Do Not Touch My Circles'

Rome completed the domination of Italy in 338 BCE (battle of Trifanum). During the next two centuries it vanquished the Carthaginian Empire (3 Punic wars, 264–146 BCE) and reduced Macedonia to a Roman province (4 Macedonian wars, 215–148 BCE). In 286 CE, Diocletian divided the Roman Empire, which marked the start of its long decline.

The rise and fall of Alexandria (as a center of learning) runs almost concurrently to that of Rome; founded by Alexander the Great in 332 BCE, it soon became the world capital of the sciences, edified by the great minds of ***Menaechmos***, ***Euclid***, ***Apollonios***, ***Eratosthenes***, ***Hero***, ***Ptolemy***, ***Diophantos*** *and* ***Pappos***.

It was just a matter of time before the two cultures ran into a collision course; around 180 BCE, Alexandria entered the Roman sphere of influence and in 80 BCE the city passed formally into Roman jurisdiction. There, Julius Caesar dallied with Cleopatra in 47 BCE while the great Alexandrian Library lay burned in ashes; there his example was followed by Antony, for whose favor the city paid dearly to Octavian, who placed over it a prefect from the imperial household. Alexandria seemed from this time to have regained its old prosperity, commanding, as it did, an important granary of Rome. This latter fact, doubtless, was one of the chief reasons which induced Augustus to place it directly under imperial power. In 215 CE the emperor Caracalla visited the city; and, in order to repay some insulting satires that the inhabitants had made upon him, he commanded his troops to put to death all youth capable of bearing arms. This brutal order seems to have been carried out even beyond the letter, for a general massacre was the result.

Notwithstanding this terrible disaster, Alexandria soon recovered its former splendor, and for some time longer was esteemed the first city of the world after Rome. But its importance no longer sprang from Pagan learning, but as a center of Christian theology and Church government. Its great library was repeatedly sacked and burned by the Roman vandals in 273, 295 and 391 CE.

It is a great fallacy to believe that the Romans had attained an advanced level in the sciences, the arts, law[209]*, architecture and engineering. Like later*

[209] It was not inherent superiority that facilitated the spread of Roman law throughout Europe, for it had borrowed heavily from both Semitic and Greek concepts. What made Roman law so widely acceptable was that people could borrow its legal concepts without finding a Roman god or a doctrinaire trap tied to the end of the paragraph. Even the Jews could borrow from Roman law without

empires in history, the Romans enslaved peoples whose cultural level was far above their own. They not only ruthlessly vandalized their countries, but also looted them, stealing their art treasures, abducting their scientists and copying their technical know-how, which the Romans' barren society was rarely able to improve on; the light of their culture was borrowed from the Greek and their other enslaved colonies.

Roman engineering was void of all subtlety; long after Heron of Alexandria (ca 150 BCE) had designed water clocks, water turbines and two-cylinder water pumps, and had written works on these subjects, the Romans were still describing the performance of their aqueducts (and charging the users) in terms of the cross-section of the flow (!), as if the volume of the flow did not also depend on its velocity.

Nevertheless, the Romans did develop the use of concrete and the arch in the building of bridges, roads, and aqueducts, creating a series of civil and military engineering projects that surpassed in scale any since those of the Assyrians.

Roman engineering, like that of the earlier watershed empires, was based upon intensive applications of rather simple principles, with plenty of raw materials, cheep labor, and time. Rome possessed abundant supplies of brick, stone, and timber. Labor was especially cheap because the swift extension of the empire had crowded Rome with thousands of slaves.

The Romans devoted more of their energy and capital to useful public works than did their predecessors. They built roads, harbor works, aqueducts, temples, forums, town halls, arenas, baths and sewers. A magnate, governor, or emperor might be a scoundrel in other respects, but he believed that he gained honor by presenting the people with some useful or entertaining public work. Under the republic this was a method of bidding for votes; and, even after elections had ceased in the early Empire, the tradition lived on.

The Roman contribution to science was mostly limited to butchering antiquity's greatest mathematicians, burning the library of Alexandria, and slowly

---

fear of becoming beholden to its Pagan deities.

Another reason for the acceptance of Romanism throughout Europe was the nature of the Roman people. Though they were cruel, they were free from prejudice, with the noted exception of their antipathy to Christians. They massacred people and gave them citizenship with equal impartiality, disregarding race, creed, color, or previous conditions of servitude. The Roman formula for tying a conquered nation to its victorious chariot was based on four basic principles – annex the land by the sword, connect it to Rome roads, bind its people with citizenship, and govern them with secular laws.

stifling the sciences that flourished in the colonies of their empire. The Naturalis Historia by ***Pliny the Elder*** *(23–73 CE) is an encyclopaedic compilation which is generally regarded as the most significant scientific work to have come out of Rome; and it demonstrates the Roman's abysmal ignorance of science when compared to the scientific achievements of their contemporaries at Alexandria, even a century after the Romans had sacked it.*

The Roman contribution to mathematics was almost nihil. Their greatest mathematician ***Poseidonius*** *(135–51 BCE), friend and teacher of Cicero and Pompey who calculated the circumference of the earth with high accuracy, was a Syrian who studied in Athens. But whatever the value of* π *used by Poseidonios, it was high above Roman brows. The Roman architect and military engineer* ***Marcus Vitruvius Pollio*** *(flourished ca 25 BCE), in De Architectura, used the value* $\pi = 3\frac{1}{8}$, *the same value the Babylonians had used at least* 2000 *years earlier.*

The alleged Roman achievements are largely a myth. What they really excelled in was warefare and blood baths. Thus, during the second Punic war, the Romans sent an expeditionary force under Marcus Claudios Marcellus[210] *(268–208 BCE) to Sicily in* 214 *BCE to "convince" the king of Syracuse to sever his alliance with Carthago. However, Roman brute force, assaulting the city of Syracuse by land and sea, ran into some smart scientific engineering. Using machines that applied the secrets of the lever, the pulley and the principle of the mechanical advantage, Archimedes was master-minding the defense of city walls for three years before the city finally fell to the Roman cut-throats (212 BCE). Inside the city was the 75-year old Archimedes, engaged in the solution of some geometrical problem.* ***Plutarch*** *tells us that a soldier came up to him and bade him follow to Marcellus, but he would not go until he had finished his problem and worked it out to the proof. "Do not touch my circles!" said the savant. Thereupon the soldier became enraged, drew his sword and slew the savant.*

The Greeks were interested in man as a creature who by nature desires to know; the Romans were interested in man for what they could get from him by force or persuasion – through the Roman legions or Latin oratory. As ***Alfred North Whitehead*** *put it "The death of Archimedes at the hands of a Roman soldier is symbolical of a world change of the first magnitude... No Roman lost his life because he was absorbed in the contemplation of a mathematical diagram".*

---

[210] Killed near Venusia, Italy, by Hannibal's forces.

247–168 BCE *Collision of the Greco-Roman and the Phoenician and Judean cultures*: Hebrew scriptures were translated into Greek during 285–247 BCE by a group of 72 Alexandrian Jews (*Septuagint*). In 216 BCE, Hannibal (247–183 BCE) stood with his army in front of the gates of Rome. **Ecclesiastes** was composed sometime between 245 and 168 BCE. The Book of **Daniel** was written during 175–164 BCE, probably close to the revolt of the Maccabees[211] in 168 BCE.

ca 245 BCE **Conon of Samos**. Greek astronomer and mathematician. The friend of Archimedes, who survived him. Wrote a work on astronomy, which contained a collection of the observations of solar eclipses made by the Babylonians. He also investigated the question of the number of points of intersection of two conics, and his researches probably formed the basis of the 4^{th} book of the *Conics* by Apollonios of Perga. Considered the inventor of the curve known as the *Spiral of Archimedes*.

Conon became court astronomer to Ptolemy III Euergetes at Alexandria; he is known in connection with the *Coma Berenices*[212].

240 BCE, Aug. 02 Historical record of a Chinese observation of a Perihelion passage of *Comet Halley*. No observations of this comet prior to this date has yet been identified in the ancient Chinese records.

This event has been recently (1981) ascertained by actually integrating the comet's equations of motion backward in time, including planetary and non-gravitational perturbations.

235 BCE **Eratosthenes of Cyrene** (276–197 BCE). A Greek mathematician and astronomer. Librarian of the Museum of Alexandria (235 BCE). Devised an ingenious way to measure the circumference of the Earth: he noticed

---

211 Antiochus IV Epiphanes began the persecution of the Jews by declaring Judaism illegal (168 BCE). Under **Jehudah Ha'macabee** (Judas Maccabaeus), the Jewish army, outnumbered 5:1, defeated the Seleucian forces in four decisive battles and gained religious independence (164 BCE). After a series of wars, the Jews gained political independence (142 BCE) and established the *Hasmonean Kingdom*.

212 Berenice II, wife of Ptolemy III Euergetes had dedicated her hair in a temple as an offering to secure the safe return of her husband from his Syrian war. It disappeared from the temple. To flatter the queen, Conon declared that it has been placed among the stars in the constellation *Coma Berenices* (Hair of Berenice).

that when the sun was overhead at Aswan (Syene), it was about 7.2 degrees from vertical in Alexandria (sun rays arrive almost parallel to both places)[213]. This simple observation sufficed to yield the desired result in terms of the distance Aswan–Alexandria (ca 800 km). His deduced length for the earth's circumference is only 160 km in excess of the present accepted value. Invented the so-called *sieve of Eratosthenes* to obtain the prime numbers, and an instrument to solve the duplication of the cube. He was the founder of scientific chronology of ancient Greece and was also a distinguished philologist.

Eratosthenes also measured the tilt of the earth's axis (relative to the ecliptic) with great accuracy and compiled a star catalogue. He became blind at old age and is said to have committed suicide by starvation.

ca 230 BCE **Apollonios of Perga** (262–200 BCE). Greek geometer and astronomer of the Alexandrian school. Founder of Greek mathematical astronomy, which used geometrical models to explain planetary theory. Flourished in the reigns of Ptolemy Euergetes and Ptolemy Philopater (247–205 BCE). His treatise *Conic Sections*[214] gained him the title of *The Great Geometer*. All his other treatises have perished, and we have only their titles handed down, with general indications of their contents, by later writers, especially **Pappos** (ca 300 CE).

Apollonios was born in southern Asia Minor. As a young man he went to Alexandria, studied under the successors of Euclid and remained there for a long time. Later he visited Pergamum in western Asia Minor, where there was a recently founded university and library patterned after that of Alexandria. He returned to Alexandria and died there.

His book on conic sections[215], comprising 8 volumes and some 400 propositions, completely superseded the earlier works on the subject by Menaechmos

[213] Syene – a place on the upper Nile River near the Tropic of Cancer (lat. $23\frac{1}{2}\,^\circ$N). The observation was made at the time of summer soltice (June 21), when the sun's noon rays were nearly perpendicular to the earth's surface, so as to shine upon the floor of a deep, vertical well. On the *same* soltice day, the sun's *noon rays* were observed at Alexandria, located approximately on the *same* meridian.

[214] For further reading, see:

- Somerville, D.M.Y., *Analytical Conics*, Bell and Sons: London, 1949, 310 pp.
- Heath, T.L. (Editor), *Apollonius of Perga: Treatise on Conic Sections*, W. Heffer and Sons: Cambridge, 1961, 254 pp.

[215] In fact, Book 8 of *Conics* is lost while 5 to 7 only exist in Arabic translation. However, we know something of his other work from the writings of others. Thus we know that he obtained an approximation for π better than $\frac{22}{7} > \pi > \frac{223}{71}$ known to Archimedes. He showed that parallel rays of light are *not* brought to

and Euclid. The names *ellipse*, *parabola* and *hyperbola* were coined by Apollonios. In Book II one finds the harmonic properties of poles and polars and theorems concerning the products of segments of intersecting chords which constitute the basic elements of today's projective geometry. Book V is the most remarkable and original of the extant books. It treats *normals* considered to be maximum and minimum line segments drawn from a point to the curve. The construction and enumeration of normals from a given point are dealt with. The subject is pushed to the point where one can write down the Cartesian equations of the *evolutes* of the three conics!

Appolonios stated the problem of constructing a circle tangent to three given circles, where the given circles are permitted to degenerate independently into straight lines or points. This is now known as the *problem of Appolonios*[216]. It had attracted many mathematicians, among them **Viète**, **Euler**, and **Newton**.

Many attempts to restore the lost works of Apollonios were made by leading mathematicians, among them **Vièta**, **Snellius**, **Fermat** and others. Indeed, the prodigious activity surrounding the study and reconstitution of his works effectively placed Apollonios in the direct line of the invention of analytic geometry and made him a powerful force in the modern development of mathematics.

220–200 BCE **Dionysodorus** (ca 250–190 BCE). Mathematician. Solved the problem of the cubic equation using the intersection of a parabola and a hyperbola. He also is believed to have invented a conical sundial.

218 BCE **Archagathos**. The first Greek physician whose name is preserved as having migrated to Rome from the Peloponnesos; but there were probably others before him.

When Greece was made a Roman province (146 BCE), the number of such physicians who sought their fortunes in Rome must have been very large. The bitter words of Marcus Porcius Cato (234–149 BCE), who disliked them as he did other representatives of Greek culture, are evidence of this.

---

a focus by a spherical mirror (as had been previously thought) and discussed the focusing properties of a *parabolic mirror* (proved by Diocles).

216 One of the first solutions, applying the new Cartesian geometry was given by Descartes' pupil **Elizabeth of Bohemia** (1618–1680), daughter of Elector Palatine Frederick V of Bohemia.

Probably the most elegant solution is that furnished by the French artillery officer and professor of mathematics, **Joseph Diaz Gergonne** (1771–1859).

214 BCE The construction of *the Great Wall of China*[217] began by emperor Shih Huang Ti of the *Ch'in* dynasty to safeguard the country against invasion from the north. He built the wall by linking together shorter walls erected by earlier times.

This defensive structure extends over 2400 km in northern China from Kansu in the west to the Yellow Sea in the east, over 22 degrees of longitude (98° to 120°E). It defines the historical boundary between China and Mongolia. Legend has it that over million workers died during the construction and their bodies were thrown into the wall. It is the longest fortified line ever built.

The wall is carried over valleys and mountains, and in places over 1300 meters above sea-level. It stand about 8 meters high. Towers from 11 to 12 meters high were build into the wall every 180–270 meters. It tapers from a width of 8 meters at the base to about 5 meters at the top. Its sides are made of earth, brick and stone. The top is paved with bricks that are set in lime, forming a roadway for horsemen. The Great Wall was built by hand and took hundreds of years to complete. Under *Sui* dynasty (589–610 CE), it was expanded, and during the Ming dynasty (1368–1644) it was repaired. Later rulers neglected it.

213 BCE '*Burning of the books*'. In China, Emperor Shin Huang-Ti proclaimed that everything was to begin with his reign. He then issued an order to burn all books. 400 scholars were burned alive for having disobeyed the imperial command. Some books were bricked up in walls and upon the collapse of the Chin dynasty in 206 BCE, were recovered from their hiding places, but many others were lost.

Chang Tsang (ca 210–152 BCE), soldier, statesman, and scholar, reconstructed the earlier *K'iu-ch'ang* (whose fragments escaped the book-burning) into the greatest mathematical work of antiquity, the *K'iu-ch'ang suan-shu* (Arithmetical Rules in Nine Sections). Tradition places the origin of the early work in the third millennium BCE. The latter book contains 246 problems classified into 9 sections. Among the topics involved are: 'Euclid's algorithm', proportion, extraction of square and cube roots, plane and solid mensuration and the right triangle.

210–190 BCE **Diocles of Carystos** (ca 240–180 BCE). Mathematician. Wrote *On burning mirrors* which *proves* the focusing property of a parabolic mirror for the first time. Largely ignored by later Greeks, it had a large

[217] The name by which that country is known to other nations, comes from a dynasty which ruled the land for only 14 years (221–206 BCE).

influence on the Arab mathematicians, in particular on Alhazen. Latin translations of Alhazen, from about 1200 CE, brought the properties of parabolic mirrors to the West. Diocles also studied the Cissoid (named after him) as part of an attempt to duplicate the cube. He also studied the problem of Archimedes to cut a sphere in such a way that the volumes of the segments shall have a given ratio.

ca 200 BCE Indirect evidence for the use of the *zero* in India.

ca 200 BCE Romans adopted and improved on an earlier Etrurian notation of numbers.

Roman numerals were written in terms of certain capital letters of the Latin alphabet (but not *successive* letters, in the manner practiced by the Syrians, Hebrew, and Greeks).

All Roman numerals are written with seven basic symbols. These are $I(1)$, $V(5)$, $X(10)$, $L(50)$, $C(100)$, $D(500)$, and $M(1000)$. There is no zero. All other numbers are written by combining these seven symbols. Roman numerals are written from left to right, using the principle of addition: e.g., $2713 = MMDCCXIII$; $MMM = 3000$. A smaller numeral (or composite number) appearing *before* a larger numeral indicates that the smaller number is *subtracted* from the larger one, e.g., $84 = XXCIV$.

It is simple to add and subtract with Roman numerals, but the system is inconvenient and clumsy for other types of calculations.

The Roman-numerals system was the most popular form of writing numbers until the widespread use of Arabic numerals began in the late 1500's. Today, the former is used to number the faces of clocks, to list important topics in outlines, to number prefatory book pages, and to record dates on monuments and public buildings.

187 BCE Plague occurred throughout Egypt, Syria and Greece. Reported by **Pliny**.

180 BCE **Zenodoros** (ca 200–140 BCE). Greek mathematician. Wrote a treatise on *isometric figures*, some fragments of which were preserved in the writings of **Theon of Smyrna** (ca 125 CE) and **Pappos of Alexandria** (ca 300 CE). Zenodoros proved that the circle has a greater area than any regular polygon of equal periphery[218]. He showed that among polygons with equal

[218] The dual statement, that of all curves enclosing a given area the circle possesses the shortest perimeter, was already known to **Aristotle** (384–322 BCE); in his book *De Caelo* he writes: "*Of lines which return upon themselves the line which bounds the circle is the shortest*".

perimeter and an equal number of sides, the *regular polygon* has the greatest area, and also studied the volume of a solid figure with a fixed surface area.

ca 180 BCE **Shimon Ben-Sirah** (ca 240–175 BCE, Jerusalem). Savant, scribe and author of one of the books of the Apocrypha entitled: *The Wisdom of ben-Sirah*, or *The Book of ben-Sirah*; a proverbial wisdom in praise of both *secular knowledge*[219] and traditional religious wisdom (Torah).

Ben-Sirah lived in Jerusalem at the time of **Simon II the Just** (d. 190 BCE). The Hebrew original of this book was considered lost until 1896, when a great part of it was found in a cellar of the Ezra Synagogue in Cairo. The book was translated in Egypt into Greek in 132 BCE by the author's grandson and the Christian Church preserved the book in Greek.

164 BCE Babylonian clay tablets (in the British Museum) documented observation of *comet Halley* apparition in the region of the Pleiades in the constellation Taurus. Recent calculation confirm its appearance in the month of November of that year.

161–127 BCE **Hipparchos of Nicaea** (**Rhodes**) (180–110 BCE). A Greek astronomer and mathematician and one of the greatest astronomers of antiquity. He fixed the chief data of astronomy – the lengths of the tropical *and sidereal years*, of the various months, and of the *synodic periods of the five planets*; determined the obliquity of the ecliptic and the moon's path; the position of the sun's apogee; the eccentricity of earth's orbit, and the moon's horizontal parallax. His borrowings from the Babylonian experts appear to have been numerous, but were doubtless independently verified. His supreme merit, however, consisted in the establishment of astronomy on a sound geometrical basis. His acquaintance with trigonometry, a branch of science initiated by him, together with his invention of the *planisphere*, enabled him to solve a number of elementary problems.

Hipparchos recognized the existence of the *precession of the equinoxes*, which for him was just an empirical fact, and so it remained until 1543. He became aware of it when he compared his own observations with those of earlier astronomers. Thus, he may have known that Alpha Draconis was the pole star for the Egyptian civilization about 3000 BCE.

To an earthbound observer, the sun's annual trace across the celestial sphere (of "fixed" stars) intersects the celestial equator at two points. At

---

[219] e.g., he advices: "*Honor thy physician. His knowledge allows him to walk with raised head, and gains for him the admiration of princes. If you fall ill, cry to the Lord, but also call for the physician, for a sensible man does not neglect the remedies which the earth offers*".

each of those points the sun is directly over the equator at noon and the length of the day and night are nearly the same everywhere on earth. This happens twice a year: once at the vernal (spring) equinox on March 20 or 21, as the sun moves *north*; the other at the autumnal equinox on Sept. 22 or 23, when the sun moves *south*. Also on those days, the sun rises precisely in the east and sets in the west, at all latitudes. The beginning of the year was reckoned in days from the start of spring, – the day when the sun crosses the celestial equator from south to north in its path around the ecliptic.

The ancient astronomers, through their amazingly careful observations, had discovered that the celestial sphere of "fixed stars", seems to turn gradually from west to east with respect to the nodal line connecting the two equinoctial points. (An observer outside the solar system would instead see a *westward* drift of the equinoctial points.) **Hipparchos** discovered this phenomenon and reported its magnitude to be about $36''$ of arc per year (the true value is $50''$).

He also recognized that the existence of this precession of the equinoxes allowed two different definitions of the year – either the time between spring equinoxes, bringing the sun back into the same positional relationship to the earth's spatial orientation, or the slightly longer time (by about 20 min) for the sun to return to exactly the same observed position with respect to the fixed stars. These times are known as the *tropical year* and the *sidereal year*, respectively.

Since 20 minutes is about $\frac{1}{26{,}000}$ year, it follows that the vernal equinox revolves once every 26,000 years. In the days of Hipparchos, the equinox had moved to constellation Aries, and now it is in constellation Pisces. The equinox will continue to move westward, reaching the constellation Taurus – the location it held in the earliest days of the Zodiac – around the year 23,000 CE. For the same reason, the earth's axis will not always point to Polaris. In the days of the Egyptians the polar star was near Thuban (Alpha Draconis), a bright star in the constellation Draconis. About 6000 years from now the axis will point to Alpha Cephei. In 14,000 CE Vega will be the polar star.

Around 160 BCE, Hipparchos built an observatory on the island of Rhodes. In 130 BCE, he made an observation at Rhodes, from which he obtained a remarkably accurate estimate of the *earth-moon distance*. His method had been suggested by **Aristarchos**, about 150 years earlier. The method involves a clear understanding of the positional relationship of sun, earth, and moon. First, he knew that sun and moon subtended almost exactly the same angle α at the earth[220]. Hipparchos measured this angle to be 0.553° ($\approx \frac{1}{103.5}$ radian);

[220] Which is why total solar eclipses are both *possible* and *very brief*.

he also knew what Aristarchos before him had found — that the sun is far more distant than the moon.

Hipparchos used this knowledge in an analysis of an *eclipse of the moon by the earth*: Assume that centers of the sun, earth and moon (in this order) are collinear, and that the rays coming from the extreme edges of the sun and tangent to the earth, cut the moon's circular orbit at two points A and B. Let the angle subtended between these two boundary rays be α radians. The moon passes through the shadow from A to B, and from the measured time that passage took, Hipparchos deduced that the angle subtended at the earth's center by the arc BA was $\measuredangle AOB = 2.5\alpha$. The rest is simple geometry: if the distance from the earth's center to the moon is D, the length of the arc AB is about $\overline{AB} = 2R_{_E} - \alpha D$ ($R_{_E}$ = earth's radius). Also $\overline{AB}/D = 2.5\alpha$. With $\alpha = \frac{1}{103.5}$, Hipparchos found $D/R_{_E} \approx 59$.

Hipparchos also discovered an ingenious method of calculating the mean duration of a synodic month; by measuring the exact interval between a lunar eclipse recorded by the Babylonians and one observed by himself, he found that 4267 full moons (lunations) occurred in the interval of 126,007 days + one hour = 3,024,169 hours. Therefore $\frac{3{,}024{,}169}{4267}$ hrs = $29^d : 12^h : 44^m : 3.3^s = 29.53^d$ is the synodic period[221] !

By ca 120 BCE, Hipparchos compiled the first comprehensive star catalogue, which listed the coordinates and brightnesses of 850 stars. During the course of this pioneering work, he compared his star positions with earlier records dating back to Aristarchos' time. Hipparchos soon noted systematic differences that led him to conclude that the north celestial pole had shifted slightly over the preceding century. This led him to the discovery of the precession of the equinoxes.

While compiling his star catalogue, Hipparchos established a system to denote the brightest of stars. His system is the basis of the magnitude scale used by astronomers today: the brightest star he saw in the sky he called *1st magnitude star*. The dimmest visible star he called a *6th magnitude star*. To stars of intermediate brightness he assigned intermediate numbers on this logarithmic scale of 1 to 6. With only a few refinements, the same system is used today.

The erratic configuration of the naked-eye stars has remained essentially unchanged since the times of the first records; all the stars that Hipparchos described can be found, with the same brightnesses and practically at the same places, in the contemporary sky. In fact, there has been no gross alteration in the constellations for millennia before his time.

221 According to Pliny, Hipparchos also observed a new star (probably a Nova) in the year 134 BCE.

The whole sky has been arbitrarily divided into 12 areas which differ greatly in angular size and shape. Each area embraces a "*constellation*", or group of stars, and is known by a mythical or a semi-mythical name. More than half the constellations were recognized and mentioned by Hipparchos. Some data of Hipparchos' star catalogue may be preserved in the star catalogue contained in Ptolemy's *Almagest*. The remaining constellations, which Hipparchos did not observe, lie in the Southern Hemisphere and were not named until the Age of Exploration in the 16^{th} and 17^{th} centuries. The constellations listed by Hipparchos were known by the Greek equivalents of their present Latin names. They were not invented by Greeks but came to Greece from the earlier civilization of Mesopotamia, and their names are found in Euphratean tables of about 600 BCE, which embody ideas of an even remoter age.

Hipparchos made great advances in both mathematics and astronomy. He was a careful observer, made new instruments and used them to measure star positions. He practically invented *spherical trigonometry* for use in his studies of the sun and moon. He constructed the first celestial globe on record. He used and probably invented the *stereographic projection*. In Rhodes (but also in Alexandria), he made an immense number of astronomical observations with amazing accuracy. He noted the existence of misty patches in the heavens which he called 'nebulae'. Yet he *did not reject the geocentric system*, and is therefore responsible for its long predominance.

Hipparchos' works are lost, and it is possible that their loss was partly the result of the fact the Ptolemy's great book, the *Almagest* (ca 150 CE) superseded them and made them superfluous. What we know of Hipparchos we know almost exclusively from Ptolemy, who quoted him often, sometimes verbatim. It is strange to think of two men separated by a barrier of 300 years – yet working as if the second was the immediate disciple of the first.

Hipparchos and Ptolemy rejected the ideas of Aristarchos of Samos (280 BCE) who had anticipated the Copernican system (1514), because they did not tally sufficiently with the observations. Their objections were of the same nature as Tycho Brahe's at the end of the 16^{th} century; a sufficient agreement between observations and the heliocentrical system became possible only when Kepler replaced circular trajectories by elliptic ones (1609).

Lunar Theory[222]*, Part I*

The celestial objects that have received the greatest attention throughout the long history of astronomy are the moon and the sun. In fact, the first astronomical phenomenon to be understood was the cycle of the moon. On a monthly basis, we observe the phases of the moon *as a systematic change in the amount of the moon that appears illuminated; the lunar phases are a consequence of the motion of the moon and the sunlight that is scattered from its surface. Half of the moon is illuminated at all times, but to an earthbound observer, the percentage of the bright side facing him depends on the location of the moon w.r.t. the sun and the earth. When the moon lies between the sun and the earth, none of its bright side faces the earth, thus producing the new-moon phase. Conversely, when the moon lies on the side of the earth opposite the sun, all of its lit side faces the earth, producing the full moon. At a position between these extremes, an intermediate amount of the moon's illumination is visible.*

The cycle of the moon through its phases requires about $29\frac{1}{2}$ *days, a period called the* synodic month, *a cycle that was the basis for the first Roman calendar. However, this is not the true period of the moon's revolution, which takes only about* $27\frac{1}{3}$ *days and is known as the* sidereal month. *The reason for the difference of* 2 *days each cycle is this: as the moon orbits the earth, the earth-moon system also moves in orbit around the sun. Consequently, even after the moon has made a complete revolution around the earth with respect to the background stars, it has not yet reached its new-moon starting phase, which is directly between the sun and earth. This additional motion takes another* 2 *days*[223].

The lunar year, consisting of 12 *synodic months, contains only* 354 *days; its conclusion consequently anticipates that of the solar year by* 11 *days, and passes an integer number of times through the whole cycle of the seasons in about* 34 *lunar years. It is therefore obviously ill-adapted to the computation of time, and all nations who have regulated their months by the moon have*

[222] To dig deeper, see: Moulton, F.R., *An Introduction to Celestial Mechanics*, Dover: New York, 1970, 436 pp.

[223] The synodic period of the moon is given by the kinematic equation: $\tau_s = \frac{2\pi}{\omega_M - \omega_E}$, where $\omega_E = \frac{2\pi}{365.256}$ is the earth's orbital mean angular velocity relative to the stars (sidereal year) in radians/day, and $\omega_M = \frac{2\pi}{27.32166}$ is the mean angular velocity of the moon in its orbit, relative to the background stars (sidereal month).

employed some method of intercalation by means of which the beginning of the year is retained at nearly the same fixed place in the seasons.

In the early ages of Greece the year was regulated entirely by the moon. ***Solon*** *(ca 639–559 BCE) divided the year into* 12 *months, consisting alternately of* 29 *and* 30 *days, the former of which were called* deficient *months, and the latter* full *months. The first expedient adopted to reconcile the lunar and solar years was the addition of a month of thirty days to every* 2^d *year. Since the difference of* $7\frac{1}{2}$ *days was still too great to escape observation, occasional corrections were made as they became necessary; but since these corrections were left to the care of incompetent persons, the calendar soon fell into great disorder, until a new division of the year was proposed by* ***Meton***[224] *(ca 432 BCE), which was immediately adopted in greater Greece.*

The ancient astronomers recognized the much greater complexity of the moon's motion as compared with that of the sun. Thus they found from observations of eclipses that the length of the synodic month is not constant, but varies within a few hours on either side of the mean $29^d : 12^h : 44^m : 3\frac{1}{3}^s$. *In addition, there were many irregularities in the moon's motion in various parts of its course. We know today that these irregularities are satisfactorily explained in the framework of the Newton-Kepler theory. But the ancient astronomers tried and failed to explain these phenomena by means of an eccentric circle alone (as they did in the case of the sun). They were obsessed with the idea that heavenly bodies whose courses were "ordained by God" could have no other than* perfect *movements, which to their minds was synonymous with* circular *movements. They thus represented the moon's motion by an ingenious device – a combination of circular motions.*

While the day, the month and the year have clear astronomical origins, the week *is a period of* 7 *days, having no reference whatsoever to celestial*

[224] The Athenian astronomer **Meton** (fl. 432 BCE), who took the length of the year as $365\frac{1}{4}$ days, discovered that 19 solar years expressed in days, hours, etc., contain *almost* exactly 235 synodic months (lunations). This is known as Meton's *19 solar year cycle*.

After the period of 19 years the full moons again occur on the same days of the solar year. Since $235 = 19 \times 12 + 7$, the period of Meton consists of 12 years containing 12 months each, and 7 years containing 13 months each, and these last are chosen to form the 3^{rd}, 5^{th}, 8^{th}, 11^{th}, 13^{th}, 16^{th}, and 19^{th} years of the cycles.

Calculations from modern data show that 235 lunations are 6939 days + 16.5 hours, while 19 solar years are 6939 days + 14.5 hours. The relation between integral numbers of months and years expressed by *Meton's rule* therefore deviates only 2 hours from the truth. Since 19 *Julian years* make 6939 days + 18 hours, the relation errs only 1.5 hours when the Julian year is used.

motions. It might have been suggested by the phases of the moon, or by the number of planets known in ancient times, an origin which is rendered more probable from the names universally given to the different days of which it is composed. (The idea of the Sabbath, however, with its social, religious and moral connotations, is exclusively Hebrew in origin.)

The plane of the moon's motion is inclined to the ecliptic, on the average by $5°8'$. *These two planes intersect along a* line of nodes: *The moon's* nodes *are the points where its orbit intersects the plane of the ecliptic. The node where the moon crosses the ecliptic from south to north is called the* ascending node. *The other, where the moon crosses from north to south is the* descending node *[eclipses can occur only when the moon is very near one of the nodes].*

The moon's orbit is an ellipse of average eccentricity $e = 0.055$. *The position along the orbit where the moon is nearest to us is called* perigee. *In the farthest position the moon is at its* apogee. *The line connecting the apogee and the perigee is the line of* aspides.

The complexity of the moon's motion is caused by gravitational action of the sun on the earth-moon system. Some of the principal perturbations are:

(1) *Evection: periodic change in the orbital eccentricity of the moon with a period of* 31.8 *days.*

(2) *Variation: an effect that makes new and full moons occur too early and half-moons too late.*

(3) *Annual equation: a perturbation in the moon's annual equation of motion due to changes in the sun's attraction, caused in turn by variations in the earth-sun distance throughout the year.*

(4) *Retrogression of the moon's nodes: a precessional motion of the moon's orbital plane due to solar attraction. It results in the backward motion of the nodes along the ecliptic [similar in effect to the precession of the equinoxes]. A complete sidereal revolution of the ascending node takes place in about* 18.61 *years.*

(5) *The inclination of the moon's orbit* varies periodically between $4°59'$ and $5°18'$.

(6) *The progression of the line of aspides* causes the whole orbit of the moon to rotate and turn once upon itself every 8.85 *years.*

The nodical *month*[225] *(27.21222 days) is somewhat variable due to the attraction of the sun, earth's equatorial bulge and the planets. It is defined as the time interval between successive passages of the moon through a given*

---

225 Also called '*draconitic*' because of the ancient belief that a dragon was supposed to swallow the sun at a total solar eclipse.

node and is a very important period in eclipse theory. There are also: sidereal *month (relative to the stars; 27.32166 days on the average),* tropical *month (relative to vernal equinox: 27.32156 days),* anomalistic *month (relative to perigee; 27.55460 days) and* synodic *month (relative to sun; 29.53059 days).*

Along with understanding the moon's phases, the early Greeks also realized that eclipses *are simply shadow effects; the moon is eclipsed when it moves within the shadow of the earth, a situation that is possible only during the full moon phase. A lunar eclipse takes place only if a full moon phase occurs when the moon lies in the plane of the ecliptic. During the total lunar eclipse, the circular shadow of the earth can be seen moving across the disk of the full moon. When totally eclipsed, the moon will still be visible as a coppery disk, because the earth's atmosphere bends and transmits some long-wavelength light (red) into its shadow*[226]*. A total eclipse of the moon can last up to 4 hours and is visible to* anyone *on the side of the earth facing the moon.*

Lunar eclipses are one of the oldest known celestial phenomena, reported in historical sources as early as 2283 BCE (the eclipse associated with the Mesopotamian town of Ur). A Chinese eclipse is again mentioned in 1136 BCE. From the beginning of the 8^{th} *century BCE, the number of eclipses observed in Mesopotamia and in the Mediterranean region has been continually growing, with later additions from the rest of Europe.*

Chaldeans found empirically that one lunar eclipse was generally followed by another at an interval of 223 synodic months, or 18 years + 11 days + 8 hours (the saros*). The explanation of this fact is as follows: The moon, which was in opposition at the time of any one eclipse, is necessarily in opposition again after a whole number of lunations. This however is not sufficient for an eclipse to take place; it is also necessary for the moon to be back in the ecliptic, that is to say at one of the nodes of its orbit. The returns of the moon to its nodes are governed by the draconic revolution of 27.2122 days, whereas the return of a state of opposition is regulated by the synodic revolution (or*

[226] The apparent paradox of the simultaneous visibility above the horizon of the setting sun *and* the eclipsed rising moon (or vice versa) was already noticed in ancient times. Since the sun, the earth, and the moon are in a straight line during the eclipse, at least approximately, and since furthermore the effect of parallax is to *lower* the moon by nearly one degree for an observer who sees it near the horizon, this effect appears inexplicable at first. But on the one hand atmospheric *refraction* lifts up the apparent sun and moon by over half a degree each, which compensates the effect of parallax, and on the other hand the center of the moon may be situated above the center of the earth's shadow at the time of observation. The simultaneous visibility is a fleeting effect, however, and never lasts more than a few minutes.

lunar month) of 29.5306 *days. Since the saros is a period after which eclipses recur, it must represent the least whole number of both synodic and draconic revolutions. It does indeed turn out that* 223 *lunations have the same total length as* 242 *draconic revolutions within an accuracy of* 51 *minutes.*

But this is not yet the entire story! Owing to its high orbital eccentricity, the moon is capable of being over 6 *degrees fast or slow when it is half-way between its perigee and apogee. This would be more than enough to make the eclipse impossible. But through a very remarkable accident it happens that* 223 *synodic months make up nearly* 239 *anomalistic revolutions (to within* 5 *hours), so that the moon returns essentially to the same point of its orbit relative to perigee*[227]*. Since the saros is* 8 *hours longer than an integral number of days (6585), the eclipsed moon will not be seen at zenith* 18 *years* 11 *days later from the same region of the earth but from a region about* 120° *further west. But after* 3 *saroses, an eclipse is visible in approximately the same longitude as the first one (There is also a slight shift in latitude).*

The Hebrew prophets were also apparently able to foretell the occurrences of eclipses, and in view of the ignorance and credulity of the masses, threatened them with coming disaster – such as darkening of the sun, moon, or stars – as a punishment for their sins[228] *[e.g., Isaiah (***13***, 10–11); Amos (***8***, 9)].*

Hipparchos found that the moon moved most rapidly near a certain point in its orbit and most slowly near the opposite point. He could reconcile this motion with a virtual moon moving uniformly in a circle in which the earth was displaced from the center by $\frac{1}{20}^{th}$ *of the radius of the orbit. (Virtual eccentricity* $e = 0.05$*). He also discovered the* 9*-year period of the motion of the line of aspides (ca 130 BCE).*

Hipparchos then set forth to determine the other elements of the moon's orbit in order to be able to predict its motion at all times. To this end he used

---

227 $223 \times 29.53059 = 6585.32157^d = 29^d 12^h 44^m 2.8^s$ (synodic) $\times 223$
$239 \times 27.55460 = 6585.55494^d = 27^d 13^h 18^m 35^s$ (anomalistic) $\times 239$
$242 \times 27.21222 = 6585.35724^d = 27^d 5^h 5^m 40^s$ (draconic, nodical) $\times 242$
$19 \times 346.620 = 6585.4^d$ (*eclipse years*).
Note that because of the *regression of the nodes*, the time between successive passages is less than one year. It is known as an *eclipse year*, equal to 346.6 mean solar days; 19 eclipse years contain 18 years and $11\frac{1}{3}$ days. During about 1200 years, there are 29 lunar eclipses and 41 solar eclipses: 10 of the latter are total.

228 The saros method does not, however, enable one to calculate the character and details of an eclipse, or even the place on the earth's surface where such an eclipse will be visible. For that one needs strictly accurate mathematical methods, using spherical trigonometry, and the laws of planetary motions.

lunar eclipses. Each eclipse gave a moment at which the longitude of the moon was different by $180°$ *from that of the sun, which he could readily calculate. Assuming the* mean *motion of the moon to be known and the perigee to be fixed, 3 eclipses observed at different points of the orbit would render 3 longitudes, that could be used to determine 3 other unknowns, namely: the mean longitude at a given epoch, the eccentricity and the position of the perigee.*

Thus, by taking three eclipses separated at short intervals, all observations could be reduced to the same epoch[229] *and knowing the mean motion and perigee, the three unknown elements could be eliminated.*

A second triplet of eclipses at as remote an epoch as possible, was then used to redetermine the three elements in order to calculate the annual variation.

*Besides the contribution of lunar eclipses to astronomy, they also played an important part in chronology. Eclipses were often reported in early historical sources as "*epitheton ornans et constans*" of many great events. According to the superstitions of the ancients, lunar eclipses were considered as evil omens, due no doubt to the bloody color of the totally eclipsed moon. In this way some historical events, especially battles, were directly influenced by the appearance of a lunar eclipse.*

Some historical lunar eclipses are:

Oct. 02, 731 BCE *A partial eclipse visible in Babylon (Ptolemy). Time intervals were measured with the aid of* clepsydra *(water clocks); the only useful* timed *observations are of eclipses occurring close to sunrise or sunset, where the effect of drift of clepsydra is minimal.*

July 16, 523 BCE *In the* 7^{th} *year of the reign of Cambyses, one hour before midnight in Babylon, the moon was eclipsed from the north over half of its diameter (***Ptolemy***).*

Aug. 27, 413 BCE *This eclipse retarded the retreat of the Athenian army under Nicias from Sicily and caused its defeat by the Syracusians (****Plutarch****).*

Aug. 19, 366 BCE *This eclipse, explained by the prophet Miltas of Dion's army, decided its departure for Sicily in order to overthrow the local tyrant Dionisios (****Plutarch****).*

Sept. 20, 331 BCE[230] *This eclipse happened eleven days before the battle of Arbela in which Alexander triumphed over Darius (****Plutarch****).*

---

229 Same vernal equinox position, such that no correction for precession and nutation are necessary.

230 This may well allude to the lunar eclipse referred to by the prophet **Joel** (*3*, 3–4): "*The sun shall be turned into darkness and the moon into blood*". Indeed, the moon often glows a deep red color during totality on account of sunlight

Sept. 01, 218 BCE *Gaulish mercenary troops were greatly alarmed by this eclipse so that Attalus, king of Pergamos, had to dismiss them (**Polybios**).*

Apr. 30, 174 BCE *A partial eclipse visible in Alexandria (**Ptolemy**). At this period, times were measured to no better than the nearest third of an hour.*

Sept. 02, 172 BCE *On the eve of the battle of Pydna the eclipse predicted by the Roman tribune, C. Sulphicius Gallus, took place (**Livy**).*

Feb. 22, 72 CE *An example of a 'horizontal' eclipse: the rising sun and setting eclipsed moon were simultaneously visible (**Pliny**).*

Sept. 14, 927 CE *Eclipse timed with 'clock stars' at Baghdad.*

Mar. 01, 1504 CE ***Columbus**, knowing in advance that this eclipse should happen, gained the reputation of a prophet among the Indians who, in consequence, supplied provisions to the Spanish expedition.*

159–137 BCE **Carneades of Cyrene** (214–129 BCE). Greek *Skeptic* philosopher of the Middle Academy. One of the earliest to develop the doctrine of *logical probabilism* , which held that certainty is unattainable and that *probability* is the only guide to belief and action. He claimed that the truth of an idea can only be probable, not certain; one discovers probable truth by means of critical analysis, synthesis and comparison.

Carneades was the founder and director of the Third or New Platonic Academy in Athens. Little is known of his life. In 155 BCE, together with **Diogenes the Stoic** and **Critolaos the Peripatetic**, he was sent on an embassy to Rome. On this occasion he delivered two speeches on successive days, one in favor of justice, the other against it. His powerful reasoning excited speculations, and the elder Cato insisted that Carneades and his companions be sent back to Athens. Thus was Greek philosophy introduced in Rome.

ca 150 BCE **Seleucus of Babylon**. Astronomer. Born in Mesopotamia and lived in Seleuceia on the Tigris. There he obtained some knowledge of Greek astronomy. His enduring achievements are:

---

being scattered in the earth's atmosphere. [The same description was given to a total lunar eclipse visible in Germany on Nov. 9, 1128 CE.] The closest total *solar* eclipse answering the above biblical narrative may have occurred in Judea on *July 04, 336* BCE at midday with a duration of totality of ca 3 minutes.

- The only supporter in antiquity of Aristarchos' *heliocentric hypothesis*. Went beyond Aristarchos in declaring the heliocentric hypothesis to be true while Aristarchos merely treated it as an hypothesis.

- Tried to account for the *oceanic tide* by the resistance opposed to the moon by the diurnal rotation of the earth's atmosphere. His conclusions are erroneous, but they showed the independence and originality of his mind.

150–120 BCE **Hypsicles of Alexandria** (ca 180–120 BCE). Mathematician. Wrote a treatise on regular polyhedra. He is essentially the author of Book 14 of Euclid's *The Elements* which deals with inscribing regular solids in a sphere. In this work Hypsicles proves some results due to Apollonios.

Hypsicles also wrote *On the Ascension of Stars* in which he was first to divide the Zodiac into 360 degrees.

146 BCE *Greece made a Roman province.* The battle of *Zama* (202 BCE) established Rome as the strongest military power in the Mediterranean[231], and almost immediately the eastern states began to court Roman assistance in their numerous wars. Within two years the Roman became embroiled in the complex affairs of the Hellenistic East, and during the course of the 2^{nd} and 1^{st} centuries they gradually gained control over the entire Mediterranean world.

As the power of Egypt declined (ca 200 BCE), the Greek states around the Aegean asked Roman protection against Macedon and the Seleucid Empire. The Roman took firm action and freed Greece from foreign domination. Rome expected Greece to accept its dictation in foreign affairs. The Greeks, however, wanted little to do with their barbarian "liberators" once the threat to their independence had been removed. When Rome continued to intervene in the affairs of the *Achaean League*, the Greek revolted.

Goaded into fury by what they considered Greek ingratitude, the Romans forgot their love for Greek culture long enough to conduct a savage retaliatory campaign in the Aegean area – the first of many – in 146 BCE. By the time the Roman armies had slashed their way up the Greek peninsula, Macedon had been recognized as a Roman province (148 BCE); the ancient city of Corinth had been leveled; other Greek cities, including Athens, had been plundered; and thousands of young Greeks had been transported to Italy as slaves.

140 BCE Alchemy said to have begun in China.

---

231 Before the Punic Wars the rulers of the Hellenistic states regarded Rome as a remote western city, hardly worthy of notice.

136 BCE, Apr. 15 Total eclipse observed in Babylonia after sunrise; Venus, Mercury, Jupiter, Mars and stars above the horizon were seen. A remarkable accurate description is contained in an astronomical diary (there is no comparable account until the 18^{th} century) – testimony to the observational skill which the Babylonian astronomers had achieved.

100 BCE Chinese began to use negative numbers. They also discovered that a magnet orients itself toward the North Pole, but did not use magnets for navigation at sea until the 10^{th} century. Their physicians formed accurate theory of the circulation of blood.

100 BCE **Andronicos of Cyrrhestes (Cyrohus)**. Greek astronomer. Architect of *Tower of Winds*, known in the Middle Ages as *Lantern of Demosthenes*; a tower in Athens bearing a weather vane, eight sundials and a water clock.

ca 100 BCE **Philo of Byzantium**. Mechanical inventor. Author of a sort of encyclopedia of applied mechanics. Invented many war engines, pneumatic machines and the so-called *Cardan's suspension* of gimbals[232].

100–70 BCE **Zenon of Sidon** (ca 150–70 BCE, Greece). Epicurean mathematician and mathematical philosopher. First considered the possibility of non-Euclidean geometry. Also discussed the principle of induction. Made deep criticism of Euclid. For example he claimed that Euclid's first proposition assumes that two straight lines *can* intersect in at most one point but Euclid does not have this as an axiom. He attacked Euclid's proof of the equality of right angles on the ground that it presupposes the existence of a right angle.

Zenon was born in Sidon, now Saida in Lebanon. In 79–78 BCE, **Cicero** (then 27 years old) was obliged by bad health to travel and he attended in Athens the lectures of Zenon.

100–70 BCE **Poseidonios of Apamea** (135–51 BCE). Greek Stoic philosopher, astronomer, geographer and encyclopedist. Teacher of Cicero. Born in Apamea (Syria), studied in Athens, settled in Rhodes and died in Rome. Estimated the circumference of the earth and its distance to the sun to a much better accuracy than Hipparchos and Ptolemy but was still far from

232 A little treatise *On the Seven Wonders of the World* is attributed to Philo, although some scholars believe that it belongs to the 6^{th} century CE.

the true values[233]. During his extensive travels he collected a large amount of geographical information, observed earthquakes and volcanoes, and recorded the elevation of a new volcanic islet among the Lipari Islands. He was *first to explain the tides by the joint action of the sun and the moon*, and to call attention to spring and neap tides.

90–50 BCE **Asclepiades[234] of Bithynia** (124–ca 35 BCE, Rome). Greek Physician. The most eminent of the earlier Greek physicians at Rome, a

---

[233] The Stoic astronomer **Cleomedes** (ca 150–200 CE) in his extant book *Theory of Revolutions of the Heavenly Bodies* gives a striking description of the method used by Poseidonios to calculate the earth's circumference. The method consists of three steps:

• Choosing two stations that lie on the same *meridian* with known distance between them: Rhodes and Alexandria are separated by 5000 stadia (1 stadion = 160 meters). Peseidonios relied on mariners' estimates of a straight course across the Mediterranean.

• On a spherical earth, the angle subtended at the center by the meridian between the stations is equal to the angle between the respective horizons (tangents) at the stations, or alternatively, by the difference between the *zenith-distances* (normals) at the stations. This angle is also equal to the difference of *latitude* between the two stations.

• A certain distant star sends parallel rays of light toward earth: the difference between the zenith-distances of the star when measured at its *meridian transit* from two stations is the number of degrees in the arc of the earth's circumference between the two stations. Since the star *Canopus* (the brightest star after Sirius in the sky) grazed the horizon (zenith distance = 90°) at Rhodes, the difference in latitude between Alexandria and Rhodes was {90° minus zenith distance at Alexandria}. The figure that Poseidonios obtained for the circumference of the earth was 250,000 stadia, within a few percent of the actual figure of 40,000 km. **Strabo** (63 BCE–24 CE) quoted a figure of 180,000 stadia. This last figure was adopted by Ptolemy, and this and other errors of Ptolemy were the basis of **Columbus**' belief that India was near. Had he known the true distance, possibly he never would have sailed. . . .

[234] Named after **Asclepios**, a Greek mortal physician, later to be elevated to the rank of god of medicine according to Homer's Illiad. He was the son of Apollo, educated by the centaur Chiron, and killed by lightening sent by Zeus, for bringing the dead back to life. A cult of Asclepios as a hero originated in the Thessalian town of Tricca. When it extended to Epidauros, Asclepios was honored as a god in the classical period. From there the cult spread to many other places (to Athens in 420 BCE); the sanctuary on Cos became very famous, and was the first of many temples of Asclepios. About 280 BCE, the cult was introduced in Rome, as a result of an epidemic.

friend of Cicero. He was born at Prusa in Bithynia (Asia Minor), traveled much when young, and seems at first to have settled at Rome as a rhetorician. In that profession he did not succeed, but he acquired great reputation as a physician. Opposed the Hippocrates (fl. 430–380 BCE) theory of disease and taught that disease is caused by a disturbance in the particles that make up the body. His remedies were baths, diet and exercise. Credited with being the first to distinguish between acute and chronic diseases. Pioneered human treatment of mental disturbances. He recommended the use of wine, and in every way strove to render himself as agreeable as possible to his patients. His pupils were very numerous, and the school formed by them was called the *Methodical*.

His system was his own, though founded upon the *Epicurean* philosophical creed; on the practical side it conformed closely to the *Stoic* rule of life, thus adapting itself to the leanings of Roman in the later times of the republic.

The *Romans* cannot be said to have at any time originated or possessed an independent school of medicine. They had from early times a very complicated system of superstitious medicine, or religion, related to disease and the cure of disease, borrowed from the Etruscans. Though the saying of Pliny that the Roman people got on for 600 years without doctors was doubtless an exaggeration, it must be accepted for the broad truth which it contains. When the medical profession appears, it is as an importation from Greece.

87 BCE Babylonian clay tablets (in the British Museum) documented observation of *comet Halley* apparition. The observation agrees with calculated perihelion passage-time in the month of August of that year. The subsequent apparition of Oct. 12 BCE was also reported. Later observations reported the apparitions of: 451, 684, 760, 837, 912, 989, 1066, 1145, 1222 CE.

81–46 BCE **Marcus Tullius Cicero** (106–43 BCE, Rome). Roman political eclectic-stoic philosopher, historian, orator and statesman whose writings had considerable influence on the formation of subsequent societies. He is most noted for his eclectic exposition of general scientific knowledge and philosophy, by which he aimed to arouse an appreciation of Greek culture in the minds of Romans. Key works[235]: *On the Republic* (54–51 BCE); *Stoic Paradoxes* (46 BCE). One of the great Latin stylists. Through his orations, letters and books influenced medieval and post-medieval cultural heritage and affected the thinkings of **Petrarch**, **Erasmus**, **Copernicus**, **Voltaire** and **John Adams**.

Cicero was born in Arpinum of a well-to-do-family. He studied law, oratory, Greek literature and philosophy in Rome and in Greece. He won his

[235] Cicero, *Selected Papers*, Penguin Books, 1976, 272 pp.

first fame and riches as a defense lawyer. His chief role as prosecutor was in representing the people of Sicily against Gaius Verres, robber-governor of the island.

Gained the office of praetor (66 BCE) and consul (63 BCE). As consul, he crushed the conspiracy of **Cataline**[236] against the Republic; his great speech at this time was his "First Oration Against Cataline" ["*Quo usque tandem abutere, Cataline, patientia nostra?*"]. He was banished from Rome during 58–57 BCE by Caesar, which caused him to write essays on philosophy and political theory[237]. As leader of the Senate in 44 BCE, he launched a great attack on Mark Antony for which he payed with his life a year later.

Cicero ranks among the greatest of ancient writers. He was responsible for developing a style in Latin prose that has become the basis of literary expression in the languages of Europe.

[236] **Lucius Sergius Catalina** (108 – 62 BCE)

[237] **Thadaeus Zielinsky**, Russian philologist, asserted that of all Julius Caesar's achievements none was as important as the fact that Caesar, by compelling Cicero to retire to the country, forced the latter to state his philosophy in writing.

Worldview III: Cicero

* * *

"I only wish I could discover the truth as easily as I can expose falsehood".

* * *

"We must conceive of this whole universe as one commonwealth of which both gods and men are members".

* * *

"Philosophy is the art of life".

* * *

"That long time to come when I shall not exist has more effect on me than this short present time, which nevertheless seems endless".

* * *

"Frivolity is inborn, conceit acquired by education".

* * *

"Fame lives in great things, but dignity lives in humility".

* * *

"While I breath I hope (Dum spiro spero)".

* * *

"By teaching we learn (Docendo discimus)".

* * *

"We are not born just for our own sake".

* * *

"Any man is liable to err, only a fool persists in error".

* * *

"To be ignorant of what occurred before you were born is to remain always a child. For what is the worth of human life, unless it is woven into the life of our ancestors by the records of history?"

* * *

"The whole passion ordinarily termed love *is of such exceeding triviality that I see nothing that I think comparable with it".*

* * *

"No one is so old as to think he cannot live one more year".

* * *

"Peace is achieved by victory, not by compromise".

* * *

"Nature abhors vacua".

* * *

"Rightly defined philosophy is simply the love of wisdom".

* * *

"It is not by muscle, speed, or physical dexterity that great things are achieved, but by reflection, force of character and judgment".

* * *

"If you pursue good with labor, the labor passes away but the good remains; if you pursue evil with pleasure, the pleasure passes away and the evil remains".

* * *

"The greater the difficulty, the greater the glory".

* * *

"If you have a garden and a library, you have everything you need".

* * *

"The more laws, the less justice".

* * *

"A home without books is a body without soul".

* * *

"We should not be so taken up in the search for truth, as to neglect the needful duties of active life; for it is only action that gives a true value and commendation to virtue".

* * *

"Justice consists in doing no injury to men; decency – in giving them no offense".

* * *

"Knowledge which is divorced from justice, may be called cunning rather than wisdom".

* * *

"Laws are silent in time of war".

* * *

"No one can give you better advice than yourself".

* * *

"No one was ever great without some portion of divine inspiration".

* * *

"The wise are instructed by reason*; ordinary minds by* experience*; the stupid by* necessity *and the brutes by* instinct*.".*

* * *

"The enemy is within the gates: it is with our own luxury, our own folly, our own criminality that we have to contend".

* * *

"To each his own".

* * *

"Never go to excess, but let moderation be your guide".

* * *

"Nothing is too hard for him who loves".

* * *

"Ask not what your country can do for you, but rather what you can do for your country".

* * *

"Cannot people realize how large an income is thrift?"

* * *

"What is more delightful than leisure devoted to literature?
That literature I mean which gives us the knowledge of the infinite greatness of nature, and, in this actual world of ours, of the sky, the land, the sea".

* * *

"It might be pardonable to refuse to defend some men, but to defend them negligently is nothing but crime".

* * *

70–55 BCE **Titus Lucretius Carus** (Lucretius, 98–55 BCE, Rome). Roman Epicurean philosopher, poet, and scientist. Author of the philosophical poem *De rerum Natura*[238] (On the Nature of Things), in which he gave an account of the total Greek knowledge of his time, together with a few prophetic views (such as a vague anticipation of the theory of natural selection). Lucretius' chief purpose was to vindicate the rights of reason against superstition.

Nothing certain is known about the life of this natural philosopher. His sole poem was published posthumously by Cicero. Virgil studied it, Ovid admired it, and many authors of didactic poems since have tried to imitate it. No one, however has equaled his passionate sincerity, his fearless logic or his breadth of vision. He was not a popular poet and was not read during the Middle Ages; his present-day fame dates from the Renaissance. The astonishing fact is that, without a true scientific method, Lucretius at least hinted at many important physical discoveries of modern times – his physical theory was superior to any which existed up to the 17^{th} century.

For example, he discusses the spontaneous unpredictable instability through which laminar flow turns into turbulent flow due to a slight perturbation.

Lucretius was an ardent exponent of the concept of plurality of worlds. In his poem he wrote: "*Nature is not unique to the visible world; we must have faith that in other regions of space there exist other earths, inhabited by other people*".

60–21 BCE **Siculus Diodoros**. Greek historian. Born at Agyrium in Sicily; lived in the times of Julius Caesar and Augustus. He traveled in Egypt between 60–57 BCE and spent several years in Rome. His writing consisted of forty books of which only fifteen are still extant. His books contain important information on various astronomical phenomena, such as comets and eclipses.

The Egyptian Calendar merited his comment (ca 50 BCE): "*They have made special arrangement concerning the months and the years. For they do not reckon days by the moon, but by the sun, putting 30 days in the months, and adding 5 days and a quarter to those of the twelve months, and thus they fill out the yearly circle*".

52 BCE *The Battle of Alesia.* The decisive battle of Caesar against a confederacy of Gallic tribes led by **Vercingetorix**, which changed the course of Roman history and Western civilization. While besieging Vercingetorix

[238] Lucretius (Titus Lucretius Carus), *On the Nature of the Universe*, Translated by R.E. Latham, Penguin Books: New York, 1951, 275 pp.

in Alesia (Alise St. Reine, near Dijon), a Roman army, 60,000 strong, was itself surrounded. Outnumbered 5:1, Caesar managed to turn a desperate struggle into a complete victory, chiefly due to his own courage, cunning and leadership, and the endurance of his men. Caesar's victory and the subsequent colonialization of Gaul as a Roman province, carried Roman influence beyond the circum-Mediterranean sphere, into the heart of Europe. A new Gallico-Roman civilization evolved, carrying the heritage of Rome long after the empire fell to the Germanic tribes.

ca 40 BCE *Wooden ball-bearings* for 4-wheeled wagon, found at Dejbjerg, Jutland.

The Julian Calendar (46 BCE)

The year is either astronomical or civil. The solar astronomical year is the period in time in which the earth performs a revolution in its orbit about the sun, or passes from any point of the ecliptic to the same point again; it consists of $365^d : 5^h : 48^m : 46^s$ *in terms of mean solar time*[239].

The civil year is that which is employed in chronology, and varied throughout history among different nations, both in respect to the season at which it commences and in its subdivisions. As far as the sun's apparent motion alone is concerned, the regulation of the year and its subdivision into days and months may be effected without much trouble. The difficulty, however, shows up when one seeks to reconcile solar and lunar periods, or to make the subdivisions of the year depend on the moon, and at the same time to preserve the correspondence between the whole year and the seasons. In the arrangement of the civil year, two objects are therefore sought: first, the equable distribution of the days among 12 *months; and secondly, the preservation of the beginning of the year at the same distance from the solstices or equinoxes.*

[239] What is generally meant by the word 'year', particularly so far as our calendar is concerned, is correctly termed *tropical year*. It is defined as the time elapsed between two successive crossings by the sun of the celestial equator at the *vernal equinox*. The tropical year has a length of $365^d 5^h 48^m 46^s$, or 365.242 mean solar days, where the *mean solar day* is the time of a complete turn of the earth w.r.t. *sun* (corrected for all known irregularities). Because one calendar year is exactly 365 days there is an excess of almost 6^h, or one quarter of a day, per tropical year. By adding a day (Feb. 29) each leap year, this excess is largely corrected. The exact duration of *the apparent solar day* (i.e. time elapsing between two consecutive meridional transits of the sun) is not constant and changes from day to day. This irregularity of solar day relative to sidereal day is a result of several circumstances, chief among which are: (1) the *obliquity of the ecliptic* (the sun's apparent annual motion is *not* in the same plane as its apparent diurnal rotation relative to the fixed stars), due to the earth's tilt relative to the (ecliptic) plane of its circumsolar orbit; (2) *eccentricity of the earth's orbit* (varying translational velocity of the earth in its orbit in conformity with Kepler's second law). An average value of the apparent solar day for the entire year is known as the *mean solar day*. *The Equation of Time* is the misnomer for the number of minutes which, on any particular day of the year, must be *added* to the apparent (true) solar time to give the mean time. Clearly, the *Equation of Time* will apply to the analog time-difference as monitored by *sundial* (solar time) versus *mechanical clocks* (mean solar time).

Now, as the year consists of 365 days and a fraction, and 365 is a number not divisible by 12, it is impossible that the months can all be of the same length and at the same time include all the days of the year. Also, because of the fractional excess of the length of the year above 365 days (explicitly: 0.242 days), the years cannot all contain the same number of days, if the epoch of their commencement is to remain fixed. But as the day and the civil year must begin at the same instant, the extra hours cannot be included in the year till they have accumulated to a whole day. As soon as this has taken place, an additional day must be given to the year.

At the time of ***Julius Caesar*** *(100–44 BCE), the civil equinox differed from the astronomical by 3 months, so that the winter months were carried back into autumn and the autumnal into summer. Caesar ordered a major reform of the calendar: With the advice and assistance of his Greek astronomer* ***Sosigenes*** *he abolished the lunar year and the intercalary month and regulated the civil year entirely by the sun. He fixed the mean length of the year at* $365\frac{1}{4}$ *days and decreed that every fourth year should have 366 days, the other years each having 365.*

In order to restore the vernal equinox to the 25^{th} *of March (the place it occupied in the time of Numa) he ordered two extraordinary months to be inserted between November and December in the current year, the first to consist of 33 days and the second of 34 days. The intercalary month of 23 days fell into that year so that the ancient year of 355 days received an augmentation of 90 days, having altogether 445 days. By means of this device, the calendar was realigned with the seasons. The Romans called it: "the last year of the confusion". The first Julian year commenced with the* 1^{st} *of January of the* 46^{th} *year before the birth of Christ, and the* 708^{th} *from the foundation of the city.*

Insofar as the distribution of the days through the months Caesar ordered that January, March, May, July (which he named after himself), September and November be given 31 days each and the other months thirty each, excepting February which in common years should have only 29, but every fourth year 30 days. His successor, Augustus Caesar, to gratify his vanity, removed a day from February and added it to his month, August, which now had also 31 days. Then, in order that three months of 31 days might not come together, September and November were reduced to thirty days and one day each given to October and December. Curiously enough, the intercalary day, added to February every fourth year, was inserted in the calendar between the 24^{th} *and the* 25^{th} *day, such that nominally, February had 28 days even on that year. In spite of the reform, the year was still too long by* $11^m 14^s$*, which amounted to a whole day in 128 years. Thus, in the course of a few centuries, the equinox retrograded appreciably towards the beginning of the year: when* *the Julian calendar was introduced, the equinox fell on March* 25^{th}*, but by* 1582*, it had retrograded to the* 11^{th}*.*

A lunar year is defined as 12 *new moons, and is about* 11 *days shorter than a tropical year. Because the earth's orbit is not quite circular, the apparent angular velocity of the sun is not strictly uniform. Also because the sun's apparent motion in the sky is not along the celestial equator, the component of its velocity parallel to the equator is variable. Therefore, for the purpose of time-reckoning, a 'mean sun' is defined which moves at the rate equal to the average of that of the true sun. The difference between mean solar time and the apparent solar time (as given by any form of sundial) is called 'the equation' of time. It may be either positive or negative.*

The interval between successive transits of the same star across the meridian is the sidereal day, which is about 4 *minutes shorter than a mean solar day. A sidereal year is the time elapsed between successive occupations of exactly the same orbital point with reference to the fixed stars. It is longer by* 20^m23^s *(mean solar) than the tropical year because of the precession of the equinoxes.*

37–15 BCE **Marcus Vipsanius Agrippa** (63–12 BCE, Rome). Soldier, statesman, engineer and builder. Accomplished great public works (aqueducts, sewers). One of the most eminent builders of the Roman world. As a builder he ranks with Rameses II and Nebuchadnezzar II.

Born into an obscure Roman family, he studied at Apollonia, (a Greek city on the Adriatic coast, opposite the heel of Italy). With him studied Gaius Octavius, the future Augustus. They became lifelong friends.

Agrippa later became praetor and won victories in Gaul and Germany. As consul in 37 BCE, he commanded Octavianus' fleet against Pompeius in Sicily waters. Later he commanded the whole Octavianist fleet at the decisive battle of Actium. In these naval campaigns he used his own inventions of two devices which gave him military advantage: One was a collapsible tower, which could be quickly raised from the deck when a ship neared the enemy. The other was a grapnel that could be shot from a catapult to catch another ship and pull it close for boarding.

Between these wars, he build a new water system for Rome, including two new aqueducts, 130 water-distributing stations, 300 large cisterns, and 500 fountains. He even took a boat ride through the Cloaca Maxima – the great sewer – to direct its renovation. He built the first public bath in Rome, another bridge over the Tiber, a series of temples and porticoes, and the Pantheon. The rest of Agrippa's life was spent on military and diplomatic missions. Amidst these activities he built roads in Gaul, Spain and Syria.

The dependence of Augustus on Agrippa was so great that in order to bind him closer, he persuaded Agrippa to divorce his first wife and marry Augustus' niece Marcella, then to divorce Marcella and wed his daughter, the promiscuous Julia. In addition, Augustus made his stepson Tiberius marry Vipsania, Agrippa's oldest daughter[240].

32 BCE–8 CE **Hillel the Elder** (80 BCE–8 CE, Israel). Tannaic scholar, moralist and logician. Founder of the scientific *Mishna*. President of the Sanhedrin. First to formulate clearly the *Seven Middot* (rules) of inductive reasoning for properly deriving new concepts from old through the use of logic (*Tosefta*, Sanhedrin **7**, 11; *Avot d'Rabbi Nathan* **37**, 10). He argued that if a deduction could be shown to stem logically from a divine proposition, then the deduction had to be as divine as the source. He thus devised the intellectual apparatus for an orderly evolution of divine principles.

Modern scholars have shown that Hillel's syllogisms went beyond those of his Greek masters, approximating the methods used in modern logic today[241].

Hillel came from Babylonia in search of a higher education (40 BCE) and lived at Jerusalem in the time of King Herod. Though hard pressed by poverty, he applied himself to study in the academies of Shemaaiah and Avtalion[242].

---

[240] After Agrippa's death, Tiberius' mother Livia prevailed upon him to divorce Vipsania and marry the amorous Julia. As Tiberius loved Vipsania, the experience soured him for life, and he became a morose and miserly emperor. (To most upper-class Romans, marriage was more a matter of business than it is with us. They traded wives back and forth as liberally as movie stars.)
Agrippa left several other children, most of whom came to violent ends. A son of one of these children became the emperor Caligula, while one of Caligula's sisters was the dreadful Agrippina, mother of Nero.

[241] For instance, one of his rules, known as *Binyan Av*, is almost identical to that of **John Stuart Mill**'s (1843) "*Method of Agreement*". Hillel's rules were used by rabbis to discover new laws of Scripture in much the same way that Mill's *inductive reasoning* was used by scientists 18 centuries later to obtain new corollaries from a given natural law.
The seven rules seem to have been first laid down as abstract rules by the teachers of Hillel though they were not immediately recognized by all as valid and binding. Hillel collected them as current in his day and amplified them.

[242] Having no financial means, he is said to have climbed the roof of an academy to eavesdrop on a class. One day the roof caved in, and Hillel fell into the

Thoroughly familiar with Greek literature, thought, and science, he taught his rabbinic pupils to be the keepers of a viable Judaism.

Hillel filled his leading position as head of the Sanhedrin for forty years. His descendants, with few exceptions, remained at the head of Judaism in Israel until the beginning of the 5^{th} century. Hillel's ancestry was tracked back to King David. He is especially noted for the fact that he gave a definite form to the Jewish traditional learning, as it has been developed and made into the ruling and conserving factor of Judaism in the latter days of the Second Temple, and particularly in the centuries following the destruction of the Temple.

Hillel lived in the memory of posterity chiefly as the great teacher who enjoined and practiced the virtues of charity, humility, and true piety. His proverbial sayings strongly affected the spirit both of his contemporaries and of his succeeding generations. In his *Maxims* (*Avot* **1**, 12) he recommends the love of peace[243] and the love of mankind beyond all else.

His charity towards men is given its finest expression in the answer which he made to a proselyte who asked to be taught the commandments of the Torah in the shortest possible form: "*What is unpleasant to thyself that do not do to thy neighbor; – this is the whole Law, all else is but its exposition*".

This allusion to the scriptural injunction to love one's neighbor (*Lev* **19**, 18) as the fundamental law of religious morals, became in a certain sense a commonplace of Pharisaic scholasticism. For the Pharisee who accepts the answer of Jesus regarding that fundamental doctrine which ranks the love of one's neighbor as the highest duty after the love of God (*Mark* **12**, 33), does so because as a disciple of Hillel, the idea is familiar to him. Paul also (*Gal* **5**, 14) learned this in the school of Rabban Gamliel.

9 CE *The Varian Disaster*: Roman army under Varus defeated in Germany by Arminius. Three Roman Legions (out of 28 overall) were annihilated in the Teutoburg Forest. It led to the abandonment of Germany east of the Rhine and thus saved Teutonic Civilization from absorption by Rome. It is considered as Rome's greatest defeat.

This defeat put an end to Augustus' plans for the conquest of Germany to the Elbe and established the Rhine as the future border between Latin and German territory. Augustus discontinued his conquest because of financial

classroom, thus becoming, presumably, history's first drop-in. Impressed with such a thirst for knowledge, the academy granted him a scholarship.

243 Hillel, *unlike* the great Rabbi Akiva, was a totally apolitical figure, which explained how he could survive under the rule of the terrible Herod.

difficulties involved in replacing the lost legions and levying enough additional forces to subdue Germany permanently.

31–65 CE **Lucius Annaeus Seneca** (4 BCE–65 CE). A Roman statesman, author and an *eclectic-stoic philosopher*.

Seneca was born at Cordova, Spain, into a distinguished Roman family. He became prominent in political and literary life in Rome. Later he became tutor and advisor to emperor Nero. Nero accused him of plotting his death and forced him to commit suicide.

The Stoic philosophy, which started with *Zeno of Citium* (ca 335–265 BCE), spanned a period of some 500 years. One of the principal issues which remained a central interest in this philosophy is the problem of determinism and free will: nature is strictly ruled by law which emanates from a supreme authority that impregnates it. The universe ends in a pristine fire and evolves all over again in an eternal repetitious cycle.

In modern times, Stoa was revived through the philosophical writings of **Spinoza**, who was strongly influenced by this tradition. Among the surviving works of Seneca there is an essay on *Naturalium Quaestionum*. We read there a statement that could have been written today:

"*The day will come when diligent research over long periods will bring to light the mysteries of nature which now lie hidden. A single lifetime, even though entirely devoted to the sky, would not be enough for the investigation of so vast a subject... And so this knowledge will be unfolded only through long successive ages. The day will yet come when our descendants will be amazed that we did not know things that are so plain to them... Many discoveries are reserved for ages still to come, when memory of us will have been perished. Our universe is a sorry little affair unless it has in it something for every age to investigate... Nature does not reveal her mysteries once and for all*". [**Book** *7*].

The above essay is a collection of physical, astronomical, geographical, geological, and meteorological questions explained from the atomistic point of view. His account of the earthquake of Feb. 5, 63 CE is the earliest detailed report of its kind. Seneca was one of the first hydrologists: he noted that because of what is now called the hydrologic cycle, the constant flow of rivers into the sea does not cause the ocean to overflow, nor does the addition of fresh water dilute the saltiness of the sea. Water is evaporated from the ocean, falls as rain, and collects in rivers to return to the sea[244].

---

[244] This was already known to the author of the book of *Ecclesiastes* (ca 330 BCE), for it is written: "*All the rivers run into the sea; yet the sea is not full*".

Seneca noted the magnification of objects seen through water-filed transparent vessels (and his friend, the Emperor Nero may have been the first to use a monocle, employing an *emerald lens* to view events in the coliseum.

Seneca was the first to express a belief in the progress of knowledge (not the progress of humanity!); this idea of progress is unique in ancient literature.

Worldview IV: Seneca

* * *

"Philosophy is the love of wisdom and the endeavor to attain it".

* * *

"What a despicable thing is man, unless he rises above the human condition!"

* * *

"Any deviation by nature from the existing state of the universe is enough for the destruction of mankind".

* * *

"Success comes to the common man, and even to commonplace ability; but to triumph over the calamities and terrors of mortal life is the part of a great man only... Toil summons the best men".

* * *

"Nothing is so deceptive as human life, nothing is so treacherous. Heaven knows! not one of us would have accept it as a gift, were it not given to us without our knowledge".

* * *

"There is nothing after death, and death itself is nothing... greedy time and chaos engulf us altogether".

* * *

"Go on through the lofty spaces of high heaven and bear witness, where thou ridest, that there are no gods*".*

* * *

"No great genius *has ever existed without a touch of madness".*

* * *

"A great fortune is a great slavery".

* * *

"It takes the whole life *to learn how to live, and what will perhaps make you wonder more – it takes the whole of life to learn how to die".*

* * *

"It is not the man who has little, but the man who craves more, that is poor".

* * *

"Philosophy... molds and constructs the soul, guides our conduct, shows us what we should do and what we should leave undone; it sits at the helm and direct our course as we waver amid uncertainties. Without it, no one can live fearlessly or in peace of mind".

* * *

*"*Liberty *cannot be gained for nothing. If you set a high value on liberty, you must set a low value on everything else".*

* * *

"Men do not care how nobly they live, but only how long, although it is within the reach of every man to live nobly, but within no man's power to live long".

* * *

"You cannot escape necessities, but you can overcome them".

* * *

"Leisure without study is death".

* * *

"I respect no study, and deem no study good, which results in money-making".

* * *

"When savants have appeared, sages have become rare".

* * *

31 BCE, Sep 2[245] *Battle of Actium*: a decisive great naval battle off the coast of Greece between Rome and an Eastern-Hellenistic coalition for the dominance of the Mediterranean world and culture.

The fleet of **Octavian** (under command of Agrippa) defeated the combined fleets of **Marcus Antonius** and **Cleopatra**; The fleets met outside the Gulf of Arta, each over 200 ships strong. Antony's heavy battleships endeavored to close and crush the enemy with their artillery; Octavian's light and mobile craft made skillful use of skirmishing tactics. During the engagement, Cleopatra suddenly withdrew her squadron and Antony slipped away behind her, but his fleet was set on fire and thus annihilated. Anthony committed suicide and Cleopatra followed suite (Aug 29, 30 BCE) and Egypt thereafter became a Roman Province. Octavian was granted supreme power by the Senate and the title of *Augustus* ('Exalted').

Cleopatra (69–30 BCE) was the last member of the Ptolemaic Dynasty to rule Egypt. She was one of the most talented and ambitious woman rulers in history. Set herself to restore the power of the Ptolemies and become an Hellenistic monarch with Roman aid. To this end she seduced the leading Roman lords Julius Caesar and Mark Anthony and when they failed to realize her dream, planned to use Octavian, who had enough sense to refuse to yield to her charms. Imperious will, masculine solidness, relentless ambition and luxurious profligacy made this tragic beautiful Macedonian woman a unique historical figure.

28 BCE–1638 CE A continuous record of sunspot activity is kept by Chinese astronomers. First recorded observation of this data made in 165 BCE.

ca 25 BCE **Marcus Vitruvius Pollio** (Vitruvius). Roman architect and engineer. In his writings sound is described as a vibratory motion of the air[246]

---

[245] On the very same day there occurred a major earthquake in Israel (ca 32 °N, 35.5 °E) which caused great destruction and numerous casualties in Judea, Qumran, Massada and Herod's winter palace in Jericho. It is mentioned in *Josephus* (AJ **15**, 5), *Mark* (**13**, 8) and *Mathew* (**24**, 2–7; **27**, 51). Among the building destroyed by the tremor was the most ancient *synagogue* in the world, built during 75–50 BCE by the Hasmonean queen Shlomzion or one of her sons, near Herod's winter palace.

[246] The possibility that sound exhibits analogous behavior to water waves was emphasized earlier by the Greek philosopher **Chrysippos of Soli** (280–207 BCE), with antecedents dating back to **Pythagoras** (ca 550 BCE), who speculated that air motion is generated by a vibrating body. The wave interpretation is also consistent with **Aristotle**'s (384–322 BCE) statement to the effect that air

and some study is made of *architectural acoustics*. Very little is known about him, save that he had worked for the state as an artillery engineer.

25 BCE–23 CE **Strabo** (ca 63 BCE–24 CE). Greek geographer and historian. Became famous for his 17 volume *Geography*, which described all parts of the known world of his time. These volumes are the best known source of geographical information about the Mediterranean countries at the beginning of the Christian Era. It summarized the works of the Greek mathematical geographers to obtain the total size of the earth, estimated the inhabited fraction, and gave a description of the climatic zones of the globe. He also wrote a lengthy history that is now lost.

Strabo was born in Amasia in Pontos (a Hellenized city, and the royal residence of the kings of Pontos). Some of his ancestors were Hellenic, others of Asiatic origin, but Strabo himself was by language and education thoroughly Greek. He studied in Rome and Alexandria and traveled in Arabia, southern Europe and northern Africa. During 25–24 BCE he accompanied the prefect of Egypt, Aelius Gallus, on his expedition to Upper Egypt. In Alexandria he remained a long time, amassing material, and studying astronomy and mathematics in its famous library.

Because he lived in an active part of the globe, Strabo believed that the crust of the earth was in a constant state of flux. He pointed out that earthquakes and volcanic eruptions make the land move vertically and cause the oceans to invade the land. The rivers, by flowing over the land, erode it and transport soil to the sea. Because of the eroded material is almost always deposited close to the shore, the oceans do not fill up so rapidly as one might expect. Strabo taught that the landscape is sculpted by the wind as well as by running water. Applying his geographic knowledge to problems in the social sciences, he pointed out that the ocean plays an important role in the development of civilization.

Strabo appears to be the first who conceived a complete geographical treatise as comprising of four divisions: mathematical, physical, political and historical geography. He endeavored, however imperfectly, to keep all these objects in view.

ca 20 BCE Chinese documents serve as the earliest known *sunspot records* made by the naked eye[247].

---

motion is generated by a source "*thrusting forward in like manner the adjoining air, so that the sound travels unaltered in quality as far as the disturbance of the air manages to reach*".

247 From 1605 to 1611, **Johannes Fabricius**, **Thomas Harriot**, **Christoph Scheiner** and **Galileo Galilei**, among others, began *telescopic* studies of

Comets[248] in the Greco-Roman World – The Advent of Astrophysics

The shape of comets and the manner of their appearance has in all generations been a source of baffled wonderment: the sun *and* moon *are far brighter,* aurorae *more impressive, and* eclipses *more startling. Yet it is* comets*, with their modest radiance and infrequent visits, that have commanded more concern.*

In the year 467 BCE, a meteorite fell at Aegospotami, in Thrace (on the European side of the Dardanelles), and a comet was seen in the same year. The meteorite fell during day time: it was brown in color and the size of a wagon load. This event made a great impression on Greek thought, and probably influenced ***Anaxagoras*** *(ca 500–428 BCE). His attempts to give a scientific account of eclipses, meteors, comets, rainbows and the sun resulted in a theory that the heavenly bodies were masses of stone torn from the earth and ignited by rapid rotation.*

Aristotle *(384–322 BCE), in his Meteorologia, believed comets would form when the sun, or planets, warmed the earth, causing the evaporation of dry, warm exhalations from the earth itself.*

In his Naturalium Quaestionum (63 CE), a work devoted primarily to meteorology and astronomy, ***Seneca*** *(4 BCE–65 CE) included newer cometary ideas of the Greek from the 4^{th} to the 1^{st} century BCE. He presented the opinion of* ***Epigenes*** *(a follower of Aristotle, fl. 4^{th} century BCE) and* ***Apollonios of Myndos*** *(a contemporary of Seneca), as well as his own ideas.*

Epigenes' ideas were but those of Aristotle slightly modified. The theory of Apollonios of Myndos is, however, close to the modern view:

"... A comet is a separate star like the sun and the moon. In shape it is not compressed into a ball, but loose and elongated; it has no definite course, but

---

sunspots. These records, as the German astronomer **Samuel Heinrich Schwabe** announced in 1843, displayed a prominent periodicity of roughly 10 years in the number of observed sunspot groups. By the 20-th century **George Ellery Hale** of the Mount Wilson Observatory in California found those dark surface irregularities to be the seat of intense magnetic fields, with the strength of several thousand gauss.

[248] For further reading, see: Yeomans, D.K., *Comets*, Wiley: New York, 1991, 485 pp.

it passes across the upper regions of the cosmos and becomes visible only on reaching the lower part of its course... The comets are many and various, and different in size and color... Some of them are blood-soaked and terrifying, ominous of future bloodshed...".

Seneca himself concluded that comets were not sudden fires but were among nature's permanent creations, and while their orbits generally differed, the two comets seen during his age had circular orbits much like the planets. Seneca suggested that comets moved in closed orbits, traveling in a uniform manner and disappearing only when they passed beyond the planets. While his views did little, in a quantitative way, to advance understanding of the phenomenon, his rejection of the prevailing Aristotelian theory inspired eventual rethinking of the nature of comets which, unfortunately, had to wait some 1500 *years. However, Seneca's belief is astrology and divination planted, with Aristotle, the seeds of superstition. This seed was to flourish under the guidance of Pliny and Ptolemy.*

***Pliny the Elder** (23–79 CE) did not acknowledge the contemporary views of Seneca, and gave more credence to comets as portents , viewing comets as terrifying apparitions by noting the disasters that followed a few cometary returns.*

***Joshua ben Hannania** (35–117 CE)*, a Hebrew astronomer and *Tanna* was probably the first man in recorded history to establish the *periodicity* of a comet. *[Babylonian Talmud,Horayoth 10^a.]*

***Ptolemy of Alexandria** (ca 94–172 CE), last of the great astronomers of antiquity, in his tetrabiblos regarded comets as mysterious signs that provoke discord among men and give rise to wars and other evils. Moreover, he expanded somewhat on the astrological implications that Pliny had outlined. Because of his great reputation, the more rational views of Seneca were quickly submerged, and in the* 15 *centuries that followed, Ptolemy's guidelines were used repeatedly to correlate cometary apparitions and terrestrial disasters. Even during the Renaissance, the bulk of cometary literature was superstitious in nature.*

The final break with Aristotelian tradition came on Mar. 19, 1681, *with the telescopic observation of **Isaac Newton** of the comet of* 1680*. Although the physical nature of comets was still largely unknown, Newton had essentially solved the problem of their dynamical behavior.*

0–50 CE The first treatises on the "*Divine Art*" appeared in Alexandria, Egypt, containing the earliest chemistry.

20–50 CE **Philo of Alexandria** (Judaeus, 20 BCE–50 CE). Jewish philosopher. Spent his whole life in Alexandria, where he was born. A contemporary of Jesus and Paul, and deeply versed in both Hellenistic and Judaic cultures.

Though we know little of Philo's own life, his numerous extant writings give the fullest information as to his views of the universe and his scientific aims, and so enable us to estimate his position and importance in the history of thought.

Although Philo borrowed much from Greek philosophy (Plato, the Stoics), he was highly modern and by far ahead of his time. For in his commentary on Genesis he refers to the history of creation in these words: "*It would be a great naivety to believe that the universe was created in time. The right thing to say is that the existence of time is conditioned by the existence of the universe since the movement of stars determines the nature of time*". Thus, 1900 years before Einstein, Philo claimed that time is not absolute, but is inherent property of the material universe and had no meaning prior to the creation of matter.

26–29 CE **Jesus (Joshua) of Nazareth** (7 BCE–30 CE, Israel). A central figure in the Christian religion. Jewish wandering preacher and social reformer. His *image* had a decisive influence on the development and history of Western culture, and through it upon the entire of humanity.

He taught that man must relinquish his earthly riches and treat his fellow men with love and mercy, even passively accepting the pains and insults inflicted on him. He proclaimed the imminence of the *Kingdom of God* as a relief to the poor in particular. His followers called themselves *Nazarenes*[249], regarded him as the anointed descendant of King David (or *Messiah*), foreseen as a redeemer in biblical prophecy.

It is clear from Jesus' own assertions that he did not aim to found a new religion (*Matt* **5**, 17). He observed scrupulously all Jewish feasts, taught Jewish doctrines and ethics. In fact, his whole system of ethics, sometimes even down to the very expressions he used, were derived from current Jewish Pharisee teachings[250].

---

[249] Originally a Jewish sect, living near the Jordan river, whose members objected to the rituals in the Temple.

[250] The widely held belief that Christianity introduced a new conception of morality into the world is, on the basis of historic record, an overstated one; the notion

Jesus (a diminutive of **Joshua**) was born[251] in Nazareth, Israel. He met no strong opposition from the authorities until he and his twelve closest associates traveled to Jerusalem, probably in 30 CE, to preach during the Passover. Like many rural prophets, Jesus was enraged by the worldliness of the capital and denounced the priests of the Temple as hypocrites. Jerusalem was crowded with pious Jews who had come from all parts of Judea for the Passover. Both Jewish and Roman authorities were prepared to take action against any rural preacher who might ignite a popular demonstration and necessitate another Roman purge.

Upon Jesus' visit to the Temple, a riot broke out which caused his arrest by Roman soldiers, his consequent trial before the Roman procurator, **Pontius Pilate**, and his crucifixion[252].

---

that the Jews believed in a God of Vengence and that Christianity first projected a God of Love is from an historical point of view quite untenable. Jewish writings *before* and *during* the time of Jesus prove this conclusively. There are innumerable references in Jewish writings, centuries before Jesus, which condemn hatred, cruelty, envy, and, conversely, which glorify truth, love of man, gentleness, generosity of spirit and forgiveness. The ethics of Jesus were *totally* Jewish, and they were derived from the Mosaic commandment: "*Love the neighbor as thyself*" (*Leviticus* **19**, 18). To cite only a few examples: The Book of Proverbs, written many centuries before the Christian movement arose, wished to establish the moral truth that: "*The reasonable man is noble, he glories in pardoning injury*" (*Prov*). **Philo of Alexandria**, a contemporary of Jesus, exhorted: "*If you ask pardon for your sins do you also forgive those who have trespassed against you. For remission is granted for remission*".

[251] The birth of Jesus is linked to *star of Bethlehem*. This event is believed to be a conjunction of Saturn and Jupiter *in Pisces*, occurring once in 900 years. Thus, Jesus was probably born on 07 September, 7 BCE. The Last Supper happened on April 06, 30 CE and the crucifixion on Friday, April 07, 30 CE.
The conjunction hypotheses goes back to **Johannes Kepler**, who observed another such conjunction from his observatory in Hradcyn, near Prague, on 17 December 1603. Kepler, in turn, drew his theory from commentary on the book of **Daniel** by **Don Isaac Abrabanel** (1497).

[252] It was tragically inevitable that Jesus should have suffered the same fate as several other "messiah" before him who were called by their followers "*King of the Jews*" [e.g., Judah of Galilee, 6 BCE; Theudas in 44 BCE and Benjamin, "the Egyptian", in 60 BCE]; the preaching of Jesus and the devoted following that clustered around him, although pacifist in nature, were also considered inimical to the security of the Roman state in Judea. To Roman ears, not used to this mystic conception of a savior, it sounded very much like high treason against the Emperor in Rome. Whatever the title "King of the Jews", by which

The teaching of Jesus might have been forgotten with the crucifixion had not a group of his followers soon appeared in Jerusalem proclaiming that Jesus had been the Messiah, that he had come back from the dead, that he had appeared to many of his disciples and commissioned them to carry on his teachings, and after 40 days he had returned to God[253]. Although these first *Christians* considered themselves practicing Jews, they were generally regarded as heretics by the other Jews of that city.

The community of *Jewish Christians* virtually disappeared after the Roman suppression of the Bar-Kochba revolt (135 CE). But by this time Christianity had already been established among the Gentiles, primarily by **Paul**.

40–60 CE **Saul of Tarsos** (Paul, Paulus, ca 4 BCE–64 CE). Transubstantiated Jesus from a Jewish preacher into a Christian redeemer and succeeded in marketing this image to the Pagans[254]. Paul stood for the direct admission of Pagans into Christianity without a prior introduction into Judaism. He taught that Jesus' death atoned for human sin, that faith in Jesus' divinity redeems without observance of the Torah (5 books of Moses), and the abrogation of the laws and rituals of the Torah[255]. It was hatred of the law (Torah) and his inability to respect it[256] that led Saul to become Paul and preach divine redemption from original sin by exploiting the death of Jesus. Paul was a Jew by birth, a Roman by citizenship, and a product of Greek

---

his followers called him, may have signified to Jesus, to the Romans it probably appeared as a challenge to imperial authority.

253 Messianic movements usually emerged throughout Jewish history after major national disasters or during long periods of oppression and persecution. It is thus very likely that after the destruction of the second Temple by the Romans (70 CE), the disciples of Jesus, in their great despair of the redemption of Israel, modified the character of his teachings, altered the story of his life and death and his ideas in order to facilitate the marketing of his ideology in the Greco-Roman Paganic world.

254 see:

- Maccoby, H. *The Mythmaker — Paul and the Invention of Christianity*, Barnes and Noble, 1986, 237 pp.

255 After the death of Jesus, the leadership of the Christian sect gravitated toward two men. One was **James**, the brother of Jesus, who tried to keep Christianity within the fold of Judaism but failed. The other was Paul. James admitted Pagans to the new Christian sect only after their conversion to Judaism.

256 **Nietzsche** (1888) denoted Christianity as being *immoral* from the outset because its object is to free the individual from the burden of Jewish tradition.

culture. Whereas Jesus was a messiah-intoxicated Jew who died a Jew, Paul was a Christ-intoxicated Jew who died a Christian. Whereas Jesus, like the Jews, had taught that man could earn God's grace through repentance and righteousness, Paul the Christian taught that salvation could only be obtained through the dead Christ.

Paul rejected the Jewish establishment and law, basing his objection upon the premise that man is *devoid of free will* and is too weak to follow percepts and commandments; man can only be saved by identifying himself with the sacrifice of the crucified Jesus. Thus man is redeemed from the original sin and becomes immortal too. By rejecting free will Paul liberated his followers from the yoke of observance of the Biblical commandments[257].

For two decades (50–70 CE), the teachings of James and Paul competed as the true creed of Jesus. The destruction of Jerusalem (70 CE) selected the victor. Both Sadducee Judaism and Jamesian Christianity perished in that holocaust. And just as Pharisee Judaism rose out of the rubble, so did Pauline Christianity. Both were universalist religions in outlook, tailored for the Jewish exile, the latter for Pagans at large.

During the Hellenistic era, the Jewish way of life made a great impression on many Greeks and Romans. They liked the non-sexualized symbols of Judaism and respected the dignity of the Jewish God. They admired the Jews for not indulging in the Bacchanalian revelry so common in those days among the Pagans, and they envied the devotion of the Jewish people to spiritual, family, and scholastic ideas rather than materialistic goals. In the two-century span 100 BCE–100 CE, thousands of Sabbath candles flickered in Grecian and Roman homes – so many in fact that **Seneca** (4 BCE–65 CE) noted this phenomena by remarking that Jewish customs were everywhere so prevalent that the Romans were in danger of being swallowed up by them[258].

[257] The Catholic Church could not accept this idea since free will is at the base of any establishment based on law and order. Thus the Church was forced to return to the premise that man has free will and therefore must accept the laws of the Church. Free will is one of the fundamental principles of the Bible; a man devoid of free will cannot be moral since he cannot differentiate between good and evil. In fact, any human culture must, by its own nature, assume that man has a limited free will or else any interaction between people is impossible.

[258] This and the heavy causalities of the Roman Legions in Israel during the War of Independence (66–70 CE), raised a wave of hatred toward Jews and their culture in the intellectual circles of Rome. It is indeed regrettable that the writings of a great moralist like **Seneca** and a great historian like **Tacitus** are fouled up by an irrational venomous hatred directed toward Jewish values, customs and religion.

Jewish virtue and ideology did indeed threaten to undermine the Pagan nations and might have done so if it had not been for the Christian sect, which began to proselytize more actively than did the Jews themselves.

In the first century CE, over 10 percent of the population of the Roman Empire was Jewish – 7 million out of 70 million. Of these 7 million professing the Jewish faith, only an estimated 4 million were Jewish by virtue of centuries of descent; the rest were converted Pagans or of converted Pagan descent. The rate of conversion would have been even greater but for two factors: the rigorous dietary laws, and the necessity for circumcision. In Paul's time, the early Christians sect dropped these two requirements, and the Pagans flocked to the Christian religion, whose entrance specifications were less demanding than the Jewish.

Paul was born in the Greek-speaking city of *Tarsos*, in Asia Minor (Turkey), to a Jewish family, wealthy enough to purchase Roman citizenship. He received traditional Hellenistic education, for he later wrote in polished Greek and was well acquainted with Greek philosophy.

In the city of Tarsos he led the life of an ordinary artisan, being a tent-maker by trade. Three things characterized him and affected his life: a body subject to some serious ailment, a gift for oratory and public disputation, and a devotion to Judaism so great as to make him impatient with its slow progress in *converting the Pagans*. He must have spent years in wondering why the ideals of Judaism, obviously so noble, failed to be accepted by the Pagans and sometimes were not lived up to by the Jews. He finally made up his mind to go to Jerusalem and study Judaism at its source (ca 35 CE) under Rabban Gamliel the Elder. Soon after his arrival, he was exposed to ideas of the followers of Jesus. He saw in Jesus a great attraction to the Pagan world. He decided to speak of him, not only as a messiah[259] who had come to redeem

[259] The period in which Jesus and Paul lived was unique in all Jewish religious experience; it marked the peak development of *Messianism* among Jews. The idea of *saviors* was already well established in the 5^{th} century BCE (*Nehemiah* **8**, 27). Because it was a time of acute suffering, much of the Jewish apocalyptic literature of that period was permeated with the expectation of the imminent coming of the Messiah. The prophets **Ezekiel** and **Enoch** had spoken awesomely of the *Last Judgment* and of the *Resurrection*, both of which had now become associated in the popular mind with the era of the Messiah. It was the tradition among Jews that the Messiah would come when the affliction of the Jewish people became unendurable.

Suffering, insecurity, and the helplessness of the Jews under the iron heel of Rome made them abandon faith in their own strength and efforts. They yearned increasingly for a supernatural redeemer who would have the invincible power to bring the enemies of Israel to justice and who would usher in the era of the

the world (as the original followers of Jesus thought), but also as an ideal, a divine personality whose example could influence each human being, whether Jew or Gentile, and lead him to perfection.

Paul then traveled through many parts of the Diaspora, especially Asia Minor and Greece, offering Judaism devoid of Jewish ceremonial and ritual together with a new non-historical image of Jesus. Being rejected by the Jews, he turned his attention almost exclusively to the Pagans. Yet to the very end he never denied his own Jewishness. On his last appearance in Jerusalem (ca 60 CE) he visited the Temple and observed all the other Jewish customs. When, however, it became known that he had violated Jewish traditions while on his travels, he was arrested and, later condemned by the Romans and crucified at Rome during Nero's persecution of the Christians in 64 CE.

What happened to Paul's teachings? – Most of the people who listened to him remembered only the connection between believing in Jesus and meriting God's mercy and ultimate resurrection. They skipped the middle part – the need to live godly lives. Thus, faith in Jesus came to be the only and entire basis of the religion adopted by the Pagan Christians, while the Judeo-Christians, who lived in Israel, continued to observe Jewish law.

But it was the *Pagan Christian* attitude which won in the end. Many Pagans who had admired Judaism either openly or secretly now had a chance to adopt a form of Judaism which appealed to them. It is not strange that Christianity spread most easily and rapidly in those cities in which Jews had lived for a long time, so that people were already acquainted with their life and religious ideas. Nevertheless, for some centuries still, it was not at all certain whether Judaism or Christianity would make the greater number of converts.

Kingdom of God on earth. The prophets, beginning with **Isaiah**, had articulated this desire and dream, which they expected would bring everlasting peace and happiness not only on the Jewish people but for all mankind. They had a vision of an ideal ruler who once more would raise up the fallen kingdom of David whose departed glories so haunted and tormented the Jews of later days.

The Silent Century (0–100 CE)

It has always been an unfailing source of astonishment to the historical investigator of Christian beginnings that there is not one single word from the pen of any Pagan writer of the first century of our era which can in any fashion substantiate the story recounted by the Gospel writers of the New Testament. The very existence of Jesus seems unknown! In other words – historical research has made it obvious that there is no way to get at the *historical events which have produced the Biblical picture of Jesus with more than a degree of probability.*

For lack of historians? There were many historians just then and some of them the most illustrious of all time – ***Tacitus****,* ***Plutarch****,* ***Livy****, the two* **Plinys**, **Philo** *and* ***Josephus****, among others; and besides these many man of literary note such as* ***Seneca****,* ***Martial****,* ***Juvenal****,* ***Epictetos*** *,* ***Plotinos*** *and* **Porphyrios**, ***Virgil****, Horace and* **Ovid**. *These were all men of great intellect, and deeply interested in the doctrines and morals of their day. Some of them held high office and therefore knew their world (Pliny the Elder was procurator of Spain, Pliny the Younger was governor of Bithynia, Josephus was governor of Galilee, Seneca was the brother of Gellio, Proconsul of Achaia at precisely the time Paul is said to have preached there). In fact, we find nothing like divinity ascribed to Christ before 141 CE.*

There is thus only one way to explain away this 'silent century': Christianity (religion and Church) are creations of the third and fourth centuries. By the third century all the science, philosophy and mythology of Greece had disappeared, mostly in flames. Rome was now the dominant power. The Romans, however, lacked the Hellenic love for learning; they had no use for philosophy. In fact they drove out philosophers. Power was their god and conquest their vocation.

And so, when the Empire declined, they finally fell, having no inner light to guide them nor inner strength to sustain them. While a few intellectuals remained, the masses sunk in abysmal ignorance, poverty and want. They were thus ripe for the mythology of Christ.

In this lies another contributing factor – the economic one. All mass movement are security inspired, being more interested in bread then philosophy, especially masses that have never known philosophy. So, as Roman prosperity vanished, the masses found themselves in desperate straits, ripe for a 'New Deal'. Christianity offered it. It was, then, the coincidence of these factors that furnished the mental soil for Christianity.

ca 43 CE **Pomponius Mela**. Earliest Roman geographer. His *De Situ Orbis* is the earliest description of the ancient world written in Latin. He divides the earth into the climatic zones: North Frigid, North Temperate, Torrid (equatorial), South Temparate, South Frigid.

Pomponius was born in southern Spain in the days of Emperor Claudius. The first edition of Mela was published at Milan in 1471.

ca 50 CE The Greek seaman **Hippalos** used the south-west monsoon to steer a direct course from the Persian Gulf to Western India. He showed that sea routes might be followed, shorter and quicker than the old coastwise sailing. Since the monsoons blow from the south-west in summer and from north-east in winter, they could be utilized both for outward and homeward voyages.

ca 50 CE *Romans* used *coal* as a fuel in Northern Europe

ca 50 CE **Aulus Cornelius Celsus**. Roman writer. Compiler of an encyclopedia on agriculture, medicine, military science, law, and philosophy of which only the portion on medicine is extant. It was one of the first medical works to be printed (1478).

Celsus, a Roman patrician, appears to have studied medicine as a branch of general knowledge, which he practiced on his friends and dependents, but not as a remunerative profession. His work *De Medicina* was one of a series of treatises intended to embrace all knowledge proper for a man of the world. It was not meant for physicians, but the whole body of medical literature belonging to Hippocratic and Alexandrian times is ably summarized, and the knowledge of the state of medical science up to and during the times of the author is thus conveyed in a way which cannot be obtained from no other source [e.g., it contains first description of sewing an artery and of heart disease and also describes hernia operation].

The influence of Celsus commenced in the 15^{th} century, when his works were first discovered and printed.

60–78 CE **Pedanios Dioscorides of Anazarba** (20–90 CE). A Greek physician and alchemist[260] who wrote the first catalogue of drugs and their

---

[260] *Alchemy* – a pseudoscience of obscure origin. Sought a *philosopher's stone*, thought capable of changing base metals into gold, and the *elixir of life* that would preserve youth indefinitely. Alchemy was academically accepted by **Robert Boyle**, **Isaac Newton** and **G.W. Leibniz**.

recipes. Described the processes of *crystallization*, *sublimation* and *distillation* of substances. Known also as Dioscorides of Cilkia (Asia Minor).

Dioscorides was the author of the herbal *De Materia Medica* which remained for 1500 years the authority in botany and pharmacopeia. It describes more than 500 plants and 35 animal products. Ninety of the plants he mentions will still be in use in the 20^{th} century. The Italian physician and botanist **Pietro Andrea Mattioli** published (1544) an Italian version of De Materia Medica.

63 CE *Israel comes under Roman rule* which ends only with the disintegration of the Roman Empire (395 CE). In a series of four revolts [66–70; 114–117; 132-135; 351 CE], the majority of the Jews in Israel perished[261] and the rest were dispersed all over the Empire. With Judea largely depopulated, the centers of Jewish culture and learning were in the Galilee and in Babylonia and later shifted to Jewish communities around the Mediterranean.

66 CE **Josephus Flavius** (Yoseph ben Matitiahu; 37–100 CE, Israel and Rome) described the apparition of comet Halley as a star resembling a sword. This he considered as an omen for the fall of Jerusalem (70 CE).

70–110 CE **Rabban Gamliel II** (ca 30–117 CE, Yavne). Mathematical astronomer and Tanna. A great-great grandson of Hillel.

Gamliel worked out the problem of the *moon's visibility*[262] and is said to have possessed an instrument resembling an astrolabe or a telescope by means

---

[261] **Josephus** in *The Jewish Wars* estimated the Roman force besieging Jerusalem in 70 CE at 80,000 soldiers [Jerusalem was defended by no more than 23,000 Jewish soldiers]. In comparison, **Alexander the Great** used 35,000 men to carve out his vast Empire. **Caesar** had fewer than 60,000 legionaries with which to conquer Gaul and to invade Britain. **Hannibal** had no more than 50,000 soldiers when he crossed the Alps to defeat the Romans.

Tacitus estimates 600,000 defenseless Jewish civilians were slain in the aftermath of the siege.

[262] The following episode, related in the Mishna [*Rosh Hashana* **2**, 8; $\mathbf{24}^b$ and $\mathbf{25}^a$], illustrates the great confidence that Gamliel had in his astronomical calculations of the moon's visibility: Once two witnesses reported that they saw the moon in the East *before* sunrise and in the West *after* sunset. When they came to Yavne, (some 30 km south of today's Tel-Aviv) Gamliel accepted their evidence (needed to establish the definite *consecration* (Kidush ha-Hodesh) of the new moon), while the other members of the Calendar Council rejected it. Those who considered the evidence false, claimed that the moon cannot be seen within an interval of 24 hours both *before* sunrise and *after* sunset. They argued that since the moon is *East* of the sun throughout the first half of the month, and West of

of which he could estimate a distance of 2000 cubits (about 1120 meters), as well as measure depths and height.

70–110 CE **Plutarch**[263] (ca 46–127 CE). Greek historian, biographer, philosopher and essayist. Wrote a large number of essays and dialogues on philosophical, scientific and literary subjects. His philosophical standpoint was eclectic and he frequently attacked both Stoics and Epicureans. He is best known for his *Parallel Lives*, biographies of eminent Greeks and Romans, generally composed in pairs, one Greek and one Roman, followed by a comparison between the two.

Plutarch was born at Chaeronea in Boeotia, Greece. He studied philosophy in Athens. In his travels through Greece, Italy, and Egypt he spent much time studying and collecting facts on men he wrote. He combined academic studies with multifarious civic activities. Through friendships formed on an official visit to Rome, he was made procurator of Achaea by Hadrian, and he also held a priesthood at Delphi. Yet much of his time he devoted to his school at Chaeronea and to his literary works.

---

it during the second half, the *New Moon* cannot be seen in the morning at the eastern horizon until *after sunrise*, and in the evening at the western horizon until *after sunset*.

However, the *Waning Moon* can only be seen in the morning *before sunrise* and in the evening *before sunset*. If, therefore, witnesses testify to having seen the moon *before* sunrise and *after* sunset, their evidence cannot be true – unless it refers to the waning moon in the morning and the new moon in the evening. If one accepts this argument, one is in for yet a new obstacle; there must be a certain *minimum angular distance* between the sun and the moon for the latter to be visible. This leads to a situation where between morning [when the moon must have been in that minimum angular distance *behind* (or to the west of) the sun] and in the evening [when the moon must have got that minimum angular distance *ahead of* (or to the east of) the sun], the moon must have covered double that angular distance. But at the rates at which the sun and the moon are traveling, **this would be impossible**!

Hence the objection of the majority of the Calendar Council members to the evidence of the witnesses.

Rabban Gamliel, however, who by his *calculations* concluded that the new moon was indeed visible on the evening in question, nevertheless accepted the witnesses' evidence, on the assumption that what they believed to have seen in the morning was a piece of cloud that looked like a very thin crescent of the waning moon.

263 For further reading, see: Grant, M., *The Ancient Historians*, Barnes and Noble Books: New York, 1970, 486 pp.

The ancient solar eclipse of March 20, 71 CE was documented in his writings and therefore bears his name. In his essay on life of the Spartan general **Lysander**, Plutarch mentioned that in a year corresponding to 467 BCE, a meteorite fell at Aegospotami, in Thrace, on the European side of the Dardanelles. Before the stone fell, a vast fiery body was seen in the heavens for 75 days continually (a comet) "*but when it afterwards came down to the ground there was no fire to be seen, only a big stone*".

The sun's corona, observed during total eclipses, was first reported by Plutarch.

ca 75–130 CE The composition of the *Evangelions*[264] and the advent of the *Christian*[265] *Church*.

Within a century of the death of Jesus, Christianity became a force in history through the rise of a new institution. In the words of **Alfred Loisy** (1857–1940): "*What Jesus proclaimed was the Kingdom of God, and what arrived was the Church*". In the name of Jesus, this new Church reversed many of his policies to gain larger membership. To achieve this, it ingested many of the ideas of *Essenism*, which has also perished with the fall of Jerusalem.

Jesus, like the Pharisee rabbis, was a layman who rejected priesthood, founded no Church and sought no institutionalized hierarchy. The Church, however, realizing it needed a devoted hierarchy for future growth, dragged in through the back door the priesthood Jesus has thrown out of the front door. The Church institutionalized its creed and established an elaborate organization of judges and tribunals. In effect, the historical Jesus stands closer to **ben Zakkai**'s Judaism, which also rejected Essenism, than to *Pauline Christianity*, which absorbed it.

76–116 CE **Cornelius Tacitus** (55–120 CE, Rome). Historian. Lived through the reigns of 9 emperors (Nero, Galba, Otho, Vitellius, Vespasian, Titus, Domitian, Nerva and Trajan). The son-in-law of Julius Agricola and a friend of Pliny the younger. His most important books, the *Histories* and the *Annals*, cover periods for which our other sources are scanty.

79 CE, Aug. 24 The eruption of Mount Vesuvius buried the towns of Pompeii, Herculaneum and Stabiae. **Pliny the Elder** (b. 23 CE), admiral of the Roman fleet that anchored offshore during the event, died of gas poisoning from the volcano, and his young nephew, **Pliny the Younger** (61–113 CE) lived to tell us about it.

264 From the Greek *evangelion* = *good news*; the "official" biographies of Jesus; any of the four gospels of the *New Testament*.

265 From the Greek *christos* = "*the anointed*", *messiah*.

79 CE **Pliny the Elder** (Gaius Plinius Secundus) (23–79 CE). Writer, civil servant, soldier and encyclopedist, perhaps the only Roman on record, to die of scientific curiosity. Holds a place of exceptional importance in the history of Western culture and its diffusion.

Born in Novum Comum in Northern Italy, he begun his career in the army, in Germany, and later held a number of procuratorships in Gaul, Africa and Spain (70–75). On his return to Rome he devoted his talents to writing. Seven works are known but only one, the *Natural History*[266], survived. It is an encyclopedic account of the state of science, superstition, art and technology in the first century CE, and contains material from works no longer extant. Hence its unique value for our assessment of early imperial science and technology. Its derivation from over 2000 earlier texts, makes it *the* major source for ancient beliefs about every form of useful knowledge[267] – from agriculture, architecture and astronomy to geography, metallurgy and zoology. Pliny's work was an extraordinary catalog of truths, half-truths, myths, and outright nonsense. He was more encyclopedist than a scientist; his knowledge was almost exclusively derived from the writing of others rather than from personal observations.

With the decline of the ancient world and the loss of the Greek texts on which Pliny had so heavily depended, the *Natural History* became a substitute for a general education. In the European Middle Ages many of the larger monastic libraries possessed copies of the work; these and many abridged versions ensured Pliny's place in European literature. His authority was unchallenged, partly because of a lack of more reliable information and partly because his assertions were not and, in many cases, could not be tested.

The first attack on Pliny's work – **Niccolò Leoniceno**'s tract on the errors of Pliny – was published in Ferrara in 1492. Thereafter, Pliny's influence diminished, as more writers questioned his statements. By the end of the 17th century, the *Natural History* had been rejected by the leading scientists.

Up to that time, however, Pliny's influence, especially on nonscientific writers, was undiminished; he was, for example, almost certainly known to William Shakespeare and John Milton. Although Pliny's work was never again accepted as an authority in science, 19th-century Latin scholars conclusively demonstrated the historical importance of the *Natural History* as one of the greatest literary monuments of classical antiquity. It is still of value to those who wish an honest resumé of 1^{st}-century Rome.

---

266 Pliny the Elder (Gaius Plinius Secundus), *Natural History* (A selection), Penguin Books: England, 1991, 400 pp.

267 Pliny coined the word '*albumen*' for egg white.

80–110 CE **Joshua ben Hannania ha-Levi** (35–117 CE, Israel). Astronomer, mathematician and *Tanna*. One of the leading scholars of the 2^{nd} generation of the *Tannaim*. First man in recorded history to establish the *periodicity* of a comet [*Horayoth* $\mathbf{10}^a$].

Joshua was born in Jerusalem to a Levite family and probably served in the second Temple for some years before its destruction (70 CE).

He was a disciple of **Yohanan ben Zakkai** and assisted in the removal of the latter from Jerusalem to Yavne during the Roman siege. He traveled extensively by sea and by land to Rome, Alexandria, Asia Minor and Babylonia for either political, academic and business reasons. He founded his own private academy at Pekiin (upper Galilee) and was also a member of the Sanhedrin at Yavne [*Shabbat* $\mathbf{75}^a$].

85–117 CE **Epictetos of Hierapolis** (ca 55–135 CE). Greek *Stoic* philosopher. Left no writings, his philosophy is known through his *Discourses* and the *Encheiridion* (handbook) of his pupil **Flavius Arrianus** (the historian of Alexander the Great).

Epictetos taught that nothing is ours besides our will. We should not demand that events happen as we want but instead want them to happen as they do. A wise, divine Providence governs all things, so that what seem to be calamities are really parts of a divine scheme that orders everything for the best. Only foolish men are upset by events they cannot control. The body which accompanies us is not, strictly speaking, ours but belongs to things outside us.

Epictetos was a native of Hierapolis (southwest of Pergia, Asia Minor). His name is merely the Greek word for "acquired", his real name being unknown. He was lame and of weakly health. Originally a slave in Rome at the time of Nero, he was freed by his master and taught philosophy in Rome until expelled (89 CE) with other philosophers by Emperor Domitian. He then settled for the rest of his life in Nicopolis (Greece). He never married.

89 CE Emperor Domitian[268] and the Roman Senate expelled from Rome all philosophers, mathematicians and astrologers.

---

268 Titus Flavius Domitianus (51–96 CE), Vespasian's second son, inherited the mantle of Empire at the age of 29. He was a man beset by suspicions and fear, and terrorized Rome for 15 years. Domitian ferreted out opponents in the Army and Senate and had them executed. He was killed at last by a member of his own household. After his death, the Senate ordered Domitian's name to be removed from all public places and refused to give him a state burial.

ca 90–120 CE **Hero** (**Heron**) **of Alexandria**. Greek mathematician, physicist and inventor. An important geometer and worker in mechanics.

His geometrical treatises which have survived in Greek are entitled respectively: *Definitiones*, *Geometria*, *Geodesia*, *Stereometrica*, *Mensurae*, *Liber Geoponicus* and *Metrica*. *Metrica* deals with areas of triangles, quadrilaterals, regular polygons of between 3 and 12 sides, surfaces of cones, cylinders, prism, pyramid, sphere etc. Methods for approximating square and cube roots are shown. For the area of a circle of diameter d, he gave the formula $\frac{11}{14}d^2$ $\left(\text{based on } \pi = 3\frac{1}{7}\right)$, in the name of **Archimedes** and **Euclid**[269]. Hero also proved the expression for the area of a triangle in terms of its sides, and determined the distance between Rome and Alexandria by observation of the same lunar eclipse in both places and drawing the analemma for Rome.

Akin to the geometrical works is *On the Dioptra*, a remarkable book on land-surveying. The *Pneumatica* describes siphons, "Hero's fountain", "penny-in-the-slot" machines, a fire-engine, a water-organ and arrangements employing the force of steam. He also wrote 3 volumes on *Mechanics*[270] and a book on *Water clocks.* In his *Catoptris* (on reflecting surfaces) we encounter the first minimum principle in physics. He reasons that when a ray of light is reflected in a mirror, the *path* (not time!) actually taken from the object to the observer's eye is shorter than any other possible path. This proposition was obtained from a generalization of the observed fact that when light travels from one point to another, its path is a straight line, that is, it travels the shortest possible *distance* between these points.

Hero's *Siegecraft* (*Belopoiika*) tells about several designs for catapults. One is the crossbow; the others are conventional darts and stone throwers. In *Dioptra* he describes a surveying system which did not seem to have come into use, being probably too far ahead of its time.

Some of Hero's inventions seem to have been for the benefit of the priesthood of Alexandria, to enable them to awe their worshipers. Of all his inventions, the one most pregnant with future possibilities was his steam engine

---

[269] **Euclid** in his *Elements*, or other writings known to us, never gives the computation of the area of the circle, nor of other areas or volumes.

[270] In this book he was mainly concerned with *mechanical advantage* which he achieved via the lever, the compound pulley, the wedge and the gear train. He showed how, with such devices, the force applied and the distance moved vary inversely according to the mechanical advantage. In fact, Hero came close to discovering the modern technical concept of "*work*" (= force × displacement). He also described cranes, methods of raising large building stones by means of tongs and keys and screw presses.

or *aeolipile*. It worked on the *reaction principle* of the rotary lawn sprinkler[271]. He had in it nearly all the elements needed to make a working steam engine of either the reciprocating or the turbine type, yet none of the devices he described under this category was such a steam engine. He simply could not attack a problem that he did not know to exist. But even so, Hero's technological accomplishments are remarkable.

Although Hero's books were not widely read in later centuries, they were never altogether forgotten. The engineers of the Renaissance would later study Hero with lively interest. In the 17^{th} century, when Europeans began to harness the power of steam, they remembered Hero's achievements.

95–136 CE **Akiva ben Yosef** (ca 50–136 CE, Israel). Scholar, philosopher and jurist; perhaps the greatest Jewish savant in the past two millennia. Through his admirable systematization and scientification of the accumulated lore of oral law (which until his time was only a subject of knowledge), he brought it into methodic arrangement, basing it on sound logical foundations and turning it into a "survival-kit" which marked the path of Judaism for next 1800 years. He is the man to whom Judaism owes prominently its activity and its capacity for development.

If the older Halakah (oral ruling) is to be considered as the product of the internal struggle between Phariseeism and Zaducceeism, the Halakah of Akiva must be conceived as the result of the external contest between Judaism on one hand and the Hellenism and Hellenistic Christianity on the other.

Akiva no doubt perceived that the intellectual bond uniting the Jews – far from being allowed to disappear with the destruction of the Jewish state – must be made to draw them closer together than before. He pondered also on the nature of that bond. The Bible could not fill the place alone; for the Christians also regarded it as a divine revelation. Still less could dogma serve the purpose, for dogmas were always repellent to Judaism, whose very essence is development and the susceptibility to development.

His first act in this direction was the final canonization of the Bible (inclusion of the books of *Song of Songs*, *Ester* and *Kohelet* and the rejection of the Apocrypha (the 14 books of the *Septuagint* included in the *Vulgate*). His underlying motive was to disarm Christians, especially Jewish Christians, who drew their "proofs" from the Apocrypha, and at the same time emancipate the Jews of the Diaspora from the domination of the Septuagint, the errors and inaccuracies in which frequently distorted the true meaning of Scripture, and were even used as arguments against the Jews by the Christians. Thus,

[271] Newton's third law was applied 18 centuries before it was formulated!

under Akiva's guidance, his pupil **Aquila** gave the Greek-speaking Jews a faithful translation of the Bible which they could use in their synagogues.

But this was not sufficient to obviate all threatening danger. It was feared that the Jews might still become entangled in the net of Grecian philosophy, and even in that of Gnosticism and must therefore be provided with some counterpoise to the intellectual influence of the non-Jewish world.

To this end, Akiva developed a remarkable method of reconciling the unchangeable legal and ethical code of the Holy Scriptures with the dynamical needs of the ever-developing Judaism.

As a speculative philosopher, Akiva brought new insight into man-God relationship. Next to the transcendental nature of God, he insists on the freedom of will, to which he allows no limitations ["*everything is foreseen; but freedom of will is given to every man... the divine decision is made by the preponderance of the good and bad in man's actions*"][272]. In opposition of the Christian insistence on God's love, Akiva upholds God's retributive justice elevated above all chance or arbitrariness.

Akiva came of humble parentage in the town of Lod, Israel. He began as an illiterate shepherd and learned to read and write together with his son

---

[272] Akiva here laid bare the solid rock on which the whole structure of Rabbinic Judaism was founded: Man *apparently* acts according to his free will, but in fact realizes, unknowingly, the divine plan. Nowhere is this idea expounded with greater lucidity then in the words of Joseph to his brothers [*Gen*, **45**, 5–8]:

"*Now therefore be not grieved, not angry with yourselves, that ye sold me hither: for God did send me before you to preserve life. For these two years hath the famine been in the land; and yet there are five years, in which there shall neither be earing nor harvest. And God sent me before you to preserve you a posterity in the earth, and to save your lives by a great deliverance. So now it was not you that sent me hither, but God: and he hath made me a father to Pharaoh, and lord of all his house, and a ruler throughout all the land of Egypt.*"

Akiva's succinct and ambiguous statement attempts *no solution* of the contradiction between divine foreknowledge and human free will, but affirms both and rests in the assurance that He who judges is good. Judgment takes account of what man *has done*. Into these few lines Akiva compressed well nigh the whole Judaic philosophy of religion expressing the fundamental conviction that divine foreknowledge and human freedom are equally well real and true, though human wisdom could not intellectually reconcile them. Akiva spoke for the *practical* needs of the religious and ethical consciousness of man, not for theoretical satisfaction of the inquiring mind.

at an age of 25 or so. He then studied in the local academy for 13 years before becoming a teacher himself. It is known that in 95–96 CE Akiva had already attained great prominence. He had made numerous journeys within and outside the Roman Empire (Spain, Babylonia, Asia Minor, Sicily, Phartia, North Africa, Athens).

In 132, the prohibition of Jewish observances by Hadrian were accompanied by a decree forbidding the study of the Torah. This he saw as a major threat to the very survival of the Jewish nation for which a Jew must risk dying for. Risking capture by the Roman soldiers he continued to study and to teach. Consequently he was arrested and executed (136 CE).

97–103 CE **Sextus Julius Frontinus** (ca 35–103 CE, Rome). Soldier and writer on subjects of military science, land surveying and water supply systems. City praetor (70 CE), Governor of Britain (75–78 CE), Trajan's water commissioner (97 CE). His chief work *De Aquis Urbis Romae* contains a history and description of the water-supply of Rome. He also wrote a theoretical treatise on military science (*De re Militari*), and a treatise on land surveying.

The Roman were, of course, not the first folk to build aqueducts. However, the Roman aqueducts were distinguished from the earlier ones mainly by their size and number. Sections of their arcades are still to be seen around within the former limits of their empire. Most Roman aqueducts took the form of gravity-powered open channels. They sometimes used the *inverted siphon* (i.e., U-shaped pipe higher at the intake than at the outlet) instead of aqueduct bridges to cross deep valleys. Frontinus tells us that water was conveyed to Rome by nine aqueducts from sources in a spur of the Apennines, some 25 km to the east[273].

---

[273] The first aqueduct brought pure water into Rome as early as 312 BCE. At the beginning of the Christian era there were six.
Modern estimates of the total volume delivered to Rome runs from 0.3 to 1.2 million cubic meters/day. About half of this enormous supply was required for the *public baths*. The baths of Caracalla, dating from about 200 CE were capable of accepting 1600 bathers at a time. Those of Diocletian, built about 80 years later, had no less than 3000 rooms. The bath, accompanied Roman civilization wherever it penetrated, and certain places became famed for the curative power of their mineral-impregnated waters. The population of Imperial Rome is estimated at one million. As nearly as we can estimate, Babylon, Nineveh, Athens, Syracuse, Carthage, Alexandria, Antioch, Capua and the Republican Rome had all at their height, harbored somewhere from 250,000 to 500,000 people. Probably larger cities were impractical because of the difficulty of bringing food from a distance to feed their populations. Roman roads

The water system consisted of arcades (aqueduct bridges), conduits and tunnels, altogether totaling about 450 km, of which only one-ninth were on arches. They were built mainly of concrete. The pipes that branched off from the main aqueducts were made of lead (poisonous!). Most of what we know of these matters comes from **Frontinus**' book. He bossed a small staff of engineers, surveyors, clerks, and a crew of 700 government slaves, including inspectors, foremen, masons, plumbers and plasterers. Frontinus bitterly complained of the frauds that had taken place under his predecessors; he was shocked to find secret, illegal pipes running to irrigated fields, shops, and even whorehouses.

Aside from the abuse of the water system by grafters and water steelers, the system suffered from natural causes, which made its upkeep a heavy responsibility to a conscientious bureaucrat like Frontinus. The water channels were always cracking and leaking, caused by the settling of the piers of the arcades. Moreover, the Romans did not understand *thermal expansion*. Hence the expansion and contraction of a straight concrete channel several km long, between a hot summer day and a cold winter night, was enough to crack the cement. As the water was heavily charged with mineral salts, the leakage built up thick limestone concretions around the piers.

---

made it possible to concentrate more people in one metropolis. Hence, Imperial Rome, and – later, for similar reasons – medieval Constantinople, Baghdad, Anuradhapura (Ceylon), and Hangchow (China) all approached or exceeded the million mark. There remained about 200 liters of water per head for the million inhabitants, the same amount that is used today by a citizen of New York or London. Thus, in 1954, four aqueducts sufficed for the needs of modern Rome. In its cleanliness, sanitation and water supply, Rome was much more akin to 20^{th} century London and New York than to medieval Paris or 18^{th} century Vienna. A 17^{th} century Londoner existed in conditions which would hardly have been tolerated by first century Roman. Public health and sanitation were more advanced in the year 300 CE than they were to be again until the middle of the 19^{th} century. The great drainage system, the *cloaca Maxima*, was built in the 6^{th} century BCE, to drain an area of marsh which later became the site of the Forum Romanum. The Cloaca gradually assumed the function of a modern sewer and its plan was copied elsewhere in Italy and the empire. The modern water closet was not devised until well over a 1000 years after the fall of Rome, but the ruins of Pompeii and Harculaneum (destroyed 79 CE) have revealed an elaborate system of waterworks connected with *flushing closets*. Public lavatories, uncomfortably hard to find in the present-day city, were common place in Rome during the 1^{th} century CE. The best known of these, a palatial building fitted with marble urinals, was erected by Vespasian in about 70 CE.

Nevertheless, Frontinus was very proud of his aqueducts as is evident from his own words: "*With such an array of indispensable structures carrying so many waters, compare, if you will, the idle Pyramids or the useless though famous, works of the Greeks*!"

ca 98 CE **Menelaos of Alexandria**. Greek mathematician. Author of *Sphaerica*, a work extant in Hebrew and Arabic, but not in Greek. In it he proves the theorems on the congruence of spherical triangles, and describes their properties in much the same way as Euclid treats plane triangles. In it are also found the theorem that the sum of the three angles in a spherical triangle exceeds two right angles. Two other celebrated theorems of his deal with plane and spherical triangles[274].

ca 100 CE **Nicomachos of Gerasa** (ca 60–120 CE). Neo-Pythagorean mathematician, astronomer, physicist and philosopher. Wrote *Arithmetike eisagoge* (Introduction to Arithmetic), the first work on the theory of numbers, in which arithmetic was treated quite independently of geometry. This work exerted a powerful influence over the study of arithmetic for more than a millennium.

The principal scene of his activity was the city of Gerasa (today in Jordan). Nicomachos is our main source of information on Pythagorean mathematics. He told in a manner intelligible to every one, and in an entertaining way, about triangular, square, rectangular and polygonal numbers, about prime numbers and geometric progressions, all illustrated by numerous examples, but never accompanied by proofs. He quoted the first four perfect numbers: 6, 28, 496, 8128 and noted that the last figure was either 6 or 8.

ca 100 CE The diseases of pneumonia, diabetes, tetanus and diphtheria first identified or described with accuracy.

ca 100 CE **Mary** (**Maria**) **the Jewess**. Alchemist. Invented chemical apparatus for *distillation* (the *ambix* or *alembic*) and for *sublimation* (the *kerotakis*; a hot-ash bath). A water-bath was later named *bain-marie* in her honor. Her writings combine practical techniques, mystical imagery, and theoretical ideas.

105 CE The Chinese discovered paper.

---

274 *Lemma of Menelaos*: "*If the three lines constituting a plane triangle be cut by a straight line, the product of the three segments which have no common extremity is equal to the product of the other three*". There exists a corresponding theorem for spherical triangles.

106 CE Chinese and Roman traders meet in central Asia. Chinese silk and spices are exchanged for gems, precious metals, glassware, pottery and wine.

ca 110 CE **Marinos of Tyre**. Greek geographer and mathematician. Regarded as the founder of *mathematical geography*. Predecessor of Ptolemy, who acknowledged his great obligations to him. His chief merits were that he assigned to each place its proper *latitude* and *longitude*[275], and introduced improvements in the construction of his maps. He also carefully studied the works of his predecessors and the diaries of travelers. His geographical treatise is lost.

117–138 CE **Soranos of Ephesos** (Alexandria and Rome). Greek physician. Practiced medicine in Alexandria and later in Rome during the reigns of Trajan and Hadrian. Founder of obstetrics and gynecology. Influenced medical practice in these fields until the 15^{th} century. His works included *On Midwifery and the Diseases of Women* and *On Acute and Chronic Diseases*. He was the chief representative of the school of physicians known as "*methodists*". It is notable that the *speculum*, an instrument invented in modern times, was used by Soranos[276].

120–150 CE **Claudios Ptolemy** (**Ptolemaeos**) **of Alexandria** (ca 85–165 CE). Astronomer, mathematician, geographer, physicist and chronologist. One of the greatest astronomers and geographers of ancient times. Introduced geocentric cosmology that was not seriously challenged for 1400 years. His observations and theories are preserved in a 13-volume work which he entitled '*Mathematike Syntaxis*' (Mathematical composition). Because of the admiration this work won, it became known as the *Almagest*, a combination Greek-Arabic term meaning *the greatest*.

Ptolemy developed his astronomical system largely from the ideas of **Hipparchos** (150 BCE) and made a critical reappraisal of the planetary records. He collected the works of Hipparchos and his predecessors, added his own observations, evolved a first-class theory and left a masterly exposition that dominated astronomy throughout the Dark Ages. He rejected the idea that the earth moves and placed a motionless earth at the center of the universe. Around it went the moon, sun and planets at various speeds. The stars were brilliant spots of light in a concave dome that arched over everything. Against this stellar background, Ptolemy traced the motions of the planets and worked out the theory of each of them.

---

[275] Marinos was, in effect, the first to invent the concept of a *coordinate system* and *coordinates of a point* with respect to it.

[276] In fact, specimens of still earlier date, showing great mechanical perfection, have been found among the ruins of *Pompeii*.

The positions of the sun, moon, and planets, relative to the fixed stars, had been mapped with angles measured to a fraction of a degree. He could therefore elaborate the system of eccentric crystal spheres and epicycles and refine its machinery, so that it carried out past motions accurately and could grind out future predictions with success. He devised a brilliant mathematical machine, with simple rules but complex details, that could 'save the phenomena' with centuries-long accuracy. In this he neglected the crystal spheres as moving agents; he concentrated on the rotating spoke (or radius) that carried the planet around, and he provided sub-spokes and arranged eccentric distances.

The general picture was this: the heavens of the stars is a sphere turning steadily round a fixed axis in 24 hours; the earth must remain at the center of the heavens – otherwise the star pattern would show parallax changes; the earth is a sphere, and it must be at rest for various reasons – e.g., objects thrown into the air would be left behind a moving earth. The sun moves round the earth with the simple epicyclic arrangement of Hipparchos, and the moon obeys a more complicated scheme.

His system was a gorgeously complicated system of *main circles* and *subcircles*, with different *radii*, *speeds*, *tilts*, and different amounts and directions of *eccentricity*[277]. Like a set of mechanical gears the system grounded out accurate predictions of planetary positions for year after year into the future, or back into the past. And like a good set of gears, it was based on simple principles: *circles with constant radii*, rotations with *constant speeds*, *symmetry*, *constant tilts* of circles, with the earth fixed in a constant position[278].

In the *Almagest*, Ptolemy described a detailed scheme for each planet and gave tables from which the motion of each heavenly body could be read off.

---

277 For the motion of the planets, Ptolemy found that he could not save the sacred principle of uniform motion even with a simple epicyclic motion; there were residual discrepancies between theory and observation, so he not only moved the earth off-center but also moved the center of uniform rotation to a new point, called the *punctum equans*. This point enabled him to say that there exists, after all, a point in space where an observer could enjoy the illusion that the planet's motion is of uniform speed.

278 Though this now seems as an unreal model, it is still fashionable as a method of analysis. Adding circle on circle in Greek astronomy corresponds to our use of a series of sines (projected circular motions) to analyze complex motions. Physicists today use such *Fourier Analysis* in analyzing time-series such as musical sounds, tides, etc. In principle, planetary motion can be represented to any desired accuracy, provided one is allowed to compare enough circular motions (Fourier components).

The book was copied (by hand), translated from Greek[279] to Latin, to Arabic and back to Latin as high culture moved eastward and then back to Europe. It served for centuries as a guide to astronomers and a handbook for navigators. It also provided basic information for astrologers.

The methodic excellence of the *Almagest* ensured the supremacy of the Ptolemaic system until the 16^{th} century, in spite of abundant criticism which became more acute as observations increased in number and precision.

Clearly, Hipparchos and Ptolemy were backward in two respects: they rejected the heliocentric ideas of **Aristarchos** and the ellipses of **Apollonios**. In retrospect, this can be understood as resulting from a combination of two factors: since heliocentricity did not lead to greater simplicity or precision, they lacked the conviction to shake off the prejudices of their own environment.

Ptolemy (Claudios Ptolemaeos) was born in Ptolemais Hermeiu, a Greek city of the Thebais, upper Egypt, and flourished in Alexandria. His influence upon later times (until the middle of the 16^{th} century) is second only to that of Aristotle. Assuming that the bulk of his facts, methods, and principles was derived from Hipparchos (in most cases Ptolemy admits it), the credit of his masterly exposition of his subjects and his mathematical treatment of them, belongs to Ptolemy himself. It seems difficult to conceive of two men separated by almost full three centuries as close collaborators, yet their fame is inseparable.

Ptolemy pointed out that the earth is round and that gravity is directed toward its center. In his *Syntax* there is a catalog of 1022 stars found in 48 constellations, each with its own celestial latitude and longitude. He discovered the irregularity of the moon's motion (evection).

In a book entitled '*Optics*' he discussed the *refraction of light*: He realized that it provided an explanation of why bodies immersed in water seem to be nearer to the surface than we find them to be when we try to grasp them.

The attempt to find a correction for "atmospheric refraction", led Ptolemy to make the first extensive physical experiments in which numerical measurements were recorded to discover the amount of bending. In his experiments

---

[279] The world in which Ptolemy lived was a Roman world, whose intellectual ideas was still predominantly Greek.

By this time, the top culture of the West was Greek, not Latin. Greek was the language of science and philosophy while Latin was the language of law, administration and business. Marcus Aurelius wrote his *Meditations* in Greek. Ptolemy and Galen would not have been able to write in Latin, even if they wished to do so. The remarkable thing about the Roman empire, from an intellectual point of view, was its *bilingualism*; every educated man in the West was supposed to know two languages, Greek as well as Latin.

he studied the passage of light from air to water, from air to glass, glass to water and vice versa. His results were not accurate enough to display the simple geometrical rules of refraction.

Ptolemy's geography includes a theory of *map projection*; places are listed with their *longitudes* and *latitudes*. However, in his map of the world he exaggerated the land mass from Spain to China, and underestimated the size of the ocean. This mistake later encouraged **Columbus** to undertake his famous voyage of discovery in 1492.

As a mathematician, Ptolemy devised new geometrical proofs and theorems. He obtained, using chords of a circle and an inscribed 360-gon, the approximations: $\pi = 3\frac{17}{120} = 3.14166$, $\sqrt{3} = 1.73205$.

His serious treatment of *astrology* helped to spread that superstition[280].

132 CE **Zhang Heng** (78–139, China). Mathematician, astronomer and geographer. Invented the first *seismoscope* (132) to record earthquakes. Heng's device was in the shape of a cylinder with 8 dragon heads around the top, each with a ball in his mouth. Around the bottom were 8 frogs, each directly under a dragon head. When an earthquake occurred, a ball fell out of the dragon's mouth into a frog's mouth, making a noise and giving a rough indication of the direction of the initial impulse.

ca 150 CE **Rabbi Nehemiah** (2^{nd} century, Land of Israel). Hebrew scholar and mathematician. Author of the *Mishnat ha-Middot*, the earliest

---

280 Along with the *Almagest*, Ptolemy wrote an astrological treatise by the name of *Tetrabiblos* which is a compilation of Chaldean, Egyptian and Greek folklore and earlier writings. The book remained a standard work until our own day. In that it was even more successful than the *Almagest*, for the simple reason that astronomy being a science was bound to develop and change, while modern astrology being a superstition is essentially the same as the ancient one. The *Almagest* is published anew from time to time for students of the history of science, but has no practical value; on the other hand, new editions of the Tetrabiblos are still issued for the guidance of practicing astrologers.

Many scholars have claimed that the same man could not possibly be the author of the rational *Almagest* and of the *Tetrabiblos*. They forget that astrology was the *scientific religion* of Ptolemy's day. At a time when the old mythology had become untenable, the sidereal religion had gradually taken its place in the minds of men who were loyal to Pagan tradition as well as scientifically minded. Stemming from Greek astronomy and Chaldean astrology, it was a compromise between the popular religion and monotheism; it was a kind of scientific pantheism endorsed by men of science as well as by philosophers, especially the neo-Platonists and Stoics.

Hebrew treatise on mathematics known to us. This book includes his own contributions, as well as those of Greek mathematics. It exerted influence on Persian-Arabic mathematics, especially Al-Khowarizmi. Nehemiah was concerned with the determination of the calendar.

Mishnat ha-Middot became known in modern times through the translation and publication of two manuscripts. The first manuscript, *Cod. Hebr. 36*, in the Münich Library, containing 5 chapters dealing with plane and solid geometry, appeared in a German translation in 1862. The other, *Ms. Hebr. c. 18* of the Oxford Bodleian Library, found more recently, is a fragment consisting of two leaves which contain parts of the 1^{st}, 2^{nd} and 5^{th} chapters already known and, in addition, the beginning of a 6^{th} chapter, hitherto unknown. The fragment, on vellum, contains explanations of the size and the construction of the Tabernacle.

Although Nehemiah had the courage to give the value $3\frac{1}{7}$ for π and offer a different explanation of the Biblical text (**Kings I** *7*, 23), the Talmud restored the canonical value of 3.

He was one of the late pupils of **Rabbi Akiva** (ca 50–134).

The Astrologers

Astrology is the ancient art of divining the fate of men from indications given by the position of the stars (sun, moon and planets). The belief in a connection between the heavenly bodies and the life of man has played an important part in human history. For long ages astronomy and astrology were identified. This combination can be traced back to the earlier phases of Babylonian history (3000 BCE) and directly or indirectly spread through them to other nations. It came to Greece in about 350 BCE and reached Rome before the opening of the Christian era. With the introduction of Greek culture into Egypt, both astronomy and astrology were actively cultivated in the region of the Nile during the Hellenistic and Roman periods. Astrology was further developed by the Arabs from the 7^{th} *to the* 13^{th} *century, and in Europe of the* 14^{th} *and* 15^{th} *century, astrologers exerted dominating influences at court.*

Astrology is based on a theory of divine government of the world. Starting with the indisputable fact that the fertility of the soil is dependent upon the sun shining in the heavens as well as upon the rain that comes from heaven, and taking into consideration the damage done by storms and inundations (to both of which the Euphratean Valley was almost regularly subject), the conclusion was drawn that all the great gods had their seats in the heavens.

In the early age of culture, known as the Nomadic stage (which predated the agricultural stage) the popular moon and sun cults produced a sect of priests (corresponding to the "scientists" of a latter day) who perfected a theory of a complete accord between phenomena observed in the heavens and occurrences on earth. The movements of the sun, moon and five planets were regarded as representing the activity of 7 gods. The system was then extended to include prominent and recognizable fixed stars and constellations. All heavenly phenomena were meticulously remote and correlated with climatic, royal and public events. In this way a mass of traditional interpretations of all kinds of observed phenomena was gathered, and once gathered became a guide to the priests for all times.

Astrology at this stage was centered almost exclusively in the public welfare and the person of the king, i.e., the movements and position of the heavenly bodies point to such occurrences as due of public import and affect the general welfare. The individual interests are not in any way involved, and we must descend many centuries and pass beyond the confines of Babylonia and Assyria before we reach the phase which in medieval and modern astrology is almost exclusively dwelt upon individual horoscope.

In the hands of the Greeks and the Hellenists both astronomy and astrology were carried far beyond the limits attained by the Babylonians, and it is indeed a matter of surprise to observe the harmonious combination of the two fields – a harmony that seems to grow more complete with each age, and that is not broken until we reach the threshold of modern science in the 16^{th} *century. The endeavor to trace the horoscope of the individual from the position of the planets and stars* at the time of birth *represents the contribution of the Greeks to astrology. The system was carried to such a degree of perfection that later ages made but few additions of an essential character.*

The system was taken up almost bodily by the Arab astronomers. It was embodied in the Kabbalistic lore of Jews and Christians, and through these and other channels came to be the substance of the astrology of the Middle Ages. It thus formed a pseudo-science which was placed on equal footing *with astronomy. Moreover, under Greek influences, the scope of astrology was enlarged until it was brought into connection with practically all of the known sciences: botany, chemistry, zoology, mineralogy, anatomy and medicine; colors, metals, stones, plants, drugs and animals were associated with the planets* *and placed under the guidance and protection of one or other of the heavenly bodies. Indeed, the entire realm of the natural sciences was translated into the language of astrology with the single avowed purpose of seeing in all phenomena signs indicative of what the future has in store.*

The fate of the individual, as that feature of the future which had a supreme interest, led to the association of the planets with parts of the body, e.g.: the right ear is associated with Saturn*, the left ear with* Mars*, the right eye (male) with the* sun *and the left eye with the* moon*, the pubis to* Scorpion*, the breasts to* Cancer*, the thighs to* Sagittarius*, etc. Not only was the fate of the individual made to depend upon the planet which happened to be rising at the time of birth or of conception, but also upon its local relationship to a special sign or to certain signs of the Zodiac. With human anatomy thus connected with the planets, with constellations, and with single stars –* medicine *became an integral part of astrology.*

A favorite topic of astrologers of all countries has been the immediate end of the world. As early as 1186 *the earth had escaped one threatened cataclysm of the astrologers. This did not prevent others astrologists from predicting universal deluge in the year* 1524 *– a year as it turned out, distinguished for drought.*

Astrology did not stop after the acceptance of the Copernican system; the postulates of astrology are independent of whether the sun or the earth is the center of our planetary system. ***Kepler*** *himself drew horoscopes.* ***Tycho Brahe****,* ***Gassendi*** *and* ***Huygens*** *subscribed to that superstition.*

George Sarton*, one of the leading historians of science in the* 20^{th} *century and an erudite deeply versed in the European cultural heritage had this to say on astrology and astrologers (1959):*

"America is leading the world in astronomy, and we have every right to be proud of that, but if we be honest, we cannot accept praise for our astronomers without accepting full blame for our astrologers. There are more astrologers than astronomers in America and some of them, at least, earn considerably more than the latter; the astrological publications are far more popular than the astronomical; almost every newspaper has an astrological column which has to be paid for and would not be published at all if a large number of people did not want it.

Astrology was perhaps excusable in the social and spiritual disarray of Hellenistic and Roman days; it is unforgivable today... We would be indulgent to Ptolemy, who had innocently accepted the prejudices endemic in his age and could not foresee their evil consequences, but the modern diffusion of astrological superstitions deserves no mercy".

The Heritage of Ancient Astronomy[281] (3000 BCE–150 CE)

A practical acquaintance with the elements of astronomy is indispensable to the conduct of human life. Hence it was most widely diffused among uncivilized peoples, whose existence depended upon immediate and unvarying submission to the dictates of external nature.

Having no clocks, they regarded instead the face of the sky; the stars served them for almanacs. They hunted and fished, sowed and reaped in correspondence with the recurrent order of celestial appearances. But these, to the untutored imagination, presented a mystical as well as a mechanical aspect. Thus, familiarity with the heavens developed at an early age, through the promptings of superstition, into a fixed system of observation. In China, Egypt, and Babylonia, strength and continuity were lent to this native tendency by the influence of a centralized authority; considerable proficiency was attained in the art of observation, and from millennial stores of accumulated data empirical rules were deduced by which the scope of prediction was widened and its accuracy enhanced. But no genuine science *of astronomy was founded until the Greek sublimed experience into theory.*

Already in the 3^{rd} *millennium BCE,* equinoxes *and* solstices *were determined in China by means of culminating stars. This is known from the orders promulgated by the emperor Yao about* 2300 *BCE, as recorded in the* Shu Chung *[a collection of documents already ancient at the time of Confucius (551–478 BCE)], and Yao was merely the renovator of a system already long established. There is no certainty that the Chinese were then capable of predicting eclipses, but they were probably acquainted with the* 19*-year cycle by which solar and lunar years were harmonized. They made observations in the meridian, regulated time by water-clocks and used measuring instruments of the nature of quadrants.*

---

[281] For further reading, see: **Agnes Mary Clerke** (1842–1907), *History of astronomy*; Pannekoek, A., *A History of Astronomy*, Dover: New York, 1989, 521 pp.

In 1100 BCE, ***Chou Kung****, as able mathematician, determined with surprising accuracy the obliquity of the ecliptic, but his attempts to estimate the sun's distance failed hopelessly as being grounded on belief in the flatness of the earth.*

Circles were divided into $365\frac{1}{4}$ *parts, so the sun described daily one Chinese degree, and the equator began to be employed as a line of reference, concurrently with the ecliptic, probably in the* 2^{nd} *century BCE. Both circles, too, were marked by star-groups more or less clearly designated and defined.*

Cometary records go back in China to 2296 BCE; they are intelligible and trustworthy from 611 BCE onward.

In Egypt the stars were observed that they might be duly worshiped. The importance of their first visible appearances at dawn (for the purposes of both practical life and ritual observance) caused them to be systematically noted. The length of the year was accurately fixed in connection with the annually recurring Nile flood, while the curiously precise orientation of the Pyramids afforded a lasting demonstration of the high degree of technical skill in watching the heavens attained in the 3^{rd} *millennium BCE. The constellational system, in vogue among the Egyptians, appeared to have been of native origin, but they contributed little or nothing to the genuine progress of astronomy.*

Babylonian science lacked the vital principle of growth imparted to it by their successors. From them the Greeks derived their first notions of astronomy: They copied the Babylonian asterisms, appropriated the Babylonian knowledge of the planets and their courses, and learned to predict eclipses by means of the saros.

Records dating from the reign of Sargon of Akkad (3800 BCE) imply that even then the varying aspects of the sky had long been under expert observation. It may be taken as certain that the heavens described by ***Aratos of Soli*** *(315–245 BCE, Greek poet) represented approximately observations made some 2500 years earlier, by the Babylonians, in or near north latitude 40°. In the course of ages, Babylonian astronomy, purified from the astrological taint, adapted itself to meet the most refined needs of civil life. The decipherment of Babylonian clay tablets supplied detailed knowledge of the methods practiced in Mesopotamia in the* 2^{nd} *century BCE. They show no trace of Greek influence, and were the improved outcome of an unbroken tradition. The Babylonian astronomers were not only aware that Venus returns in almost exactly 8 years to a given starting-point in the sky, but they have established similar periodic relations (with periods 46, 59, 79 and 83 years respectively) for Mercury, Saturn, Mars and Jupiter. They were accordingly able to fix in advance the appropriate positions of these objects with reference to ecliptical stars, which served as fiducial points for their determinations. In* *the Ephemerides published year by year, the times of new moon were given, together with the calculated intervals to the first visibility of the crescent, from which the beginning of each month was reckoned. The dates and circumstances of solar and lunar eclipses were predicted, and due information was supplied as to the forthcoming risings and settings of the sun, conjunctions and oppositions of the planets. The Babylonians knew the inequality in the daily motion of the sun, but misplaced by* $10°$ *the perigee of its orbit. Their sidereal year was* $4\frac{1}{2}$m *too long*[282]*, and they kept the ecliptic stationary among the stars, making no allowance for the shifting of the equinoxes. On the other hand, it has been recognized (1900) that* ***Hipparchos*** *had borrowed from Chaldea the lengths of the synodic, sidereal, anomalistic and draconitic months.*

A steady flow of knowledge from East to West began in the 7^{th} *century BCE. The Babylonian* ***Berossos*** *founded a school about* 640 *BCE in the Island of Cos, and perhaps counted* ***Thales of Miletos*** *(624–546 BCE) among his pupils.* ***Pythagoras of Samos*** *(fl. 540–510 BCE) learned on his travels in Egypt and the East to identify the morning and evening stars, to recognize the obliquity of the ecliptic, and to regard the earth as a sphere freely poised in space. The tenet of its axial movement was held by many of his followers; in an obscure form by* ***Philolaos of Croton*** *(ca 450 BCE), and more explicitly by* ***Ecphantos*** *and* ***Hicetas of Syracuse*** *(*4^{th} *century BCE), and by* ***Heracleides of Pontos*** *(a disciple of Plato in 360 BCE).*

A genuine heliocentric system, developed by ***Aristarchos of Samos*** *(fl. 280–264 BCE), was described by* ***Archimedes*** *in his Arenarius, only to be set aside with disapproval. The long-lived conception of a series of crystal spheres, acting as the vehicles of the heavenly bodies, and attuned to divine harmonies, seems to have originated with Pythagoras himself.*

The first mathematical theory of celestial observations was devised by ***Eudoxos of Cnidos*** *(408–355 BCE). The problem he attempted to solve was to combine uniform circular movements so as to produce the resultant effects actually observed. With this end in view, the sun and moon and the* 5 *planets were accommodated each with a set of variously revolving spheres, with their numbers totaling* 27*. The Eudoxian system, after it had been further elaborated and modified by* ***Aristotle*** *and* ***Apollonios of Perga*** *(fl. 250–220*

---

[282] Yet, their observations were amazingly precise; *they computed the length of the year with a deviation less than 0.001 percent from the current value* and their figures relating to the motions of the sun and the moon have only 3 times the margin of error of the 19^{th} century astronomers, armed with mammoth telescopes. Their observations were verifiable, and enabled them to make precise predictions of astronomical events.

BCE), held sway for 1800 *as the characteristic embodiment of Greek ideas in astronomy.*

Greek astronomy culminated in the school of Alexandria. Soon after its foundation, ***Aristyllos*** *and* ***Timocharis*** *(ca 320–260 BCE) constructed the first catalogue giving star-positions as measured from a reference-point in the sky. This fundamental advance rendered inevitable the detection of precessional effects.* ***Aristarchos of Samos*** *made his observations at Alexandria (280–264 BCE). His general conception of the universe was comprehensive beyond that of any of his predecessors.* ***Eratosthenes*** *(276–196 BCE), a native of Cyrene, was summoned from Athenes to Alexandria by Ptolemy Euergetes to take charge of the royal library. He determined the obliquity of the ecliptic*[283] *at* $23°51'$ *(a value too large by* $5'$*), and introduced an effective method of arc-measurement.*

Among the astronomers of antiquity, two great names stand out with unchallenged pre-eminence; ***Hipparchos*** *and* ***Ptolemy*** *entertained the same large designs; they worked on similar methods, and, as the outcome, their performances fitted so accurately together that between them they re-made celestial science. Hipparchos fixed the chief data of astronomy – the lengths of the tropical and sidereal years, of the various months, and of the synodic periods of the five planets, the obliquity of the ecliptic and of the moon's path, the place of the sun's apogee, the eccentricity of its orbit, and the moon's horizontal parallax, all with appropriate accuracy. His loans from Chaldean expertise appear to have been numerous indeed, but were doubtless independently verified. His supreme merit, however, consisted in the establishment*

---

283 The Greek astronomers must have noticed the correlation between the march of the seasons, the yearly variations in the sun's altitude angle above the horizon, the length of day and the changes in distribution of sunlight. Knowing the yearly relative motion of the sun and the earth, and the inclination of the earth's equatorial plane to the sun rays (ecliptic), they must have understood that when the North pole points away from the sun, the northern hemisphere experiences *winter*, and when the North pole points toward the sun, that hemisphere experiences *summer*.

Furthermore, they must have associated the *summer soltice* with the sun's vertical rays striking $23\frac{1}{2}°$ north latitude, and the *winter soltice* with the sun's vertical rays striking $23\frac{1}{2}°$ south latitude. Likewise they knew that at both *equinoxes*, the sun's vertical rays strike the equator. It is questionable however, whether they understood the physical aspect of the situation, namely that rays striking at low angle must traverse more of the atmosphere than rays striking at a higher angle and thus are subjected to greater depletion by scattering and absorption.

of astronomy on a sound geometrical basis. His acquaintance with trigonometry, a branch of science initiated by him, enabled him to solve a number of elementary problems, and he was thus led to focus special attention upon the position of the equinox, as being the common point of origin for measures both in right ascension and longitude. Its steady regression among the stars became manifest to him in 130 *BCE, on comparing his own observations with those made by* ***Timocharis*** *a century and a half earlier, and he estimated it to be not less than* $36''$ *per year. An interval of* 250 *years elapsed before the constructive labors of Hipparchos obtained completion in Alexandria. The Ptolemaic system was, in a geometrical sense, defensible; it harmonized fairly well with observations, although physical reasoning had not been extended to the heavens. To the ignorant it was recommended by its conformity to crude common sense, while to the learned it appealed by the wealth of ingenuity expended in bringing it to perfection.*

Nevertheless, the Ptolemaic model of the universe was wrong. It survived for so long in part because its ad hoc machinery was marvelously adaptable; it survived also because it took for granted elements of physics which were not *calculable at that time and so had to be accepted, willy nilly. But it failed in the end for the same reasons: its calculable results were found wanting, its incalculable bases were seen to be unfounded, and its increasingly baroque architecture was no longer to the mathematical taste of a new generation of thinkers.*

122 CE Romans build *Hadrian's Wall* in Britain to defend against northern tribesmen. The wall, built mainly of stone, runs 115 km from Tyne to Solway.

138–165 CE **Marcion of Sinope** (ca 100 CE – ca 165 CE, Asia Minor and Rome). Created *Gnostic*[284] *Christianity* by a syncretism of Gnosticism

[284] Judaism had never sought to convert outsiders and attract recruits so long as circumcision and ritual food restrictions were enforced. Christianity might have remained a sect of unorthodox Jews, had not one of its adherents set himself to broaden the basis for membership. Paul of Tarsus, a hellenized Jew and Christian, removing these external obstacles, made Christianity universally acceptable.

Still, to the hellenized citizens of the Empire it would not do that Christ should be the son of the God of the Jews. This blemish was avoided by Gnosticism, a syncretic movement that arose at the same time as Christianity. According and Paulian Christianity (Marcion's Church). Although later condemned as a heretic over his unorthodox views, Christianity kept parts of Gnosticism at Nicaea (325 CE) and his replacement theology has infiltrated into the Church of today.

At the beginning, after all the apostles died, the leaders who replaced them were mostly Gentile pagans. These Gentiles had comparatively little understanding of the Old Testament Scriptures unlike the Jewish apostles who had been exposed to the teaching of the Law and the Prophets since birth. This caused a shift in focus to the New Testament (written by fellow converts) and the elimination of anything Jewish. It was very true of the moral codes which Jesus exalted his followers to obey.

---

to Gnosticism the sensible, material world was created by Yahweh, who was really a minor deity, having fallen out with the supreme godhead and thereafter practiced evil. At last the son of the supreme god came to live among men in the guise of a mortal, in order to upturn the false teaching of the Old Testament. These, along with a dose of Plato, were the ingredients of Gnosticism. It combines elements of Greek legend and Orphic mysticism with Christian teaching and other eastern influences, rounding it off with an eclectic admixture of philosophy, usually Plato and Stoicism. The Manichaean variety of later Gnosticism went so far as to equate the distinction between spirit and matter with the antithesis of good and evil. In their contempt for things material they went further than the stoics had ever ventured. They forbade the eating of meat and declared sex in any shape or form to be altogether a sinful business. From their survival for some centuries it seems proper to infer that these austere doctrines were not practiced with complete success.

While orthodox Christians believe that Creation (physical world and men) became corrupt with Adam and 'the Fall', Gnostics believe that Creation was corrupt to begin with, and that the God of Israel (who created the material universe) was a totally different God from the Father spoken in the gospel of Christ.

All this ran contrary to the Hebrew Scriptures. In Hebrew thought, the chief virtue is in oneness, wholeness, "shalom".There is *one* God, Yahweh. There is *one* world consisting of the heavens, the earth, and sheol under the earth, and all creation is good. Each human being is wonderfully made as one cohesive unit. Salvation is found in living life in covenant relationship with Yahweh, and salvation is experienced in immediate time, as well as in the future.

In Hebrew thought, the Messiah is a human being, raised up from the people, chosen by God and anointed to serve and cause redemption to come to the people of Israel. In Gnostic thought, the savior is god, sent down to earth by the main good god to teach all.

It was Marcion who then caused the Church to virtually ignore the Law, the Hebrew Prophets, all the Apostles (except the Gnostic John), and even Jesus himself and focus full attention to Paul and his writing on *grace*.

Marcion was born at the Black Sea port of Sinope to a pagan family. Around 139 CE, he traveled to Rome and converted to Christianity. As a wealthy ship-owner, he made large contributions to the Church and became a respected member in the Christian community.

Marcion's reference was always to the teaching of Paul (the only apostle whom he trusted). He held the Gnostic idea that the whole creation is faulty, being the creation of a lesser god, thus containing no element of the divine. In this he was influenced by *Persian dualism* (*Zoroastrianism*).

Marcion believed that the lawgiver of the Old Testament was the bad God and that no good could be found in the Old Testament and that after Jesus Christ, the Law was obsolete. Jesus has come to free man from the Law. Marcion, therefore, rejected the entire Old Testament, and viewed the Law as opposed to grace.

All this put Christians in a quandary; they wanted the moral authority of the Old Testament, yet they just did not want to follow it.

For several generations, Marcion's Church survived. His anti-Jewish, pro-Paul churches spread throughout the Roman Empire and became a threat to the Messianic faith.

As Christianity became more firmly established, its hostility to the religion of the Old Testament grew fiercer. The Jews, it held, had failed to recognize the Messiah announced by the prophets of old, and therefore must be evil. From Constantine onwards anti-semitism became a respectable form of Christian fervor, though in fact the religious motive was not the only one. It is odd that Christianity, which had itself been suffering appalling persecution, should, once in power, turn with equal ferocity on a minority that was just as steadfast in its beliefs.

156 CE A census estimated the Chinese population of over 50 millions (compared with 70 millions estimated by scholars for the population of the Roman Empire).

160–190 CE **Claudius Galen (Galenus)** (129–200, Greece and Rome). Anatomist, physician, philosopher. The greatest physician of antiquity after Hippocrates, and the father of experimental physiology. Discovered a large number of new facts in the fields of anatomy, physiology, embryology, pathology, therapeutics and pharmacology. Galen made various physiological experiments, e.g., to determine the mechanism of respiration and pulsation, the function of the kidneys, of the cerebrum, and of the spinal cord. He proved experimentally that arteries contain and carry blood (and not air as had been taught up to his time). He also knew that the heart set the blood in motion, but he failed to discover how the blood circulates through the human body (Harvey, 1628), although he came very close to it. He was first to use the pulse as a diagnostic aid.

In his writings (over 500 works, of which only 83 are extant), Galen systematized and unified Greek anatomical and medical knowledge and practice. It was used until the end of the Middle Ages. He dissected numerous animals, but very few human bodies. His writings contain many errors which were accepted by physicians and scholars throughout the Middle Ages because his authority was unquestioned.

Galen was born in Pergamum, Asia Minor. His father, Nicon, gave him his early education. He began his study of medicine at the age of 16 in his native city, and continued his medical studies in Smyrna and Alexandria. In 158 CE he returned to Pergamum and was appointed surgeon of gladiators. From there he went to Rome (161 CE), where he enjoyed great success as a physician. In Rome he gave lectures in the public theater and performed experiments with animals before large audiences. He later became court physician under Marcus Aurelius (169 CE).

161–180 CE **Marcus Aurelius Antoninus** (121–180, Rome). Emperor and *Stoic Philosopher*[285]. Author of *Meditations* (written in *Greek*), a collection of percepts of practical morality. The bulk of his reign was spent in efforts to ward off the attacks of the Germanic tribes across the upper Danube (166–180). He visited Egypt and Athens (176). Worn out at the age of 59, Aurelius died near Vienna, in the midst of a campaign.

He was master of the Empire during one of the most troubled period of its history[286]. His imperial administration, lasting 19 years, was marked by

---

[285] Founded by **Zeno** (336–264 BCE) in Athens and spread to Rome. Stoicism remained dominant through the early Roman empire (31 BCE–192 CE) and claimed among its chief exponents the statesman **Seneca** (4 BCE–65 CE), and the slave **Epictetos** (60–135). But it had to compete with mystical tendencies which found expressions in astrology, the oriental religions (Egyptian *Isis* and Persian *Mithras*), and *Christianity* by which it was finally assimilated.

[286] In the years from the accession of **Marcus Aurelius** (160) to the accession of **Diocletian** (284), basic weaknesses became apparent in the government, in the army, in the economy, and in the society. It was an age of moral corruption – the last effulgence of a dying culture. The military victories of Aurelius gave the Roman civilization two hundred more years of life, in which Christianity might rise to strength so that the collapse of the political order would not mean the destruction of Western civilization.

prudent and generous reforms at home, conceived in a human spirit[287], and by decisive victories on the Parthian and German frontiers; and in all these the Emperor himself was the moving force. The comprehensiveness of his legal and judicial reforms is very striking: slaves, heirs, women and children were benefited.

During his reign, the atmosphere of Roman society was heavily charged with the popular Greek philosophy to which Christianity was diametrically opposed. His upbringing was such that he felt that the policy of the Flavian emperors was the only logical solution to the problems of Roman society. Since the Christians taught a unity which transcended that of the Roman empire, they were regarded as antagonistic to the existing political and social organism. In this age of decadence, the Stoic philosophy held together the civil social order of imperial Rome, and taught *thinking men* the nature of true freedom, which is not dependent upon swords and laws. It was a philosophy imported from Greece blended with the high old Roman virtue, the sense of piety and honesty and office.

Aurelius' *Meditations*, not generally known until late in the 16^{th} century, were written in the midst of public business, and on the eve of battles (166–168) on which the fate of the empire depended – hence their fragmentary appearance, but hence also much of their practical value and even their charm. His thoughts represent a transitional movement, and it is difficult to discover in them anything like a systematic philosophy.

He held the view of **Anaxagoras** – that God and matter exist independently, but that God governs matter. The soul of man is most intimately united to his body, and together they make one animal which we call man;

His Stoic philosophy, on the other hand, prepared the way for the acceptance of Christianity in the dying classical world. The era of competent and conscientious emperors ended with his death in 180 CE. During the century that followed, the army placed a succession of ruthless, uncouth, and politically inept provincial generals on the imperial throne, known as barrack-emperors. Under them the civil service came to be stuffed with semi-literate peasants with little understanding of Greco-Roman political and cultural traditions.

[287] Compelled by the force of depraved public opinion, to be present at the gladiatorial shows and receive the salutes of the poor wretches below in the arena, he refused to look at the slaughter. Detesting these inhuman displays, he read books, or gave audience during the course of the spectacle, and for that he was jeered by the crowd for his aversion. When, in an hour of great public peril, he recruited gladiators in the city to fill the ranks of the decimated legions, the mob threatened to rise against their savior, crying that he designed to turn them all into philosophers by depriving them of their sport.

and so deity is most intimately united to the world or the *material universe*, and together they form one whole.

The goal of life is not happiness, but tranquility or equanimity. This condition of mind can be obtained only by "living conformably to nature", i.e., one's *whole* nature. Consequently, man must cultivate the four chief virtues, each of which has its own sphere: *wisdom* (knowledge of good and evil), *justice* (giving to every man his due), *fortitude* (the enduring of labor and pain), *temperance* (moderation in all things). Man should not yield to the persuasion of the body, when they are not conformable to the rational principle which must govern. This legislative faculty within a man which can be looked from one point of view as conscience and from another as reason, must be implicitly obeyed. He who obeys it will attain a tranquility of mind; nothing can irritate him, for everything is according to nature. As much as life is a composition of elements, death is a decomposition into the same, and altogether not contrary to the reason of our constitution.

The morality of Marcus Aurelius cannot be said to be new when it was given to the world. What gives his sentences their enduring value and fascination is that they are simply the records of his *practice*, not a saintliness of the cloister but the wisdom of the man of the world;

As a Roman Stoic, Aurelius had little understanding of all Eastern cultures, which he held in contempt.

ca 180–211 CE **Clement of Alexandria** (**Clemens Alexandrinus**; ca 150–215 CE; Athens and Alexandria). Greek Father of the Church. With his disciple **Origen of Alexandria** (ca 185–254 CE) laid the groundwork for welding of Christian and Hellenistic thought. Argued that Christianity could profitably utilize pagan Greek philosophy and learning since the latter is based on natural reason and therefore pointed toward truth. Philosophy and secular learning in general could be used to interpret Christian wisdom and therefore philosophy *and* science could be used to understand the Holy Scriptures. This attitude was a compromise between the rejection of pagan learning and its full acceptance[288].

Clement was born of heathen parents in Athens, but lived in Alexandria, where he converted to Christianity. Succeeded his teacher **Pantaenus** as head

[288] This had already been advocated by **Philo of Alexandria** a century earlier, who sought to reconcile the revealed religion of the Pentateuch with philosophical reason as influenced by Plato, Aristotle, Neo-Pythagoreans, Cynics and Stoics. On the other hand, the Latin ecclesiastic writer **Tertullian** (ca 155–225 CE) spoke for the rejectionists when he asked: "What indeed has Athens to do with Jerusalem? What concord is there between the Academy and the Church?"

of Catechetical school in Alexandria. He left Alexandria during persecutions of Emperor Severus (ca 201 CE) and visited Cappadocia, Jerusalem and Antioch.

The recognition that Christianity could not turn away from Greek learning was an essential precondition for the scientific revolution during the late Renaissance.

186 CE Major volcanic eruption at Taupo, New-Zealand.

190 CE Chinese mathematicians use powers of ten.

ca 200 CE Compilation and codification of the *Mishna*, the early oral interpretation of the *Torah* (law of Moses); a collective endeavor of about 350 savants (known as *Tannaaim*). Its formulation extended over a period from 300 BCE to 200 CE when it was committed to writing. The *Tannaaim* labored to formulate a new set of laws which would reinterpret the ancient Mosaic concepts to the sons of Israel living in a Pagan world. As long as the second Temple existed, the rituals, ceremonies and observances, sacrifices, commands and prohibitions made the *Torah* a living spirit of Israel. It was both a state law and religious fountainhead, the guide to daily conduct and the basis for family and social structure of all the adherents to the Covenant[289].

But with the sudden advent of the overbearing and hostile Caesarian Empire, which culminated with the destruction of Jerusalem, the binding ties of Jewish life changed from national institutions, like a land and a government, to religious institutions, like the synagogue and the regulations of everyday life. A thousand practical problems arose that called for immediate solutions: problems concerning marriage and divorce and other aspects of family life; concerning personal hygiene and ritual parity; concerning civil and ceremonial law; dietary obligations and sacrificial cults; concerning the observation of holidays and festivals; the keeping of the Sabbath; the treatment of illness; the care of the poor; and so on.

It was then that the achievements of the spiritual leaders over more than 500 years of the Second Commonwealth were crystallized into a definite rules of conduct under the editorship of **Rabbi Yehuda ha-Nasi**. He summed it up in logical order into a volume of six books known as the *Mishna*, which became a companion to the Bible. Moreover, together with the later *Talmud*,

---

[289] Hebrew: *repetition*, *oral learning*. Outdoor teaching was practiced in Israel and Babylonia ancient academies. Neither teacher nor pupils carried notebooks, as all lessons were committed to memory. The lesson was a discourse, after which the pupils asked questions or engaged in discussions.

it proved to be a time-capsule which metamorphosed the lost land and independence into spiritual values sufficient to maintain and nourish the Jews in exile for almost 18 centuries – a unique phenomenon in the annals of mankind.

According to the traditional view, the canon of the Old Testament closed with the work of **Ezra** (458 BCE). He was followed by the *sofrim* (scribes), to the *Maccabean age* (167 BCE), and these again by the *zugoth* (pairs; the reputed heads of the Sanhedrin), down to the *Herodian age* (150–30 BCE). The codification process culminated with in **Hillel** (80 BCE–8 CE) and **Shamai**, the founders of the two great rival schools, and to this famous pair the work of collecting the *Halakah* ("legal decisions") has been ascribed. It was Hillel who gave *Mishna* its scientific foundation.

The ensuing period of the *Tannaaim* ("teachers"; about 10–220 CE) is that of growth of the *Mishna*. The best known representatives of the said generations are listed in Table 1.4.

The *Mishna* was created amidst one of the most tragic and bloody periods in the history of the Jewish nation, through which it lost major parts of its homeland. The *Tannaaim* witnessed three great national disasters [the war for Jewish independence, 66–70 CE; the Diaspora rebellion, 114–117 CE; Bar-Kochba revolt, 132–135 CE] in which a total of $2\frac{1}{4}$ millions perished (out of 3 millions) over a period of 100 years.

With the codification of the *Mishna*, Jewish destiny shifted from Rome to Parthia.

Table 1.4: Leaders of the five generations of Tannaaim

I. (40–90 CE)	**Rabban Gamliel the Elder** (ca 30 BCE–52 CE) (teacher of the apostle Paul; astronomer) **Rabban Yohanan ben Zakkai** (7 BCE–77 CE) (founder of the Academy of learning at Yavne[290])
II. (90–115 CE)	**Rabban Gamliel II** (ca 30–117 CE) **Rabbi Eliezer ben Horkanos** **Rabbi Joshua ben Hannania** (35–117 CE) (astronomer) **Rabbi Eleazar Ben Azariah**
III. (115–135 CE)	**Rabbi Akiva ben Yosef** (55–136 CE) (fixed the official text of the canonical books) **Rabbi Ishmael** **Rabbi Tarfon** **Rabbi Yossi ha-Glili**
IV. (135–170 CE)	**Rabbi Shimeon Bar-Yohai** (80–160 CE) **Rabbi Meir** **Rabbi Nehemiah** **Rabbi Yohanan ha-Sandlar** **Rabbi Nathan of Babylon** **Rabbi Yossi ben-Halafta**
V. (170–210 CE)	**Rabbi Yehuda ha-Nasi** (137–210 CE) (known as the *Patriarch*; brought the *Mishna* into essentially its present shape; a close friend of Emperor **Caracallah** (Marcus Aurelius Severus Antoninus, 211–217 CE).

[290] *Massada* and *Yavne* have come to symbolize two antithetical aspects of Jewish history, the former that of a resistance, the latter that of a surrender. The spirit of *Massada* permeated the first act through which the Hebrews took on Canaanites, Philistines, Assyrians, Egyptians, Babylonians, Greek and Romans, scrapping their way through defeats and victories in a struggle for national survival.

The spirit of *Yavne* permeates the second act, representing the Jewish response called for by new world order. The secret of Jewish survival is summed up in Jewish ability to select the right weapon at the right time.

During the next 300 years the *Mishna* was supplemented by many recorded discussions or commentaries, contributed by Babylonian as well as Israeli scholars. Some of these were legalistic, some philosophic, some folklorist, some allegorical. These later writings known as the *Gemara* (Aramaic: *learning*), were intended to expound the Mishna and to facilitate the understanding of its difficult passages.

200–250 CE **Shmuel the Astronomer** (Yarchinai, 165–254 CE, Babylonia). Jewish jurist, educator, astronomer and physician. He became the director of the Mesopotamian Academy of Nehardea. Opposed the medical superstitions of the day and introduced more rational methods. His astronomical interests were centered upon the *Hebrew Calendar*, which he improved.

ca 250 CE **Diophantos of Alexandria** (206–290 CE). Greek mathematician. Author of *Arithmetica*[291], one of the greatest mathematical treatises of ancient times. It is a masterly exposition of algebraic analysis, so thorough and complete in its time, that most previous works in its field ceased to be of interest and passed into oblivion. In the *Arithmetica*, algebraic methods advanced to a peak of achievement which was not to be surpassed before the 16^{th} century. Following the rediscovery of a manuscript of Diophantos in the late Renaissance (1570 CE), **R. Bombelli** (1572 CE) included many problems of the *Arithmetica* in his *Algebra*.

In 1621, **Bachet de Meziriac** (1581–1638 CE, France) published an edition of the *Arithmetica* which contained the Greek text as well as his Latin translation. Bachet's edition was made famous by the notes written in the margin of a copy of his book by **Fermat**. Since that day, Fermat's notes have stimulated a prodigious output in the theory of numbers.

Diophantos solved indeterminate equations of second and higher degrees[292] in integers by ingenious devices (but no general method). Used *abbreviations*

---

[291] The *Arithmetica* is a collection of 130 problems giving numerical solutions of determinate equations (those with a unique solution), and indeterminate equations. The method for solving the latter is now known as Diophntine analysis. Only 6 of the original 13 books survived.

Diophantos was always satisfied with a rational solution and did not require a whole number. He did not deal in negative solutions and one solution was all he required to a quadratic equation. In fact, most of the *Arithmetica* problems lead to quadratic equations. Although he did not use sophisticated algebraic notation, he did introduce an algebraic symbolism that used an abbreviation for the unknown.

[292] Diophantos never dealt with the simpler *linear* equations. This was left to **Aryabhata** (476–550 CE) and **Brahmagupta** (598–678 CE) in India.

for powers of numbers and for relationships and operations throughout the six surviving books of the "Arithmetica". He was familiar with the rules of powers combination, equivalent to our laws of exponents, and he had special names for the reciprocals of the first six powers of the unknowns, quantities equivalent to our negative powers.

Thus the identity

$$(a^2 + b^2)(c^2 + d^2) = (ac + bd)^2 + (ad - bc)^2 = (ac - bd)^2 + (ad + bc)^2,$$

which played important roles in Medieval Algebra and modern trigonometry, appears in the work of Diophantos. Various new properties of numbers were discovered by him: e.g., no number of the form $8n + 7$ can be the sum of three squares. As far as notation is concerned, Diophantos has a good claim to be known as the 'Father of Algebra'.

The few details of the personal life of Diophantos available to us, are all contained in his epitaph. It is said to have been composed shortly after his death by a close friend. It states that the $\frac{1}{6}^{th}$ of his life was spent in childhood (14 years), after a $\frac{1}{12}^{th}$ more had elapsed he grew a beard (at 21), that when a $\frac{1}{7}^{th}$ more had passed he married (at 33), and that five years later his son was born (at 38). The son lived to half his father's age and 4 years later the father died (84).

A commentary on his work (first six books out of the original 13) written by **Hypatia** (d. 415), daughter of **Theon of Alexandria**, is the ultimate source of all extant manuscripts and translation of the *Arithmetica*. The remainder of the work was probably lost before the 10^{th} century.

Book I of the *Arithmetica* opens with the following dedication: "*Knowing, my most esteemed friend Dionysios, that you are anxious to learn how to investigate problems in numbers, I have tried, beginning from the foundations on which the science is built up, to set forth to you the nature and power subsisting in numbers. Perhaps the subject will appear rather difficult, inasmuch as it is not familiar* (*beginners are, as a rule, too ready to despair of success*)*. But you, with the impulse of your enthusiasm and the benefit of my teaching, will find it easy to master. For eagerness to learn, when seconded by instruction, ensures rapid progress*".

253 CE **Plotinos** (204–270 CE, Rome). Philosopher. The most important representative of *Neoplatonism*. Under Ammonius Saccas he became imbued with the eclectic spirit of the Alexandrian school. Having accepted the Platonic metaphysical doctrine, he applied to it the Neo-Pythagorean principles and the Oriental doctrine of Emanation. The results of this introspective mysticism were collected by him in a series of 54 treatises arranged in 6 *Enneads* which constitute the most authoritative exposition of Neoplatonism.

The principal doctrine of Plotinos states that God is a *transcendental principle* who creates the universe out of himself in a process which is timeless and eternal. Although present in all objects of creation, he is distinct from them, supreme, above and before all things. God cannot be categorized or classified as spiritual, material, soul substance, or in any other category, but must be regarded as *One* who, without possessing specific attributes, yet creates all things.

God is the absolute permanent One (as **Parmenides** taught), but the universe as his creation comprises a changeable plurally (as **Heraclitos** taught). The physical and spiritual universe (living and nonliving matter) is the by-product of the One, embracing **Anaxagoras**' *Nous*, as well as **Plato**'s concepts of ideas, substance, and matter as emanations from God. The ideas, inasmuch as they are immanent in the *Nous*, are not subject to error. But the soul, being a product of the *nous*, is only its image, and hence is fallible.

Plotinos was born of Roman parents at *Lycopolis*, Egypt. At Alexandria he attended the lectures of Ammonius Saccas. He joined the Persian expedition of Gordian III (242 CE), with the object of studying Persian and Hindu philosophy on the spot. After the assassination of Gordian (244 CE), he was obliged to take refuge in Antioch, whence he made his way to Rome and set up as a teacher there. He soon attracted a large number of pupils. The Emperor Gallienus and his wife Salonina were also among his enthusiastic admirers, and favored his idea of founding a Platonic Commonwealth (Platonopolis) in Campania, but the opposition of Gallienus counselors and the death of Plotinos prevented the plan from being carried out.

268–301 CE **Porphyrios (Malchos)** (ca 234–305 CE, Tyre and Rome). Greek scholar, historian, logician and *Neoplatonic*[293] *philosopher.* Exerted great influence on Neoplatonic trends in philosophy and theology in the Middle Ages. Contributed indirectly to mathematics (in his commentary on Aristotle) through the *Tree of Porphgry*[294] (now called "*binary tree*"): categories are split into two mutually exclusive and exhaustive parts on the basis of a property

[293] *Neoplatonists* resolutely reaffirmed the *Pythagorean* conviction that mathematics had a decisive heuristic value as regards man's search for the patterns of the physical world.

[294] A *connected graph* is a set of points (vertices) joined by line segments in such a way that a path can be found from any point to any other point. If there are no circuits, a connected graph is called a *tree*. In 3D, real trees, crystals, river tributaries, brittle solid cracks and electric discharges are few examples of natural *trees*. Sets of 2–12 points have respectively 1, 1, 2, 3, 6, 11, 23, 47, 106, 235, 551 topologically distinct *trees*.

possessed by one part but not the other. This prepared the use of genealogical trees and the division of a subject matter into hierarchic categories.

Porphyrios was born at Tyre. After studying grammar and rhetoric under Longinus he went to Rome (262 CE) and studied under Plotinos (262–268 CE). He then lived a few years in Sicily and returned to Rome (273 CE). His most distinguished pupil was **Iambilichus**. When advanced in years, he married Marcella, a widow with seven children and an enthusiastic student of philosophy.

Porphyrios was a violent opponent of Christianity and defender of Paganism. He wrote numerous books on a great variety of subjects, among them a biography of Pythagoras, comments on Aristotle, history of philosophy and history proper. He dated the Book of Daniel to the time of Antiochus Epiphanes.

269 CE The great library at the Alexandria Academy was partially burned. The Queen of Palmyra, Septimia Zenobia, captured Egypt.

ca 300 CE **Iambilichus** (ca 260–330 CE, Syria). Neoplatonic Greek philosopher. Follower of Plotinos and Porphyrios. Born in Chalcis, Syria to a rich illustrious family.

Although lacking in originality, he gave a more systematic application of Pythagorean number-symbolism. He went beyond the Pythagoreans in making mathematics a principle for *all* that can be observed in the cosmos. (*"I believe we can attach mathematically everything in nature and in the world of change"*).

Iambilichus defined mathematics as the "prognostic science of nature". He stated that his search for causes, or the causal approach to nature, consisted "in positing mathematical things as causes" from which the objects in the perceptible world arise. His was the Pythagorean belief that only what was possible in mathematics was possible in the structure of nature, and nothing could exist that implied a mathematical impossibility. He formulated a program that had a ring strongly reminiscent of some aspirations of twentieth-century physics.

The Origins of Chemistry[295] (0–400 CE)

Chemistry, or the study of the composition of substances, had its origin about the beginning of the Christian era in the Hellenistic-Egyptian city of Alexandria, and was probably the result of blending together of material from two sources: (1) the speculative philosophy of the Greeks, and (2) the Egyptian practical arts of working in metals and glass, the dyeing of tissues and the falsification of precious metals and gems.

Alexandria has a mixed population of native Egyptians, Greeks, Syrians, and Jews, but was essentially Greek in culture. It contained a temple of the god Serapis, two libraries and the Museum (or University) and, in later times, the Christian Church of St. Mark and the famous Pharos or lighthouse, 152 *m high. One library, said to contain* 700,000 *books, was destroyed by fire in* 47 *BCE. The Museum was mainly interested in classical literature, philosophy, mathematics, and medicine.*

Under the merger of the above two streams of knowledge, the technical arts gradually assumed a new form, and the result was the "divine" or "sacred" art of making gold or silver. This contained the germ of chemistry, and during the first four centuries a considerable body of positive, practical chemical knowledge came into existence – the early chemistry.

The Egyptian technique, handed down in the workshops, is described in the papyri of Leyden and Stockholm, discovered at Thebes in 1828. *It is written in Greek and dates probably from about* 300 *CE, although much of the material is probably derived from older Egyptian sources. It summarizes technical information on metallurgy, dyeing, and imitation of precious stones.*

The earliest of the true chemical treatises, written in Greek at Alexandria during the first 4 centuries CE, speak clearly of the artificial production of gold and silver and the imitation of valuable dyes. The earliest name for chemistry is the "divine art"; the name chemeia *appears about 250 CE and seems to derive from the Egyptian word* chemi*, meaning "black or burnt", or "Egyptian", or both. There were Greek treatises on the divine art in existence as early as the first century CE. Practical operations and apparatus were invented about the same time by* ***Maria the Jewess****, who described apparatus for distillation.*

The most copious author who wrote a kind of chemical encyclopedia was ***Zosimos of Panapolis*** *in Egypt, who lived about 250–300 CE, and first used the name* chemieia*. His books contain interesting descriptions and illustrations of chemical apparatus and experiments (solution, filtration, fusion, sublimation, distillation, etc.) and several chemical substances and reactions*[296]*. During his time there arose belief in transmutation of metals.*

300–1000 CE **Tiahuanaco**. Andean Empire (Peru and Bolivia). A dominant pre-Inca civilization which built large stone buildings decorated with carvings of animals and geometric figures. It had a strong understanding of science, especially of astronomy and medicine. The remains of a great ceremonial center are still to be seen on the Altiplano in Bolivia, near Lake Titicaca (Puma Punku Temple) at an altitude of 4200 m. Their architectural megalithic stone work presupposes a social organization, a strong central government which could direct the use of manpower into non-food-producing channels on such a large scale. All this must have been done by a large supply of workers with a long technical tradition.

The empire declined rapidly after 1000 CE as a result of a major climatic change, causing a drought that lasted for 80–100 years.

The livelihood of this one-million people empire depended on a sophisticated agricultural system of raised fields interlaced by water channels. The water served as solar collectors, which kept away the killing frost during night by radiating infra-red heat over the ground crops. Due to the prolonged drought, water could not be replenished and the frost controlled the environment of the valley.

---

[296] E.g., he explains the burning of limestone to form quicklime ($CaCO_3 \Leftrightarrow CaO + CO_2$). The Alexandrian chemists were very near to recognition of gases.

ca 320–350 CE **Pappos of Alexandria**. Greek geometer and scientist. The greatest mathematician of the final period of ancient science and the last mathematical giant of antiquity. One of his theorems is cited as the basis of modern *projective geometry*. A prolific writer on mathematical and scientific subjects. His main work (340 CE) is "*Synagoge*" (*Collection*), in 8 books. It is an account of previous research, equally valuable for the historical information it contains and for the additional explanations. It includes the definition of conic sections by means of the directrix, involution of points, and the theory of center of gravity.

His surviving books form one of the richest sources of information about ancient mathematics and exerted a stimulating force upon the greatest scholars of the 17^{th} century[297]. Building upon his teachings, **Descartes**, **Fermat**, **Pascal** and **Desargues** opened the way for the development of modern mathematics.

Ptolemy's gigantic efforts were followed by lull of more than a century. So much so that when Pappos, the next great mathematician, appeared he felt obliged to prepare a summary of earlier books. Pappos was not a teacher like Euclid or Ptolemy, but a learned man who was familiar with the whole Greek mathematics and tried to summarize it in his own peculiar way. He was a good commentator because he was on the level with his greatest predecessors and was able to add ingenious theorems and problems of his own, but he was not very methodical. He had taken notes on the mathematical classics, invented and solved problems, and then classified them in eight books. Each book is preceded by general reflections which give to that group of problems its philosophical, mathematical and historical setting.

Book I covered arithmetic (and is lost) while Book II is mostly lost but the remaining part deals with large numbers. In Book III he gives a construction of the arithmetic, geometric and harmonic means. Book IV contains properties of curves including the *spiral of Archimedes* and the *quadratrix of Hippias*.

---

297 Pappos was among the first keen observers of mathematical patterns in nature. Thus he noticed that the bees use the regular hexagon exclusively for the shape of the cells in the honeycomb:

"*Though God has given to men the best and most perfect understanding of wisdom and mathematics, he has allotted a partial share to some of the unreasoning creatures as well... This instinct is specially marked among the bees. They prepare for the reception of the honey the vessels called honeycombs, with cells all equal, similar and adjacent, and hexagonal in form*".

It is of interest to note that **Pliny the Elder** reported inaccurately in his *Natural History* (ca 75 CE) on the rectangular and circular shape of honeycombs.

Book VII includes the famous *Pappos' problem*: "*given several straight lines in a plane, to find the locus of points, such that when straight lines drawn from it to the given lines at a given angle, the products of certain segments shall be in a given ratio to the product of the remaining ones*". This problem exercised Descarte's mind and caused him to invent the method of coordinates explained in his *Géométrie* (1637). It acted like a seed lying dormant for more than 1300 years and then producing the flowering of analytic geometry.

The final Book VIII is mechanical and largely derived from Heron of Alexandria. This book may be considered as the climax of Greek mechanics and helps us to realize the great variety of problems to which Hellenistic mechanicians addressed themselves.

The whole *Collection* is the culmination of Greek mathematics. Little was added to it in the Byzantine age and the Western world, having lost its knowledge of Greek together with its interest in higher mathematics, was not able to avail itself of all the riches which Pappos has put together.

The ideas collected or invented by Pappos did not stimulate Western mathematicians until very late, but when they finally did, they caused the birth of modern mathematics – analytical geometry and projective geometry. That rebirth, from Pappos' ashes, occurred within four years (1637–1640). Thus was modern geometry connected immediately with the ancient one as if nothing had happened between.

Table 1.5: The Greatest Greek Mathematicians

Name	Life-span	Major contribution
Thales of Miletos	624–548 BCE	The first geometer
Pythagoras	580–500 BCE	Notions of 'Axiom' and 'proof' in geometry
Hippasos of Metapontum	490–430 BCE	Irrationality of $\sqrt{2}$; Dodecahedron
Zeno of Elea	490–430 BCE	Infinity and Infinitesimals
Antiphon the Sophist	480–411 BCE	Method of 'Exhaustion'
Hippocrates of Chios	470–410 BCE	Use of letters in figures; Reductio ad absurdum
Theodoros of Cyrene	470–410 BCE	Irrationality of $\sqrt{3}$; $\sqrt{17}$; $\frac{1}{2}(\sqrt{5}-1)$
Archytas of Tarentum	428–347 BCE	Arithmetic; Harmonic and geometric series; Theory of music
Theaetetos of Athens	415–369 BCE	Incommensurability; Regular polyhedra
Eudoxos of Cnidos	408–355 BCE	Approximate 'integration' procedure ('Exhaustion')
Menaichmos	380–320 BCE	Discovery of conic sections
Euclid	330–260 BCE	Plane geometry; Platonic solids; 'E. algorithm'
Aristarchos of Samos	310–230 BCE	Father of Astronomy; Trigonometry
Archimedes	287–212 BCE	Father of Mathematical Physics

Table 1.5: (Cont.)

Name	Life-span	Major contribution
Eratosthenes	276–197 BCE	Applied geometry; Number Theory
Apollonios	262–200 BCE	Properties of conic sections (circle, ellipse, parabola, hyperbola)
Zenodoros	200–140 BCE	Isometric figures
Hipparchos of Nicaea	180–110 BCE	Spherical trigonometry; Father of trigonometry
Heron of Alexandria	60–120 CE	Areas and volumes; Engineering
Menelaos	65–130 CE	Spherical trigonometry; 'M. Theorem'
Ptolemy of Alexandria	85–165 CE	Mathematical astronomy; Law of sines
Diophantos of Alexandria	206–290 CE	Father of algebra
Pappos	350–410 CE	Advent of projective geometry

Avantgarde Chinese Mathematics (300 BCE–1303 CE)

Unlike the early Greeks, who were interested in formal logic, the practical minded Chinese were at heart applied mathematicians and numerical analysts. To them, the primacy of arithmetical operations was their main concern. The notation of a number, in the Pythagorean sense, as an atomic *and invisible entity did not trouble them. Neither did Chinese mathematicians have to face the dilemma of the irrational numbers, which perplexed the Greeks. Their 'dialectical logic' is best exemplified in their method of solving equations. A solution is assumed beforehand, and the answer is obtained to the desired accuracy by performing as many iterations as are necessary. Thus, they invented the 'rule of double false position' (ca 300 BCE), one of the oldest methods of approximating a real root of an equation*[298].

For over a thousand years, the Chinese used this method, refining and extending it, passing it to the Arabs, who in turn passed it on to the Europeans. The method still continues to have basic applications in modern numerical analysis under the name of the chord or chain rule.

*Other notable contributions of Chinese mathematics which, at the time of their conception were yet unknown (and remained so until the 14th century) were associated with the solution of a system of simultaneous linear equations. Although composed sometime between 300 BCE to 200 CE it nevertheless failed to lead to the concept of determinants before the 17th century (**Seki Kowa**, Japan, 1683).*

As an example consider a single linear equation in one unknown $ax+b=0$. *Let* g_1 *and* g_2 *be two preliminary guesses for the value of* x *and let* f_1 *and* f_2 *be the errors arising from these guesses; Then* $ag_1+b=f_1$; $ag_2+b=f_2$. *From these we obtain by simple manipulation*

$$a(g_1-g_2)=f_1-f_2; \qquad b(g_2-g_1)=f_1g_2-f_2g_1$$

and hence

$$x=-\frac{b}{a}=\frac{f_1g_2-f_2g_1}{f_1-f_2}=\frac{1}{f_1-f_2}\begin{vmatrix} f_1 & f_2 \\ g_1 & g_2 \end{vmatrix}$$

The method can be easily extended to system of simultaneous equations. It is known as the 'rule of double false position'. The later transmitted it, through India, to the Arabs, who in turn passed it to the West. Other important contributions are:

- *The concept of negative numbers appears for the first time in China near the beginning the Christian era.*

[298] Variants of this method are to be found in *Babylonian* mathematics, in *Alexandrian* mathematics (Heron's method), and in *Hindu* mathematics.

- *The development of an algorithm for extracting square and cube roots was first explained in the Chiu Chang, and elaborated and refined by* ***Sun Tsu*** *(ca 300 CE). The 13^{th} century mathematicians extended the algorithm to the extraction of roots of any order. The Arab mathematician* **Al-Kashi** *(ca 1400 CE) and later European adopted the method.*

- *The development of numerical methods of solving high-order equations in the 13^{th} century – methods similar to those associated with* ***Horner*** *and* ***Ruffini****, at the beginning of the 18^{th} century (****Ch'in Chiu-Shao****, 1247).*

  Thus, to solve the equation $x^2 + 252x - 5292 = 0$, *Ch'in first established that there is a root between 19 and 20. He then used the transformation* $y = x - 19$ *to obtain the equation* $y^2 + 290y - 143 = 0$, *with a root between 0 and 1. His final approximate solution is* $x = 19 + \frac{143}{1+290}$.

  Similarly, to solve the equation $x^3 - 574 = 0$ *he set* $y = x - 8$ *to obtain* $y^3 + 24y^2 + 192y - 62 = 0$, *yielding as an approximate root* $x = 8 + \frac{62}{1+24+192} = 8 + \frac{2}{7}$.

  Indeed, 'Horner's method' must have been well known in medieval China; it was used by several Sung mathematicians for the numerical solution of cubic and even quartic equations. The unknown quantity in these equations was represented by a monad and the zero by a little circle, (the Chinese zero may have come directly from India with Buddhism or it may have been imported later by Muslims). Red and black ink were used respectively to represent positive and negative numbers.

  A mathematician, ***Li Yeh*** *(1178–1265), wrote treatises in 1248 and 1259 involving problems on quadrilaterals and circles, with their solutions. Instead of using red and black colors to designate positive and negative numbers, Li differentiated the latter by drawing diagonal strokes across them.*

- *Pascal's triangle of binomial coefficients was known in China as early as 100 CE. Chinese mathematicians used it to solve numerical equations of higher degree.*

- *The value of π estimated by* ***Liu Hui*** *(ca 200 CE) and* ***Tsu Chung Chin*** *(ca 400 CE), namely*

  $$3.141\,592\,6 < \pi < 3.141\,592\,7,$$

  (by successive application of the Pythagorean theorem to polygons with up to 24576 sides!), remained the must accurate values for a thousand years.

- *A method of solving system of simultaneous linear equations (up to 5 unknowns), which is basically a variant of a method developed by **Gauss** 1500 years later. It appeared in a text 'Nine Chapters on the mathematical Arts' by an unknown author.*

- ***Sun Tsu** (c 300 CE) and **Chin Chiu Shao** (ca 1250) devised a novel approach to the solution of* indeterminate equations *of the first degree. It culminated with the* Chinese Remainder Theorem *of elementary number theory. Their general solution predated the work of **Euler** and **Gauss** by the five hundred years.*

  Indeterminate analysis arose from problem in Calendar making and astronomical calculations. All Calendars need a beginning. A Calendar constructed during the Wei dynasty (220–65 BCE) took as its starting-point the last time that winter solstice coincided with the beginning of a lunar month and was also the first day of an artificial 60-day cycle, known as chia tsu. *The objective was to locate exactly the number of years (measured in days) since the beginning of the calendar.*

  Other practical problems of indeterminate analysis arose from engineering and military applications, and architecture.

  To restate the problem of the calendar in modern symbolic notation, let y be the number of days in a tropical year, N the number of years since the beginning of the calendar, d the number of days in a synodic month, r_1 the number of days in the 60 day cycle between winter solstice and the last day of the preceding chia tsu, *and r_2 the number of days since the beginning of the lunar month. The number of years since the beginning of the calendar can then be calculated from*

  $$yN \equiv r_1 (mod\ 60) \equiv r_2 (mod\ d).$$

  More complex alignments, including planetary conjunctions, were built into models for estimating the beginning of Calendars, and as early as the 5^{th} century CE Chinese astronomers solved a set of 10 linear congruences.

Through history China has been relatively isolated from other cultural centers due to the natural barriers such as the Himalayas and the Central Asian plains. Yet, these geographical barriers were not sufficient to exclude all contacts:

By 2^{nd} century CE trade over the Silk Routes from China to the West was at its height, and along with the goods went ideas and techniques. In the centuries to come, the Classical civilization of both East and West would suffer invasions small and large, culminating in Mongol hegemony over vast *stretches of the Eurasian plains, which both served as instruments for diffusion and led to the convergence of ideas and technological practices. In examining the dissemination of Chinese mathematics, one needs to look at the Hindu and Arab connections.*

While there is little evidence of Chinese science in any of the extant Hindu texts, we have evidence of from 7th century on that translations were made of Hindu astronomical and mathematical texts which were mentioned in the records of the Sui and Tang dynasties. The texts contain sections on Hindu numerals and operations, and sine tables. A surviving Chinese block-print text contains Hindu numerals, including the use of a dot to indicate zero.

There is evidence of Chinese diplomats posted at the Court of the Guptas in India in the middle of the 1st millennium CE. A number of Chinese Buddhist scholars made their pilgrimage to holy places in India, bringing back many texts for translation.

The Arab connection is better documented: there are a number of reports of political and diplomatic links between the Arab world and China to supplement trade relations. Arab travelers (including ***Ibn Battuta****, ca 1350 CE), gave detailed accounts of Chinese society and science.*

Chinese mathematics may have made specific borrowings from Arab sources: it is possible that trigonometric methods used in astronomy may have been transmitted through Arab and Hindu contacts. In constructing a calendar in the 14th century, ***Kou Shou Ching*** *used spherical trigonometric methods which seem to have Arab origins.*

Avenues of direct transmission of mathematical lore from China to the West did probably exist: as early as the 3rd century BCE, Chinese silk and fine ironware were to be found in the markets of Imperial Rome. And a few centuries later a whole gamut of technological innovations found their way slowly to Europe. Thus, it is reasonable to expect that mathematical knowledge from China diffused westwards to Europe, there perhaps to remain dormant during Europe's Dark Ages, but coming to life once more with the cultural awakening of the Renaissance.

Finally, during the late 17th and 18th centuries, Europe became aware of the Chinese intellectual heritage and there began an 'East-West Passage' of scientific ideas through the Jesuit connection.

The question is often asked as to why did modern science evolved in the West and not in China? The answer is quite simple. In the absence of the concept of a divine being who acted to legislate what went on in the natural world and whose decrees formed inviolate 'laws' of nature, Chinese and Japanese science was condemned to a curious stillbirth. It is interesting *to ponder whether science would have flourished in medieval and Renaissance Europe were it not for the Judeu-Christian theology.*

Although differences in scientific progress between East and West can indeed be traced to theological differences, other factors are also responsible: Eastern philosophy lacked the ingredient of reductionism*, whereby the properties of a complicated system are understood by studying the behavior of its component parts.*

Eastern philosophy emphasized holistic *interconnectedness of physical things. The ability to dissect natural systems has been crucial to the progress of science in the West. On the other hand, the notion that the whole is more than the sum of its parts arrested the motivation of Eastern thinkers to know something without knowing everything!*

Finally, in the East (especially in China) stability was much more prized than freedom and the rulers had a powerful vested interest in not being challenged. Thus, the continuous interest in science in the West may be sought in the Western tendency to be dissatisfied with the status quo*. In China, a philosopher like Thomas Aquinas would have become an unchallenged authority; in Europe, his system was questioned within a generation after his death.*

Mathematics in Ancient India[299] (320–500 CE)

During the Gupta dynasty, Hindu mathematics and astronomy reached its zenith. The Hindus had long been interested in these subjects and surpassed even the Greeks of the Hellenistic period in some branches of Mathematics. Using abstract principles of algebra, the Hindus could cope with much more difficult concepts than found in the visible *Greek demonstrations of geometry.*

[299] For further reading, see: Joseph, G.G., *The Crest of the Peacock*, Princeton University Press, 2000, 455 pp.

Greek algebra was rudimentary, but the Hindus invented the concept of negative quantities, solved quadratic equations, and calculated the square root of 2.

In 1881, *in a sequestered village called Bakhshali (on the north-west border of India), a farmer came upon an old manuscript, known today as The Bakhshali manuscript. The content of this document proved to be mathematical, ranging over topics in arithmetic, algebra and mensurational geometry. It was written in an old form of Sanskrit and its content were composed not later than the* 4^{th} *century CE.*

Most of the illustrative problems are of the type requiring the solution of linear equations or of an indeterminate equation of the second degree. The solutions display the writer's knowledge of average value, and series, and a considerable skill in operation with fractions. Consistent use is made of the positional decimal system, where a heavy dot serves the purpose of a zero. Calculations involve positive and negative numbers, the sign (+) *is used to denote a negative number or subtraction, and multiplication is often indicated by juxtaposition.*

The Hindus summed (algebraically!) arithmetical and geometrical progressions, and solved commercial problems in simple and compound interest, discount and partnership, mixture and cistern problems, similar to those found in modern texts. They admitted negative and irrational numbers and recognized that a quadratic has two formal roots. They also showed remarkable ability in indeterminate equations, and were perhaps the first to devise general methods in this branch of mathematics. Unlike ***Diophantos****, who sought only one rational solution to an indeterminate equation, the Hindus endeavored to find all possible solutions especially for linear indeterminate equations, which Diophantos did not treat at all. The Hindu work on indeterminate equations reached Western Europe too late to exert any beneficial influence. The Hindus were not proficient in Geometry. Postulational developments were nonexistent. Their geometry was largely empirical and generally connected with mensuration.*

In trigonometry, the Hindus introduced the notion of the sine and calculated[300] *tables of 24 sines, progressing by intervals of* $3^\circ 45'$.

300 The sine of $3^\circ 45' = 225'$ was considered equal to the arc of $225'$. The other sines up to sin $86^\circ 15'$ were calculated by the identity

$$\sin(n+1)\alpha = 2\lambda \sin(n\alpha) - \sin(n-1)\alpha,$$

where $\alpha = 225'$, $\lambda = \cos\alpha$, and λ was approximated by the number $\left(1 - \frac{1}{450}\right)$.

The Hindu astronomers knew that the earth was round and that it rotated and they had some understanding of gravitation. Their most famous invention, however, was the system of the so-called 'Arabic numerals', which first appeared in India in the 3^{rd} *century BCE.*

By the time of the Guptas, Hindus were using a sort of decimal system. The zero first appeared in the works of scholars who were familiar with the Hindu numerals. It is significant that Christian Europe did not know of Hindu-Arabic numerals until the 12^{th} *century and did not use them extensively until the* 16^{th}*. The two civilizations were too far apart, and contacts between them were too infrequent, for even such obviously useful ideas to travel quickly from one region to the other.*

At about 412 CE the Gupta state began to decline, chiefly because of internal disorders. By the 6^{th} *century the Gupta kingdom had collapsed. During the next six centuries India suffered a succession of internal wars and foreign invasions, and the overwhelming influence of Brahman priests made it difficult for secular rulers to exercise effective political control. When a new Hindu Empire finally emerged, it was ruled by the Muslims, not the Hindus.*

Nevertheless, Hindu mathematics continued to flourish up to 1400 CE with considerable achievements in the field of algebra, trigonometry and infinite series, in contradistinction to the Greeks who excelled in geometry.

321 CE The edict of the Emperor **Flavius Valerius Aurelius Constantinus**[301] (274–337 CE), known as **Constantine**[302], enacted that magistrates, citizens and artisans were to rest from their labors 'on the venerable day of the Sun, namely *Sunday*, the first day of the week. In the same cen-

---

301 Proclaimed emperor in 306 CE; won his first campaign against his rival Maxentius (312 CE) by virtue of the fact that Christians sided with him, and that Christian centurions led his legions. Constantine set aside all persecution of Christians and admitted them to his court at the very beginning of his reign. When he defeated the Eastern Roman Emperor Licinius, he established full equality for Christians, and shortly thereafter he began a cautious repression of the Pagans. In 329 CE, he began a series of legal actions which expressed his hatred for the Jews. In the year 330 CE, all people of the Roman Empire were forbidden (under death penalty) to convert to Judaism. The death penalty was also specified for all Jews who taught the *Torah* to gentiles or encouraged gentiles to embrace Judaism. The death penalty was prescribed for any Jew who married a gentile. All intermarriage was forbidden, unless a Jew converted to Christianity. Judaism was referred to in imperial pronouncements as the *secta nefaria* ("abominable religion"), or the *secta feralis* ("mournful religion") or the "bestial religion". As a final touch, Constantine forbade any Jew to set foot in Jerusalem.

So long as the early Christians were persecuted by Imperial Rome, the Christians did not turn upon the Jews. They needed them too desperately: Christians were saved from death by Jewish bribes; and thousands of Christians were brought out of slavery to Jews. During these early years, Christians were regarded as Jews by Jews – a condition that lasted into to 4^{th} century CE in some cities of Asia Minor. It was only when Christianity became the official state religion of the Roman Empire that the separation of Jew and Christian was complete, and *anti-Semitism* became one of the foundation stones of the new religion. By the time of Emperor Constantine, Christianity had won the tacit approval if not the total commitment of the most viable and thoughtful section of the Roman Empire's population. The need for Jewish help that had been lessening over the 3^{rd} century CE, now ceased.

Thus, Christianity was established in the Western world in the holy hatred of Judaism – a Hatred that would exact from the Jew suffering beyond description, untold millions of lives, and a river of blood.

It is of no credit to the Christian Church that it erased the years of Jewish-Christian brotherhood, so that the murderous attitude of so many Christians toward Jews, in the centuries that followed Rome's acceptance of Christianity, might not be softened by any memory of Jewish mercy and loving kindness toward Christians.

302 Hadas, M., *Imperial Rome*, Time-Life International: The Netherlands, 1966, 190 pp.

tury, Christmas was assigned to 25 December, because on that date each year was celebrated the birth of the sun to a new life after the winter soltice. Easter, being a lunar feast in origin, retained a variable date.

325 CE *The Council of Nicaea* (Asia Minor) marks the rigidification of the Christian Church. Although the Julian calendar removed much of the confusion of civil reckoning of time, and was adopted throughout the Roman Empire, the *moon* continued to cause complications. The feasts of the Jewish and Christian years were fixed by the moon; the Passover was set by the date of the full moon in the month of which the 14^{th} day (from new moon) fell on or after the *vernal equinox*. The date of Easter, in turn, depended on the date of Passover: most Christians wanted Easter to be the Sunday following the 14^{th} day of the moon (those who placed it *on* the 14^{th} day were regarded as heretics, and called *Quartodecimans*).

The problem of the date of Easter was officially settled at the Council of Nicaea: Easter Day was to be (and still is) the first Sunday after the 14^{th} day of the moon that occurs on, or directly after, the vernal equinox. At that time, March 21 was the date of the vernal equinox. (It was on March 25 in 46 BCE, the date of the Julian reform, but slipped back to the 21^{st} on account of the accumulated discrepancy between the Julian year and the tropical year.) Thus the date of Easter is set by luni-solar reckoning, and its fluctuations by more than a month from year to year are a good illustration of the complication involved. At any rate, the possibility of an occasional coincidence with the Jewish Passover was avoided.

At the bottom of these 'calendar-exercises' was the desire of the Christian Church to separate the Jews from the Christians, segregate them, make Judaism illegal and finally make Judaism disappear altogether.

The fact was that in 325 CE Judaism still appealed to a great many people among the Pagans as well as among Christians. There were many Christians who respected the Synagogue and its traditions as institutions of Mother Religion. Since Christianity was a movement among the lower classes of the empire's society, the more cultured Pagans had more respect for Judaism which had for centuries been a part of the Roman world.

Thus, the bishops prevailed upon the emperor to prevent Pagans from becoming converts to Judaism, and also take away from the Jews one of the political privileges which they had long enjoyed. Many of the Christian clergy, who now stood close to the Roman government, urged the emperors to deal harshly with Judaism. But the Roman government had a great deal of respect for old Roman law, and the law had always permitted Judaism to be practiced. As the Church acquired power, it began to use unfair methods which have flagrantly contradicted the great ideas for which Christianity stands.

The council of Nicea marks an important change in the attitude of the Church towards the Jews. Until now the rivalry for converts had been based upon an idealogical basis. Now, however, the Church took up the fight and carried it on with the assistance of the government. The immediate results were the litigations of empire-wide anti-Jewish laws, religions and economical harassments and violent persecutions, especially in Israel (351 BCE). Many of the Talmudic scholar there had to flee the country and escape to Babylonia.

355–390 CE **Oribasius of Pergamum** (ca 325–400 CE). Greek physician. Personal physician of Emperor Julian. Compiled a medical encyclopedia. Reputed discoverer of the *salivary glands*.

358 CE **Hillel III** (286–365, Israel). Reformer of the Hebrew Calendar. Jewish patriarch in Israel from 330 to 365 BCE. Political persecution made it impossible for the dispersed Jewish communities to communicate each year with the Judean Sanhedrin for the determination of the fasts and feasts. Hillel III fixed the calendar for the whole Diaspora and for all time to come in 358 CE.

Hebrew Mathematics (200 BCE–500 CE)

The Talmud, which literary means "the study", is the name given to a work of many volumes, written partly in Hebrew and partly in Aramaic, which embodies the teaching and opinions, on religious and sociological matters, of the ancient Jewish sages during a period of some 700 years (200 BCE *to 500* CE*). In addition it contains the theological, theosophical and philosophical views, as well as the moral and ethical maxims, of those sages. It is further interwoven with many anatomical, physiological, medical and anthropological observations of scientific character. The Talmud consists of distinct portions:*

(1) The Mishna contains the teachings transmitted from generation to generation by word of mouth. It represents the legal traditions (based on the written law of the Pentateuch) of some 310 eminent scholars over 14 generations (zugoth and Tanaaim) dating from the time of **Simon the Just** *(fl. ca 200* BCE*) to that of* **Yehuda ha-Nasi** *(137–210* CE*),*

who compiled and edited it. It was canonized sometimes during 210–220 CE.

(2) *The Gemara consists of commentaries on the Mishna. It represents the discussions and disputations of the Amoraaim, who were the directors and members of the Babylonian or Jerusalem academies (220–470* CE*). They numbered about 2000 savants, over a span of 7 generations.*

Each school of Amoraaim, that of Babylonia and that of Israel, expounded the Mishna in somewhat different manner from the other: The Talmud Bavli ("Babylonian Talmud") was compiled in the Mesopotamian academies of Nehardea, Sura, and Pumbedita. Its compilation began by **Rav Ashi** *(375–427* CE*) and it was canonized in 525* CE*. The Talmud Jerushalmi ("Jerusalem Talmud") was compiled by the Israeli academies. It is much smaller in size and scope and its discussions do not exhibit the same dialectical acumen as is shown in the Babylonian edition.*

While the primary substance of the Talmud *lay in expounding and developing civil and religious law, a considerable acquaintance with the various branches of* mathematics *was mandatory in connection with such legislation.*

Thus, the determination of the calendar, legislation regarding the sowing of fields, as well as certain other religious observances, demanded a knowledge of branches of mathematics such as algebra, geometry and trigonometry. None of these sciences are dealt with in any systematic manner in the Talmud, but scientific problems are alluded to casually in relation to the legal questions under consideration. Hence we find that statements of mathematical and astronomical interest are scattered about, in a haphazard way, throughout the many thousands of pages of the numerous treatises comprising the Babylonian and Jerusalem Talmuds and their various addenda.

The astronomical facts directly or indirectly mentioned in the Talmud show that the participants of the discussions must have possessed a considerable ingenuity and skill in mathematical computations and geometrical constructions. In fact, as far as astronomical lore is concerned, the Talmud reflects the best definitive knowledge available in the 5^{th} *century* CE*. The following example will substantiate this claim:*

In the field of pure mathematics, the knowledge of the Hebrews equaled that of the Babylonians, Egyptians and Romans, but certainly did not equal that of the Greeks in their geometrical speculations. Not only did they not produce mathematicians on the level of Thales, Pythagoras, Euclid and Archimedes, but there is no evidence whatever that they discovered anything original in mathematical theory.

While the Greeks studied mathematics for its own sake and felt a strong craving to speculate and discover new mathematical facts, the Talmudic sages were satisfied with applying (with varying levels of skill) what simple mathematical tools they possessed to the various practical problems with which they had to deal in their exposition of civil and religious laws. For this reason and others, the foundations *of the classical physical sciences were laid during* 1550–1750 *without direct Jewish participation.*

Thus, for example, the Tannaaim and the Amoraaim used the Babylonian value of $\pi = 3$ *as late as the* 5^{th} *century CE while Archimedes in the* 3^{rd} *century BCE (as well as the Egyptians before him!), had given more exact values. Likewise, they used the Pythagoreans' approximation*[303] $\sqrt{2} \approx 1.4$, *which they needed in their calculations of areas.*

In the field of applied mathematics, *however, the Hebrew scholars exhibited great ingenuity and originality, which led them, serendipitously, to the brink of great discoveries in 5 distinct areas:*

I. Problems of the Hebrew Calendar[304]

Before the departure of the Israelites from Egypt (ca 1250 BCE) their year commenced at the autumnal equinox; *but in order to solemnize the memory of their deliverance, the month of Nisan (or Aviv) in which that event took place, and which falls about the time of the* vernal equinox, *was afterwards regarded as the beginning of the ecclesiastical or legal year. In civil affairs, and in regulation of the Jubilees and sabbatical years, the Jews still adhere to the ancient calendrical year, which begins with the month of Tishri, about*

---

303 $\sqrt{2} > \sqrt{\frac{49}{25}} = \frac{7}{5}$ [an *upper bound* is obtained by *Heron's approximation* $\sqrt{a^2+b} \leq a + \frac{b}{2a}$ for $a = 1$, $b = 1$, leading to $\sqrt{2} < \frac{3}{2}$]. They knew that 1.4 is not the exact value for $\sqrt{2}$ but did not bother to estimate the difference [Talmud Yerushalmi, *Erubin* **2, 1**] because further accuracy was not necessary for their applications.

304 For further reading, see:

- Feldman, W.M., *Rabbinical Mathematics and Astronomy*, Hermon Press, 1978, 239 pp.
- Reingold E.M. and H. Dershowitz, *Calendrical Calculations*, Cambridge University Press, 2001, 422 p.

the time of the autumnal equinox. After their dispersion, the Jews found it necessary to utilize the astronomical rules and cycles of the more enlightened heathen, in order that their religious festivals might be observed on the same day in all the countries through which they were scattered.

The canon of the Old Testament was closed with the work of ***Ezra*** *(fl. 458 BCE). He was followed by the Sopherim (scribes), and the sages of the Talmud (200 BCE–500 CE). While the primary work of the Talmudic savants lay in expounding and developing the civil and religious law of the Bible, a considerable acquaintance with the various branches of science was necessary in connection with such legislation.*

The determination of the calendar required sound knowledge of astronomy, since not only were the Jewish festivals fixed on given days of the lunar month, but they also depended on the position of the sun. Passover, for instance, which begins on the 15^{th} *day of the month of Nisan, must also occur in the month of the wheat harvest or Aviv (Deut* **16**, *1). The month of Tishri must take place in the autumn. Further, the position of the moon in relation to the sun, as well as its height above the horizon at any moment, had to be computed mathematically, for the purpose of ascertaining whether the new moon could be visible at that given moment. This procedure was necessary for the purpose of fixing the beginning of every new month.*

In about 200 CE, ***Mar Shmuel*** *proposed to adopt the Metonic cycle of* 19 *solar years, by which the Jewish lunisolar year is regulated to the present day. The determination of the beginning of a month by the Phase Method prevailed until* 358 CE, *when it was replaced by the Fixed Calendar Method which makes use of the Mean Conjunction, or Molad (literally, "birth"), to determine the beginning of the month.*

The Phase Method operated as follows: to determine whether the moon is visible at any moment, and to ascertain the exact moment of true conjunction, it is necessary to know the moon's true position (celestial latitude and longitude) at that moment. First, the moon's mean longitude was determined. Then, the Talmudic rabbis were confronted with the ascertainment of the moon's mean longitude at sunset, or at any given interval after sunset on a given day. (The time of sunset is calculated by first finding the sun's longitude on the day in question, and using the longitude to compute the sun's declination on the same day.)

Prior to Kepler's time, the above calculations were not based on the elliptic motion of the planets. Instead, the moon's path was constructed by means of eccentric circles with epicycles, a device which however ingenious from a mathematical standpoint, is a purely fantastic one, devoid of any physical basis. In such a theory, the moon's apparent diameters when nearest to and furthest from the earth, should be in a proportion of about $2:1$ *instead* *of about 1.14: 1, which is the actual value. Moreover, complicated as the epicyclic theory was, it became still more involved if one tried to explain a few of the numerous irregularities of the lunar orbit.*

The theory of Keplerian motion is not only simple, but has the merit of being true. Indeed, the calculation of solar and lunar longitudes on the basis of an elliptical orbit is extremely simple.

Having found the moon's longitude, the Talmudic rabbis next had to ascertain whether in that position in the heavens the new moon would be visible *in the neighborhood of Jerusalem. For as the beginning of the month was fixed on the accredited evidence of witnesses, who reporting having seen the new moon soon after sunset on a certain day, it was the duty of the Calendar Council not only to test their evidence by stringent cross-examination, but also to ascertain by* mathematical calculations*, whether the moon could in fact be seen at that particular moment, at the particular place from which the witnesses came. (This involves laborious and detailed calculations which were ingeniously perfected in the Middle Ages by* ***Maimonides****, although they were somewhat inaccurate.) The council sat in Jerusalem on the* 30^{th} *of each Hebrew month to receive witnesses. If after cross-examination and further confirmation of their evidence by mathematical calculations, the Council concluded that the new moon was indeed seen by the witnesses at the time they mentioned, that day was proclaimed to be the* 1^{st} *of the month without any further delays.*

A month of 29 days was called a defective month *and one with 30 days was called a* full month*. It was possible for 3 months to be consecutively full if (owing to unfavorable atmospheric conditions) the new moon was not visible. If however, no witness appeared for 3 months, then the beginning of the next month was determined by calculations alone. No year was allowed to have more than 8 or less than 4 full months so that no lunar year lasted more than 356 or less than 352 days.*

When the Court was satisfied that a new moon had actually been seen, the President declared the new moon to be consecrated and news spread to people outside Jerusalem by means of bonfires on the top of the mountains. When the awaited signal was observed at neighboring mountains, similar fire signals were lit, and thus information was rapidly transmitted to distant places.

This method was continued until deliberate attempts to confuse the Jews were made by the Samaritans, who maliciously lit signals at improper times. Therefore, these fire signals were altogether abolished toward the end of the 2^{th} *century* CE *by* ***Yehuda ha-Nasi*** *(137–210* CE*), and couriers were sent instead (seven times a year) to convey the tidings. As these could not reach the more distant places before the* 31^{st} *day of the old month, the residents of those places used to celebrate two days for their holidays because they were* *not sure whether the first of the month was the* 30^{th} *or the* 31^{st} *day. In the case of New Year (Rosh Hashana), two days were (and still are) kept even in Jerusalem, in case witnesses arrived late in the day.*

Note that the beginning of the month was not fixed by the moment of the true conjunction but by the moment the crescent of the new moon was seen — which was at least 18 *hours after the conjunction.*

In the construction of the Fixed Calendar, numerous details require attention. The calendar is dated from the creation, which is considered to have taken place in the year 3761 BCE[305]*. The year is luni-solar with the following structure: as the average length of the synodic month is about* $29\frac{1}{2}$ *days, and as a calendar month must have an integral number of days and must start at the same hour of the day — viz.,* 6 *p.m. — it has been agreed to make a civil month consist alternatively of* 30 *days (full month) and* 29 *days (defective month). Thus, Nisan (1), Sivan (3), Av (5), Tishri (7), Kislev (9) and Shvat (11) are full, while Iyar (2), Tamuz (4), Elul (6), Marheshvan (8), Teveth (10) and Adar (12) are defective in an ordinary regular year consisting of* 354 *days =* 50 *weeks +* 4 *days. This arrangement must, however, be modified in a number of ways due to the following disparities:*

- *The astronomical lunar year exceeds the civil lunar year by*

$$12 \times [29^d : 12^h : 44^m : 3\frac{1}{3}^s - 29^d : 12^h] = 8^h : 48^m : 40^s.$$

  Hence it is necessary, at fixed intervals, to add a day to the ordinary year by making one of the defective months full, giving rise to an ordinary full year of 355 *days. The defective month chosen is Marheshvan. Such a procedure, if adopted, say, every* 3^{rd} *year, necessarily overbalances the disparity, and hence at other (longer) fixed intervals, the excess so introduced is adjusted by subtracting a day from one of the full months, making that particular year only* 353 *days. Such a year is called an ordinary defective year, and the full month chosen for this purpose is Kislev.*

- *The Hebrew calendar, being based on the Metonic cycle of* 19 *years, adopts a fictive mean solar year of length*

$$\frac{235}{19} \times [29^d : 12^h : 44^m : 3\frac{1}{3}^s] = 365^d : 5^h : 55^m : 25\frac{25}{57}^s,$$

305 From Biblical, Talmudic and other traditional lore the period between Adam and the Exodus amounted to 2448 years, and between the latter and the destruction of the 2^{nd} Temple there elapsed another 1380 years, making a total of 3828 years; and as the destruction of the Temple is considered to have taken place in the year 68 BCE, the above fiducial follows.

which exceeds the tropical year by 6.6 minutes. With respect to this year, the lunar year of 12 lunations falls short by $10^d : 21^h : 6^m : 45\frac{25}{57}^s$*. This amounts to* $\frac{10^d : 21^h : 6^m : 45\frac{25}{57}^s}{29^d : 12^h : 44^m : 3\frac{1}{3}^s} = \frac{7}{19}$ *of a synodic month.*

Hence, if in the course of every cycle of 19 years 7 extra months are intercalated, making 12 ordinary years of 12 months each (= 144 lunations), and 7 leap years of 13 months each (= 91 lunations), the sun and the moon will have (almost) exactly the same relative mean positions in the heavens at the end of the cycle as at its beginning (it would be exactly right if one could neglect the 6.6^m *discrepancy between the Hebrew solar year and a tropical year*[306]*). The order of the leap years, in each cycle of 19 years, is*

---

306 The 'solar year' of $365^d : 5^h : 55^m : 25.44^s$ is an *arbitrary* figure designed to make the solar year *exactly* $\frac{1}{19}$ of 235 lunations. Since it is about 6.6 minutes *longer* than the present value of the tropical year, the accumulated difference during the 1500 years that the Fixed Calendar has been in use, is about 7 days. Hence, the beginning of Passover (which according to Biblical injunction should fall in the *first spring month*, viz., during the 30 days between the 21^{st} of March and 19^{th} of April) has been shifted forward by a complete week. Indeed, already in 1929 the Passover began on April 25, i.e., 6 days later than the Biblical limit. In order to remedy this it is necessary to *reform the Hebrew Calendar by introducing a different cycle with a different sequence of leap years*. This is done in the following way:

$$\frac{\text{present length of tropical year} - \text{present length of astronomical lunar year}}{\text{present length of synodic month}} \approx$$

$$\frac{10^d : 21^h : 10^s}{29^d : 12^h : 44^m : 3^s} = \frac{939610}{2551443}.$$

Converting this ratio into a continued fraction, we get

$$\cfrac{1}{2 + \cfrac{1}{1 + \cfrac{1}{2 + \cfrac{1}{1 + \cfrac{1}{1 + \cfrac{1}{17 + \ldots}}}}}}.$$

If we stop at the dotted line, the value of the fraction becomes $\frac{123}{334}$, which means that very approximately the excess of a tropical year over a lunar year is $\frac{123}{334}$ of a synodic month. Hence, if in the course of every cycle of 334 years we introduce 123 leap years, the excess would be practically wiped out. Indeed, such an arrangement would make the 334 modified civil years only about 39 minutes less than 334 tropical years, and it would take about 12,500 years (instead of about 200 years as it does now) for the difference to accumulate to one day.

As $334 = 19 \times 17 + 11$, the order of the leap years could continue as at present

$\{3, 6, 8, 11, 14, 17, 19\}$. *A Hebrew year,* $Y = x + 3761$, *is leap if the residue of* $\frac{Y}{19}$ *is a member of the above series, where* x *is the Gregorian year*[307]. *The intercalary year is inserted as Adar bet ("*2^{nd} *Adar"), just after Adar aleph ("*1^{st} *Adar").*

The Hebrew month begins at 6 p.m. of the day on which the moon is in conjunction (Molad). Hence, if the Molad of any given month is known, that of the next month is ascertained by adding an average lunation $L = 29^d : 12^h : 44^m : 3\frac{1}{3}^s$. *Thus, if the Molad of any given month is known, (say, day number =* M_1*) then that of any other month (*M_2*),* n *months after or before the given month, is found from the relation:* $M_2 = M_1 \pm nL$.

The most important Molad of each year is that of the month of Tishri which determines the New Year Day of that year. Having found the Molad of Tishri of the first year of any given cycle, the Molad of Tishri of any year in that cycle easily follows [e.g., the year 5606 was the first of the 296^{th} *cycle, and the mean new moon appertaining to the* 1^{st} *of Tishri for that year was Oct. 01, 1845,* $15^h : 42^m : 43\frac{1}{3}^s$*].*

There are five separate occasions which necessitate the postponement of the New Year Day by one or even two days. These postponements depend on the exact moment at which a Molad occurs, and necessarily entail a lengthening of the year by one or two days (with the consequent lengthening of one or two months in that year). A full embolismic (leap) year may have up to 385 days, in order that certain festivals may fall on proper days of the week for their due observance.

Note that whereas the accuracy of the phase method hinges on the determination of the appearance of the crescent of the new moon, the accuracy of the Fixed Calendar Method depends on the interval between true and mean conjunction, which is at most 15 hours (positive or negative). In one respect, however, the Phase Method was more accurate: the lunar year was made to keep pace with the solar year by intercalating an extra month whenever there was an actual need for it (as found by the size of the discrepancy between the date of Passover and that of the calculated, or observed, vernal equinox) instead of intercalating at regular intervals – as is done under the Fixed Calendar Method. But on the whole, the advantages of the Fixed Calendar Method considerably outweigh its disadvantages.

The Jewish Calendar was progressively improved during the ages by three distinguished astronomers:

---

for 17 complete Meton cycles of 19 years, as well as the first 11 years of the 18^{th} cycle. After that, a new 343 year's cycle would have to begin.

307 We ignore here the Gregorian calendar's own slight fluctuations about the earth's (current) astronomical tropical year.

- ***Rabban Gamliel II*** *(30–117 CE)*
- ***Shmuel*** *(165–254 CE)*
- ***Hillel III***, *(286–365 CE)*

In the year 357 CE, political persecutions made it impossible for the dispersed Jewish communities to communicate each year with the Judean Sanhedrin for the determination of the fasts and feasts. Hillel III thus fixed the calendar for the whole Diaspora and for all time to come in 358.

II. General Astronomy and Cosmology

Although there was no Hipparchos or Ptolemy amongst them, the Rabbis certainly produced several astronomers of considerable merit: ***Yohanan ben Zakkai*** *(7 BCE–77 CE);* ***Gamliel II*** *(ca 30–117, Yavne);* ***Joshua ben Hannania*** *(35–117);* ***Shmuel*** *(165–254);* ***Eliezer Hisma***[308] *(ca 60–120);* ***Yohanan ben Gudgada*** *(ca 60–120);* ***Jossi ben Halafta***[309] *(ca 95–150);* ***Nathan of Babylon*** *(ca 90–160);* ***Abayei***[310] *(278–338);* ***Hillel III*** *(286–365).*

The physical nature of comets and their orbits was unknown until Newton showed them to move in ellipses or in parabolas. It is therefore not surprising that the Talmudic astronomer ***Shmuel*** *(ca 200 CE) acknowledged his ignorance of the nature of these celestial bodies (Berachot* **58**^{b}*). It is, however, remarkable that although, until the middle of the* 17^{th} *century, even the most civilized nations did not know the period of any comet, the period of at least*

---

308 Rabban Gamliel II was rebuked by Rabbi Joshua ben Hannania for having refused to promote his pupils Eliezer Hisma and Yohanan ben Gudgada in spite of their great excellence. Consequently, Gamliel sent for them offering them promotion, but in their great humility they refused to accept it. He then sent for them a second time and said: "*Do you suppose I am offering you greatness? It is slavery that I am offering you since it is said* (*I Kings* **12**, 7) *that a king is a servant of his people*".

309 **Jossi ben Halafta** defined the differential positions of the sun in the heavens at different times of the year as well as the relation between the ecliptic and the equator [*Erubin* **56**^{a}].

310 **Abayei** understood the motion of the planets very well and knew the 28 year Solar Cycle [*Berachot* **59**^{b}].

one comet was known to **Joshua ben Hannania** *(ca 85* CE*), for he said [Horayoth* $\mathbf{10}^a$*]:*

"A star appears every 70 *years and leads ships astray" (by causing the captains to steer by it erroneously). Apparently Joshua possessed some data on the apparitions of comet Halley during his lifetime and before his time [87 BCE, 12 BCE, 66* CE*].*

The biblical account of the creation of the universe *is presented in* Genesis **1***, 1–4; it is very incomplete but highly attractive, because it is pervaded by a breath from primitive times.*

The Talmudic scholars noticed immediately that in the biblical cosmology, the existence of light apart from the sun is presupposed. Their way of interpreting the biblical revelation is not inconsistent with the current Big Bang theory:

- *"Rabbi Abahu said: God used to create universes and destroy them, recreate them and destroy them again..." (Genesis Rabba* **9***).*
- *"Rabbi Judah said in the name of Rav: When God created the universe, it kept expanding until God ordered it to halt, and it stopped" (Hagiga* **12***).*
- *"The universe is made in the form of a sphere" (Yerushalmi, Avoda Zara* **3***).*
- *"Rabbi Eleazar said: The light that God created on the first day, is used by man to observe the Universe from one end to the other" (Hagiga* **12***).*

Another important astronomical problem was the determination of sidereal periods *on the basis of* synodic periods*.*

Synodic period *is defined as the time of orbital revolution of a planet (or asteroid, or earth's moon) w.r.t. the sun-earth line. In practice, it is measured as the time interval between two successive conjunctions or between two successive oppositions. At their conjunctions, Mercury and Venus are not visible, but by interpolations carried out over many years (or even centuries), these times have seen computed, and the synodic periods are known with great accuracy. Because of the* elliptical *orbits of earth and other planets (and asteroids) about the sun – and of the moon about the earth – the times of conjunction or opposition do not occur with exact regularity.*

The synodic periods result from the difference between sidereal periods of the planets and that of the earth. The more distant the planet is from the sun, the slower it travels and the longer is its sidereal period (the time required for a planet to complete one orbit around the sun). The inner planets gain a lap on the earth between similar conjunctions, whereas the outer planets lose a lap between oppositions.

The relation between sidereal and synodic period can be developed by determining the fraction of a lap gained or lost each day. Thus (ignoring non-uniform angular speeds attributed to orbital ellipticities), we denote by $\frac{1}{S_i}$ *the fraction of its orbit that a planet travels in one day, by* $\frac{1}{E}$ *the fraction of its orbit the earth travels in one day, and by* $\frac{1}{S_y}$ *the fraction of a lap that the planet gains or loses on the earth each day. Here* S_i *and* E *denote the mean sidereal years of the given planet and earth, respectively, while* S_y *denotes the planet's mean synodic period.*

We find in the Talmud (Shabat **75**^{a}*; Genesis Raba* **10***, 4) that the calculated sidereal periods of the planets Venus, Mars, Jupiter and Saturn are respectively* 10 *months,* $1\frac{1}{2}$ *years,* 12 *years and* 30 *years. Clearly these periods could not have been directly observed, nor precisely calculated before the times of Kepler, Galileo and Newton. The only data that the Talmudic sages could have used were the synodic periods of the five planets, known to* ***Hipparchos*** *(ca 150 BCE). With the aid of these, the sidereal periods can be evaluated arithmetically, using the simple approximate relations based on additivity of angular speeds:*

$$\frac{1}{S_i} = \frac{1}{E} + \frac{1}{S_y} \qquad \text{(Mercury, Venus)}$$

$$\frac{1}{S_i} = \frac{1}{E} - \frac{1}{S_y} \qquad \text{(Mars, Jupiter, Saturn)}$$

where

S_i = *sidereal period (m days, say)*
S_y = *synodic period*
E = *365.2422 mean solar days (tropical year).*

The following table compares modern values with the results quoted by the Talmudic savants:

Planet	*Synodic period (mean solar days)*	*Sidereal period (tropical years)*	
		Talmud (ca 450 CE)	*Modern*
Venus	*584*	*0.8*	*0.615*
Mars	*780*	*1.5*	*1.881*
Jupiter	*399*	*12*	*11.865*
Saturn	*378*	*30*	*29.650*

III. The Eulerian limit $\frac{1}{e} \approx \left(1 - \frac{1}{n}\right)^n$, n large [Euler 1748].

The Talmudic scholars needed to know how to divide an inheritance among ten daughters and one son in a rational way such that the son is not deprived [Jerusalem Talmud, Ketuboth **6***, 6; Babylonian Talmud, Nedarim* **39***].*

If each daughter took an equal share of ten percent, the poor son would be left empty handed. So, ***Rabbi Yehuda ha-Nasi*** *(fl 180 CE) devised the following scheme: the first daughter takes $\frac{1}{10}$ of the property value, the second daughter receives $\frac{1}{10}$ of the remaining property, etc. Finally, the son gets what is left after all ten daughters collected their shares. Clearly, the share of the k^{th} daughter is $\frac{1}{10}(1 - \frac{1}{10})^{k-1}$, $k = 1, 2, ..., 10$, while the son gets*

$$\left(1 - \frac{1}{10}\right)^{10} = 0.348678440 > \frac{1}{3}.$$

Now, the Talmud says that: "...the son receives a little bit more than one third and the daughters receive together a little bit less than two-thirds...".

There is no way that the Rabbis in the 2^{nd} century CE could have calculated the value of $(1 - \frac{1}{10})^{10}$ with the mathematical tools available in the Hellenistic period. Although they were acquainted with the contemporary Alexandrian mathematics of **Heron** *(90–120 CE),* **Nicomachos***(100 CE), and the earlier results of* **Euclid** *(300 BCE),* **Archimedes** *(250 BCE) and* **Apollonios** *(230 BCE), this feat was beyond the capability of even Greek mathematics.*

My guess is, therefore, that the result $(1 - \frac{1}{10})^{10} > \frac{1}{3}$ was derived either empirically or geometrically (e.g. using Euclid's method of dividing a line segment into n equal parts).

Only in the 17th century, with Napier's logarithms (1614) and Newton's Binomial Theorem (1676), could one see that

$$e = \lim_{n\to\infty}\left(1+\frac{1}{n}\right)^n = \lim_{n\to\infty}\left[1+1+\frac{n(n-1)}{2!n^2}+\frac{n(n-1)(n-2)}{3!n^3}+\cdots\right]$$
$$= 2+\frac{1}{2!}+\frac{1}{3!}+\cdots = 2.718281828459045...$$

and

$$\lim_{n\to\infty}\left(1-\frac{1}{n}\right)^n = \frac{1}{e} = 0.36787944...$$

IV. Probability – Prior and Posterior Probabilities – Bayes' Theorem (1736)

The factor that ensured the primacy of Jewish thinkers in pioneering ways of thinking about chance in practical situations was that Orthodox Jews were forbidden to gamble. The Greeks might have discovered probability, for they were addicted to dice-throwing. But the dice they used were made from the astragalus bones of a sheep (what would be the knuckle-bones if sheep had knuckles). These were very irregular in shape, so that dice were biased and there was not an equal likelihood of each side falling uppermost. Because of the astragalus' imbalance, it was not a random device, so it was impossible for the statistical law of large numbers ('If the number of tests of an event is large, then the proportion of successes in the tests is close to the likelihood of the event') to manifest itself. By contrast, the elaborate system of casting lots used by Jewish priests did exactly what it was devised to do; that is, gave everyone an equal chance of being chosen.

The historical origin of the lottery system is the annual choice of one of two goats to be the 'scapegoat', carrying the heavy load of sin into the wilderness as the Goat of Azazel. (The other goat was sacrificed). Since the choice here was between only two participants, it would be demonstrable that the chances of being chosen were equal for both. This idea could be easily extended to include the whole group of temple priests who were daily caught up in casting lots for all sorts of purposes. The concept of an equal chance of being chosen in a 'fair' lottery would be the prime motivation of the whole system. In turn, the notion of equal probabilities, and the fact that such chances would be shown by the equal numbers of votes for each participant over a period, would naturally emerge. [And indeed, the statistical law of large numbers, the *formulation of which was credited to* ***Jacob Bernoulli*** *(1709), actually was first declared by Rabbi* ***Isaac Aramah*** *(1420–1484, Spain)].*

Consider the following example (Babylonian Talmud: Yevamoth **4***): A widow married her brother-in-law three months after her husband's death and there were no signs that the widow was pregnant prior to her second marriage. Six months after the marriage she gave birth to a child. Was the child full-term baby (the first husband being the father) or was it premature (the second husband being the father)? The question was relevant to the child's inheritance rights. If the mother was already pregnant by the first husband when she married his brother (no visible sign of pregnancy) it would affect the child's right to inherit from the brother. If would also invalidate the second marriage and complicate the widow's right to support. Thus a good deal hinged on the court's decision. Two cases must therefore be weighted against each other:*

a. *The deceased husband is the father (full-term baby) while the woman showed no signs of pregnancy. In ancient Israel the probability of the first premise was* $\frac{9}{10}$ *while the probability of the second premise was* $\frac{2}{10}$. *The product of these probabilities is* $\frac{9}{10} \times \frac{2}{10} = \frac{18}{100}$.

b. *The second husband is taken to be the father with probability of* $\frac{1}{10}$. *Since in this case the widow would show no sign of pregnancy with certainty, the overall probability here is* $\frac{1}{10} \times 1 = \frac{1}{10}$.

The judges rightly rejected a third possibility that the two partners breached the law by having intercourse within the 3-month waiting period. This would invalidate a levirate marriage and work against the interests of the widow herself and her offspring. The probability that the widow would intentionally harm herself is very low.

The comparison is therefore between a probability of 18 chances in 100 that the deceased husband is the father, as against only 10 in 100 that his brother fathered the child. The first or deceased husband is nearly twice as likely as his brother to be the father.

In Europe, it was only in 1736 that this kind of double-barreled question could be asked, and answered precisely. A scientific formula was worked out by ***Thomas Bayes****. (His theorem states that if there is no ground to believe one of a set of alternative hypotheses rather than another, their prior probabilities are equal. When in addition, posterior evidence is available, then in retrospect the most probable hypothesis is the one that would have been most likely to lead to that evidence).*

The rabbis solved the problem much earlier, but expressed the argument in words, not numbers. They also thought of the analysis as a way to solve moral and legal problems, not as an end in itself. The degree of precision that they aimed at was quite adequate for this.

Working with whole numbers, we can verify the rabbinical analysis by means of Bayes' theorem. His method was as follows: work out the relative probabilities (in this case 18 and 10), add these to give the total probability, 28; then divide each relative probability by this total. Using his theorem, we can confirm that the court decision was correct. The chances that the deceased husband was the father are 9 in 14; those that his brother was the father are 5 in 14. The relative probabilities remain the same, *but we now know the* absolute probabilities *as well. The chances are similar in both cases (but not quite 50:50). They still favor the deceased husband as father by about* $6\frac{1}{2}$ *in 10, against about* $3\frac{1}{2}$ *in 10 in favor of his brother as the father.*

There is no suggestion here that the Talmud *discussion anticipated Bayes' theorem. It lacks the clarity of Bayes' analysis. We must remain content with relative, not absolute probabilities. None the less, the rabbis understood the logic underlying this analysis. They recognized the need for an estimate of prior and posterior probabilities, of evaluating (if only in words) the different levels of credibility of different hypotheses, and the need for some method of establishing these results.*

V. Game Theory

Although modern game theory proper began in the 1920's, its roots are 2000 years old. Indeed, in the Mishna *(*Seder *'Nashim',* Masehet *Kethubot* **10**, *4) we find a* marriage contract problem: *a man has three wives whose marriage contracts specify that in the case of his death they receive* $d_i = 100$, *200 and 300 Dinars respectively, with* i *ranging over* $1, 2, 3$. *How should the value of the property be divided among the three women?*

The Mishna stipulates the divisions as follows:

Value of estate, E	*Contract specification*		
	wife I	*wife II*	*wife III*
	$d_1 = 100$	$d_2 = 200$	$d_3 = 300$
100	$33\frac{1}{3}$	$33\frac{1}{3}$	$33\frac{1}{3}$
200	*50*	*75*	*75*
300	*50*	*100*	*150*

When $E = 100$, *equal division makes a good sense, because when the estate does not exceed the smallest contract debt* $\min(d_i)$, *any amount of debt to one person that goes beyond the entire estate might well be considered irrelevant – you cannot get more than there is.*

The case $E = 300$ *is based, apparently, on a different principle of proportional division. The figures for* $E = 200$ *look mysterious: but whatever they mean, they do not fit any simple extension of either equal or proportional division.*

The principle behind the Talmud solution for $E = 200$ *is based upon a famous Mishna ruling (Baba Metzia 2a) which states: "Two hold a garment; one claims it all, the other claims half. Then the one is awarded* $\frac{3}{4}$, *the other* $\frac{1}{4}$*." The principle is clear: the lesser claimant concedes half the garment to the greater one. It is only the remaining half that is at issue; this remaining half is therefore divided equally (this is quite different from the proportional division). The relevancy to the marriage contract problem is immediate: When the estate value* $E \leq min(d_i) = 100$, *all claimants divide it equally. As E grows, this continues until all have received* $\frac{1}{2}d_1 = 50$. *At this point the lesser claimant stops receiving payments and each additional payment is divided equally between the remaining claimants until* $E = d_2 = 200$, *for which case the algorithm leads to the division 50, 50+25, 50+25.*

A common rational for all three cases is not apparent. Consequently, this particular Mishna has baffled Talmudic scholars for two millennia. In 1985, it was recognized [Aumann[311] *R.J., and M. Maschler, J. Economic Theory* **36**, *195–213] that the Talmud had anticipated the modern theory of Cooperative games.*

---

311 Won the 2005 Nobel Prize for Economy for his contribution to the theory of games.

Of course, it is unlikely that the sages of the Mishna were familiar with the general notion of a coalitional game. But it can be shown that the ruling fits well with other Talmudic principles *which are independent of game theory. However, without modern Game Theory, it is unlikely that one could have hit on this retroanalysis.*

VI. Combinatorics – The Josephus Problem

We know from the Mishna (Yoma **2***, 2), Jerusalem Talmud (Yoma* **22***, 2) and the Babylonian Talmud (Yoma* **2***, 1), that the priests of the second Temple [515 BCE–70 CE] used to win their various daily service-jobs by the following* 'lottery' *arrangement: they stood in a circle, each pointing one or two fingers toward a man in charge at the center. This man would then announce a number (usually 100 or 60), which was larger than the total number of participating priests, and then* count fingers *in a specified direction from a certain fiducial person, ending the count of the preassigned number at the winner.*

The Latin writer ***Hegesippus*** *(340–397 CE) tells us that the Jewish historian* ***Josephus*** *(37–100 CE) saved his life by knowing the solution to a simpler* deterministic *problem. According to his account, after the Roman captured Yodfat (67 CE), Josephus (the Northern commander of the Jewish revolt) and 40 other warriors took refuge in a cave. His companions were resolved to die rather than fall into the hands of the Romans. Josephus and one friend, not wishing to die, yet not daring to dissent openly, feigned to agree. Josephus even proposed an arrangement by which the deaths might take place in an orderly manner: the men were to arrange themselves in a circle; then every third man was to be killed until but one was left, and he must commit suicide. Josephus and his friend placed themselves in places 16 and 31, thus guaranteeing their survival.*

There is no closed-form solution to the Josephus problem for the general case, not even a recurrence relation.

369–375 CE *Hospital* of St. Basil is built in Caesarea, Israel (369). It heralded start of hospital-building movement by Christians. Charity hospital with 300 beds for plague victims was set at Edessa in the Eastern Roman Empire (375 CE).

378, Aug 09 CE *Battle of Adrianople* (480 km west of Constantinople) between the Romans and the Visigoths. The Visigoths defeated and killed the Emperor Valens. It signifies the beginning of the collapse of the Roman Empire under the pressure of the Barbarian's demographic invasion. Two years earlier, Valens allowed them to cross the Danube and settle in lower Moesia. Faced with the unprecedented problem of these refugees, the Roman government bungled the administration, failed really to disarm the Goths and ultimately had to fight a two-year war with them.

This defeat of the Roman infantry by mounted warriors forecast the revolution in the art of war which determined the military, social, and political development of Europe throughout the Middle Ages.

390–405 CE **Eusebius** (**Sophronius**) **Hieronymus** (Jerome, ca 345–420 CE). Christian Latin scholar and writer. Translated the Old Testament directly from the Hebrew, with the aid of Jewish scholars. The translation is known as the *Vulgate*.

Hieronymus was born to wealthy Christian parents at Strido (Dalmatia) and received a grammatical rhetorical and philosophical education at Rome. In 373 he went on a pilgrimage to the Holy Land. In 385 CE he settled at Bethlehem and engaged in literary activity for the remaining years of his life.

His knowledge of Greek, Latin and Hebrew and his excellence as a scholar made him the ideal erudite for translation of the bible.

393 CE Chinese observed a supernova in the constellation Scorpio. It remained visible for eight months.

397–426 CE **Aurelius Augustinus** (Augustine, 354–430 CE, Numidia). Platonist philosopher and metaphysician who had a marked influence on **Pascal**, **Descartes**, **Leibniz** and **Kant**. Although concerned principally with matters of religious doctrine, and although his conclusions might be classified as highly motivated, his philosophy of history enunciated a doctrine that was impressed upon the consciousness of Western civilization until the time that **Hegel**'s dialectic and **Comte**'s positivistic approaches shed new lights on the possibilities of history. Thus Augustine's influence on subsequent thought is not confined to theology. As a link between the Pagan and the Christian world, he reinterpreted the ideals of antiquity, and in a sense created the modern soul with its conflicts and its unfathomable depths.

To science, Augustine contributed the first serious elaboration on the concept of *time* since Aristotle. He emphasized the *subjective character of time* as being part of the mental experience of man, and placed *historical time* as intermediary between *subjective time* and *physical time* (the same subjective interpretation of time is found in Kant, who makes it a form of understanding). This approach led Augustine to foreshadow the Cartesian doctrine that the only thing that one cannot doubt is what one thinks. One of the features of time that puzzled Augustine was the difficulty of defining it.

Augustine was born at Tagaste in the African province of Numidia (now Constantine, Algeria), a son of a Pagan father and a pious Christian mother. He received a thoroughly Roman education and at twenty went to Rome together with his mistress and their young son. A little later we find him in Milan where he made his living as a teacher of rhetoric. On the religious side he was a Menichaean during this period. But in the end, the continued pressure of remorse and a scheming mother brought him within the orthodox fold. In 387 he was baptized, and ordained a priest in 391. He returned to Africa, became Bishop of Hippo in 396 and so remained until his death.

Augustine lived in the period of the disintegration of the Roman world, and his time was marked by the fall of the Western Empire[312]. (In fact, Rome was sacked by Alaric's Goths (410) during his own lifetime.) It was the end of the twilight era between the decline of Hellenistic Paganism and the advent of the Judeo-Christian one-way view of time in the philosophy of history. Thoroughly impregnated with the Judaistic notion of creation out of nothing, Augustine set himself to counter the Greek pantheistic view, for which God is the world, and adopt the Creator of the Old Testament, a God outside the world, a timeless spirit, not subject to causality or historical development; when he created the world, he created time along with it[313].

---

312 Large-scale trade had collapsed, and slavery had disintegrated too, as supplies dried up and the population fell. The empire was a society based on impoverished serfs, bound to the land and raising subsistence foodstuffs for powerful landlords: virtually the entire population was reduced to a level of not much above slaves. Diocletian took the road of repression with savage and widespread persecutions. When this failed, Constantine took the other road of merger, converting to Christianity and almost immediately subordinating the Church to imperial rule. Many Christians revolted against the idea of alliance with the empire they had fought so long. But many more saw the advantages to the Church of a new powerful friend. Augustine was the most prominent of the latter. He formulated the ideology of the new alliance of Church and state, an alliance that would shape the next 1000 years of Western history.

313 To the Greeks, it would have seemed quite absurd that the world could be conjured up out of nothing. If God created the world, he is to be thought of as the master builder who constructs from raw materials that are already there. That something could come from nothing was alien to the scientific temper of the Greek mind.

ca 400 CE Invention of the Candle[314] (Lat, *Candela*, form *candera*, to glow). Relatively few candles were used in the home until about the 14^{th} century, however they were an important symbol of the *Christian* religion. The best candles were made of beeswax and were used chiefly in church rituals because the bee was regarded as a symbol of purity. But because beeswax was expensive, crude tallow candles had to be used by the common people. Tallow was smelly and smoky. The candles dripped badly and generally gave a feeble light.

The energy effective in the form of light emitted by a source of light through a given surface per unit time per unit solid angle is known as the *luminous intensity* of one *candle-power*. In 1948 a modern unit was adopted and named the *candela* (cd). One candela is equal to $\frac{1}{60}$ of the luminous intensity per square centimeter of a blackbody radiation at a temperature at which platinum solidifies (2042 degrees Kelvin).

ca 400 CE Chinese mathematician **Sun Tsu** in his *Suan Ching* (Mathematical Manual) began the study of indeterminate equations of the first degree.

400–500 CE End of compilation and codification of the *Jerusalem Talmud*[315] (ca 400 CE) and the *Babylonian Talmud* (ca 500 CE). It is an encyclopedia of knowledge which incorporates the collective endeavor of about 2000 scholars (known as *Amoraaim*[316]) over a period of 300 years (7 generations) both in Israel and Babylonia (219–500 CE).

The *leading* scholars in the *Babylonian academies* are listed in Table 1.6.

Table 1.6: Leading scholars of the Hebrew Babylonian academies (Amoraaim)

1st generation	**Rav** (Rabbi Abba bar Ayvu)	(175–247 CE)
	Shmuel the Astronomer	(165–254 CE)
2nd generation	**Rabbi Huna**	(218–298 CE)
	Judah bar Ezechiel	(ca 210–300 CE)
	Rabbi Hisda	(217–310 CE)

[314] The biblical 'candlestick' (*ner* in Hebrew) had a wick of flax which was saturated with oil in the container. Although there is no direct description of a lamp in the Bible, it was certainly not made of solid fatty or waxy matter.

[315] Hebrew: *teaching*, *learning*; the name *Gemara* is used for the *Talmud* without the *Mishna*.

[316] Aramaic: *speakers*, *interpreters*.

Table 1.6: (Cont.)

3rd generation	**Raba bar Nahmani**	(261–321 CE)
	Rav Joseph bar Hamma	(ca 260–323 CE)
	Rabbi Zeira	(ca 250–325 CE)
4th generation	**Abayei**	(278–338 CE)
	Raba	(278–352 CE)
5th generation	**Rabbi Pappa**	(ca 300–372 CE)
6th generation	**Rav Ashi**	(352–427 CE)
	Rabbina I	(334–422 CE)
7th generation	**Rabbi Tosfaah**	(ca 410–474CE)
	Rabbina II	(ca 415–475 CE)

The final editing of the Babylonian Talmud began with Rav Ashi and Rabbina I and ended with Rabbi Tosfaah and Rabbina II. By the year 500 CE, no new material was added to the Talmud. The last of the Babylonian *Amoraaim* was Rabbina II. The Parthian *Arsacid* Empire existed during 129–226 CE. The new *Sassanian* Persian Empire followed through 226–542 CE.

The *Jerusalem Talmud* was created by 5 generations of scholars. Their leading members flourished in the academies of Tiberias, Zippori (Sepphoris), Caesarea and Lydda (Table 1.7).

Table 1.7: Leading scholars of the Jerusalem Talmud

1st generation	**Hiyya the Great**	(Tiberias; 155–240)
	Yannai	(Zippori; 165–250)
	Hoshaya Rabba	(Caesarea; ca 180–240)
	Hanina bar Hama	(Zippori; 155–240)
2nd generation	**Yohanan bar Naphha**	(Zippori and Tiberias; 190–279)
	Shimon ben Lakish	(Zippori and Tiberias; ca 195–280)
	Eleazar ben Pedat	(Tiberias; ca 210–289)
3rd generation	**Hiyya bar Abba**	
	Abahu	(Caesrea; fl. 300)
	Ammi	(Tiberias; ca 220–305)

Table 1.7: (Cont.)

	Assi	(245–315)
4th generation	**Yossi**	(Tiberias; d. 351) [*Moed Katan* **25**]
	Jeremiah	(Tiberias; d. 350)
	Hillel III	(Zippori; 286–365)
5th generation	**Yona**	(Zippori and Tiberias; fl. 375)
	Yossi bar Avin	(Tiberias; fl. 375)
	Tanhuma bar Abba	(Tiberias; fl. 390)

By the time Rome succeeded in driving the Jewish community of Israel into poverty, ineffectiveness and obscurity, the Jewish community in Babylon has awakened from a slumber of centuries and was ready to carry on. In their relative safety, under the Parthian rule, they established schools and led an active intellectual life, continuing the traditions of Judaism that begun and developed in Israel.

The downfall of the *Hasmoneans* (37 BCE), the defeat of the independence war against the Romans (70 CE) and the failure of the Bar-Kochba insurrection (135 CE), were three occasions where the Babylonian Jewish population received a large influx of Israeli refugees. But during the intervening periods, too, a steady exchange of scholars went between the two centers. Before 135 CE, Babylonian scholars went to the Israel academies (e.g., Hillel, 40 CE) to complete their education and staying there. The opposite example is that of **Rav** (219 CE) who had been a pupil of **Yehuda ha-Nasi** and returned to Babylonia to establish the Academy of Sura.

Despite war and other misfortunes, the Israel academies kept up their studies. The completion of the *Mishna* (ca 200 CE) served a further incentive for discussions and applying the laws and customs of Jewish life. More teachers arose, and more students came to their academies; every town had its school for children, and it was the Mishna which now became a sort of textbook, every sentence of which gave rise to discussions. In this very fashion, the *Jerusalem Talmud* was created during 200–400 CE. However, the persecutions of Constantine brought about the decay of the Israeli schools and there was an imminent danger that the oral tradition, achieved by generations of great scholars and sages was likely to be forgotten. Thus, following the riots of 351 CE it was decided to *collect and arrange* the existing material, which was never quite completed. This task fell to the 5th generation of Israeli scholars in Tiberias and the process finally ended in 429 CE.

At the beginning of the 5^{th} century **Rabbi Ashi** took in hand the *arranging* of the framework of the Babylonian Talmud. Under **Rabbi Tosfaah** and **Rabbina II**, heads of the Academy of Sura[317], the recension of the Babylonian Talmud became practically complete (499 CE). As the Babylonian schools decayed, Talmudic learning was assiduously pursued outside its oriental home and some Babylonian Talmudists apparently reached the West. After the compilation of the Talmud, the commentaries and addenda have never ceased up to the present days. In the Middle Ages, the philosopher **Maimonides** (fl. 1180), the commentator **Rashi** (fl. 1080), and the codifier **Joseph Karo** (1488–1575) were among those who brought about a renaissance of Talmudic study in Western Europe.

Although the Talmud is an academic product and may be characterized in the main as a report of the discussions of the schools, it also sheds a flood of light on the culture of the people outside the academies. The Talmud thus became an important source for the history of civilization, discussing the most varied branches of human knowledge – astronomy and medicine, mathematics and law, anatomy and botany, and *furnishing valuable data for the history of science too.*

The peculiar form of the Talmud is due to the fact that it is composed almost entirely of individual sayings and discussions on them, this circumstance being a result of its origin: the fact that it sought especially to preserve the *oral tradition* and the *transaction of the academies*, allowed the introduction only of the single sentences which represented the contributions of teachers and scholars to the discussions.

The Talmud preserved and fostered in the Diaspora, for many centuries and under most adverse external conditions, the spirit of deep religion and strict morality. Moreover, it had an exceedingly stimulating influence upon the intellectual powers of the Jewish people, which were then directed toward other department of knowledge. The Talmud gradually became an intellectual activity having no ulterior object in view – a model of study for the sake of study.

The excessive legalism which pervades the Talmud was the scholarship of the age. Talmudic discussions are sometimes more exhibition of dialectic skill, but it is this predilection for casuistry that impelled Jewish scholars of the Middle Ages to study or translate the learning of the Greeks. *This trend played a necessary part in the development of European science and philosophy* and benefited common humanity.

---

[317] The other two great academies in Babylon were *Nehardea* and *Pumbedita*. In Israel, learning flourished in Caesarea, Tiberias, Zippori, Usha, Shefaraam and Lydda.

409–418 CE **Pelagius** (354–420 CE, Rome and Jerusalem). Early British theologian. Revived the Ionian's idea of a nature distinct from the human will, a nature whose working and processes can be learned by *observation*. He taught that nature is ruled by a process that all can see, not by punishment devised by a capricious God.

Born in Ireland (his name graecized from the Cymric 'Morgan'), he came to Rome in ca 405 and by 409 CE refuted Augustinian doctrines of predestination and total depravity, asserting freedom of will. After the sack of Rome by the Goths (410), he crossed to Africa and met Augustine. He proceeded to the Land of Israel (410), where he was accused of heresy, but acquitted by the Synod of Jerusalem (415). Innocent I called upon him to abjure his teachings and later excommunicated him (417), banishing him from Rome in 418. Pelagius expounded his worldviews at a point on the time scale midway between Thales and Copernicus. His disciple, Julian, exclaimed: "*The merit of one single person is not such that it could change the structure of the universe itself*". Words like these were spoken for the first time in a millennium, and will not be spoken for yet another millennium when the Ionian methods again became accepted wisdom.

Pelagius thus planted a seed that would blossom only at the time of Copernicus. But before the rise of the scientific worldview would occur, the two central concepts of medieval cosmology had to be overthrown – the idea of a decaying universe, finite in time and space, and the belief that the world could be known merely through reason and authority.

5th century Chinese solved problems with arithmetical series.

415 CE Since 300 BCE the city of *Alexandria* reigned as the world's foremost center of science, engineering and philosophy. There lived and created **Euclid** (mathematics), **Eratosthenes** and **Aristarchos** (astronomy), **Dionysios of Thrace** (ca 100 BCE) (language), **Herophilos** (physiology), **Hero** (engineering), **Apollonios** (mathematics), **Diophantos** (mathematics), **Archimedes** (mechanics), **Ptolemy** (astronomy and geography) and **Hypatia**[318] (mathematics and astronomy). Famous for its research facilities, observatory, Museum and above all its legendary library in which the accumulated lore of the ancient world lay encapsulated in the form of some 700,000 papyrus scrolls.

In 389 an edict of Emperor Theodosius I ordered the destruction of the Serapeum, and its books were pillaged by the Christians. But as often happens in history, the destruction of books was followed by the destruction of people. In March 415, **Hypatia** (b. 370 CE), the first woman mathematician to be mentioned in the annals of mathematics and one of the first martyrs of science, was barbarously killed by Christian fundamentalists in Alexandria.

---

[318] Her father, **Theon of Alexandria** (ca 335–395 CE) was a professor of mathematics and astronomy. Further details about her are found in Osen, L.M., *Women in Mathematics*, Massachusetts Institute of Technology Press: Cambridge, 1988, 185 pp.

History of Biology and Medicine[319] *I – Ancient Time*

From early times, perhaps predating the appearance of modern humans, people must have had and passed on knowledge about plants and animals to increase their chances for survival. For example, they had to know how to avoid (or sometimes use) poisonous plants and animals and how to track, capture and butcher different species of animals. They had to know which plants could be prepared to make good nets or baskets. In this sense, biology predates the written history of humans.

Agriculture requires specialized knowledge on plants and animals. Ancient Oriental people knew about the pollination of date palm from a very early point of time. In Mesopotamia they knew that pollen could be used in fertilizing plants. A business contract of the Hammurabi period (c. 1800 BCE) mentions flowers of the date palm as an article of commerce.

In India texts described some aspects of bird life. In Egypt the metamorphosis of insects and frogs was described. Egyptians and Babylonians also knew of anatomy and physiology in various forms. In Mesopotamia, animals were sometimes kept in what can be described as the first zoological gardens.

However, superstition often blended with facts. In Babylon and Assyria organs of animals were used in prediction, and in Egypt medicine included a large amount of mysticism.

The biological sciences emerged from traditions of medicine and natural history reaching back to the ancient Greeks. For example, the idea of biological evolution was supported in ancient times, notably among Hellenists such as ***Anaximander****,* ***Empedocles****,* ***Democritos*** *and his student* ***Epicuros****. As early as 400 BCE the Greek atomists taught that the sun, earth, life, humans, civilization, and society emerged over aeons without divine intervention.*

Later on, in the Greek and the Hellenistic worlds scholars became more interested in empiricism. ***Aristotle*** *is one of the most prolific natural philosophers of Antiquity. He made countless observations of nature, especially*

the habits and attributes of plants and animals in the world around him, which he devoted considerable attention to categorizing. Aristotle's successor, ***Theophrastos*** *(c. 300 BCE), wrote a series of books on botany,* History of Plants*, which survived as the most important contribution of antiquity to botany, even into the Middle Ages.*

In ancient Rome, ***Pliny the Elder*** *was known for his knowledge of plants and nature. The Roman medical writer* ***Dioscorides*** *provided important evidence on Greek and Roman knowledge of medicinal plants. Around 60 BCE the Roman atomist* ***Lucretius*** *wrote the poem* On the Nature of Things *describing the development of the living earth in stages from atoms colliding in the void as swirls of dust. Later,* ***Claudius Galen*** *became a pioneer in medicine and anatomy.*

Table 1.9 lists 14 leading thinkers in ancient Greek and Rome whose influence extended over 2200 years into the Middle Ages and up to the 19th *century.*

Table 1.9: LEADING THINKERS IN THE LIFE-SCIENCES (560 BCE–450 CE)

Name	*fl.*	*Specialization*
Anaximander of Miletos	*ca 560 BCE*	*(ET)*
Alcmaeon of Crotona	*ca 500 BCE*	*(M)*
Empedocles of Acragas	*ca 450 BCE*	*(ET)*
Democritos of Abdera	*ca 420 BCE*	*(ET)*
Hippocrates of Cos	*ca 430–390 BCE*	*(M)*
Aristotle	*ca 354–322 BCE*	*(B), (A)*
Theophrastos	*ca 328–286 BCE*	*(BO)*
Epicuros of Samos	*ca 310–301 BCE*	*(ET)*

A = *Anatomy*

M = *Medicine*

ET = *Evolutionary Thinking*

BO = *Botany*

Herbalism and Medicine

All human societies have medical beliefs that provide explanations for, and responses to, birth, death, and disease. Throughout the world, illness has often been attributed to witchcraft, demons, averse astral influence, or the will of the gods, although the rise of scientific medicine in the past two centuries has altered or replaced many historic health practices.

There is no actual record of when the use of plants for medicinal purposes first started, although the first generally accepted use of plants as healing agents were depicted in the paintings discovered in the Lascaux *caves in France, which have been radiocarbon dated to between 13,000–25,000 BCE.*

Over time and with trial and error, a small base of knowledge was acquired within early tribal communities. As this knowledge base expanded over the generations, tribal culture developed into specialized areas. These 'specialized jobs' became what are now known as healers or shamans.

Medical information contained in the Edwin Smith Papyrus *date as early as 3000 BCE. The earliest known surgery was performed in Egypt around 2750 BCE.* ***Imhotep*** *in the 3rd dynasty is credited as the founder of ancient Egyptian medicine and as the original author of the Edwin Smith papyrus, detailing cures, ailments and anatomical observations. The Edwin Smith papyrus is regarded as a copy of several earlier works and was written circa 1600 BCE. It is an ancient textbook on surgery and describes in exquisite detail the examination, diagnosis, treatment, and prognosis of numerous ailments.*

Additionally, the Ebers papyrus *(c. 1550 BCE) is full of incantations and foul applications meant to turn away disease-causing demons and other superstition. In it there is evidence of a long tradition of empirical practice and observation. The Ebers papyrus also provides our earliest documentation of a prehistoric awareness of tumors.*

Medical institutions are known to have been established in ancient Egypt since as early as the 1st Dynasty. By the time of the 19^{th} Dynasty their employees enjoyed such benefits as medical insurance, pensions and sick leave. Employees worked 8 hours per day.

The earliest known physician is also credited to ancient Egypt: ***Hesyre****, "Chief of Dentists and Physicians" for King Djoser in the 27^{th} century BCE. Also, the earliest known woman physician,* ***Peseshet****, practiced in Ancient Egypt at the time of the 4^{th} dynasty. Her title was "Lady Overseer of the Lady Physicians." In addition to her supervisory role, Peseshet graduated midwives at an ancient Egyptian medical school in Sais.*

In 2001 archaeologists studying the remains of two men from Mehrgarh, Pakistan, made the discovery that the people of Indus Valley Civilization, even from the early Harappan periods (c. 3300 BCE), had knowledge of medicine and dentistry. Later research in the same area found evidence of teeth having been drilled, dating back 9,000 years.

Ayurveda (the science of living), the Vedic system of medicine originating over 3000 years ago, views health as harmony between body, mind and spirit. Its two most famous texts belong to the schools of Charaka and Sushruta. According to Charaka, health and disease are not predetermined and life may be prolonged by human effort. Sushruta defines the purpose of medicine to cure the diseases of the sick, protect the healthy, and to prolong life.

The student of Ayurveda was expected to know ten arts that were indispensable in the preparation and application of his medicines: distillation, operative skills, cooking, horticulture, metallurgy, sugar manufacture, pharmacy, analysis and separation of minerals, compounding of metals, and preparation of alkalis. The teaching of various subjects was done during the instruction of relevant clinical subjects. For example, teaching of anatomy was a part of the teaching of surgery, embryology was a part of training in pediatrics and obstetrics, and the knowledge of physiology and pathology was interwoven in the teaching of all clinical disciplines.

China also developed a large body of traditional medicine. Much of the philosophy of traditional Chinese medicine derived from empirical observations of disease and illness by Taoist physicians and reflects the classical Chinese belief that individual human experiences express causative principles effective in the environment at all scales. These causative principles, whether material, essential, or mystical, correlate as the expression of the natural order of the universe.

Thus, already during the reign of the ***Yellow Emperor*** *(2696–2598 BCE), the influential* ***Neijing Suwen*** *(Basic Questions of Internal Medicine) was composed. This was expanded and edited by* ***Wang Ping*** *during the Tang dynasty, and again revisited by an imperial commission during the 11^{th} century CE. The result is the extant representation of the foundational roots of traditional Chinese medicine. Acupuncture was advocated during the Chin dynasty by* ***Huang-fu Mi*** *(215-282 CE).*

Most of our knowledge of ancient Hebrew medicine during the 1^{st} millennium BCE comes from the Old Testament of the Bible which contain various health related laws and rituals, such as isolating infected people (Leviticus ***13****:45-46), washing after handling a dead body (Numbers* ***19****:11-19) and burying excrement away from camp (Deuteronomy* ***23****:12-13).* ***Max Neuberger****, writing in his "History of Medicine" says:*

> *"The commands concern prophylaxis and suppression of epidemics, suppression of venereal disease and prostitution, care of the skin, baths, food, housing and clothing, regulation of labor, sexual life, discipline of the people, etc. Many of these commands, such as Sabbath rest, circumcision, laws concerning food (interdiction of blood and pork), measures concerning menstruating and lying-in women and those suffering from gonorrhea, isolation of lepers, and hygiene of the camp, are, in view of the conditions of the climate, surprisingly rational."*

As societies developed in Europe and Asia, belief systems were replaced with a different natural system. The Greeks, from ***Hippocrates****, developed a humoral medicine system where treatment was to restore the balance of humors within the body.* Ancient Medicine *is a treatise on medicine, written roughly 400 BCE by Hippocrates. Similar views were espoused in China and in India. In Greece, through* ***Galen****, until the Renaissance, the main thrust of medicine was the maintenance of health by control of diet and hygiene.*

Anatomical knowledge was limited and there were few surgical or other cures, doctors relied on a good relation with patients and dealt with minor ailments and soothing chronic conditions. But they could do little when epidemic diseases, growing out of urbanization and the domestication of animals, then raged across the world.

Metallurgy in China – The Missed Opportunity

During 300 BCE–450 CE China grew into a powerful empire. Its culture flourished and great technological advancement were made. The invention of cast-iron (ca 300 BCE) was a feat in which the Chinese had pioneered, some 1700 years ahead of the Europeans!

The military technology which built the Great Wall (ca 214 BCE) went far beyond the achievement of the Wall itself. Recently (1975) Chinese archaeologists discovered that weapons (swords, spears and arrowheads) dating from the second century BCE were made of sophisticated alloys of 15 different metals. The major ingredients are copper, tin and lead, but also other which have come to use in the West in our own time (Aluminum, Titanium, Vanadium, Cobalt etc).

A different kind of advanced technology is represented by this set of intricate casting: They are the trigger-release mechanism of the weapon that armed the emperor Chin troops in holding the barbarians at bay on the Great Wall – the crossbow*; this is a weapon which will not appear in the West for another 1400 years! Clearly, the exploitation of cast iron by the Chinese in ca 300 BCE marks one of the most significant advances in all history of metals.*

We know that the main barrier to the wider use of iron, after the collapse of the Bronze age, was that it could not be melted. Iron workers could not therefore cast objects in iron as their predecessors had cast them in Bronze. This inability meant drudgery at the anvil and frustrated the further use of iron in Europe for more than a millennium. However, unknown to Europe, that particular threshold had already been crossed in the East.

An iron blast furnace of remarkable proportions, weighting ca 25 tons, dating from before the dawn of the Christian era, was discovered in China (1975). No one outside China handled iron in this quantity until the Industrial Revolution in Britain. The furnace operated with temperatures in excess of 1400° C. The Chinese then liquefied iron, treating it as they treated bronze by pouring it into moulds. With this they made ploughshares and haws.

But casting was only part of the Chinese achievement. Cast iron was high in carbon, which made it too brittle for useful tools.

By 450 CE, Chinese metallurgists knew how to remove the carbon on the surface of cast iron and create a steel jacket *around the cast iron case. It was this discovery which finally made it possible for the Chinese to use iron so comprehensively so early in history.*

How did they attain and maintain the required high temperature in their furnaces? The answer is in more efficient bellows; the more air one blows into the furnace in a unit of time – the hotter it gets.

Whereas in the West blacksmith's bellows operated on a vertical principle, the Chinese system was horizontal. Very large bellows could be suspended from an overhead beam and driven by waterwheels or by animal power. The Chinese control of air supply to the furnace was superior to that in the West. In addition, Chinese used double acting box bellows: *the handle operates two pistons, in upper and lower chamber of the box; simple flat valves control the* *air-flow such that air is pumped both on the pull and the push action. It supplies twice as much air into the furnace by continuous flow. This was the key to the Chinese success in high-temperature furnace.*

But the more evidence that emerges for the technological lead that China established over the West in the early Iron Age, the more intriguing becomes her failure to sustain it. All the conditions seem to exist for China to lead the world into an industrial and scientific revolution 1300 years before it occurred in the West.

Historians think that the reasons were political and social. China was an extremely conservative society in which stability was much more prized than freedom and where rules had a powerful vested interest in not being challenged. China's belief that it was a universe in itself led to dangerous contempt to development elsewhere. The rise of a stifling bureaucracy anesthetized innovation. The iron masters of the Han period who were well placed to launch a power-driven industrialized revolution went on to making plows and haws. China lost an advantage to the West that was not yet regained.

From the first through the thirteenth centuries, as Europe passed from late antiquity through the Dark Ages, science in China flourished. It kept pace with Arab science, even though geographic isolation deprived Chinese scholars of the ready-made base that Greek culture provided their Western counterparts.

The Chinese made brilliant advances in subjects such as descriptive astronomy, mathematics, and chemistry. But they never acquired the habit of reductive analysis in search of general laws that served Western science so well from the seventeenth century on. They consequently failed to expand their conception of space and time beyond what was attainable by direct observation with the unaided senses. The reason was their emphasis on the holistic properties and harmonious relationships of observable entities, from stars to trees to grains of sand.

Unlike Western scientists, they had no inclination to search for abstract codified law in nature. Their reluctance was stimulated to some degree by the historic rejection of the Legalists, who attempted to impose rigid, quantified law during the transition from feudalism to bureaucracy in the fourth century BCE.

But of probably greater importance was the fact that the Chinese steered away from the idea of a supreme being who created and supervises a rational, law-governed universe. If there is such a ruler in charge, it makes sense – Western sense at least – to read a divine plan and code of laws into physical existence. If, on the other hand, no such ruler exists, it seems more appropriate to search for separate rules and harmonious relations among the diverse entities composing the material universe.

In summary, it can be said that Western scholars but not their Chinese counterparts hit upon the more fortunate metaphysics among the two most available to address the physical universe.

ca 435 CE **Martianus Minneus Felix Capella** (North Africa). Latin encyclopedic compiler. His comprehensive treatise *Satyricon* was a complete encyclopedia of the liberal culture of the time, and was in high repute during the Middle Ages. A passage in book 8 contains a very clear statement of the *heliocentric system of astronomy.* It has been supposed that **Copernicus**, who quotes[320] Capella, may have received from this work some hints towards his own new system.

The author's chief sources were Varro, Pliny, Solinus, Aquila Romanus and Aristides Quintillanus.

Capella was a native of Madaura in Africa. He appears to have practiced as a lawyer at Carthago.

ca 450 CE **Proclos of Byzantion** (410–485, Alexandria and Athens). Philosopher, mathematician and historian of Greek science. Chief representative of the later Neoplatoists. Head of Plato's Academy in Athens. The most illustrious philosopher and teacher of his time. Discovered an equivalent postulate to Euclid's 5^{th}; it states that if a straight line intersects one of two parallels, it will intersect the other also.

He seems to have been the first to state explicitly the fact that the three altitudes of any triangles are concurrent (it is not in Euclid, although Archimedes implies it).

---

320 In the words of Copernicus: "*Therefore it seems to me that it would be wrong to ignore certain facts well-known to Martianus Capella, who wrote an encyclopedia, and some other Latins. He believed that Venus and Mercury do not go around the earth like other planets, but turn around the sun as their center and therefore cannot go further away from the sun than the sizes of their orbits permit. What else does this mean but that the sun is the center of their orbits and that they turn around him?... Therefore we do not hesitate to state that the moon and the earth describe annually a circular orbit placed between the outer and inner planets round the sun, which rests immobile in the center of the world*".

Proclos was born in Constantinople, but brought up at Xanthus in Lycia. After studying grammar and philosophy at Alexandria, he proceeded to Athens. There he attended the lectures of the Neoplatonists Plutarch and Syrianus, and about 450 CE succeeded the latter in the chair of philosophy. As an ardent upholder of the old Pagan religion, Proclos incurred the hatred of the Christians, and was obliged to take refuge in Asia Minor. After a year's absence he returned to Athens, where he remained until his death.

Although possessed of ample means, Proclos led a most temperate, even ascetic life, and employed his wealth in generous relief of the poor. His great literary activity was chiefly devoted to the elucidation of the writings of Plato, but he also wrote treatises in the fields of mathematics and astronomy.

451 CE *The Hun Invasion.* The Huns, a nomadic Mongol tribe headed by Attila, established an empire in Eastern Europe in a region extending from the Danube River to the Baltic Sea, and from the Rhine River to the Caspian Sea. During 441–447 they looted the provinces of southeastern Europe and forced the East Roman Empire to pay a yearly tax[321]. In 450, Attila demanded Honoria, sister of Emperor Valentinian III, as his bride, and half the West Roman Empire as her inheritance. Valentinian refused. Attila stormed into Gaul (now France), but a combined Roman and Visigoth army repulsed him near Troyes. He retreated east to the Rhine River and invaded Italy in 452, capturing and destroying many cities north of the Po River. But famine and plague forced his troops to withdraw.

Although he seriously threatened the East and West Roman Empire, he was unable to win decisive victories over them. His kingdom collapsed soon after his death in 453.

---

[321] One theory holds that the westward movements of the Huns started because of virulent *smallpox* in Mongolia; the disease traveled with them, was communicated to the Germanic tribes upon whom the Huns were pressing and, in turn, infected the Romans who were in contact with the Germans.

Downfall of the Roman Empire – plague-ridden decadence

The causes of this fall have been argued by historians for many years past; some of these causes are connected with disease.

Although in its cleanliness, sanitation and water supply, Rome was much more akin to 20th century London and New York, Romans, like 17th century Londoners, did not know the cause of disease. This lack of essential knowledge rendered the magnificent health measures of Imperial Rome entirely useless during the long years of her decline.

Imagine Rome as a bloated spider sitting in the center of its web. This web, in the height of Roman expansion stretched from the Sahara in the south to the borders of Scotland in the north, from the Caspian Sea and the Persian Gulf in the east to the western shores of Spain and Portugal. To the north and west lay the oceans; to the south and east, vast unknown continents in which dwelt less civilized people, Africans, Arabs, the savage tribes of Asia. Beyond, in the dim shadows, lay the older civilizations of India and China.

The long land frontiers were manned by garrisons scattered at strategic points; from these frontier garrisons stretched back the filaments of the spider's web, the sea routes from Africa and Egypt, the straight, legionary-made roads, all of which led to Rome. Along these very roads crept the micro-organisms of foreign disease, reaching the center of a highly civilized organization lacking the most rudimentary means of combating infection.

Given a conjunction of circumstances such as this, it is little wonder that the story of the last centuries of Roman power is a long tale of plague:

It started in the 1st century BCE; a very severe type of malaria *appeared in the agricultural district around Rome and remained a problem for the next 500 Years. All fertile land of market gardens which supplied the city with fresh vegetables, went out of cultivation; the small farmers who tilled it added to the overcrowding of Rome, bringing infection with them. It caused the live-birth rate of the Italo-Roman to fall steeply at the time when the birth-rate throughout the empire was rising. Moreover, chronic illness and ill-health caused by untreated malaria decreased life-expectancy and enervated the nation. Possibly malaria rather than decadent luxury imported from the East, accounted for the slackness of spirit which characterized the later years of Rome.*

The first of the great epidemics occurred about the year 79 CE, shortly after the eruption of Vesuvius. This may have been fulminating malaria *compounded by an epidemic of* anthrax*, resulting in the large-scale destruction of livestock. The infection was raging destructively in the cities of Italy. For about a century there was much sickness (mostly malaria); then came the* plague of Orosius *(125 CE), a famine-plague sequence, for the sickness was preceded by an invasion of* locust *which destroyed large areas of crops. The pestilence that followed killed hundred of thousands in Numidia and on the north coast of Africa. The plague then passed to Italy.*

Forty years later there followed the plague of Antoninus *(164–189 CE) through which the Roman Empire was swept by three separate waves of plague. It began by causing great mortality among the legions under the command of Avidius Claudius, who had been sent to repress a revolt in Syria (164–166 CE). The plague accompanied this army homewards, spreading throughout the countryside and reaching Rome in 166 CE. It rapidly extended into all parts of the known world, causing many thousands of deaths.*

The plague of Antoninus caused the first crack in the Roman defense lines. Until 161 CE the empire continually expanded and maintained its frontiers. In that year a Germanic barbaric horde (the Marcomanni *from Bohemia and the* Quadi *from Moravia) forced the north-eastern barrier of Italy. Owing to the disorganization produced by the plague, it was not until 169 CE that the whole weight of the Roman army was thrown against the invaders. Possibly the failure of this invasion was as much due to the legions carrying plague with them, thus infecting the Germans. One of the victims of the plague was the Roman emperor,* **Marcus Aurelius** *(d. 180 CE).*

A new wave of epidemic originated in Ethiopia (ca 250 CE) and spread, via Egypt, to the Roman colonies in North Africa. It engulfed all countries from Egypt in the south to Scotland in the north. It advanced with appalling speed, decimating the entire Roman empire.

It lasted no less than 16 years and indisputably changed the course of history; wide areas of farmland throughout Italy reverted to waste; some thought that the human race could not possibly survive. But despite warfare in Mesopotamia, on the eastern frontiers and even in Gaul, the empire managed to survive this catastrophe; but by 275 CE the legions had fallen back from Transylvania and the Black Forest to the Danube and the Rhine, and so dangerous did the position seem to have become that Aurelian decided to fortify the city of Rome itself.

Throughout the next 3 centuries, while Rome slowly collapsed under the pressure of the Goths and Vandals, there were recurrent outbreaks of a similar plague. Gradually the evidence became less exact, degenerating into a *generalized story of war, pestilence and famine, as the darkness descended over Rome and her mighty empire collapsed.*

476 CE *Goths* under Odovacar deposed Romulus Augustus; the "official" end of the Western Empire.

Since Attila's death in 453 CE, Germanic army commanders governed Italy behind the facade of puppet emperors. Odovacar, the leader of a band of German mercenaries, tired of the pretense and became king of Italy. All Roman territories west of the Adriatic were now under barbarian rulers.

Although this was just a symbolic act, the passing of the Latin-speaking part of the Empire under Germanic rule was a watershed in history; the Latins became barbarized and the Greek became orientalized. Thus, the two halves of the Roman world drifted apart, preparing the way for the later split between Eastern and Western Europe.

For a while the East, on account of its superior stability saved itself from the Germans, but could not repel the next great attack, that of the Arabs. The "Fall of the Empire" was not a political episode of the year 476; it was a deadly crisis in the history of civilization.

Origins of the European Civilization

On Assyrian monuments the contrast between Asu = (the land of the rising sun) and ereb = (the land of the setting sun), is frequent [erev = evening in Hebrew; Genesis **1***, 5]. These names were probably passed on by the Phoenicians to the Greeks, and gave rise to the names of Asia and Europe. The earliest mention of Europe is in the Homeric Hymn to Apollo. The distinction between Europe and Asia is found, however, in Aeschylos in the* 5^{th} *century BCE.*

In places where the names originated, the intervention of the sea clearly marked the distinction between Europe and Africa. As the knowledge of the world extended, the difficulty of fixing the land boundary between Europe and Asia caused uncertainty in the application of the two names, but never obscured the necessity for recognizing the distinction. Even in the 3^{rd} *century BCE, Europe was regarded by Eratosthenes as including all that was then known of Northern Asia. But the character of the physical features and climate finally determined the fact that what we know as Europe came to be occupied by more or less populous countries in intimate relation with one another, but separated on the east by unpeopled (or very sparsely peopled) areas from the countries of Asia.*

Within the limits thus marked out on the east and on other sides by the sea, the climatic conditions are such that inhabitants are capable of and require a civilization of essentially the same type, based upon the cultivation of European grains. Those inhabitants have led a common history in a greater measure than those of any other continent, and hence are more thoroughly conscious of their dissimilarities from, than of their consanguinity with, the peoples of the east and the south. Within these geographical limits, the tradition of the Roman Empire, and above all the organization of the Catholic Church gave to the European nations, and the states based upon them, a homogeneity which without them could not have survived. The history of Europe is the history of this civilization and of the forces by which it was produced, preserved and developed.

Broadly speaking, European civilization may be traced to four principal origins: (1) The Aegean civilization (Hellenic and pre-Hellenic); (2) the Roman Empire; (3) Christianity; (4) the break-up of the Roman Empire by the Teutonic invasions. All these forces helped in the development of Europe as we now know it.

To the Aegean civilization [whether transformed by contact with Rome, and again transformed by the influence of Christianity, or rediscovered during the classical Renaissance] Europe owes the characteristic qualities of its thought and of its expression in literature, art and the sciences. From republican Rome it largely drew its conceptions of law and of administrative order. From the Roman Empire it inherited a tradition of political unity which survived (in visible form, though but as a shadowy symbol) until the last Holy Roman emperor abdicated in 1806.

Yet more does Europe owe to Christianity, basically a Hebrew religion, modified by contact with Greek thought and powerfully organized on the lines of the Roman administrative system. The Roman Church remained a reality when the Roman Empire had become little more than a name. Indeed, throughout the period of chaos and transformation that followed the collapse of the Roman Empire, the Church remained the most powerful instrument for giving to the heterogeneous races of Europe a common culture and a certain sense of common interests.

The history of Europe, then, might well begin with the origins of Greece and Rome, and trace the rise of the Roman Empire and the successive influence upon it of Hellenism and Christianity.

ca 490 CE **Tsu Ch'ung-Chi** (430–501) and his son, whose joint book is now lost, found the remarkable rational approximation 355/113 to π, correct to 6 decimal places. They further discovered that $3.1415926 < \pi < 3.1415927$. This rational approximation was not rediscovered in Europe until 1573. The precision of π achieved by the Tsu's seems not to have been surpassed until about 1420 when the astronomer **Al-Kashi** of Samarkand found π correctly to 16 decimal places. Western mathematicians did not surpass the Tsu approximation until around 1600.

ca 499–530 CE **Aryabhata the Elder** (476–550, India). The first great Hindu mathematician and astronomer. The author of '*Aryabhatiya*' (written in verse, 499 CE), the first Hindu astronomical text to contain a section devoted to mathematics. It is a summary of Hindu mathematics up to that time and includes rules for computational procedures, the extraction of square and cube roots, the solution of quadratic equations, the sum of powers of the first n natural numbers [e.g., he gave the formula $\sum n^2 = \frac{1}{6}n(n+1)(2n+1)$], arithmetic progressions[322] and the trigonometric sine function. It gives formulas for the areas of a triangle and a circle which are correct, but the formulas for the volumes of a sphere and a pyramid are wrong.

Aryabhata gave $62,832/20,000 = 3\frac{177}{1250} = 3.1416$ as an approximate value of π [it may have come from some earlier Greek source or from calculating the perimeter of a regular inscribed polygon of 384 sides][323]. His work contained one of the earliest attempts at the general solution of a linear indeterminate equation by the use of continued fractions. Thus he found the integral solutions of the linear indeterminate equation $ax + by = c$ (a, b, c integers). He also solved the indeterminate quadratic equation $xy = ax + by + c$ by a method later reinvented by **Euler**.

As an astronomer he taught that the apparent rotation of the heavens was due to the axial rotation of the earth and explained the cause of eclipses of sun and moon.

Aryabhata was born near the present day city Patna on the Ganges.

500 CE *Polynesians* began to inhabit the islands of Hawaii.

ca 500 CE **Joannes Philoponus** (John the Grammarian). Philosopher. Flourished in Alexandria. Contested the Aristotelian ideas on motion and vaguely anticipated the concept of *inertia*. He denied that bodies of greater weight fall more quickly, referring to *experiment*. Nor did he accept the Aristotelian doctrine about the impossibility of vacuum.

Philoponus applied Severus' unity of soul and matter to cosmology. Reviving the Ionian ideas, he argued that these same ideas apply to the heavens and the earth; stars are neither divine nor perfect, beings but material bodies on fire. The heavens are not unchanging but governed by the same changes as are earthly objects. In supporting his assertion that stars are lighted by fire, he pointed to their obvious differences in color: this shows, he said, they cannot be simple bodies, made of pure ether (the rarefied medium filling the heavens), as dualism claimed, since we know that on earth different material produce different colorations in fire, implying that thus the stars must be composed of different materials, like these on earth. Thus, Philoponus hit on the basis of *spectrography*, which centuries later allowed scientists to figure out what the stars are made of.

His work, however, could not have led to an early revival of science, for he lived during the collapse of the Mediterranean civilization. The trade

[322] It contains the rule for summing an arithmetic series from the p-th term on.

[323] At about the same time, the scholars of the *Talmud* still used the Biblical approximation $\pi = 3$ for all practical purposes of mensuration (*Eruvin*, 14).

that demanded and supported scientific research was disrupted by Byzantine attempts at reconquest and its futile battles with Persia.

Joannes Philoponus represents the last flicker of ancient science.

ca 500 CE Chinese began the use of *gunpowder*.

ca 500 CE The *Zero* symbol is introduced in India.

Zero – The Mathematics of Nothing[324]

* * *

"Thirty spokes are made one by holes in the hull,
By vacancies joining them for a wheels' use.
The use of clay in moulding pitchers
Comes from the hollow of its absence;
Doors, windows, in a house,
Are used for their emptiness:
Thus we are helped by what is not
To use what it".

Lao Tsu, 570 BCE

* * *

"Each act of creation could be symbolized as a particular product of infinity and zero. From each such product could emerge a particular entity of which the appropriate symbol was a particular number".

S. Ramanujan (1887–1920)

[324] Includes quotations from: "zero" by Charles Seife. Penguin Books, 200, New York.

* * *

"The zero is the most important digit. It is a stroke of genius, to make something out of noting by giving it a name and inventing a symbol for it".

Bartel Leendret van der Waerden (1903–2000)

Riddle: "The Babylonians invented it, the Greeks banned it, the Hindus worshiped it, the Church used it to fend off heretics; once harnessed, it became the most important tool in mathematics; starting as an Eastern philosophical concept, its struggle for acceptance in Europe ended with its apotheosis as the mystery of the black hole. Today it lies at the heart of one of the biggest scientific controversies of all time, the quest for the theory of everything. Its companion concepts are infinity and void, and it has been an ever-present threat to modern physics".

What is it? It is a number known as Zero.

The first symbol for zero was introduced by the Babylonians in about 300 BCE out of the practical need to give a sequence of digits a unique meaning[325] *Yet, their symbol for zero (two slanted wedges) was merely a symbol for a blank space on the cuneiform, a placeholder; it did not really have any numerical value of its own. It was a digit, not a number.*

Like the Babylonians, the Mayans (ca 300 BCE) had a place-value system of digits using the vigesimal (base 20) system, and needed a zero to keep

325 To see how this need arose, consider the representation of different numbers in their sexagesimal (base 60) system; Today, we would write (*with* zero)

$$\begin{aligned} 61 &= 1\cdot 60^1 + 1\cdot 60^0 &&\equiv 11\\ 3601 &= 1\cdot 60^2 + 0\cdot 60^1 + 1\cdot 60^0 &&\equiv 101\\ 3660 &= 1\cdot 60^2 + 1\cdot 60^1 + 0\cdot 60^0 &&\equiv 110 \end{aligned}$$

But *without* the placeholder 0, all three numbers would be written as 11. (The Babylonian actually used the wedge symbol

𒁹

instead of the Arabic 1).

track of what each digit meant. But the Mayans went one step further than the Babylonians (and the Egyptians) in their solar calendar – they started numbering days with the number zero; the first day of the month was day zero, the next day was 1, and so forth. This is conceptually equivalent to placing zero at the origin of the number-line, giving it both a cardinal and an ordinal value.

Most ancient people believed that only emptiness and void were present before the universe came to be. There was always a fear that at the end of time, disorder and void would reign once more. Thus, to the ancients, zero represented that void and its odd mathematical properties[326] *were inexplicable, as shrouded in mystery as the birth of the universe.*

In the Greek universe, created by Pythagoras, Aristotle and Ptolemy, there was no zero. To begin with, the framework of the Pythagorean universe was controlled by ratios and the zero, with it odd properties "would punch a hole in the neat Pythagorean world order". For that reason zero (void, vacuum) was totally excluded from Greek science and mathematics. Because of this, the West could not accept zero for nearly 2000 years! Pythagorean doctrine became the centerpiece of Western philosophy: all the universe was governed by ratios and shapes; the planets moved in heavenly spheres that made music as they turned. Since infinity (the inverse of zero) was also rejected, the number of those spheres, according to Aristotle and Ptolemy, must be finite – the cosmos was finite in extent and entirely filled with matter: there was no infinite and there was no void.

Moreover, since the Greek rejected the number zero, *they could not refute Zeno's paradox ('Achilles and the tortoise')*[327]*. This rejection is the biggest failure in Greek mathematics, and it is the only thing that kept them from discovering the calculus. This state of affairs continued into the Dark Ages; As the medieval thinkers imported the philosophy and science of the ancient, they inherited the ancient prejudices: a fear of the infinite and a horror of the void. "The fear of the void was so great that Christian scholars tried to fix the Bible*[328] *to match Aristotle rather than vice versa".*

In the 4^{th} century BCE, Alexander the Great marched with his troops from Babylon to India, carrying with him the gospel of the Babylonian system

---

[326] $0+a=0$; $0\times a=0$; $a/0=\infty$ $(a\neq 0)$; $\infty\cdot 0=$ *indeterminate*; $0/0=$ *indeterminate*.

[327] They did not believe that adding infinite terms could lead to a finite result $[\lim\left(1+\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\cdots+\frac{1}{2^n}\right)=2,\ n\to\infty]$. To them, terms in an infinite series did not have a *limit* or a destination.

[328] The Judeo-Christian story of creation was Semitic, and Semites did *not* have a fear of the void.

of numbers and with it the Babylonian 'place-holder zero'. "Unlike Greece, India never had a fear of the infinity and the void". Consequently, India, as a society that actively explored the void and the infinite – embraced the mathematical zero. Moreover, India transformed it, changing its role from a mere placeholder to a number.

So, sometimes around 500 CE the Hindus moved to a base-10 system representing all numbers, negative *as well as* positive *in the number line. No longer did zero sit to the right of nine – it had a position in the number line that was all its own, just in the middle between +1 and -1. "Numbers were stripped of their geometrical significance; mathematician no longer had to worry about mathematical operations making geometric sense*[329]*. This was the birth of what we now know as* algebra*".*

When the Arabs conquered India (ca 710 CE), they learned quickly all about Hindu numerals and their zero. They accepted it and soon rejected Aristotle.

Christianity initially rejected zero, but trade would be soon demanding it. The man who introduced zero to the West was **Leonardo of Pisa** *(Fibonacci) in his book Liber Abaci (1202 CE). After many vicissitudes, and thanks to the persistence of both the Muslims and the Hindus, the zero and its companion, infinity, have by 1430 arrived throughout Western Europe.*

In the century that followed, **Nicholas of Cusa** *["Terra no est centra mundi", 1440 CE] and* **Nicolaus Copernicus** *(1543 CE) cracked open the nutshell universe of Aristotle and Ptolemy. The Church was now under attack both from the inside (***Luther***, 1517) and the outside. For if the universe were infinite, then there could be no center. How could earth, then be the center of the universe?*

"Zero became a heretic!"

The Catholic Church stroke back by re-rejecting the void and the infinite. It did so with the establishment of the Jesuit order (1530 CE), the Inquisition (1543 CE), and the Index of forbidden books. "This counter-Reformation *was the Church's attempt to rebuild the old order by crushing the new ideas".*

In the meantime the scientific revolution was on its way, but its first harbingers were somewhat ambiguous: For example, **Descartes** *(being himself a Jesuit) "would bring zero to the center of the number line, yet, being*

---

[329] Negative number did not have necessarily to mean a negative area. **Brahmagupta** (ca 630 CE) gave rules for dividing numbers of the same or mixed polarity ($\frac{\pm}{+} = \frac{-}{-} = +, \qquad \frac{\pm}{-} = \frac{-}{+} = -$), but he wrongly asserted that $\frac{0}{0} = 0$ and failed to attach any sensible meaning to $\frac{1}{0}$.

indoctrinated with the Aristotelian philosophy, denied the existence of the vacuum (1637)".

Not for long. It was Galileo's secretary, ***Evangelista Torricelli****, who proved this was not true by creating the first vacuum (1643). Aristotle was defeated, and scientists stopped fearing the void and began to study it. Then an unexpected help for the Church came from within the scientific camp:* **Pascal***, a devout Jansenist, combined mathematical theory (probability theory), with zero and infinity to* prove *(?!) the existence of God.*

Then, from deep within the scientific world emerged a new language – the Calculus of Newton and Leibniz: the most powerful mathematical method ever by dividing by zero and adding an infinite number of zeros together – the language of nature!

The Church, however, refused to admit defeat. Its last battle was fought via an Irish bishop, ***George Berkeley*** *(1734). He ridiculed infinitesimals, arguing that Newton himself could not explain how his infinitesimals disappeared when squared. He charged the mathematicians of his day that they just accepted the fact because making them vanish at the right time gave the correct answer. Berkeley's attack forced mathematicians to re-examine the foundation of analysis. There followed 200 years of intense efforts by the best minds in Europe. The result was a rigorous calculus as we know it today.*

This process was started by ***D'Alambert*** *(the idea of the* limit*; 1754) and* ***Lagrange*** *(1797), in what we call today 'the Arithmetization of the Calculus'. It was then followed by the French geometer* **Poncelet** *(point at infinity in projective geometry; 1822), and by* ***Gauss*** *(1827) and* ***Riemann*** *(1854) in their new differential geometry. The concept of infinity was finally harnessed by the studies of* **Cantor** *(1872).*

While infinity and zero have been inseparable essential mathematical entities for over 2500 years, these concepts became truly relevant to physicists only in the 20^{th} century: In thermodynamics *zero became an uncrossable barrier; in Einstein's GTR clockrates vanish and densities diverge in black holes and cosmological solutions; in quantum mechanics zero-point motion is an infinite source of energy present even in the deepest vacuum.*

Toward the end of the 20^{th} century, physicists began to realize that the zero of the vacuum might explain the lumpiness of the universe. Since the vacuum everywhere in the universe is seething with a quantum foam of virtual particles, the fabric of the universe is filled with infinite zero-point energy. Under the right conditions this energy is able to push objects around.

Moreover, "zero might also hold the secret of what created the cosmos. Just as the nothingness of the vacuum and the zero-point energy spawn particles, they might spawn universes. Perhaps the universe is just a quantum *fluctuation on a grand scale. Zero might hold the secret to our existence – and the existence of an infinite number of other universes".*

"Zero is so powerful because it unhinges the laws of physics. It is the zero hour of the Big Bang and the ground zero of the black hole. It not only holds the secret to our existence, it will also be responsible for the end of the universe."

510–530 CE **Anthemios of Tralles** (ca 474–534 CE). Mathematician and architect. Best known for the *Hagia Sophia* at Constantinople. Described the construction of an ellipse with a string fixed at two foci. His famous book *On Burning Mirrors* describes the focusing properties of a parabolic mirror.

ca 510–524 CE **Anicus Manilus Severinus Boethius** (480–524 CE, Italy). Roman philosopher, statesman and writer on mathematics. Played a role in the history of mathematics because his writings on geometry and arithmetic remained standard texts in the monastic schools for centuries.

Boethius was born in Rome into an aristocratic Christian family, during the reign of Odoacar. After the death of his father, a consul, (487 BC) he was taken under the patronage of men of the high nobility. He befriended Theodoric, Ostrogoth ruler of Rome, who made him consul (510), and later head of government and court services (520). But his good fortune did not last: accused of conspiring against Theodoric[330], he was arrested, imprisoned at Pavia, and finally executed without trial. His work *De consolatione philosophiae* (the Consolation of Philosophy) was written in prison. In the year 996, Otto III, ordered the bones of Boethius to be placed in the church of S. Pietro in Ciel d'Oro within a splendid tomb, for which Gerbert, afterwards Pope Silvester II, wrote an inscription.

The very meager works of Boethius came to be considered as the height of mathematical achievement, and thus well illustrate the poverty of the subject in Christian Europe during the Middle Ages: For the *Geometry* consists of nothing but the statements of the propositions of Book I, and a few selected propositions of Books III and IV of Euclid's *Elements*, and the *Arithmetic* is founded on the tiresome and half mystical work of Nicomachos of four

330 When Boethius published his works on philosophy, contemporaries assumed they were about the occult sciences, and he was accused of being an astrologer and magician.

centuries earlier. With these works, and his writings on philosophy, Boethius became the founder of Medieval scholasticism.

510–538 CE **Severus of Antioch** (465–538 CE). Greek monk – theologian and prelate. Undermined the base of the dominant ideology of the Church by attacking the notion that soul and body are separate. Revived *causality*[331] – the idea that one event leads to other events, that man and nature can be understood as historical phenomena, autonomous of divine intervention. Severus sees human beings as *processes* whose individuality is based on their *history* – their parentage, their education, their actions and moral decisions – which shape them to what they are. Evil arises historically, from people's relations with one another in society – rather than from the inherent sinfulness of man or matter. Therefore – to combat evil, society must change. This justified revolution. But if the affairs of humanity can be understood in terms of historical causes and effects, then the *world as a whole* can be understood in the same way.

Severus thus revived the battle between an *evolving world* and the one created once and for all.

Severus lived as a monk in the land of Israel; became a leading exponent for Monophysitism. He became a confidant of Emperor Anastasius who made him patriarch of Antioch (512 CE); fled to Egypt on accession of Justin I (518). He then became formulator and head of the Monophysite movement in Egypt and Syria.

ca 510–540 CE **Eutocius of Ascalon** (ca 480–540 CE). Lived as a monk in the city of Ascalon in Israel. Wrote commentaries on works of Archimedes and Apollonius. Does not appear to have done any original work.

520 CE **Bodhidharma** (d. 528, India and China). Founded in China the *Zen* (Ch'an) school of Buddhist meditation. It is not a philosophy or religion in the proper sense. It has nothing to teach and no rituals. Zen is a method of self-restraining that leads to understanding of reality. Its basic idea is that a person can discipline his mind so that he comes into touch with the inner workings of his being. He aims to grasp *intuitively* what he cannot grasp *rationally*. This larger *awareness* cannot be taught and each person must find it for himself.

Bodhidharma was born in Southern India. In 520 CE he came by sea to Canton, China, amongst Hindu refugees. He settled in the monastery of Shaolin near Lo-Yang, where he founded his school. He realized that scholastic and

[331] The Platonic-Augustinian worldview was *anti-historical*; God created the universe once and for all. Cause and effect was excluded – things happen because God willed it, and thus science could not begin to take root.

philosophical Buddhism had become dominant in China and that the schools of Buddhism had failed to grasp the reality of its basic ideas. This led him to promulgate Zen.

Against rational knowledge, on which Western Science is based, Zen has placed intuitive knowledge that is not enkindled by mathematical formulae and scientific treatises. Zen preaches that segmented knowledge, as science offers through its emphasis on rationality, is hardly wisdom. Zen believes that in order to penetrate the nature of man, a language beyond the confines of man must be employed. Man cannot *know himself* through his own language. He must resort to the language of universal scope, that of *no-knowledge*. Perhaps wisdom is the artful way in which rational knowledge, intuitive knowledge and no-knowledge can be integrated and applied.

529 CE Byzantine emperor Justinian closed the *Academy* (founded by Plato in 387 BCE) and the *Lyceum* (founded by Aristotle in 335 BCE) in Athens. This move was made to defend the state religion, Christianity, from what was then perceived as Pagan influence. Under Rome the status of science sank to a point where philosophers, astronomers, and charlatan magicians often were grouped together and stigmatized, even outlawed as *mathematicians*.

The end of the Roman Empire[332] is traditionally placed in the year 476 CE in which Odovacar set aside the titular ruler, Romulus Augustus; but

[332] Nobody knows precisely what caused the fall of Rome. There is, however, a consensus among contemporary historians that it was a result of a series of contingent events. Major among them were:

- *Social inequality* - the impoverishment of the masses by an economic system which enriched a small propertied minority.
  Whereas the Western Empire went under, the Eastern sector endured as Byzantine civilization for a very long time. In the East, much more of the land was owned by peasant proprietors than in the West, and therefore a correspondingly larger proportion of the total agricultural yield went to them. In the West, however, a landed aristocracy had a stranglehold on government administration and used its power and connections to funnel cash into its own coffers, creating a class of idle rich.
  The empire was already structurally flawed in the extreme by the 3^{rd} century. The taxes levied to maintain the army were massive, and they fell largely on the poor. The Roman rulers also managed to ruin the middle class. It was this class that had held the culture of the ancient world together, and by the 4^{th} century, it was going under. By the 5^{th} century it was gone, and it did not reappear in Italy until the rise of the mercantile families of the High Middle Ages.
- *Bankruptcy of the State*: By the 3^{rd} century nearly every denarius col-

from an intellectual point of view other dates have greater significance. The Greek schools of philosophy at Athens had lost much of the vitality they enjoyed during the days of Aristotle, but they continued to serve as a focus of scholarly activity until their dissolution in 529 CE. This year marked also the founding of the monastery at *Monte Casino*, a coincidence which may be taken as symbolic of the shift in interest from secular learning to religious activity.

The attitude of the early Church fathers to natural science had been characteristically expressed by **Lucius Caecilius Firmianus Lactantius** (ca 240–320 CE) [the "Christian Cicero" and tutor (at Trier) to Crispos, the son of Constantine], when he wrote:

"*To search for the causes of things; to inquire whether the moon is convex or concave; whether the stars are fixed in the sky, or float freely in the air; of what size and what material are the heavens; whether they be at rest or in motion; what is the magnitude of the earth; on what foundations is it suspended or balanced; to dispute and conjecture upon such matters is just*

---

lected in taxes was going into military and administrative maintenance, to the point that the state was drifting toward bankruptcy. The standing army rose from 300,000 troops in 235 CE to about 600,000 in 300 CE. This caused further debasement of the coinage and enormous inflation. Rome's policy of geographic and military expansion, became nonviable. By the time of the 5^{th} century, Rome was an empire in name only.

• *Spiritual and intellectual collapse.* For centuries, the aim had been to hellenize or romanize the rest of the population - to pass on the learning and ideals of Greco-Roman civilization. But as the economic crisis deepened, a new mentality arose among the masses, and based on *religion*, which was hostile to the achievements of higher culture. The new "intellectual" effort were designed to cater to the masses, until intellectual life was brought down to the lowest common denominator, primitive forms of life finally drowning out the higher ones. i.e. the gradual absorption of the educated classes by the masses and the consequent simplification of all functions of political, social, economical and intellectual life – the barbarization of the ancient world.

Religion played critical role in these developments: by the 3^{rd} century there was an attitude among many Christian that education was not relevant to salvation, and that ignorance had a positive spiritual value. Consequently, there was a sharp increase in mysticism and a belief in knowledge by revelation. The cognitive ability of comparing different viewpoints or perspectives had disappeared by the 6^{th} century. Even by the 4^{th} century, what little that had survived from Greek and Roman philosophy was confused with magic and superstition. In fact, the study of Greek (and therefore of *science* and philosophy) was completely abandoned.

as if we chose to discuss what we think of a city in a remote country, of which we never heard but the name".

Eusebius of Caesarea (ca 260–339 CE), adviser to the Emperor Constantine, one of the most learned men of the age, explained that it was not through ignorance of natural philosophy that he had turned from science, but through contempt for the uselessness of its activity, devoting himself to the direction of souls to better things.

Science Progress Report No. 1

The Earth Becomes Flat Again

"For a man, in those days, to have had an idea that his ancestors hadn't had, would have brought him under suspicion of being illegitimate".

Mark Twain, 1889 (1835–1910)

In the first centuries of the Christian era, mathematics was not in a flourishing state. It was suspect because of its close connection with heathen philosophy. Many even considered it the work of the devil, since the soothsayers and the astrologers often called themselves mathematicians.

The year 529 *marks the end of ancient mathematics and the beginning of the 'Dark Ages' in the history of science. When in* 527 *Justinian became emperor in the East, he evidently felt that the Pagan learnings of the Platonic Academy in Athens and other philosophical schools at Athens were a threat to orthodox Christianity. Hence in* 529*, the philosophical schools were closed and the scholars dispersed.*

As a result, there began a migration of scholars into Persia, where they established, under King Chosroes, the 'Athenian Academy in Exile'. Henceforth, the seeds of Greek science were to develop in Near and Far Eastern countries, until, some 600 *years later, the Christian world was in a more receptive mood.*

Mathematics did not disappear entirely from Europe in 529*. The spirit of mathematics languished, however, and was replaced by barren theological scholasticism.*

As far as the earth and the heavens were concerned, the Ptolemean geocentric cosmology reigned supreme. The actual architecture of the world was thought to approximate Aristotle's scheme of crystal spheres. But this purely descriptive scheme left an obvious epistemological void, which the theologians moved in to fill. The early leaders of the Christian Church insisted on a literal interpretation of the relevant Biblical passages, and the earth became flat again[333]*.*

[333] In 1993, the supreme religious authority of Saudi Arabia, issued an edict (fatwa), declaring that the world is flat. The edict also stated that anyone of the round persuasion does not believe in God and should be punished.

Among many ironies, the lucid evidence that the earth is a sphere, accumulated by Ptolemy, was transmitted to the West by astronomers who were Muslim and Arab; It the 9^{th} century, they named Ptolemy's book (in which the sphericity of the earth is demonstrated), the *Almagest*, "The Greatest".

“*O sweet spontaneous* earth,
How often have the doting fingers
    of prurient philosophers *pinched and poked thee,*
    has the naughty thumb of science *prodded thy beauty;*
How often have religions *taken thee*
    upon their scraggy knees, squeezing and buffeting thee
    that thou mightest conceive gods.
But true to the incomparable couch of death–
    thy rhythmic lover,
Thou answerest them only with spring”.

E.E. Cummings (1923)

Monasteries and Monks or,– the case of the ignorant copyists (529–1100)

The period of history which lies between ancient times and modern times, from the fall of the Western Roman Empire to the fall of Constantinople and the end of the Eastern Roman Empire, is generally known as the Middle Ages.

It was a period when the removal of the strong, central government of Rome left Europe in chaos. The mighty empire was fragmented into small kingdoms, and in many places rule was by local lords, each of whom exercised power only in the immediate vicinity of his own castle.

In Europe, this was a time of hardship and poverty. With the lack of wealth and consequently of people able to act as patrons, there was a decline in learning. Gradually however, nationalistic feelings grew and strong kings began to shape countries out of their lands. The rise of the feudal system created a structure on which secular governments could be based.

The drop in literacy in the Roman Empire was particularly sharp after the 3^{rd} *century. There was a decline in the availability of texts, and the period saw a basic cultural shift, an expansive loss of awareness of past achievements in the writing of history, as well as in philosophy and literature. Even by 400 CE, works by Cicero were difficult to find, and by the end of the* 6^{th} *century, the very few leading intellectuals of the Latin West who did exist, such a* **Gregory of Tours**[1] *(538-594), could barely write coherent sentences. From 600 to 1000, most people forgot to read and think, and, in fact, forgot that they had forgotten. There was an inability to approach texts critically, even among the leaders of European culture. Scholarship consisted of collecting quotes and facts, and the reasoning used by these scholars in their own works bore little resemblance to the classical texts they admired. Real scholarly debates and understanding, genuine logical interaction, did not appear until the* 11^{th} *century. Thus the proverbial lights went out in Western Europe.*

One may therefore ask: how did the Phoenix rise from its ashes 600 years later? To answer this question one must consider what the sources of cultural preservation were between roughly 500 and 1100 BCE, *and what difference these made for the cultural reawakening of Western Europe that began toward the end of the* 11^{th} *century and then lurched unevenly toward the Italian Renaissance and the Scientific Revolution.*

---

[1] He was ignorant of the rules of grammar, his spelling was faulty, his syntax shaky, and his arguments elementary. He wrote in the vernacular language of his time.

During the 6^{th} and 7^{th} centuries, monasteries, especially Irish ones, began to stow away the nuggets of intellectual achievement from Roman civilization, and, to a lesser extent, that of Greece. By 700 BCE, *while Europe was sacked by Goths, Arabs, and Vikings, a few scholars as the* ***Venerable Bede*** *(672–735), preserved the knowledge of the classics, carrying the seeds of Western life through the grim winter of the Dark Ages. In the 7^{th} century alone, 200 new monasteries were founded in Gaul. For 300 years, Irish monasteries produced a series of remarkable men who exerted a profound influence on thought and letters in Western Europe. Their missionary work extended to Scotland and the Continent, and disciples flocked to these regions. Monasteries such as those founded by the Irish monks* ***Columba*** *(521–597) and* ***Aidan*** *(590–651) became important study centers.*

In the monasteries, monks were busy in the scriptorium transcribing old manuscripts[2]. Most of them did not understand the implications of the texts they were copying. Passages got transcribed without any inquiry as to whether they made sense, or contradicted other authorities. In fact, many Benedictine monks had entered the monasteries as children, handed over by their parents. The scriptoria thus became the loci of cultural preservation, but the copying of manuscripts was more a manual training than an intellectual one: calligraphy rather then philosophy.

Moreover, monasteries, from the 4^{th} century on, were not schools for sacred study, but, rather, of ascetic practice. Monks and clerks regarded philosophy as a source of heresy. By 500, the monastic ideal included the notion that learning was incompatible with Christian culture. The idea of the monastic school was to break with classical learning, and to teach the "science" of ascetic contemplation instead. Thus, it appears that the intellectual disciplines of distinction, definition, and dialectic were lost to the readers of the Dark Ages. Their apprehension of the world rested on myth and magic, and the prevalent mind-set was one of symbols, analogies, and images. Both Columba and Aidan renounced classical learning, implanting instead the desire to meditate on Scripture.

By 800, then, written civilization has disappeared, and only a tiny elite had access to intellectual culture. And yet, this warped form of classical preservation did serve an important purpose. Manuscripts were copied, libraries were accumulated, and the later dispersion of this material made the

---

[2] Supposedly, the monastic built-in schools taught the old curriculum of the *trivium* (grammar, rhetoric, and dialectic) and the *quadrivium* (arithmetic, geometry, music, and astronomy). However, the anglo-saxon clergy, knew little or no Latin and they were in fact, as ignorant as the majority of laymen. By 600, even leading intellectuals were not able to think in the sense that the people of antiquity or of the 12^{th} century were able to do.

subsequent revival of learning possible. When the cognitive revolution *(that began in the late* 11^{th} *century) finally took hold, the ancient material was at least available, now to be looked at through new eyes.*

So the texts had to be there for a 12^{th} *century renaissance to occur, and the monks of the Dark Ages managed to preserve them, even if they did not understand them very well and despite the fact that their own purposes were ascetic rather then intellectual.*

Finally, the steady growth of power and wealth within the church provided another unifying force, and gave some men leisure to pursue lives of scholarship and study.

The great monasteries founded throughout continental Europe during the Middle Ages preserved ancient learning. These were inhabited by communes of monks and nuns who lived by the so-called 'rule' of the monastery. The greatest 'rule' was that of ***St. Benedict of Nursia*** *(480–542) who founded the monastery of Monte Cassino in Italy at about 529. Under the guidance of Pope Gregory VII, some monks became scholars and teachers. At a time when few laymen could read or write, they preserved much classical learning which would otherwise have been lost*[3]*. Monks prayed for the souls of the dead, and had practical duties such as caring for the sick and feeding the poor. The religious houses – both male and female – provided almost all the medical skill available then. The monastic libraries preserved much classical learning, but books disapproved of by the church, were kept hidden away or destroyed.*

In the Germanic kingdom, the Benedictine monasteries exerted powerful influence. Their emphasis on obedience to higher authority helped hold the church together at a time when any sort of centralization was hard to achieve. In many parts of Europe the Benedictines introduced valuable new techniques, such as stone masonry and organizing agriculture around the large estate. Thus they served as nuclei for the growth of towns, for they were usually more prosperous than the neighboring countryside.

Monasteries spread rapidly throughout most of the Germanic kingdoms, often more rapidly than organized dioceses and parishes.

---

[3] It was the monks who *preserved* the cultural heritage of the ancient Greeks by copying and recopying the old parchments to save them from decaying. It was the Christian Church, however, who decided what should be copied and what should not. These decisions affected mainly works of literature and philosophy. Thus, the Church held the power to censor and exterminate any piece of cultural item which in its opinion threatened the Christian dogma.

ca 530 CE **Simplicius**. Greek philosopher. Disciple of Ammonius and Damascius. Author of commentaries on some of Aristotle works.

A native of Cilicia and one of the last of the Neoplatonists. When in 529, the school of philosophy at Athens was disendowed and the teaching of philosophy forbidden, the scholars **Damascius**, Simplicius, **Priscianus** and four others resolved in 531 or 532 to seek the protection of Chosroes, king of Persia. They returned to Greece when Chosroes, in his peace treaty with Justinian (533 BCE), expressly stipulated that the seven philosophers should be allowed "*to return to their own homes, and to live henceforward in the enjoyment of liberty of conscience*".

Simplicius was not an original thinker, but his remarks are thoughtful and intelligent and his learning is prodigious.

530–540 CE **Dionysius Exiguus** (497–540, Rome). Chronologist. A Christian monk, introduced in ca 525 the method of dating years of the Christian Era. He chose its first year to be the year of Christ's birth (the *actual* time of that event was a few years earlier). Since he started from year 1 and not year 0, the previous year is called 1 BCE.

Prior to this date, Near-Eastern, Greek and Roman Calendars were all related to local fiducials, centered on current monarchs or specific events such as the *fall of Troy* (1183 BCE, recommended by Eratosthenes), the great *earthquake* at the time of the prophet Amos (Amos I, 759 BCE), the *olympic games* (Greece, 776 BCE, 772 BCE etc.), the *founding of Rome* (A.U.C.=ab urba condita, ca 754 BCE), the *battle of Salamis* (480 BCE) and other examples.

The era most commonly used in Dionysius' day was the *Diocletian era*, which the Christians called the *era of martyrs*. It began on August 29, 284. Dates were often established with reference to the Roman consuls.

The Christian era was not adopted at once; in the Byzantine Empire, Dionysius' reform was not accepted at all. Byzantines numbered their years with reference to the 15 years indiction-cycles[4] and to the creation of the world. The Christian era was introduced in Russia only in the time of Peter the Great. The habit of counting pre-Christian years with reference to the Christian era is a recent innovation.

530–548 CE **Cosmas of Alexandria** (**Indicopleustes**). Greek navigator and explorer of the Indian Ocean. (The surname is inaccurate since he never

[4] **Diocletian** fixed a 15-year assessment of property tax. It was used as a chronological unit in ancient Rome and incorporated in some medieval systems.

reached India proper; further, it is doubtful whether Cosmas is a family name, or merely refers to his reputation as a cosmographer.)

In his early days he had sailed the Red Sea and the Indian Ocean, visiting Abyssinia and Socotra and apparently also the Persian Gulf, coast of western India and Ceylon. He subsequently became a monk, and at about 548 CE, in the retirement of a Sinai cloister, wrote a work called *Topographia Christiana*.

According to Cosmas' map the earth is a rectangular plane, covered by the vaulted roof of the firmament, above which lies the heaven. In the center of the plane is the inhabited earth, surrounded by an ocean, beyond which lies the paradise of Adam. His was probably the oldest Christian map. In it the sun revolves round a conical mountain to the north – round the summit in summer, round the base in winter, which accounts for the difference in the length of the day. Cosmas is believed to have been a Nestorian.

537 CE Dedication of the church *Hagia Sophia*[5] in Constantinople (now Istanbul), the finest and most famous example of Byzantine architecture (East Roman) in the world. It was built as a Christian cathedral by **Justinian I, the Great**, (482–565 CE) between 532 and 537 CE. The architects employed were **Anthemias of Tralles** and **Isidoros of Miletos**.

The main problem they had to solve was that of carrying the dome (which measures 56 m high and 33 m across) on four arches. The building itself is 76 m from east to west and 72 m from north to south. The four arches formed a square on a plane, and between them were built spherical pendentives, which, overhanging the angles, reduced the center to a circle on which the dome was built. During the earthquake of 555 CE, this dome fell down, and when rebuilt was raised higher and pierced round its lower part with 40 circular-headed windows, which give an extraordinary lightness to the structure. This was done between 558 and 563 CE. After 1453, when the Turks conquered the city, the building was used as a mosque. Since 1953, Hagia Sophia has served as a museum.

The inside appearance is one of great space, height and richness. The rare and costly building materials were brought from many parts of the Roman Empire. The marble-lined walls have many colors and designs. Mosaic decorate the vaults, and beautiful pictures decorate the walls.

542–594 CE Waves of *Bubonic Plague* over Europe, Asia and Africa. Known as the *Plague of Justinian*, it began in lower Egypt and from there spread to Israel, Asia Minor, Italy, the North coast of Africa and Gaul. Many millions died over the whole Roman world.

---

[5] A Greek phrase meaning 'Holy Wisdom'.

ca 550 CE **Asaf ha-Rofeh**; **Asaf Yudaeus** (Israel and Babylonia). Physician and medical scholar from the pre-Arabian period. Known for his extant "*Book of Medicine*". Although the book is, in the main, based on the teachings of the Greek Hippocratic school, it was modified to suit Near-Eastern climate, national tastes and habits, with important Talmudic and ancient Israeli sources. The book was originally written in Hebrew and later translated into Greek, Latin and Arabic. It serves today as a source of ancient medicine (terminology, prognostics, diagnostics, hygiene, diet, pathology, anatomy, pharmacology etc.).

ca 550 CE **Olympiodoros (the Younger) of Alexandria** (ca 510–570 CE). A Greek Neoplatonic philosopher. Maintained Platonic tradition in Alexandria after suppression of Athenian school (529 CE) by Justinian. Wrote commentaries on Plato and Aristo. Euclid's and Heron's discovery that light (reflected from a plane surface) takes the path of least time prompted him to say in his *Catoptrica*:

"Nature does nothing superfluous or any unnecessary work."

In medieval times it was commonly accepted that nature behaved in this manner. Indeed, **Leonardo da Vinci** said: "Nature is economical and her economy is quantitative". Later on, **Robert Grosseteste** said: "Nature always acts in the mathematically shortest and best possible way."

ca 550 CE *The map of Madaba.* The oldest true geographical map extant. It is a mosaic map of Israel, discovered in Moab in 1896.

550–580 CE **Varahamihira** (505–587, India). Astronomer. Produced a revised version of the Indian Calendar. His works on mathematical astronomy include a number of trigonometrical identities, apparently derived by him for the first time:

$$\sin x = \cos(\frac{\pi}{2} - x); \qquad \sin^2 x + \cos^2 x = 1; \qquad 1 - \cos 2x = 2\sin^2 x.$$

Also, extending the work of Aryabhata the Elder, he gave more accurate sine tables. He also produced a Pascal's triangle for the binomial coefficients C_r^n.

550–580 CE **Alexander of Tralles** (Trallianus, ca 525–605 CE). Byzantine physician. Practiced in Rome; author of major work on pathology and therapy circulated in Greek, Arabic and Latin (*Libri duodecim de re medica*) into the 16^{th} century. Born at Tralles in Lydia.

560–760 CE Decline and eradication of the *Moche civilization* (since 100 CE) in Northern Peru due to destruction of their water irrigation canals by repeated El-Ninio weather systems.

ca 600 CE The first documentary evidence of *Chess*. There is supportive evidence that places it in North India in 455 CE. Some historians place the origin of Chess even prior to the invasion of India by Alexander the Great in 326 BCE. From India, Chess spread to Persia and China.

600–650 CE A dry period preceded the great wave of Arab outburst out of Arabia.

600–800 CE Arabs carved themselves an empire from the Indian Ocean to the Atlantic within one century.

622–633 CE **Isidore of Seville or Isidorus Hisplensis** (ca 560–636, Spain). Encyclopedist and historian whose books served to keep alive, throughout the Dark Ages, some little knowledge of the antique culture and learning. One of the most important links between the learning of antiquity and the Middle Ages. His chief works were:

- *Chronica* – a history extending to his own time.
- *Originum sive etymologiarum* – an encyclopedia in 20 volumes which deals with geography, law, medicine, natural history, architecture, etc. It was based on available knowledge of Greek learning, borrowed from **Pliny the Elder**, **Suetonius** and a wide range of other authorities, to whom credit is not given. It is an unsystematic, uncritical treatise, merely reproducing at second hand the substance of antique sources. Yet even this inadequate encyclopedia was very influential in early Medieval times. It contributed to the acceptance of astrology in Medieval Europe.

Isidore was educated in a monastery and became archbishop of Seville (602–636). He was of Jewish birth[6] and was made a Saint of the Catholic Church.

[6] It is a fact that the founders of Christianity, many of the Church Fathers (including the first three Popes), and a considerable number of the Catholic Saints, were of Jewish origin. So was Saint Isidore of Seville, one of the most commanding and devout figures in Spanish Church History of the Visigothic period. Yet, it is these apostates out of spite, that generated the greatest hate against the Jews. In his polemic book *De fide Catholica... contra Judaeos* (630) he endeavored to 'prove', using biblical quotations, the 'wrong' religious perception of Jews.

622 CE, July 16 (**Friday**) *Commencement of the Muslim Calendar*, on the day of the flight of **Muhammad**[7] (570–632 CE) from Mecca to Medina

[7] Founder of *Islam*. In 595 CE, he married a wealthy widow, who had employed him as a camel-driver for her caravans. It is at this point, while traveling throughout Arabia, that Muhammad came into contact with Jews and Judaism and began to reflect on the differences between the naive pagan pantheism of his people and the lofty religious concept of the Jews.

The Islamic religion is embodied in the *Koran* (from the Arabic work "reading"). Muhammad rejected the concepts of Virgin Birth and Trinity, and insisted with the Jews that God was one, needing neither a family nor companions. He was also repelled by the Christian worship of saints, which he viewed as idolatry, and like the Jews banned all statue worship. The predominant non-Arabic figure in the Koran is **Moshe**, not Jesus.

Of the six basic tenets of Islam, four are derived from Judaism (belief in the immortality of the soul; belief in one invisible God; the belief in a God-sent prophet; the belief in the Book as the revealed text) and two from Christianity (Judgment day; total surrender of the human will to God). The correspondence is Jehovah-Allah; Moses-Muhammad; Torah-Koran; "God's grace"-Islam.

The mosque, like the church, was modeled on the synagogue. In the matter of prayers, forbidden foods, circumcision, hygiene, marriage and divorce, and the study of sacred Scripture, Muhammad and his successors also followed Jewish models faithfully. This may explain why Arabic and Jewish culture during the first 5 centuries of Islam showed such a remarkable affinity, and why in Spain, North Africa and Babylonia they went through an almost parallel development.

Whether from conviction or expediency, Muhammad, at the outset of his prophetic career, addressed his preachings almost exclusively to the Jews of Arabia. He borrowed much of the narrative material as well as the doctrine for the *Koran* from the *Talmud* and *Midrash*. In composing his poetic *Suras* he used the well-known Jewish Bible stories of Adam, Abraham, Lot, Joseph, Moshe, Saul, David, Solomon, Elijah, Job and Jonah.

When Muhammad first raised the standard of militant Islam in Mecca, he was persecuted and had to flee (622 CE). He went to Medina, where he expected that a large part of the Jewish population would accept him as the Prophet of Allah since, as he saw it, their religion was the same as his. He posed as a prophet of Israel and preached to the Jews of Medina in a style he thought rabbinical. Furthermore, he made Jerusalem his *Kibla* (the direction in which he turned his face while at prayer).

But when the Jews of Medina, who were well acquainted with their sacred writings, proceeded to expose his brand of *Torah* as fraud, Muhammad turned furiously away from them after many acrimonious disputes with their rabbis. He then changed his *Kibla* from Jerusalem to Mecca.

(*Hegira*). The years of the Hegira are purely lunar, and always consist of 12 lunar months, commencing with the approximate new moon, without any intercalation to keep them to the same season w.r.t. the sun, so that they retrograde through all seasons in about $32\frac{1}{2}$ years. They are also partitioned into cycles of 30 years, 19 of which are common years of 354 days each, and the other 11 are intercalary years having an additional day appended to the last month. The mean length of the year is therefore $354\frac{11}{30}$ days, or $354^d : 8^h : 48^m$, which upon division by 12 gives $29\frac{191}{360}$ days or $29^d : 12^h : 44^m$, as the time of a mean lunation. This differs from the astronomical mean lunation by only 2.8 seconds, and leads to an error that amounts to a day in about 2400 years.

625 CE In *Chiku Suan Ching* (Continuation of Ancient Mathematics), Chinese mathematician **Wang Hsiao Tung** presented approximate solutions of algebraic equations of the third degree with practical applications to problems encountered by engineers, architects and surveyors.

628 CE **Brahmagupta of India** (598–670 CE). Astronomer and mathematician. Head of an astronomical observatory at Ujein. Wrote a book on

---

Jews arrived in Arabia as early as the days of King Solomon (900 BCE), when his ships sailed the seas in search of new markets. During the period of the *Hasmonean Kingdom* (142–64 BCE), Israel became too small to hold the growing Jewish population, and numerous Jews went forth to seek homes in Syria, Egypt and the western coast of Arabia. It is also possible that when the Nabatean Arabs invaded Israel (as they did on several occasions) they took away some captives who eventually made their way further south. The defeat by Rome (70 CE), and the ill effects of the subsequent rebellions, increased the Jewish population in this part of the Eastern world.

By the middle of the 5^{th} century Jews were to be found as far as the Kingdom of Yemen. The Jews helped found the city of Yathrib (Medina), which, by that time, had become the largest, most important city in Arabia, its 10,000 Jews constituting the majority of the population. Far from the centers of Jewish culture in Israel and Babylonia, the Arabian Jews possessed little learning. They did know and revere the Bible and therefore were known to the pagans around them as "the People of the Book". Their belief in the unity of God, their higher personal morality, their dignified observance of Jewish feast and fast days, their rest from work on the Sabbath and their refusal to permit a fellow Jew, even of a different tribe, to remain in slavery, left a deep impression upon their neighbors. In this way, their presence and example prepared the mind of the heathen Arabs for the acceptance of a higher form of religion.

Thus Judaism in Arabia served as a foundation for Islam in the same way that Diaspora Judaism in the Roman Empire had served as a foundation for early Christianity.

algebra and trigonometry. Brahmagupta also wrote an important work on astronomy in 21 chapters *Brahma-sphuta-siddhanta* (628) (The Opening of the Universe). His understanding of the number systems was far beyond others of his period. He developed some algebraic notation. In his trigonometry he gave not only Heron's formula for the area A of a triangle in terms of the three sides but also the remarkable extension for the area of a cyclic quadrilateral having sides a, b, c, d and a semiperimeter $s = \frac{1}{2}(a+b+c+d)$, namely[8]

$$A = \sqrt{(s-a)(s-b)(s-c)(s-d)}.$$

For the sides of right-angled triangle, Brahmagupta gave the two sets of values $\{2mn, m^2-n^2, m^2+n^2\}$ and $\{\sqrt{m}, \frac{1}{2}(\frac{m}{n}-n), \frac{1}{2}(\frac{m}{n}+n)\}$, values that he probably obtained from Greek sources.

Among other mathematical topics taught by Brahmagupta were rules for elementary operations with positive and negative numbers, progressions and Diophantine equations of the first and second degree.

He perhaps used the method of continued fractions to find integral solution to indeterminate equations of the type $ax + c = by$.

Brahmagupta also solved quadratic indeterminate equations of the type $ax^2 + c = y^2$ and $ax^2 - c = y^2$. For example he solved $8x^2 + 1 = y^2$, obtaining the solutions:

$$(x, y) = (1, 3), (6, 17), (35, 99), (204, 577), (1189, 3363), \ldots$$

For the equation $11x^2 + 1 = y^2$ Brahmagupta obtained the solution

$$(x, y) = (3, 10), (161/5, 534/5), \ldots$$

He also solved $61x^2 + 1 = y^2$, which has

$$(x, y) = (226\ 153\ 980, \quad 1\ 766\ 319\ 049)$$

as its smallest solution.

[8] Brahmagupta wrongly believed that it held good for any quadrilateral. The Greek mathematician **Hero** had, however, pointed out that the area of the general quadrilateral is not determined by the four sides alone. Indeed, medieval mathematicians discovered the general formula

$$A^2 = (s-a)(s-b)(s-c)(s-d) - abcd\cos^2\left(\frac{A+C}{2}\right),$$

where A,C is a pair of opposite vertex angles of the quadrilateral.

He gave explicit expressions for the sum of squares of the first n natural numbers as $n(n+1)(2n+1)/6$ and the sum of cubes of the first n natural numbers as $(n(n+1)/2)^2$. No proofs are given so we do not know how Brahmagupta discovered these formulas.

Brahmagupta derived an interpolation formula which he used to compute values of sines. The rule is equivalent to the *Newton-Stirling* interpolation formula to second order differences.

The great Hindu mathematicians (500 BCE–1400 CE)

There are many differences between Greek and Hindu mathematics. In the first place, the Hindus who worked in mathematics regarded themselves primarily as astronomers, and thus Hindu mathematics remained largely a handmaiden to astronomy; with the Greeks, mathematics attained an independent existence and was studied for its own sake. Also, due to the caste system, mathematics in India was cultivated almost entirely by the priests; In Greece, mathematics was open to anyone who cared to study the subject. Again, the Hindus were accomplished computers but mediocre geometers; the Greeks excelled in geometry but cared little for computational work. Even Hindu trigonometry, which was meritorious, was arithmetical in nature; Greek trigonometry was geometrical in character.

The Hindus wrote in verse and often clothed their works in obscure and mystic language; the Greeks strove for clarity and logic in presentation. Hindu mathematics is largely empirical, with proofs or derivations seldom offered; an outstanding characteristics of Greek mathematics is its insistence on rigorous demonstration. Hindu mathematics is of very uneven quality, good and poor mathematics often appearing side by side; the Greek seemed to have an instinct which led them to distinguish good from poor quality and to preserve the former while abandoning the latter.

In the period between the demise of the Greek world and the rise of Islam, it was India that occupied the center of the mathematical stage. We know that there was some mathematical activity during the first millennium BCE, *but we have no texts earlier than the* 5^{th} *century CE. The degree of influence of Greek, Babylonian, and Chinese mathematics on Hindu mathematics, and vice versa, is still an unsettled matter, but there is ample evidence that influence in* *both directions was appreciable. One of the pronounced benefits of the Pax Romana was the diffusion of knowledge between East and West, and from a very early date India exchanged diplomats with both the West and the Far East. From about 450 CE until ca 1500 CE, India was subjected to numerous foreign invasions: Huns, Arabs (8^{th} century)and Persians (11^{th} century). During this period there were several Hindu mathematicians of prominence.*

Hindu mathematics and astronomy reached its zenith during the period of the Gupta dynasty (320–550 CE). The Hindus had long been interested in these subjects and surpassed even the Greeks of the Hellenistic period in some branches of Mathematics. Using abstract principles of algebra, the Hindus could cope with much more difficult concepts than found in the visible Greek demonstrations of geometry. Greek algebra was rudimentary, but the Hindus invented the concept of negative quantities, solved quadratic equations, and calculated the square root of 2.

Hindu astronomers during the Gupta period were interested in predicting the positions of the planets for astrological purposes, having a deep belief in the cyclic nature of the world. Thus, for example they believed that it takes the planets 4,320,000 years to return to their identical positions. This time span they called Maharyuga (great yuga). According to the Hindus, once in about 4 million years, the planets come into grand conjunction (roughly in line as seen from Earth). According to two pieces of Sanskrit from the Bhagavad-Gita this occurred on Friday, 18 February 3102 BCE.

Furthermore, the Hindus believed that the entire universe went through alternating periods of 'awake' and 'sleep' every 1000 Maharyuga (= 4.32 billion years) just like the oscillating universe in modern cosmology. Aryabhata's task was to fit the Greek description of planetary motions developed by Apollonios and Claudius Ptolemy at Alexandria, into a Hindu religious settings.

The degree of influence of Babylonian algebra on the pre-Diophantine geometric algebra of the Greeks, on Diophantos himself, and on algebra in India, has been considerable. This may have been brought about through trade relations and by frequent foreign invasions of India throughout the first millennium CE, when Hindu algebra and trigonometry were being developed mostly by **Aryabhata the Elder** *(476–550 CE),* **Brahmagupta** *(598–670 CE),* **Mahavira** *(ca 850 CE),* **Bháskara** *(1114–1185 CE) and* **Madhava** *(ca 1400 CE).*

Nevertheless, there is sufficient evidence today, from a number of independent sources, to support the claim that original ideas, methods and computational systems in the fields numeration, algebra, trigonometry and even mathematical analysis (!), originated for the first time in the minds of Hindu *mathematicians throughout 19 centuries before the High Renaissance in Europe. Let us summarize their achievements, one by one:*

- `Algebra:` *Permutations and combinations, notations for indices and laws of their operations, including fractional powers. Binomial theorem. Extraction of roots. Solution of indeterminate equations of the first and second degree. Solutions of Pell's equation.*

- `Trigonometry:` *First use of the sine function as we know it today. Basic trigonometric identities and construction of sine tables. Second-order interpolation to compute intermediate functional values. Infinite power-series expansions of trigonometric functions (without the use of infinitesimal calculus). Power series for* π.

- `Geometry:` *Discovery of the formula for the circumradius of a cyclic quadrilateral.*

- `Advent of mathematical calculus:` *by the* Kerala *school of astronomy (**Narayana**, **Madhava** and **Nilakantha**). This incorporates the concept of* instantaneous motion *of the moon at a given point in time; they calculated this quantity from the formula (in modern notations)*

$$u' - u = v' - v \pm e(\sin w' - \sin w) \tag{1}$$

where

$$\begin{aligned} u &= \text{moon's true longitude,} \\ v &= \text{moon's mean longitude,} \\ w &= \text{moon's mean anomaly} \end{aligned}$$

all at a particular time; (u', v', w') *are the same entities after a specific time interval;* e *is the orbital eccentricity at this stage. The Hindu mathematicians recognized the important conceptual step that for short time intervals*

$$(\sin w' - \sin w) \approx (w' - w)\cos w \tag{2}$$

In modern notations (1) and (2) are written as

$$\delta u = \delta v \pm e \cos w(\delta w) \tag{3}$$

***Bháskara** then made the decisive step of isolating the fundamental mathematical idea of the* differential *from its astronomical manifestation. Clearly, equation (2) implies in modern notations that*

$$d(\sin w) = \cos w dw.$$

He noted that when a variable attains the maximum value, its differential vanishes.

He also gave us the trigonometric identities

$$\sin(\alpha \pm \beta) = \sin\alpha\cos\beta \pm \cos\alpha\sin\beta.$$

- `Present-day numerals, decimal place-notation and first use of the zero. Representation of unknown quantities and negative signs.`

  The Hindu-Arabic decimal numeral system $(0, 1, 2, 3, 4, 5, 6, 7, 8, 9)$ *is named after Hindus, who invented it, and after the Arabs, who transmitted it to Western Europe. This was the most significant achievement of Hindu mathematics during the European Dark Ages. Final maturation of this notation into a place-value system probably took place around 500 CE.*

  The last and most difficult step was the promotion to full membership of a tenth numeral: a round symbol for zero – or sunya (which means 'empty'), as the Hindus called it. Confusion about the status of this mysterious numeral persisted for centuries as 'a symbol that merely causes trouble and lack of clarity'. How, it was asked, could a symbol which means 'nothing', when placed after another numeral, enhance its value tenfold?

  The Hindus were not proficient in geometry. Rigid demonstration were unusual in their works, and postulational development were nonexistent. Their geometry was largely empirical and generally connected with mensuration. Yet some of their algebraic results in geometry are remarkable. Among these are the area A *and diagonals* $\{D_1, D_2\}$ *of a cyclic quadrilateral having sides* (a, b, c, d) *and semiparameter* s*, given by* ***Brahmagupta****:*

$$A = \sqrt{(s-a)(s-b)(s-c)(s-d)}$$

$$D_1^2 = \frac{(ab+cd)(ac+bd)}{ad+bc}; \qquad D_2^2 = \frac{(ac+bd)(ad+bc)}{ab+cd}$$

$$D_1 D_2 = ac + bd$$

  In algebra, Brahmagupta solved quadratic equations and allowed for the possibility of negative solutions (665 CE).

  In his astronomical treatise Khanda Khadyaka (665 CE) he derived an interpolation formula for the sine function which in modern notation is *equivalent to the Newton-Stirling interpolation formula*[9] *up to second order differences,*

$$f(a + xh) = f(a) + x\frac{\triangle f(a) + \triangle f(a - h)}{2} + x^2\frac{1}{2!}\triangle^2 f(a - h)$$

where $\triangle$ *is the first-order forward-difference operator,* $\triangle^2$ *is the second-order difference operator.*

- *`First use of continued fractions`.* ***Aryabhata****, in particular, used them to solve linear indeterminate equations.*

Narayana Pandit *(1340–1400) obtained a rule to calculate approximate values of a square root of a non-square number. He did this by using an indeterminate equation of the second order,* $Nx^2 + 1 = y^2$*, where* N *is the number whose square root is to be calculated. If* x *and* y *are a pair of roots of this equation with* $x < y$ *then* $\sqrt{N}$ *is approximately equal to* y/x*. To illustrate this method Narayana took* $N = 10$*. He then found the solutions* $x = 6$*,* $y = 19$ *giving for* $\sqrt{10}$ *the approximation* $19/6 = 3.16666666666666666667$*, which is correct to two decimal places. Narayana then gave the solutions* $x = 228$*,* $y = 721$ *which render the approximation* $721/228 = 3.16228070175438596949$*, correct to four places. Finally Narayana gave the pair* $x = 8658$*,* $y = 227379$ *which yield the approximation* $227379/8658 = 3.16227766227766227777$*, correct to eight decimal places. Note for comparison that* $\sqrt{10}$ *is, correct to 20 places, 3.16227766016837933320.*

Madhava of Sangamaramma *(1350–1420), astronomer and mathematician, clinched the mathematical analysis trend began by his predecessors Bháskara and Brahmagupta. By giving a* geometric *derivation to infinite power series expansion of circular and trigonometric functions, as well as a finite-series approximation to them, he discovered the sine and cosine power series, about 300 years before* **Isaac Newton***. These series made their first appearance in Europe (1676) in a letter written by Newton to the secretary of the Royal Society, Henry Oldenburg.*

The series are

---

9 With the aid of this formula one interpolates the sines of intermediate angles from a sine table. The interval is h and $\triangle\theta$ is the residual angle.

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots \tag{4}$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots \tag{5}$$

Newton was not aware of their earlier discovery. Using his calculus (which obviously was unknown to Madhava) he started from the definite integral representation

$$\sin^{-1} y = \int_0^y \frac{dt}{\sqrt{1-t^2}}$$

and used the binomial series

$$(1+a)^p = 1 + pa + \frac{p(p-1)}{2!}a^2 + \frac{p(p-1)(p-2)}{3!}a^3 + \dots$$

with $a = -x^2$, $p = -1/2$ *to obtain (after term by term integration)*

$$\sin^{-1} y = x = y + \frac{1}{2}\frac{y^3}{3} + \frac{1}{2}\frac{3}{4}\frac{y^5}{5} + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}\frac{y^7}{7} + \dots$$

Assuming $y = a_0 + a_1 x + a_2 x^2 + \dots$ *and substituting this into the r.h.s. of the above equation, the coefficients* $\{a_0, a_1, a_2, \dots\}$ *can successively be obtained by comparing with the coefficients on the l.h.s. This yields*

$$y = \sin x = x - \frac{x^3}{6} + \frac{x^5}{120} - \frac{x^7}{5040} + \dots$$

Madhava also gave a series for the inverse tangent function, $\tan^{-1} x$*, three centuries before* ***James Gregory*** *(1667):*

$$\tan^{-1} x = x - \frac{x^3}{3} + \frac{x^5}{5} - \dots \qquad x \le 1 \tag{6}$$

He went on to anticipate ***Brook Taylor*** *(1712) with his expansions for* $h \ll 1$

$$\sin(x+h) \simeq \sin x + h\cos x - \frac{1}{2}h^2 \sin x \tag{7}$$

$$\cos(x+h) \simeq \cos x - h\sin x - \frac{1}{2}h^2 \cos x \tag{8}$$

Now Madhava put $x = 1$ into (6) to obtain

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \dots \tag{9}$$

and he also put $x = \frac{1}{\sqrt{3}}$ into (6) to obtain

$$\pi = \sqrt{12}\left[1 - \frac{1}{3 \cdot 3} + \frac{1}{5 \cdot 3^2} - \frac{1}{7 \cdot 3^3} + \dots\right]. \tag{10}$$

From these results he calculated π correct to 11 decimal places

$$\pi = 3.141\ 592\ 653\ 59$$

which can be obtained from (10) by taking only 22 terms.

Perhaps even more impressive is the fact that Madhava gave a remainder term for his series. He thus improved the approximation of the series for $\pi/4$ by adding a correction term R_n to obtain

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \dots \frac{1}{2n-1} \pm R_n$$

Madhava gave three forms of R_n which improved the approximation, namely

$$R_n = \frac{1}{4n} \qquad \text{or}$$

$$R_n = \frac{n}{4n^2 + 1} \qquad \text{or}$$

$$R_n = \frac{n^2 + 1}{4n^3 + 5n}.$$

There has been a lot of work done in trying to reconstruct how Madhava might have found his correction terms. The most convincing argument is that they come as the first three convergents of a continued fraction which can itself be derived from the standard Hindu approximation to π, namely 62832/20000.

Madhava's outstanding contribution in the field of infinite series expansion of circular and trigonometric functions with the finite series approximations to them, predates European work on the subject by two to three hundred years. Historians claim that the method used by Madhava to derive the above results amounts to term by term integration. Thus, this was a decisive step toward modern classical analysis.

635 CE The value of $\pi = 3.1415927$ was given in decimal notation in the official history of the Sui dynasty.

638 CE *The Muslims conquered Jerusalem* and allowed Jews to resettle there. Upon their conquest of Babylonia (642), Jewish life entered a new cultural phase: an inevitable fusion between Greco-Arab and Jewish-Babylonian civilizations. Aramaic, which had been the Jewish vernacular since the first return of the Exiles (538 BCE), gave way to Arabic, although Hebrew continued to be the language of prayer and religious study.

640–646 CE The remains of the great Alexandria library were burned to ashes by the Saracens and the Arabs (previously pillaged in 48 BCE, 269, 273, 295, 389 and 415). The story is told that the precious manuscripts in the great library were used by the Arabs as fuel to heat the baths of the city.

ca 650 CE The first definite trace of the Hindu numerals outside of India. **Severus Sebokht** praises the Hindus for "… *their subtle discoveries in this science of astronomy, discoveries that are more ingenious than those of the Greeks and the Babylonians; their valuable methods of calculation; and their computing that surpasses description. I wish only to say that this computation is done by means of nine signs*".

From this it is clear that the Hindu numerals had somehow reached the monastic schools of Mesopotamia.

650–690 CE **Paul of Aegina** (Paulus Aegineta, ca 625–690 CE). Greek surgeon. His *Epitomae medicae libri septem* contained nearly everything known of medicine in his time and greatly influenced Arab physicians.

725 CE The Chinese invented the escapement of the *mechanical clock*.

732 CE **Charles Martel**, ruler of the Franks, defeated the Moslems at *Tours*, thus halting their northward advance into Europe. They finally retreated over the Pyrenees in 759. It was the first unsuccessful effort of Islam to take over Western civilization. At this very time, civilization was passing from the *thalassic* to the *oceanic* stage. The Mediterranean was losing its hegemony as a cultural center of the world for cities were widely established throughout Europe to the Atlantic coastline.

732–735 CE **Bede** (672–735, England). Anglo-Saxon scholar, historian, naturalist and theologian. Father of English history. Writer about the calendar, the shape of the earth, and the tides, giving a correct account in each case.

Bede was born at Jarrow, England. Ordained (703); associated with the monastery of St. Paul at Jarrow throughout his life. Taught Greek, Latin, Hebrew and theology. Concluded (732) his ecclesiastical history of England. It may be said that his works, scientific, historical and theological, practically sum up all the learning of Western Europe in his time. Though Bede makes no pretensions to originality, freely taking what he needed, and (what is very rare in medieval writers) acknowledging what he took, still everything he wrote is informed and impressed with his own special character and temper.

746–749 CE Plague devastated Constantinople and spread into Greece and Italy. Ca 200,000 die.

ca 760 CE **Yehudai ben Nachman Gaon** (ca 700–770, Babylonia). Scholar, legalist and perhaps the *Talmud redactor*. Head of the Sura Academy (760–764), when the *Abbasides* were in power. Composed a digest of the Talmudic law, the *Halakhot Psukot* (Law as Decided) to answer fundamental questions at a time when few copies of the Talmud were available.

Yehudai was already old and blind when he was appointed Gaon of Sura, but he radically changed the Jewish world. As Jews spread through the Christian and Muslim Empires, there were more and more legal questions. The Geonim of Babylonia, enjoying the respect of the Abbasid leadership, were recognized as the world's Jewish legal authorities, and communities sent them their questions. Yehudai was the first Gaon to answer such questions systematically. These questions and answers were called *Responsa*. Yehudai was pushing for the authority of the Talmud throughout the Jewish world.

773 CE Hindu works translated into Arabic: A set of astronomical tables was taken to Baghdad and translated from the Sanskrit into Arabic (on the caliph's command) by **Al-Fazari**. It is probable that the *Hindu numerals*, including the zero, were made known in Baghdad at this time.

781–804 CE **Alcuin** (732–804, Babylonia). Monk and scholar. Organized a reform of the Latin language, Roman Alphabet and education under Emperor **Charlemagne**[10] (742–814). A prominent figure of the *Carolingian*

[10] **Charlemagne** inherited his throne as king of Franks (768). He overrode the claims of rivals and relatives, subdued the Saxons, conquered Lombardy, and finally organized an empire that included northern Italy, France and most of modern German and Eastern Europe. As an ally of the Pope and a passionate Christian, Charlemagne was shocked by the decay of Christian learning. He was dismayed by the crude Latin in the letters he received even from bishops. The Carolingian Renaissance that he sparked was a Latin Renaissance. In his famous edict (789), written by Alcuin, Charlemagne ordered: "*In each bishopric*

Renaissance. He transmitted to the ignorant Franks the knowledge of Latin culture which had existed in England since the time of Bede.

Alcuin's main achievement was the *reformation of the Latin script*: Before the age of Charlemagne, letters were strung together without space between words, without periods, commas, or paragraphing. With the Carolingian reform in script, came now the practice of separating words by empty space between them. This helped prevent ambiguities in meaning and so preserved the pure text.

Alcuin was born at Eboracum (York). He was educated at the cathedral school of York. Upon his visit to Rome (781) he met Charlemagne, who persuade him to come to Aachen to organize a reform of language and education. Charlemagne's rich library in his palace at Aachen became a cultural center drawing scholarly Christian refugees from the Moors in Spain, and even from the distant islands of Ireland. He ordered every school to have a *scriptorium*. From monasteries in Germany, Italy and Bulgaria came manuscripts to be copied in Reformed Latin in the scriptorium. Alcuin had the knowledge and the taste to devise new standards. Charlemagne had the administrative power and the will to enforce them. At his school of Calligraphy in the monastery of St. Martin's in Tours, Alcuin taught his reformed script.

700 years later, when movable type came to Europe, letters were fashioned on the model of Alcuin *Carolingian Minuscule*. Long after other monuments of Charlemagne's empire have crumbled, the pages of books published today remain a vivid reminder of the power of well-designed written word. What we call the Roman alphabet is really Alcuin's alphabet.

789 CE **Charlemagne** (Charles the Great, ca 742–814). Roman emperor and king of the Franks; ordered that *schools*[11] should be established in every diocese. The main effect of these schools was to elevate the education of the rude and ignorant priesthood of the age, restore Latin to its position as a literary language, and introduce a correct system of spelling and an improved

---

and each monastery let the psalms, the notes, the chant, calculation and grammar be taught and carefully corrected books be available."

[11] From ancient times until the first half of the 19^{th} century, most people – even in advanced societies – never attended school. In ancient Greece, for example, only the sons of citizens could attend school, and most Greek residents were not citizens. During the Middle Ages (400–1500's), the Roman Catholic Church ran cathedral and monastery schools in Europe, chiefly to train young men for the priesthood. Widespread development of *public schools* began in the early 1800's, when government leaders in many countries acted on the belief that a nation's progress depends on educated citizens. By the mid-1800's, the United States and many European countries had established public school systems.

handwriting. The manuscripts of the time are accurate and artistic, copies of valuable books were made, and the texts were purified by careful collation. At that time, no further result ensued from this measure, since the available knowledge was to remain stagnant for a long time to come.

Charlemagne introduced a new system of *weights* and *measures*, introduced a new *calendar*, reformed the coinage, and condemned medical superstitions.

790–880 CE The Chinese introduced the ancestor of *paper money*. Appeared first as bank drafts (790) on money deposited; it could be exchanged for hard cash at a later date. Real paper money i.e. printed paper money used as a medium of exchange, was first used (880) in Szechuan Province in China.

800–1000 CE Vikings assaulted France and England and penetrated deep into Russia. Feudalism settled over Europe as the continent sank into its cultural nadir. Islam rose to its intellectual zenith. Capetian dynasty founded in France, and Saxon in Germany.

ca 800 CE **Mashallah** (ca 750–817, Egypt). Astronomer and astrologer. One of the earliest medieval astronomers. Egyptian Jew. Wrote: *De Scientia Motus Orbis* (translated from Arabic by Gerhardo of Cremona) which was very popular in the Middle Ages.

830–860 CE **Yaqub al-Kindi**, **Alkindus** (ca 800–873, Baghdad). Mathematician, philosopher and encyclopedic scholar. The first Arab philosopher. Made a deep study of Aristotle from the Neo-platonic point of view. Relatively few of his numerous works are extant. They deal with mathematics, physics, music, medicine, pharmacology and geography. He wrote four books on the use of the Hindu numerals. Many translations from the Greek into Arabic were made or revised by him or under his direction. He considered alchemy as an imposture.

Al-Kindi made significant contributions to the theory of knowledge and being: His metaphysics recognized five primary substances – matter, form, motion, place and time – from whose interactions the universe is formed. He was first to apply mathematics not only to the physical world but also to Materia Medica, where he calculated the effect of medicines from the proportions and qualities represented in the various mixtures.

In his manuscript '*on Deciphering Cryptographic Messages*', al-Kindi was perhaps the first author to discuss how contents of a scrambled message can be revealed simply by analyzing the *frequency* of the characters in the ciphertext. The technique is known today as *frequency analysis*[12]

Al-Kindi was born in Basra and flourished in Baghdad, under al-Mamun. A son of a South Arabian governor, he was given the best possible education at Basra and Baghdad. His life was spent in the service of the court as tutor, astrologer, translator and editor of many Greek philosophical works. He was persecuted during the orthodox reaction led by al-Mutawakkil (847–861) and died in Baghdad.

---

[12] The method is not valid for short texts (less than 100 letters, say). Longer texts are more likely to follow standard frequencies, although this is not always the case. The following table of relative frequencies in English, is based on passages taken from newspapers and novels with total sample length of ca 100,000 alphabetic characters:

Letter	Percent	Letter	Percent	Letter	Percent	Letter	Percent
a	**8.2**	**h**	**6.1**	o	**7.5**	v	1.0
b	1.5	**i**	**7.0**	p	1.9	w	2.4
c	2.8	j	0.2	q	0.1	x	0.2
d	**4.3**	k	0.8	**r**	**6.0**	y	2.0
e	**12.7**	**l**	**4.0**	**s**	**6.3**	z	0.1
f	2.2	m	2.4	**t**	**9.1**		
g	2.0	**n**	**6.7**	u	2.8		

Thus, the arrangement of the alphabet in order of decreasing frequency is {e,t,a,o,i,n,s,h,r,d,l,u,c,m,w,f,y,g,p,b,v,k,j,x,z,q}.
Clearly, the frequency test fails for the short sentence:
'From Zanzibar to Zambia and Zair, ozone zones make zebras run zany zigzags.'
Since the distribution of frequencies depends on the particular language used in ciphertext, it can be used to identify the language. For example, in German, the letter 'e' has the extra ordinary high frequency of 19 percent. In Italian, there are 3 letters with a frequency greater than 10 percent, and nine letters with frequency less than 1 percent.
If the correlation is sympathetic with English, but the plain text does not reveal itself immediately, the code breaker will focus on *pairs of repeated* letters. In English, the most common repeated letters are 'ss', 'ee', 'tt', 'ff', 'll', 'mm' and 'oo'. Other clues may come from the identification of words containing just one, two or three letters. The only one-letter words are: *a* and *i*. The commonest two-letter words are: *of, to, in, it, is, be, as, at, so, we, he, by, or, on, do, if, me, my, up, an, go, no, us, am.* The most common three-letter words are *the* and *and*.

The Translators

Except for two of his logical treatises, Aristotle's work had been unknown before 1100 CE – buried and forgotten, together with the works of Archimedes, Euclid, the atomists, and the rest of Greek science. What little knowledge survived had been handed down in sketchy, distorted versions by the Latin compilers and the Neoplatonians. Insofar as science is concerned, the first 600 years of established Christendom (500–1100 CE) was a glacial period.

During 600–800, the Muslims on their way from the Arab peninsula through Mesopotamia, Egypt, and Spain have picked up the wreckage of Greek science and philosophy in Asia Minor and in Alexandria, and carried it in a circumambient and haphazard fashion into Europe. From 1100 onwards the fragments of works of Archimedes and Hero of Alexandria, of Euclid, Aristotle and Ptolemy found their way into Christendom.

How devious this process of Europe's recovery of its own past heritage was, may be gathered from the fact that some of Aristotle's scientific treatises, including his Physics*, had been translated from the original Greek into Syriac, from Syriac into Arabic, from Arabic into Hebrew and, finally, from Hebrew into medieval Latin. With Euclid, Aristotle, Archimedes and Ptolemy recovered, science could start again where it had left off a millennium earlier.*

From about 750–1100 CE, Arabic *was the scientific and progressive language of mankind.*

During the period 950–1580 *a 'life line' of science was constantly in operation: Ancient Greek, Hindu, Persian and Arabic lore were steadily flowing to Western Europe via Constantinople, Baghdad, North Africa, Sicily and Spain.* Transmission *is as essential as discovery. For if the results of Ptolemy's investigations had been lost in transit, it would almost be as if they had never existed!*

At the time when Western Europe was weak, its cities almost non-existent and its scholars limited to the study of theology, both Byzantium and Islam had well-organized bureaucratic states, large commercial cities and eminent scholars. About the year 1000*, the Byzantine empire gained control over Asia Minor and the entire eastern Mediterranean, and was at the apex of its power. This political ascendancy was accompanied by intellectual revival. Although not universities of the Western type, schools of philosophy and law were established in Constantinople, where professors were paid regular salaries and held high positions at the imperial court. These scholars however, spent most of their energy copying and commenting on ancient texts, which served* *to preserve many books that otherwise would have been lost. These works include the translation of Plato into Latin. No original work was done.*

In spite of the felt influence of Byzantium in Western Europe (especially in Italy), Western scholars preferred to acquire the Greek-Arabic-Latin translations done in Europe than avail themselves of the more direct Greek-Latin translation that was available in Byzantium. Because Western translators were primarily interested in Aristotle, they overlooked the opportunity to increase the stock of Platonic works available in Latin.

Nevertheless, some important texts, such as the advanced works of Euclid, would have been unknown to Western medieval scholars, had it not been for the efforts of the translators at Constantinople.

During the 11^{th} *century, the Latin and the Greek churches drifted apart. Finally, in* 1054*, pope and patriarch excommunicated each other and the two churches broke off relations in a split that never healed.*

Outside the Byzantine Empire, intellectual activity was going on in the Abbasid Caliphate.

The lands of the Caliphate, which reached its peak of power and wealth under ***Harun ar-Rashid*** *during* 706–809*, stretched from Morocco to the Indus River, from the steppes of central Asia to the Sudan. In this vast territory, which was traversed by all the important east-west trade routes, there were dozens of populous and prosperous cities, of which Baghdad was the largest and the richest.*

This city attracted books and scholars just as it did merchandise and traders. The Abbasids did even more than the Ommiads to transform their empire into a center of scholarship. Hundreds of Greek works, especially on philosophy, science and mathematics, were translated into Arabic and much was learned from Persian and Jewish sources.

Chinese scholarship had little influence, but the Abbasids borrowed many ideas from the Hindus, notably the system of arithmetic notation *and what we call the* Arabic numerals*.*

By the 9^{th} *century, Muslim scholars had assimilated the work of their predecessors and were beginning to make original contributions of their own. From* 900 *to* 1200*, the most important work done anywhere in the world in mathematics, astronomy, physics, medicine and geography, was done in Muslim countries.*

Much Arabic scholarship merely added details to support established scientific theories [accurate observations of star positions; many stars still bear

Arabic names today[13]*]. However, their most remarkable contribution was in physics and algebra.*

Chemistry among the Arabs was cultivated principally by ***Jabir ibn Hayyan Geber*** *(ca* 721*–ca 803), court physician to Caliph Harun ar-Rashid and author of large number of works on alchemy. He enjoyed high reputation with later alchemists and his theory of mercury and sulfur as fundamental substances contributed to later theory of the phlogiston. Jabir was aware that addition of sal* ammoniac *(ammonium chloride, said to have been first derived from camel stables near the Egyptian temple of Jupiter Ammon) to nitric acid enables it to dissolve gold, a fact of considerable metallurgical importance.*

In physics they performed interesting experiments in reflection and refraction of light. In mathematics, besides greatly simplifying arithmetical operations through the use of the new Arabic figures, they carried trigonometry far beyond the Greek accomplishments. And their work in algebra was even more impressive, for they fashioned a whole mathematical discipline out of a few hints provided by the Greeks. Most notable was the illustrious figure of ***al-Khowarizmi*** *(780–850).*

Muslim interest in mathematics and the natural sciences had a decisive influence on the course of Western science. The Byzantines tended to neglect these subjects, and little was known about them in Western Europe.

The Chinese had great technical skill, but they developed no general theories. Hindus, after a promising start, lost their interest in mathematical and scientific problems.

Thus, the Muslim world was the only region that was both actively interested in science and close enough to Western Europe to touch off a revival of scientific interest there.

Western European scholars made their first attempts to recover ancient scientific texts by going to the Muslims of Spain and Sicily. Only after the revival was well underway, did they begin to seek manuscripts in Constantinople.

The Moore invasion of Spain began in 711 *and they conquered almost all of the Visigoth Kingdom by* 718*. The Moores (mostly Berbers from North Africa, converted to Islam), had a more advanced culture than did most of*

[13] E.g.: *Algol*, *Altair*, *Antares*, *Aldebaran*, *Betelgeuse*, *Deneb*, *Sabik*, *Rigel*. The Arabs also generated the terms: *Zenith*, *Nadir*, *Alchemy*, *Algebra*, *Algorithm*, *Alcohol*, *Alkali*.

The word *Zero* probably came from *ziphirum*, a Latinized form of the Arabic word *sifr*. *Sifr* is the translation of the Hindu word sunya (void or empty).

medieval Europe. The Muslims carried with them the Greco-Indian heritage of mathematics, medicine and other fields of study. They also preserved many of the writings of the ancient Greek, Roman and Middle Eastern civilizations.

About the time of ***Gerbert*** *(980), the Greek classics in science and mathematics began to filter into Western Europe. A period of transmission followed during which the ancient learning preserved by the Muslim culture was passed on to the Western Europeans. This took place partly through Latin translations made by Christian scholars traveling to Muslim centers of learning.*

The conquest of Toledo by the Christians in 1085 *was followed by an influx of Christian scholars to that city to acquire Muslim learning. Other Moorish centers in Spain were infiltrated and the* 12^{th} *century became, in the history of mathematics, a century of translators. One of the earliest Christian savants to engage in this pursuit was the English monk* ***Adelard of Bath*** *(1075–1160).*

By the middle of the 12^{th} *century, the scholars of the West had absorbed the Latin classics and the Roman law. Searching about for new materials, they seized upon the rich stone of learning from the East (acquired partly through the Crusades, which brought Christianity into close contact with the East) which had never been translated into Latin. Though the scholars were deeply interested in astronomy and astrology, they had only a few brief texts of those subjects, while the Greeks and Arabs had scores of volumes. The same applied to mathematics and physics – all the really advanced works were in the Eastern languages; in Latin there were only elementary textbooks.*

To correct this deficiency, the Western scholars began the task of translating into Latin the works of Aristotle and the scientific writings of the Greeks and Arabs. The difficulties were formidable – there were no grammars, no lexicons, none of the scholarly apparatus we take for granted in learning foreign languages. The Romans had never been particularly interested in science and had not developed a scientific vocabulary. Consequently, even when a translator knew the meaning of a Greek or Arabic word, he had trouble finding a Latin equivalent. Moreover, many of the important texts had been corrupted by repeated translation.

However, by ca 1250, *they had translated into Latin almost all the works of Aristotle and a great mass of other material.*

The West had acquired the philosophy and science of the East – just in the nick of time, for during the 13^{th} *century, both Byzantium and the Arab world were shattered by civil wars and foreign invasions. Though they made a partial recovery later on, they were never again the intellectual centers they had been in the early middle ages. The scientific tradition which the Greeks had originated and the Arabs had preserved, might have been lost had it not been for the efforts of the translators of the* 12^{th} *and* 13^{th} *centuries.*

The diffusion of Arabic learning into northern Europe was largely due to two factors:

(1) the influence of Jewish physicians (themselves educated in the Moorish schools of Spain and imbued with intellectual independence) who founded the medieval schools of medicine;

(2) the development of scientific navigation before the tradition of the Moorish schools had been finally extinguished. Two features of Catholic tradition and organization forced the universities of Western Christendom to open their doors to the Moorish learning. One was the humanitarian ideology which prompted the monastic orders to found hospitals and seek the assistance of experienced physicians.

The other, which encouraged monks like ***Gerhardo of Cremona*** *or* ***Adelard of Bath*** *to visit the schools of Spain during the Moorish occupation, was the social function of the priesthood as custodians of the calendar.*

In conformity with their role as timekeepers, the Augustinian teaching had endorsed astronomy as a proper discipline of Christian education. So, although the patristic influence was mainly hostile to pagan science, clerical education was not completely immune to influence from non-Christian world.

ca 830 CE **Muhammad Ibn Musa al-Khowarizmi** (780–850). Mathematician, astronomer and geographer. The first to use *zero* as a place holder in positional base notation. Blended the accumulated Greco-Hindu mathematical achievements into the systematic treatise *Hisab al-j'abr w'al-muqabala*[14] ("science of transpositions and cancellations"). The book was introduced to Spain by the Arabs and became known in Western Europe only after the conquest of Spain (1085–1118). The name of the branch of mathematics to which the treatise is devoted, *algebra*, is derived from the title of this work. Al-Khowarizmi's influence upon writers in the field of algebra can be traced directly or indirectly for more than 700 years after his death.

Al-Khowarizmi recognized the value of the *Hindu numerals* (known in Baghdad by that time) and wrote a small book explaining their use[15]. [This

---

[14] The Arabic word '*al-j'abr*' means "the bonesetting". Only later it came to acquire the connotation of the setting of the parts of an equation.

[15] Some historians believe that Al-Khowarizmi visited India at about 825 CE and was influenced there by the works of **Brahmagupta**. On his return (ca 830

book was translated into Latin by Adelard of Bath (ca 1120) under the title *Liber Algorismi de numero Indorum*].

The Hindu numerals, adopted by the Arabs were brought to Spain at about 900 CE. From there they diffused to the rest of Europe by traders in the Mediterranean area and by scholars who attended the universities in Spain. It finally came into general use in Europe by the invention of the printing press in the mid 1400's.

In the complete absence of axiomatic foundations and of proofs dependent upon them, al-Khowarizmi's algebra evidenced the author's marked preference for Hindu over Greek methods.

Al-Khowarizmi was born in Persia in the city of Khowarezm (Khiva). He may have been of Zoroastrian descent and had acquired his early knowledge of Hindu mathematics and astronomy from Zoroastrian clergy. He was encouraged by the Caliph al-Mamun (who succeeded Harun ar-Rashid) to join his court at Baghdad in the early 9^{th} century to participate in the work of his newly organized Bayt-al hikma (House of Wisdom). Al-Mamun constructed two astronomical observatories for his new academy, and he made strenuous efforts to obtain extant scientific works for it. In his eagerness to collect scientific manuscripts, he went so far as to send a mission to the Byzantine Emperor Leon for the purpose of securing Greek works. The writings collected by al-Mamun were immediately translated into Arabic by the scholars of his academy. It was in this scholarly atmosphere that al-Khowarizmi worked and reached the peak of his activities.

Al-Khowarizmi also constructed a set of astronomical tables that was to remain important in astronomy for the next five centuries. His *geographical* work is not less important: he helped measure the length of one degree of latitude at the latitude of Baghdad (91 km), and used astronomical observations to determine the latitude and longitude of 1200 important places on the earth's surface, including cities, lakes and rivers. He incorporated these and additional findings in his book *"The Image of the Earth"*.

CE) he brought with him the Hindu numeral system, which he later expounded in his books. However, the Hindu forms described by al-Khowarizmi were not used by the Arabs. The Baghdad scholars evidently derived their forms from some other source, possibly from Kabul in Afghanistan, where they may have been modified in transit from India. **David Eugene Smith** (1860–1944), a historian of mathematics, raised the possibility that the numerals were taken from Egypt to Afghanistan by the Lost Tribes of Israel after being exiled there by the Assyrians (721 BCE). [*Cabul* is a Biblical name: *I Kings* **9**, 13; *Joshua* **19**, 27.] This assumption is strengthened by the Hebrew origin of some of the numeral names in the 10^{th} century: *arbas* (4), *quimas* (5), *temenias* (8).

840–880 CE **Abu-Máshar** (**Albumazar**; 805–885, Baghdad). Muslim astrologer and astronomer. Was born at Balkh, flourished at Baghdad, and died at Wasid in Central Asia. His principal works are: *De Magnis Conjunctionibus* (Latin translation); *Introductorium in Astronomiam*, and *Flores Astrologici*.

Second[16] to offer a rational explanation (although incorrect) of the *causes of ocean tides*, not by invoking supernatural agencies but in terms of the perceived physical nature of the universe: His works, being translated into Latin already in the 12^{th} century, circulated widely in Europe. **Robert Grosseteste** (ca 1200) adopted Albumazar's theory of the tides. The correct gravitational theory was first given by **Newton** (1687).

ca 848 CE First important medieval *medical school* at Salerno, Italy, gained notice. It helped stimulate medical advances between 9^{th} and 11^{th} centuries.

ca 850 CE **Mahavira** (fl. 850 CE). Indian mathematician from Mysore, Southern India, where he lived at the court of one of the Rashtrakuta monarchs. His book *Ganita Sara Samgraha* contributed to the history of *indeterminate equations* and general polynomial equations of the first and second degree. Yet his claim to fame is in giving our rule for dividing one fraction by another in the same words which a school-teacher might use today:

> *"Make the denominator the numerator and then multiply"*

namely

$$\frac{a}{b} : \frac{c}{d} = \frac{a}{b} \times \frac{d}{c} = \frac{ad}{bc}.$$

855 CE **Johannes Scotus Erigena** (ca 810 – ca 877, Ireland and France). Philosopher and Theologian. Born in Ireland and educated in Irish schools. Was called by Charles II the Bald (843) to head the Schola Palatina (court school) at Paris. One of his more important works is *De divisione naturae* (on the division of nature), which was condemned by the Church because of pantheistic learning. It was an attempt to reconcile Neoplatonistic and Church philosophy of creation[17], i.e. to demonstrate rationally all the truths of the

---

[16] He was preceded in this respect by **Seleucus the Babylonian** (fl. 150 BCE).

[17] From Plato to Erigena philosophers had been explaining the universe as a union of *ideas* (or forms) and *matter*. **Plato** thought of ideas as existing before things. **Aristotle** taught that forms existed in things but were distinct from matter. The Christian taught that ideas or forms existed in the mind of God and moulded matter into things of the universe. All these philosophers have been called *realists* since they taught that ideas or forms are real things existing independently of whether or not they ever come into contact with matter.

Christian faith. He was a more rigorous thinker than Augustine – the technical quality of the argumentation is higher, and his intellectual points drive deeper. One of his arguments was to the effect that since God is unknowable and undefinable, man cannot expect, with his little and limited brain, to understand God or to comprehend his ways. Although, not an original idea (*Job* **25**; *38–39*), this insight was generalized by **Kant** into the point that it is impossible for a human being to understand its own nature.

Erigena taught that God created the world out of nothing or 'out of himself', the causeless first cause. Before God created the world, he had a complete pattern of the world in his mind. Then, as a light radiated from its source, so the world was radiated from God. Consequently, the universe and God are one, but God is more than the universe: God is in his creation and his creation is in him. The universe is a unity. *The universe is "an expression of the thought of God"*. And therefore cannot exist apart from him.

Erigena was the only large-scale systematic philosopher in the West during a period of 600 years (5^{th} to 11^{th} century).

855 CE **Thabit Ibn Qurra al-Harrani** (836–901, Mesopotamia). Physician, mathematician and astronomer. One of the greatest translators from Greek into Arabic, and a founder of a school of translators. Improved the theory of *amicable numbers* and generalized Pythagoras' theorem to an arbitrary triangle (as did Pappos).

Thabit was born in Harran and lived in Baghdad where he obtained his mathematical training. He returned to Harran but his liberal philosophies led to a religious court appearances when he had to recant his 'heresies'. To escape further persecution he left Harran and was appointed court astronomer in Baghdad. A hitherto unknown Arabic translation of Thabit of a work by **Archimedes** was discovered (1919) which contains a construction of a regular *heptagon* (7 sides).

His grandson **Ibrahim Ibn Sinan Ibn Qurra** (908–946 CE, Baghdad) was also a known mathematician. He worked on the quadrature of the parabola, where he introduced a method of integration more general than that of Archimedes. He also studied the geometry of shadows.

858 CE **Amram ben Sheshna Gaon** (ca 810–875, Babylonia). Talmudic scholar. Composed the oldest extant Jewish book of prayers. Head of the Sura Academy. In his book he introduced for the first time a systematic and logical arrangement of liturgy for the whole annual cycle as well as the pertinent laws. It is known as the *Seder* or *Siddur*. Amram's sources, in addition to the Talmud, were the works of the Geonim and the rites of the Babylonian Academies. The *Seder* had a wide influence in Europe and the Middle East. It enjoyed a very wide circulation and was extensively quoted by leading scholars of Spain, France and Germany. It served as a basis for later orders of prayers.

865–950 CE Decline of the *Khazar state* influenced by a climatic change.

868 CE The first printing press (block printing) appeared in China.

877–910 CE **Muhammad al-Battani**; **Albategnius** (ca 858–929, Mesopotamia). The greatest Muslim astronomer. Rather than using geometrical methods as **Ptolemy** had done, al-Battani used trigonometrical methods. His main work is an astronomical treatise with tables (“*De scientia stellarum*”, “*De numeris stellarum et motibus*”), which was extremely influential until the Renaissance. Discovered the motion of the sun's apogee.

He made astronomical observations of remarkable range and accuracy from 877 on. His tables contain a catalogue of fixed stars for the years 880–881. From his observations at *al-Raqqa* he was able to correct some of Ptolemy's results, previously taken on trust. He compiled two tables of the sun and the moon, subsequently accepted as authoritative. He found that the longitude of the sun's apogee had increased by $16°47'$ since Ptolemy; that implied the discovery of the motion of the solar apsides and of a slow variation in the equation of time. He determined many astronomical coefficients with great accuracy: *Precession*, $54.5''$ a year; *inclination of the ecliptic*, $23°35'$. He proved the possibility of annular eclipses of the sun.

The third chapter of his astronomy book is devoted to trigonometry, where (perhaps independently of **Aryabhata**, ca 500), he introduced the regular use of *sines* with a clear awareness of their superiority over the *Greek chords*. He completed the introduction of our *cotangents* and *tangents* and gave a table of cotangents by degrees. He knew the relation between the sides and angles of a spherical triangle which we express by the formula

$$\cos a = \cos b \cos c + \sin b \sin c \cos .A$$

Al-Battani was born near Harran, flourished at al-Raqqa (on the Euphrates) and died near Samarra.

880–890 CE **Eldad ha-Dani** (ca 830–890). Jewish traveler and philologist. Native of South Arabia who journeyed in Egypt, Mesopotamia, North Africa and Spain. Spent several years at Kairawan in Tunisia and died on a visit to Cordova, Spain. He is the supposed author of a travel-narrative (in Hebrew) on the question of the Lost Ten Tribes. His story is supported by the known Hebrew physician of his own time, **Zemah Gaon**, the rector of the Academy of Sura, Mesopotamia (889–898 CE). Eldad is quoted as an authority on linguistic difficulties by leading medieval grammarians and lexicographers. The *Book of Eldad ha-Dani* was first published in Mantua (1480) and had since been translated into several languages.

880–920 CE **Abu Kamil Shuja** (al-Hasib) (850–930 CE, Egypt). Mathematician. Worked on integer solutions of equations. He also gave the solution of a 4^{th} degree equation and of a quadratic equation with irrational coefficients. Abu Kamil's work was one of the sources of **Fibonacci's** books.

880–930 CE **Itzhak ben Shlomo Israeli the elder**[18] (832–932 CE, North Africa). Jewish physician, medical scholar of consequence and philosopher. Regarded as father of medieval Jewish Neoplatonism. Author of scientific and philosophical treatises renowned among Latin scholastics. His works, written in Arabic and translated into Latin, were studied and admired by **Albertus Magnus**, **Vincent of Beauvais** and **Thomas Aquinas**. His medical treatises "On Fever" and "On Diet" remained authoritative for some 500 years.

Israeli was born in Egypt and served as court physician to two Fatimide caliphs in al-Qayrawan (today in Tunisia). He died in Kairawan. His medical ideas, enunciated one thousand years ago, sound astonishingly modern:

- "*The most important problem of the doctor is how to prevent illness...*".
- "*The majority of diseases are cured by the help of Nature without the aid of a doctor...*".
- "*If you can cure a patient by means of a diet, forbear to prescribe drugs...*".
- "*Hold forth the prospects of recovery of patients, even if you are not sure of them yourself, so that at least you shall second the efforts of Nature to care them*".

ca 900 CE The diseases of smallpox and measles first identified or described with accuracy.

ca 900–925 CE **Abu Bakr Muhammad ibn Zakariya al-Razi**, known in the West as **Rhazes** (ca 865–925, Persia). Physician, medical scholar and philosopher. Considered the greatest physician of the Islamic world[19]. Chief physician of hospitals in Rayy and Baghdad; believed in atomist theory

[18] His Arab name was **Abu Yaqub ibn Suleiyman al-Israeli**.

[19] As in the parallel case of the Roman conquest of Greece, the superior culture of the conquered race asserted its supremacy over their Arab conquerors. After the Muslim conquests became consolidated, and learning began to flourish, schools of medicine, often connected with hospitals and schools of pharmacy, arose in all

of nature. Author of numerous treatises in medicine, especially a survey of Greek, Syrian and early Arabic medicine and a treatise on smallpox and measles. Some of his works were translated into Latin and had great influence on medical science in the Middle Ages.

Rhazes realized that fever could be a defense against disease. *Continens Liber*, one of his 200 or so treatises, gained him fame.

Al-Razi was also a skilled practical alchemist. He talked about *soda* (natron), common salt, kali (potash), salpeter, vitriol, arsenic, magnesia and mercury.

900–930 CE **Muhammad al-Farabi**; **Alpharabius** (ca 870–950, Aleppo). Philosopher, musicologist and encyclopedist. Continued the harmonization of Greek philosophy with Islam (begun by al-Kindi), preparing the way for Ibn Sina. He wrote a number of commentaries on Aristotle (physics, meteorology, logic) and his own work on the classification and fundamental principles of science. Al-Farabi was conversant with the whole range of scientific thought of his day.

---

the chief seats of Muslim power. At Damascus, Greek medicine was zealously cultivated with the aid of *Jewish* and *Christian* teachers. In Baghdad, under the rule of Harun al-Rashid and his successors, a still more flourishing school arose, where numerous translations of Greek medical works were made. At the same time Arabs became acquainted with Indian medicine, and Indian physicians lived at the court of Baghdad. The Islamic rulers in Spain were not long behind those of the East in encouraging learning and medical science. In that country much was due to the *Jews*, who had already established schools in places which were afterwards the seat of Muslim dominion.

Thus, Arabian medicine was in the main Greek medicine, modified to suit other climates, habits and national tastes, and with some important additions from Oriental sources. The greater part is taken from Hippocrates, Galen, Dioscorides and later Greek writers. The *Latin* medical writers were necessarily unknown to the Arabs. In anatomy and physiology the Arabians distinctly went back; in surgery they showed no advance upon the Greeks; in practical medicine nothing new can be traced, except the description of certain diseases (e.g., smallpox and measles) unknown or imperfectly known to the Greek). The only real advance was in pharmacy and the therapeutical use of drugs. By their relation with the farther East, the Arabs became acquainted with valuable new remedies which have held their ground till modern times. Also, their skill in *chemistry* enabled them to prepare new chemical remedies, and form many combinations of those already in use.

They produced the first pharmacopeia, and established first apothecaries' shops.

He was born near Farab, Turkestan, of a Turkish family. He studied in Baghdad and flourished chiefly in Aleppo. Died in Damascus.

913–942 CE **Saadia (ben Yosef) Gaon** (882–942, Babylonia). Philosopher, philologist and trained mathematician. Creator of the Jewish philosophy of religion.

Equally versed in Arabian culture, Biblical and Talmudic scholarship, Christian dogma, Hindu and Greek philosophy, and the doctrines of Zoroaster and the Manicheans, he attempted to reconcile rationalism with the Jewish faith and render a rationalistic interpretation of Talmudic law. Saadia criticized Platonic cosmology, refuted gnostic doctrines and tried to reconcile the freedom of man with the all-embracing knowledge of God.

His major philosophical work, *Kitab al-Amanat wa-al Itiqadat* (The Book of beliefs and opinions), makes ample references to Biblical and Talmudic authority, but in addition draws on medicine, anatomy, mathematics, astronomy and music. His work reflects the mathematics of his day (which he had thoroughly mastered), and in his systematic theology there were already present some of the methods and the processes of thought which characterized 19^{th} and 20^{th}-century mathematics.

In Saadia's writings, one finds the process of *abstraction*, the use of the syllogism including some interesting logical devices as "proof by contradiction". There are also certain modern logical concepts such as the formation of the unit class consisting of a sole element[20]. Furthermore, there is the realization of the central role that *existence* and *uniqueness* theorems must play within a theory.

He composed the first Hebrew dictionary, prayer book and grammar, and was the founder of scientific Hebrew philology. His Arabic translation of the old Testament, with commentary, remained the standard translation to this day.

Saadia Gaon *influenced the future course of Judaism*; he removed the threat of *Karaism* and thus re-established the supremacy of Jewish tradition, saved Jewish unity and fought successful battles against the alluring influence of Muhammadian philosophy. All this he achieved through the richness of his knowledge, the depth of his learning, the keenness of his intellect and the ruggedness of his personal courage.

Saadia was born in Fayyum, Egypt and educated there. He went to Israel and then to Babylonia, where he was appointed head of the academy in Sura

[20] Such logical concepts have become standard since **Russel** and **Whitehead** (1910).

in 928. But he soon came into conflict with the exilarch and was banished. He was reinstated a Gaon of Sura close to the end of his life, and died there.

ca 925–930 CE **Aharon ben Moshe ben Asher** (ca 890–950, Tiberias[21], Israel). Hebrew grammarian and scholar. The last and foremost of a Karaite[22] family of *Masoretes* that was active in Tiberias for five generations [Asher I (fl. 785); Nehemiah (fl. 820); Asher II (fl. 855); Moshe (fl. 890); Aharon (fl. 925)], standardizing the Biblical text and its chanting.

The *Masoretes* were Jewish scholars who annotated and attempted to remove errors from the Old Testament. They began their work in the 2^{nd} century CE, and their principal effects took place in the 5^{th} to the 12^{th} centuries CE. Their final text (the *Masorah*) included the rows markings that had been omitted from previous texts, as well as explanatory annotations. Prior to the *Masoretes*, there was no rigorous system for ensuring textual accuracy, nor is it certain that absolute literal accuracy was always deemed necessary.

Aharon was the first systematic Hebrew grammarian. He laid the foundations of the Hebrew Grammar in his works *Mahberet ben Asher* (ca 925) and *Dikdukei ha-Te'amim* (Grammar of the Vocalization). These were original collection of grammatical rules and masoretic information. In 930 CE he produced corrected and annotated edition (so-called *Aleppo Codex*) of the Old Testament including diacritical marks and marginal notations that serve as precise directions of vocalization, accentuation and chanting the Hebrew text. His standard will be compared and followed for generations prior to invention of printing (1450 CE) and will bear tremendous influence on the world of Biblical grammar and scholarship.

930 CE The *Althing*, the world' first parliament, was set up by the settlers of *Iceland*. A civil war in the 13^{th} century put an end to democracy in the Icelandic commonwealth, and the country came under Norwegian rule.

940–980 CE **Shabbethai ben Avraham Donnolo** (913–983, Southern Italy). Jewish physician and writer on medicine. Wrote the first book on

---

[21] Between the two great destructive earthquakes of 18 Jan 749 and 05 Dec 1033, the city of Tiberias served as a center of Hebrew language and the Biblical Masorah. We know that already by 895 CE, Tiberians had a complex system of punctuation and vocalization, which began to form there in ca 650 CE.

[22] **Saadia Gaon** attacked the Karaites in general and **Ben Asher** in particular, considering them to be outsiders. It was unthinkable to him that traditional "normative" Jews world accept the work of a Karaite. Nevertheless, being a Karaite did not disqualify Aharon ben Asher in the eyes of **Maimonides** and all subsequent generations of leading Jewish scholars.

pharmacology in Europe after the fall of the Western Empire and before the influence of Arabian medicine began to be felt.

Donnolo was born in Oria, Italy. When 12 years of age, he was made prisoner by Arab pirates, but was ransomed by his relatives at Otranto, Southern Italy. He turned to medicine for livelihood, studying the sciences of the Greeks, Arabs, Babylonians and Hindus.

His book *Sefer ha-Yakar* (Precious Book) contains practical directions for preparing medicinal prescriptions. His medical science is based on Greco-Latin sources.

940–980 CE **Hasdai Ibn Shaprut** (ca 915–990, Spain). Physician, medical researcher and statesman. Physician to the caliphs Abdurrahman III and IV. Experimented with drugs and invented cares for a number of diseases. Gained reputation of being an excellent diplomat, and on several occasions helped maintain peace between Muslims and Christians. Established communication with the Jewish Kingdom of Khazar.

Hasdai was born in Jaen, Spain and died in Cordova.

ca 960–990 CE **Albucasis** (936–1013, Spain). Physician. One of the greatest surgeons of the Middle Ages. Born in Cordova. Wrote *Al-Tasrif*, the first illustrated book of surgery and manipulations of spinal deformities. It also contains the earliest description of haemophilia.

ca 960 CE **Abu Hassan al-Uqlidisi** (ca 920– ca 980). Mathematician. Wrote the earliest known text offering direct treatment of *decimal fractions*.

968, Dec. 22 CE The earliest description of the solar corona during a total eclipse visible in Europe and the Near-East, and observed at Constantinople. It was only in the 18^{th} century that the phenomenon began to be studied in detail.

The Hebrew Golden Age of Reason[23] (900–1600)

With the conquest of southern Spain by the African Moors (711 CE), a new era of Arab-Jewish *culture began. The Jews had enjoyed equal treatment in Arab lands under the enlightened rule of the Mohammadian Caliphs. Accordingly, as soon as the Moors had established their first foothold in Spain, the Jews began to arrive in great numbers from all parts of the Islamic world. Every encouragement was given them to develop their own religious communal life.*

This held especially true during the 10^{th} *century in the reign of the enlightened Umayyad Caliphs* ***Abd ar-Rahman*** *(891–961) and his son* ***Al-Hakim II*** *(929–996) who made Cordova the most important center of learning in Europe. It was a time marked by liberality of mind and the advancement of the sciences and the arts.*

Despite Muhammad's attempts to suppress Greek cultural influences among the Arabs, they nonetheless persisted; Greek-Arab *civilization reached its most brilliant development during this period. The Jewish intellectuals became enthusiastic co-workers of the learned Arabs in every branch of knowledge and cultural creativity.*

When the Jews began to emigrate from Spain into Southern France, Italy and other Mediterranean countries, they brought with them into those still backward Christian lands elements of the superior Greek-Arab-Hebrew *culture.*

The historical fact seems somewhat paradoxical: the Jews and the Arabs who were nurtured by the Orient were, in a cultural sense, the first Europeans. They planted the intellectual seed of Western civilization on the continent.

In Arab lands, where there had existed a free intermingling of many cultures, there had blossomed a rich and unique Jewish culture. It has spread to Babylonia after its conquest in 642 by Muhammad in the course of his holy war. In the centuries of Babylonian Jewry's declining preeminence as the world center of Jewish learning, there emerged a galaxy of highly gifted philosophers, scholars, poets and scientists whose writings showed the impact of Greek thinking. In a way, this Jewish Renaissance was a resurgence of Hellenism. The Jews, who during their Greco-Roman period had inveighed against the Epicureans, Aristotelians and Platonists now opened their minds to the ideas of these philosophers and tried to reconciliate their teachings with Jewish theology.

Moreover, unheard-of occupations became respectable Jewish professions; they became astronomers, mathematicians, alchemists, architects, translators, finance ministers and international businessmen. And yet, though the door to assimilation was wide open, they stayed in the house of Judaism.

How had Hellenism found its way back into Jewish life in an Arabic world? The simple fact is that in rescuing Greek works for the Arabs, the Jews became imbued for the first time with the true essence of Greek philosophy and science. As the early Christians had no use for the writings of the heathen Greeks, and the invading barbarians had no use for the Greek language, most of the former were lost and the latter forgotten.

Greek literary and scientific works, however, survived in Syriac translations and in the libraries of wealthy and cultured Jews and unconverted Roman pagans. When the Arabs heard of this wealth of knowledge, they encouraged its translation into Arabic, and the task fell mainly to the Jews, the cosmopolitans of that age, who spoke Hebrew and Arabic, Greek and Latin, Syriac and Persian with equal facility.

These 'Channels to Europe', the transmission of Greek Science and humanism to Europe, were reopened by the Jews in the 8^{th} *century, and the work continued through 1400. Their first translations were from the Greek and the Syriac into Arabic, but soon they began to translate Greek and Arabic works into Hebrew, and finally Hebrew literature and philosophy into Arabic. A two-way cultural communication had been established. It soon included a third partner.*

The enlightened crowned heads of Europe heard of these Jewish achievements and invited Jewish scholars, linguists, and translators to come to their capitals to translate the works of the Greeks and the Arabs, as well as their own Hebrew literature, into Latin, at the time the international language of

European scholarship. So, for instance, Frederick II [King of the Romans (1212), King of the Germans (1215), King of Jerusalem (1229)] appointed Jewish scholars to teach Hebrew at the University of Naples.

Now that there was no danger of being absorbed into Hellenism (the Greeks vanished, but the Jews survived), they began to examine more closely the wisdom of the Greeks. They had opened a Pandora box of reason and looked at everything with the new glasses of rational scrutiny. The result was inevitable – a split between faith and reason developed. Into the breach rushed the conservatives to explain that reason and faith were but opposite sides of the same coin, and the liberals to prove that they were incompatible. A new tension developed out of which grew science and philosophy.

Numerous were the thinkers, philosophers, astronomers, mathematicians, jurists, physicians, nautical scientists, linguists, grammarians and biblical exegetes that the fecund Jewish culture milieu produced in Spain, France, Holland, Italy, North Africa and Babylonia during the millennium 700–1700 *CE. Of these, the following names (Table 2.1) can be directly associated with the accumulated wisdom and knowledge that opened the floodgates of modern science; unfortunately, some of these names did not receive the recognition they deserve. Many of their fate sakes which are not of this list, or any other list for that matter, will always remain the 'unknown soldiers' in the service of science.*

The Jewish Age of Reason took the same course that, centuries later, was taken by its Christian counterpart. The Age of Reason in Europe, born by the 18^{th} *century with the French encyclopedists, collapsed in the* 20^{th} *century revolutionary age of totalitarianism. The Jewish Age of Reason, born in the* 8^{th} *century with the great Talmudists, collapsed in the* 16^{th} *century revolutionary age of Reformation. Slowly the pendulum swung back to faith as the people rejected the mechanistic Jehovah of the rationalist philosophers and responded to the humanistic Jehovah of the Romantics. By the time the Muhammadian Empire collapsed, the Jews had made the transition back to faith, which was to sustain them in Europe's gethos. By shear irony of fate, the Jews stepped into their 'private' Middle Ages just when the rest of Europe emerged from it. The two cultures would meet again in the* 19^{th} *century.*

The tradition of preserving the text of scripture and its vocalization is known as Masorah and the tradition of text is called Masoretic. The people who were active in this work are known as Masoretes. This work of handling the past over to the future was neither simple nor quickly accomplished; it took a number of generations of scholars to do it. Moreover, these scholars thereby laid the foundation for the study of Hebrew grammar. For a discussion of words and how they are to be read in various connections was bound to lead to the fixing of grammatical rules. The Israeli Masoretes, down to the

10^{th} *century, did not go that far; the real beginning of Hebrew grammar was made by their followers in Babylonia and Spain.*

The 10^{th} *century marked a turning point in Hebrew and Biblical studies. Original masoreti researches reached their high water-mark in Israel in the works of* ***Ben-Asher****, a famed contemporary of* ***Saadia Gaon*** *(882–942). The vowel-system became definitely established, with the Tiberian system predominating. Studies of Hebrew then began to direct their attention to purely grammatical problems, without regard to their implication for biblical exegesis.*

Occasional grammatical observations are to be found already in the Talmud and he Midrashim. The masoreti notes and comments, likewise, contain a number of significant grammatical remarks. Considerable grammatical material is found in the Sefer Yetzirah, an anonymous ancient Kabbalistic work. But it was not until ***Saadia*** *that Hebrew grammar was treated as an independent science, and not merely as an aid to the clarification of biblical texts. This versatile scholar laid the foundation for the scientific movement in Hebrew philology. Saadia was prompted to undertake the task of writing Hebrew grammar because he was irked by the ignorance of the language and by the disregard for grammatical accuracy among the Hebrew writers and poets of his day.*

As long as the writers confined themselves to conventional themes, such as liturgical compositions and legal discourses, the available vocabularies, idioms and word-forms in the Bible and the Talmud were adequate and could be readily employed as vehicles for self-expression. When, however, the writers began to deviate from conventional themes, whether because of the influence of the Arabic culture of medieval Spain or as a result of independent creative urges, a departure from the stereotyped linguistic pattern became essential. New words had to be coined and new word-forms had to be constructed. Since Hebrew was not the vernacular of the people, ignorance of grammar was proving most serious handicap and threatened to corrupt the language. Even some of the grammarians of that period fell into glaring etymological errors.

As time went on, the philological movement initiated by Saadia gathered momentum, especially under spur of Arabic philological pursuits, and the urge for literary and religious expression in Hebrew. The rise of the Karaite sect (toward ca 790), which rejected rabbinic tradition as expressed in the Talmud and emphasized diligent scrutiny of the Bible as a basis for its tradition, was also a significant factor in focusing the attention of Hebrew scholars on a more searching study of the language of the Bible. The knowledge of Hebrew grammar, consequently, became a vital need.

Grammatical accuracy served as a criterion for the recognition of the mer-

Table 2.1: Prominent Medieval Hebrew Thinkers, Savants and Scientists

Name	Life-Span	Vocation	Country
Itzhak Israeli	850–950	philosopher and physician	North Africa
Saadia Gaon	882–942	philosopher and grammarian	Babylonia
Aharon ben Asher	890–950	grammarian	Israel
Shabbethai Donnolo	913–982	physician and pharmacist	Italy
Yehudah Hayyuj	940–1005	philosopher, grammarian, lexicographer	Spain
Jonah ibn Janah	990–1050	grammarian, philosopher, physician	—
Shlomo Ibn-Gabirol (**Avicebron**)	1021–1058	philosopher, poet	Spain
Rashi	1040–1105	Biblical and Talmudic exegete	France
Avraham bar Hiyya (**Savasorda**)	1065–1136	mathematician, astronomer	Barcelona and Provence
Yehudah Halevi	1071–1141	philosopher-poet, physician	Spain, Israel
Avraham Ibn-Ezra	1089–1167	scientist, physician, philosopher	Spain
Avraham Halevi	1110–1180	philosopher, translator, physician	Spain
Moshe ben Maimon (**Maimonides**)	1135–1204	philosopher, physician	Spain and Egypt
David Kimhi	1160–1235	linguist, grammarian, lexicographer	—
Yaacov Anatoly	1194–1256	translator, philosopher, physician	France, Italy
Moshe ben Nachman	1194–1270	philosopher and physician	Spain, Israel
Meir of Rothenburg	1215–1293	Talmudist and jurist	Germany
Yaacov Ibn Tibbon (**Prophatius**)	1236–1307	astronomer and physician	France
Levi ben Avraham	1240–1315	astronomer, mathematician	France
Moshe de Leon	1245–1305	philosopher	Spain
Levi ben Gershon (**Gersonides**)	1288–1344	mathematician, astronomer, physician	Perpignan and Avignon

Table 2.1: (Cont.)

NAME	LIFE-SPAN	VOCATION	COUNTRY
Yosef Caspi	1297–1340	philosopher and grammarian	France
Immanuel Bonfils	1310–1385	mathematician, astronomer, physician	Tarascon
Hisdai Crescas	1340–1411	philosopher and logician	Spain
Yosef Albo	1380–1444	philosopher and Talmudist	Spain
Itzhak Aramah	1420–1494	mathematician, logician and Talmudist	Spain
Yehudah Ibn Verga	1430–1499	astronomer, mathematician	Spain and Portugal
Itzhak Abravanel	1437–1508	philosopher, statesman and Talmudist	Spain, Italy
Shmuel Zarfati	1450–1519	physician	Italy
Avraham Zacuto	1450–1515	astronomer, mathematician	Spain
Yehudah Abravanel (**Leone Ebero**)	1460–1530	philosopher, physician, astronomer	Italy
Pedro Nuñes	1492–1577	mathematician and cartographer	Portugal
Garcia da Orta	1500-1560	botanist and physician	Goa
Amatus Lusitanus	1511–1568	physician, medical scientist	Portugal, Italy
Azariah dei Rossi	1511-1578	savant and physician	Italy
Yehudah Liwa of Prague	1512–1609	philosopher and Talmudist	Bohemia
Moshe Isserles	1525–1572	philosopher, codifier, Talmudist	Poland
Avraham Ortelius	1527–1598	cartographer and geographer	Antwerp
Itzhak Luria Ashkenazi	1534–1572	philosopher and mystic	Israel
Avraham Zacuto II	1576–1642	medical researcher and physician	Amsterdam
Yosef Delmedigo	1591–1655	astronomer, mathematician, philosopher, linguist and physician	Italy

its of literacy and religious composition, and grammatical knowledge constituted a badge of honor and the measure of Jewish learning and scholarship. Interest in Hebrew grammar was, therefore, not confined to professional grammarians, but gained vogue among poets, philosophers and even statesmen. The celebrated poet, statesmen and Talmudist ***Shmuel ha-Nagid*** *(993–1056), the eminent physician and poet* ***Yehudah Halevi*** *(1071–1141), the brilliant philosopher and poet* ***Shlomo Ibn-Gabirol*** *(1021–1058), the poet and scientist* ***Avraham Ibn Ezra*** *(1089–1167), the grammarian* ***Jonah Ibn Janah*** *(995–1050) and others, all concerned themselves with Hebrew grammatical problems to a greater or lesser degree and wrote about them.*

The study of Hebrew grammar as an independent science was pursued with zeal and profundity by Saadia's immediate successors. An important lexical work of ***Menahem ben Saruk*** *(910–970), entitled Mahberet, inaugurated Hebrew grammatical research on Spanish soil and provoked a vehement attack by a pupil of Saadia,* ***Dunash ben Labrat*** *(920–990). Dunash advanced views which already forecast the triliteral theory*[24]*, later scientifically and systematically expounded by* ***Yehudah Hayyuj*** *(ca 975 CE). Although* ***Dunash*** *had a glimpse into the operation of these phonetic principles, Hayyuj is undoubtedly entitled to the credit of being the first grammarian to observe*

---

24 The stem (root) of a word is determined by removing the prefixes, infixes and suffixes. In the majority of cases the residual number of radicals clearly amount to three. In good many instances, however, the number of these radicals seems to be reduced to two and even to one [e.g. in *wa-tofehu* (1 *Samuel* **28**, 24), "and she baked it", the f is the only stem letter that remains after the removal of prefixes an suffixes]. Hence, all the predecessors of **Hayyuj**, with the exception of **Dunash**, who on occasion had an insight into triliteral basis of the Hebrew stems, operated with the idea of the biliteral and even uniliteral stems. These grammarians failed to recognize the special character of *assimilated stems*. In Hebrew, as in other Semitic languages, stems from which nouns and verbs are derived consist of consonants and meaning depends on these consonants. The vowel sounds, which in Indo-European languages are generally on a par with the consonants as regard their essential role in the stem or root, play a minor part in the Hebrew word; they merely serve to indicate different shading of the inherent meaning. A change in vowels will transform an active into a passive verb, or a verbal into a nominal form.

Thus, the consonantal stem *ktb* will yield such forms as *katab* (wrote), *koteb* (writes), *katub* (written), *ketab* (script) and a lots of other forms, in all of which the concept of "writing" is inherent. These basic consonants, which are never dropped in all the modifications of the word, were designated by the Medieval Hebrew grammarians the *shoresh* (radix, root). It therefore became customary among Christians grammarians to refer to these letters as "radicals" or "root letters".

the overall pattern of triliterality in Hebrew language as a design in which the structure of nouns and verbs fitted in a perfect mosaic fashion.

Another significant contribution by the medieval grammarians is the arrangement of the paradigms, that is, model of verbs and their various inflections in the different conjugations*. Once a nature of a given consonantal stem is understood, it is possible to construct a long series of derivative forms, all having the same basic meaning. The various semantic shadings and modifications, as well as the differences in person, number and gender, are indicated by mere changes in vowels or by additions of prefixes and suffixes as the case may be. There are seven most common conjugations in biblical Hebrew and are known as* binyanim *(literally in Hebrew, building forms). In all formations of the various* binyanim *the basic meaning is more or less in evidence. Consequently, an understanding of the nature of* binyanim *opens up the wide vistas of the language and provides an insight into its linguistic pattern. Equipped with this understanding it is possible to get along on a comparatively small basic vocabulary and to manipulate the language with relative ease and facility.*

Saadia was the first to attempt the arrangements of paradigms. He, however, confined himself only to two conjugations. The standard arrangement of the seven conjugations is to be credited to ***Moshe Kimhi*** *(ca 1130–1190). His brother* ***David Kimhi*** *(ca 1160–1235) assumed the role of a "gleaner after the reaper", whose task was to compile and present succinctly and simply the voluminous scientific findings of their predecessors. Kimhi's works mark the closing of the "Golden Era" of Hebrew medieval philology.*

The reaction which set in against the works of Maimonides toward the end of David Kimhi's days, marked the waning of all rationalistic pursuits, including grammatical research, and of any studies outside of the Talmud. Furthermore, the deterioration of the Jewish economic and political position in South-Western Europe, resulting largely from persecution and from the internal rivalries and quarrels within the Jewish communities, led to a serious decline among the Jews in general cultural interests and activities.

The Jewish people, faced by an accelerated rise in jealousies and prejudices among the Christian populace and in persecutions and repressions by the Catholic Church, sought shelter in their own shell, as it were. Their interest shifted accordingly from the luxury of pursuing poetry, philosophy and grammar to the necessity of fortifying themselves by means of a better understanding of Judaism and a stronger faith in their religious destiny. This interest found its outlet in the study of the Talmud and of the mystic philosophy of the Kabbalah, which began to flourish around that period.

Most of the Jewish scholars of the subsequent generations regarded the study of grammar as a waste of time, and some even saw in it lack of piety.

Even the study of the Bible began to be regarded as of secondary importance and was dwindling to such an extent that a German rabbi of the 17^{th} *century complained that there were rabbis in his generation "who had never in their lifetime seen a text of the Bible".*

As interest in Hebrew grammar waned among Jewish scholars, it began to flourish among Christians. The Renaissance, which initiated in Italy, grew apace and crossed the Alps into the Netherlands, France and Germany, reached its peak during 1450–1550. This intellectual movement brought in its wake the Reformation which split the Christian world into two warring camps.

One of the main motives of the Reformation was to break the shackles of the Church's authority and to reassert the right of individuals to search on their own for the word of God, without the Church as intermediary. They therefore turned to the study of Hebrew as the master key to the Judaic background of Christianity, in order to discover for themselves the pristine meaning of the Bible and the original principles of the Christian faith. Many of the early leaders of the Reformation achieved considerable proficiency in Hebrew and familiarity with its literature.

The center of interest in Hebrew grammar and lexicography accordingly shifted from Jewish to Christian scholars. The father of Hebrew grammar among the Christians was the humanist ***Johannes Reuchlin*** *(1455–1522). The Christian grammarian, whose work enjoyed widest currency and influence, was* ***Wilhelm Gesenius*** *(1786–1842). The contribution of the Christian scholars to Hebrew grammar was considerable. They resumed the comparative study of Hebrew and Arabic and extended these studies to include the other Semitic languages. However, being unconversant with the source materials of the Golden Age Hebrew grammar, and being handicapped by the tendency to restrict themselves to the language of the Bible, their work was robbed of progressive and dynamic value.*

There was a renewed spurt of zeal for the study of the Hebrew language and Hebrew grammar among the Jews during the Jewish enlightenment movement in the first half of the 19^{th} *century. Only two grammarians of that period made any notable and original contribution to the science of Hebrew grammar, namely* ***Shmuel David Luzzato*** *(1800–1865) and* ***Simhah Pinsker*** *(1801–1864).*

Transmission of the Bible

Once canonized, the Five Books of Moshe became divine. Thereafter, no changes, additions, or deletions were permitted, and the job of maintaining the *text was entrusted to a class of scribes known as Masoretes. The* 20^{th} *century discovery of the Dead-Sea Scrolls, which yielded Old Testament manuscripts dating 200* BCE, *show what an excellent job these scribes did in preserving the original text.*

The accuracy of the present-day Hebrew version of the Old Testament is a result of the fastidious care with which the Sopherim and the Masoretes transmitted it. The Sopherim copied manuscripts of the Hebrew Scriptures from about 300 BCE *until 500 CE. According to the Talmud, they came to be called "Sopherim" because, in their endeavor to preserve the text from alteration or addition, they counted the number of words in each section of Scripture, as well as the number of verses and paragraphs.*

During this time, there were two general classes of manuscript copied, the synagogue rolls and private copies. Even the private copies, or "common copies" of the Old Testament text, which were not used in public meetings, were preserved with great care. For the synagogue rolls, however, there was a very elaborate set of rules for the copyist. The manuscript had to be prepared by a Jew, written on the skins of clean animals and fastened together with strings taken from clean animals. Every skin was to contain a certain number of columns, equal throughout the codex. The length of each column was to be no less than 48 and no more than 60 lines. The breadth was to be 30 letters. The ink was to be prepared according definite special recipe. An authentic copy was to be used from which to copy, and the transcriber was not to deviate from it in the least.

No word or letter, nor even an iota (yod), was to be written from memory. The scribe was to examine carefully the codex to be copied. Between all of the consonants of the new copy, a space of at least the thickness of a hair or thread had to intervene. Between every parashah, or section, there was to be a breadth of nine consonants. Between every book, there was to be three lines.

During the period 500–900 CE, the text of Hebrew Bible was standardized by the Masoretes, who were also very careful in the transmission of the text. They counted every letter and marked the middle letter and middle word of each book, of the Pentateuch and of the whole Hebrew Bible, and counted all parashas (sections), verses, and words for every book. These procedures were a manifestation of the great respect they had for the sacred Scriptures, and secured their minute attention to the precise transmission of the text.

The Torah scroll, used for reading in the synagogues, contains only consonants of the Hebrew words; there are no vowel indications such as are to be found in printed books. There are hardly even paragraph divisions to be seen, and no sentence markings.

How then did people know how to read and where to stop? They were *in the same position as one would be if English had no vowels and one came across the letters "ct". Only the sense of the sentence would tell one whether to read it "cut", "cot" or "cat". A word of three Hebrew letters like* שכל *might be read* sachal *(he acted cleverly), or* sechel *(good sense), or* shikel *(lost his children), or* shekol *(that all). The meaning depends upon the vowels, according to which consonants are read.*

Until the 6^{th} *century, people learned this from teachers and the division into phrases, sentences, paragraphs and chapters was handed down by tradition. But that certainly was not a satisfactory situation when troubles prevented people from studying, when the Jews were scattered all over the world and teachers were few, and when Hebrew had ceased to be the spoken language by any part of the people.*

The Jews, both in Babylonia and Israel, learned a lesson from the Muhammedians and from certain Christian groups who lived near them. These people, confronted with the same problem in their Arabic and Aramic languages, had invented little signs to indicate the vowels. Jewish scholars in Babylonia began to use a variety of lines and dots written above *the letters of the Hebrew alphabet to show how they were to be read.*

Certain scholars in Israel, at the same time, suggested another set of signs, written mostly below *the line of letters. The Israeli system turned out to be the easier and more efficient, and was soon adopted universally by all Jews. These scholars were very careful to follow the* traditional pronunciation *of the words, and then wrote under them the sign appropriate to indicate that tradition. They also used another set of signs, below or above the words, to indicate the phrases and stops within the sentence. These are signs now used as musical notes for chanting. For the chanting, too, was traditional, and the new signs now fixed the chant for the future.*

Their most important use, however, was as commas, colons, and periods rather than musical notes.

Finally, the same Israelis wrote footnotes *to the words of the Bible into which mistakes had crept,* they counted every word and letter, *all with the object of handling the traditional readings of the sacred books down to the future exactly as they had been handed down to them from the past.*

To sum up, the Masoretes introduced a complete system of vowel pointings and punctuation for the text. Because of their high regard for faithfulness to the text in transmission, wherever they felt that corrections or improvements should be made, they placed them in the margin. They retained certain marks of the earlier scribes relating to doubtful words and offered various possibilities as to what they were. Among the many lists they drew up was one containing *all the words that occur only twice in the Old Testament.*

A number of texts of the Masoretes are still extent:

- *Cairo Geniza fragments* (6^{th} *to* 9^{th} *century CE).*
- *The Cairo Codex (895 CE), copied by* ***Moshe ben Asher****. Includes the Former and Latter Prophets. Found in the Karaite synagogue in Cairo.*
- *The St. Petersburg Codex (916 CE), containing only the Latter Prophets.*
- *Aleppo Codex (930 CE), copied by* ***Aharon ben Moshe ben Asher****; It used to be a complete copy, but was partially destroyed in a synagogue fire in 1948. Used by* ***Maimonides****.*
- *The British Museum Codex (950 CE). It is a complete copy of the Pentateuch.*
- *The St. Petersburg Codex (1008 CE). It is the largest complete manuscript of the entire Old Testament, on which the ben Asher family worked for five generations. Copied by the masorete* ***Shmuel ben Yaacov****.*
- *The Reuchlin Codex (1105 CE). Copied by* ***Moshe ben Naphtali*** *(890–940, Tiberias), a rival of ben Asher. Now in Karlsruhe, Germany.*
- *The Dead Sea Scrolls (200* BCE*– 70 CE). The earliest copies of Old Testament books, discovered (1947) in a cave at Qumran, near the Dead Sea. Yet when the scroll of Isaiah was examined and compared with the codex from 1000 years later it was found that the two texts are almost identical.*

  This shows the accuracy with which the Bible was copied by the scribes through the ages. Indeed, the attention which the Bible has received in the search for the true text, in exegesis, hermeneutics and commentary, exceeds by far that devoted to any other work of literature. Nor is this interest disproportionate, because it has been the most influential of all books.

969–985 CE **al-Quhi** (940–1000 CE, Persia). Astronomer and mathematician. Worked in Baghdad. Built an observatory in Shiraz to study the planets. Worked chiefly in geometry and considered problems leading to quadratic and cubic equations.

968 CE Drought in Africa that caused low Nile in Egypt, resulted in ca 600,000 deaths.

970 CE Al-Azhar University founded in Cairo, Egypt.

970 CE **Abu al-Wafa al-Buzjani** (940–998, Baghdad). Persian astronomer and mathematician. Contributed considerably to the development of trigonometry. He was probably the first to show the generality of the sine law relative to spherical triangles. He gave a new method of constructing sine tables, his value of sin $(30')$ being correct to 8 decimal places. He knew relations equivalent to ours for $\sin(\alpha \pm \beta)$ (though in an awkward form) and to $2\sin^2\frac{\alpha}{2} = 1 - \cos\alpha$, $\sin\alpha = 2\sin\frac{\alpha}{2}\cos\frac{\alpha}{2}$. He was first to use the tangent function, calculated a table of tangents and introduced the secant and cosecant. His trigonometric tables are accurate to 8 decimal places (converted to decimal notation) while Ptolemy's were only accurate to 3 places. Worked at the observatory in Baghdad (from 959).

ca 975 CE **Yehudah ben David Hayyuj** (ca 940–1005, Spain). Perhaps the most important grammarian of the Hebrew language. Solved the mystery of the Biblical Hebrew verb. He demonstrated that, despite the way they looked, all Biblical verbs consisted of three letters (root), Hence he derived the rules surrounding the Biblical verbs and explained the difficult Hebrew nouns. His work ended and decided century-old debates on Hebrew grammar and paved the way for modern analysis of Hebrew. He also wrote a book, cited by **Ibn Ezra**, explaining for the first time linguistically difficult verses in the Old Testament. Hayyuj's work spread rapidly throughout the Jewish world.

Hayyuj was born in Fez and arrived in Cordova, Spain in 960 CE at the time of the famous dispute between Menahem ben Saruk and Dunash ben Labrat and sided with ben Saruk. Little is known about his life.

980 CE **Gerbert of Aurillac** (ca 945–1003, France). Mathematician and natural scientist. A remarkable Medieval Figure. One of the first Christians to study in the Muslim schools in Spain. May have brought with him to Christian Europe the Hindu-Arabic numerals (without the zero)[25]. He is said to have

[25] He went to Spain in 967 and obtained his knowledge in the convent of Santa Maria de Ripoll, a well-known center of learning near Barcelona. There is con-

constructed, terrestrial and celestial globes, a clock, and perhaps an organ. He was considered a profound scholar and wrote on astrology, arithmetic and geometry[26].

Gerbert was born in Auvergne, France. He became teacher at Reims; archbishop of Reims (991); befriended by emperors Otto II and III; archbishop of Ravenna (998). Elected to the papacy (999) as Sylvester II.

ca 985 CE **Muhammad al-Karkhi** (ca 950–1029, Baghdad). Mathematician. Among the last of the real contributors to mathematics in the city of the caliphs. His first work of note was on arithmetic, the *Kafi fil Hisab* (ca 1010), and drawn largely from Hindu sources. His second book was on algebra[27], called the *Fakhri* (ca 1020), named after his patron Fakhr al-Mulk, the grand vizier of Baghdad at the time.

His algebra is largely based on Diophantos. Gave complete solutions of quadratic equations with proofs, and the reduction of equations of the type $ax^{2p} + bx^p = c$ to quadratic equations. Treated addition and subtraction of radicals (e.g.: $\sqrt{8} + \sqrt{18} = \sqrt{50}$), and summation of series such as $\sum_1^n n^2$, $\sum_1^n n^3$.

"Of course, America had often been discovered before, but it had always been hushed up."

Oscar Wilde

986–1006 CE Norse discovery, exploration and settlement in North America, as attested in old Scandinavian sagas from the 12^{th} and 13^{th} centuries,

siderable evidence to support the belief that the monks in this cloister obtained their knowledge of these numerals through mercantile sources which were in communication with the East, rather than through any Moorish channels in Muhammadean Spain.

[26] Gerbert improved the abacus by labeling separate beads.

[27] Al-Karkhi gave an approximation of radicals: $a + \frac{h}{2a+1} < \sqrt{a^2+h} < a + \frac{h}{2a}$; $0 < h \leq a$. He also gave a solution in rationals to $x^3 + y^3 = z^2$, namely

$$x = \frac{n^2}{1+m^3}, \qquad y = mx, \qquad z = nx$$

where (m, n) are arbitrary rational numbers.

the account of the German priest **Adam von Bremen** (ca 1075), and excavations in Newfoundland (1961). According to these sources the following story can be reconstructed:

Bjarni Herjolfsson sighted (986 CE) the North American continent, probably in the region of Frobisher Bay [63.30°W–66°W], at the southern end of Baffin Island.

Leif Eriksson (ca 980–1025), a Norse explorer, led the first European expedition to the mainland of North America in ca 1000 CE. (He was the son of **Eric the Red**, who established the first settlement in Greenland.) Returning from Norway to Greenland, he was driven onto the American coast, which he called *Vinland* (Wineland), probably in Newfoundland. Some scholars believe Eriksson sailed further south, and that Vinland was near Cape Cod.

Thorfinn Karlsefni set out from Greenland in 1003 with three ships to settle in Vinland. He and his party spent three winters on the American continent. How long the Norsemen continued to visit America is an open question. The last definite mention is for 1189 CE, but there is some reason to believe that they came at least as far as southern Labrador for ship's timber as late as 1347. After this date the Vinland colonies declined[28].

The Viking[29] Invasions in the Medieval Warm Period (MWP) (787–1066)

Scandinavia developed in isolation until ca 200 CE. But the combined effect of population pressure (over population), tribal warfare and a global

[28] It is believed, that the Greenland colonies were so weakened by the *Black Death* (1346–1361) and by failure of supplies from enfeebled Norway that they could not withstand Eskimo attacks. The last Viking settlers disappeared in the 15^{th} century and Greenland became unknown country until rediscovered by **John Davis** (1550–1605; England) in 1585. It is thought that the Viking settlements maintained sporadic contact with "*Vinland*" (part of the coast of Canada or Newfoundland), and so the Black Death may have entirely altered the history of North America.

[29] From the Icelandic (Old Norse): vik = bay, inlet; vikingr = sea-rover, pirate; viking = predatory voyage.

climatic warming period (ca 600–1150 CE) disturbed the balance of marginal Scandinavian farming, causing the Norsemen to set off on 'land taking' and voyages of plunder in Western Christendom. Their ships spread out across the North Atlantic to Iceland, Greenland and North America; they emerged into the Mediterranean; they sailed down the great rivers of Central Asia, setting up the Russian state, and reaching Constantinople; they won control of Northern Britain and Normandy. Finally, in 1066, a family of Norse descent won the crown of England.

The viking aggressive expansion was facilitated by a number of factors:

- *The development of the Viking ship: they were expert seamen and they had perfected a type of long, shallow-draft ship which was very effective for raiding. With its flexible hull and its keel and sail, this boat was far superior to vessels used by other people at the time. They used a sail when the wind was astern, but they were usually propelled by oars. Equipped with such craft, the vikings could swoop down from the sea and loot a whole river valley before the local troops, moving slowly over bad roads, could be mobilized to repel them. (Note that the men who sailed these ships had neither compass nor loadstone and had no way of reckoning longitude!)*

- *Improved metallurgical techniques enabled them to construct better weapons, such as their war axes.*

- *The political weakness of Europe at that time: the Frankish Empire was disintegrating; the British Isles were split into small, warring kingdoms and the Slavs in Eastern Europe were politically disorganized. Thus, the continent lay open to any group of determined men bent on marauding and looting.*

- *Recent studies of the oxygen isotopic record, tree-ring data (dendrochronology), history of glacier waxing and waning and historical data of North Atlantic drift-ice led to the conclusion that during the MWP, temperatures were typically above normal. Data from North America and Peru support a global Warm Period consistent with the MWP. [There are several competing theories to explain the climatic changes experienced during the MWP. These include: sunspot variation, volcanic eruptions, changes in the large-scale ocean current conveyor belt, and to a lesser extent – changes in the earth's albedo. It is likely that each of these mechanisms played a role].*

  The warm climate during the MWP allowed the viking migration to flourish. Decreased drift-ice posed less hazards to sailors, and warmer climate would also result in a greater harvest in Iceland. Thus, the *warmer climate brought the vikings in increasing numbers to Greenland and Iceland.*

The participation of Scandinavia in the viking expansion through Europe was as follows: (there was never a mass-migration!)

(1) Norwegians raided Scotland, Ireland, France;

(2) Danes raided the British Isles, France, the Low Counties. Though the Scandinavian raiders called themselves vikings, the rest of Europe usually referred to them as Northmen. In their first serious raids against Ireland early in the ninth century they rapidly occupied the east coast. They met somewhat stiffer resistance from the Anglo-Saxons in England, but by 870 they had subdued all the Anglo-Saxon kingdoms except the southern state of Wessex. They had already begun to attack the Frankish lands. Year after year the Northmen pushed their long ships up the Rhine, the Seine, and the Loire to collect tribute and loot from towns and monasteries. Finally, an especially strong band of raiders forced the West Frankish king to cede them the land at the mouth of the Seine. This outpost, founded about 911, became the nucleus of Normandy, the most famous of the viking states.
In a show of bravado, the Northmen even sailed their ships into the Mediterranean and plundered a few coastal cities in Spain, southern France, and Italy.

(3) Swedes moved across Slavdom to Byzantium: They began to push down the Russian river valleys toward Constantinople. They had known this route for a long time, and eastern goods and eastern coins had been common in Scandinavia long before the great raids began. In the late ninth and tenth centuries, however, the Swedes began to settle in Russia and to bring the scattered Slavic population under their control. The fortified trading posts where the vikings settled soon burgeoned into towns; the most famous of them was Kiev, which became the capital of a large principality. Once they had gained a footing in Russia, the vikings, with typical boldness, turned their eyes south to Constantinople. Their attacks on the imperial city were unsuccessful, but they did manage to wrest a favorable commercial treaty from the emperor. These early viking princes and warriors gave the eastern Slavs their first effective political organization; in fact, the word Russia itself probably comes from Rus, the name of a Swedish tribe.

Although the vikings shot around the Northern Hemisphere, terrorizing and plundering vast swaths of territories with the rapacity of a Ghengis Khan, they were also traders, explorers and settlers: their sites stretched from Russia to Newfoundland, and they became the first Europeans to set foot in the Americas.

The pagan vikings learned rapidly from the more civilized people they attacked; they quickly adopted the Christian religion. As they became more civilized, they gave up their cruelty and their savage love of destruction and shifted from piracy to peaceful and productive commerce. They disturbed the old way of life in medieval Europe and their invasion finally helped create a new Europe.

Table 2.2: The Viking Timeline

787	*First recorded appearance of vikings in England (Dorset)*
795	*First viking raid on Ireland*
798	*Vikings raid the Isle of Man*
834	*Vikings sack Utreaht*
836	*Vikings sack Antwerp*
840	*Viking settlers founded the city of Dublin in Ireland*
844	*Vikings raid Seville, Spain*
845	*Vikings sailed up the river Seine and destroy Paris (again in 856)*
848	*Vikings took Bordeaux*
851	*Vikings sailed up the Elbe and burned Hamburg (again 880)*
859	*Vikings sailed through the strait of Gibraltar and attacked coastal cities in Spain, Southern France and Italy; defeated the Moors in Morocco (again in 900)*
860	*Norwegian vikings discovered Iceland (colonized 874)*
862	*Swedish Russ vikings founded Novgorod in Russia*
867	*Danish vikings established a kingdom in York, England*
by 870	*Viking subdued all Anglo-Saxon kingdoms except the southern state of Wessex*
871	*Vikings took London*
879	*Rurik established Kiev*
881	*Vikings sacked Aachen*
911	*Viking chief Rollo was granted Normandy by the Franks*
941	*The vikings attacked Constantinople*
981	*Viking leader Eric the Red discovered Greenland*
986	*Viking ships sailed in Newfoundland waters*
1000	*Leif Eriksson explored the coast of North America*
1003	*Vikings explorer Thorfinn Karlsefni attempted to establish settlements in North America*
1013	*The Danes conquered England*
1015	*The vikings abandoned the Vinland settlement on the coast of North America*
1016	*The Danes under Knut rule England*
1066	*William duke of Normandy defeated the Saxon king Harold at the Battle of Hastings*

990–1007 CE **Ibn Yunus** (ca 940–1009, Cairo). Astronomer and mathematician. Prepared improved astronomical tables based on his observations at the Cairo observatory. Improved the values of astronomical constants (inclination of the ecliptic, $23°35'$; longitude of the sun's apogee, $86°10'$; solar parallax, $2'$; precession, $51.2''$ a year). Introduced the trigonometric formula $\cos\alpha\cos\beta = \frac{1}{2}[\cos(\alpha-\beta)+\cos(\alpha+\beta)]$. Ibn Yunus described 40 planetary conjunctions accurately and 30 lunar eclipses used by Simon Newcomb (1876) in his lunar theory.

ca 1000 CE Collapse of the Andean *Tiahuanaco Empire* due to a prolonged drought lasting some 80 years.

1000–1030 CE **Alhazen (Ibn al-Haitham)** (965–1039, Cairo). Optician, physician, mathematician and astronomer. Gave the first correct explanation of vision, showing that light is reflected from an object into the eye. One of the greatest students of optics of all times. He went beyond Philoponus and any reliance on the speculative method of ancient natural philosophy. He started from systematic, repeated experiments, which were arranged to yield quantitative measurements, and from these he developed hypotheses expressed in mathematical form. These were inspired guesses as to the physical relationships underlying various sets of measurements. If an hypothesis was seen to fit the measurements, further experiments were devised to see if the proposed relationship could accurately predict new measurements. He was thus a pioneer of the *scientific method*, which he used to demolish the old optics of Ptolemy and establish the framework for a science of light.

The Latin translation of Alhazen's main work, the *Optics* (Kitab al-manazir) exerted a great influence upon Western science (**Roger Bacon**, **Peckham**, **Vitelo**, **Alberti**, **Kepler**, **della Porta**) and showed a progress in experimental methods. Alhazen conducted research with spherical and parabolic mirrors, studying magnifying power of concave and convex lenses, spherical aberration, catoptrics[30], dioptrics and reflection[31]. He also studied

---

[30] The following problem in catoptrics is known as *Alhazen's problem*, states: Given a light source and a spherical mirror, find the point on the mirror where the light will be reflected to the eye of an observer. This can be reduced to the planar geometrical construction: from two points in the plane of a circle, draw lines meeting at a point of the circumference making equal angles with the normal at that point. It leads to an equation of the 4^{th} degree. Alhazen solved it by the aid of an hyperbola intersecting a circle. In a similar way he also solved the cubic equation $x^3 + c^2b = cx^2$, which results from the *Archimedean problem* of dividing a sphere by means of a plane into two segments at a given voluminal ratio to one another.

[31] He investigated reflection from non-planar surfaces (concave, convex-spherical,

the phenomena of atmospheric refraction (attempted to measure the thickness of the atmosphere on the basis of his observation that the twilight only ceases or begins when the sun is 19° below or above the horizon).

Alhazen gave a correct account of the structure of the eye (although he considered the lens as the sensitive part), contested Plato's idealism which made the eye a *source* of illumination, and appeared to have recognized the eye as what we now call *camera obscura*. Alhazen seems to have been well acquainted with the projection of images of objects through small apertures, and to have been the first to show that the arrival of the image of an object at the retina, corresponds with the passage of light from an object through an aperture in a darkened box.

In mathematics, Alhazen solved problems involving congruences, using what is now called *Wilson's Theorem* [if p is prime, then $(p-1)!+1$ is divisible by p].

He was born in Basra, and there he acquired such a scientific reputation that he was called to Cairo by the Caliph to apply his knowledge to the use of the waters of the Nile for the irrigation of lower Egypt. After examining the situation (as well as the failures of his predecessors), he realized that the feat was impossible. Fearing the anger of the Caliph, Alhazen feigned madness, for which he was confined and his property confiscated. Upon the death of the Caliph, he regained his liberty and property – as well as the opportunity to continue his study of science.

1006 CE The eruption of the volcano *Merapi* believed to have destroyed the Hindu-Javanese state of *Mataram*.

1010–1040 CE **Abu ar-Rayhan al-Biruni** (973–1048). Arabian scholar, historian and writer on mathematics, astronomy and medicine. His *History of India* (ca 1030 CE) became the principal introduction of Hindu numeration for the Arabs. Biruni transmitted Hindu knowledge to the Muslims and vice versa. Gave a clear account of Hindu numerals (positional notation) and the sum of a geometrical progression. Simplified the stereographic projection. Made accurate determinations of latitudes, geodetic measurements, and specific gravities of precious stones and metals. Remarked that the speed of light is immense relative to that of sound. Explained the works of natural springs and artesian wells in terms of the hydrostatic principle of communicating vessels.

---

cylindrical, etc.) and finally formulated *Alhazen's law of reflection*, namely: that the incident ray, the normal of the point of reflection, and the reflected ray, all lie in the same plane.

Biruni was probably born to *Persian* parentage in Khwarizm (Khiva)[32], and was a Shi'ite in religion. He devoted his youth to the study of history, chronology, mathematics, astronomy, philosophy and medicine. For some years he lived in India, where he remained for a few years, teaching Greek philosophy and learning the Hindu language. In 1017 he was taken by Mahmud of Ghazni to Afghanistan, where he remained for the rest of his life.

1010 CE **Ibn Sina (Avicenna)** (980–1037, Persia). Physician, astronomer, philosopher and encyclopedist. Wrote a 5-volume treatise (the *Qanun* = Canon) on Greek and Arabic medicine that dominated the teaching of medicine in Europe until the 17^{th} century. Wrote many philosophical works, among them a philosophical encyclopedia (*Kitab al-Shifa*), and made a profound study of various physical questions. He observed that if the perception of light is due to the emission of some sort of particles by the luminous source, the speed of light must be finite. Many of his writings are devoted to mathematical and astronomical subjects.

He abandoned the various creation myths and studied geological formations in order to understand the origin of the present day earth; he correctly concluded that nearly all land today was once under water, that sedimentary rocks formed under water, and that the land was subsequently lifted by earthquakes.

Ibn Sina was born at Afshana, near Bukhara[33], and died in Hamadhan.

1020–1050 CE **Jonah Ibn Janah** (ca 990–1050, Spain). Leading Hebrew grammarian, philologist, logician, poet and physician. Wrote books on grammar and medicine. In such works as *al-Mustalhak* and *Kitab at-Tenkiyeh* established Hebrew syntax, grammar and lexicon. His work is of permanent value. A huge number of scholars from 11^{th} through 13^{th} centuries quoted his work, and it became the basis for understanding Hebrew grammar and philology. Ironically, Rashi and his students apparently did not know his work.

---

[32] He may have been born at *Byrun* in the valley of the Indus.

[33] He is said to be of Jewish origin [see A. Soub: Avicenna, *Prince des Medicins*, Paris 1935]. There is, indeed, nothing improbable in this; for near Bukhara, the Jews had been settled from time immemorial. But, whether it is so or not, it is a fact that a large proportion of Avicenna's writings reached Europe through the medium of Jewish scholars and translators who worked in Spain, Italy, and Provence, and whose activity was important and influential in the earlier stages of the Renaissance, The material on which they worked was partly Avicenna's own, partly that of the series of scholars who carried on and developed his tradition.

Ibn Janah was born in Cordova, studied in Lucena under Itzhak ibn Gikatilla. In Cordova he studied medicine, which provided him with a livelihood throughout his life.

ca 1025 CE **Guido of Arezzo** (ca 995–1050 CE, Italy). The father of modern music. Music teacher and a Benedictine monk in the monastery of Pomposa. Invented the *musical alphabet*: the four-line staff, the F cleft and the first 6 notes of the scale, *ut* (later renamed *do*), *re*, *mi*, *fa*, *sol*, and *la*. These reforms made the teaching of music much easier. In his theoretical writings he assumes a thoroughly practical tone, which differs greatly from the clumsy scholasticism of his contemporaries and predecessors.

Of his life little is known. He taught singing at Pomposa and invented there his educational method, by means of which, according to his own statement, a pupil might learn within 5 months what formerly it would have taken him 10 years to acquire. Envy and jealousy, however, were his only reward, and he was compelled to leave his monastery. He moved to Arezzo, and there, about 1030, received an invitation to Rome from Pope John XIV. He obeyed the summons, and the pope himself became one of his most proficient pupils. He died as Prior of Avellana.

1040–1058 CE **Shlomo Ibn-Gabirol**, **Avicebron** (1021–1058, Spain). Poet[34]-philosopher and thinker of striking originality. His philosophical system had powerful impact on medieval Christian thinkers, as well as on Spinoza and Schopenhauer. A man of broad vision and keen penetration who saw further than the ordinary poet and felt deeper than the ordinary philosopher, and even cultivated science in his effort to grapple with riddle of the universe and of man's existence in it. Influenced by the Neoplatonism of Plotinus (253 CE) and the pseudo-Empedoclean writings, Ibn-Gabirol's doctrine contains not only certain teachings not to be found in these sources, but others irreconcilable with Neoplatonism.

Ibn-Gabirol, unlike other medieval philosophers, pursued his philosophical studies regardless of the claims of religion, keeping his speculations free from every theological admixture. In fact, his work shows a total and absolute independence of Jewish religious dogma; not a verse of the Bible nor a line from the Rabbis is cited. For this reason Ibn-Gabirol exercised little influence upon his Jewish successors (though this may be accounted for on the ground of the predominance of *Aristotelianism* from the 12^{th} century) and was accepted by the scholastics as a non-Jew. The odor of heresy which clung

[34] In the days of Ibn-Gabirol, the art of versification was not limited to emotional subjects. Law, medicine, and even mathematics were considered legitimate themes for the poet.

to him prevented Ibn-Gabirol from exercising a great influence upon Jewish thought; his theory of *emanation* was irreconcilable with the Jewish doctrine of creation, and the tide of Aristotelianism turned back the slight current of Ibn-Gabirol's Neoplatonism.

The "*Source of Life*", his chief work in philosophy was translated from the Arabic into the Latin in the middle of the 12^{th} century by **Dominicus Gundissalvus**, archdeacon of Segovia, with the assistance of a converted Jewish physician, Ibn Daud (afterwards called Johannes Hispalensis). Henceforth, the *Fons Vitae* as it is called in Latin, became a work to be reckoned with in the world of scholasticism. And just as Ibn Sina was corrupted into **Avicenna** and Ibn Rushd into **Averroes**, so Ibn-Gabirol traveled down the ages under the disguise of **Avicebron**[35].

The main themes of the *Fons Vitae* are:

(1) All that exists is constituted of matter and form (i.e., physics and geometry). This includes all created things, spiritual or corporeal. The various species of matter being but varieties of the universal matter, and similarly all forms being contained in one universal form. Ibn-Gabirol's many arguments in proof of the universality of matter is among his most original contributions to philosophy.

(2) Everything that exists may be reduced to three categories: the first substance, God; matter and form (the world); the divine will as intermediary and cause of the union of matter and form. This will is above the distinction of form and matter; it is neither attribute nor substance.

Ibn-Gabirol was born in Malaga and lived in Saragossa. Little is known of his life there except that his residence was embittered by strife. Envy and ill-will pursued him, which accounts for the pessimistic strain underlying his work. Life finally became unbearable in Saragossa, and he fled. He thought of leaving Spain, but remained and wandered about. After years of wandering and ill-health, he died in Valencia.

---

[35] In the course of time and after much *recopying*. It was not until 1846 that the author's true identity was discovered. The Dominican and Franciscan scholars who fought about his philosophy had no idea he was a Jew and celebrated as a writer of religious hymns used in the Synagogue. Ibn-Gabirol nowhere betrays his Judaism in *Fons Vitae*, and so for centuries, he marched through the philosophical schools of medieval Europe, some taking him as a Christian and some for a Muhammadian. The most zealous of the champions of Ibn-Gabirol's theory of the universality of matter is **Duns Scotus** (1265–1308), through whose influence the basal thought of the *Fons Vitae*, the materiality of spiritual substances, was perpetuated in Christian philosophy, influencing later philosophers even down to **Giordano Bruno**, who refers to "*The Moor Avicebron*".

He had written twenty books, most of which were lost. In his great metaphysical poem, *The Royal Crown*, he renders the following poetic description of the *big-bang*:

> "*Calling unto the void and it was cleft,*
> *And unto existence and it was urged,*
> *And to the universe and its was spread out*".

1041–1049 CE **Pi Sheng** (fl. 1022–1063, China). Alchemist. Invented *typography* – the printing with movable type. His type was made of a baked-clay-and glue amalgam. Its usefulness was limited by China's own non-alphabetic writing system.

1045–1087 CE **Constantine the African** (ca 1020–1087, Italy). Also known as **Constantinus Africanus**. Translator. Latin scholar. Born at Carthage. Spent most of his life in the Benedictine monastery of *Monte Cassino*, translating into Latin Arab works on Greek medicine, philosophy and Aristotelian physics.

Constantine was aptly called "*magister orientis at occidentis*" and was indeed one of the great intermediaries between East and West. First to transport the medical literature of the Arabs into the Western world. The results of his activity considerably stimulated the hunger of European scholars for Greco-Arabic knowledge.

1054 CE, July 04 Chinese astronomers observed a supernova explosion (the creation of a neutron star that occurred some 5000 years ago) in the Crab nebula, in our galaxy. It was visible for 22 months[36].

1055 CE The Arabs introduced the Hindu decimal system into Spain.

---

[36] Other reported observation of *supernova* are:

- 1006 CE: reports from Switzerland and Arab sources; the only known observation outside the Far-East before the Renaissance.
- 1572 CE: European reports on supernova of varying brightness in the constellation of Cassiopeia. First detected by **Maurolycus** and **Schüler** on Nov. 06, 1572. Seen until Feb. 1574. The amount of energy released in a supernova explosion is awe-inspiring. The star will shine as brightly as ten thousand million suns, and the total energy given out during the outburst is greater that released by the Sun over its entire lifetime.
- 1604 CE, Oct. 8–9: Reported from Europe, Japan and Korea. Seen by **Tycho Brahe**, **Kepler** and **David Fabricius**.

ca 1060 CE **al-Zarqali** (**Arzachel**, 1028–1087). Arab astronomer; flourished in Toledo, Spain. Compiled the *Toledan Astronomical Tables*. Suggested that planetary orbits are *elliptical*.

1064–1072 CE Drought in Africa caused a 7-year failure of Nile flooding, resulting in a wide-spread famine.

1066 CE *Battle of Hastings*; William of Normandy (the 'Conquerer') with a motley of invasion forces defeated Harold II; Western civilization was thus introduced to England.

1070–1105 CE **Rabbi Shlomo Itzhaki** (1040–1105, Troyes, Northern France), known by the acronym RASHI. Commentator on the Old Testament and the Talmud. The greatest teacher and educator that the Jewish nation had for the past millennium. His commentary on the Talmud influenced Jewish destiny; his subsequent commentary on the Bible influenced Christian destiny[37].

Unlike Maimonides (1135–1204) and Gersonides (1288–1344), both ardent followers of Aristotle and both rationalists (who believed that the Bible was not to be taken in its strict literal meanings but should be interpreted freely and allegorically), Rashi took a diametrically opposite point of view[38]. His commentary was written with such warmth and humanity, in such clear He-

---

[37] The most profound Jewish influence on European civilization has been exercised through the Bible. The clergy studied it, and, through them, its ideas penetrated into the minds of the people. European law and morals, beliefs and hopes for the future derived largely from what the Christian called the Old Testament. Many Christian reformers of the Middle Ages based their doctrines on interpretations of the Bible text. During the first thousand years of the Christian era, when relationships between Jews and Christians were friendly and direct, such influence came through personal contact and, therefore, have been left unrecorded. **Nicolas de Lyra**, of the early 14^{th} century, wrote a Bible commentary that was admittedly influenced by that of Rashi. He quoted Rashi constantly, either in approval or refutation.

The German humanist **Johannes Reuchlin** (1455–1522), after studying the work of de Lyra, took up the cause of Jewish humanism in his bitter conflict with the Dominicans. One of Reuchlin's ardent supporters was **Martin Luther** (1483–1546); in his monastic cell Luther read both de Lyra and Reuchlin and the fury of the coming *Reformation* took shape in his mind. When Luther translated the Bible, as part of his religious reform movement, he leaned heavily upon Lyre's commentary and thus, indirectly, upon Rashi.

[38] Except for his exegesis of the *Song of Songs*.

brew, so artfully interspersed with French vernacular[39] (where Hebrew lacked the precise words), that it became loved as literature as much as it was revered as Scripture. He laid down an undeviating rule: "*Scripture must be interpreted according to its plain natural sense, each word according to the context*".

Rashi was born in Troyes. He worked his way through the Yeshivas (Talmudic academies) in Germany as a wandering student. After graduation he settled in his home town where he founded an academy of his own which attracted scholars from all over the world.

Rashi was the right man for the times. Life in the 11^{th} century Europe no longer related to many percepts of the Talmud. The people did not understand Aramaic, did not understand the phraseology, and did not understand its application to modern life. There was a need for a *universal Talmud* which could be understood without interpreters. It was this need that Rashi served.

In the 15^{th} century, classic Talmudic learning split off in two directions. The Italian and German schools, continuing the former Babylonian traditions, led to an affirmation of the *past*. The Spanish schools, resurrecting the Greek tradition, led to inquity into the *future*. The former produced a few more brilliant scholars whose influence died with them; the latter produced *philosophers* like Maimonides and Spinoza, whose influence lived after them.

ca 1074 CE **Omar Khayyam**[40] (ca 1044–ca 1123, Persia). Mathematician, astronomer, freethinker and poet. One of the greatest mathematician of medieval times. His reform of the Persian calendar achieved extraordinary accuracy. The first mathematician to study and classify cubic equations and to employ conic sections in their solutions[41]. His standard work on algebra, written in Arabic, and other treatises of a similar character, raised him at once to the foremost rank among the mathematicians of that age and induced Sultan Malik-Sāh to summon him in 1074 to institute astronomical observations on a large scale, and to aid him in his enterprise of reforming the calendar and calculating the length of the solar year with great accuracy.

---

[39] As over 3000 of the French words he used have disappeared from the language, Rashi's writings have become important source book on medieval French.

[40] His full name is: **Ghiyath ud Din Abu'l Fatah Omar bin Ibrahim al-Khayyami**. 'Al-Khayy'am' means 'the tent-maker', but this occupation was most likely far back in his ancestry, his immediate forebears having been a literary family.

[41] The algebra of Khayyam is *geometrical* solving linear and quadratic equations by methods appearing in Euclid's *Elements*. He devised a geometrical method to solve cubic equations by intersecting a parabola with a circle.

Far ahead of his time in mathematical methods, Omar supported his algebraic solutions by geometrical constructions and *proofs*. He is also known for his critical treatment of Euclid's parallel postulate, showing him to be a forerunner of **Saccheri**'s ideas (1733) that finally led to the creation of non-Euclidean geometry[42].

Omar's scientific fame is nearly eclipsed by his still greater poetical renown, which he derives from his 'rubais' (quatrains). In these he appears as a radical free thinker forcibly protesting against the narrowness, bigotry and austerity of the orthodoxy. He has often been called the Voltaire of the East. His articulation of an inexorable fate, which dooms to eternal oblivion, still rings true today as the sentence of a universe that has been set in motion by the initial conditions of the 'Big Bang' cosmology:

> "*With Earth's first clay They did the Last Man knead,*
> *And there of the Last Harvest sow'd the Seed*:
> *And the first Morning of Creation wrote*
> *What the Last Dawn of Reckoning shall read*".

His phenomenal rise to fame in all parts of the civilized world began in 1859 with the anonymous publication of a hundred of his four-lined verses in a book entitled the *Rubaiyatt of Omar Khayy'am*. It was translated rather freely into English by Edward FitzGerald (1809–1883), an Irish writer and student of Iranian philology. Within 50 years after the appearance of that edition, more than 300 English editions were published, and within 70 years after 1859, more than 1300 works connected with the *Rubaiyatt* have appeared.

Omar Khayyam died in Naishapur. He once said that his tomb would be located in a spot where the north wind would scatter rose petals over it. In 1884, William Simpson, a traveling artist of the *Illustrated London News*, visited Naishapur and found the tomb of Omar. It was just outside a rose garden. Boughs hanging over the garden had dropped many blossoms on the grave. He plucked from these a few of the hips still hanging on the bushes. These seeds were planted successfully in the Kew Botanical Gardens, and on Oct. 7, 1893, one of these rose trees was transplanted to FitzGerald's graveside in a little English churchyard at Boulge, Suffolk.

---

[42] **Alhazen** (ca 1000 CE) presented a "proof" of Euclid 5^{th} (parallel) postulate, but like the Greeks before him, he also ran into problems with circular reasoning. **Khayyam** was not satisfied with this proof and presented one of his own. **Saccheri** (1697) assumed the postulate false and tried to reach a contradiction. In doing so, he unknowingly derived many of the theorems of non-Euclidean geometry. Others, such as **Legendre** and **Lambert**, improved upon Saccheri's work, but fell into the trap of circular reasoning themselves, while striking perilously close to discovering non-Euclidean geometry.

1090 CE **Shen Kua** (1030–1093, China). Government official, engineer and astronomer. Wrote *Meng chi pi t'an* (Dream Pool Essays) which contain first reference to the *magnetic needle*, first account of relief maps, a rather accurate explanation of *fossils*, and other valuable scientific contributions in medicine, optics, astronomy, cartography and mathematics.

He entered imperial government service (1063); appointed commissioner for prefectural civil and military affairs in Yen-chou province (1077); banished from office after defeat of his troops by the Khitan tribes (1081).

1092 CE **Su Sung**, built an *astronomical clock* at the imperial observatory at K'ai Feng: a cross between the water-clock and the spring driven clock. It was powered by a water-wheel which advanced in step by step motion and its time-keeping ability could be adjusted by weights. It struck a gong to indicate the passing hours by a system of bamboo revolving and snapping springs. An astronomical check on timekeeping was made by a sighting tube pointed to a selected star.

1096–1291 CE *The Crusades*[43]. Christian military expeditions to free the Holy Land from the 'infidel' Muslims (Saracens). The men who fought in them came from Western Europe. There were 8 expeditions: 1096–1099; 1147–1149; 1189–1192; 1201–1204; 1217–1221; 1228–1229; 1248–1254; 1270[44]. Jerusalem changed hands several times (1099, 1187, 1243, 1244).

The first Crusade (proclaimed by the Council of Clermont on Nov 26, 1085) captured much of the Holy Land from the Saracens. Later Crusades were less successful, and in the 4^{th} the Crusaders, unable to pay the Venetians for shipping, were persuaded to sack the Christian city of Constantinople instead. This event was disastrous to Greek culture: quantities of works of art and manuscripts were lost forever. Moreover, the ensuing Latin domination

---

[43] The word *Crusade* comes from the Latin *crux*, meaning cross. Members of the expedition sewed the symbol of the cross on their tunics. (For further reading, see: Benvenisti, M., *The crusaders in the Holly Land*, Israel University Press, Jerusalem, 1970, 408 pp. and Prawer, J., *A History of the Latin Kingdom of Jerusalem*, Mosad Bialik, 1971, 561+654 pp.)

[44] An additional one in 1212, known as *The Children's Crusade*, ended tragically: some 50,000 children from France and Germany went on a long march south to the Mediterranean sea. Many perished of hunger and cold. Other were sold into slavery. None reached the Holy Land.
During the first Crusade (Sept – Dec 1097), a severe outbreak of plague afflicted Egypt and Israel. About 100,000 died. A second wave broke out in 1218.

(1204–1261) was a terrible blow from which the Byzantine culture was never able to fully recover.

Another disaster which the returning crusaders inflicted on Europe was an epidemic of *leprosy* which reached its peak towards the middle of the 13^{th} century. It was finally controlled by isolating lepers in special houses.

Christians were aroused to organize the Crusades primarily by religious faith. But the expeditions were also part of a larger effort by the Europeans to increase their power, territory and riches (by the time of the first Crusade, the Christians had already retaken southern Italy and Sicily and had put the Muslims on the defensive in Spain).

In addition, the Crusades were in the common interests of kings *and* popes in Europe: Pope Urban II, for example, viewed the first Crusade as an opportunity to win glory for the Church[45], while at the same time help to reduce

[45] The Crusades were not simply a war against Islam; they were also, though less openly, a war against the Jews. As it turned out, the Crusades were not a profitable business – neither morally nor financially (except for Venice!). It is chiefly in that age that the seeds of the most virulent form of anti-Semitism were sown. In 1096, the Crusaders massacred and tortured many thousands of Jews in the Rhine Valley. Later (1099) they burned Jews alive in Jerusalem and killed 70,000 Muslims and Jews in one week. These outrages were repeated in Europe during the 2^{nd} and 3^{rd} Crusades, when they occurred in England as well (1189–1190). These anti-Jewish outbreaks of 1096 and 1146 are so important that they may be considered turning points in the history of the people of Israel. Before that time Jewish persecutions had been exceptional in Western Europe. They now became more frequent. Moreover, they were the cause of anti-Jewish legislation by Innocent III and other rulers. The enormous amount of money needed for the Crusades were partly obtained by special taxation of the Jews and confiscation of their goods.

During the Crusades, the persecution of the Jews tended to become more vicious and more petty; in 1215 a *yellow badge* was enforced upon the Jews by the Fourth Lateran Council, under Innocent III. The segregation of the Jews into ghettos, voluntary at first (for mutual protection), obligatory later, was almost a natural consequence of that branding. But one cannot persecute people without reason, and new reasons were needed all the time. It was hoped that a critical examination of the Jewish writings, and especially the *Talmud*, would provide the justification for their treatment as outcasts. Gregory IX ordered the confiscation of all the Talmuds (1240) on the allegation that it consists of the main source of Jewish antagonism to Christendom. A great number of Talmuds and other Hebrew books were burned in Paris (1242). The tide of persecution once started could not be stemmed. Evil begets evil:

In Spain, a vigorous anti-Jewish propaganda was carried on by the Dominicans.

warfare among European kings and nobles.

On the other hand, some crusaders hoped to win glory, wealth, and new lands, whereas merchants, such as those in the Italian seaports of Genoa and Venice, joined in search of new markets.

In 1291, after the last Crusade, the Muslims seized Acre (now Akko, Israel), the last Christian foothold.

By this time Europeans were losing interest in the Holy Land. Europe was turning its attention westward, to the Atlantic Ocean and beyond. [In 1492, the Spaniards drove the Muslim Moors out of Europe, and in the same year Columbus sailed to the New World.]

The expeditions to the Holy Land prepared Europe for expansion into America. Europeans acquired new tastes in food and clothing. Their desire to travel increased. They learned how to make better ships and better maps, and they learned new ways to wage war. The Crusades quickened the pace of progress of Western Europe by bringing profit and prosperity to Italian trading cities.

1100–1123 CE **Avraham bar Hiyya ha-Nasi**; **Savasorda**[46] (ca 1065–1136, Barcelona and Provence). Mathematician, astronomer and philosopher. The author of the first major book of mathematics written in Hebrew. Introduced Arab trigonometry to the West. He was one of the leaders of the movement which caused the Jews of Provence, Spain and Italy to become transmitters of Muslim science to the Christian West. He helped Christian scholars to translate scientific works from Arabic into Latin. His book *Hibbur*

In 1263 they obliged the great Jewish physician, Moshe ben Nahman, to defend his faith in a public disputation at Barcelona, against the Jewish renegade Pablo Christiani. Pablo seems to have had the worst of it, but this only added fuel to the fire, and the persecution was renewed with increased vigor. Once more the Talmud was scrutinized and attacked.

In England things were hardly better. The financial success of some Jews excited the hatred and covetousness of their Christian neighbors. More and more vexations were piled upon them, and the hostile feelings which they inspired accumulated throughout the 13^{th} century, gathering more and more intensity. The Spanish method of persuasion was tried in 1280 when they were obliged to attend Dominican sermons, but this could only make matters worse. The almost inevitable climax occurred in 1290: Edward I ordered all the Jews to leave England before All Saints Day, their immovable property being confiscated to the crown's profit. Sixteen years later the Jews were expelled from France.

[46] He held the honorary title *captain of the guard*, the Arabic name of which was condensed into **Savasorda**.

ha-meshiha ve-ha-tishboret (1116) was translated by Plato of Tivoli in 1145 under the title of *Liber embadorum*. It contains a complete solution of the quadratic equation $x^2 + b = ax$, showing that it has two roots. The book exerted a deep influence upon the development of Western mathematics and was used by Leonardo of Pisa as the foundation for his text-book on Hindu arithmetic, geometry and trigonometry.

Avraham also composed an encyclopedia, treating mathematics, astronomy and optics, and Sefer-ha-ibbur (1122) – the oldest Hebrew treatise specifically devoted to calculation of intercalation. Avraham was one of the creators of Hebrew scientific language.

While Christianity and Islam met each other on the battlefield, Avraham bar Hiyya, called by his fellow Jews "the prince", took a leading part in promoting spiritual interchange between the representatives of the Christian and Arabic civilizations.

Through his translations, Muslim trigonometry, and more specifically the sine and tangent functions, were introduced into the Latin world. Although starting as an abacist (he wrote a treatise on the abacus before his Arabic contacts), he later became one of the earliest algorists.

1100–1500 CE *Christian pilgrimage*[47] *in medieval times*. Journeys of devotion to the Holy Land, Rome and other sanctified places.

The medieval Church adopted the custom of pilgrimage from the ancient Church. The young Germanic and Romance nations did precisely as the Greek and Romans had done before them, and the motives of these journeys (now much more difficult of execution in the general decay of the great world-system of commerce) remained much the same. They were undertaken to the honor of God, for purposes of prayer or in quest of assistance, especially health. But the old causes were reinforced by others of equal potency.

The medieval Church was even more profoundly convinced than its predecessor that the miraculous power of Deity is attached to the body of saints and their relics. But the younger nations – French, English and German – were scantly endowed with saints; while, on the other hand, the belief obtained that the home-countries of Christianity, especially Rome and Jerusalem, possessed an inexhaustible supply of these sanctified bodies. Far more important consequences, however, resulted from the fact that the medieval mind associated the pilgrimage with the forgiveness of sins, an idea foreign to the ancient Church. The pilgrimage became an act of obedience. The place to be visited

[47] From the French *pelegrin*, Latin *peregrin*, meaning: to travel. (Similarly *saunter* is derived from *saintre terre*, meaning: stroll.)

was not specified, but the pilgrim lay under the obligation, wherever he went, to offer his prayers to the tombs of the saints.

As the system of indulgences developed, a new motive came to the fore which rapidly overshadowed all others: to obtain the indulgence which was vested in the respective church or chapel. By the close of the Middle Ages there were thousands of churches in every Western country, by visiting of which it was possible to buy an almost indefinite number of indulgences. A system was thus formed through which a repentant sinner could buy himself out of guilt and obtain total absolution. Simultaneously, the opportunity was offered of acquiring an indulgence for the souls of those already in purgatory! Consequently, during the whole period of medievalism, the number of pilgrims was perpetually on the increase, and so were the accumulated riches of the Church.

The pilgrimage to Rome received their greatest impetus through the inauguration of the so-called *Year of the Jubilee* (1300 CE), on which the bull of Boniface 8^{th} promised Plenary indulgence to every Christian who should visit the churches of Peter and Paul on 15 days during the year. This placed the pilgrimage to Rome on a level with the crusades – the only mode of obtaining a plenary indulgence. The success of the papal bull was indescribable: in the year of the Jubilee, on the average, 200,000 strangers were present in Rome during the day, the greatest number of pilgrims coming from Southern France.

In the years 1350, 1390, 1423, 1450, 1475, 1500, the troops of pilgrims again came steaming into Rome to obtain the cherished dispensation.

Next to Rome, the shrine of St. James of Compostella (Santiago, Spain) became the most favored devotional resort, and a pilgrimage road from France to that resort was known as the *Way of St. James*.

Science benefited from pilgrimage in a number of ways: it enabled exchange of ideas and information between various cultural centers. It also accelerated the fusion and diffusion of knowledge from the East into Europe.

1109–1140 CE **Yehudah ben Shmuel Halevi** (1071–1141, Spain and Jerusalem). Philosopher-poet and physician. Presented his *philosophy of history* in general and of the history of the people of Israel, in particular, in his famous book *Kitab Al Khazari* (1139), written in Arabic and translated into Hebrew under the title *Sefer Ha'Kuzari* (Book of the Khazar). It is a profound meditation on the interrelations between the histories of Hebrews and non-Hebrews and an acute demarcation between philosophy and religion.

According to Halevi, the knowledge of God is attained not through rationalistic discussions or theoretical philosophical scholasticism (which only lead to controversies and disagreements), but via personal inner *experience*[48] such as experienced by the Hebrew prophets.

He maintains that the universe was created by intentional God's will out of nothing, a belief which is at the common root of the three great religions. The laws of nature were established *arbitrarily* by God and are manifested both in the physical world *and in history*. He rejected Epicurean metaphysics which maintained that the universe was created by chance.

Halevi seeked to free Judaism from a dependence on the intellectualization of creed and Aristotelianism which he reproached for subjecting the Deity to necessity and for becoming incompatible with the idea of a personal God. Platonic tradition seemed more fitting to him, for he was inclined to regard God as a principle of form that moulds the eternal material principle. He maintained that Judaism does not center in the person of its founder as the other religions do but in the people to whom the Torah has been given. Jewish history is the work of Divine Providence which he regarded as the continuation of the Divine creative activity. Halevi became the first philosopher to speculate on the meaning of the Diaspora in Jewish destiny; in his view, the successful conclusion of the Diaspora and the restitution of the Land of Israel would herald the redemption of not only the Jews but of all mankind.

Halevi was born in the city of *Tudela* (*not* Toledo), Northern Spain. His well-to-do parents sent him to best schools where he studied algebra, grammar, Arabic, astronomy and poetry. He left his home town at an early age (ca 1086) and wandered to Southern Spain, visiting Cordova and Granada. He studied the Talmud at the academy of *Lucena*, and medicine at the medical school of *Cordova*. Finally, at the age of 24 he established a successful medical practice in *Toledo* and married into a prominent family in that city. As the persecution of the Jews reached an intolerable level, Halevi left Christian Spain (1109), gave up his career as physician and abandoned his family to take up the life of a wandering poet.

With his friend, the poet-scientist-physician, Avraham Ibn Ezra, he roamed the cities of Muslim Spain for many years and at least once, visited North Africa. (The two poets became related by the marriage of Halevi's daughter with Ibn Ezra's son.) In 1140 Halevi decided to make a pilgrimage to Jerusalem, despite the dangers to travelers in those days and the risk of going to Israel while the crusading movement was in progress. He arrived in Alexandria on Sept. 8, 1140, and apparently died in Egypt some six months later. Legend has it that at the very moment when he knelt to kiss the ground at the gate of Jerusalem, an Arab horseman hurled his spear at the prostrate figure and cut short the poet's life.

---

[48] In *The Varieties of Religious Experience* (1902), **William James** expresses these very ideas.

1116–1142 CE **Adelard of Bath** (1075–1160, England). Philosopher, translator and mathematician. English monk, who in 1120 studied in Spain and traveled extensively through Greece, Syria and Egypt. He is credited with Latin translations of Euclid's '*Elements*' and of al-Khowarizmi's astronomical tables. Adelard had to run physical risks in his acquisition of Arabic learning: to obtain the jealously guarded knowledge, he disguised himself as a Muhammadan student.

1120–1160 CE **Ibn Zuhr (Avenzoar)** (ca 1090–1162, Spain). Physician. A Muslim of a Jewish descent. Greatest clinician of the Western Caliphate. Described pericarditis, mediastinal abscesses, surgery for cataracts, kidney stones. His most important work, *Taysir* (Aid to Health), was influential throughout Europe in Latin and Hebrew translations[49]. Avenzoar was born in Seville.

1134 CE A Sicilian coin bearing this date serves as the earliest known example of the official use of the Arabic numerals in the West.

ca 1140–1164 CE **Avraham** (**ben Meir**) **Ibn Ezra** (1089–1167, Spain and Western Europe). One the greatest Jewish savants of the Middle Ages. A roving scholar who developed unusually rich literary and scientific activity in his roaming existence under the stress of circumstances, and who wrote works of lasting importance: poet, philosopher, physician, mathematician, astronomer, chronologist, Hebrew philologist, grammarian and biblical commentator. He wrote on the history of numbers, the calendar, astronomy and the astrolabe.

Ibn Ezra translated astronomical works from the Arabic (al-Biruni and al-Khowarizmi) and wrote at least five books on mathematics and astronomy (some of which were translated from the Hebrew into Latin!) [*Sefer-ha-Ehad* – peculiarities of numbers; *Sefer-ha-Mispar* on arithmetic and combinatorics; *Luhot* – astronomical tables; *Sefer-ha-Ibbur* – on the Calendar; *Klei-ha-Nehoshet* – on the astrolabe]. He adopted the positional decimal system for integers (with place values from left to right) of the Hindus, using the first nine Hebrew letters for the numerals 1–9 (with the tens to the left of the units etc.), and denoting the zero by the special sign $\circ$ or $\bar{\circ}$ (*galgal*=wheel in Hebrew). This lore he spread all over Western Europe, sixty years before Fibonacci. He was thus instrumental in propagating Eastern mathematics and astronomy into Italy, France and England. He was fitted for this mission through the versatility of his learning.

Ibn Ezra was born in Tudela, northern Spain, and afterwards settled in Cordova, where he practiced medicine and raised a big family, winning for

49 Translated from Hebrew into Latin (1280) by a Paduan physician.

himself a name of a poet and a thinker. At about 1137 he emigrated from Spain and led a wandering life of a lonely exile for nearly three decades; he visited Northern Africa, Egypt, the land of Israel, Mesopotamia and India, and then returned to Europe and lived in Rome (1140), Salerno (1141), Mantua (1145), Verona (1146), Lucca (1148), Beziers (1156), London (1158), Narbone (1160). Longing to see his old Spanish home, he left Rome, but died on the way at Calahorra.

Ibn Ezra was one of the greatest Biblical commentators of the Middle Ages. He was also one of the forerunners of modern Biblical criticism, and much admired by **Spinoza** on that account. (His conclusion that the Book of Isaiah contains the sayings of two prophets, has been confirmed by modern criticism.)

1144 CE **The Norwich blood libel**. Concoction of the first ritual murder fantasy - a pernicious medieval superstition which would encourage the most virulent Jew-hatred in subsequent centuries[50]. Invented in Norwich, England, following the murder of a Christian boy just before Easter, who would later be venerated as medieval's Europe first child martyr. The crime was then attributed without any evidence to local Jews. They were accused of crucifying him in mockery of the passion of Jesus, and the fantasy gained acceptance because people wanted a local saint to work miracle cures and the Norwich clergy realized that his shrine would enhance the city's standing on the pilgrim route.

1145–1149 CE **Robert of Chester** (England). Mathematician, astronomer and alchemist. Translated al-Khowarizmi's book into Latin using '*Algebra*' for 'al-jabr' and 'Algorism' for the author's name. From this is

---

[50] Similar accusations spread across England and to the Continent. A famous blood libel in Italy is the *Trent episode* (1473) which resulted in the burning of all the Jews of the city, with the approval of the Pope. The Church revoked its accusations in the Trent libel only as late as 1965!

Throughout the Middle Ages and into the modern era, blood libels have abounded in the Christian world and frequently provoked persecutions and massacres of the Jews. Even in the late 19^{th} century there were notorious blood libel cases: *Tisza-Eszlar*, Hungary (1882); *Corfu*, Greece (1891); *Xanten*, Germany (1891); *Blondes*, Russia (1900); *Konitz*, Germany (1900).

As late as 1911 the Russian government sought to exploit popular antisemitism by putting on trial a poor Jewish artisan in Kiev, Mendel Beilis, who was eventually acquitted (the *Beilis trial*, 1913). The Czarist minister of justice stopped at nothing to prove the charge, but he failed. Even his handpicked judge and jury being unable to find Beilis guilty. The affair brought ridicule upon Russia. German Nazi publications also used the blood libel to whip up antisemitism.

derived today's word *algorithm*, meaning: a method of calculating in any particular way. Introduced the Latin word *sinus* (1149) into trigonometry.

The Hindus have given the name 'jiva' to the 'half-cord' in trigonometry, which the Arabs took over as 'jiba'. In the translation he confused it with the Arabic word 'jaib' meaning 'bay' or 'inlet' – which he translated into the Latin 'sinus'.

He lived in Spain during 1141–1147 and in London about 1147–1150.

ca 1145 CE **Gerhardo of Cremona** (1114–1187, Italy). A most industrious translator who translated into Latin over 90 Arabian works, among which were Ptolemy's *Almagest*, Euclid's *Elements*, al-Khowarizmi's algebra and the works of Aristotle.

Gerhardo was perhaps the greatest of all translators. He was born in Cremona, Lombardy and died in Toledo. Being anxious to read the Almagest, which was not yet available in Latin, he went to Toledo, where he studied Arabic and carried on a prodigious activity as translator until the time of his death.

ca 1150 CE **Bháskara** (1114 – ca 1185, India). Also known as *Bhaskaracharya* (the Teacher). Hindu astronomer and mathematician. In his book *Sidd'hanta-siromani* he presented algorithms for solving Diophantine problems (including the Pell equation[51] $y^2 = px^2 + 1$), problems in permutations and combinations, operations with zero (excluding division by zero) and rules for employing positive and negative numbers.

Gave the remarkable identities

$$\sqrt{a \pm \sqrt{b}} = \sqrt{\frac{1}{2}\left(a + \sqrt{a^2 - b}\right)} \pm \sqrt{\frac{1}{2}\left(a - \sqrt{a^2 - b}\right)}.$$

These identities are also found in Book X of **Euclid**'s 'Elements', but are given there in an involved language which is difficult to comprehend. He also gave the trigonometric identities

$$\sin(\alpha \pm \beta) = \sin\alpha\cos\beta \pm \cos\alpha\sin\beta$$

Bháskara represents the peak of mathematical knowledge in the 12^{th} century. It shows an understanding of the number system and solving equations which was not to be reached in Europe for several centuries.

---

[51] A complete theory for this equation was worked out by Lagrange in 1766–1769. Bháskara studied the Pell equation for $p = 8, 11, 32, 61, 67$. For $p = 61$ he found the solutions $x = 1776, 319, 049$; $y = 22, 615, 390$.

1154 CE **Muhammad al-Idrisi** (1100–1166, Spain and Sicily). An Arab cartographer, geographer and traveler who lived in Sicily, as a court geographer of King Roger II. He was born in nowadays Ceuta, Spain and died in Sicily.

Al-Idrisi was educated in Cordova. Later he traveled far and wide in connection with his studies and then flourished at the Norman court in Palermo.

In 1154 al-Idrisi issued a large map of the "inhabited earth" (as far as it was known to the author) and an accompanying book, named *Geography.* Taken together, they were named *Kitab Rudjar* ("Roger's Book"). This book was based on reports of emissaries which Idrisi sent to observe and describe various countries and regions including Scandinavia, Germany, France, Italy, Syria, Asia Minor and Egypt.

In his book he divided the "inhabited earth" into seven "climates" beginning at the equinoctial line, and extending northwards to the limit at which the earth was supposed to be rendered uninhabitable by cold. Each climate is then divided by perpendicular lines into eleven equal parts, beginning with the western coast of Africa and ending with the eastern coast of Asia. The whole world is thus formed into seventy-seven equal square compartments. The geographer begins with the first part of the first climate, including the westernmost part of the Sahara and a small (north-westerly) section of the Sudan (of which a vague knowledge had now been acquired by the Moslems of Barbary), and thence proceeds eastward through the different divisions of this climate till he finds its termination in the Sea of China. He then returns to the first part of the second climate, and so proceeds till he reaches the eleventh part of the seventh climate, which terminates in north-east Asia, as he conceives that continent. The inconveniences of the arrangement (ignoring all divisions, physical, political, linguistic or religious, which did not coincide with those of his "climates") are obvious.

His major contribution lies in medicinal plants as presented in his other books, specially *Kitab al-Jami-li-Sifat Ashtat al-Nabatat.* He studied and reviewed all the literature on the subject of medicinal plants and formed the opinion that very little original material had been added to this branch of knowledge since the early Greek work. He, therefore, collected plants and data not reported earlier and added this to the subject of botany, with special reference to medicinal plants. Thus, a large number of new drugs plants together with their evaluation became available to the medical practitioners. He has given the names of the drugs in six languages: Syriac, Greek, Persian, Hindi, Latin and Berber.

Al-Idrisi, later on, also compiled another geographical encyclopedia, larger than the former entitled *Rawd-Unnas wa-Nuzhat al-Nafs* ("Pleasure of men and delight of souls") also known as *Kitab al-Mamalik wa al-Masalik.*

Apart from botany and geography, Idrisi also wrote on fauna, zoology and therapeutical aspects. His work was soon translated into Latin and, especially, his books on geography remained popular both in the East and the West for several centuries.

Though Idrisi was in such close relations with one of the most civilized of Christian courts and states, we find few traces of his influence on European thought and knowledge.

1155 CE A map of western China *printed* in China. It is the oldest known printed map.

12–13th centuries Chinese mathematicians knew how to solve problems involving equations of the second and higher degrees.

1157 CE **Frederick Barbarossa** founded the holy Roman Empire, abolished by **Napoleon Bonoparte** (1806)

1160–1195 CE **Muhammad Ibn Rushd**; **Averroës** (1128–1198, Spain). Philosopher, physician and jurist. An outstanding Muslim philosopher who deeply influenced Christian philosophy in various ways. His main contribution was to free Aristotelian studies from the distorting influence of Neo-Platonism. He believed, as did Aquinas later, that God's existence can be proved on rational grounds alone. As for the soul, he held with Aristotle that it is not immortal.

He wrote three commentaries[52] on the works of Aristotle (as he knew them through Arabic translations. Most of these are preserved in Hebrew translation, or in Latin translation from the Hebrew) in which he tried to reconcile philosophy (reason) with religion (faith) by the doctrine of *twofold truth*: the one (more esoteric) for the philosophers, the other more concrete and literal (theological) for the masses ("teach the people what they can understand"). The success of the commentaries had caused orthodox revulsion everywhere – first among the Muslims in Spain, and finally in Christendom. Consequently, he was violently attacked by the Muslim clergy, his doctrine condemned and his books burned. In the eyes of the Church, Ibn Rushd came to be regarded as the arch-infidel, and the greatest enemy of the faith.

He wrote a medical encyclopedia (1160). His theories of the evolution of pre-existent forms, and of the intellect, anticipated modern concepts.

[52] A "commentary" was a medieval form of publishing one's views on a definite subject. To write a commentary on Aristotle meant to compose a philosophic and scientific encyclopedia, using Aristotle's writings as a framework and guide. Such commentary might be original or not, but its being labeled a "commentary" does not in itself justify any presumption one way or the other.

Ibn Rushd was born in Cordova of a line of qadis. He studied there law and medicine, amongst other subjects, and was a qadi in Seville and later in Cordova. In 1182 he became physician to the caliph in Marrakesh, but in 1194 he was banished to Cordova for holding philosophical views instead of contending himself with the faith. In 1198 Ibn Rushd was forgiven and recalled to Morocco, where he died soon thereafter.

Ibn Rushd was the greatest and the last of the Muslim philosophers. Although his influence on the members of his own faith was insignificant, he made a tremendous stir in the minds of men for centuries. His originality must be understood in a relative sense: it appeared chiefly in his way of interpreting anew the teaching of the wise men who had come before him. His philosophy was essentially a return to the purer Aristotelianism, a return to positivism or *scientific philosophy* which was largely stimulated (as most philosophical systems are) by opposite tendencies – mysticism and pragmatism.

1160–1200 CE **Moshe ben Maimon**; **Maimonides**; "RAMBAM" (1135–1204). Philosopher, physician, astronomer and mathematician. The leading Jewish savant and philosopher of the Middle Ages.

For Muslim scholars, as for medieval Christians, science was merely one aspect of philosophy. Aristotle, the great authority on science for both religions, was thought of primarily as a philosopher, and one of the chief intellectual problems of the Middle Ages was to reconcile his philosophy with the truths of religion. Moshe ben Maimon was the most prominent figure of this category, who exerted great influence on the Catholic scholastic philosophers [in particular upon Thomas Aquinas (1225–1274)].

Born in Cordova, Spain, his family was forced by persecution to leave their home in 1148 when he was thirteen. For the next ten years they drifted from place to place; at some time they crossed to Morocco and by 1158 were settled in Fez. It is not known exactly what Maimonides was doing during that time, but we may be sure that he seized every opportunity of increasing his knowledge; he studied theology, philosophy, and medicine. In 1165 the family sailed to Acre, where they traveled to Jerusalem and to Cairo. They established themselves at the end of 1165 in Fustat, where he made his living as a physician. He later became physician to Salah-al-din, and to the latter's son. He fell ill in 1200 and probably ended medical practice or reduced it considerably, being then able to devote the remnant of his life to writing. He died in Cairo at the age of 69; his remains were carried to Tiberias, Israel, where his tomb may still be seen.

Maimonides was at one and the same time an Arabic physician and a Jewish theologian. This implied no contradiction, yet his life was a double life. His activity was prodigious, for he was a physician and astronomer, a

Talmudist, a rabbi, and a philosopher. He was at the same time an ardent Aristotelian, a lover of reason and science, and an orthodox and pious Jew. He wrote many works on astronomy, medicine, logic and law, and devoted his philosophy to the reconciliation of Aristotelian philosophy with the Jewish theology – of *reason* with *faith*.

To this end, he gave an allegorical interpretation of Biblical anthropomorphism and concreteness, steering clear of both mysticism and religious skepticism; for example, he explained prophetic visions as psychical experiences, and Jewish laws and customs from the point of view of comparative ethnology. He insisted that human perfection is inseparable from knowledge, and that the *acquisition of knowledge is one of the highest forms of religion*. To that extent Maimonides was the champion of *science against Biblical* "*fundamentalism*". He thus gave a tremendous stimulus to philosophical studies, and helped check Kabbalistic extravagances as well as theological obscurantism[53].

Maimonides' medical writings have deeply influenced Muslim, Jewish and Christian physicians. In his astronomical works he rejected eccentric move-

---

[53] One of the distinguished anti-Maimonidean was **Moshe ben Nahman**.

Another famous anti-Maimonidean was **Moshe de Leon** (1245–1305, Spain), a Jewish occultist, and probable author or editor of the Kabbalistic compilation, the so-called *Sefer ha-Zohar* (Book of Splendor: title derived from **Daniel** *12*, 3).

The Zohar is a mystical commentary on the Torah. It deals with such subjects as astronomy, cosmogony, physiognomy, psychology, demonology, etc. It is derived from many sources: Neo-Platonism, Neo-Pythagoreanism, gnosticism, Hinduism, and the mysticism of many nations.

The recrudescence of Kabbalism at the end of the 13^{th} century, and the appearance of the Zohar, are partly explained as reactions against the excessive intellectualism fostered by Maimonides and his followers. The triumph of Jewish philosophy has repressed other fundamental tendencies beyond endurance – these emotional, sexual, and mystical needs which are normal constituents of human nature. The Zohar completed the establishment of the Kabbalah as a definite body of doctrine, and put it on a level of equality with the two other great streams of Jewish thought, the *rabbinical* and the *philosophical* (Maimonidean).

The influence of the Zohar was immense: while containing admirable thoughts and some sound knowledge, it was adulterated by many superstitions and extravagances. It stimulated magical tendencies and as such has strong attraction for unbalanced minds, whose destruction it helped to complete. But its influence did not stop there: every Jewish thinker was more or less affected by it.

One of the central theories of the Kabbalah is the *theory of emanation*, which is the result of reconciling the Aristotelian notion of eternity of the world with the Biblical dogma of creation.

ments as contrary to Ptolemaic views. In fact, Maimonides carried these views with him to Egypt in 1165. Their transmission to Eastern Islam was largely due to him and to his disciple **Joseph ben Yehudah Ibn Aqnin**. Thus, the most advanced astronomical lore was diffused in the East by Jews.

The subtitle 'astronomer', may seem a little ambitious and to claim more for Maimonides than he would have claimed for himself. Yet, in his philosophical synthesis and even in his rabbinical commentaries, he had been obliged to investigate the scientific knowledge available in his time in order to understand the universe. This meant primarily cosmogony, and, as far as science was concerned, astronomy. Although he was not a practical or creative astronomer, he was deeply versed in both the Eastern and Western astronomical literature of his time.

He did however made a significant contribution to science proper, namely to the concept of *time*; in his work *The Guide to the Perplexed* (1190) he wrote (in Arabic): "*Time is composed of time-atoms, i.e., of many parts, which on account of their short duration cannot be divided... An hour is, e.g., divided into* 60 *minutes, the minute into* 60 *seconds, the second into* 60 *parts and so on; at last after ten or more successive divisions by sixty, time-elements are obtained which are not subjected to division, and in fact are indivisible...*". He thus concluded that these were 60^{10} or more such time-atoms in one hour![54]. The notion of Maimonides that time is composed of time-atoms and that the universe would exist only for one of them, were not for the continual intervention of God, was also held by Descartes.

In the field of mathematics proper he will remembered among the first who claimed clearly and unequivocally that π *is not rational* and that it can only be *approximated* by a ratio of integers. He further stated, although without proof, that squaring the circle by rules of Greek geometry is impossible[55].

Maimonides condemned astrology in the most uncompromising manner, describing it as a system of superstitions. In this he was too far ahead of his

---

[54] In todays jargon such unit is known as *chronon*. If indeed space-time is discrete (quantized), then the scale must be very small to agree with experimental observations. Indeed, the present smallest directly observable division of a second, which is better than 1×10^{-13} sec, is coming close to Maimonides' division of $60^{-10} \sim 5 \times 10^{-15}$ sec.

[55] In his exegesis to the MISHNA (*Eruvin* **1**,5). **Archimedes** found the upper bound $\frac{22}{7}$ for π in the 3^{rd} century BCE. **Adrian Anthoniszoon** (1583) found the lower bound $\frac{333}{106}$. The irrationality of π was established by **Lambert** (1767). **Legendre**, in his *Elements of Geometry* (1794) proved the irrationality of π (and π^2) more rigorously. Finally, **Lindemann** (1882) proved that π is not algebraic, thus closing the lid on the 2400 year long quest for the circled square.

time to be understood. The world according to Maimonides is one indivisible whole, rational through and through; for without rationality, there could not be any knowledge, or morality, or religion. But he rejected the Aristotelian view of the eternity of matter and accepted the account of Genesis. In this he reconciled reason and faith, for he believed that both the world *and* faith derive from God[56]. This gives us a measure of his rationalism – he was ready to carry it to any extent compatible with his creed – but no further.

The influence of Maimonides was tremendous and far reaching in space and time. It affected not only the Jews, but also the Christians, chiefly the Dominicans (while **Ibn Gabirol** inspired the Franciscans). It can be strongly detected in **Spinoza**, and even in **Kant**.

In spite of the violent antagonism raised by Maimonides' work[57], he succeeded in his main object, the Aristotelization of Jewish philosophy. To be sure, he did not convince those who rejected every kind of philosophy. But aside from these, the ulterior development of Jewish philosophy was mainly a contest between Aristotelians and Neo-Platonians (most of these Kabbalists), a contest strikingly similar to the one which was waged at the same time in the Latin world.

The history of Maimonidism, like that of Averroism, is essentially the history of a continuous battle against fundamentalism on the one hand and mysticism (Kabbalism, or its Muslim and Christian equivalents) on the other. And is not this the very battle fought by men of science? For this reason alone, Maimonides would deserve a place of honor in the history of science.

1160–1173 CE **Benjamin ben Jonah of Tudela**, in Navarra (ca 1120–1175, Spain). Jewish traveler who visited, more than a century before Polo, all the known countries of the 12^{th} century. Slowly and carefully he went through Southern Europe, North Africa, the Near East, Arabia, Persia, India, Ceylon and penetrated up the frontiers of China. The record of his journeys is one of the most valuable travel accounts of Medieval times. He left Saragossa in 1160 and came back by way of Egypt and Sicily to Castile in 1173. His book was first published in Constantinople in 1543, translated into Latin in 1575, and into English in 1625.

1161 CE **Avraham ben David Halevi**, **Ibn Daud**, "RABED"[58] (1110–

[56] If one identifies the Biblical story of creation with the contemporary Big Bang theory, then the synthesis of Maimonides does not contradict the ideas of modern cosmology!

[57] In 1234, copies of the works of Maimonides had been destroyed by Christian authorities at the instigation of the conservative rabbis of southern France.

[58] Acronym: *Rabbi Avraham ben David*. Also known as **Johannes Avendahut Hispanus**.

1180, Spain). Philosopher, historian, physician, translator, astronomer and Talmudist. Author of books on astronomical measuring instruments. First Jewish philosopher to draw systematically on Aristotelian thought. Translated Hebrew, Greek, and Arabic literature into Latin. Introduced Arabic numerals and the concept of the *zero* into European mathematics. The RABED was born in Cordova and died in Toledo, a martyr of the Inquisition.

1170–1185 CE **Petahyah of Regensburg** (ca 1130–1195, Germany). Traveler. Visited Eastern Europe and Western Asia. His travelogue (1595), *Sibuv Ha'olam* (Journey of the World) was apparently written by a pupil, based on his notes or on dictation.

Starting from his home-town Regensburg (Ratisbon), Petahyah traveled through Bohemia, Poland, Southern Russia, Armenia, Kurdistan, Khazaria, Persia, Babylonia, Syria and Israel (1180).

Rise of the European Universities (1050–1582)

The economic, political and religious revival in Western Europe after 1000 *stimulated the growth of towns, especially in Italy and Flanders. During the* 11^{th} *century, Italian shipping in the Mediterranean increased steadily. With the Byzantine Empire weakening and the Muslim Caliphate breaking up, the Italian merchants had little competition. In addition, the Italian monopolized the trade in oriental goods for Western markets, and these markets were becoming steadily more profitable, thanks to the general increase in prosperity and security throughout the West. The great seaports of Venice, Pisa and Genoa flourished. As the Italian merchants carried their wares north through France and Germany, they stimulated the growth of other trade centers along the routes they traveled. Simultaneously, the towns of Flanders found their nourishment in their textile industry. By the* 12^{th} *century the Flemish textile towns of Ghent, Brugs and Ypres rivaled the flourishing seaports of Italy in wealth and population.*

Outside Italy and Flanders old towns were expanding and new towns were springing up, and rational division of labor between town and country was set up. Eventually towns gained freedom for their people and a separate system of municipal government.

The economical revival was accompanied by political and religious revivals. Slowly Christianity became less and less a matter of external observance, more and more a matter of strong internal conviction. A great wave of popular piety swept through Europe in the 11^{th} *and* 12^{th} *centuries, changing the whole character of European society. This revival continued unabated into the* 12^{th} *century. The men of this era, with much energy and originality, laid the foundations for a new architecture, a new literature, and a new system of education. All these activities drew on the Church for intellectual inspiration and material support, and in many of them Church men played a leading role.*

From 1000 CE on, there had been a great wave of church-building in Western Europe. These cathedrals were larger and more beautiful than any that had been built before in Europe. The cathedrals and monasteries soon became centers for theological studies. But 12^{th} *century scholars had a wider range of interests such as Latin classics, Roman law and especially Canon law, which opened the road to high office in the church.*

The cathedral and monastery schools developed slowly into universities. The oldest was ***Salerno*** *(ca 1050)*[59]*. The next was the University of* ***Bologna****, founded in 1088. It has existed as a law school since 890. The* ***University of Paris***[60]*, founded in 1167, also developed from a pre-existing theological school. Many other universities evolved from church schools, such as* ***Oxford*** *(1167),* ***Padua*** *(1222),* ***Cambridge*** *(1231),* ***Montpellier***[61] *(1220),*

59 The University of Salerno developed gradually from a medical school. One of the founders of this school was **Shabbethai ben Avraham ben Joel Donnolo** (913–982, Italy), a physician and pharmacist, and one of the earliest Jewish writers on medicine (in Hebrew). Donnolo wrote at the crossroads of the Greco-Latin and Arab cultures. The Salerno school is said to have taught in Hebrew, Latin and Arabic, and the Jewish element appears to have been important among the students and the professors. The reputation of the school was great till the 13^{th} century.

60 During its period of glory – the 13^{th} century – the leading teachers in the University of Paris were almost all foreigners: **Roger Bacon** (England), **Albertus Magnus** (Germany), **Thomas Aquinas** (Italy) and others. This was less surprising than it seems at first view, for the University of Paris was not a Parisian or a French institution; it was neither regulated nor subsidized by town or country; its ideals were Christian ideals, and it was controlled by an international organization, the Catholic Church. It is true the situation was far from being the same in the following century, especially when the popes were "captive" in Avignon under the thumb of the French Kings; Indeed, in the 14^{th} century the main teachers of Paris are no longer foreigners, but Frenchmen.

61 The *medical* school of Montpellier existed since early in the 12^{th} century. It owed its foundation largely to Jewish teachers, themselves educated at the Moorish

Salamanca *(1243) and the* ***Sorbonne***[62] *(1257).*

These universities were founded largely to serve the professions. They provided the first unified teaching of law, medicine and theology. The medieval Latin term 'Universitas' (from which the English word "university" is derived) was originally employed to denote any community or corporation. In the course of time, probably toward the latter part of the 14^{th} *century, the term began to be used exclusively for a community of teachers* and *scholars recognized and sanctioned by civil or ecclesiastical authority or by both. Other customary names were '*studium generale*' and '*universitas studii*'.*

The university at its earliest stage of development, appears to have been simply a scholastic gild – a spontaneous combination of teachers, of scholars (both called 'students'!), or of both combined, and formed probably on the analogy of the trades gilds, and the gild of aliens in foreign cities.

At Bologna, for example, the university was a corporation of the students. They hired the teachers and controlled the school's politics: the many foreign students there, felt that they were being cheated by the Italian boardinghouse keepers, and sometimes by their professors as well. Their union kept down the price of food and lodging and made sure that teachers covered the adequate amount of material in their lecture courses.

At Paris, the chief problem was to determine at what point the student was entitled to set himself up as a teacher. So the teachers themselves formed a union to which they admitted only students who had passed a rigorous examination. They also collected fees from the students and directed the policies of the university.

Medieval science, as taught at the universities, was based on authority and developed its ideas through formal logic rather than through observation and experimentation, and it was contaminated by the wishful thinking of philosophers and magicians. Nevertheless, it was an attempt to explain the physical

---

schools of Spain, and imbued with the intellectual independence of the Averroists. Its rising prosperity coincided with the decline of the school of Salerno. Montpellier became distinguished for the practical and empirical spirit of its medicine, as contrasted with the dogmatic and scholastic teaching of Paris and other universities.

62 Founded by **Robert de Sorbon** (1201–1274) in Paris. It started as a modest establishment which accommodated seven priests charged with the duty of teaching theology gratuitously. To this was added a college of preparatory studies. In 1257 a site was given by King Louis IX in the heart of the Latin Quarter. Destined originally for poor students, the Sorbonne soon became a meeting-place for all the students of the University of Paris.

world and find ways of summing up seemingly unrelated phenomena by general laws. Sometimes, meaningful questions were asked about the nature of the universe, and from that questioning our modern science has evolved.

The attitude of the Church toward the universities was ambiguous. Although it favored these organizations, it was suspicious of the new learning, which carried philosophical doctrines that diffused from the Pagan Greeks through the Arab commentators on Aristotle. Since any corporate group had to be recognized by some higher authority, the Church saw obvious advantage in patronizing associations of scholars: it could more easily control the new learning and use the professors as experts to examine the suspect doctrines.

The famous scholars of the 13^{th} *century were university professors, and university graduates filled high offices in the Church and important positions in secular governments. Thus, during the* 13^{th} *century, the universities took over the intellectual leadership of Western Europe.*

Control of the scholars gradually passed to permanent bodies of administrators. During the Renaissance, in the 15^{th} *century, the universities helped direct the revival of interest in Greek and Roman learning. Discussion of a new method of inquiry (the so-called 'scientific method') began in the universities in the late* 13^{th} *and* 14^{th} *centuries, and came to fruition in Western Europe after 1600. The new method was essentially a combination of two elements: careful observation and controlled experimentation on the one hand, and rational interpretation of results by the use of mathematics on the other.*

In the 13^{th} *and* 14^{th} *centuries, a small but increasing number of scholars began to question existing explanations of astronomical problems. Many of these were Franciscans, inspired by their founder's sensitive feeling for nature. Stimulated by the current study of Greco-Arabic science, a group of teachers at Oxford and Paris began to apply mathematical reasoning to problems of physics and astronomy, such as accelerated motion. Their speculations were continued by professors at the University of Padua in the* 15^{th} *and* 16^{th} *centuries. At Padua, a center of medical training for 3 centuries, the proper method of studying nature was vigorously debated in the course of arguments about Aristotle. Medieval universities had kept interest in science alive, and the first faint beginning of the scientific revolution may be seen in Oxford, Paris and Padua.*

Other known universities were established in the following chronological order: ***Prague*** *(1348),* ***Cracow*** *(1364),* ***Vienna*** *(1364),* ***Heidelberg*** *(1385),* ***Leipzig*** *(1409),* ***Basel*** *(1460),* ***Uppsala*** *(1477),* ***Copenhagen*** *(1479),* ***Königsberg*** *(1544),* ***Jena*** *(1558),* ***Leyden*** *(1575),* ***Edinburgh*** *(1582),* ***Utrecht*** *(1634),* ***Harvard*** *(1636),* ***Yale*** *(1701),* ***Göttingen*** *(1737),* ***Princeton*** *(1746),* ***Columbia*** *(1754),* ***Moscow*** *(1755),* ***Berlin*** *(1809).*

The idea of the university was one of the most important medieval contributions to modern civilization. Prior to their establishment, schooling was mainly the privilege of the wealthy (private tutoring by individual teachers) or through instruction of novices by priests.

It must be remembered, however, that institutions of higher learning existed already 1500 *years prior to the first European university, in the form of the Athenian or Alexandrian Academies, and later as the religious schools (Yeshivot) of the Jews in Babylon, North Africa, Spain and France and also at the Muslim Al-Azhar University in* ***Cairo*** *(established 970).*

It is remarkable that the Chinese did not develop similar institutions: they did not have the conviction that people can dominate nature and they were not interested in the scientific method. Consequently, their theories remained divorced from observation and experimentation.

The Friars (ca 1200)

The growing dissatisfaction of town people with the clergy in Southern Europe, the influx of new ideas along the Eastern trade routes, and the nucleation of free thinkers in circles of the new universities, increased the heresy in the Church. By 1207, *the church saw no other way than to suppress this movement by sheer force. The heretic movement then went underground or dispersed to England and Scandinavia, to escape the claws of the Inquisition.*

*In another vein, the church responded in an internal reform movement through the establishment of the Franciscan and Dominican Orders [**Francis of Assisi** (1182–1226,* Italy*) and **Dominic of Caleruega** (1170–1221, France)]. These orders were founded in the first quarter of the* 13^{th} *century, and they played a prominent part in the scientific revolution. So many of their members contributed to the development of science and philosophy that it is impossible to understand the thought of their times and of subsequent centuries without paying considerable attention to them.*

The Franciscan Order was founded in 1210, *and the Dominical Order in* 1215. *While the majority of Christian monks shunned the people and spent their lives in secluded monasteries, the Friars went to the people. They established themselves in growing towns where they could reach the multitudes. They were not attached to monasteries, but simply to their Order, and wandered about as missionaries. They soon realized that it would be impossible to influence the masses without controlling the education of the leaders, and tried to obtain chairs in the universities, notably in Paris. Thus the Franciscans established themselves in Paris in* 1219, *and obtained a chair of theology in the University about* 1232. *The Dominicans played a very important role in the development of medieval universities. (However, the organization of the Inquisition was also essentially the work of Dominicans.) They established themselves in Paris in* 1217 *and obtained the first chairs of theology in* 1229 *and* 1231.

The spiritual attitude of these two orders were almost antagonistic. The Franciscans spoke to the heart, continuing the Platonic *tendencies of early Christianity. They had less intellectual curiosity but more intellectual freedom.*

The Dominicans, on the other hand, spoke to the head, and made it their special task to develop Aristotelian *philosophy. It is not a mere matter of chance that Roger Bacon (1214–1292) was a Grey Friar (Franciscan), and Thomas Aquinas (1225–1274) a Black Friar (Dominican).*

The Dominicans established schools, and the graduates of these schools soon dominated the faculties of theology of European universities. Both Orders met with immediate success. Thousands of men joined their ranks during the 13^{th} *century.*

The creation of these two orders had a decisive influence on the intellectual development of Christendom. It is impossible to explain the vicissitude of medieval philosophy from this time on without paying attention to the complications and the new incentives and rivalries caused by the existence of these two militant organizations.

They took part in the immense educational expansion which was then taking place in Western Europe. To understand properly the educational revolution *of the* 13^{th} *century one must try to imagine the creation of some* 15 *universities in four countries at a time when such opportunities were unknown except in a very few places.*

There is perhaps a touch of irony to the fact that the movements that sprang out of a need to suppress 'heresy', carried with it the seed of the forthcoming scientific revolution through men like ***Roger Bacon*** *(Franciscan friar) and* ***Giordano Bruno*** *(Dominical friar).*

Science Progress Report No. 2

The Inquisition (1231–1834)

Up to a point, Church influence had been for the public good. She preserved a limited peace in times of strike, tried to impose a code of human behavior, and acted as school-mistress. The Church harnessed and nourished intellect, taught and provided administrators, lawyers, physicians, encouraged and preserved architecture. literature, and art. But, although creative work might be encouraged, creative thought, so essential to the development of science, was sternly repressed, suppressed and oppressed. The doctrine of persecution formed an integral part of medieval Christianity. Those whose written and spoken thoughts did not follow the rigid line permitted by the Church stood in danger of persecution as heretics.

Pope Gregory IX created in 1231 *a special court to investigate, punish and eliminate so-called 'heretics'. It was known as the Inquisition*[63]*. Dominican and Franciscan friars served as Inquisitors. The Inquisition operated chiefly in France, Germany, Italy and Spain. It later followed the Spaniards and the Portuguese in their overseas conquests to Central and South America.*

The censure of books was established in 1502 *by Ferdinand and Isabella as a state institution. All books had to pass through the hands of the bishops; in* 1521 *the Inquisition took upon itself the examination of books suspected of Lutheran heresy. In* 1547 *the Suprema produced an Index of prohibited books, drawn up in* 1546 *by the University of Louvain. In* 1558 *the penalty*

[63] The first 'Inquisition' was established by **Augustine** (414 CE) when he promulgated a doctrine to justify the persecution of heretics by church *and* state, working together. He mobilized the church's own vast resources to hound the leaders of the *Donatist* heresy. [A powerful sect which arose in the Christian church of Northern Africa at the beginning of the 4^{th} century, named after **Donatus of Bagoi**, executed in 350 CE.] Donatists led an open revolt against Rome which the imperial legions could not defeat. Donatist peasants and agricultural workers terrorized landlords, tax collectors, and creditors, liberated slaves, destroyed rent rolls and land titles, and unraveled the fabric of Roman rule. The Donatists were crushed by the combination of *Catholic inquisition* and imperial force. This civil war and the ensuing schism in the church, helped the invading Vandals, after their sack of Rome to conquer North Africa (430 CE), and enabled them win over the enserfed population of the empire. The Donatist finally disappeared prior to the Saracen onslaught two centuries later.

of death and confiscation of property was decreed against any bookseller or individual who should keep in his possession condemned books.

After the expulsion of the Jews under Isabella the Catholic (1492) and the Moriscoes (Spanish Moors) under Philip III (1609), the Inquisition attacked especially Catholics descended from infidels, the Marranos and Conversos. As late as 1715, *a secret association was discovered in Madrid, consisting of twenty families, having a rabbi and a synagogue, and was prosecuted with the utmost rigor. A great number of people were sent to the galleys, or burnt, for having returned to their ancestral religion, on the flimsiest evidence.*

It is estimated that 30,000 'heretics', mostly Jews, were burned at the stakes in 2000 auto da fé public executions or tortured to death in the Inquisition chambers during its overlong 600 *year reign, most of them in Portugal and Spain. About* 100,000 *were punished after being imprisoned. Among the burned were* ***Jan Hus*** *(1415) and* ***Giordano Bruno*** *(1600). One of the most brutal and bloodthirsty Inquisitors was the Dominican friar Tomas de Torquemada*[64] *(1420–1498).*

In 1632 ***Galileo Galilei*** *was summoned to appear before the Inquisition, following the publication of his book: "A Dialogue on the Two Principal Systems of the World". After a long trial, which included threats of physical torture, Church officials forced him to publicly renounce his belief in the Copernican theory, and sentenced him to an indefinite prison term. Before he published his Dialogues, he became blind. He lived only five more years, but the Inquisition constantly watched him in his home during that time. The prosecution of free thinkers did not end with Galilei and continued with full vigor throughout the* 18^{th} *century: The naturalist* ***José Calvigo y Faxarcho*** *(1730–1806), the mathematician* ***Benito Bails*** *(1730–1797) and the poet* ***Tomas de Iriarte*** *were prosecuted as "philosophers", under a special papal bull (1738).*

The Inquisition died late and hard: Napoleon, on his entry into Madrid (December 1808), at once suppressed the Inquisition, and on the 12^{th} *of February,* 1813 *it was declared to be incompatible with the constitution, in spite of the protests of Rome. The census of books was abolished earlier in* 1812. *Ferdinand VII restored the Inquisition (July 21, 1814) on his return from exile,*

---

64 He was himself a descendant of Marranos(!) Universally hated, he was in constant dread of being poisoned or assassinated, but always traveled with a bodyguard of 250 men. He viewed with alarm the heresies sweeping Europe and felt that to save the purity of Spanish Catholicism, the threat of incipient heresy posed by worldly Marranos, relapsed Muslims, and cynical Christians would have to be stamped out before it was too late. Torquemada elevated the *auto-da-fé* into a masterpiece of showmanship, deliberately planned to resemble the popular concept of the Last Judgment.

but it was impoverished and almost powerless. In 1816 *the pope abolished torture in all tribunals of the Inquisition. The inquisition was again abolished as a result of the Liberal resolution of* 1820, *but was restored in* 1823 *after the French military intervention under duke d'Angoulême.*

The last auto-da-fé of the Spanish Inquisition took place in Valencia, Spain in 1826. It finally disappeared on the 15^{th} *of July* 1834, *when Queen Christina allied herself with the Liberals. It was not however till the* 8^{th} *of May* 1869 *that the principle of religious liberty was proclaimed in the Iberian peninsula; and even since then it has been limited by the constitution of* 1876, *which forbids the public celebration of dissident religions.*

The Abacus

Early man used the fingers of his two hands to represent numbers. In this way it is comparatively easy to count up to ten. The next major step, taken by the early river-valley civilizations, was to represent numbers by means of pebbles arranged in heaps of ten. This, in turn, led to the development of the abacus[65] *, or counting frame through which arithmetic problems could be solved.*

This device, in its simplest form, consists of a tray covered with dust or sand in which a number of grooves are made, or of a wooden board with grooves cut in it. A number is represented by pebbles (or beads) put in the grooves; as many pebbles are put in the first groove as there are units in the number to be represented, as many in the second groove as there are ten, and so on. Objects are counted by placing, for each object, a pebble in the first groove. As soon as there are ten pebbles in that groove, they are removed, and a single pebble is placed in the second groove, and so on.

[65] Greek: $\alpha\beta\alpha\xi$, a slab.

The abacus is one of the hallmarks of early civilization. Since it was in use in so many widely disparate cultures, it is believed to have been invented independently in several centers. It was to be found throughout the Mediterranean world in the first millennium BCE. ***Herodotos*** *(ca 450 BCE) remarks that the Egyptians reckoned with pebbles, bringing the hand from right to left, while the Greeks proceeded in the opposite direction!*

On the other side of the world, the Spaniards would later find in South America abaci which were in common use in the pre-Columbian civilizations of Mexico and Peru. The Aztec form of abacus consisted of a set of parallel rods stuck into a piece of wood, on to which beads could be threaded. Several different types of abacus were in use in Rome: the instrument is mentioned, for instance, by ***Pliny***, ***Juvenal*** *and* ***Cicero***. *Some Roman abaci were quite elaborate, being provided with a number of additional grooves to facilitate the addition of fractions.*

An early form of abacus using bamboo rods instead of pebbles or beads was used in China at the time of Confucius (it survived in Korea until quite recently). The modern form of Chinese abacus, the su pan, came into general use about the 12^{th} *century. There is some evidence that it was introduced into China from Rome (!). The Chinese abacus was in turn introduced into Japan in the* 15^{th} *or* 16^{th} *century. Today the Japanese abacus, in the hands of a skilled operator, is certainly a most impressive instrument*[66]. *It can be used to add, subtract, multiply, divide, and to calculate square roots and cube roots.*

There can be little doubt that, viewed in the perspective of human history, the humble abacus is the second most significant aid to calculation that has ever been invented. For many centuries it was in sole possession of the field; even today, more people probably compute with the aid of abacus than in any other way – to say nothing of the still larger number who rely on their fingers.

---

[66] After World War II there has been a marked revival of interest in the abacus in Japan, and operational techniques have been greatly simplified and improved. The Japanese Chamber of Commerce and Industry sponsored an *Abacus Research Institute* and a *Central Committee of Abacus Operators*. This latter body lays down methods of training, formulates standards of performance and awards certificates of proficiency at various levels.

On November 12, 1946, a contest was staged between a Japanese abacus operator and an American operator of an electric desk calculating machine. The contest covered five types of calculation involving the four basic arithmetic operations, each being judged on speed and accuracy. The abacus' victory was complete, its operator winning by 4:1.

1180 CE **Alexander Neckam** (1157–1217, England). Man of science and encyclopedist. In his books *De Naturis rerum* and *De utensilibus* Neckam has preserved to us the earliest *European* notices of the nautical use of the *magnetic needle*. It was probably in Paris, the chief intellectual center of his time, that Neckam heard how a ship can be guided in murky weather or on starless nights by a needle (previously placed upon a magnet) that would revolve on a pivot until it settled into a northern orientation.

Neckam, the foster-brother of King Richard I, was born in London. He was educated at St. Albans Abbey school, and began to teach as schoolmaster of Dunstable. Later he resided several years in Paris, where by 1180 he had become a distinguished lecturer of the university. By 1186 he was back in England. Having become an Augustinian canon, he was appointed abbot of Cirencester in 1213.

The Compass (ca 1080–1269)

The early history of the compass is very obscure. It would seem that Chinese have known the fundamental property of a magnetic needle for a considerable time, but have applied it chiefly for occult and pseudo-scientific purposes. The first clear mention of the magnetic needle in any literature occurred in ca 1070 *by* ***Shen Kua*** *(1030–1093), a Chinese author, mathematician, astronomer, and instrument maker*[67]*. The earliest Chinese mention of the use of a magnetic needle for navigation refers to the period* 1086–1099*, where it was used by Muslim sailors between Canton and Sumatra. Thus although the Chinese were first to perceive the directional property of the magnetic needle, they failed to apply it to any rational purpose.*

It is not surprising that the origin of the discovery cannot be dated, if one considers that the first pilots who had the wit to make use of the needle

[67] His books also contain the earliest Chinese example of summation of a progression, and the earliest description of printing with movable type. We know, however, that as early as 1037 a 'south-pointing needle' was submitted to the Sung emperor Jen Tsung.

to direct their course, had no reason to publish their discovery, and on the contrary had every inducement to keep and transmit it as a trade secret. Since maritime trade between the Far East on the one hand, and India, Persia, Arabia, and Africa on the other was a Muslim monopoly, we may assume that this great discovery was made probably around 1080 *CE. Considering its origin, it is curious that the earliest reference to it outside of China, are found not in Arabic or Persian writings, but in French and Latin ones.* **Neckam** *(1180) does not speak of the compass as of a novelty, and* **James of Vitry** *(1219) describes it as having come from India. The earliest Muslim references are in* 1228*.*

It would seem that the Muslims attached more importance to the southern *end of the needle, owing to the fact for Muslims in Syria and Asia Minor, the southern end pointed roughly toward Mecca.*

Italian sailors were among the first to use the compass, and such use necessarily led to gradual improvements. The first technical description of a compass was given by **Peter the Stranger** *in 1269.*

The Triple Point

The web of Renaissance was extremely complex, because there were incessant conflicts in many directions.Three great waves of creative wisdom came from the Orient: The first, and the most fundamental of all, came from Egypt and Mesopotamia *(3100–1650* BCE*); the second, of incalculable pregnancy, came from* Israel *(800–300* BCE*), though it influenced science only in an indirect way; the third, came from* Arabia *and from* Persia *(750–1250 CE).*

It took Islam only 90 *years (622–712 CE) to bring under its rule a large belt of the world, all the way from Central Asia to the Far West [Damascus (635); Jerusalem (637); Egypt (641); Persia (642); Spain (712)]. A new Muslim civilization was formed from the fusion of Arabic and Persian cultures. Under* *the guidance of a series of Abbasid caliphs who had a passion for knowledge – the new civilization developed with incredible speed and efficacy: From the Hebrews they took, with very few modifications, Semitic monotheism and morality; from the Hindus and Persians they learned arithmetic, algebra, trigonometry, iatrochemistry; from the Greeks logic, geometry, astronomy and medicine. With the aid of the Christian Syrians they translated the whole Greek scientific heritage into Arabic.*

The cultural importance of Islam lies in the fact that it finally brought together the two great intellectual streams which had flowed independently in ancient times. Previous attempts had failed; Jews *and* Greeks *had mixed in Alexandria but, in spite that Jews learned the language of the Greeks and that Philo (fl. 40 CE) had made a deep study of both traditions, there has been no real fusion. The* Christians *had not succeeded any better, because of their excessive devotion to the new Gospel, which reduced everything else to futility in their eyes. Now, for the first time, Semitic religion and Greek science actually combined in the minds of many people all over the world.*

The contacts between Muslims and non-Muslims was generally friendly for the Muslims who treated their subjects with tolerant condescension. Under their patronage, many important works were published in Arabic by non-Muslims: Sabians, Christians and Jews. Down to the 12^{th} *century, Arabic was the philosophical and scientific language of the Jews [e.g., the earliest Hebrew grammars were composed in Arabic;* **Maimonides** *wrote his* Guide to the Parplexed *in Arabic].*

However, the major part of the activity of Arabic-writing scholars consisted of the translation of Greek works and their assimilation; the Arabic-writing scientists elaborated algebra *and* trigonometry *on Greco-Hindu foundations; they collected abundant* astronomical observations *and their criticism of the Ptolemaic system helped to prepare the astronomical reformation of the* 16^{th} *century; they enriched enormously our* medical experience*; they were the distant originators of modern* chemistry*; they improved the knowledge of* optics*, and* meteorology*; their geographical investigations extended from one end of the world to the other.*

During 1000–1050 *there was a splendid mathematical school in Cairo, made famous by the astronomer,* **Ibn Yunus** *and the physicist* **Ibn al-Haitham***;* **al-Karkhi** *was working in Baghdad,* **Ibn Sina** *in Persia,* **al-Biruni** *in Afghanistan. These mathematicians and others, were not afraid to tackle the most difficult problems of Greek geometry; they solved cubic equations by the intersection of conics, they investigated the regular heptagon* ($n = 7$) *and enneagon* ($n = 9$)*, developed spherical trigonometry, Diophantine analysis.*

Nothing of this sort existed in the West at that time: some little treatises *on the calendar, on the cite of the abacus, on Roman duodecimal fractions and geometry on the pre-Pythagorean level – a truly pitiful state.*

We may say then, that from ca 750 *CE to ca* 1100 *CE, the Arabic-speaking people (including Jews and some Christians) were marching at the head of mankind with Arabic being the international language of science, and almost the only key to the new expanding culture. However, Oriental supremacy ended about* 1100 *CE; the power and knowledge of the Latin world was growing faster and faster; whereas the main task of the Arabic scientists was already completed, and after that time the relative importance of Muslim culture declined steadily.*

By the middle of the 13^{th} *century Islam was already on the downward path, while Latin Christendom had finally realized the richness of the Greco-Arabic knowledge and made gigantic efforts to be allowed to share it: Consequently, Christians and Jews were feverishly pouring out the Greco-Arabic learning from the Arabic vessels into the Latin and Hebrew ones. But the Christians were far ahead of the Jews in this new stage of transmission. By the end of the* 12^{th} *century, the main body of Greco-Arabic knowledge was already available to Latin readers. By the end of the* 13^{th} *century, there was little of real importance in the Arab scientific literature which they were not aware of.*

At first the Eastern Jews and those of Spain were much better off than the Christians, for the whole of Arabic literature was open to them without effort. But in the 12^{th} *century the scientific life of Judaism began to move from Spain across the Pyrenees, and in the following century it began to decline in its former haunts. By the middle of the* 13^{th} *century a great many Jews had already been established so long in France, Germany, and England, that Arabic had become a foreign language to them. Up to this period the Jews had been generally ahead of Christians, and far ahead; now for the first time the situation was reversed. Indeed, the Christians had already transferred most of the Arabic knowledge into Latin; the translations from Arabic into Hebrew were naturally far less abundant, and hence the non-Arabic-speaking Jews of Western Europe were in a position of political inferiority (the crusades had caused many anti-Semitic persecutions and the Jews of Christendom were everywhere on the defensive).*

The gravity of the change is well illustrated by the appearance in the 14^{th} *and following centuries of an increasing number of translations (e.g., of medical works) from Latin into Hebrew. Thus the stream of translations which had been running from East to West was again reversed in the opposite direction. Note that a curious cycle had been completed, for the source of these writings was Greek; their Arabic elaborations had been translated into Latin and had inspired new Latin treatises; these treatises were now translated into Hebrew. From East to East via the West!*

But other cycles were even more curious. In the 14^{th} century and later, Arabic, Persian, and Latin writings which were ultimately of Greek origin were re-translated into Greek. For example, the most popular logical textbook of the Middle Ages, the Summulae logicales *of Peter of Spain (Pope John XXI), was not only translated into Hebrew, but also into the very language from which its main sustenance had been indirectly derived. From Greek to Greek via Arabic and Latin!*

During the 12^{th} century the three civilizations which exerted the deepest influence upon human thought and which had the largest share in the molding of the future, the Jewish, the Christian, and the Muslim, were remarkably well balanced; but that state of equilibrium could not last very long, because it was due to the fact that the Muslims were going down while the two others were going up. By the end of the 12^{th} century it was already clear (that is, it would have been clear to any outside observer, as it is to ourselves) that the Muslims would soon be out of the race, and that the competition would be restricted to the Christians and the Jews.

Now the latter were hopelessly jeopardized by their political servitude and by the jealous intolerance (to put it mildly!) of their rivals. Moreover, for the reason explained above, the main sources of knowledge were now less available to them than to their persecutors. This went much deeper than it seems, for whenever an abundant treasure of knowledge becomes suddenly available to a group of people, it is not only the knowledge itself that matters, but the stimulation following in its wake. The Jews were steadily driven into the background, and in proportion as they were more isolated, they tended to increase their isolation by devoting their attention more exclusively to their own Talmudic studies.

Towards the end of the 13^{th} century, the Christians enjoyed the political and intellectual hegemony. The center of gravity of the learned world was in the West and it has remained there until our own days (West = Europe + the United States).

Of course Muslim and Jewish efforts went on and both faiths produced many great men in the following centuries, yet the Western supremacy continued to wax until a time was reached, in the 16^{th} century, when the expanding civilization was so deeply Westernized that the people – even those of the Orient – began to forget its oriental origins, and when the very conception of Muslim and Jewish science almost disappeared.

The final result of science are, of course, independent of the people who discovered them. After the 16^{th} century, when science was finally disentangled from theology, the distinction between Jewish, Christian, and Muslim science ceased to be justified, but it keeps its historical value. In spite of his deep Jewishness and of his abundant use of Jewish sources, we do not count Spinoza *any more as a Jewish philosopher in the same sense that we count Maimonides or Levi ben Gershon; he is one of the founders of modern philosophy, one of the noblest representatives of the human mind, not Eastern not Western, but the two unified.*

1178, June 25 Apollo asteroid (2 km in diameter) of the *Taurid stream* impacted the moon, creating the *Giordano Bruno Crater*.

1195–1215 CE **Yehudah ben Shmuel Ben Kalonymus 'He-Hasid'** ('The Pious'; ca 1150–1217, Germany). Philosopher and moralist. A central figure of the school of Jewish *Hassidism* in Western Europe. From his center at Regensburg he led the Hassidic movement, which heralded the Hassidic branch of Judaism in the 18^{th} century in Central and Eastern Europe.

Teaching the religious value of self-restraint, Yehudah is the author (ca 1200 CE) of *Sefer Hassidim* (Book of the Devout) and *Sefer ha-Kavod* (Book of Glory). These books achieved enormous popularity among plain folk and its vogue persisted for 800 years, down to modern times! Throughout the ages, his numerous disciples strove diligently and ardently to hasten the redemption of Israel, first through Hassidism and eventually via Zionism.

Yehudah denied all possibility of human understanding of God; Man must fulfill his religious duties, as they are prescribed in the Bible, without reasonable knowledge of the Almighty, but, by purification, obedience to ceremonial life and ascetics, he may obtain union with God that is beyond reasoning.

He was born in Spier, Germany and lived most of his life in Regensburg. It is believed that Jewish mysticism diffused from Babylonia to Italy and from there by the Kalonymus family to Germany.

The Kalonymus family began in Italy, where in the 8^{th} and 9^{th} centuries, they were a primary force (along with the **Anav** family) in establishing an academy in Rome. Most of the family was induced by Emperor Charles the Bald to move to Mainz, where they established a school of rabbinic learning.

Many of the family were wiped out in the Rhineland Massacres during the First Crusade. Other family members became major figures in the creation of the Hassidic Ashkenaz movement in the 13^{th} century, among them **Shmuel he-Hassid**, his son **Yehudah he-Hassid** and his son **Eleazar of Worms** (1160–1238).

ca 1199–1202 CE Severe drought in Africa caused several year of low Nile. More than 100,000 perished.

ca 1200 CE Widespread fires on the South Island of New Zealand, created by a comet impact.

1200–1235 CE **David Kimhi**[68] (1160–1235, France). Linguist, grammarian, lexicographer, philosopher and biblical exegist. The most accomplished of a family of Hebrew linguists and exegets in Narbonne, Provence, who were among the founders of Hebrew scientific philology and grammar.

David Kimhi summarized the conclusions arrived by the earlier Spanish grammarians and presented a scientific analysis of the Hebrew language which did much for its study later both by Jews and Christians. He also wrote a commentary on the greater part of the Bible which is considered next in importance to those of Rashi and Ibn Ezra.

His father, **Joseph Kimhi** (1105–1170), a native of southern Spain, emigrated to Narbonne, Provence. [The Provence was the bridge physically and intellectually, between Spain and Central Europe. Many of the important literary products of the Jews of Spain were worked over by those of the Provence and they found their way into the thoughts of Jews of Northern and Central Europe.] Introduced a new grammatical classification of the *stems of verbs*, and translated Arabic treatises into Hebrew.

Moshe Kimhi (ca 1130–1190), was first to introduce the now usual sequence in the enumeration of stem-forms of verb conjugation.

David was the pupil and brother of Moshe, and eclipsed the fame of both his brother and father.

1200–1250 CE *Mongol* outbreak into China and Europe correlated to drought or moist conditions in Mongolia.

1202–1247 CE *Mathematical revival*. This period witnessed the activities of five outstanding mathematicians: **Fibonacci**, **Nemorarius**, **al-Hasan al-Marrakushi**, **Ch'in Chiu-Shao**, and **Li Yeh**. These men represent four different countries: Italy, Germany, al-Magrib, and China. The main accomplishments of this period were:

- The publication of *Liber abaci* (1202) marked the beginning of European mathematics.
- The diffusion of Hindu-Arabic methods into Europe, by Fibonacci and by many minor mathematicians.

---

[68] known as the 'RADAK', acronym of *RA*bbi *DA*vid *K*imhi.

- **Fibonacci**'s interpretation of a negative solution as a debt (1225).
- His problems of Diophantine analysis (1225).
- General proof of the fundamental theorem of stereographic projection, by Nemorarius.
- Contributions to the theory of numbers by **Fibonacci** and **Nemorarius**.
- Publication of astronomical tables in Marseilles and London (ca 1231–1232). The needs, which brought these tables into being were astrological rather than astronomical.
- The 'Jami' of **al-Hasan al-Marrakushi** (1229), which was the most elaborate trigonometrical treatise of the Western caliphate. It was also the best medieval treatise on practical astronomy, on gnomonics and the best explanation of graphical methods.
- Introduction of astronomy into the Latin world by **Michael Scot** (1217).
- Translation of the Almagest into Hebrew by **Yaacov Anatoli** (ca 1231).
- Development of the *t'ien yuan shu* by **Ch'in Chiu-Shao** and **Li Yeh** (1247–1248).
- Numerical solution of equations of any degree by **Ch'in Chiu-Shao** (1247).

1204–1248 CE *Political events*:

- 1204. Constantinople taken and sacked by the Crusaders. It was almost a death blow to Greek culture.
- 1214. Battle of Bouvines (near Lille), won by Philip Augustus over the emperor Otto IV, supported by English and Flemish contingents.
- 1238–1241. Tatar invasion of Russia, Hungary, Bohemia, and Poland. Kiev and Cracow destroyed, Pesth besieged. The Mongol tide was stopped by the battle of Wahlstatt (near Legnitz) in 1241.
- 1236–1248. The Moors were slowly driven out of Spain. Cordova reconquered by the Christians in 1236 and Seville in 1248. By the middle of the century the Moors were restricted to the little Kingdom of Granada.

1202–1220 CE **Leonardo of Pisa (Pisano) or Fibonacci** (1170–1250, Italy). The most skilled mathematician of the Middle Ages who played an important role in reviving ancient mathematics and made significant contributions of his own. His book, *Liber abaci* (1202), played an influential role in spreading knowledge and use of the Hindu-Arabic numerical system into Europe.

Liber abaci was the first complete and systematic explanation of the Hindu numerals by a Christian writer; and also, the first complete exposition of Hindu and Muslim arithmetic. Leonardo, however, gave more rigorous demonstrations than the Muslims. (It is apparent that he had a good knowledge not only of Muslim, but also of Greek mathematics, largely derived from Latin translations of Euclid, Archimedes, Heron and Diophantos.)

Liber abaci contains sections on Roman and Indian numerals and on finger counting. Later chapters are devoted first to commercial calculations and then to puzzles and recreational mathematics – including the famous 'rabbit problem' which lead to the Fibonacci sequence. He deals with approximating square roots, cube roots and problems on volumes, in which he takes π to be $3\frac{1}{7}$.

In his later book *De practica geometriae* (1220) he obtained the value 3.141818 using Archimedes' 96-sided polygonal representation of the circle. This book also contains various geometrical and arithmetical problems, notably an extension of the Pythagorean proposition to solid geometry and the rule to calculate the volume of a pyramid frustum.

Fibonacci used algebra to solve geometrical problems, which was a novelty in Christendom. In his book *Flos*, Fibonacci considered, among other things, the equation $x^3 + 2x^2 + 10x = 20$. Showing that there is no rational solution, he gave an approximate solution, using the sexagesimal number system. In *Liber Quadratorum* (1225), a work on indeterminate analysis, he emerged as the outstanding number theorist between Diophantos and Fermat. Thus, this book contain a solution in integers of $x^2+y^2 = z^2$, and a proof of the theorem that the difference of two biquadrates is not a square. His works were quite beyond the abilities of contemporary scholars, and he certainly appears as the lone mathematical beacon of his time in Europe.

The transition from the Roman number scheme was surprisingly slow, because computation with the abacus was quite common and in this case the advantages of the new scheme are not nearly so apparent as in calculations with pen and paper today. For three centuries there was a keen competition between '*abacists*' and '*algorists*' and the latter won only close to 1500.

Thus came to an end the saga of the round zero, which started its slow wheeling from India (876 BCE) through Persia and Arabia (825).

It is remarkable that the extremely tedious arithmetic of Roman numerals[69], lacking as it does the zero and positional notation, did not induce the Europeans to invent the zero earlier.

Fibonacci[70] was born in Pisa. His father was called 'Bonaccio' (a nickname with the ironical meaning of "a good stupid fellow"). To Leonardo himself, another nickname, Bigollone (dunce, blockhead), seems to have been given. The father was a secretary in one of the numerous factories erected on the southern and eastern coasts of the Mediterranean by the warlike and enterprizing merchants of Pisa. Leonardo was educated at Bugia on the Barbary coast and taught by a Muslim master; later he traveled in Sicily, Syria and Egypt, where he made the acquaintance of the Hindu-Arabic methods. The influence of Greek, Arabian and Indian mathematics may be clearly discerned in his methods. He returned to Italy in 1202 and published *Liber abaci*, which procured him access to the learned and refined court of the emperor Frederick II.

The Fibonacci Sequence

One of the problems appearing in Liber abaci *is as follows: Each month, the female of any pair of mature rabbits gives birth to a pair of rabbits (of different sexes). Two months later, any female of a new pair gives birth to a pair of rabbits, and continues to do so each successive month. Find the number of rabbits at the end of the year if there was one pair of rabbits in the beginning of the year. This problem leads to a sequence, wherein the terms are the numbers of pairs of rabbits present in successive months* $1, 1, 2, 3, 5, \ldots, x, y, x + y, \ldots$. *This sequence has become known as the Fibonacci sequence and it occurs in an astonishing number*[71] *of unexpected situations. It has applications to art,*

69 The reader who questions this characterization should try multiplying 57,498 by 837 in Roman numerals!

70 The nickname **Fibonacci** was given by the 18th century French mathematician **Guillaume Libri**.

71 One of the distinguishing characteristics of ordinary honeybees is a system of controlled reproduction: It seems that early in her career a queen bee goes on a spree, collecting sperm from eager males. The queen produces many eggs, and

to the propagation of bees, to phyllotaxis (arrangement of leaves), florets of composite flowers, population genetics, ray optics and various other topics in mathematics and physics[72].

Biologists have tried to explain the peculiar prevalence of Fibonacci num-

---

it is the general rule that unfertilized eggs hatch into males and fertilized eggs into females. Thus male honeybees do not have fathers. The queen bee is able to store the collected sperm for months and even years and, upon information supplied by her attendants, she can regulate the gender of the offsprings to meet the needs of the hive. Female bees are undoubtedly the superior sex; they do everything; the male's only function is in his role in the production of the prized female.

Let us trace the ancestry honeybees of either gender, on the assumption that each male contributes a single sperm during his lifetime, and each female produces one unfertilized egg per generation (we ignore the rate of female mortality). Denote by a_n the total number of males *and* females in the n^{th} generation. Since any female has both a father and a mother, the number of *females* in a generation is simply the number of bees in the previous generation. On the other hand, since only females have fathers, the number of *males* in a generation is just the number of females present in the previous generations. Hence $a_n = a_{n-1} + a_{n-2}$ for $n > 2$.

While on the subject of bees, there are $a_{n+2} = a_{n+1} + a_n$ paths by which the bee can crawl over hexagonal cells in the hive [one path to cell 0, two paths to cell 1, three to cell 2, five to cell 3, and so on], yielding again the Fibonacci sequence.

72 One encounters the Fibonacci sequence, for example, in ray-optics and information theory:

- A light-ray impinges upon a stack of m planar glass plates welded together, such that at each interface (except the upper boundary) the ray may either be reflected or transmitted. It is shown that for $m = 2$, the number F_n of paths by which a ray can be reflected n times in the system, is governed by the difference equation $F_{n+1} = F_n + F_{n-1}$, yielding the sequence of reflections 1, 2, 3, 5, 8, ... for $n = 0, 1, 2, \dots$.
- Imagine a signaling system that has only two signals s_1 and s_2 (e.g., the dots and dashes in telegraphy or "low" and "high" voltage [light-intensity] levels in a binary digital electronic [optical] telecommunication system). Messages are transmitted over some channel by first coding them into sequences of these two signals. Suppose s_1 requires exactly t_1 units of time and s_2 exactly t_2 units of time to be transmitted. Let N_t denote the *number of possible message sequences* of duration t. A message of duration t must end in either s_1 or s_2, but there are N_{t-t_1} possible messages to which a last s_1 may be appended and N_{t-t_2} possible messages to which a last s_2 may be appended. Therefore $N_t = N_{t-t_1} + N_{t-t_2}$. We consider the special case $t_1 = 1$, $t_2 = 2$ (one signal takes twice as long to be transmitted over the channel as the other). Then $N_t = N_{t-1} + N_{t-2}$.

bers in phyllotaxis. Symmetry may play a major role, because symmetry maintains a mechanical equilibrium of a stem, gives the leaves the best exposure to light, and supports the regular flow of nutrients. However, science is still far from a satisfactory explanation.

The Fibonacci numbers appear as the coefficients of the power series expansion of

$$(1-x-x^2)^{-1} = a_0 + a_1 x + a_2 x^2 + \cdots,$$

$$a_0 = 1, \quad a_1 = 1, \quad a_2 = 2, \quad a_3 = 3, \ldots.$$

The n^{th} term of the sequence a_n, obeys the difference equation $a_n = a_{n-1} + a_{n-2}$ with $a_0 = 1, a_1 = 1$; or $a_{n+1}a_{n-1} = a_n^2 + (-1)^{n+1}$, $n \geq 2$. Its solution is

$$a_n = \frac{1}{\sqrt{5}}\left[\left(\frac{1+\sqrt{5}}{2}\right)^n - \left(\frac{1-\sqrt{5}}{2}\right)^n\right]$$

*[**De Moivre**, 1730; **Binet**[73], 1843.] Both numerators and denominators of the convergents of the continued fraction representation of the Golden[74] Ratio $\frac{1+\sqrt{5}}{2}$, are formed from the sequence of Fibonacci numbers: $\frac{1}{1}, \frac{2}{1}, \frac{3}{2}, \frac{5}{3}, \frac{8}{5}, \ldots$. It would seem that nature strives to approximate the famous golden ratio.*

---

73 **Euler** and **Daniel Bernoulli** were also in possession of this result a century earlier. However, Binet did make the discovery independently, and he has so little claim to mathematical fame that it won't hurt these giants to let Binet take the credit for this crumb.

74 Was the Fibonacci sequence known to the Greeks? The Greek theater at Epidaurus (ca 300 BCE) was designed by an architect called **Polyelitos** (not the sculptor). The main objective there was to ensure perfect acoustics; and although most of the stage buildings have long since disappeared, the auditorium is so well preserved that the acoustics remain extremely good. From the point of view of numerology is it only a coincidence that the numbers of rows and of seats below and above the *diazoma* (azimuthal passage across the auditorium) are respectively 34 and 21? These are two successive numbers in the Fibonacci sequence. Their ratio $\frac{34}{21} = 1.6190\ldots$ approximates the true value of the Golden Ratio: $\frac{1+\sqrt{5}}{2} = 1.6180\ldots$.

*The Fibonacci sequence also appears in different parts of mathematics. For instance, in the Euclidean algorithm for finding the greatest common divisor (g.c.d.) of two given positive integers, a certain number of successive divisions is required. In 1844, **Gabriel Lamé** proved, by using some properties of the Fibonacci sequence, that the number of divisions required to find the g.c.d. of two positive integers is never greater than 5 times the number of (decimal) digits in the smaller number.*

*The Fibonacci sequence has also played a prominent role in determining the primeness or compositeness of some "astronomically" large numbers. Indeed, **Edouard Lucas** (1842–1894, France) employed certain divisibility properties of the Fibonacci numbers to establish a test for the primality of any given Mersenne number. The literature on the ubiquitous Fibonacci sequence and its many properties is incredibly large and continues to grow. The interesting relations seem, like the geometry of the triangle, to be inexhaustible. In 1963, a group of Fibonacci-sequence enthusiasts founded the Fibonacci Association and began publication of a journal, The Fibonacci Quarterly.*

Man's yearning for a unifying principle aside, 'universal truths' are often so extraordinary that they entice the faithful to push into realms where the law does not belong: Fibonacci sequences are not omnipresent; for all the fruit blossoms that have pentagonal symmetry, there are tulips, lilies and hyacinths that do not. Nature does work in many *strange ways, not just one.*

1206–1260 CE *The Mongols*. Under the leadership of **Jenghis Khan** (1167–1227), and his successor **Kublai Khan** (1216–1294), the united Mongol and Kirghiz tribes carved out one of the biggest empires in history, stretching east-west from Japan to the Caspian Sea, and north-south from Siberia to Tibet.

In the Middle Ages the Mongols were a group of nomadic tribes living in Central Asia. They were herdsmen and fierce warriors. Temujin, later called Jenghis Khan, organized the wandering inhabitants of the steppe along rigid military lines.

Throughout the years 1206–1218, the Mongols swept over China, Azerbaijan, Georgia, and Northern Persia[75]. This conquest brought the Mongolian power to the frontiers of the Muslim state of Khorezum, which Jenghis Khan

[75] It was suggested that the outbreak of the Mongols was stimulated by drought or moist conditions in Mongolia at that time.

attacked and destroyed. In 1220 and 1221 he took and totally destroyed Bukhara, Samarkand, and Gurgan, then the centers of Muslim-Persian culture. In 1223 the Mongols defeated a strong force of Russians and Cumans.

After Jenghis' death, Mongol armies overrun and conquered southern and central Russia and then invaded Poland and Hungary (1237–1240).

In 1241 the Mongols defeated the Poles and Germans in the battle of Liegnitz in Silesia, while another army defeated the Hungarians. But because of political complications arising from the death of the Great Khan, the Mongols withdrew from Western Europe. Subsequently, they settled on the lower Volga, where a Tatar state was organized under the name Golden Horde.

Kublai Khan completed the conquest of China and founded the Yuan dynasty there. During 1245–1253, the Mongols continued to ravage Mesopotamia and Armenia. In 1258, Hulagu captured and sacked Baghdad and executed the caliph. He then invaded Syria and took Aleppo. Finally, in 1260, the Mamluks of Egypt secured a victory over the Mongols at Ain Jalut. This checked the Mongol advance and saved Egypt, the last refuge of Muslim culture.

Kublei Kahn was too great an administrator not to realize the need for mathematicians and astronomers, and it is typical of the cultural mixture organized by him that his scientific assistants were drawn from many nations. In 1263 he appointed **Isa the Mongol** (in Chinese, Ai-hsieh) the head of the astronomical board. In 1267 a new calendar was devised for Kublai Kahn by the Persian **Kamal al-Din al-Farisi**, who also introduced new astronomical instruments.

1209–1229 CE The *Albigensian Crusade* mounted by Pope Innocent III[76] against the entire population of the Albigens[77]. The Albigense, in the south of France, was then the most populous, the most technically, socially, and economically advanced part of Europe. Its population was largely *Gnostics*[78] and *Arian Christians*, and a sanctuary for Jews who were persecuted almost

---

76 He also reinstated a prohibition against the owning or reading of Bibles by anyone other than the clergy, under penalty of death.

77 They took their name from the town of *Albi* in Languedoc in Southern France. There and in Northern Italy the sect acquired immense popularity. The movement was condemned at the Council of Toulouse (1119) and by the Third and Fourth *Lateran Councils* (1179, 1215).

78 *Gnosticism* usually refers to an esoteric cult of divine knowledge (a synthesis of Christianity, Judaism, Greek philosophy, Hinduism, Buddhism, and the mystery cults of the Mediterranean), which flourished during the 2^{nd} and 3^{rd} centuries CE, and had influence on early Christianity.

everywhere else in Europe. All of these groups had a high percentage of literacy and read the Bible, which was prohibited by the Vatican.

The slaughter of the Albigensians sealed the fate of the brilliant Provencal culture. In the reign of Louis IX, the County of Toulouse passed under the Capetian administration and the royal domain was extended to the Mediterranean.

Hunted down by the Inquisition and quickly abandoned by the nobles of the district, the Albigensians became more and more scattered, hiding in forests and mountains, and only meeting surreptitiously. The sect was finally exhausted and could find no more adepts in a district which, by fair means or foul, had arrived at a state of peace and political and religious unity.

1215 CE *Magna Carta*. English barons force King John to agree to a statement of their rights.

1218–1288 CE Period of great storminess in the North Sea, causing catastrophic floods on the coasts of Holland: 1228 (100,000 victims); 1282 (200,000 people drowned under 2 meters of water); Dec. 14, 1287 (50,000 victims).

The coasts of the Netherlands are exposed to the strong tides of the North Sea and have been *slowly sinking*: Since Roman times they have sunk 2 meters! At high tide, the sea is several meters above the land. This sinking, in turn, is caused by subsidence of the land under the weight of huge quantities of *sediments* transported by the *rivers* to the North Sea, and is accentuated by the building of gigantic *dikes*.

ca 1220–1240 CE **Ibn al-Baitar** (ca 1197–1248, Spain and Syria). Botanist, pharmacist, herbalist and physician. Left Spain to travel in North Africa (1219), in Bulgaria (1220), Tunis, Tripoli (1221–1223), Egypt (1224), Damascus (1237), Cairo (1238). Considered greatest botanist and pharmacologist in Islam. Traveled extensively in Greece, Egypt and Asia Minor in search of medical herbs, which he later described in his comprehensive treatise. Contemporary of **Grosseteste** and **Anatoli**, which together represent the three main streams of culture in the first half of the 13^{th} century.

Al-Baitar was born in Malaga, Spain and died in Damascus.

ca 1220–1230 CE **Jordanus Nemorarius** (ca 1185–1237, Germany). Mathematician. The founder of the medieval Christian school of mechanics and first to correctly state the law of the inclined plane. Second only to Fibonacci as a medieval mathematician.

The first one widely to use letters to represent general numbers, although his practice had little influence on subsequent writers. He wrote several books on arithmetic, algebra, geometry, and astronomy. His book *De triangulis* is a geometric work in four books containing topics such as the centroid of a triangle, curved surfaces and trisection of an angle. In his *Tractatus de numeris datis* he solved problems in which a given number is to be divided in some stated fashion.

Nemorarius was a contemporary of Fibonacci. The Arabic *sifr* was introduced by him into Germany as the word *cifra*, from which the word *cipher* was later derived[79].

In his arithmetical treatises he showed that $n(n+1)$ is neither a square nor a cube $(n \neq 0, -1)$. His book on algebra contains problems leading to quadratic equations, using letters to replace numbers. Finally, his geometrical treatises deal with the determination of the center of gravity, and contain the first general demonstration of the fundamental procedure of *stereographic projection*. Here, he projected a globe on a plane tangent to the North Pole, and showed how circles are projected into circles (going beyond Ptolemy who had proven it only in special cases).

Nemorarius influenced the rebirth of *mechanics* and his writings include the germs of concepts like *impetus*, *statical moment*, *principle of virtual displacements*, *angular velocity*, *mechanical advantage of a lever*, concepts which culminated hundreds of years later in the discoveries of Galileo, Newton, and J. Bernoulli (1717).

Little is known for certain about his life, and even that is controversial. Most historians believe, however, that Nemorarius was born in Westphalia, joined the Dominican order in Paris (1220) and died at sea on the homeward journey from the Holy Land.

1220–1235 CE **Robert Grosseteste** (1168–1253, England). Ecclesiastical statesman, bishop and one of the foremost mathematician and physicist of his age. In these fields of thought he anticipated some of the most striking ideas to which Roger Bacon subsequently gave wider currency. Thus, he understood, far ahead of his time the principles and methods of empirical science. In 1220, influenced by the writings of Augustine and the scientific method of Islam, he presented a concept of an infinite isotropic Euclidean universe. In *De luce seu de inchoatione* and *De motu corporali et luce* he suggested that light was the first form of matter and propagated isotropically in all directions according to mathematical laws.

In *De generatione sonorum* he asserted that sound was a vibratory motion, propagating through the air from the source to the receiving ear. In his

---

79 The word *zero* probably comes from the Latinized form of *zephirum* of the Arabic *sifr*, which in turn is a translation of the Hindu *sunya*, meaning “void” or “empty”. On the other hand, the Arabic *sifr* could have originated from the Hebrew verb *safor* meaning “to count”.

commentaries on Aristotle's *Physics* he presented views on proper scientific methodology, encouraging the search for general principles, the testing of hypotheses against observations and the use of mathematics.

Grosseteste was greatly influenced by the Latin translation of Alhazen's writings on optics, and in his own work on optics he suggested that *rainbows* are caused by the refraction of sunlight inside clouds. He made Latin translations of many Greek and Arabic scientific writings.

He was born at Stradbrook in Suffolk to humble parents and received his education at Oxford (1199–1209) and Paris (ca 1210), where he became proficient in law, medicine, theology and the natural sciences. He settled in Oxford as a teacher and was pre-eminent among his contemporaries for his knowledge in the natural sciences. He was chancellor of Oxford University from 1215 to 1221. In 1235, after a severe illness, he relinquished his teaching and research career and became the bishop of Lincoln (for this he is also known as **Robert of Lincoln**). In this capacity he was deeply involved in the struggle to maintain the independence of the English clergy against the alliance of King Henry III and pope Innocent IV.

Robert Grosseteste was born at the decisive moment when Greek and Arabic science became accessible in Latin versions. Due to his unusual interest in the study of languages and in the sources of knowledge, he became interested in science and the scientific method; and he paid particular attention to optics, which he regarded as the key to an understanding of the physical world. He was conscious of the dual approach to knowledge by means of induction and deduction. This approach to science was not far removed from that of Aristotle, but Robert gave it a clarity and sharpness that allowed him and his 14^{th} century successors to make the first moves towards the creation of modern experimental science.

It is certain that the Bishop of Lincoln placed an emphasis upon experimentation which has been regarded as characteristic only of later periods. Indeed, **Roger Bacon**, his most famous pupil, said of him that he neglected the books of Aristotle for his own experiments, and with the aid of other authors and scientists, treated *independently* scientific questions (e.g., the study of the *rainbow*) which had occupied Aristotle.

1220–1250 CE **Vincent of Beauvais** or VINCENTIUS BELLOVACENSIS (ca 1190–1264, France). Dominican friar and encyclopedist. His *Speculum Majus* is the greatest encyclopedia written before the 18^{th} century.

Vincent entered the Dominican order at Beauvais (ca 1217) and held the post of "reader" at the monastery of Royaumont near Paris (ca from 1250). He was also chaplain to the court of Louis IX of France.

He labored on his encyclopedia during 1220–1244. It contains three parts: *Speculum Naturale* – a vast summary of all the natural history known to Western Europe towards the middle of the 13th century; *Speculum Doctrinare* – a summary of all scholastic knowledge of the age; *Speculum Historiale* – the history of Christianity and the evolution of Christian theology.

Vincent undertook a systematic and comprehensive treatment of all branches of human knowledge of his time. In the preparation of this colossal work he was helped in the purchase of books by his royal patron Louis IX.

1225–1235 CE **Michael Scot** (ca 1175–1235, Scotland, Spain and Italy). Translator, mathematician and magician. Studied at Oxford and Paris. Devoted himself to mathematics, philosophy and theology. Ordained as a priest. Went from Paris to Bologna, Palermo and Toledo (1217). There he acquired a knowledge of Arabic. This opened to him the Arabic version of Aristotle. He was one of the savants in the Napolitan court of Frederick II and at the instigation of the latter translated Aristotle into Latin.

His own books on astrology, alchemy and the occult are mainly responsible for his popular reputation. [He appears in the *Inferno* of Dante, *Canto* **20**, 115–117, among the magicians and soothsayers.]

1229–1262 CE **Al-Hasan al-Marrakushi** (Morocco). Mathematician and astronomer. His book, the *Jami* (1229), was the most elaborate trigonometrical treatise of his age, the best medieval treatise on practical astronomy (instruments and measuring methods), on gnomonics, and the best explanation of geographical methods.

1231–1256 CE **Yaacov (ben Abba Mari) Anatoli** (1194–1256, France and Italy). Translator, philosopher and physician. His translations from Arabic into Hebrew of the works of Aristotle, Averroes and Ptolemy contributed to the evolution of the ideas of the Renaissance.

A pupil and son in law of Shmuel Ibn Tibbon. He was invited to Naples (1231) by the enlightened ruler Frederick II (Emperor, 1212–1250) to serve as a physician, and under this royal patronage and in association with **Michael Scot**, made Arabic learning accessible to Western readers.

ca 1240–1250 CE **Dogen** (1200–1253, Japan). Philosopher. The most famous exponent of *Zen* Buddhism in Japan. His work *Shobogenzo* is the first Buddhist text written in Japanese. It is said to be the first truly philosophical work in Japan.

1240–1242 CE *The Talmud on trial* – the Paris disputation[80] (June 12, 1240) and the first public burning of the Talmud (June 6, 1242) under the Bull of Pope Gregory IX.

On a certain summer Saturday, while the Jews were in the synagogue, police surrounded their homes and carried off what books they could find. Then a trial was arranged in Paris: the prisoner was a book, the *Talmud*. The prosecution was led by a renegade Jew, Nicholas Donin; the defense by a group of rabbis led by **Yehiel of Paris** (ca 1192–1268). The judges were a number of bishops; and the queen-mother (of Louis IX) presided. Donin was given every opportunity to poke fun at the Talmud by pointing out the naive tales and legends which it contained, and to twist a number of its statements into attacks upon Christianity. Rabbi Yehiel did not have the right to point out equally naive ideas to be found in Christian literature. The judges being what they were – the cause of the defense was lost from the start.

Consequently, the Talmud was condemned to be an evil, a dangerous book to Christianity, and ordered to be burnt in a great public ceremony arranged by the Dominicans. In June 6, 1242, twenty-four cartloads of copies were burnt in the public square in Paris. To leave no loophole for the Jews, Donin persuaded pope Gregory IX to issue a Bull, a first of its kind, for the burning of the Talmud *everywhere*, and to establish inquisitions and censors over other Jewish writings, a practice which tormented the Jews for centuries.

Yehiel and his pupils came to Israel (1259) and established an academy at Akko.

1241 CE The Mongols withdrew from central Europe following the death of Ogadai Khan.

1245 CE **Yehudah ben Shlomo ha-Kohen**, **Ibn Matka**. Translator and encyclopedist. Wrote an encyclopedic treatise in Arabic including such subjects as astronomy, logic, mathematics, metaphysics, philosophy and natural history. His sources were Aristotle, Ptolemy and Euclid. It was later translated into Latin under the title *Inquisito sapientiae*. He was born in Toledo, Spain. Corresponded with Duke Frederick II of Babenberg, who invited him to Toscana, Italy, to participate in his translation project.

---

[80] Characteristic of the age, the disputations were called by the medieval Church "*Tournaments for God and Faith*". But there was little of the chivalrous element in these so-called "tournaments", the position of the combatants being so flagrantly unequal. Almost always the verdict was against the Jewish debaters, with the direct consequences to the practice of their religion, to themselves and to their fellow-Jews.

Table 2.3: TRANS-ASIATIC JOURNEYS (1245–1307)

Within half a century the innumerable risks of such journeys were faced and successfully overcome by the following 14 persons (not counting the many less known or anonymous ones who traveled in their wake independently):

- Giovanni Pian del Carpine (1245–1247)
- Hayton the Elder and his brother Sempad (1251–1254)
- William of Rubruquis (1253–1255)
- Niccolo, Maffeo and Marco Polo (1272–1295)
- Giovanni da Montecorvino (1272–1307)
- Bar Sauma (1280–1287)
- Ricoldo di Monte Croce (1288–1301)
- Buscarello de Ghizolfi
- Al-Juwaini
- Chang Te
- Yeh-lu Hsi-liang

1245–1247 CE **Giovanni Pian del Carpine** (1182–1252, Italy). The first of the great travelers from Europe to Asia. A Franciscan Friar who crossed Asia to contact the Mongols on behalf of Pope Innocent IV (in line with a policy of opening diplomatic intercourse with a power whose alliance might be invaluable against Islam).

In his forward journey, the Friar crossed a distance of some 5000 km (Lyons–Karakorum) in 463 days [April 16, 1245–July 22, 1246]. He left Lyons, traveling by a northern route through Bohemia, Poland and the Ukraine. In November 1247, Carpine delivered the Great Khan's reply to the Pope. It was, to say the least, discouraging:

... "*You must come yourself at the head of all your kings and prove to Us your fealty and allegiance, And if you disregard the command of God and disobey Our instructions, We shall look up on you as Our enemy. Whoever recognizes and submits to the Son of God and the Lord of the World, the Great Khan, will be saved. Whoever refuses submission will be wiped out*".

Though not yielding an immediate panacea for the medieval world's ills, Carpine's trail-blazing journey – undertaken when the Friar had already turned 60 years of age – had opened up the first real dialogue with the East. Moreover, Carpine was an astute observer, and his account of his travels, *Historia Mongolorum*, furnished Europe with the first insightful glimpse into Eastern culture.

1245–1260 CE **Albertus Magnus** (1206–1280, Germany). Naturalist and philosopher, known as the 'Doctor Universalis'. One of the most learned men in the Middle Ages, and the first serious naturalist since the Plinys who taught men to think again. He knew neither Greek nor Arabic, and his only sources were Latin translations. He wrote a series of encyclopedic treatises, presenting the entire body of knowledge: natural science, logic, rhetoric, mathematics, ethics, economics, politics and metaphysics. His influence was great, but did not last long because his works were too eclectic and too superficial. Nevertheless, his writings remained for centuries a treasury of information. He had the courage to reject *some* superstitious ideas (but he continued to believe in many others). He advocated that a visible object alters the medium between the object and the eye, and this alteration is propagated to the eye. He studied insects, whales, and polar bears, and gave a fairly complete description of German mammals and birds. He also made original contributions in biology, zoology, chemistry and geology.

Albertus excelled all his contemporaries in the width of his learning. In his scientific works he was a faithful follower of **Aristotle** as presented by Jewish, Arabian and Western commentators; in voluminous commentaries on the writings of Aristotle he comprehensively documented 13^{th}- century European knowledge of the natural sciences, mathematics and philosophy. He also engaged in alchemy, although his works express doubts about possibility of transmutation of the elements, and gave a detailed description of the element arsenic.

He was born Albrecht von Bollstädt in Lauingen, Swabia, Germany; studied in Padua and joined the Dominican order in 1223. He taught theology and philosophy in various schools, especially is Paris, until 1254, and was bishop of Ratisbon during 1260–1262. He died at Cologne.

1246–1286 CE **Meir of Rothenburg** ("MAHARAM", 1215–1293, Germany). Talmudist, jurist and poet. Foremost Rabbi of Western Germany and greatest German legalist in the 13^{th} century. A religious leader who exercised much influence on subsequent development of Judaism. He wrote glosses to the Talmud (*tosaphot*) and many *Responses* of the utmost value for historical research.

Maharam was born in Worms. He studied in Wuerzburg, Mainz, and France. He witnessed the famous *Talmud Disputations* of 1240 and saw the burning of the 24 cartload of parchments in 1242. He wrote an elegy about their destruction which is still used in Jewish Ashkenazic communities.

After the Talmud-burnings, he returned to Germany and settled in Rothenburg. Although only in his early thirty's, he was already recognized as a leading Talmudic authority. Communities began to send him legal questions. He wrote almost a thousand responsa, thus having a tremendous influence on shaping custom and lifestyle. His modification of synagogue and home rituals became the accepted forms for the Ashkenazic world.

The Maharam lived in Rothenburg for forty years, thus gaining the title "Meir of Rothenburg". He wrote commentaries and discussions on 18 tractates of the Talmud.

In 1286 he left Germany on account of severe persecution by Rudolf I of Habsburg (1218–1291), King of Germany and emperor of the Holy Roman Empire. He was arrested[81] in Italy, returned to Germany and then thrown into prison in Alsace, where he eventually died.

[81] The reason given was that, as a Jew, the Rabbi was a serf of the emperor's treasury; by leaving, he was depriving the treasury of a source of income: Rudolf demanded a tremendous sum as ransom, which the Jews were ready to pay. But the Rabbi declined the deal, fearing that the precedent would lead to extortion in other cases. After his death, the emperor refused to release the body for Jewish burial unless the ransom is paid. Finally, after 14 years a rich man named **Alexander Suesskind Wimpfen** paid the ransom in full on the condition that, upon his death, he would be buried by the Rabbi's side. Maharam was laid to rest on Feb. 7, 1307 and Wimpfen is buried by his side.

1247–1259 CE **Ch'in Chiu-Shao** (ca 1202–1261). Chinese mathematician. He wrote *Mathematical treatise in Nine Sections* (1247). It contains simultaneous integer congruences, the Chinese Remainder Theorem, algebraic equations, areas of geometrical figures and linear simultaneous equations. Developed methods of successive approximations to solve numerical polynomial equations of any degree, a method not discovered in Europe until the 19^{th} century. Ch'in invented a method of solving these numerical equations which is substantially identical with the Ruffini-Horner procedure[82]. The unknown quantity in these equations was represented by a monad and the zero by a little circle, like ours (the Chinese zero may have come directly from India with Buddhism or it may have been imported later by Muslims). Red and black ink were used respectively to represent positive and negative numbers. A contemporary mathematician, **Li Yeh** (1178–1265), wrote treatises in 1248 and 1259 involving problems on quadrilaterals and circles, with their solutions. Instead of using red and black colors to designate positive and negative numbers, Li differentiated the latter by drawing diagonal strokes across them.

1250 CE **Johannes Campanus of Novara** (d. 1296, Italy). Mathematician and astronomer. A chaplain of Pope Urban IV. Translated Euclid's *Elements* from Arabic into Latin.

ca 1250–1272 CE **Nasir al-Din al-Tusi** (1201–1274, Persia). Mathematician, astronomer, physicist, physician and philosopher. One of the greatest mathematicians of medieval times.

In geometry, he made first attempts to determine whether Euclid's parallels postulate can be derived from the other Euclidean postulates. In trigonometry he presented the law of sines and began to separate trigonometry from astronomy. His work in these two areas may have influenced the further advances of Regiomontanus (1464) and Saccheri (1733). In 1259 al-Tusi began the construction of a major astronomical observatory at Marãgha[83], where

[82] Thus, to solve the equation $x^2 + 252x - 5292 = 0$, Ch'in first established that there is a root between 19 and 20. He then used the transformation $y = x - 19$ to obtain the equation $y^2 + 290y - 143 = 0$, with a root between 0 and 1. His final approximate solution is $x = 19 + \frac{143}{1+290}$. Similarly, to solve the equation $x^3 - 574 = 0$ he set $y = x - 8$ to obtain $y^3 + 24y^2 + 192y - 62 = 0$, yielding as an approximate root $x = 8 + \frac{62}{1+24+192} = 8 + \frac{2}{7}$. Indeed, '*Horner's method*' must have been well known in medieval China; it was used by several Sung mathematicians for the numerical solution of cubic and even quartic equations.

[83] The means to construct the observatory were given to him by Hulagu. It was an institute for scientific research, with a rich library. Under al-Tusi's direction, Marãgha became the outstanding astronomical center of the time and one of the leading scientific centers of the world. Mathematicians, astronomers and

he used his self-made quadrants to observe star positions. During 1256–1265 he conducted observation which served as a basis for his astronomical tables (1272). His criticism of Ptolemaic astronomy was an additional step toward the Copernican reform.

Al-Tusi's discussion of the 5^{th} postulate of Euclid was taken up later by **Girolimo Saccheri** (1733). In other words, the history of non-Euclidean geometry can be traced back through Saccheri to one of Nasir al-Din's writings. His independent textbook of trigonometry, plane and spherical, can be considered the climax of a long Greek-Hindu-Arabic tradition. Some spherical problems were solved by implicit considerations of polar triangles. This treatise was almost equivalent to the Latin treatise composed by Regiomontanus two centuries later.

Al-Tusi was born in Khurasan. Under Mongol occupation (1256) he became astrologer to the Mongol chief, Hulagu Khan, and went with the Khan when the latter sacked Baghdad in 1258. He resided in Marãgha from 1259 until almost the end of his life. In 1274 he went to Baghdad and died there.

The work of al-Tusi was continued by his pupil, the astronomer and physician **Qutb al-Din al-Shirazi** (1236–1311, Persia). In 1281 the latter suggested an alternative planetary model to that of Ptolemy, making more use of uniform circular motions. He was the first to give a satisfactory qualitative account of the *rainbow* (excepting, of course, the colors). He explained it by the study of passage of a ray of light through a transparent sphere (drop of water): the ray is reflected once and refracted twice. This explanation is essentially similar to that of Descartes. Further details on al-Shirazi's correct theory are found in a comment by his student **Kamal al-Din al-Farisi** (ca 1260–ca 1320; Tabriz), on the *Optics* of Alhazen. Both, however, lacked the quintessence of physical theory – a *quantitative explanation*.

Al-Shirazi was born in Shiraz. He belonged to a family of learned men, and received part of his medical training from his father and uncles. He traveled extensively in the Middle East, partly in the service of the Khans of Persia. He finally settled down in Tabriz and died there.

1251–1254 CE **Hayton the Elder** (d. 1271, Armenia). Trans-Asian traveler, King of Little Armenia. With his brother Sempad, made a journey to Mongol capital Karakorum, the record of which by one of his courtiers was one of the earliest written accounts of Mongolian geography and ethnology.

---

instrument makers gathered there from both near and distant countries (Caucasus, Morocco, China). The main task of the Marãgha astronomers was the compilation of new tables. Unfortunately this center did not long survive its founder.

1252–1273 CE **Thomas Aquinas** (1225–1274, Italy). Theologist. One of the first Christian scholars to recognize the '*light of reason*' as an independent source of knowledge. Aquinas was one of the leading scholars of Aristotelian physics of his day and was responsible for the general acceptance of Aristotelian physics[84] throughout Europe. In his attempt to reconcile religion and science, Aquinas set himself the task of harmonizing 631 questions between Christian and classical science. He made some efforts to appeal to common sense and the natural word but in most of his cases the desired answer was simply assumed: Faith always got priority over Reason.

By using Aristotle as a mental catalyst, he and **Albertus Magnus** contended that there is no conflict between faith and reason. In this sense he followed Maimonides and Ibn-Rushd, and did for Christianity what the latter had done for Judaism and Islam respectively, a century before him. He wrote 21 volumes of mental gymnastics to defend the doctrines of the Catholic Church. These are still studied today in Catholic seminaries.

Aquinas was born near Aquino, Italy, in the province of Naples. He attended the University of Naples in 1239 and then joined the Dominican Order. His family opposed the idea so strongly that his brothers seized him as he was traveling to France, and imprisoned him for a year. After he was released, he left for Paris in 1245 to study under Albertus Magnus, and then followed the latter to Cologne. He ended his studies in 1259 and taught at the papal court from 1259 to 1268. He went to Italy in 1272 to organize the Dominican school of theology in Naples, and died on his way to Rome.

1253–1255 CE **Rubruquis** (Willem van Ruysbroeck, Flanders). Flemish Franciscan Friar and traveler to the East before Marco Polo. He was sent by Louis IX of France to Mongolia as an unofficial representative in 1253. He left Constantinople, sailed to the Crimea, crossed South Russia and a large part of Asia, and finally reached the Mongolian capital Karakorum in April 1254. He left the capital in August, and reached Tripoli, Syria, a year later. He was the first to describe the Caspian as an inland sea. His travel account was praised and used by **Roger Bacon**.

1256–1312 CE **Yaacov ben Machir Ibn Tibbon** (1236–1312, Provence). Also known as **Prophatius**. Astronomer, physician and translator. A distinguish medical man who worked in the medical faculty of the University of Montpellier. One of the most famous astronomers of medieval times. His works, translated into Latin, were quoted by Copernicus and Kepler. He compiled new astronomical tables for the longitude of Montpellier and the year beginning on March 1, 1300.

[84] Although Aristotelian physics was wrong, it was an essential precursor of modern physics.

Invented a new instrument, the *quadrans novus*, meant to be of the same service as the astrolabe. Yaacov was one of the greatest translators of scientific works from Arabic into Hebrew (and Latin). Among his translations: Euclid's *Elements* and Ptolemy's *Almagest*.

He was born in Marseilles, studied at Lunel, and flourished at Montpellier, where he died.

The Jewish family of **Ibn Tibbon** comprised at least four generations of authors and translators, instrumental in the infusion of Arabic learning into Europe. The head of this clan was **Yehudah Ibn Tibbon** (1120–1190); born in Granada, Spain and immigrated to Lunel, in Southern France, where he practiced medicine and became a famous physician in the King's court. Through his translations from Arabic into Hebrew, he saved the books of the great Jewish thinkers from oblivion, and through this also enlarged the vocabulary of the Hebrew language to include scientific concepts and terms.

His son **Shmuel Ibn Tibbon** (1150–1232), physician and philosophic writer, was born in Lunel and died in Marseilles. He received a thorough education in Arabic and Jewish literature, and in all the secular knowledge of his age. Later he lived in several cities of Southern France and traveled to Spain and Alexandria (1210–1213). He translated Aristotle, Ibn Rushd and Maimonides into Hebrew. His son **Moshe Ibn Tibbon** (ca 1200–1283), born in Marseilles, was a physician and a prolific translator of Arabic works on philosophy, mathematics, astronomy, and medicine. His brother was the father of **Yaacov Ibn Tibbon**. Finally, Moshe's two sons, **Yehudah** and **Shmuel Ibn Tibbon**, were also famous translators.

ca 1260 CE *The invention of gunpowder*[85]. Probably made by alchemists in Western Europe, but it is impossible to say where or by whom.

[85] Ordinary gunpowder is an explosive mixture of finely powdered *salpeter* (potassium-nitrate, KNO_3, also known as nitre or neter), *sulphur* and wooden *charcoal*. The proportions of the constituents (by weight) and the main products of the combustion correspond roughly with the equation $2KNO_3+S+3C=K_2S+N_2+3CO_2$, which by atomic weights yields the ratio $202:32:36 \approx 6:1:1$. Other gaseous products include CO_2, H_2S, CH_4, H_2, and the residue contains potassium carbonate (K_2CO_3) and sulphate (K_2SO_4). The reaction is ignited at about 300°C and creates a heat of explosion of ca 750 cal/g, together with ca 250 cc/g permanent gases, at 0° and 760 mm. The temperature of the explosion reaches 2200°C, or even higher. Under these conditions, a *strongly confined gunpowder* produces a shattering effect.

Of course, sulphur and charcoal have been known from time immemorial. The 'invention' of gunpowder thus essentially implies a *knowledge of pure salpeter and of the proper mixture*. The word salpeter = sal petrae, or its equivalent, niter, has been taken to mean many different things. By niter (nitrum, natron), Fuming, fiery and flaming composition of many kinds ("wild fire") were known and used before the introduction of gunpowder. These consisted of mixtures of such ingredients as charcoal, sulphur, resins, fats, and natural petroleum, pitches and bitumens. The celebrated *Greek fire*, used in the Byzantine period, was probably a mixture of this kind. It is easy to imagine that enterprizing alchemists would not fail to try the effect of adding familiar mineral materials to these mixtures, and so eventually the particular virtue of *salpeter* would be recognized.

Recipes for pyrotechnics and explosives are found in the works of several men: (1) *Liber ignium* (ca 1300) by **Marc the Greek** (Marcus Graecius, unknown author of a collection of recipes who flourished during 1260–1300); (2) *Kitab al-furusiya* by **al-Rammah** (ca 1260–1295); (3) *Opus tertium* by **Roger Bacon**[86], composed 1266–1267. Therein he describes inflammable mixtures, such as were used for fireworks, and an explosive one which was probably gunpowder. It is clear from all these sources that the said authors were not the inventors, although it is evident that gunpowder was discovered within Bacon's lifetime.

On the other hand, there is no evidence at all that the Chinese discovered gunpowder (let alone firearms). [They did however use pyrotechnic devices comparable to the Greek fire in the battles of 1161 and 1162, and again at the battle of 1232 against the Mongols.] The discovery of gunpowder depends on the isolation and purification of potassium nitrate. It was necessary to distinguish that kind of saltpeter from others which were of no use for this special purpose, and to sufficiently purify it from the impurities which compromised its usefulness.

In the light of this situation it is very probable that gunpowder was actually made, in diverse places, before 1300 CE, at the end of a *process of slow and gradual evolution*.

It should be remembered that the great invention which revolutionized the world was not, after all, that of saltpeter, nor even gunpowder, but the

---

the ancients meant any alkaline salt, such as potash (KNO_3), soda ($NaNO_3$) or sodium carbonate ($NaCO_3$) [used by the early Egyptians for embalming, cleansing, curing meat, smelting ores, and as medicine]. The Hebrew word for neter occurs in **Proverbes** *25*, 30 and **Jeremiah** *2*, 22.

86 There is no reason for ascribing the invention of gunpowder to him. His epistola is apocryphal, and the cipher supposed to contain the recipe of gunpowder, has no reference whatsoever to a known manuscript. He may have known something of gunpowder, and he was acquainted with various inflammable and pyrotechnic materials; but there is no reason for believing that he knew the explosive properties of gunpowder, nor that he purified and isolated saltpeter.

application of gunpowder to the propulsion of missiles. When gunpowder was invented in ca 1280, nobody understood as yet the implication of that invention.

1261–1275 CE **Yang Hui** (ca 1238–1296, China). Mathematician. Wrote books which use *decimal fractions* (in the modern form) and gave the first account on *Pascal's triangle*.

1263–1270 CE **Moshe ben Nahman**; **Nahmanides**; RAMBAN (1194–1270, Spain and Israel). Talmudist, philosopher, physician, Kabbalist, and one of the few biblical commentators that have withstood time's test.

In his *Commentary on Genesis* (1267), Nahmanides renders an amazingly prescient description of the early moments of the universe, which almost reads like a quotation from Steven Weinberg's *The First Three Minutes* (1977). Translated from the Hebrew text, it reads:

"*At the briefest instant following creation all the matter of the universe was concentrated in a very small place, no larger than a grain of mustard. The matter at this time was so thin, so intangible, that it did not have real substance. It did have, however, a potential to gain substance and form and to become tangible matter.*

From the initial concentration of this intangible substance in its minute location, the substance expanded, expanding the universe as it did. As the expansion progressed, a change in the substance occurred. This initial thin incorporeal substance took on the tangible aspects of matter as we know it. From this initial act of creation, from this ethereally thin pseudosubstance, everything that has existed, or will ever exist, was, is, and will be formed".

Commenting further on the first chapter of *Genesis*, Nahmanides reached the conclusion that prior to the creation of the universe, neither time nor space existed; the creation of the universe brought with it not only the time in which it flows, but also the space into which it expands. Thus, Nahmanides and cosmologists discuss the events of the Big Bang in uncannily similar terms.

Like other biblical scholars before him, Nahmanides had a well-developed understanding of the phenomena that produced the day-night cycle on earth. He summarized his knowledge: "*On the earth both evening and morning are always present. There are on earth at every moment ever changing places where it is morning and in the places opposite them it is evening*".

This reveals quite an exact comprehension of the illumination of the sun's light on a spherical earth, at time in the history of mankind when most of Western humanity dreaded falling off the edge of a flat earth.

He was born in Genova, Aragon, and became chief rabbi of Catalonia. In 1263, he was obliged by James of Aragon (king from 1213 to 1276) to discuss publicly at Barcelona the respective merits of Christianity and Judaism with the apostate and renegade Pablo Christiani, a Dominican. The discussion lasted four days and turned in Moshe's favor, but soon afterwards the Dominicians caused him to be exiled from Aragon, and the Talmud to be censored[87].

After spending a few years in Castile and Southern France, he moved in 1266 to the Holy Land; he lived in Jerusalem and Acre (Akko) and is buried at Haifa.

1266 CE **Theodoric Borogoni of Lucca** advocated the use of narcotic-soaked sponges to put surgical subjects to sleep.

1266–1278 CE **Roger Bacon** (1214–1292, England). Philosopher and scientist. One of the founders of the experimental method and a leading figure in the development of science during the Middle Ages. His writings and experiments helped lay the foundations for the scientific revolution that occurred in Europe during the 1500's and 1600's.

Advocated direct observations, some experimentation and the application of mathematics to the various sciences ("*Mathematics is the door and key to the sciences*"). In that he paved the way to the emancipation of men's intellect from total reliance on the search for regularity and perfection in the material universe as advocated by the Pythagorean school and by Plato. He asserted that the temptation to search for patterns of regularity in nature must be balanced by the equally powerful inclination of the human mind to seek simplicity and mathematical definiteness.

Bacon attached to *logic* only a subordinate importance. For him the main avenue to knowledge was not logic, but linguistic and mathematical ability. Logical ability he thought to be almost instinctive, but languages and mathematics had to be learned. He was not an original mathematician, and his knowledge of mathematics was very limited. But he was imbued with the Platonic idea of the transcendental importance of mathematics, and he helped to spread that idea. He was equally convinced of the practical utility of mathematics in almost every study, and explained it at great length.

His most important mathematical contribution is the application of geometry to *optics*. He performed experiments with mirrors and lenses, chiefly burning lenses, and foresaw vaguely both the compound microscope and the

---

- Maccobi, H. *Judaism on Trial: Jewish – Christian Disputations in the Middle Ages*, London, 1993.

telescope. He had some understanding of spherical aberration and of its correction by the use of paraboloidal and hyperboloidal surfaces. In opposition to **Grosseteste** he claimed that the passage of light through a medium cannot be instantaneous. *Gunpowder* was discovered probably within Bacon's lifetime, but there is nothing to indicate that he was the inventor. He had great interest in *alchemy*, although he made a distinction between practical and speculative alchemy.

Bacon explained to the Pope the importance of undertaking a complete and accurate survey of the world. He indicated the possibility of reaching the Indies by sailing westward from Spain, and assumed that these countries were considerably nearer than they in fact are, as did Columbus later. Bacon made few experiments himself, and in a sense he never understood the experimental method as we now understand it. Like his countryman **Francis Bacon**, more than three centuries later, he laid down many percepts which he never followed himself. To be sure, some of the experiments proposed by him were fantastic, and in spite of his own efforts to separate experimentation from magic, he did not always succeed. However, in his time, even to speak of the superior value and indispensability of experimentation was an immense achievement; the essential soundness of his experimental point of view is proved by his readiness to sacrifice theories to facts and to confess his own ignorance.

Bacon realized the supreme importance of the texts written in Greek, Hebrew and Arabic, and insisted upon the necessity of studying these languages. He attached great importance to the study of the Bible in its original form, and to this end he advocated the study of Hebrew and Greek. He believed that all knowledge is explicitly or implicitly set forth in the Bible.

Bacon was born at Ilchester, Somerset. He studied in Oxford under Grosseteste. Before 1236 he went to Paris, and later seemed to have traveled to Italy.

Bacon returned to Paris, lectured there as a regent master of the university, and returned to Oxford in 1251. Sometime between 1251 and 1257 he joined the Franciscan Order, but soon got into difficulties with his superiors in matters of censorship of his writings. Happily for him, he was ordered (1266) by Pope Clement IV to send him copies of his works, as secretly as possible. This papal request, made over the head of Bacon's superiors, made him anathema to them. After the pope's death (1278) Bacon was condemned for teaching "suspected novelties" and imprisoned from 1278 to 1292. He died soon afterwards.

1268–1286 CE **William of Moerbeke** (ca 1215–1286, Greece and Italy). Scholar, Orientalist, Philosopher and translator of scientific and philosophical texts from the Greek into Latin. One of the most distinguished men of letters of the 13^{th} century. Held intellectual intercourse with **Aquinas**, **Witelo** and

Campanus. His translations were influential in his day, when few competing translations were available, and are still respected by modern scholars.

He translated the works of **Aristotle**, **Hero of Alexandria**, **Archimedes** and **Proclos**.

ca 1269 CE **Peter Peregrinus** (the Stranger) **of Maricourt**. French physicist, perhaps one of the greatest of medieval times. Discovered the fundamental properties of magnets: the two kind of poles, their attractions and repulsions, magnetization by contact, breaking of a magnetic needle into smaller ones, and the exertion of magnetic force through water and glass. He even traced the lines of force on a loadstone from one pole to another. One can find in his writings a vague suggestion of terrestrial magnetism.

He described floating and pivot compasses, provided with a fiducial line and a circle divided into 360 degrees.

Peregrinus was in the army of Crusaders which besieged Lucera in 1269. He was a teacher of Roger Bacon, who payed him the highest tributes in the *Opus tertium* and in the *Opus maius*. According to Bacon, Peregrinus was a recluse who devoted himself to the study of nature, and was able to work metals.

1269, June 19 Louis IX of France decreed that all Jews must wear a *yellow badge*. The Jews of Europe continued to wear the badge for the next 529 years; on Feb 15, 1798, the Jews of Rome were allowed to remove the badge. However, in 1935, the Germans renewed the practice of the badge, branding their victims prior to their final extermination.

1270–1290 CE **Zerahia (ben Itzhak ben Shaaltiel) Chen of Barcelona** (ca 1230–1292, Spain and Italy). Physician, philosopher and translator. Translated Greek medical and philosophical writings from Arabic into Hebrew, especially the writings of Aristotle. Lived in Barcelona during 1277–1290, where most of his translations work was done.

1271–1295 CE **Marco Polo** (1254–1324, Italy). The greatest medieval traveler, who traced a route across the whole longitude of Asia, naming and describing kingdom after kingdom which he had seen with his own eyes. The first traveler to reveal China in all its wealth and vastness, and tell the West about Tibet, Burma, Laos, Siam, Japan, Sumatra, Nicobar and Andaman, India, Ceylon, Abyssinia, Zanzibar, Madagascar, Siberia and the Arctic Ocean.

In 1271, Marco Polo (then 17) and his father and uncle[88] sailed from Venice to Acre (now Akko, Israel). From there they rode camels to the Persian port

[88] Nicolo (Marco's father) and his brother Maffeo Polo, Venetian Jewel traders in the Black Sea, embarked in 1254 on a travel to Central Asia. After spending

of Hormuz, and from there on camel back across the deserts and mountains of Asia. More than three years after leaving Venice, they reached Kublai Khan's summer palace in Shang-tu. During 1274–1292 the Polos stayed in the Chinese empire. Young Marco served the Kahn on many official tours of the kingdom, taking detailed notes during his travels. On their way back, the Polos sailed from Southern China (Zaitun) in the South China Sea to what is now Singapore then around the southern tip of India. They crossed the Arabian Sea and the Gulf of Oman to Hormuz. From there they traveled overland to the Turkish port of Trebizond and over the Black Sea to Constantinople.

The Polos returned to Venice in 1295 after covering a total distance of 24,100 km. In 1296, the Genoese captured and jailed Marco Polo for a year. In prison he met a popular writer, Rustichello of Pisa and dictated to him his story. Polo told about Kublai Khan's prosperous, advanced empire. He described the Khan's *communication system*, which consisted of a network of some 10,000 courier stations throughout the Kingdom; horseback riders relayed messages from one station to another, covering some 700 km per day.

Polo commented on many Chinese customs, such as mining and the use of coal as fuel (coal had not yet been used in Europe). He also marveled at the Chinese use of paper money, which bore the seal of emperor. Europeans still traded with heavy coins made of copper, gold or lead.

Marco Polo's book *Description of the World* was completed in 1298. The book may have helped bring to Europe such Chinese inventions as the *compass*, *papermaking*, *paper money, printing* and *explosives* (which according to Polo were in use in China already in 1237).

Printing had not yet been invented in Europe, and so scholars copied Polo's book by hand. It soon became the most widely read book in Europe. Historians believe it may have influenced many explorers including Christopher Columbus. Yet, in Polo's time and through the century that followed, people did believe most of his stories.

It is told that when asked, on his deathbed, whether his reports were true or not, Marko Polo replied: "I have not told you even half of what I saw".

ca 1272 CE **Alfonso X, El Sabio**; '**the learned**' (reigned 1252–1284, Spain), ordered the compilation of new astronomical tables to replace the

---

three years in Bokhara they proceeded to China, meeting Kublai Khan in 1266 in Peking. They reached Acre in 1269, bearing letters to the Pope from the Mongol ruler, only to find out that Clement IV had died the previous year and that the Cardinals had not yet elected a successor. And so they returned to Venice, where Nicolo's wife had died in his absence, leaving a son – Marco, who was then 15 years old.

Toledan tables which had been edited by al-Zarquli two centuries before in the same city. The so-called *Alphonsine Tables* were prepared in 1272 under Alfonso's direction, in Toledo, by **Yehudah ben Moshe ha-Kohen** (Jewish physician and astronomer), and **Itzhak ha-Hazzan**[89] (Jewish astronomer, constructor of instruments, and translator from Arabic into Spanish). The original tables are lost, but the introduction is extant, and thus we have a definite idea of the nature of these tables.

The scientific fame of Alfonso is based mainly on his encouragement of astronomy. He was brought up in an intellectual atmosphere which was impregnated with Muslim and Jewish influences. He completed the incorporation of the University of Salamanca in 1254, and gathered around him a number of Jewish and Christian scholars to continue the transmission of Muslim knowledge to Christendom and the translation of Arabic writings into Spanish. Within this framework, he ordered the translation into Castilian of the Quran, of Talmudic and Kabbalistic writings, and of a number of astronomical treatises. Thus Alfonso was one of the greatest intermediaries between Arabic and European knowledge (on the other hand it must be confessed that he showed but little ability as a king and statesman!).

The Alfonsine Tables became known in Paris only in 1292. In their Spanish form they could hardly exert any influence outside of the Iberian peninsula. They owed their immense popularity to the Latin versions, which were printed for the first time in 1483. They were superseded by the *Rudolphine Tables* computed by Kepler in 1627.

1275–1289 CE Severe drought depleted the agricultural resources of the corn-growing Anasazi Indians in Mesa Verde, Colorado (USA today), causing then to migrate far from their ancient cultural centers.

1272–1307 CE **Giovanni da Montecorvino** (1247–1328, Italy). Trans-Asian traveler and diplomat. Franciscan prelate. Missionary in Armenia and Persia (ca 1280). Papal emissary to Il-Khan of Persia (1289). Founded first Catholic mission in India and China; reached Peking (1294). First archbishop of Peking and patriarch of the Orient (1307).

---

[89] He is also called in the Spanish documents **Itzhak Ibn Sid**, and was the main collaborator of King Alfonso. He flourished in Toledo ca 1263–1277, made observation of eclipses in 1263–1266, and invented or improved various astronomical instruments. He is said to have introduced two periods of 49,000 and 7,000 years respectively for the precession and the "*trepidation*" (a fictitious periodic variation in the precession of the equinox based on an error in Ptolemy's determination of the precession. It figured in astronomical tables until the time of Copernicus). One recognized here a Kabbalistic influence, in the form of sabbath and jubilee extended to astronomy.

1275–1305 CE **Raymond Lully** (Ramon Llull, 1235–1316 CE). Catalan scholar, linguist, poet, philosopher, alchemist and mysticist. Originated symbolic logic. His principle philosophical concern was with attempting to reconcile the seeming contraries of life, such as art and science, rationalism and mysticism, abstract philosophy and practical life.

His *Ars Generalis* (1275) intended to serve as a basis for all sciences and as a key to invention and discovery. This work was much admired, even several hundred years later by Giordano Bruno and Leibniz.

In his main work *Ars Magna*[90] (1305–1308) he set out his theosophical attempt to encompass all knowledge in a Neoplatonic schema; he broke away from the scholastic system, criticized *fraudulent* alchemy and made himself some contributions to chemistry[91] and mathematics. Because of his great learning he has often been called *Doctor Illuminatus*.

Lully was born and reared at Palma on the Spanish island of Majorca, where Christian civilization was in close contact with both Jewish and Arabic lore. He was the first Christian scholar to study the Kabbalah, which he regarded as a divine science and a true revelation of the rational soul. He was a great linguist and obtained (1311) the consent of the Council of Vienna for teachers of Hebrew and Arabic to be admitted to the papal schools and the great universities.

Lully traveled throughout Asia Minor and North America, attempting to convert Muslims. According to legend he was stoned to death at Bugia (Tunisia).

1275–1310 CE **Levi ben Avraham ben Hayim** (ca 1240–1315, France). Natural philosopher, astronomer and mathematician. Recognized heat as a form of motion four centuries before **Robert Boyle** (1675).

Levi was born in Villefranche-de-Confluent to an illustrious rabbinic family. He studied at Perpignan and Montpellier and was instructed in astronomy and mathematics by **Yaacov ibn Tibbon**. He was the grandfather of **Levi**

---

[90] Lully, searching for the way to break through the stranglehold which Scholasticism had upon science, used the Kabbalah and the works of the Spanish Jew *Avraham ibn Latif* (1220-1290) as a basis for his book *Ars Magna*. Avraham merged Kabbalah, Aristotelianism, mathematics, and natural science into a unified system. His works were translated into Latin and caught the attention of Lully.

[91] He is credited with the discovery of *ammonia* and supported the importance of *sulfur*. His work makes him also as one of the precursors of *symbolic notation* and *combinatorics*.

ben Gershon. His book *Loyat Chen* (adornment of grace) is a comprehensive encyclopedia of the sciences known in his day.

Levi lived in poverty, seeking a living through the teaching of science and foreign languages. Persecuted by the rabbinic establishment because of his rationalistic interpretation of the Bible[92], he was forced to wander in Provene. He died in Arles.

Medieval Cosmology

In 1227 CE the Bishop of Paris, Etienne Tempier, issued 219 condemnations of all professors who dared to place limits on the power and scope of the supreme being.

Pierre Duhem (1906), the French historian of science showed that the condemnation stands as a landmark in the history of cosmology, and that the year 1277 could serve as a fiducial for the birth of modern science for the following reason:

In the Middle Ages, Arabs, Jews and then Christians, in their philosophical and theological studies, adopted the Aristotelian system of concentric celestial spheres. The Arabs created the primum mobile*, an outer sphere that transmitted motion to all other spheres and was itself driven by divine will. The high Middle Ages became an age of scribes translating Arab and Greek manuscripts. The new knowledge exceeded the scope of the monastery and cathedral schools, and communities of learned scholars founded the universities. Students flocked to these centers of learning, and the translated works of Aristotle, Euclid, Ptolemy, Galen, and other sages of the ancient world revealed vistas of knowledge that exalted the power of the human mind. The earth-centered universe of Ptolemy was especially congenial to the way medieval scholars thought. Once it was introduced to Europe in the 12th century*

---

[92] Levi endeavored to render rational explanations to biblical miracles. e.g. he interpreted *Joshua* **10**, 12–14 as Joshue's *prayer* onto God to grant him enough strength to reach Gibeon before sunset and then arrive at the valley of Ayalon before moonset. The Biblical narrator then confirms that his prayer was indeed accepted.

(by way of translation from the Arabic texts of the ancient Greeks), it swept through the universities like wildfire.

But ecclesiastical authorities grew alarmed. The wholesale adoption of ancient beliefs about the nature of the universe threatened to transform Christian doctrine beyond recognition. Granted that the earth rests at the center of the universe, and granted that the heavens consist of rotating spheres; but to go further and assert that even God, if he so willed, could not move the earth, or could not create other worlds than the earth, as taught by professors in the school of art, controverted the tenets of sacred doctrine. Tempier's condemnations were aimed at the new Greek learning that was being taught in the academies. His main objection seemed to be that by talking about laws of nature, the science faculties were somehow limiting the power of God.

By proclaiming Aristotle's fallibility and by undermining his already besieged finite anthropocentric system*, the bishop's condemnation alerted scholars and divines to the need for a system more compatible with the idea of* omnipotent and omniscient supreme being*. Thus, scholars of the high and late Middle Ages were inspired to seek a more ample system to accommodate the works of a supreme being of greater power and extent.*

In any case, the Ptolemaic universe was quickly amalgamated with Christian thought. The Ptolemaic universe fitted the preexisting view of a moral universe in which man occupied a middle place, with hell beneath his feet and heaven above. The spheres of the stars and planets were thus between man and heaven. Volcanoes provided glimpses into the underworld, and the blue of the daytime sky was a reflection of the glory of heaven. Demons walked at night, when the heavenly glow was blocked by shadows – further proof of the validity of this cosmology. Thomas Aquinas' doctrine of the right of scientific reason to operate according to its own rules within the larger framework of the Christian faith only strengthened the idea of the earth-centered cosmology; it went hand in hand with the Christian faith. The medieval universe, then, combined the best of both worlds: the rational, phenomenon-oriented astronomy of the Greeks and the secure and emotionally satisfying spiritual interpretation of life offered from the earliest times by mythology. No wonder church and secular authorities of the late Renaissance were so reluctant to abandon this synthesis.

ca 1280 CE **Nathan ben Eliezer ha-Meaati** (of Cento, Italy). Translated medical Arabic work into Hebrew. Lived in Rome 1279–1283.

1280–1288 CE **Rabban bar Sauma** (ca 1220–1294, China). Trans-Asiatic traveler and diplomat. Born in Peking. Started on a pilgrimage to Jerusalem but settled in Armenia, becoming a Nestorian Christian monk (1243). He gained fame as ascetic and became a Nestorian prelate and later traveled to Baghdad. Became a European ambassador to Arghun Khan, the Mongol ruler of Persia. The purpose of this was to form an alliance with the chief states of Christendom against the Mameluke power. In 1287, Arghun Khan sent him back with letters to the Byzantine Emperor, the pope and the Kings of France and England, to gain support for a crusade against Muslims in the Holy Land. His Asian travels were then narrated in the book, giving a picture of medieval Europe at the close of the crusading period, painted by a keenly intelligent, broad-minded and statesmanlike observer.

ca 1280 CE **Peter Olivi** (Pierre fils de Jean Olivi, 1248–1298, France). Physicist and theologian. Anticipated the concept of *inertia*. Further developed the '*impetus theory*' of motion (outlined in ca 500 CE by **Joannes Philoponus**), and asserted that after an object is placed into motion by an initial *impetus*, it can continue to move even though the propellant force is no longer applied (this counters Aristotelian tradition, in which motion required the *continued* action of an external motive force).

Olivi was born in Sérignan, Languedoc, and joined the Franciscan Order in Beźiers (1260). He studied in Paris and died in Narbonne.

1281 CE A typhoon sank the entire fleet of *Kubla Khan* just as it landed in Kyushu, Japan, aborting the possible occupation of Japan by the Mongols. This event is the source of the Legend of the Divine Wind – the *Kamikaze*.

1285–1289 CE *Spectacles*[93] (lens for myopia) were invented in Venice [called 'Occhiali']. Popularized by **Alessandro della Spina** (d. 1313), a

[93] It is well known that **Goethe** was no friend to spectacles, of which he said (1830): "*Whenever a stranger steps up to me with spectacles on his nose, a discordant feeling comes over me, which I cannot master. It annoys me so much, that on the very threshold it takes away a great part of my benevolence, and so spoils my thoughts, that unconstrained natural play of my own nature is impossible... It always seems to me as if I am to serve strangers as an object for strict examination, and as if with their armed glances they would penetrate my most secret thoughts and spy out every wrinkle of my old face. But while they thus endeavor to make my acquaintance, they destroy all fair equality between us, as they prevent me from compensating myself by making theirs. For what do I gain from a man into whose eyes I cannot look when he is speaking, and the mirror of whose soul is veiled by glasses that dazzle me?*".

Dominican at Santa Caterina monastery of Pisa, and **Slavino degl' Armati** (d. 1317). Their production spread to the south Netherlands, where they were called 'brillen'. The earliest mention of spectacles was in 1316.

1286 CE Appearance of *Sefer ha-Zohar* (The Book of Splendor): an allegorical, symbolic and mystic commentary on the Torah. Building on earlier Kabbalistic works, the *Zohar* deals with the nature of God, the nature and design of human soul; the mysteries of Creation, the Messiah and redemption.

There are two way of dealing with the problems of *religion*. One is the way of the *philosophers*, like Saadia and Maimonides, who use reason to arrive at whatever religious truth is humanly comprehensible. This method results in a system of religious thought which is called *theology*.

Obviously, theology cannot appeal to everybody, for it is the product of fine-spun reasoning and systematic logic, requiring acute *intellectual powers* and large resources of *knowledge*. The masses of the people could not be interested in this method of describing their religion. Moreover, when difficult times come upon a religious group, it wants a warm faith, some assurance that God is near and friendly, not a theology which depends upon cold logic.

The method of *mysticism* was, therefore, more suitable for the Jews of the 13^{th} and 14^{th} centuries. For to the mystics God was a matter of daily experience in direct and intimate contact. They had no objection to speaking of him in human terms. No wonder that mysticism grew among the Jews in Spain in direct proportion to the somber difficulties of their life as Jews. It is not surprising, therefore, that the *Zohar* became the chief expression of Jewish mysticism. Apart from the tremendous impact it had on Jewish life, it has also influenced Christian theology. It carried the Jewish Messianic fervor over more than 700 years under the guise of Hasidism and eventually Zionism.

Nobody knows for sure who wrote *Sefer ha-Zohar*. Some believe that parts of it were composed by **Avraham ben Shmuel Abulafia** (1240-1291, Spain). It is however certain that its final editor was **Moshe ben Shem-Tov de Leon** (1245–1305, Spain).

1288–1301 CE **Ricoldo di Monte Croce** (1242–1320, Italy). Near-Eastern traveler and Dominican missionary. Traveled extensively in Israel, Mesopotamia, Asia Minor, Armenia and Persia, and described his journeys in a detailed *Itinerarius*. As a traveler and observer his merits are conspicuous.

1290 CE *Expulsion of the Jews from England*[94]. They were readmitted on Feb 4, 1657, under **Cromwell**.

---

[94] *A mass-expulsion of* 16,000 *people by Edward I*.
Jews first arrived in England in 1066 at the invitation of William the Conqueror, who depended on their capital to forge a strong English state. King William

For the next 484 years, the mass-expulsion of Jews by European monarchies was often exercised; e.g.: **France** [1394, 1615]; **Italy** and **Sicily** [1492-3, 1569]; **Germany** [1450]; **Russia** [1727]; **Vienna** [1670] **Prague** [1774].

1291–1455 CE **Ugolino** *and his brother* **Vadino Vivaldo**. Genoese explorers. Headed the first expedition in search of an ocean way from Europe to India. They left Genoa in May 1291 in two galleys. The galleys were well armed, and sailed down the Moroccan coast to a place called Gozora (Cape Nun), in 28°47′N, after which nothing more was heard of them. In 1315, **Sorleone de Vivaldo**, son of Ugolino, undertook a series of distant wanderings in search of his father, and even penetrated to the Somali coast. In 1455 another Genoese seaman, **Antoniotto Uso di Mare**, sailing in service of Prince **Henry the Navigator** of Portugal, claimed to have met, near the mouth of the Gambia River, with the last descendant of the survivors of the Vivaldo expedition. He was told that the two galleys had sailed to the sea of Guinea; in that sea one was stranded, but the other passed on to a place on the coast of Senegal, where the Genoese were seized and held in captivity.

Rufus, successor to William, even forbade Jews to convert to Christianity because that would "rid him of valuable property and give him only a subject". At one time the Jews sent a deputation begging permission to leave the country. It was refused, because they were still too useful to the treasury. Slowly their wealth was drained out of them, until by the end of the 13^{th} century their financial value was nil. Besides, the Lombards, Italian bankers, had come to England and had taken the place of the Jews in England's economic life. Under the vigorous urging by the Church, the kingdom felt it could get along without them and expelled them. As Jews became essential again to English economy, they began to resettle there under Cromwell in 1657.

A Jewish community lived in *Oxford* since 1090 CE. On Sept 3, 1189, many Jews were killed in a riot that broke during the coronation of Richard the Lion-Hearted. On Jan 31, 1253, Henry II forbade Jews in England to build new synagogues. After the expulsion, their synagogue became a tavern (1309) and is now a part of Christ-Church. Their cemetery (in use 1231–1290) is now part of the Botanical Gardens and of Magdalen College.

Time Reckoning in Antiquity

In the ancient Near East and the world of Greece and Rome, all systems of time reckoning used cues provided by the periodic motions of the earth, sun and moon, which functioned as time-standards. Two parallel systems of time-reckoning were recognized. The first, known already to dynastic Egypt, consisted, like our modern one, of 24 hours of equal length and used by astronomers ('equinoctial hours' or 'equal-day hours').

In the second, known as 'seasonal hours' or 'temporal hours' [which Herodotos attributed to the Babylonians] the period of daylight is divided into 12 hours and the night into 12 hours or 'watches'. Consequently, the length of the hour depended on latitude and season.

The interval between two successive returns of a fixed point on the sphere to the meridian is called the sidereal day, *and* sidereal time *is reckoned from the moment when the vernal equinox passes the meridian, the hours being counted from* 0 *to* 24*. Clocks and chronometers regulated to sidereal time are only used by astronomers, to whom they are indispensable, as the sidereal time at any moment is equal to the* right ascension *of any star when just passing the meridian. For ordinary purposes solar time is used.*

The solar day, as defined by the successive returns of the sun to the meridian, does not furnish a uniform *measure of time, owing to the slightly variable velocity of the sun's motion and the inclination of the orbit to the equator, so that it becomes necessary to introduce an imaginary* mean sun *moving in the equator with uniform velocity. The* equation of time *is the difference between apparent (or true) solar time and the mean solar time. The latter is that shown by clocks and watches used for ordinary purposes. Mean time is converted into apparent time by applying the equation of time with its proper sign. (As the equation of time varies from day to day, it is necessary to take this into account, if apparent time is required for any moment different from noon.)*

While it has, for obvious reasons, become customary in all civilized countries to commence the civil day at midnight, astronomers count the day from noon, being the transit of the mean sun across the meridian. The ancient astronomers, although they left us ample information about their dials, water or sand clocks, and similar timekeepers, are very reticent as to how these were controlled. ***Ptolemy****, in his* Almagest*, states nothing whatever to show how the time was found when the numerous astronomical phenomena which he recorded took place.*

However, ***Hipparchos*** *gives a list of 44 stars scattered over the sky at intervals of right ascension equal to exactly one hour, so that one or more of them could be on the meridian at the commencement of every sidereal hour. (It has been shown that the right ascensions assumed by Hipparchos agree within about* $15'$*, or one minute of time, with those calculated back to the year 140 BCE from modern star-places and proper motions.) The accuracy which, it thus appears, could be attained by the ancients in their determinations of time was far beyond what they seem to have considered necessary, as they only recorded the hours of astronomical phenomena (e.g. eclipses, occultations) without ever giving minutes.*

The Arabs had a clearer perception of the importance of knowing the accurate time of phenomena, and on observing lunar eclipses, never failed to measure the altitude of some bright star at the beginning and end of the eclipse. A sketch of the principal method of determining time is as follows:

In the spherical triangle ZPS *between the zenith* (Z)*, the pole* (P) *and the star* (S)*, the side* $ZP = 90^\circ - \phi$ *(*ϕ *being the latitude),* $PS = 90^\circ - \delta$ *(*δ *being the declination) and* $ZS = \zeta = 90^\circ -$ *observed altitude. The angle* $ZPS = t$ *is the star's hour angle or, in time, the interval between the moment of observation and the meridian passage of the star. We have then*

$$\cos t = (\cos\zeta - \sin\phi\sin\delta)/\cos\phi\cos\delta.$$

This formula can be made more convenient for the use of logarithms by putting $\zeta + \phi + \delta = 2S$*, which gives*

$$\tan^2\left(\frac{1}{2}t\right) = \sin(S-\phi)\sin(S-\delta)/\cos S\cos(S-\zeta).$$

According as the star was observed west or east of the meridian, t *will be positive or negative.*

The sidereal time $= t + \alpha$*, (where* α *is the right ascension) and* δ *are taken from an ephemeris. If the sun had been observed, the hour-angle* t *would be the apparent solar time. The latitude observed must be corrected for refraction, and in the case of the sun also for parallax.)*

Time in antiquity was kept by sundials, sand-clocks or water-clocks which were the only mechanical time-recorders. Of these, the sand clock is the earliest timekeeper independent of celestial bodies, but is inefficient for measuring time for more than a limited duration.

A combination of water-clock and mechanical clock appeared for the first time in China (1092), but totally mechanical clocks (that is, clocks equipped with a weight drive setting a train of wheels in motion with a simple oscillatory escapement) appeared for the first time in Western Europe in the late 13^{th} *century.*

The English word 'clock' is related to the French word 'cloche', meaning a bell. Bells played an important part in medieval life, and it is probable that mechanisms for ringing them, made of toothed wheels and oscillating levers, paved the way for the invention of mechanical clocks. The earliest public clock known on the European continent outside Italy was constructed at the Strasbourg cathedral in 1352. *The builder (unknown) worked at it for two years. Nothing remained of that old clock except the rooster, preserved in the Frauenhaus, Strasbourg.*

Chaos and Misery[95] (1300–1450)

The 13^{th} *century represented the acme of scholastic thought and medieval culture. Contributions of the time to literature, philosophy, science, and the pure and applied arts rose to the highest levels since antiquity. But what advance could be anticipated during the* 14^{th} *century, during which the decline in learning was accelerated by war and pestilence?*

Yet, strangely enough, the century seems to have been responsible for more striking additions to science and technology than was its predecessor. Gunpowder, the compass, spectacles and mechanical clocks may have been adumbrated before 1300, but it was the 14^{th} *century which saw their effective introduction into European civilization.*

In mathematics *the graphical representation of functions, and in* physics *the revival of the concept of impetus or inertia and the suggestion of new laws for the motion of a freely falling body, are among the outstanding examples of the development of scientific thought of the time.*

---

[95] For further study, see:

- Tuchman, Barbara W., *A Distant Mirror*, Ballantine Books: New York, 1978, 677 pp.

In the 14^{th} *century there was hardly a place, certainly not a country in Europe which was ever free for a whole year from war, plague, or starvation. No place was ever delivered from fear for a single day, for to the natural fears caused by physical calamities, wars, revolts, and general lawlessness were added the artificial fears bred by superstitions and unreason. One could possibly escape natural miseries, but no one could escape the nightmares of his own mind: devils, witches and evil eye.*

The Church dominated everything and every person. Every action or idea had its theological aspect; every form of nonconformism, or protest was construed as heresy. Thus, anything concerning the church would affect everything else.

From 1305 *to* 1377 *the papal court was removed from Rome to Avignon, in Southern France, to escape the turmoil which was raging in Italy (the so-called 'Babylonian Captivity'). This was followed by the Great Schism (1378–1417), dividing Western Christendom into two hostile parties which excommunicated each other (*popes *in Rome and* anti-popes *in Avignon). All this shattered the spiritual basis of Europe; people began to wonder and doubt, and the Church was so weakened that it was unable to resist the greater and lasting Schism which was to occur a century later. The Great Schism was, indirectly, one of the main causes of the Reformation.*

The most obvious cause of the troubles of the last medieval centuries was economic depression*; by* 1300*, Western Europe had reached the limit of its capacity to produce food and manufacture goods. There were no more reserves of fertile land to bring into cultivation. For many years there was no significant increase in industrial output; most towns barely held their own (the Italian towns fared better due to increased Mediterranean trade on account of the Crusades). Until Europe found new markets and new forms of production, economic stagnation created a climate hostile to innovation and efforts to cooperate for the common welfare. Each individual, community or class was eager to preserve the monopolies and privileges that guaranteed it some share of the limited wealth available.*

Economic weakness led to weakness of most governments. Rulers were always short on money, for the old taxes brought in less and less and it was very difficult to levy new ones. Salaries of government officials were low and most officials supported themselves by taking fees, gifts, and bribes from private citizens. Secular rulers had neither the ability to make realistic plans for the welfare of their people, nor the authority to impose such remedies as they did devise. Most secular rulers could think only of increasing their revenues by conquering new lands or robbing their own wealthy classes[96]*. Such a policy solved no problems; it merely postponed them for the victor*

[96] In France, for example, Philip the Fair (Philip IV, reigned 1285–1314) expelled

and aggravated them for the vanquished. With governments discredited by futile and costly wars, many men lost faith in their political leaders and turned to rebellion and civil war.

The leaders of revolt were members of the landed nobility, who still had wealth and influence though they had lost their old rights of feudal government. Their main purpose was to preserve their privileges or to direct government revenues to their own pockets. The other classes fared no better than the nobles. The bourgeoisie were inept at running their own municipal government.

The townsmen split into factions – old families against new families, rich against poor – and the faction in power tried to ruin its opponents by discriminatory taxation. As a result, local self-government collapsed in town after town. As for the peasants, they were far more restive and unhappy than they had been in the 13^{th} *century. With no new lands to clear and no new jobs to be had in the towns, they had little hope of improving their lot. Some of them managed to ease the burden of payments and services to landlords by renegotiating their leases or by moving from one estate to another. The peasants rebelled in country after country, killing landlords, burning records, and demanding that payments for their lands be lowered or abolished altogether.*

Feudal institutions were thus breaking down everywhere with lords ground between the royal yoke on the one hand, and the growing independence and insubordination of the townspeople on the other. The feudal world was on the decline. Its two pillars, the papacy and the kingship, were crumbling.

The main series of wars was the Hundred Years' War (1337–1453) between England and France. Those wars were fought on French territory, aggravated by civil wars among the French people, and caused much misery. It has been estimated that 1/3 of the French population was destroyed; the destruction of wealth was at least as great.

One of the main causes of chaos and misery was the existence of mercenary troops, recruited by captains from among the most lawless and restless elements of many nations. These companies were hired by princes or towns when the latter needed military assistance, and discharged when the need was over. In times of peace between two campaigns, however, these companies, drawing no pay, robbed and tormented the peasants, and sacked or blackmailed the cities.

---

the *Jews* (1306) and confiscated their money. He then cooperated with Pope Clement V (French too) and the Inquisition to abolish the wealthy *Order of the Knights Templar* and made their treasury a section of the royal finance administration (1307–1312).

The effects of economic depression, political confusion and religious uncertainty were intensified by terrible outbursts of the bubonic plague, known as the Black Death (1347–1400). The panic caused by the plague drove the sorely tried people of Western Europe into emotional instability. It is no accident that the bloodiest peasant rebellions *and the most senseless* civil wars *took place after the plague, and that the* witchcraft delusion, *unknown in the early Middle Ages, then reached its height. Innocent men and women were falsely accused of practicing black magic. The rationalism and confidence in the future that had been so apparent at the height of medieval civilization were gone.*

Concurrent with the economical regression of Western Europe, there appeared a new military danger in the East – the Turks. The Turks arose in Central Asia in the 6^{th} *century CE. They converted to Islam in the* 9^{th} *and* 10^{th} *centuries, and in the* 11^{th} *century began to attack the Byzantine Empire. Under Osman I, the Turks advanced towards the heart of the Empire through gradual infiltration. Later, in a series of military campaigns (1317–1340), they completed the conquest of Anatolia and the Black-Sea ports with the exception of Constantinople. In* 1345, *these* Ottoman Turks *first crossed into Europe, and by* 1400, *under Bayazid I, they were in partial control of the Balkans, challenging the Mediterranean commercial lines of Venice and Genoa, and had Constantinople under siege.*

Another Turkish Muslim tribe, under Timur (Tamerlane, ca 1336–1405), began (1370) a long series of raids and wars, conducted with incredible energy and ferocity. Timur conquered, destroyed, and decimated many of the leading cities of his time: Isfahan (1387), Edessa, Moscow (1395), Delhi (1398), Aleppo, Damascus, Baghdad (1401), Bursa, Smyrna (1402). In many places he built pyramids of human skulls to serve as warnings. His expeditions and conquests influenced the whole of Asia and Eastern Europe, either directly or indirectly through the nomadic populations which were hustled out of their usual territories, or through the sedentary populations which were uprooted and violently displaced.

The Timurian invasions caused a fantastic reshuffling of Asiatic cultures, because whatever blows Timur delivered were transmitted from one end of Asia to another with incredible speed due to the extreme mobility of nomadic tribes. Thus, the Arabic cultures of the Middle East [already weakened by the destruction of Baghdad by Hulagu (1258), the Black Death (1348, 1381), and the Turkish Hegemony] suffered upheavals and decline in 1393 *when Timur conquered and sacked Mesopotamia and Baghdad (its population nearly exterminated!).*

Consequently, the destruction of the Eastern Islamic world begun by

Jenghis Khan in the first half of the 13^{th} *century, was completed by Timur*[97] *a century and a half later. It never recovered from this calamity.*

In 1400 *Timur invaded Anatolia and challenged Bayazid for the leadership of the Turkish peoples. A military confrontation was inevitable: on July* 20, 1402, *the two armies met at Angora (Ankara), with nearly one million combatants on either side. The Ottomans were completely defeated, and Bayazid was captured. Fortunately for Europe, Timur turned east, to conquer China, and died in* 1405 *before embarking on this mission.*

The Ottoman Turks, however, made a rapid recovery: by 1453, *Constantinople was taken and soon became the Turkish capital.*

The misery that befell the population of Europe was amplified in the case of the Jews. In 1306 *they were expelled from France, in* 1348 *from Germany, in* 1349 *from Hungary, in* 1394 *from Provence, in* 1421 *from Austria, in* 1492 *from Spain, in* 1495 *from Lithuania, and in* 1497 *from Portugal.*

1295–1318 CE **Rashid al-Din Fadlullah** (1247–1318, Persia). Physician, theologian and historian. Of Jewish descent. Physician to the Mongol sovereigns of Persia in Tabriz. Vizier of the empire (from 1298). Composed encyclopedic universal history *Jami al-tawarikh* ('Collection of chronicles').

Held office under the Mongol sultan Abaqa Khan and his successors Ghazan, Uljaytu and Abu Said. The envy aroused by his great wealth and grandiose benefactions enabled his enemies to procure first his deposition from office and then his execution on the charge of having poisoned Uljaytu.

His great history was begun as a history of the Mongols at the invitation of Ghazan Khan, who put the state archives at his disposal, and continued as a universal history, for Uljaytu. The work is notable for impartiality, clarity of style, and the wide range and authority of its sources.

[97] Timur's raids also finished the destruction of the irrigation system which had made the Mesopotamia of earlier days a paradise. It is said that in Sassanian times (before the Muslim conquest) a squirrel could travel from Seleucia to the Persian Gulf without ever having to come to ground. The canals and ditches without which the earth lost its fertility were neglected or destroyed, and gradually disappeared. Timur completed the job.

1297–1307 CE **John Duns**[98] **Scotus** (1265–1308, Scotland). Philosopher. One of the earlier forerunners of the scientific method. A Franciscan monk. Probably born in the Scottich village of Duns. He was educated at Oxford and the University of Paris. He taught theology at Oxford (1301) and at Paris (1303), and died at Cologne. He is most noteworthy for his criticism of the views of Augustine and Aquinas, for which he suffered great personal ridicule; his name was disparaged by his opponents who, after his premature death, publicly burned his books and distorted the meaning of his doctrine.

Duns Scotus emphasized separation of philosophy from theology, of reason from faith, of independent thought from dogma. Contrary to his own expectations, the movement generated by his thought (*Scotism*) led away from the Church rather than toward it. His insistence on demonstrative proof (perhaps because of a mathematical background in his Oxford education) led him to a demarcation between rationalism and empiricism that has followers among modern philosophers. He taught that philosophy must be regarded as a science, within which logic is given a scientific realm of its own. He anticipated aspects of *Gestalt psychology*, *Gegenstands theory* and *Existentialism*. In several of his views, Duns Scotus was inspired by **Shlomo Ibn-Gabirol**'s *Fons Vitae* (Source of Life, ca 1050) which influenced many Franciscans.

In spite of his great success as a teacher, both in London and Paris, he was removed from Paris to Cologne (1308) due to jealousy and in the same year died of apoplexy (according to some tradition he was buried alive).

Since the middle of the 19^{th} century, Duns Scotus has been ranked among the important thinkers of the Middle Ages. His influence has continued into modern philosophy down to the present.

William of Ockham was one of his disciples.

1298–1338 CE Ritual-murder accusations (*blood libels*) and *Host-desecration* in libels lead to massacres of Jews in Southern and Central Germany in the name of God and for the sake of their pockets. In 1298, more than 15,000 Jews were killed and 146 communities destroyed in six months. Among the communities affected were Röttingen, Würzburg, Nüremberg and Bavaria. Again, during 1336–1338, 10,000 more were killed and 120 communities were destroyed.

The pattern had been set, and in the ensuing two centuries *ritual-murder accusations* against the Jews reached epidemic proportions throughout the

[98] The stubborn opposition of Scotists to classical studies of the Renaissance gave rise to the use of the word *dunce* for pedant or blockhead. It signifies the age-old contempt in which his posterity has held the man who dared criticize Aquinas.

continent. By the 15^{th} century, ritual-murder accusations had died out, although they were briefly revived in the 17^{th} century Poland and late czarist Russia. *The stealing-of-the-Host* hysteria reached its height in 14^{th}-century Germany. By the end of the century, Host-stealing accusations also died out. The Jews had began to flee Germany, and the rulers, seeing the economies of their duchies stagnate, quickly stopped the canard by hanging those who spread such false accusations. The Jews were invited to return, with assurances that such charges would never again be brought against them again.

The Germans, perhaps because they were still closest to the barbaric strain, which had nursed them, were the most barbaric in their persecutions. Most of the anti-Jewish measures are popularly attributes to the entire Middle Ages were of German-Austrian origin, and grew only on German soil. Here the ritual-murder charges, the Host-desecration libels, and Black Death accusations were used to whip the population into a frenzy by sadists and fetishists.

It was here in Germany that the cheating of the Jews reached its noblest and purest forms. Local German princes enticed Jews to their realms under sacred promises to protect them and solemnly gave them liberal charters, swearing on the cross they meant it all, only to rob them later of their wealth, confiscate their land, and then sell them protection, gangster style. One can marvel that in spite of it all, the Jewish spirit survived, and Jewish culture life continued. Talmudic learning still exerted its power, something realized by Jean-Jacques Rousseau, who wrote in his *Social Contract* (1762):

"*Through it alone* [*the Talmud and its ritualistic legislation*] *that extraordinary nation so often subjugated, so often dispersed and outwardly destroyed, but always idolatrous of its Law, has preserved itself unto our days... Its moves and rituals persist and will persist to the end of the world...*".

1299 CE The city of Florence passed an ordinance prohibiting the use of the new Hindu numerals (i.e. 1,2,3,4,5,6,7,8,9,0) since they were more easily altered (e.g. by changing 0 to 6 or 9) than Roman numerals or numbers written out in words[99].

ca 1300 CE **Dante Alighieri** (1265–1321, Italy). Poet. Urged a reform in the Julian Calendar for its being out of step with the tropical year by more than a week.

---

[99] As late as the end of the 15^{th} century, the Mayor of Frankfurt ordered his officials to refrain from calculating in Hindu numerals. Even after the decimal numeral system was well established, Charles XII of Sweden (1682–1718) tried in vain to ban the decimal system and replaced it with a base 64 system, for which he devised 64 symbols!

1303 CE **Chu Shih-Chieh** (ca 1270–1330, China). Mathematician. In a text marking the peak of Chinese mathematics, Chu presented an iteration scheme for solving equations (used up to degree 14) rediscovered by Horner and Ruffini. It also contains *Pascal's triangle* and gives explicit formulas for summation of series of polygonal numbers.

1304–1310 CE **Dietrich (Theodoric) of Freiberg** (ca 1250–1311, Germany). Dominican scholar, optician, meteorologist and philosopher. In his book *De iride* (On the rainbow), he reports on his experiments with globes of water and correctly explains many aspects of rainbow formation. According to Dietrich, the rainbow arises due to two refractions and one reflection of solar rays. The first refraction occurs when the light ray first enters a raindrop, the reflection occurs within the raindrop, while the second refraction occurs as the ray exits the raindrop. He explains the less-frequent secondary arcs as resulting from *double* reflection of light rays entering near the bottom of the raindrop[100].

Dietrich had also made simple experiments on the dispersion of light by crystals, some 362 years before Newton.

Dietrich was a Teutonic member of the Order of Preachers. He had been a professor of theology in Germany, and the author of at least 30 works on metaphysics and optics, of which about a dozen are now lost. From 1285 to 1296 he was the Dominican master of the large province including Germany, Austria and the Low Countries. He then earned the degree of Master of Theology at Paris (1297). In 1304 he was sent as German elector to the General Chapter of the Order; and in this year at Toulouse he undertook, at the instigation of the Master-General, Aymeric de Plaisance, his work on the rainbow. In 1310 he went to Paris as Master of Theology. After 1311 there is no further information about him, from which one may conclude that this is approximately the year of his death.

1305 CE Spain banned the study of all science. Among the first victims of the *Inquisition* were Christian scientists. Since this was done *before* the Renaissance could gain a foothold in that country, no major scientific discovery had been made in the Iberian Peninsula.

[100] It is remarkable that Dietrich's theory of the rainbow was proposed at about the same time by the Persian **Qutb al-Din al-Shirazi** (1281). A complete explanation of the main rainbow could only be given after the genesis of colors had been correctly explained by Newton in 1672, and this was done by Newton himself in 1704. So Dietrich and al-Shirazi went just as far as it was possible to go without knowledge of the exact law of refraction and the *dispersion* of light.

1306–1322 CE **Estori ben Moshe ha-Parhi** (1280–1355, France and Israel). Physician, translator, geographer and natural historian. First scientific topographer of Israel. His family originated in Florenzia, Andalusia, hence the name Parhi [= flower in Hebrew]. He studied in Montpellier under his relative **Yaacov ben Machir Ibn Tibbon**. When the Jews were expelled from Montpellier (1306) he moved to Barcelona, Toledo and finally to Egypt. He then proceeded to Israel (1313) and established himself in Beth-Shan in the Jordan Valley, near the Sea of Galilee. He spent some seven years (1313–1320) in studying Israelian topography. This work he completed in 1322 and described in his book *Kaftor u-Perah*. In it, he was the first to try to identify systematically Biblical, Talmudic and Arabic place names. His work is valuable also from the point of view of archeology and natural history (botany, zoology, history).

While in Barcelona, ha-Parhi translated into Hebrew medical and astronomical treatises. His astronomical knowledge was derived from Avraham bar Hiyya and Yaacov ben Machir. He was acquainted with the writings of Hippocrates, Galen, Aristotle and Ptolemy.

1316–1343 CE **Levi ben Gershon**, or **Leo de Banelis**, or **Gersonides**; known also as RALBAG (1288–1344, Perpignan and Avignon, France). Mathematician, astronomer, physicist, philosopher and physician. One of the leading mathematicians and astronomers of the European Middle Ages. Was first to apply the algebraic algorithm of mathematical induction, if not actually inventing it. Foreshadowed Copernicus in his firm objection to the Ptolemaic system. Stressed the importance of the sine function; emphasized the importance of plane trigonometry and developed it, including the *law of sines*. In his book 'Sefer ha-mispar' ('Book of Numbers') he calculated, for the first time, the number of permutations of n objects, taken r at a time, and the number of combinations of n objects taken r at a time[101]. He proved his results by the *method of induction*[102] (1321), a hitherto unknown principle, first used by him.

---

[101] Levi's results, in modern notation, are: $P_{n,n} = n!$, $P_{n,r} = n(n-1)\cdots(n-r+1)$, $C_{n,r} = \frac{P_{n,r}}{P_{r,r}}$. He also found that $\sum_n n^3 = (\sum_n n)^2$, and proved that the numbers 2^n, 3^m differ by more than a unit, except for $(n,m) = (1,0),(1,1),(2,1),(3,2)$. This latter theorem has connections with Fermat's Last Theorem through the so called "ABC conjecture" – a topic of great interest among number theorists.

[102] The first to *formulate* the principle of mathematical induction was **Francesco Maurolico** (1575).

The *Principle of Mathematical Induction*: If for a given assertion $P(n)$ we can prove that:

1°. The assertion is true for $n = 1$;

2°. If it is true for index $n = k$, then it is also true for index $n = k + 1$;

Levi invented a new astronomical instrument bearing the name *cross-staff*. [It is a long graduated staff with a short perpendicular crosspiece, later called *transversary*. To measure an angle, e.g., the altitude of the sun, the observer holds the staff in his hand and, sighting from one end of it, moves the crosspiece until one end touches the horizon and the other the center of the sun.] It remained for centuries one of the main tools of navigation.

In physics he completed the invention of the *camera obscura* (Alhazen, 1026) in the sense that he rationalized it, popularized it, and tried to account for the dimensions of the images. He then used the camera and his cross-staff to determine more exactly the variation in the apparent diameters of sun and moon. These determinations were important elements in the comparison of conflicting planetary theories.

Levi realized the prodigious distances of the stars from the earth: the stars may be considered as points, their rays as parallel, and the size of their images in the camera depends only on the size of the aperture. He explained how to observe the progress of lunar and solar eclipses. He compiled astronomical tables (1320) and wrote a treatise explaining in detail the motion of stars and planets, criticizing the Almaghest and the leading medieval Arab astronomers, whose observations and calculations he corrected. As his astronomical writings were soon available in Latin and were very well received, he influenced Western astronomy strongly and rapidly.

Then the assertion is true for every positive integer n.

Consider for example the inequality $2^n < n^{10} + 2$. It is found to be true for all $n < 59$, but $2^{59} \approx 5764 \times 10^{14} > 59^{10} + 2 \approx 5111 \times 10^{14}$. It is not hard to prove that the inequality is *false* for all $n > 59$.

Another example, this time from geometry, also serves to show how intuitional induction may lead us astray: n points are marked arbitrarily on the circumference of a circle, each joined to all others by straight lines. What is the maximum number of regions formed altogether? Simple counting yields for the first five cases the sequence 1, 2, 4, 8, 16 and one would have liked to stop explicit construction there, hoping that $a_n = 2^n$. But alas! The next term for $n = 6$ is 31, breaking the convenient pattern. The general formula, obtained via induction, is

$$\frac{1}{24}(n^4 - 6n^3 + 23n^2 - 18n + 24) \equiv n + \binom{n}{4} + \binom{n-1}{2}.$$

It yields the following sequence for $n = 1, 2, \ldots, 12$:

$$1 \quad 2 \quad 4 \quad 8 \quad 16 \quad 31 \quad 57 \quad 99 \quad 163 \quad 256 \quad 386 \quad 562 \quad \cdots$$

Pascal borrowed the idea from Maurolico and clarified it in his *Traité du triangle arithmétique* (1655) [*Bull. Amer. Math. Soc.* **16**, 70–73, 1910; *Amer. Math. Mont.* **24**, 199–207, 1917].

Yet, he shared with his Arabic, Latin, and Greek contemporaries and predecessors the inability to use the zero and the positional decimal notation, and used no numerals except Hebrew letters.

He was born at Bagnols in Languedoc, the maternal great grandson of **Nahmanides**. Little is known of his life. His family had been distinguished for piety and exegetical skill, but though he was known in the Jewish community for his commentaries on certain books of the Bible, he never seemed to have accepted any rabbinical post; the freedom of his opinions may have put obstacles in the way of his advancement. He is known to have been at Avignon and Orange during his life. Part of his writings consists of commentaries on the portions of Aristotle then known. Some of these were printed in the early Latin editions of Aristotle's works.

His most important treatise, which secured him a place in the history of science, is entitled *Milhamot Adonai* (The Wars of God), and was thirteen years in the making (1316–1329). A portion of it, containing an elaborate survey of astronomy as known to the Arabs, was translated into Latin in 1342 at the request of Pope Clement VI. Medieval astronomers have used the astronomical instruments invented by him. On account of his boldness and the suspicion of heresy that clung to him, *Milhamot Adonai* was a forbidden book[103]. There is evidence that Spinoza was influenced by the writing of Gersonides.

1320–1330 CE **Maximus (Manuel) Planudes** (1260–ca 1330). Prominent Byzantine scholar and mathematical writer. Author of numerous works, among them two books on the *Arithmetic* of Diophantos and arithmetic based upon Hindu-Arabic numerals. Planudes possessed a knowledge of Latin at a time when Rome and Italy were regarded with hatred and contempt by the Byzantines. By his translation, he paved the way for the introduction of the Greek language and literature into the West.

He seems to have been among the first of the mathematicians to use the word *million*[104], which is not found anywhere before the 13^{th} century.

---

103 Levi ben Gerson was the intellectual product of Greek-Arabic thought that streamed from Babylonia, Alexandria and Spain. Both the content and method of his religious writings were influenced by his training and outlook as mathematician, astronomer and philosopher. The orthodox followers of **Rashi** rejected his daring discussions of religious matters.

104 One of the most striking features of ancient arithmetic is the rarity of large numbers. There are exceptions, as in some of the Hindu traditions, in the records of some of the Babylonian tablets, and in the *Sand Reckoner* of Archimedes, with its number system extending to 10^{63}, but these are all cases in which the élite of the mathematical world were concerned; the people, and indeed the substantial

Planudes was born at Nicomedia in Bitynia (Asia Minor), but the greater part of his life was spent in Constantinople, where as a Greek Orthodox monk he devoted himself to study and reading. At one time he was appointed (1327) ambassador to Venice.

His arithmetic is of value chiefly as showing the influence of Baghdad upon the mathematical thought of Constantinople.

1320–1340 CE **Yosef Caspi ben Aba Mari** (Don Bonafous de Largentra, 1297–1340, France). Philosopher, grammarian and exegete. Maintained that natural phenomena can sometimes violate the laws of nature over small intervals of time[105]; he used this argument to render a *logical explanation* to biblical miracles.

Caspi was born in L'Argentiere[106], Southern France and died in Tarascon. He traveled much, visiting Spain, Majorca and Egypt. He was one of the most prolific writers of his age.

In his *Will and Testament*, which he wrote in 1332, he described his travels and his studies, shedding much light on the literary and religious conditions of the period as well as expressing his personal views on philosophy and theology. He wrote no less that twenty-nine works (most of which are still extant in manuscripts), mainly on philosophy and logic.

ca 1325 CE *Invention of firearms*. The use of cannons and guns[107] implied not only the availability of quality gunpowder, a task for the alchemist, but

---

mathematicians in most cases, had little need for or interest in numbers of any considerable size. By the 15^{th} century the 'million' was known to the Italian arithmeticians, and first appeared in print in 1478. Until the World-War of 1914–1918 taught the world to think in *billions* (10^9) there was not much need for number names beyond millions (except in physics and astronomy).

105 *Example*: In hindsight we can say today that classical physics fails to explain the *shining of the sun* (!) and that the sun shines by a quantum 'miracle' namely, by *proton tunneling*: there is an electrostatic repulsion barrier preventing hydrogen nuclei from fusing to form Helium. Indeed, the probability of fusion per encounter between two hydrogen nuclei in the sun is shown to be 10^{-434}. However, with tunneling, probability rises to 10^{-20}, but since there are ca 10^{57} hydrogen nuclei in the sun's core, fusion happens to each hydrogen nuclei some of the time. i.e. the 'miracle' occurs to *some* nuclei at any given time.

106 Hence the Hebrew equivalent: *Caspi* = made of silver.

107 The list of munitions at Windsor Castle in 1330 mentions a "large ballista" called *Lady Gunhilda*, which gives us our *gun*. *Mortar* was an alchemist tool. The word *cannon* is derived from the Hebrew-Greek *qaneh*, *kanna* = reed, since

also the making of guns, a task for the armorer, blacksmith and founder. It hinged on the progress made in the 13^{th} and 14^{th} centuries by the workers in brass and bronze. The art of the founder, however, remained a very subtle one, full of pitfalls and of secrets. As with gunpowder, it is unknown where or by whom the discovery was made that exploding gunpowder could exert a propelling force and drive a body through the air. We do, however find an illustration of a primitive gun in a manuscript of 1327; moreover, there was a powder-works at Augsburg in 1340, and both gunpowder and cannons were being manufactured in England in 1344, and probably earlier.

The use of explosive power for the propulsion of projectiles, and the inventions of guns and mortars, probably originated in Germany[108] during the third decade of the 14^{th} century – at about the same time in various places. By the end of the 14^{th} century, firearms were being manufactured all over Europe. By the middle of the 15^{th} century, artillery would become a decisive weapon against feudal stone castles and the traditional curtain walls of towns.

The abundance of references to the cannon in accounts of various sorts is very remarkable. They are mentioned in the archives and chronicles of England, France, Spain, Italy, Germany, Flanders, etc. Those early firearms were very inefficient and did not make much impression, either military or psychological. The revolution brought about by their use was very gradual; it was not fully realized until the 16^{th} century. Indirect evidence of that slowness is provided by the continued popularity of armor. The day would come when armor would no longer protect the bodies of men and horses, but that day was still very distant, and in fact the period 1400–1550 was the golden age of armor.

1325–1354 CE **Muhammad Ibn Battuta** (1304–1369, Morocco). One of the greatest travelers in medieval times. During his 29 years of travel he covered, at the very least, some 120,000 thousand kilometers by land and sea

---

cannons had the form of a long hollow tube.

The ballista was not necessarily a gun, and could be used for throwing stones and inflammable substances. We know for sure that cannons were used by the English at the siege and capture of Calais in 1347, but they could have been used as early as 1327 by Edward III in his war against the Scots.

108 The discovery of gunpowder and firearms is sometimes attributed to a legendary monk known as '**Berthold der Schwarze**' who flourished in Freiburg im Breisgau, and made his invention in 1380. Since firearms, not to speak of gunpowder, had already been invented by that time, he may at most have introduced some improvements. Since there is no evidence of this either, we are led to assume that he was the symbolic incarnation of the popular conception of a satanic environment characterized by flashes of fire and the smell of brimstone.

(not counting detours), and visited all the Islamic lands, India, China, Africa, Siberia, Russia, the Balkan and Spain. On his return the Sultan of Morocco provided him with a secretary, who transcribed and corrected his manuscripts.

He had seen more of the known world than any man before him, and much more than the most indefatigable travelers since his time; even the list of the regions and cities he visited resembles a gazetteer. His point of view was never that of a geographer or a historian. He was not interested in nature, but very much so in people, yet his account has considerable geographical and historical value, natural history included.

Ibn Battuta was born at Tangier (Tunisia) to the Berber tribe of the Lawata (Tunisia) into a respected family of scholars and Islamic judges (qais). At the age of 21, after finishing his education, he set out to make the pilgrimage to Mecca. Along the way, the young man studied under well-known scholars of Islam. These studies qualified him to become a judge.

In 1326, Ibn Battuta completed his first pilgrimage to Mecca. But instead of returning home, he decided to see as many parts of *Dar al-Islam* as possible, vowing never to travel the same road twice. In 1333, Ibn Battuta arrived in India after traveling through much of west Asia. Here too, he was well-received by the sultan of India. The sultan honored him with feasts and gifts and gave him an important position as grand judge of the capital. After seven years in India, the sultan appointed the traveler as ambassador to China.

Even this famed traveler was greatly impressed by China: "*China is the safest, best regulated of countries for a traveler. A man may go by himself on a nine-month journey, carrying with him a large sum of money, without any fear. Silk is used for clothing even by poor monks and beggars. Its porcelains are the finest of all makes of pottery and its hens are bigger than geese in our country.*"

He was surprised by the well-established Muslim community he found in China's ports. China's first mosque was built 350 years before his arrival. Muslim merchants had come to live permanently in China to manage the far end of their businesses. They had grown wealthy, built mosques and developed into a thriving community.

After his return in 1354 he was appointed a qadi in Fez and died there.

1327–1335 CE **Richard of Wallingford** (1292–1336, England). Mathematician contributed to astronomy, horology[109] and trigonometry, but is best known for the *astronomical clock* he designed (1327).

[109] To dig deeper, see:
- North J., *God's Clockmaster: Richard of Wallingford and the Invention of Time*, Oxford Books, 2004.

Richard was born, the son of a blacksmith, at Wallingford in Berkshire (now Oxfordshire) in England. He studied 15 years at Oxford University before becoming abbot of St Albans. The clock was completed about 20 years after his death (1356) by William of Walsham, but was destroyed during Henry VIII reformation and the dissolution of St Albans abbey (1539).

Richard also designed and constructed a calculation device, known as *equitorium* (which he called *Albion*). This could be used for astronomical calculations such as lunar, solar, and planetary longitudes and could predict eclipses.

He died from what was then thought to be leprosy (although it might have been syphilis, scrofula or tuberculosis).

1327–1367 CE **Francesco Petrarca, Petrarch** (1304–1374, Italy). The most remarkable man of his time: Poet, and first true reviver of learning in medieval Europe. Exerted great influence upon his contemporaries.

Although not a man of science himself, he was instrumental in bringing about the downfall of scholastic philosophy, a prerequisite for the development of experimental science. He sharply criticized astrology, alchemy, Aristotelianism and Averroism.

Petrarca is considered to be the '*first modern man*'; he was intensely anti-medieval and the first to consider the Middle Ages as *dark ages*. With him began the return to secular ideas – a rebirth of interest in the secular culture of the ancients, in both the arts and sciences, and a break with the clerical traditions of the Middle Ages. Petrarca is rightly called the father of a new *Humanism*[110].

He opened for Europe a new sphere of mental activity. By bringing the men of his own generation into sympathetic contact with antiquity, he gave a decisive impulse to that European movement which restored to freedom, self-consciousness, and the faculty of progress to the *human intellect*. He was the first man to collect libraries, to accumulate coins, to advocate the collection of classical manuscripts. For him the authors of the Greek and Latin world were living men, and the rhetorical epistles he addressed to Cicero, Seneca, and Varro prove that he dwelt with them on terms of sympathetic intimacy.

• Watson, E., *The St Albans Clock of Richard of Wallingford*, Antiquarian Horology, 1979, 372–384 pp.

[110] The medieval science was dominated by preoccupations with *God*. The Renaissance thinkers were more interested in *man*. From this circumstance the new cultural movement derives the name *Humanism*.

Petrarca regarded the orator and the poet as teachers, bound to complete themselves by education, and to exhibit to the world an image of perfected personality in prose and verse of studied beauty.

The life of Petrarca was that of a spectator rather than a participant. He did not actually take part in the administration of government, and did not ever practice a profession, marry or fight a battle.

Petrarca was born in Arezzo to a notary that was banished from Florence. The impoverished family wandered to France and settled in Carpentras. During 1320–1326 Petrarca studied law at Bologna. In 1326 he settled in Avignon and began an ecclesiastical career (he never went further than the minor orders). There he came to the attention of Cardinal Giovanni Colonnas and his brother, the Bishop Giacomo, who where Petrarca's reliable patrons for many years. Through their financial support he improved his social standing, and lead the good life of a carefree traveler and bibliophile (he was a keen collector, hunter and discoverer of manuscripts, including Greek texts he could not read himself).

During 1330–1336 he traveled extensively in France, Germany, Italy, Spain and England, and in 1341 was crowned Poet Laureate by Robert of Naples on Capitoline in Rome. During 1343–1361 he served on papal political missions as ambassador to Naples, Milan, Prague and Paris. He had two children by an unknown woman (son 1336; daughter 1343) which he eventually legitimatized. After 1361 he wandered restlessly about Italy, invited by churchmen, princes and friends. Wherever he found himself, he wrote incessantly, composing new works and polishing old ones, releasing them when he thought them sufficiently elegant to circulate. In 1368 he settled in Arquà[111] with his daughter and son-in-law and died there four years later.

1328–1349 CE *The Oxford Calculators*: a group of four Merton Collage scholars consisting of **Thomas Bradwardine** (1290–1349), **William Heytesbury**, **Richard Swineshead** (also known as Richard Suiseth) and **John Dumbleton**.

These skillful mathematicians and logicians were first to differentiate *kinematics* from *dynamics*. Their studies emphasized *kinematics* and included the concept of *instantaneous velocity*. They were the first to enunciate the *mean speed theorem* which states that a body traveling at constant velocity will cover the same distance in the same time as an accelerated body if its velocity is half the final speed v_f of the accelerated body with constant acceleration a. They were able to demonstrate this theorem even without Galileo's

[111] A village in the Euganean hills overlooking the Adriatic. On the 18^{th} of July 1374, his people found the old poet and scholar dead among his books in the library of his little house.

formulation,

$$\bar{v} = \frac{d}{t} = \frac{\frac{1}{2}at^2}{t} = \frac{1}{2}v_f.$$

Thomas Bradwardine (1328) discussed the issue of the hypothetical free fall of bodies in void and concluded that two bodies of the same material but different size, will fall with the same terminal velocity, contradicting the Aristotelian view that the heavier body falls faster. He was afterwards raised to the high offices of chancellor of Oxford University and professor of divinity. From being chancellor of the diocese of London, he became chaplain and confessor to Edward III, whom he attended during his wars in France.

In 1349 he was appointed archbishop of Canterbary, but died of the plague at Lambeth forty days after his consecration. At about 1350, Richard Swineshead (Suiseth) became the first person to show that a sum of an infinite series may converge to a finite number; specifically, he showed that

$$\sum_{n=1}^{\infty} \frac{n}{2^n} = 2,$$

thus braking the Zeno curse which hang over mathematics for two millennia. (At about the same time the Frenchman **Nicole Oresme** demonstrated the *divergence* of the *harmonic series*.)

1330 CE **William of Ockham** (1285–1349, England). Natural philosopher and logician. One of the most profound speculative minds of the scholastic period. His logico-metaphysical system foreshadowed the trend of science and natural philosophy prevailing today. Followed to its conclusion, his secular attitude would adumbrate our present predisposition towards observation, experiment and theory. Encouraged stronger emphasis on observations, and the separation of science and theology. Advocated the building of a theory on the least number of simple premises necessary for explanation of the facts – "Pluritas non est pondera sine necessitate", which is known as "Ockham's Razor" (principle of economy).

This principle, traceable back to Aristotle and the Jewish *Talmud*, has become one of the foundations of modern science. Thus, when two, otherwise equally successful, theories, compete for explaining a set of observations, the advantage goes to the one theory which rests on the least number of premises.

In accordance with the scholastic legacy of Augustine (354–430) and Thomas Aquinas (1225–1274), the theory of knowledge in all its diverse aspects was completely dependent on theology and ontology. Science in the modern sense of the word was practically unknown, and what did exist was totally subservient to the Church. It is without doubt the inalienable merit of this Franciscan scholar that he sundered anew the calamitous union of faith and reason. The 'razor' clearly entails the rejection of the Platonic conception that universals exist apart from and prior to so-called real things.

Ockham emphasized the distinction between statements referring to language and statements referring to things. Denying independent reality to mere abstractions, he anticipated the phenomenalist and positivist schools and **Mach**'s economy of thought.

We may say that Ockhamism was a powerful factor both in the disintegration of medieval thought and in the slow elaboration of modern science. It became one of the main guides used by scientists to choose between alternative views. It asserts that there is no special virtue in elaborate and complex explanations, as opposed to a few, simple hypotheses that imply the observed facts.

Ockham was born in Southern England. He joined the Franciscans and eventually became prominent in that religious order. Ockham studied at Oxford University and then taught theology. In 1324, Pope John XXII summoned him to Avignon, France, to answer charges of heresy. Ockham remained in Avignon for four years. In 1328 he fled from Avignon to the protection of Louis of Bavaria, who was the Holy Roman emperor and an enemy of the Pope. Ockham lived in Münich, Germany from 1330 until his death.

1332 CE Millions perished in India and China by an outbreak of Bubonic plague.

1337–1345 CE Parching drought with consequential famine in Central Asia and China may have caused and accelerated the migration of rodents carrying the bubonic plague westward into Europe.

Diseases and History[112]

"He that is in the field shall die with the sword; and he that is in the city, famine and pestilence shall devour him."

Ezekiel **7**, 15 (ca 590 BCE)

[112] For further reading, see:

- Cartwright, F.F., *Disease and History*, Dorset Press: New York, 1972, 248 pp.

* * *

"Typhus, plague, cholera, typhoid, dysentery had decided more campaigns than Alexander, Caesar, Hanibal, Napoleon, and the inspector general of history. The epidemics get the blame for defeat, the generals for victory. It ought to be the other way around."

Hans Zinsser

For 10,000 years, since the first hunter-gatherers settled in villages, infections had killed more people than war, natural disasters and famine.

Disease is as old as life. Infection was already ubiquitous when higher organisms left their first fossil traces, some 500 million years ago. Dinosaur bones 250 million years old have marks of bacterial infection, as do the remains of mastodons and saber-toothed tigers. Evidence has accumulated to support the idea that all *complex cells evolved through the merger of simpler ones, in what began as parasitism and ended in symbiosis.*

Indeed, cellular invasions can be witnessed today that resemble those theorized for the past. The adaptation of parasite and host goes through stages called epidemic, endemic, and symbiotic. A germ entering a virgin population – one that is unfamiliar and has few defenses against it – often causes acute diseases in people of all ages. This is the classical picture of an epidemic: *if it involves much of the world, it is called* pandemic. *The survivors are usually left with improved defenses against reinfection; over generations, additional defenses may develop. The disease eventually becomes* endemic, *a widespread, lower-grade infection or routine childhood disease.*

For several millions years, the main causes of human deaths were accidents and wounds. With the coming of sedentary life, nutrition and longevity declined, famine and infection became the leading causes of death. For the next 10,000 years, it was common for microbes to strike people down at every stage from infancy to late life.

Farming, timbering, animal domestication, irrigation, pollutions and other traumas to natural ecosystems have created new breeding grounds for malaria, and such intensional diseases as dysentery and cholera. Plowing, irrigation and fertilizer invited other diseases into Neolithic settlements. Domesticated animals brought new diseases to Neolithic humans. Virtually, every step our ancestors took to increase and vary food supply invited more infections. Furthermore, when they had turned to farming 5000 years ago, a diet heavy in carbohydrates caused their size and health to decline.

Malaria *was not very important until humans created villages; than it became one of the most influential diseases in human history. (It still kills million children each year in Africa and another million in the rest of the world. Together, malaria, schistosomiasis and tuberculosis cause more sickness and death world-wide than any other three infectious diseases). For thousands of years, malaria, sleeping sickness, helminth infections and diarrheal diseases limited the size of human populations.*

The population explosion of the Bronze age, 6000 years ago, took city dwellers beyond a critical threshold. By the late Neolithic, irrigated fertile plains around the world supported cities as large as 100,000 people. These first appeared in the valleys of Tigris and Euphrates in Mesopotamia, then along the Nile in Egypt, the Indus in India, and the Yellow River in China.

Urban masses became sufficiently large and dense to support 'crowd diseases' (zymotic), what in other species are called 'herd diseases'. For the first time, infection became humanity's chief cause of death. (despite a few respites, this would remain true in the West until 20^{th} *century.) The reason epidemics did not take hold until urban times is simply the conditions imposed by numbers. While nomads were not free of infection, their most common diseases were chronic, not acute. People did not live densely packed together, aiding transmission of germs from one person to another. Their settlements were sufficiently far apart, and travel was sufficiently limited, to keep outbreak of diseases localized.*

Furthermore, most bacterial and viral infections with epidemic potential leave survivors temporarily or permanently immune. When such disease did jump from an animal to nomads or villagers, they flashed through the population; soon most of people in a community were either dead or immune. The microbes, having run out of susceptible hosts died off. Only years or generations later could the germ attack successfully again depending on new crop of susceptibles and another accident of reintroduction.

When farmers and villagers began crowding into cities, this immunologically virgin mass offered a feast to germs lurking in domesticated animals, wastes, filth, and scavengers. Countless people were sickened and killed by previously unknown epidemics – smallpox, measles, mumps, influenza, scarlet fever, typhus, bubonic plague, syphilis, gonorrhea, and common cold.

Plague became epidemic only 3000 years ago, when people began to live in large settlements. In the years 1490–1920 *typhus* killed more people than armies had. Thus, from their beginnings until the 20^{th} century, cities have been pestholes. Only when towns became big cities did massive die-off become regular part of human life.

Diseases associated with civilization is older than written history, for civilization of a kind existed before the earliest records were kept. The earliest known textbook of medicine, the Great Herbal *of the Emperor* ***Shen Lung****, dates from about 3000* BCE*, and there is a Babylonian physician's seal of approximately the same date in the Welcome Historical Medical Museum, London. Epidemic fevers are mentioned in the* Ebers Papyrus*, found in a tomb at Thebes (1862) and dated about 1500* BCE.

In the Old Testament (book of Exodus*), there is an account of a plague which smote Egypt about 1500* BCE*. The war-pestilence sequence is well described in* ***Samuel I****. The disease spread throughout Israel, bringing death (ca 1141* BCE*) to about 50,000 people. The plague of Athens (430* BCE*) provides a striking example of the effect of disease upon the course of history. The pestilence is supposed to have started in Ethiopia; from there it traveled to Egypt and was carried across the Mediterranean by ship to Piraeus and Athens. This plague undoubtedly contributed to the downfall of the Athenian empire.*

In general, foci of infections have developed in Mediterranean, Europe, Egypt, Mesopotamia, India and China. Each area, with its own climate, ecosystem, and germs, had a distinctive set of infections, to which people adapted with a distinctive complex of immune defenses. But commerce*,* war *and* travel *caused epidemics to spread across the world and merge all local foci into one. There were more people, bigger armies, better transport.*

Thus, for example, the conquest of South and Central America by the Spaniards in the 16^{th} *century ended with disastrous consequences for the Amerindians: In 1568, less than 50 years after Cortés arrived in Mexico, its total population was decimated from 30 million to mere 3 million. According to one estimate, smallpox alone killed 18 million people in Mexico in the* 16^{th} *century. In Peru, the Inca population sank from 8 million to 1 million. In North America and Australia, the native suffered similar slaughter by the European microbes.*

In the centuries after 1500, exploration, technology, and diseases gave Europe control over much of the world. By about 1700, most of its own diseases had been domesticated to endemics; the traffic of unfamiliar microbes was unidirectional: from Old World to the New. Pandemics, which began with *the Black Death, were now a regular feature of human life and the movement of hosts and pathogens all over the world would keep increasing.*

By the late 18^{th} *century, the Industrial Revolution was under way, and urban population soared. Social changes had never run at such a pace. The shift from nomadism to farming had taken millennia; the rise of industry and the megalopoli spanned only a couple of centuries. From the Neolithic to 1820, world population rose from 5 million to about 1000 million; much of the increase came at the end of the span. After population surges such as those of the Roman era and the Late Middle Ages, famine and plague had erased much of the gains. The growth that began in the* 17^{th} *and* 18^{th} *centuries was unique; it continued at an ever faster pace, and it ran out of control to this day.*

During 1951–1993 new diseases had their first appearance or recognition. Among them Ebola fever, Legionnaires' disease, AIDS. On the other hand, limited or controlled revival became widespread (e.g. Cholera, Diphtheria, Malaria, Syphilis, Tuberculosis). Even in places where they are controlled, they break out lethally when natural disaster, social chaos, or war disrupts modern defense against them.

Table 2.4 lists some historically significant epidemics since the first recorded worldwide plague of 767 BCE.

1332–1364 CE **Ibn al-Shatir** (1306–1375, Damascus). Astronomer. Made valuable astronomical observations with instruments of his own design, and criticized the accepted astronomical theories. He fully realized the need for continued and precise observations if one would discover the true motions of heavenly bodies. He determined the obliquity of the ecliptic[113] at Damascus in 1363/4 to be $23°31'$. (The correct value extrapolated from the present one is $23°31'19.8''$.)

1335 CE **Yaácov ben Asher** (1270–1343, Germany and Spain). One of the great codifiers of Jewish law. Fused three generations of European Talmudic thought into one great code. Through subsequent centuries this

[113] The value obtained by **Ibn Yunus** (990) was $23°35'$. That obtained by **William of Saint-Cloud** (fl. in Paris 1292–1296) for 1290 was $23°34'$ (the value for that year computed by means of LeVerrier's formula is ca $23°32'30''$).

Table 2.4: Historically significant epidemics

Year	Location	Disease	Comments
ca 1350 BCE	Asia Minor, Hittite Empire	unknown	
ca 1235 BCE	Egypt	Bubonic plague	*Exodus* **12**, 29
ca 1050 BCE	Israel	Bubonic plague	*Samuel* **5**, 9-12
767 BCE	Europe and Mediterranean world	Bubonic plague	First recorded world-wide epidemic
480 BCE	Persian army of Xerxes	Dysentery	Herodotos
430 BCE	Ethiopia, Egypt, Athens	Scarlet fever	Thucydides
187 BCE	Egypt, Syria, Greece	unknown	Pliny
79–88	Egypt, Syria, Italy, Rome	Bubonic plague	
165–189	Roman Empire	Smallpox	Galen
251–270	Roman Empire, Rome	Smallpox, measles and malaria	caused mass conversion to Christianity
542–594	Europe, Asia, Africa	Bubonic plague	Old world pandemic; began in Ethiopia and Egypt; millions perish
735–736	Japan	Smallpox	Facilitated spread of Buddism
746–749	Constantinople, Greece, Italy	Bubonic plague	200,000 perish
1097	Near East (1^{st} crusade)	Typhoid fever	100,000 die
1218	Egypt		67,000 die
1235	England		40,000 die
1332–1370	Europe and Asia	Bubonic plague	ca 50 million die; 'Black Death' pandemic;
1408–1551	England	Bubonic plague	("Sweating Disease")
1494–1495	Europe	Syphilis	

Table 2.4: (Cont.)

YEAR	LOCATION	DISEASE	COMMENTS
1507–1595	South and Central America	Smallpox, typhus	ca 80 million natives die
1528–1530	Italy	Typhus	More than 100,000 die
1591	Philippines	Smallpox	
1600	Russia	Bubonic plague	500,000 perish
1590–1711	European cities (Italy, England, France)	Bubonic plague	ca 2.5 million perish
1760–1799	North Africa, Egypt, Syria	Bubonic plague	ca 1.2 million perish
1812–1813	Napoleon's army	Dysentery	ca 500,000 die
1817–1893	Worldwide (5 waves)	Cholera	ca 10 million perish in the pandemic; spread by contaminated water
1851–1855	England	Tuberculosis	250,000 die
1889–1890	Worldwide	Influenza	ca 3 million die; moves with a speed of trains and steamships
1898–1923	China, India, North Africa and South America	Bubonic plague	ca 20 million die
1917–1920	Europe and Asia	Influenza, typhus	ca 25 million die
1921–1923	India	Cholera	ca 1 million die
1926–1930	India	Smallpox	ca 500,000 die
1981–	Worldwide	AIDS	

code formed the cornerstone of Jewish legislation. Moreover, it played a direct and vital part in the creation of the legal system of Western civilization[114]

Ben Asher was born at Cologne, Germany. Due to local persecution of Jews he was forced to flee, with his father (1303), through Savoy and Provence to Barcelona. About 1314 he was living in poverty and sickness in Toledo, and in fact he endured privation throughout his life, but declined a position as a rabbi. Through his father, a great Talmudist in his own right, he became acquainted with the works of the Franco-German scholars; in Spain he became acquainted with the Spanish Talmudists, and his subsequent wandering through Western Europe familiarized him with the customs of its varied communities.

His life work, which revealed a profound knowledge of Jewish literature, was his *Arba Turim* (The Four Columns), after the four columns of Jewels on the breast place of the high priest. It was intended to supply coordinated information for the average Jew, and therefore concerned itself only with those laws which were still in force after the destruction of Temple. Ben Asher started this monumental undertaking when he was a young man. The laws are grouped in the form of connected arguments, recording all the decisions of earlier rabbis down to his own. They terminate in a decision, and the author usually makes his father the decisive authority. Yaacov writes very objectively and never tries to force an opinion upon the reader. The work became so popular that it was regarded as "the people's possession and people's lawbook of the entire Jewish world". Many commentaries on it were written, and glosses were frequently added to it; it eventually became the basis of the *Shulhan Aruch*.

Ben Asher's code answered the need of the times because it combined the rich strands of French, German, and Spanish learning into one tapestry of

---

114 When the Jews arrived in England, the English method of settling legal disputes was through trial by combat. The Jews, on the other hand were accustomed to judicial procedure base on evidence, examination of witnesses and impartial judges. Thus, they demanded and were granted the right to use Talmudic guidelines in dispute with Christians. As early as the 2^{nd} century CE Talmudic law had specified that in property disputes the verdict of 12 men, agreed upon the litigants would be legally binding on both parties. After a century, even the Anglo-Saxons found the Jewish method of settling disputes better then trial by combat. By the 13^{th} century this "Jury" method found its way into British common law.

The famed due process of law concept, so firmly embedded in the Fifth and Fourteenth Amendments of the American Constitution, and derived from the Magna Carta, stems from the 10^{th} century interpretation of the Talmud. This Talmudic concept of due process of law was stated most succinctly by Maimonides several decades before the signing of the Magna Carta.

European Talmudism. His lucid writing, his logical arrangement of subject matter, his encyclopedic knowledge of the entire gamut of Talmudic development over 300 years, and his clever way of presenting dissenting opinion while pointing a way out of the jungle of dissent, made his *Four Columns* the most popular and definitive code.

1337–1453 CE The *Hundred Year War*. A struggle between England and France for control of France that consisted of a successions of wars broken by truces and treaties. It extended over the reign of five English and five French kings and culminated in the *battle of Agincourt* (1415), where Henry V won one of the most famous victories in English history with an army that was the best-trained and best equipped fighting force since the Roman legions (this battle was immortalized by **Shakespeare** in his historical play *Henry V*).

The English won most of the battles, but the French won the War. By the time the war ended in 1453, England had lost all its territory on the continent of Europe, except Calais, which was regained by France in 1558.

Firearms were first used in the Hundred Year's War. *Artillery* came into use during 1335–1345 and the major battle involving firearms was on Aug 26, 1346: Edward II of England invaded France with 10,000 man and defeated some 20,000 Frenchmen at Crécy.

1338–1353 CE **Giovanni dei Marignolli** (ca 1285–1357, Italy). Traveler Franciscan Friar. Left a journal of his travels in China, India, Ceylon, Persia, Mesopotamia, Syria and Jerusalem (1352). He was sent on a mission to the court of Emperor Togon Temür of China by Pope Benedict XII (1338), reaching Peking (1342), where he remained for four years. He returned to Arignon (1353), delivering a letter from the Mongol-Chinese Emperor to Pope Innocent VI. Later (1354), Marignolli became chaplain to Emperor Charles IV.

ca 1340–1377 CE **Immanuel ben Yaacov Bonfils** (14^{th} century, France). Physician, mathematician and astronomer. Taught and wrote in Orange and Tarascon. Published the highly regarded astronomical tables, *Kanfe Nesharim* (Wings of Eagles; *Exodus* **19**, 4; *Isaiah* **6**, 2) [which were translated into Latin in 1406 and commented upon in Greek], primarily as an aid in the determination of the Hebrew calendar.

Manuscripts of 15 of his works have survived to our time [nine of them are in the National Library of Paris]. One of them, *Derech Hilluq*, contains an exposition of an arithmetic which consistently employs the *decimal system* of notation for integers and fractions, and positive and negative exponents. It also includes an algorithm for root extraction.

Immanuel of Tarascon thus took his place in the line of the contributors to the development of the decimal system.

Mathematics in the Medieval world[115] (800–1500 CE)

A. Jewish contribution (1100–1500 CE)

Talmudic scholars in South-Western Europe were among the leading mathematicians in the Middle Ages (see Table 2.1).

Bar Hiyya *was a key figure in the transmission of mathematics to the Christian West, translating texts from Arabic and Hebrew into Latin. In his book Liber embadorum he presented a complete solution of the quadratic equation*

$$x^2 + b = ax,$$

showing that it has two roots. The book exerted deep influence upon the development of Western mathematics and was used by Leonardo of Pisa as the foundation for his text books on arithmetic, geometry and trigonometry.

Levi ben Gershon *was one of the leading mathematicians and astronomers of the European Middle Ages. In his book 'Sefer ha-Mispar' ('Book*

- Johnson, Paul, *The Renaissance*, The Modern Library, 2000, 196 pp.

of Numbers'), he calculated, for the first time, the number of permutations, $P_{n,r}$, of n objects, taken r at a time.

$$P_{n,r} = n(n-1)\dots(n-r+1), \qquad P_{n,n} = n!.$$

He then calculated the number of combinations, $C_{n,r}$, of n objects taken r at a time.

$$C_{n,r} = C_{n,n-r}, \qquad C_{n,r} = \frac{P_{n,r}}{P_{r,r}}.$$

He also found that

$$\sum_{n=1}^{N} n^3 = \Big(\sum_{n=1}^{N} n\Big)^2,$$

and proved that the numbers 2^n, 3^m differ by more than a unit, except for $(n,m) = (1,0), (1,1), (2,1), (3,2)$.

He proved his results by the Principle of Mathematical Induction, hitherto an unknown principle, first used by him in 1321. As we now formulate this method of the proof, a property $S(n)$ of natural numbers n is proved to hold for all n if we can prove $S(1)$ (the base step) and, for arbitrary n, $S(n) \Longrightarrow S(n+1)$ (the induction step).

***Francesco Maurolico** (1575) was the first to formulate the principle of induction. **Pascal** (1655) borrowed the idea from Maurolico and clarified it in his treatise Tracté du triangle arithmetique.*

Levi foreshadowed Copernicus in his firm objection to the Ptolemian system. Stressed the importance of the sine function, emphasized the importance of plane trigonometry and developed it, including the law of sines.

***Aramah** was active during 1470–1494 as a philosopher, mathematician and Talmudic scholar. He was first to formulate the statistical law of large numbers (1470) in his book 'Akedat Itzhak' (published in Saloniki: 1522). There he stated, over two centuries ahead of **Jacob Bernoulli** (1770):*

> *"Ordinary lots due to chance are without any tendency to one side or the other... They are not a 'sign', for matters of this kind are not established unless they are found many times... The casting of a lot indicates primarily a reference to chance."*

Aramah was born in Zamorah, Spain and served as a head of rabbinical academies in various Jewish learning centers. He was expelled from Spain (1492) and died in Naples, Italy. His philosophical system was influenced by Aristotle and Maimonides, and deals specifically with such major questions as faith and reason. Aramah became popular and influential and his thinking represents the mainstream of Jewish medieval philosophy.

Immanuel Bonfils *calculated highly regarded astronomical tables, employed the decimal system of notation for integers, fractions and positive and negative exponents (1340 CE). He also developed an algorithm for root extraction.*

Avraham Ibn Ezra *wrote five books on mathematics and astronomy, including research on arithmetic, number theory, combinatorics and astronomical tables. He adopted the positional decimal system (1140 CE) for integers with place-values from left to right, and denoting the zero by a special sign of the wheel ('galgal'* in Hebrew*). In his book 'Ta'hbulah' he discussed the Josephus problem. In his Sefer-ha-Mispar* (book of numbers) *we find the rule of summation of an arithmetical progression: "Whoever would know how great the sum of the numbers is which follow one another in a series to a certain number, multiply this by its half increased by $\frac{1}{2}$." That is*

$$S_n = n\left(\frac{n}{2} + \frac{1}{2}\right) = \frac{n(n+1)}{2}.$$

Ibn-Gabirol *(fl 1040–1058) was a philosopher of striking originality, whose philosophical system had powerful impact upon medieval Christian thinkers as well as on* **Spinoza** *and* **Schopenhauer**. *His chief work, the 'Source of Life' was translated from the Arabic into the Latin in the middle of the* 12^{th} *century by* **Dominicus Gundissalvus**, *archdeacon of Segovia, under the name 'Fons Vitae'. And just as Ibn Sina was corrupted into* ***Avicenna*** *and Ibn Rushd into* ***Averroes***, *so Ibn-Gabirol traveled down the ages under the disguise of* ***Avicebron***.

Since his work shows a total and absolute independence of Jewish religious dogma, he exercised little influence upon Jewish thought. His doctrine of creation is at the base of the Lurianic cosmology which itself was later found to be coherent with modern cosmology.

Maimonides *was first to claim clearly that π is not rational (1160 CE) and can only be approximated by ratio of integers. He further stated (without proof) that squaring the circle by rules of Greek geometry is impossible.*

In his book Mishneh Torah ("Repetition of Teaching" the most distinguished code of Jewish law), Maimonides discusses the mathematical theory of visibility of the moon, needed for ascertaining the beginning of the month ('consecration of the moon'). Therein he developed a simple approximation method of ascertaining whether the moon was visible from the West point. In this connection he writes (Hilchoth Kiddush Hachodesh, Chapter ***11***, *1-17):*

> *"Lest any mathematician think that the approximate methods sometimes described are due to my ignorance of the more accurate*

> *mathematical ones, let him dismiss such an idea from his mind. I have only employed such methods when I was convinced by comparison with the results obtained by the strictly mathematical - but more laborious - methods that the calculation of the moon's visibility is not appreciably affected by such approximations. He will further find that any appreciable positive or negative differences incidental to such approximate methods cancel themselves out, with the consequence that sufficiently accurate results are finally obtained without the labor of a long calculation which might frighten away the non-mathematical reader".*

No modern applied mathematician could have issued a better apologia for approximate methods them did Maimonides 800 years ago!

Maimonides made a significant contribution to the physical concept of time. In his work The Guide to the Perplexed (1190) he wrote (in Arabic):

"Time is composed of time-atoms, i.e., of many parts, which on account of their short duration cannot be divided... An hour is, e.g., divided into 60 *minutes, the minute into* 60 *seconds, the second into* 60 *parts and so on; at last after ten or more successive divisions by sixty, time-elements are obtained which are not subjected to division, and in fact are indivisible...".*

He thus concluded that there were 60^{10} *or more such time-atoms in one hour!*

The notion of Maimonides that time is composed of 'time-atoms' is known today in the parlance of physicists as chronon. *If indeed space-time is discrete (quantized), then the scale must be very small to agree with experimental observations. Indeed, the present smallest directly observable division of a second, which is better then* 1×10^{-13} *sec, is coming close to Maimonides' division of* $60^{-10} \sim 5 \times 10^{-15}$ *sec.*

Levi ben Avraham *was a natural philosopher, astronomer and mathematician. Recognized heat as a form of motion, 400 years before* ***Robert Boyle*** *(1675 CE).*

Levi was the grandfather of Levi ben Gershon. He lived in poverty, making a living through the teaching of sciences and foreign languages. Persecuted by the rabbinic establishment because of his rationalistic interpretation of the Bible, he was forced to wander in Provance (Narbonne, Beziers). He died in Arles.

Yosef Caspi*, in his book Will and Testament (1332), maintained that natural phenomena can sometimes violate the laws of nature over a small interval of time. (He used this argument to render the logical explanation to biblical miracles). This idea was ahead of its times by more than 600 years.*

Yehudah ibn Verga *invented (Lisbon, 1457) a new instrument to determine the sun's meridian and wrote a number of books on mathematics and astronomy. He died in the dungeons of the Portuguese Inquisition (1499).*

Zacuto*'s astronomical tables, maritime charts and new astrolabe played an important role in the Spanish and Portuguese discoveries, especially in the voyages of Columbus and Vasco da Gama.*

Zacuto's achievements in astronomy were many: his astrolabe of copper, the first of its kind (previously they had been made of wood), enabled sailors to determine the position of the sun with greater precision; his astronomical tables, based on the Alphonsine tables, were an improvement on the latter. They permitted sailors to ascertain latitudes without recourse to the meridian of the sun, and to calculate solar and lunar eclipses with greater accuracy.

Columbus used Zacuto's tables on his voyages, and on one occasion they were instrumental in saving him and his crew from certain death. Knowing from the Zacuto tables that a lunar eclipse was imminent, Columbus threatened the natives that he would deprive them of the light of the moon as well as of the sun. (A copy of the tables, with Columbus' notes, is preserved in Seville). Zacuto's astronomical work Ha-Hibbur ha-Gadol (the Hebrew original is extant in several manuscripts) enjoyed a wide reputation during his lifetime.

Yehudah Abravanel *(fl. 1490–1520 CE) was a mathematician, astronomer, physician and one of the great philosophers of the Renaissance. In 1497 he drew attention to the periodic conjunction of Jupiter and Saturn, occurring about every 20 years. The sign of the Zodiac in which they occur changes from one conjunction to the other. This study was consulted by* ***Johannes Kepler*** *(1603) and prompted him to advance the hypothesis that the 'star of Bethlehem' was indeed a conjunction of Jupiter and Saturn in Pisces in 7* BCE.

B. Muslim contribution (800–1400 CE)

Hindu work on mathematics and astronomy during 200–1400 CE spread westward, reaching the Arabs who, in turn, absorbed, refined and augmented what they received, before transmitting the results to Europe. By far, the greatest contribution of the Arabs was to pursue a process of creative synthesis in which they blended a variety of earlier mathematical traditions including the Babylonian, Greek, Indian, Persian and Chinese.

This they did with an openness of mind and clear understanding of need in mathematics (and other sciences) to balance empiricism and theory. It is most apparent in their astronomical tables, their algebraic approach to applied mathematical problems, the popularization of our present-day numerals, the first systematic treatment of trigonometry and the bringing together of the geometric and algebraic approaches to the solution of equations.

The astronomers and mathematicians who contributed mostly to this program were: ***al-Kharki*** *(950–1029);* ***al-Khowarizmi*** *(780–850);* ***abu-Mahsar*** *(805–885);* ***al-Kindi*** *(815–873);* ***ibn-Qurra*** *(826–901);* ***al-Harrani*** *(836–901);* ***al-Battani*** *(850–929);* ***al-Wafa*** *(940–998);* ***Ibn Yunus*** *(940–1009);* ***al-Haitam*** *(965–1039);* ***al-Biruni*** *(973–1048);* ***Omar Khayyam*** *(1048–1126);* ***al-Marakushi*** *(1190–1265);* ***al-Tusi*** *(1201–1274);* ***al-Shirazi*** *(1236–1311);* ***al-Shatir*** *(1306–1375)* and ***al-Kashi*** *(1360–1436).*

The Arabs played a seminal role in transmitting mathematics to Western Europe, setting the stage for the development of modern mathematics. But they were not just custodians of Greek learning and transmitters of knowledge. They brought together two different mathematical strands - the algebraic *and* arithmetic *traditions so evident in the mathematical cultures of Babylonia, India and China, and the* geometric *traditions of Greece and the Hellenistic world. The intertwining of these strands had already begun with the latter Alexandrian mathematicians* ***Heron****,* ***Diophantos*** *and* ***Pappos****, who had absorbed much of their mathematics from Babylon and Egypt. They could not, however, break loose from the constrains imposed by the straight jacket of Greek mathematical tradition.*

It was left to the Arabs to bring together the best of both traditions. In doing so, they provided us with an efficient system of numeration*, in which calculations, were no longer tied to mechanical devices, an* algebra *which was both practical and rigorous, a* geometry *which was no longer an intellectual pastime, and a* trigonometry *freed from its ties to astronomy to become indispensable tool in fields as diverse as optics and surveying.*

Even before the beginning of Arab rule, knowledge of Hindu numerals had spread westwards. Christian sects, particularly the Nestorians and Syrian Orthodox denominations, needed to calculate an accurate date for Easter, and various astronomical texts were examined with this in mind, In fact, it was a problem that continued to occupy mathematicians, including ***Gauss****, down to the* 19^{th} *century. There is also the possibility, given the thriving commercial relations between Alexandria and India, that the Hindu numeral system reached the shores of Egypt as early as the* 5^{th} *century CE. It would have been regarded as a useful* commercial device *rather then a tool for scientific and astronomical calculations since Alexandrian scientists continued to use the die-hard Babylonian sexagesimal system.*

***Fibonacci** (1170–1250), who was first introduced to Hindu numerals by his Arab teachers, quickly recognized the enormous advantage of the Hindu system. The change was, however, a slow process, primarily because the abacus remained popular for carrying out calculations, and traders and others engaged in commercial activities were reluctant to adopt the new system which was difficult to comprehend.*

Before Muhammed, the Arabians wrote out all numbers in words. Less then a century after the Hegira (622 CE) their empire extended from India to Spain, including North Africa, Southern Italy and large parts of Western Asia. In 775 the Islamic Empire split into a Western Kingdom with its capital at Cordova and an Eastern Kingdom centered on Baghdad. Both kingdoms rapidly developed a rich culture, absorbing intellectual nourishments from the Greek, Jewish, Persian and Hindu worlds. The 9^{th} *century was the Golden Age of Arab mathematics. Baghdad, with its fine library and lavishly equipped astronomical observatory, became the new Alexandria.*

*The first Arabic arithmetic known to us is that of **al-Khowarizmi**, who is believed to have visited India. On his return, about 830* CE, *he wrote his algebra treatise, which was founded on the work of **Brahmagupta**. The Hindu numerals, adopted by the Arabs were brought to Spain at about 900 CE. From there they diffused to the rest of Europe by traders in the Mediterranean area and by scholars who attended the universities in Spain. It finally came into general use in Europe by the invention of the printing press in the mid 1400's. His second book on algebra also shows little originality.*

*Although **al-Khowarizmi** is often hailed as the 'Father of Algebra', in two respects he looked backwards rather than forward: he rejected both algebraic symbolism (his treatment is entirely rhetorical) and the Hindu acceptance of negative roots and negative coefficients of equations.*

***Omar Khayyam** went beyond al-Khowarizmi to investigate cubic and even some quadratic equations. However, he mistakenly believed that the general cubic equation could not be solved algebraically, but that geometrical methods, involving the use of conic sections, were necessary. He also did not recognize negative numbers.*

Arab mathematicians addressed problems of inheritance posed by Islamic law; geometric solutions of cubic equations, introduction of 6 basic trigonometric functions and the construction of highly detailed trigonometric tables with the aid of various interpolation procedures.

*One of their greatest scholars was **Nasir al-Din al-Tusi**, mathematician, astronomer, physician and philosopher. In geometry, he made first attempts to determine whether Euclid's parallels postulate can be derived from the other Euclidean postulates. In trigonometry he presented the law of sines and began to separate trigonometry from astronomy. His work in these two* *areas may have influenced the further advances of* ***Regiomontanus*** *(1464) and* ***Saccheri*** *(1733).*

In 1259 al-Tusi began the construction of a major astronomical observatory at Marãgha, where he used his self-made quadrants to observe star positions. During 1256–1265 he conducted observation which served as a basis for his astronomical tables (1272). His criticism of Ptolemaic astronomy was an additional step toward the Copernican reform.

Some highlights from the works of other Arab mathematicians of the 9^{th} *and* 10^{th} *century are:*

- ***Al-Harrani*** *(855 CE) proved that if*

$$p = 3 \cdot 2^n - 1, \quad q = 3 \cdot 2^{n-1} - 1, \quad r = 9 \cdot 2^{2n-1} - 1,$$

  and if p, q *and* r *are primes, then* $2^n pq$ *and* $2^n r$ *are amicable numbers.*

- ***Abu al-Wafa*** *(970 CE) Contributed considerably to the development of trigonometry. He was probably the first to show the generality of the sine law relative to spherical triangles*[116]*. He gave a new method of constructing sine tables, his value of sin* $(30')$ *being correct to 8 decimal places. He knew relations equivalent to ours for* $\sin(\alpha \pm \beta)$ *(though in an awkward form) and to*

$$2\sin^2\frac{\alpha}{2} = 1 - \cos\alpha, \qquad \sin\alpha = 2\sin\frac{\alpha}{2}\cos\frac{\alpha}{2}.$$

  He calculated a table of tangents and introduced the secant and cosecant.

- ***Al-Kharki*** *(985 CE) gave a solution in rationals to* $x^3 + y^3 = z^2$ *namely*

$$x = \frac{n^2}{1+m^3}, \quad y = mx, \quad z = nx,$$

  where (m, n) *are arbitrary rational numbers.*

- ***Ibn Yunus*** *(990 CE) Prepared improved astronomical tables based on his observations at the Cairo observatory. Improved the values of*

---

[116] It is hard to determine who discovered the planar *sine law*

$$a/\sin A = b/\sin B = c/\sin C.$$

It is quite certain that **Ptolemy** knew it. It may however been rediscovered by Abu al-Wafa or his disciple **Abu Nasr Mansur** (970–1036 CE).

astronomical constants (inclination of the ecliptic, $23°35'$; longitude of the sun's apogee, $86°10'$; solar parallax, $2'$; precession, $51.2''$ a year). Introduced the trigonometric formula

$$\cos\alpha\cos\beta = \frac{1}{2}[\cos(\alpha-\beta)+\cos(\alpha+\beta)].$$

Ibn Yunus described 40 planetary conjunctions accurately and 30 lunar eclipses used by Simon Newcomb (1876) in his lunar theory.

- ***Alhazen** (1000 CE) solved the following problem: given a light source and a spherical mirror, find the point on the mirror where the light will be reflected to the eye of an observer. This can be reduced to the planar geometrical construction: from two points in the plane of a circle to draw lines meeting at a point of the circumference and making equal angles with the normal at that point. It leads to an equation of the 4^{th} degree. Alhazen solved it by the aid of an hyperbola intersecting a circle. In a similar way he also solved the cubic equation* $x^3 + c^2b = cx^2$, *which results from the* Archimedean problem *of dividing a sphere by means of a plane into two segments at a given ratio to one another.*

The Muslim contribution to the development of mathematics, viewed as a whole, exhibits a nice blending of Greek, Babylonian and Hindu influences. While making small advances, some of their achievements, when viewed against the scientifically sterile backdrop of the rest of the world of the time, seem greater then they really were. Yet, there remains the outstanding fact that they served admirably as custodians of much of the world intellectual possessions, which were transmitted to the later Europeans after the Dark Ages had passed.

The debt of the West is twofold. First, the Islamic scholars collected, preserved and translated the Classical Greek mathematical texts. Secondly, they adopted the fully developed Hindu system of numeration, which was in due time transmitted to the West and eventually to the whole world. Although the new system had become known in the West by the year 1000, it took several centuries to displace the Roman number-language in Western Europe and the Ionic Greek number-language in the Byzantine Empire. We must remember that most arithmetical calculations were performed on an abacus or a counting-frame; only the results needed to be recorded on paper, and for this the Roman or Greek numerals were quite adequate. Indeed, both the medieval abacus and the counting-frame were direct physical analogues of the Hindu decimal system of numeration, with the symbol for zero corresponding *to the empty column. The battle between the 'abacists' (the supporters of the old Roman numbers) and the 'algorists' (who advocated the new system of al-Khowarizmi) continued for centuries. As late as 1299 the city of Florence issued an edict prohibiting the commercial use of the Hindu-Arabic numerals; they were thought to be too easy to falsify on accounts.*

The loss of Toledo by the Moores to the Christians (1085 CE) was followed by an influx of Christian scholars to that city to acquire Muslim learning. Other Moorish centers in Spain were infiltrated and the 12^{th} *century became, in the history of mathematics, a century of translators. Another center of interaction and transmission was the island of Sicily.*

The location and political history of Sicily made that island a natural meeting ground of East and West. Sicily started as a Greek colony, became part of the Roman Empire, linked itself with Constantinople after the fall of Rome, was held by the Arabs for about 50 years in the ninth century, was recaptured by the Greeks, and then taken over by Normans. During the Norman regime the Greek, Arabian, and Latin tongues were used side by side, and diplomats frequently traveled to Constantinople and Baghdad. Many Greek and Arabian manuscripts in science and mathematics were obtained and translated into Latin. This work was greatly encouraged by the two rulers and patrons of science, Frederick II (1194–1250) and his son Manfred (ca. 1231–1266).

Among the first cities to establish mercantile relations with the Arabic world were the Italian commercial centers at Genoa, Pisa, Venice, Milan, and Florence. Italian merchants came in contact with much of Eastern civilization, picking up useful arithmetical and algebraical information. These merchants played an important part in the dissemination of the Hindu-Arabic numeral system.

C. Christian contribution - Arithmetic comes of age (1200–1600 CE)

After the absorption of the Hindu-Arabic number system, and the stabilization of the numeral forms, the time was ripe for the standardization of the four fundamental operations – addition, subtraction, multiplication and division. All these evolved slowly from the times of ancient Egypt and Babylon, and their final form became common in Europe not before the dawn of the 17^{th} *century.*

Addition: The operation has not changed much since Hindu-Arabic numerals began to be used, as is evident from ***Bháskara*** *(ca 1150) in his Lilavati.*

The "carrying" process dates from the time when a counter was actually carried on the line abacus to the space or line above.

The evolution of the arithmetical procedure can be followed in the writings of ***Fibonacci*** *(1202),* ***Pacioli*** *(1494),* ***Gemma Frisius*** *(1540),* ***Recorde*** *(1542) and* ***Digges*** *(1572). The name of the operation has had its vicissitudes: writers used 'aggregation', 'composition', 'collection', 'assembling', 'joining' and 'summation'.*

Subtraction: The name of the process since Fibonacci (1202) went through the phases: extraction, detraction, subduction, deduction, rebating and diminishing. Only in the 19^{th} *century (!) did subtraction become common in England and America. There have been, throughout the past nine centuries about five different processes of subtraction, some of which are practical today. Among them, the plan of simple borrowing (e.g. in the operation*

$$\begin{array}{r} 42 \\ -\underline{27} \\ 15 \end{array}$$

the computer says: "7 from 12 is 5, 2 from 3 is 1"). This plan is very old and goes back to ***Avraham ibn Ezra*** *(ca 1140). The computer always begins at the right and looks ahead to take care of the borrowing. This feature is Oriental and used in the work of* ***al-Khowarizmi*** *(ca 825).*

Multiplication: We know little about the methods of multiplication used by the ancients. The Egyptians probably made some use of the duplation plan, which accounts for the presence of the chapter on duplation in so many books on the Renaissance period. Indeed, even a good a mathematician as ***Stifel*** *(ca 1525) still multiplied by successive duplation according to the scheme*

$$\begin{array}{rl} 1 \cdot 42 = & 42 \\ 2 \cdot 42 = & 84 \\ 4 \cdot 42 = & 168 \\ 8 \cdot 42 = & 336 \\ 16 \cdot 42 = & 672 \\ \hline 31 \cdot 42 = & 1302 \end{array}$$

The basic idea here is the expansion of one of the multipliers in the binary system $(31 = 1.2^0 + 1.2^1 + 1.2^2 + 1.2^3 + 1.2^4)$. *Our common form appears in Pacioli's Suma (1484) together with seven other plans of multiplication.*

The oldest multiplication-tables are found already in Babylonian tablets, where they appear in columns. The square form is found in the arithmetic[117] *of* ***Boethius*** *(ca 510) and* ***Bede*** *(ca 710), and became common in the* 13^{th} *century, as is evident from the writings of* ***Jordanus Nemorarius*** *(1225).*

---

117 *Arithmetic*: from the Greek *arithmeein* - to number, to count.

Many of the 16^{th} *century writers found it necessary to urge their pupils very strongly to learn the tables, showing that the custom was relatively recent in countries where the abacus had only just been abandoned.*

Division: Defined as an unknown number R*, satisfying the equation* $a = bR$ *when* a *and* b *are given. The oldest form of division (known also as 'partition' in the* 13^{th} *century) is the one used by the Egyptians. The process was based upon duplation and mediation: e.g. to divide* 19 *by* 8*, they prepared a list of multipliers of* 8 *by* 2, 1, $\frac{1}{4}$, $\frac{1}{8}$*, namely* 16, 8, 4, 2, 1 *and then selected from these numbers these which have* 19 *for their sum. Since* $19 = \left[2 + \frac{1}{4} + \frac{1}{8}\right] \times 8$, *the result of the division is* $\frac{19}{8} = 2\frac{3}{8}$ *(in modern notation).*

It is impossible to fix an exact date for the origin of our present algorithm of long division, partly because it developed gradually over some 600 *years from the time of* ***al-Khowarizmi*** *(ca 825).* ***Gerbert*** *(ca 980) introduced the operation of 'long division'. It may be, illustrated by the simple case of* $\frac{900}{8}$*. The process consists of dividing* 900 *by* $10 - 2$ *(2 being the complement of the divisor) and runs essentially as follows:*

$$
\begin{array}{l|l}
900 & 10 - 2 \\
\underline{900 - 180} & 90 + 18 + 3 + 1 + \frac{1}{2} = 112\frac{1}{2} \\
\quad 180 & \\
\quad \underline{180 - 36} & \\
\qquad 36 & \\
\qquad \underline{30 - 6} & \\
\qquad\ 6 + 6 = 12 & \\
\qquad\qquad \underline{10 - 2} & \\
\qquad\qquad\ 2 + 2 = 4, \qquad \frac{4}{8} = \frac{1}{2} &
\end{array}
$$

The method was refined by ***Calandri*** *(ca 1491) who was first to exhibit it in a printed book. With the opening of the* 17^{th} *century it began to replace other methods.*

Roots: ***Theon of Alexandria*** *(ca 390) used sexagesimals and Euclid's identity* $(a+b)^2 = a^2+2ab+b^2$ *to extract the square root of an integer. From Greece the method passed over to the Arabs and Hindus, with no particular improvement.*

Robert of Chester *(England) introduced (1145–9) the current mathematical terms: 'Algebra' (for 'al-jabr' of* ***al-Khowarizmi****), 'algorism' (algorithm), 'sine' (trigonometry). The Hindus have given the name 'jiva' to the* *'half-cord' in trigonometry, which the Arabs took over as 'jiba'. In the translation he confused it with the Arabic word 'jaib' meaning 'bay' or 'inlet' – which he translated into the Latin 'sinus'.*

One of the first, and certainly the most influential, of the medieval textbooks on the new arithmetic was the Liber abaci*, which was completed in 1202 and revised in 1228. Its author,* ***Leonardo of Pisa*** *(ca 1175–1250), is better known as* ***Fibonacci*** *('son of good nature'). His father was a Pisan merchant who also served as a customs officer in North Africa. The young Leonardo traveled widely and learned the Arabic methods from a Muslim teacher. His extended trips to Egypt, Sicily, Greece, and Syria brought him in contact with Eastern and Arabic mathematical practices. Thoroughly convinced of the practical superiority of the Hindu-Arabic system, Fibonacci published his* Liber abaci *soon after his return home. This work contains a large collection of problems which served later authors as a storehouse for centuries.*

Liber abaci *was the first complete and systematic explanation of the Hindu numerals by a Christian writer; and also, naturally the first complete exposition of Hindu and Muslim arithmetic. Leonardo, however, gave more rigorous demonstrations than the Muslims. (It is apparent that he had a good knowledge not only of Muslim, but also of Greek mathematics, largely derived from Latin translations of Euclid, Archimedes, Heron and Diophantos.)*

Liber abaci *contains sections on Roman and Indian numerals and on finger counting. Later chapters are devoted first to commercial calculations and then to puzzles and recreational mathematics – including the famous 'rabbit problem' which lead to the Fibonacci sequence. He deals with approximating square roots, cube roots and problems on volumes, in which he takes* π *to be* $3\frac{1}{7}$.

The 14^{th} *century was a relatively mathematically barren one. It was a century of* Black Death*, which swept away more than a third of the population of Europe, and in this century the* Hundred Years' War*, with its political and economic upheavals in Northern Europe, got well under way.*

Four significant events influenced the evolution of mathematics and science in Western Europe from the 15^{th} *century onward:*

- *The collapse of the Byzantine Empire, culminating in the fall of Constantinople to the Turks (1453). Refugees flowed into Italy bringing with them treasures of Greek civilization. Many Greek classics, hitherto known only through the often inadequate Arabic translations, could now be studied from original sources.*

- *The invention of printing (1440). It enabled the dissemination of knowledge at an unprecedented rate.*

- *The discovery of America (1492) and the consequent circumnavigation of the Earth.*
- *The ruin of the Arab centers of learning and the virtual imprisonment of the Jews in their ghettos left Christians alone at the center stage of science for the next 300 years. The Jews will return with great vigor, following their emancipation in the Napoleonic era.*

The mathematical activity in the 15^{th} *century was largely centered in the Italian cities and in the central European cities Nüremberg, Vienna and Prague. It concentrated on arithmetic, algebra and trigonometry and flourished principally in the growing mercantile cities under the influence of trade, navigation, astronomy and surveying. With the interest in education and tremendous increase in commercial activity, hosts of popular textbooks in* arithmetic *began to appear.*

New ideas in the 14^{th} *and the* 15^{th} *century were advanced by 'three Nicolas':*

1370	*Nicole Oresme*	*1323–1382*	*France*
1440	*Nicolas of Cusa*	*1401–1464*	*Germany*
1485	*Nicolas Chuquet*	*1445–1488*	*France*

Another important mathematician, belonging to the same period is ***Johannes Müller (Regiomontanus)****. Being both astronomer and mathematician he advanced* spherical trigonometry *(1470).*

1344 CE **Gregorio da Rimini** (d. 1358, Italy). Augustinian Hermit, theologian and Ockhamist. Studied in Rimini and Paris (1323–1329). In 1351 he left Paris and returned to the Augustinian house in Rimini. Died in Vienna. Gregorio addressed the issues of continuity and infinity, discussing such problems as whether an infinite spiral can exist on a finite body.

1347–1351 CE The *Black Death* epidemic of bubonic plague wreaked havoc throughout Europe and Asia killing about 50 million people. One of History's greatest natural disasters. It started in 1338 near Lake Issyk-Kul (ca 78 °N, 43 °E, south of Alma-Ata) in one of the zones in which it lied endemic, and thence it spread out, eastward into China, south to India and west along the trade routes to reach the Crimea some eight years later. In 1347 it appeared in Cyprus and by the following year had spread to France, Italy, Germany and England. In 1349 it was in Poland, Scandinavia and Scotland and in 1351 it ravaged Russia[118].

About 25 million Europeans died – a depletion of about one quarter of the continent's population. The Black Death caused a great shortage in labor and wages rose enormously. The result was to strengthen the position of the workers and to hasten the end of the feudal system on which medieval society was based.

In spite of the Calamity, the second half of the 14^{th} century was not essentially different from the first, as far as the history of science and learning is concerned. It is certain that the plague caused the untimely death of many scholars or potential scholars, but apparently other scholars took their place and continued their work.

The medieval pandemic did not strike out of the void; earlier outbreaks were recorded. One of these began in Arabia, reached Egypt (542 CE), fatally weakened the Roman Empire of Justinian and moved on across Europe to England and Ireland, which it laid waste in 664 CE. One of its parting flourishes was the Great Plague of London (1665), which seemed to have died out in the 17^{th} century. Finally came the pandemic which started in 1892 in Yunnan and reached Bombay in 1896, killing some six million people.

Bubonic plague is endemic to certain areas in the world: Uganda, Western Arabia, Kurdistan, Northern India and the Gobi Desert. From time to time it erupts there from a minor, localized epidemic. Far more rarely it breaks its bounds and surges forth as one of the great pandemics.

In the endemic state, the bacillus *Pasteurella Pestis* exists in the bloodstream of an animal or the stomach of a flea such as *Xenopsylla Cheopsis*, which in turn resides in the hair of some rodents. In 1338 it was the tarbagan, or *Manchurian marmot*, a beguiling squirrel-like creature much hunted for its skin.

To disturb the harmless steady-state existence of the bacillus, something had to happen to make the rodents leave their habitat. It is believed that extreme *ecological environments and climatic changes* such as locust, earthquakes, floods and prolonged droughts (known to occur during 1333–1337 in the plains watered by the rivers Kiang and Hoai, in Honan and the mountains of Ki-Ming-Chan) can affect rodent migration. Even without this incentive, an increase of rodent population can put too great a strain on the available supplies of food.

At all events a massive exodus took place and it was above all *rattus rattus*, the tough, nimble, by nature vagabond, black rat which made the move. By

118 It could have been carried earlier into Europe by the armies of Jenghis Kahn.

the middle of the 14^{th} century rats abounded in Europe, probably having been imported originally in the boats of the returning Crusaders.

The Black Death must have seemed to be of supernatural origin, a punishment inflicted by higher power upon unknown sinners for unknown crimes. Culprits were sought: nobles, cripples and Jews in turn came under suspicion. The Jews, in particular, were suspected of purposely spreading plague by contaminating wells. Their persecution started at Chillon on Lake Geneva (1348) and rapidly spread to Basel, Bern, Freiburg and Strasbourg. Jews were herded into large wooden buildings and burned to death. At Strasbourg over 2000 are said to have been hanged on a scaffold set up in the Jewish cemetery. So bitter did the persecution become that Pope Clement VI issued two Bulls declaring Jews to be innocent. Many fled from Western Europe into east Germany and Poland. The Black Death intensified the medieval Christian tradition of the scapegoat-Jew.

The Paris Quartet (1350–1370)

In the middle of the 14^{th} century there arose at the University of Paris a quartet of brilliant scholastic philosophers, two of whom are sometimes referred to as initiators of the modern age of science.

*One of them was **Jean Buridan**, whose opposition to Aristotelian doctrines made him one of the founders of modern dynamics. One historian of science, **Pierre Duhem**, places the precise line separating ancient from modern science at the time (ca 1350) when Buridan applied the theory of impetus to the heavens, thus breaking the ancient distinction between terrestrial and celestial motions. It has been claimed that from Buridan, **Galileo** borrowed the idea of momentum, **Descartes** borrowed the principle of the quantity of motion, and **Leibniz** took the doctrine of vis viva (kinetic energy). While such claims must be properly qualified, and although the notion of inertia has roots in antiquity, nevertheless Buridan was by any reckoning an outstanding figure in the history of science.*

*A second member of the quartet, a close associate of Buridan, was **Nicole Oresme**. He was hailed as a man whose contributions to physics, astronomy, and mathematics marked the beginning of the modern period in experimental science. The holder of more precursorship claims, advanced by modern* *admirers, than any other medieval scientist, he has variously been regarded as a forerunner of Copernicus, Galileo, and Descartes. His appreciation of* the relativity of motion *led him to advance arguments in favor of the diurnal rotation of the earth; but more important, probably, were his contributions to mathematics. His introduction of* generalized powers *in algebra, his anticipation of the* graphical representation of functions *in analytic geometry, and his study of* instantaneous rates of change*, all show the originality and power of his "hunches". In particular, his observation that the rate of change of a variable quantity is least at its maximum value (ca 1360), played a key role in the* calculus.

Albert of Saxony *(1316–1390), a third member of the scientific quartet at Paris and transmitter of this science to Vienna, wrote on logic, physics, mathematics, and geology. His work on the void, on centers of gravity, and on terrestrial erosion may well have been used later by* ***Leonardo da Vinci***.

Albert studied at Prague and then at Paris. He was the rector of the University of Paris (1353–1362), the founder and first rector of the University of Vienna (1365–1366), and bishop of Helmstädt (1366). Albert helped spread the nominalist logic of ***William of Ockham*** *and the ideas of* ***Bradwardine***, *Oresme and others. He was mainly a transmitter of good mathematical ideas but did not contribute his own work to those.*

The 4^{th} *member of the closely-knit Parisian group was Albert's associate* ***Themo Judaei*** *(Themon son of the Jew; fl. 1349–1361). Author of commentaries on physics, astronomy, and meteorology which were also probably used by Leonardo.*

Themo was born in Westphalia, and spent part of his youth in Münster. After converting to Christianity he proceeded to Paris and studied at the Sorbonne, passing his final examination in 1349. He became a prominent teacher at the University of Paris and trained many students. His discussion of the rainbow *is very elaborate, comparable to that given by* ***Dietrich of Freiberg***, *and superior to that given by* **de Dominis** *(1611).*

So intimately was the work of the four men interwoven that it is virtually impossible to disentangle the literary threads to determine the original authorship in cases in which all of them wrote similar works on the same topic. All four of them were, of course, strongly influenced by Aristotle; but during the 13^{th} *and* 14^{th} *centuries a reaction had set in against servile acceptance of Peripatetic teachings. There arose an increasing awareness of the need for a mathematical treatment of physics and a definite inclination to regard quantitative formulations as adequate explanations of natural phenomena. Emphasis on the metaphysical "why" was being shifted, in scientific discussions, to the physical "how". This attitude foretold for advances in understanding of physical phenomena.*

The Buridan school was primarily responsible for the triumph of the mathematical over the philosophical approach to physical problems.

Later, the teachings of Buridan, Oresme, Albert of Saxony, and Themo found their way to other centers of learning. Paris and Oxford in particular were at the time closely related by scholarly ties, and Buridanian doctrines flourished in England as well as France.

ca 1350 CE **Jean Buridan**; **Joannes Buridanus** (1295–1358, France). Post-Aristotelian philosopher of the Ockhamist school of Paris and a methodological contributor to science. In a commentary on the *Physics* of Aristotle he showed that Aristotelian physics with its *unmoved movers*, its *natural* and *violent* motion etc., was empty verbiage. He made considerable advances in the study of motions, momentum, acceleration, and the theory of falling bodies, and came very close to formulating Newton's Law of Inertia.

These ideas, clearly expressed by Buridan, had been slowly taking shape at Merton College and at the Sorbonne during the 14^{th} century, and contributed to the eventual downfall of Aristotelian physics and cosmogony.

Buridan insisted that scientific truth is not absolute, like mathematical truth, but has degrees of certitude. The kind of certainty Buridan had in mind consisted of indemonstrable principles that formed the basis of natural science but are derivable from inductive generalization and accepted because they have been observed to be true in many instances, and to be false in none. Moreover, Buridan regarded these inductively generalized principles as conditional because their truth is predicted on the assumption of "common course of nature". This was a profound assumption that effectively eliminated the effect on science of unpredictable, divine interventions and with it the need to worry about miracles in the pursuit of natural philosophy.

Miracles could no longer affect the validity of natural science. Nor could chance occurrences that might occasionally impede or prevent the natural effects of natural causes. On this basis Buridan proclaimed that "*for us the comprehension of truth with certitude is possible*". Using reason, experience, and inductive generalizations, he sought to "save the phenomena" in accordance with the principle of *Ockham's Razor* – that is, by the simplest explanation that fits the evidence[119]

---

[119] The widespread use of the principle of simplicity was a feature typical of me-

Buridan studied in Paris under William of Ockham. He was a professor of philosophy in the University of Paris and its rector in 1327. An ordinance of Louis XI, in 1473, prohibited the reading of his works.

1350–1370 CE **Nicole Oresme** (1323–1382, France). One of the greatest men of science of the 14^{th} century who meditated and theorized on motion, infinity and the continuum – all concepts of which are fundamental to modern mathematics. A bishop who wrote numerous works in both French and Latin on scholastic, political, scientific and mathematical problems. Introduced notions that correspond to the idea of rational (fractional) exponents as well as a concept similar to that of a *function*. Invented the basic idea of coordinate geometry before Descartes (1350). Foreshadowed Galileo in his *mathematical* formulation of uniformly accelerated motion. His translations of Aristotle served to popularize science.

While accepting the Ptolemaic system of the Universe, Oresme, in a commentary (1370) on Aristotle's *De Coelo et Mundo*, attributed the apparent daily motion of the stars to the rotation of the earth about its axis. He argued that the earth's rotation is compatible with other observed astronomical phenomena, such as eclipses of the sun and conjunctions and oppositions of the planets.

In his unpublished *Algorismus proportionum* he was first to introduce (1360) *fractional exponents*, which were not widely used until the 17^{th} century. In his tract *De uniformitae at difformitate intensionum* (1350) he introduced the idea of graphical representation of functions, as the independent variable was permitted to take on small increments, thus foreshadowing Cartesian coordinate geometry through the logical equivalence between tabulated values and their graphical display. A century after Oresme's tract was written, it was extant in several printings, and in this way came to the attention of **Descartes**.

Among other contributions of Oresme was his proof, apparently the first in the history of mathematics, that the *harmonic series* is divergent[120].

---

dieval natural philosophy. It was also characteristic of science in the 17^{th} century, as when **Johannes Kepler** declared that "*it is the most widely accepted axiom in the natural science that Nature makes use of the fewest possible means*".

120 His proof was:

$$\frac{1}{2} + (\frac{1}{3} + \frac{1}{4}) + (\frac{1}{5} + \frac{1}{6} + \frac{1}{7} + \frac{1}{8}) + \cdots + \frac{1}{n} + \cdots > \frac{1}{2} + \frac{2}{4} + \frac{4}{8} + \frac{8}{16} + \cdots \to \infty.$$

This was shown again by **Pietro Mengoli** (1626–1686, Italy), who also demonstrated that the harmonic series with *alternating signs* converges to $\{\log_e 2\}$.

Oresme was born in Normandy. In 1348 he was a student in the College of Navarre at Paris, of which he became head in 1356. In 1361 he was named dean of the cathedral of Rouen. He was advisor to Charles V of France, who appointed him bishop of Lisieux (1377).

1360 CE **Henry de Vick of Württemburg** built the first mechanical clock (with iron movement) for King Charles V of France.

1362 CE One of the North-Sea greatest stormtides. Destroyed the Island of *Strand* and the city of *Ronghold*.

1368 CE In China, the **Ming** dynasty (militantly Chinese and exclusive) replaced the Mongol Yuan dynasty (cosmopolitan and tolerant). Thus ended for centuries the European prospects of Christianizing China, and also of obtaining allies in Eastern and Central Asia with whom to crush the Muslim hosts of the Near East. After a century of intercourse with the West, China became again a remote, inaccessible country.

ca 1375 CE **Narayana Pandit** (1340–1400, India). Mathematician. Gave a rule to calculate the approximate value of a non-square root number N, using the equation $Nx^2 + 1 = y^2$. He thus calculated $\sqrt{10}$, correct to 20 decimal places.

1375–1440 CE **Avraham** and **Yehudah Crescas**[121] (or **Cresques**) (ca 1330–1387; 1360–1440, Majorca, Barcelona and Portugal). Father and son. The greatest cartographers of their age, nautical instrument makers and founders of the Majorcan school of cartography. **Avraham** issued the famous *Catalan map of the world* (1375). Discarding Ptolemy, it shows India (for the first time!) as a peninsula.

In the second half of the 14^{th} century, Jewish cartographers and instrument makers (astrolabes, compasses, etc.) were active in Majorca under the patronage of the kings Peter III and IV of Aragon. The maps were originally intended for the use of seamen navigating in the Mediterranean and along the coasts of the Atlantic, but in the course of time they were extended to the mainland and ultimately developed into maps of the whole world, as then known.

---

[121] Personal or family name common among the Jews of Southern France and Catalonia. It comes from the Latin verb *crescere* (= to grow, increase) and is a French form of *Joseph* (= may God increase, *Gen* **30**, 24). Bearers of the name include **Hisdai Crescas**, the above Majorean map-makers, **Crescas Elijah** (physician to Pedro IV of Aragon), and the astrologer **Cresques de Vivers**.

Avraham, who held the title *magister mappamundorum et buxolarum* was in the service of the infante John of Aragon, who in 1381 presented the world map to king Charles VI of France. He was originally from Barcelona.

His son, Jehuda Crescas, collaborated for a while with his father in Majorca and after his father's death (1387) continued as cartographer and compass maker for the kings John I and Martin I of Aragon. During the riots in Spain (1391), about 50,000 Jews in Majorca were massacred and Yehudah was forcibly converted to Christianity to save his life. His name was changed to Jayme Ribes. After staying in Majorca for a while, where he was known as *Io Jucu buscoler* ("Jew of the map"), he moved to Barcelona (1420), migrated (1427) to Portugal, where he instructed Prince Henry's pilots in their art.

1391 CE **Geoffrey Chaucer** (ca 1340–1400, England). The greatest English poet of the Middle Ages. Wrote *A Treatise on the Astrolabe*, describing the construction of the astrolabe and its use in calculating the position of a star.

The astrolabe is an instrument that ancient astronomers used to measure the angles of celestial bodies above the horizon. It consists of a metal disc suspended from a frame so that the disk remains vertical. The disk has sights for observing a star, and graduations for measuring its elevation. The astrolabe became obsolete with the invention of more modern instruments, such as the *sextant*.

A reduced version of the astrolabe was the *quadrant*, which is shaped like a quarter of a pie with scales marked on its curved edge.

ca 1400 CE **Madhava of Sangamaramma** (1350–1425, India). Astronomer and mathematician. Discovered the series expansion equivalent to the Maclaurin expansion of $\sin x$, $\cos x$ and $\tan^{-1} x$, about 300 years before they were discovered in Europe (Newton 1676, Gregory 1677, Taylor 1715). This outstanding contribution was a decisive step toward modern classical analysis.

1405–1433 CE **Zheng He (Cheng Ho)** (1371–1435, China). Chinese mariner and navigator, '*Admiral of the Western Seas.*'

China's most famous navigator and explorer. For 28 years he traveled to the West, totaling more than 50,000 km (in seven expeditions, and visiting some 30 countries and territories including: Java, Sumatra, Vietnam, Siam, Singapore, Cambodia, Philippines, Ceylon, Yemen, Arabia, Bangladesh, and Somalia).

China has a very old seafaring tradition. Chinese ships had sailed to India as early as the Han Dynasty. Chinese sailors had an important invention to help them – the compass. The compass, or “south pointing spoon,” started out as a fortune-telling instrument.

Along the Silk Road, warfare and chaos were commonplace. The dangers of travel were increased by roving armies, bandits and unpredictable governments. Each small kingdom along the route taxed merchants, making their goods more expensive to the buyer. None of this decreased demand for the goods of the Silk Road trade. But in did propel merchants to search for other ways to transport their wares.

Merchant ships had always traveled the seaways between China and Egypt. But the disturbances in the interior of the continent, combined with improvements in shipbuilding and navigation, gave merchants all the reasons they needed to sell their camels and invest in ships. The seas were safe by comparison. Ships were faster than camels and could carry more cargo. In addition, the countries on the coasts of the Indian Ocean were generally far removed from the warring Mongols and the rebellions against them.

After the Mongols were overthrown in 1368, the emperor of the new Ming Dynasty[122] wanted to assert Chinese power. Because China was no longer part of a land empire that stretched from Asia to Europe, the emperor turned to the sea. He decided to build a navy. The Chinese made elaborate plans that would not be fulfilled for many years. A shipyard was built at the new capital of Najing (Nanking). Thousands of varnish and tung trees were planted on nearby Purple Mountain to provide wood for shipbuilding. The emperor established a school of foreign languages to train interpreters. While all this was going on, the man who would lead the navy was still an infant.

Chinese shipbuilders also developed fore-and-aft sails, the stern post rudder, and boats with paddlewheels. Watertight compartments below decks kept the ship from sinking. Some boats were armor plated for protection. All these developments made long distance navigation possible.

At the orders of the then emperor, Cheng Zu, a vast fleet set sail in July, 1405 from Liujia Harbor near Suzhou on a distant voyage. The purpose was to establish relations with foreign countries, to expand trade contacts and to look for treasures to satisfy the desire of the sovereign for luxuries. The man who was given charge of the fleet was Zheng He, a eunuch. Under his command was a vast fleet of 62 ships manned by more than 27,800 men, including sailors, clerks, interpreters, officers and soldiers, artisans, medical men and meteorologists.

On board the ships were large quantities of cargo including silk goods, porcelain, gold and silver ware, copper utensils, iron implements, cotton

[122] The Ming dynasty lasted until 1644. Mongol incursions and Japanese sea pirate attacks occurred during 1522–1566.

goods, mercury, umbrellas and straw mats. The fleet sailed along the coast of Fujian, down south to Zhancheng and, after crossing the South China Sea, reached such places as Java and Sri Lanka. On the way back, it sailed along the west coast of India and returned to the home port in 1407.

Between 1405 and 1433, Zheng He had, over a period of 28 years, been ordered eight times to act as envoy to countries lying to the west of China. Each time he had under his command a big fleet and a staff of more than 20,000 men. His fleets had sailed in the South China Sea and the Indian Ocean. They had gone further south to Java in today's Indonesia. Sailing then in a northwest direction, they had visited Yemen, Iran and Mecca and further west to today's Somalia in East Africa. All this had taken place about half a century before Columbus' voyage to America.

On each voyage Zheng He was acting as the envoy and commercial representative of the Ming court. No matter what country he visited, he called on the ruler of the land, presenting to him valuable gifts in token of China's sincere desire to develop friendly relations and inviting the host sovereign to send emissaries to China. Wherever he was, he made a careful study of the customs and habits of local residents. Showing them due respect, he bartered or dealt with them through consultation and negotiation on the basis of equality and mutual benefit. In this way, he obtained large quantities of pearls and precious stones, corals, ivory and dyestuffs for the Chinese emperor. He also brought back several kinds of rare and precious animals such as giraffe, lion, ostrich and leopard.

In ancient India, Chinese sailors made a good impression on the local people by observing local trading customs and practices such as clapping hands to clinch a deal in full view of others and never going back on it.

When he visited Sri Lanka on his third voyage, Zheng He offered a quantity of gold and silver, Buddhist ceremonial vessels and silk-knit religious pennants to local temples on whose ground steles were set up to mark the occasion of his visit.

Wherever he went, he was warmly received. At Zhancheng, the king of the land, in full royal regalia, came in person on elephant back with 500 cavalrymen to meet him at the wharf and then take him back to the palace. On the way they were greeted by local inhabitants who blew trumpets made of coconut shells and performed national dances at a solemn and joyous ceremony. Even today, people in Somalia and Tanzania look upon Ming China as a symbol of the traditional friendship between their own country and China. In Thailand today, there are places named after Zheng He's childhood name Sanbao (tree treasures) such as Sanbao Harbor and Sanbao Pagoda. Malacca of Malaysia is known also as the City of Sanbao. At Java in Indonesia, there is the Sanbao Temple. In Calicut (Kozhikode today) of India, there is an inscribed tablet set up in Zheng He's memory.

On his first voyage overseas, the largest ship in the fleet had a length of 400 feet and a width of 180. Manned by more than 200 sailors and able to accommodate 1,000 passengers, it was equipped with nine masts which flew 12 big sails. This was probably the largest sea-going vessel of the day[123]. Other vessels might not be of the same size but on an average each one was able to carry aboard four to five hundred passengers.

Many of the navigational problems encountered were solved in a rational, scientific way. For instance, the way fresh water was collected and stored, the stability of the hull and its buoyancy, the making of sea charts and the use of navigational apparatuses like the compass. This accounted for the fact that in spite of terrible storms, this fleet had ploughed the waves day and night in full sail.

It is generally believed that Zheng He had the largest, most advanced fleet in the world in the 15^{th} century. On each of his 8 voyages, Zheng He kept a detailed logbook and made many charts which were later collected in what was called Zheng He's Nautical Charts, which was the first of its kind in the world. From this we can say that China in those days probably led the world in the technology of ship-building and the science of navigation.

Zheng He was born in 1371 in Kunyang, a town in southwest Yunnan Province. His family, named Ma, were part of a minority group known as the Semur. They originally came from Central Asia and followed the religion of Islam. Both his grandfather and father had made the Muslim pilgrimage to Mecca. Zheng He grew up hearing their accounts of travel through foreign lands.

Yunnan was one of the last strongholds of Mongol support, holding out long after the Ming Dynasty began. After Ming armies conquered Yunnan in 1382, Zheng He was taken captive and brought to Nanjing. The eleven year old boy was made a servant of the prince who would become the Emperor.

When his prince seized the Chinese throne from a nephew, Zheng He fought well on his behalf. As a result, Zheng He became a close confidant of the new emperor and was given an important position at court.

When Zheng He came back from his seventh voyage in 1433, he was sixty-two years old. He had accomplished much for China, spreading the glory of the Middle Kingdom to many countries that now sent tribute and ambassadors to the court. Though he died soon afterward, his exploits had won him fame.

---

[123] In comparison, the flagship of Columbus, the *Santa Maria* was only 75 ft $\times$ 25 ft in size.

Plays and novels were written about his voyages. In such places as Malacca and Java, towns, caves, and temples were named after him.

However, a new Ming emperor had come to the throne. His scholar-officials criticized Zheng's achievements, complaining about their great expense. China was now fighting another barbarian enemy on its western borders and needed to devote its resources to that struggle. When a court favorite wanted to continue Zheng He's voyages, he was turned down. To make sure, the court officials destroyed the logs that Zheng He had kept. We know about his voyages only from the pillar and some accounts that his crew members wrote.

Thus, China abandoned its overseas voyages. It was a fateful decision, for just at that time, Portugal was beginning to send its ships down the west coast of Africa. In the centuries that followed, European explorers would sail to all parts of the world. They would establish colonies in Africa, America, and finally in the nations of East Asia. China would suffer because it had turned its back on exploration. Zheng He had started the process that might have led the Middle Kingdom to greater glory. Unfortunately the rulers of the Ming Dynasty refused to follow his lead.

The British submarine engineer and historian Gavin Menzies gave a seminar on March 15, 2002 to the Royal Geographical Society in London to support his theory that Zheng He beat Columbus by more than 70 years in discovering America. Using evidence from maps dated before Columbus' trip, and astronomical maps traced back to Zheng He's time, Menzies claimed that the Zheng he should be honored as the first discoverer of America.

The Voyagers (1405–1550)

"There will come a time in future ages when the ocean will loosen the chains of the universe and a vast land will appear, new worlds will be seen and Iceland will not be the end of the earth."

Lucius Annaeus Seneca, '*Medea*' (4 BCE–65)

Almost concurrently with the collapse of the Byzantine Empire and the 'printing revolution', the energy accumulated during the long intellectual hibernation of the middle ages suddenly burst forth in yet another endeavor – the geographical revolution.

The European 'discovery' of the Indian Ocean in the 15^{th} *and* 16^{th} *centuries was only new to them as Western Europeans. The Ancient Egyptians had traded on the African shores of the Indian Ocean. The Arabs began to settle it in the* 8^{th} *century CE: Mogadishu (ca 720), Sofala (ca 780), Madagascar (*9^{th} *century). These were the bases from which their subsequent explorations began.*

Chinese junks were in the harbor of Malacca when Albuquerque arrived there. Chinese texts as early as 860 *CE describe the south coast of the Gulf of Aden and the Somali coast. Malindi (Mo-Lin) was known at about* 1060 *and the Zanzibar coast (Tsheng-Pa) and Madagascar at about* 1178. *Chinese coins and porcelain dating from the* 7^{th} *century onwards (the majority from the Sung dynasty 960–1279) are so abundant on the east coast of Africa that they must have been used in payment for goods.*

In the early 15^{th} *century the great Chinese voyages to the Indian Ocean began and they are as well documented as any in the West. There were seven expeditions in all. In the first (1405–1407), the Emperor Cheng Zu commissioned* 62 *junks carrying* $37,000$ *men under the command of the Imperial Palace Eunuch Cheng Ho. They set sail from Liu-Chia Kang in the province of Suchow, reached Indo-China, Java, Sumatra, Ceylon and Calicut.*

In the second expedition (1407–1409) they reached Siam, Cochin and other parts on the west coast of India. The third, based on Malacca, voyaged in the East Indies and the southwest coast of India and Ceylon.

On the fourth voyage, based on Ceylon, they explored the Bengal coast, the Maldive Islands, and reached Hormuz.

On the fifth voyage the fleet divided into squadrons: A Pacific squadron reached the Ryukyu Islands and Brunei in northwest Borneo, while squadrons in the Indian Ocean explored the coast between Hormuz and Aden, Mogadishu in Somalia, Malindi and the coast further south.

The sixth expedition (1421–1422) was an amplification of the previous one, visiting 36 *states between Brunei and Zanzibar.*

The last expedition (1431–1433) covered the areas north and west of Java as far north as Jiddah in the Red Sea. It was the last great venture of the Ming Navy. From now on the inward-looking Confucians faction was in the ascendant. It regarded things brought from beyond the seas as superfluous. Among them were the tusks of elephants, rhinoceros horns, pearls and aromatics from Africa and, above all else, spices.

It is more than possible that they got as far as the southern Atlantic and some of their captains may have doubled the Cape and seen the West African shore. Thus, upon the death of the last Ming Emperor, ended the age of Chinese maritime glory. Could they discover America ahead of Columbus?

In 1400, *Europeans knew scarcely more about the earth than the Romans had. The oceans around the continent were still an impenetrable barrier. In fact, many people in those days believed that further south the sea grew boiling hot, or that ships could fall off the edge of the earth.*

The man who helped overcome such fears, at least among his own men, was ***Prince Henry the Navigator*** *(1394–1460), the third son of King John of Portugal from an English mother. Henry was a soldier, not a sailor, and did not himself take part in any journeys of discovery. As a driving force he had no peer in the history of navigation, blending his vision with the skill of his sailors and the wisdom of medieval scholars.*

In 1415 *Henry took part in the campaign in which Spain captured the North African port of Ceuta from the Moors. A substantial link between Moorish science and the medieval universities of Christendom already existed when the growth of mercantile navigation renewed the impetus to astronomical discovery. From* 1419 *onwards, Henry dispatched a series of expeditions down the western coast of Africa and spent most of his time organizing and financing the exploration fleets. About* 1439 *he retired to Sagre, in southern Portugal, where he erected an observatory, and founded a college of navigation. He assembled a team of geographers and navigators, and developed ships suitable for voyages of exploration.*

For 40 *years he devoted himself to cosmographical studies, while equipping and organizing expeditions which won for him the title of* ***Henry the Navigator****. For the preparation of maps, nautical tables and instruments, he enlisted Jewish cartographers and astronomers of the* **Zacuto** *and* **Crescas** *families, employing them to instruct his captains and assist in piloting his vessels. The development of astronomy once more became part of the everyday life of mankind.*

The motives that prompted the Europeans, rather than the Chinese or Muslims, to 'discover' the rest of the world were both religious (convert the heathen and weaken Islam by placing Christian allies in the Muslim rear) and economic (need to find precious metals to pay for Eastern spices).

A third cause, not less important, was the challenge of fresh ideas that took hold in Europe during the Renaissance. The learning that was brought to Europe by the fleeing savants of Byzantium spread rapidly, with the aid of printing. It boosted the questioning of established dogmas in religion, art and science. Scholarship began to develop independently of the church, and the human rather than divine in life and art was underlined; the well-rounded *individual* became an ideal. This gave impetus to explorers and reformers alike.*

By the late 15^{th} century a restless, energetic, and bold seafaring population was scattered along Europe's Atlantic Coastline. Resourceful sailors, fishermen, and merchants had developed techniques and the ships for making long voyages. They had religious and economic motives strong enough to overcome their superstitious fears of what lay beyond unknown waters[124]*, and their governments were often ready to back them. Europe needed Asia more than Asia needed Europe, and Europeans believed that it would not be too difficult to reach Asia by sailing West.*

Ptolemy in the 2^{d} century had underestimated the size of the globe and had overestimated the span of Asia, and the geographers of the 15^{th} century, accepting his miscalculations, were convinced that Japan and China lay only a few thousand miles West of Europe. The journey seemed possible, and the psychological environment was favorable for an age of discovery.

After Henry's death, his grandnephew, King John II, speeded up the effort to find an all-water route to India that would short-circuit the Venetian-Arab monopoly. Within ten years (1487–1497), two voyages took place which raised Portugal from a nation of peasants, fishermen and seafaring adventurers to a great maritime power. By 1488 **Bartholomeu Dias** *(1450–1500) rounded the Cape of Good Hope and in 1497,* **Vasco da Gama** *(1469–1524) followed his route and with four ships reached Calicut, India in* 1498. *In* 1500, *a larger fleet under* **Pedro Álvars Cabral** *(1467–1520) touched the coast of Brazil, and headed for India in da Gama's wake.*

Once the Portuguese had overcome the natural hazards of the sea journey from Europe to India, they moved purposefully to establish a commercial dominance in south-east Asia. King Manoel sent a permanent force to India, led by **Francesco de Almeida** *(1450–1510) in* 1505. *On the way, Almeida took Kilwa and razed Mombasa, before setting himself up as Governor-General of India, based at Cochin. His son Laurenco reached Ceylon, an important source of spices, and the Maldives, an island chain in the Indian Ocean.*

---

[124] When seamen left Portugal for the unknown, their wives cried at their departure, dressed in black as if they were becoming widows. They spoke of *saudade* or "regret of absence". This word which best explains the soul of the *Fado* (fate), the traditional song of Portugal, has no exact translation in any other language (the English *longing*, the French *nostalgia*, and the German *sehnsucht* are part of it). One may call it "sweet sadness" – a longing for something very dear but impossible to achieve. *Fado* is the expression for this feeling. Today, the lady singers of the *Fado* are always dressed in black, lights are muted and the public listens in silence.

In 1509, off Diu Island, a small force of 19 ships under the command of Almeida totally vanquished the combined Muslim fleet of 100 vessels. It was the end of Arab power east of Aden.

Almeida was succeeded as Governor-General of India by one of the great empire-builders of Portuguese history, ***Alfonso d'Albuquerque*** *(1453–1515), in 1509. He seized Goa, on the Indian mainland, captured Malaca to control the trade between the Spice Islands and the Indian Ocean and secured Hormuz to dominate the entrance of the Persian Gulf. The capture of these strategic points opened before the Portuguese the seaway to China and Japan. Indeed, the first Portuguese mission reached China in 1514 and then Japan in 1542.*

In 1557, in recognition of the assistance that they rendered to the Chinese in exterminating Chinese pirates, the Portuguese were granted a lease on the peninsula of Macau.

The voyagers had made large profits, but the cost to the Portuguese government of equipping fleets soon ate up those profits. Italian, German and Flemish bankers soon dominated the Portuguese trade, and the spices that arrived at Lisbon were sent on directly to Antwerp. The burden of the empire was already proving heavy when Portugal fell into the grip of Spain in 1580.

Before da Gama's successful voyage, a Genoese navigator, ***Christopher Columbus*** *(1446–1506) had persuaded Queen Isabella of Spain to finance an expedition to find a westward route to India. Columbus was using the ancient maps of Ptolemy, according to which the size of the Atlantic was underestimated. Finally, in 1492 he sailed across the Atlantic Ocean and discovered the Indies, believing them to be his goal. Columbus never did realize he had found a whole new continent.*

However, a later adventurer, ***Amerigo Vespucci*** *(1451–1512) [director of the Medici branch bank in Seville], claimed that he had sailed on both Spanish and Portuguese voyages and described what he saw in letters that were widely read throughout Europe. In one, he referred to the great southern continent in the west as 'Mundus Novus' (New World). A German mapmaker,* ***Martin Waldseemüller****, labeled the two new continents in 1507, by the name 'America' in honor of Vespucci.*

In 1513, the Spanish explorer ***Vasco Núñez de Balboa*** *(1475–1519) crossed the Isthmus of Panama and became the first European to see the Eastern Pacific. Balboa is known as the European discoverer of the Pacific because he realized that it was a great unknown sea.*

The first round-the-world voyage was the inspiration of a Portuguese navigator, ***Ferdinand Magellan***[125] *(Femão de Magalhaes; Fernando de Mag-*

[125] It took **Magellan** to prove that the world was round, but as early as 350 BCE

allanes, 1480–1521). Out of favor in his own country, Magellan offered his services to Spain, whose ruler, Emperor Charles V, provided a fleet for the voyage.

Magellan set sail in 1519 *with five ships, aiming for the southern tip of South America, where he was sure there was a route to the Western Ocean. Despite tremendous storms, Magellan found his route – the strait that now bears his name – and sailed into a calm sea which he named 'Pacific'; he had lost one ship, and one had turned for home. Magellan sailed across the Pacific to the Philippines, where he was killed in a skirmish with the natives. The epic voyage was completed by* ***Juan Sebastian del Cano*** *with one ship, returning by way of the Cape of Good Hope in* 1522*, the first ship to sail around the world. In that year Europe has begun to cast a web of communication and influence around the earth.*

During the next four centuries that web was to draw all of the world under the influence of European civilization.

The Leading Edge of Western Civilization (1300–1600)

In spite of all the chaos and misery that afflicted Europeans during 1300-1450 CE, science and technology prevailed. Why? Although the scholarly work of the period was mostly unoriginal it was important in the sense that it was useful to men with ideas of their own. Columbus drew most of his notions about geography from books written in the fourteenth and early fifteenth centuries. And not all the work was unoriginal. In philosophy there was a sharp attack on the system of Thomas Aquinas which freed scholars, to some extent, from their adherence to the Aristotelian ideas that had been incorporated into Thomas' theology. Once Aristotle's ideas had been challenged, there could be wider speculation on scientific questions, especially on explanation of motion

---

the idea was generally accepted by the *Greeks*.

and acceleration. The studies through which Galileo revolutionized the science of physics were based on problems raised by fourteenth-century scholars.

More important than any specific achievement was the very fact that interest in scientific problems persisted. Up to the end of the Middle Ages, Western scholars, relying largely on the work of the Greeks and Muslims, had made no outstanding contribution to scientific knowledge. But they were remarkably persistent and kept working on scientific problems after other peoples had given up. The Greeks and Muslims eventually lost interest in science, as did the Chinese, who had their own independent scientific tradition. But from the twelfth century on, there were always some scholars in the West who were interested in science, and this long-term devotion led, in the end, to the great discoveries of the early modern period. Men like Copernicus and Galileo were trained in universities that used the methods and the books of the later Middle Ages.

No one has ever given a completely satisfactory explanation of this continuing interest in science. Certainly Westerners were paying more attention to the things of this world during the later Middle Ages and less attention to the aims of the Church. But Chinese society was far more secular, yet the Chinese, in the long run, fell behind the Europeans. Perhaps more important was the Western tendency to be dissatisfied with the status quo*, a tendency that was especially evident in the crucial years between 1300 and 1600. In China, a philosopher like Thomas Aquinas would have become an unchallenged authority; in Europe his system was questioned within a generation after his death. Europeans respected authority, but they always felt that authoritative treatises needed to be reinterpreted. Finally, there was a curious patience with details, a willingness and an enthusiasm to work very hard for very small gains.*

These qualities also explained some of the advances in technology *that were made in the last medieval centuries. These are:*

- *The development of firearms.*
- *The invention of printing (ca 1446).*
- *Ocean shipping.*
- *The invention of the mechanical clock (ca 1352).*

In the field of firearms the Europeans capitalized on a technique known to other peoples. The Chinese, for example, were probably the first to discover gunpowder, and they had cannons about as early as the Europeans. But Chinese guns were never very efficient, and the Chinese never developed an army that was primarily dependent on firearms. The Europeans carried *their experiments with cannons much further than the Chinese. Although the European guns were not very good - they were as apt to kill the men who fired them as those against whom they were aimed - they had become fairly reliable by the end of the fifteenth century. The military significance of this development is obvious. It reduced the power of local feudal lords by making their castles untenable; conversely, it increased the power of kings and great princes like the Duke of Burgundy, for they were the only ones who could afford the expensive new weapons.*

The development of firearms caused a rapid growth in other branches of technology. In order to make gun barrels that would not burst under the shock of an explosion, much had to be learned about metallurgy. And in order to make gun barrels that were truly round and hence could deliver the full effect of the charge, better metalworking tools and more precise instruments had to be developed. Better techniques in using metals led to greater demands for metals, and this in turn stimulated the mining industry. The miners of Germany (including Bohemia and Austria), supplying the chief source of metals for Europe, learned to push their shafts deeper and devise ways of draining off underground water. Increased use of metals and greater skill in mining in the long run transformed European industry. To take the most famous example, pumps operated by a piston traveling in a cylinder were developed in order to remove water from mines; it was this kind of pump that eventually furnished the model for the first steam engine.

The invention of printing *in the fifteenth century also owed much to developments in metallurgy. The essential element in printing was the use of movable type, and good type in turn depended on the availability of a metal that would take the exact shape of the mold into which it was poured. Thanks to their knowledge of metallurgy, the Germans succeeded in developing an alloy that expanded as it cooled, so that it fitted the mold exactly and gave sharp, clear impressions.*

Another technical advance of Western Europe in the latter Middle Ages was in ocean shipping. *Here there was at first more patient experimentation than striking discoveries. By the end of the thirteenth century the sailors of Western countries had ships that could tack against the wind and were seaworthy enough to survive the storms of the Atlantic. The navigators of the period could find their latitude, though not their longitude, by star and sun sights; they knew that the earth was round and that the distance to the rich countries of the East was not impossibly great. Very little more was needed for the great voyages of discovery except practice, and during the fourteenth and fifteenth centuries daring men were mastering the art of oceanic navigation. French and Spanish seamen had discovered the Canary Islands at least by the fourteenth century, and by 1400 the Portuguese had pushed down to the bend in the African coast, claiming Madeira and the Cape*

Verde Islands along the way.

These voyages illustrate the point that was made earlier: Europeans were no more skillful or intelligent than other peoples, they were simply more persistent or more aggressive. During the same years in which the Europeans were making their first sorties into the Atlantic, the Chinese were sending expeditions into the Indian Ocean. There they found rich kingdoms, ancient civilizations, and profitable sources of trade. In contrast, the Europeans discovered only barren islands and the fever-stricken coast of Africa. Yet the Chinese abandoned their explorations because they, or at least their rulers, were satisfied with what they had at home. The Europeans persisted, though it was almost two centuries before they reached the thriving trading centers of the East or the treasures of Mexico and Peru.

Not as striking as the early voyages, but almost as significant, was the invention of the mechanical clock. The first clocks, which appeared in the fourteenth century, were not very accurate, but they were soon improved by the discovery of the principle of the escapement - that is, the system by which the train of gears moves only a precise distance before it is checked and then released to move the same distance again – thus ensuring uniformity of the time-keeping motions. Crude as the first clocks were, they modified, in the long run, the mental outlook of the Western peoples.

For several centuries one of the sharpest differences between the West and the rest of the world lay in attitude toward precise measurement, especially the precise measurement of time. Western civilization has come to be dominated by the clock and the timetable, and Westerners have had little sympathy with people who have escaped this domination.

1410 CE **Hisdai ben Avraham Crescas** (1340–1411, Spain). Philosopher. The first European thinker to establish the feasibility of *infinite magnitude* and *infinite space*, thus paving the way for the modern conception of the Universe. A pioneer in his criticism of Aristotle and in his revival of the views of pre-Aristotelian Greek philosophers.

Crescas rejected Neo-Platonism and Aristotelian physics and metaphysics. He stated that "*there are no other worlds*" than the one system in which the earth is situated. This inspired such Christian thinkers as **Nicolas of Cusa** (1401–1464), **Giordano Bruno** (1548–1600), **Marsilio Ficino**[126]

[126] Translated (1484) the complete works of **Plato** from Greek into Latin. His

(1433–1499) and **Pico della Mirandola** (1470–1533). He deeply influenced **Spinoza**, who was indebted to Crescas for his concept of the Universe.

Crescas launched a sharp criticism of Maimonides and Gersonides because of their efforts to reconcile Judaism with Greek philosophy. He refuted the Aristotelian conception of one finite Universe and believed in the *unification of forces of nature* (including magnetic attraction!). These ideas he expounded in his principal work on *Or Adonai* (Light of God) to the completion of which he devoted many years of his life.

Like almost all Jewish philosophers in the Middle Ages, Crescas developed his philosophical system in the face of persecution and imminent personal danger. He endured much personal persecution during the first Spanish Inquisition, but still defended his views with a spiritual originality and courage uncommon in the history of the Middle Ages.

He was born in Barcelona and was denounced and victimized there, imprisoned and fined (1367), despite the recognition of his innocence. He moved and settled in Saragossa (1390). Crescas became an authority on Jewish law and ritual tradition, and often intervened diplomatically on behalf of his co-religionists in Aragon and the neighboring kingdoms. In 1401–2, at the request of Charles III (the Noble), he spent some time in Pamplona. A son of Crescas suffered a martyr's death in Barcelona in the anti-Jewish riots of 1391. Afterwards he received permission (1393) from the King of Aragon to marry a second wife, since his first wife was unable to have any more children. He died at Saragossa.

---

teaching, translations, and Platonic interpretations formed the basis of a thriving literary culture which formed the pillar of European thought over subsequent ages.

1413–1414 CE *The Tortosa Disputation*, the most remarkable of its kind ever held[127]. It took place in the presence of the anti-pope[128] Benedict XIII, many cardinals, bishops and a vast audience. It began Feb. 7, 1413 and lasted 21 months in 69 sessions. The principal matter debated was whether the Messiah had already arrived or not. The renegade Jew Joshua Lorki opened for the Christians and the learned Vidal Benveniste for the Jews. The disputations degenerated into the usual interpretations and misinterpretations of Biblical and Talmudic passages. Naturally, the Jews were declared ignominious losers by the anti-pope, the Talmud was condemned and a ban was placed on the study of the Talmud by Jews.

The Jewish defenders counted among them the philosopher **Joseph Albo** (1380–1444), who rigorously presented the Jewish viewpoint of the Talmud. He attained popularity among medieval scholars (both Christians and Jews alike) for his book *Sefer-He-Ikkarim* (Book of root principles, 1425; published, 1485). It is important to the general philosophy of religion because it establishes criteria whereby the primary fundamental doctrines may be distinguished from those of secondary importance.

---

127 Other well-known disputation book place in Paris (*Yehiel of Paris*, 1240) and Barcelona (*Nahmanides*, 1263). A modern chapter of medieval disputation occurred at the McGill University, Montreal on 31 January 1961 between the Ambassador of Israel to Canada. **Yaacov Herzog** (1921–1972) and the British historian **Arnold Toynbee** (1889–1975). Toynbee declared publicly (and in his books) that the entire life of the Jewish Diaspora from 132 years after Jesus of Nazareth until our own day was a fossilized relic of an obsolete culture that no longer had the right to exist. This indictment was lodged against the Jewish people from an academic rostrum of world repute, with an air of quiet certainty, without any anti-Semitic wrapping, relying solely on the authority of pure philosophical objectivity. The gauntlet had been thrown down before the entire Jewish people and the truth of history, and the young ambassador picked it up on the public platform, confronting the professor as equal in McGill University. At the end of a conclusive and convincing demonstration, Toynbee was compelled to admit defeat and apologized for his analogy.

128 Most Christians did not consider him the legitimate pope; only Spain recognized his claim to the papacy. Consequently, he thought he could add to his reputation by focussing the eyes of all Christians on an elaborate attempt which he would conduct to refute Judaism. Nowadays we would call it a propaganda trick to the anti-Jewishness for personal advancement. The Jews, of course, did not want to take part in anything of the kind. They knew that, far from being a free and open debate, in which they would have an equal right with their Christian opponents to speak their mind, this was but another attempt to humiliate Judaism. But there was no refusing the invitation; threatened with fines, imprisonment and expulsion, they were forced to appear.

Albo stated that three principles are basis to every revelational religion: a belief in God, the concept of divine revelation and divine retributive justice. His object was to show that all religions grow out of the same ideas; only after they grow out of these roots do various religions begin to differ from one another. The branch principles which make up Judaism are purer and more in harmony with philosophy than the branch principles which compose Christianity.

Maimonides in the 12^{th} century had formulated the principles of Judaism in thirteen articles; Albo reduced them to three.

Albo set the example of minimizing Messianism in the formulation of beliefs. Though he fully maintained the Mosaic authorship of the Law and the binding force of tradition, he discriminated between essential and the non-essential in the practices and beliefs of Judaism.

1413–1436 CE **Filippo Brunelleschi** (1377–1446, Italy). The greatest architect of the Early Italian Renaissance. His interest in mathematics led to his invention of *linear perspective* as plane representation of objects in three-dimensional space. The first formal account of the laws of perspective was given by **Leon Battista Alberti**[129] (1404–1472, Italy), the *Universal man* of the Early Renaissance. Alberti, mathematician, architect, painter and writer, is also credited as the originator of scientific cryptography.

The art of the *Renaissance* derived its influence from two main sources. The first was classical: the use once again, after an interval of almost a millennium, of the forms generally applied in Greek or Roman art. The second was the application of the newly discovered technique of perspective. This device gave the artist access to graphic and mathematical rules that enabled him to reproduce on paper or any other flat surface, with scientific accuracy, the appearance of 3-dimensional reality. The examples provided by classical art were of interest above all to architects, who could draw inspiration from monuments of classical antiquity still in existence.

When, relatively early on, the new movement came to be called *Renaissance*, the influence on it of Greek and Roman antiquity was also the most

---

[129] **Alberti** studied the representation of 3-dimensional objects and wrote the first general treatise *Della Pictura* on the laws of perspective (1435). He also worked on maps and collaborated with **Toscannelli** who supplied **Columbus** with the maps for his first voyage.
For further reading, see:

- Gadol, J., *Leon Battista Alberti, Universal Man of the Renaissance*, University of Chicago Press: Chicago, 1973, 266 pp.

obvious. Its proponents considered themselves heirs to the traditions of classical art, and consciously sought the 'rebirth' of its forms, or at least of its spirit. They rejected completely the artistic achievements which had succeeded those of Greece and Rome. They were led to this attitude partly by admiration for classical art but mainly by a deep-rooted conviction that art, like science, had its own laws and that these had been discovered and applied by the artists and craftsmen of ancient Greece and Rome.

Perspective, the second source of influence on the art of the Renaissance, was in fact the most striking of a whole series of revolutionary discoveries. It was a decisive element in the development of the arts because it enabled the artist to show, by means of a realistic sketch – a form which everyone could understand – how a proposed work might look like when finished.

Brunellechi's knowledge of Roman construction principles combined with an analytical and inventive mind permitted him to solve an engineering problem that no other man of the 15^{th} century could have solved – the design and construction of a *dome* (cupola) for the huge crossing of the unfinished *Cathedral of Florence*. The problem was staggering, since the space to be spanned was 44.5 meters in diameter, much too large to permit construction with the aid of traditional wooden centering. Nor was it possible, because of the plan of crossing, to support the dome with buttressed walls

Brunellechi seems to have begun work on the problem about 1417 and erected this revolutionary structure between 1420 and 1436. With exceptional ingenuity he not only discarded traditional building methods and devised new ones[130] but also invented much of the machinery that was necessary for the job (e.g. lifting construction materials into position).

Although he might have preferred the hemispherical shape of Roman domes, Brunellechi raised the center of his dome and designed it around an *ogival section* (ovoid shape) which is inherently more stable, as it reduces the outward *thrust* around the dome's base. To reduce the *weight* of the structure to a minimum, he designed a thin *double shell* (the first in history) around a skeleton of 24 ribs, of which the 8 major ones are visible on the exterior.

Finally, in almost paradoxical fashion, he anchored the structure at the top with a *heavy lantern*. This lantern, although adding to the weight of the dome, has the curious effect of *stabilizing* the entire structure, since without the pressure of the weight the ribs have a tendency to tilt outward from the center, spreading at the top (the cupola is about 113 meter high).

---

[130] To avoid the need for reinforcements or scaffolding, Brunellechi used techniques of brickwork taken from antiquity, but the *form* of the dome is pointed and therefore *Gothic* in style.

Alberti's Cipher (1535)

Codes and cyphers are methods of writing a message so that only persons with a key can read it. The science of making and breaking of codes is known as cryptography.[131]

*An early substitution cipher is found in the Old Testament (**Jeremiah 25**:26 and **51**:41). There, the prophet wrote Sheshach for Babel* (Babylon). *The second letter of the Hebrew alphabet (b) was replaced by the second-to-last letter (sh), and the twelfth letter (l) was replaced by the twelfth-to-last letter (ch). (This cipher is known as Athbash, meaning that the first letter a of the Hebrew alphabet corresponds to the last letter th, the second from the beginning .b, corresponds to the second from the end, etc.) Another Biblical example is found in **Isaiah 7**:6 where Tabeal is written for Remaliah. In this cipher, known as Albam, the first letter a is replaced by the* 12^{th}, *the second, b, by the* 13^{th}, *etc.*

*The Spartans wound a belt in a spiral around a stick, wrote a message along the length of the stick, and unwounded the belt. In this transposition cipher, no one could read the message unless he had a stick exactly the right size. **Caesar** (50* BCE*) used a simple substitution cipher; each letter of the plain text was replaced by the letter three positions to the right in the normal alphabet.*

***Gabriel de Lavinde** wrote the first manual on cryptography (1379). **Sico Simonetta** wrote the first treatise on cryptoanalysis (1474). **John Trithemius** (d. 1516) was an important writer on cryptography.*

In every language, the letters of a lengthy plain text exhibits a predictable frequency; In English the letter that occurs most often is e, and the next in order of frequency is t. The rest, grouped in order of decreasing recurrence are: a, o, i, n, s, h, r, d, l, u, c, m, w, f, y, g, p, b, v, k, s, j, x, z, q.

The drawback of an elementary substitution cipher is that it can be cracked simply by analyzing the frequency with which each symbol occurs. If, on the basis of frequency count, the cryptoanalyst can decipher the nine most common letters e, t, a, o, i, n, s, h, r - he has generally broken 70 percent of

[131] For further reading, see:

- Singh, Simon, *The Code Book*, Anchor Books: New York, 1999, 411 pp.

the cipher. The most modern of code-breaking techniques are based on the age-old method of frequency analysis[132].

*All the single letters must be a or i. Doubling letters are ee, oo, ff, ss, etc. The common words of two letters are (roughly arranged in the order of their frequency) of, to, in, it, is, be, by, or, as, at, an, so etc. The common words of three letters are: the, and (in great excess), for, are, but, all, not, etc.; and of four letters - that, with, from, have, this, they, etc. [**Edgar Allan Poe** (1843) made use of these statistics in his tale The Gold Bug].*

Alberti came up with an ingenious scheme to sabotage a frequency count with his Polyalphabetic substitution cipher in which more than one alphabet is used during encryption. His idea, the basis of modern cryptography, makes use of the so called vigenere table and a keyword agreed upon by the communicating parties.

Say the keyword is LOVE and the plaintext message is SEND MORE MONEY. The sender would then write (Table 2.5)

```
keyword:    L O V E   L O V E   L O V E L    x-axis
plaintext:  S E N D   M O R E   M O N E Y    y-axis
```

The sender, starting from the left, finds in the table the letter corresponding to the coordinates X=L, Y=S, which is the letter D. He then moves to the next pair (O, E) which gives him the letter S, etc. The ciphertext then reads DSIHXCMIXCIIJ. Decryption is the inverse process: (L, D) yields S, by moving on the row L to the letter D and reading the letter S on the x-axis.

The polyalphabetic cipher belongs to the family of homophonic ciphers which equalize the frequencies of the ciphertext letters since a given letter of the alphabet will not always be encrypted by the same ciphertext letter. Consequently, it cannot be described by a single set of ciphertext alphabet corresponding to a single set of plaintext alphabet. The equalization is effected in such a way that the number of ciphertext symbols assigned to a plaintext letter is determined by the frequency of that letter: a(8), b(1), c(3), d(4), e(12), f(2), g(2), h(6), i(7), j(1), k(1), l(4), m(2), n(6), o(7), p(2), q(1), r(5), s(6), t(10), u(3), v(1), w(2), x(1), y(1), z(1).

---

[132] If it had not been for frequency analysis, **Mary Queen of the Scots** might have kept her head (1587). She used a simple substitution cipher to write her perfidious correspondence, interspersing the letters with meaningless symbols (nulls). Nevertheless, **Francis Walsingham**, the founder of the British Secret Service, managed to weed out the nulls and do a frequency count of the remaining symbols, thus breaking her code.
Had she known the work of **Alberti** (1535), she might have avoided the chopping block.

Table 2.5: Polyalphabetic Substitution Cipher

Key Word Letters

		A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	U	V	W	X	Y	Z	→ x-axis

The beauty of the Alberti's cipher is that the table of cipher alphabets - can be made public[133]*, so long as the keyword is kept secret, without jeopardizing the security of the cipher. After Alberti, cryptography continued to develop through the works of* ***Giovanni Battista della Porta*** *(1563),* ***Blaise de Vigenère***[134] *(1586) and* ***Francis Bacon*** *(1613).*

Cardinal Richelieu *(Armand-Jean du Plessis, 1585–1642) invented a grille; he would place a card with holes in it over a sheet of paper, write his secret message in plain language in the holes, then fill in the rest of the paper to look like an innocent letter. Only a man with an identical grille could read the secret message.*

For 300 years Alberti's polyalphabetic cipher was thought to be invulnerable, but then, ***Friedrich Kasiska*** *(1865, Prussia), discovered a few intrinsic weaknesses, overlooked by the sender but exploited by the wily eavesdropping cryptoanalyst. He found, for example, that if a sequence of plaintext letters, that come up more than once, happens to be enciphered each time by the same keyword letters, identical ciphertext results.*

For example, in the message SEND MORE MONEY, the key-letter sequence LO, twice enciphers the plaintext sequence MO into XC. If bits of the ciphertext repeat often enough, the cryptoanalyst can figure out the length of the keyword and, hence, the number of cipher alphabets employed. Then it is just a matter of cataloging which ciphertext letters came from which cipher alphabet. For each cipher alphabet, a frequency count will reveal the plaintext letters.

Thus, careless use of the best cipher can compromise its security, making codebreaking much easier in practice than in theory. Diplomatic and military communications often begin and end with characteristic pleasantries ("Greetings!", "Respectfully yours", etc.) which are footholds for the analyst. Certain proper names (especially ones that are overly long) can also give the show away[135]*. Information can often be coaxed out of the enemy*[136]*. In this*

[133] Modern cryptographers, drawing on innovative mathematical methods, have been able to take this trend to an amazing extreme: *both* the encryption method and the key itself can be made public without compromising the cipher. In other words, the power to encipher a message is not the same as the power to decipher it.

[134] A French diplomat (1523–1596). His book *Traicte des Chiffres ou Secretes d'Escrire* (1586), earned him the title: 'father of modern cryptography'.

[135] In WWII, German communications spoke in cipher of the *Wehrmachtnachrichtenverbindungen* (a 32-letter word).

[136] In May 1942, the American high command knew that a vast Japanese naval force was going to strike soon, but did not know where. Japanese radio dis-

day and age, when cryptography is increasingly computerized, breakdowns in technology can have severe consequences[137].

Mathematics and Art – the story of perspective: Brunellechi (1413) to Chasles (1852)

Although Hellenistic painters could create an illusion of depth in their works, there is no evidence that they understood the precise mathematical laws which govern perspective.

***Alhazen** was first to give correct explanation of vision, showing that light scattered from an object into the eye (ca 1000 CE). Although he did not apply*

patchers referred again and again to AF. To find out, American intelligence agents instructed the U.S garrison at Midway to radio Pearl Harbor that it was running out of water. Shortly afterwards, the Americans intercepted a Japanese dispatch that reported a water shortage at AF. This helped to win the great naval battle of Midway.

137 In October 1985, the Reagan administration learned from intelligence sources that Egypt was lying about the whereabouts of the four terrorists who had hijacked the Italian cruise ship *Achille Lauro* and murdered an American citizen aboard. Contrary to what Egypt had publicly stated, the hijackers were still on Egyptian soil, preparing to leave the country quietly by air via an EgyptAir Boeing 737 jetliner. The Pentagon counterterrorist experts came up with a plan for intercepting the civilian getaway plane with F-14 Tomcats. Reagan, then aboard Air Force One, ordered the reluctant Defense Secretary, Weinberger (on flight in a different military plane), via an open *uncoded* shortwave radio channel, to proceed with the daring mission. An amateur radio operator overhead every word and immediately tried to sell the story to CBS News, who chose not to report the president's order. A few hours later the EgyptAir jet was forced down.

his ideas to paintings, the Renaissance artists later made important use of his optics.

By the end of the 13^{th} *century* ***Giotto*** *was painting scenes in which he was able to create the impression of depth by using certain rules which he followed: he inclined lines above eye-level downwards as they moved away from the observer, lines below eye-level were inclined upwards as they moved away from the observer, and similarly, lines to the left or right would be inclined toward the center. Some of his last works suggested that he may have come close to the correct understanding of linear perspective. A timeline history of linear perspective is given bellow:*

1413 ***Brunellechi*** *gave the first correct formulation of linear perspective. He understood that there should be a single vanishing point to which all parallel lines in a plane (other than the plane of the canvas) converge. He correctly calculated the relation between the actual length of an object and its length in the picture, depending on its distance behind the plane of the canvas.*

1435-6 *Using both the principles of geometry and the science of optics,* ***Alberti*** *was the first to give the mathematical description of perspective needed for a proper understanding of painting: setting up a system of triangles between the eye and the object, he gave a precise concept of proportionality which determines the apparent size of an object in the picture relative to its actual size and distance from the observer.*

1447 ***Lorenzo Ghiberti*** *applied Alberti's principles to the design of his bronze doors.*

ca 1470 *In his treatise 'On perspective for painting',* ***Piero della Francesca*** *gave a complete account of the geometry of vision, proving theorems which relate to the perspective of plane figures, prisms and more complicated objects such as a human head, the decoration on the top of columns and other more difficult shapes. To this end he measured both width and height along different axes. In fact, he was using a coordinate system (!), computing the correct perspec-*

tive position of many points of the 'difficult shape' from which the correct perspective of the whole object could be filled in.

1490 ***Leonardo da Vinci*** *was first to study the converse problem of perspective: given a picture drawn in correct linear perspective – compute where the eye must be placed to see this correct perspective*[138].

1525 *In his book 'Unterweisung der Messung mit dem Zirkel und Richtscheit',* **Albrecht Dürer** *made an important addition to the theory of the Italian School by stressing the importance of light and shade in depicting correct perspective. He also invented a variety of mechanical tools which could be used to draw images in correct perspective.*

1639 ***Desargues*** *laid the foundations to projective geometry in his treatise 'Brouillon project d'une atteinte aux evenemens de recontres du cone avec un plan' in which he was motivated by the problem of finding the perspective image of a conic section. He dealt with the properties of pencils of straight lines and ranges of points lying on a straight line, and used them to investigate the properties of conics. The modern term "point at infinity" appears for the first time in this treatise.*

1673 ***Philippe de la Hire*** *introduced the cross-ratio of 4 points. In his book 'Conic sections' (1685) he expounded a projective approach to conics.*

1719 ***Brook Taylor*** *published 'New principles of linear perspective'. The work gave the first general treatment of vanishing points. The*

[138] He realized that a picture painted in correct linear perspective only looked right if viewed from one exact location. Thus, for a painting on a wall, many people would *not* view it from the correct position. Indeed, for many paintings it would be impossible for someone viewing them to have their eye in this correct point, as it may have been well above their heads.

phrase 'linear perspective' was coined by Taylor in this work and he defined the vanishing point of a line, not parallel to the plane of the picture, as the point where a line through the eye parallel to a given line intersects the plane of the picture. He also defined the vanishing line of a given plane, not parallel to the plane of the picture, as the intersection of the plane through the eye parallel to the given plane, with the plane of the picture. The main theorem in Taylor's theory of linear perspective is that the projection of a straight line not parallel to the plane of the picture, passes through its intersection with the picture plane as well as through its vanishing point.

Taylor readdressed mathematically the inverse problem, which is to find the position of the eye necessary in order to see the picture from the viewpoint that the artist intended.

Taylor's work was an important step towards the theory of descriptive and projective geometry as developed by ***Gaspard Monge*** *(1799),* ***Jean-Victor Poncelet*** *(1822) and* ***Chasles*** *(1852).*

ca 1420 CE **Jamshid al-Kashi of Samarkand** (d. 1436). Arab mathematician and astronomer. Noteworthy for the accuracy of his computations, especially in connection with the solution of equations by Horner's method and his practice of using decimal fractions, both of which he derived from the Chinese. Calculated π correctly to 16 decimal places. No mathematician approached this accuracy until the late 16^{th} century.

Al-Kashi found a patron in the prince **Ulugh Beg**[139] (1393–1449), grandson of the Mongol conqueror Tamerlane. At Samarkand, where he held his court, Ulugh Beg had built an observatory (1428), and al-Kashi joined the group of scientists gathered there. With his death, the account of Arab mathematics was closed, since the cultural collapse of the Muslim world was more complete than the mere political disintegration of the Empire.

[139] **Muhammed Targai Ulugh Beg** and his teacher **Quadi Zada** (1364–1436) compiled trigonometric tables to a high degree of accuracy (8 to 12 decimal places). Ulugh was eventually put to death at the instigation of his own son. After the death of Al-Kashi, Quadi Zada became the director of the Samarkand Observatory. He computed the sine of one degree to an accuracy of 10^{-12} in decimals.

However, Arab mathematics had a crucial impact on modern science: the mathematical tradition handed over to the Latin world in the 12^{th} and the 13^{th} centuries, was richer than that with which the unlettered Arabic conquerors had come into contact in the 7^{th} century.

1427–1444 CE **Leonardo Bruni** (Aratino, ca 1370–1444, Italy). Humanist, historian and scholar. Promoter of Greek learning. Born in Arezzo. Secretary to the papal Chancery under Innocent VII and John XXII. Chancellor of Florentine Republic. A key figure in ushering the Renaissance of ancient Greek lore in art, literature and science.

1430–1466 CE **Piero della Francesca** (1406–1492, Italy). Painter and mathematician. Recognized as one of the most important painters of the Renaissance. Three of his books survived[140]: Abacus treatise (*Trattato d'abaco*), short book of the five regular solids (*Libellus quinque corporibus regularibus*) and on perspective for painting (*De perspectiva pingendi*). In the first he came up with some entirely original 3-dimensional problems involving two of the *Archimedean polyhedra* (truncated tetrahedron and cuboctahedron). Four more Archimedean appear in the second book: the truncated cube, the truncated octahedron, the truncated icosahedron and the truncated dodecahedron (all these modern names are due to **Kepler**, 1619). Piero appears to have been the independent rediscoverer of these six solids. Moreover, the way he describes their properties makes it clear that he has in fact invented the notion of truncation in its modern mathematical sense.

On perspective for painting is the first treatise to deal with the mathematics of *perspective*[141]. Piero was determined to show how this technique is firmly based on the science of vision (as it was understood in his time). He accordingly started with a series of mathematical theorems, some taken from the optical work of Euclid (possibly through medieval sources) but some original to Piero himself.

Though non of Piero's mathematical work was published under his own name in the Renaissance, it seems to have circulated quite widely in manu-

---

[140] His pupil, the Franciscan **Eva Luca dal Borgo**, usurped his master's books and after Piero's death published them as his own works! This we know from "*Lives of the Artists*" of Giorgio Vasari (1511–1572). Vasari says that Piero was regarded as "*a great master of the problems of regular polygons, both arithmetical and geometrical... Made an intense study of painting and perspective... acquired an intimate knowledge of Euclid...*". Vasari added that he was prevented by his blindness (which overtook him through an attack of catarrh at the age of 60) from publishing his written mathematical manuscripts.

[141] A technique for giving an appearance of the 3^{rd} dimension in 2-dimensional works such as painting or sculptured reliefs.

script form and became influential through its incorporation into the works of others. Thus, much of Piero's algebra polyhedra appears in Pacioli's *Suma* (1494), much of his work on the Archimedean polyhedra appears in Pacioli's *De divina proportione* (1509), and the simpler parts of Piero's perspective treatise were incorporated into almost all subsequent treatises on perspective addressed to painters.

1440–1446 CE **Lorens Janszoon Coster of Haarlem** invented printing with movable cast-metal types (typography).

1440–1450 CE **Nicholas of Cusa** (Nicolaus Cusanus, Nicholas Krebs; 1401–1464, Germany). Theologian and scholar in the 'twilight zone' between medieval and modern times. Broke with scholasticism while it was still the orthodox system, and proposed scientific ideas ahead of his time. Although his knowledge of mathematics and natural philosophy did not go beyond the Greeks, he responded to their ideas, and reached conclusions not found among the savants of antiquity:

- Challenged, the Augustinian finite universe. Revived the Ionian cosmological model of an *infinite* universe in which all heavenly bodies are essentially alike. Seriously considered that the earth might be rotating daily on its axis due to an initial impetus imparted to it at the beginning of time. Maintained that it might be equally possible to build an astronomical theory on the basis of the earth moving around the sun (1440). But like **Oresme** before him (1370), he did not work out a new theory.
- Proposed to reform the calendar following a method later adopted (1582) by Pope Gregory XIII.
- Recommended timing the pulse rate as an aid in medical diagnosis (1450).
- Gave the first known description in the West of a hygrometer (1450).
- Suggested that plants grew by assimilation of water.
- Believed in the 'impetus theory' of motion of a spherical ball: the motive force is due to an initial impulse and lessens gradually.
- Vaguely anticipated the concept of *infinitesimals*, and had some intuitive feel for the procedure of the *limit*[142]. However, measured by modern standards his accomplishments are not exciting. Nevertheless, he contributed

[142] Through his futile efforts to square the circle and trisect an angle, he constructed the following scheme: a unit circle O is intersected by a diameter AB. At A a tangent is drawn normal to AB, and a point T is marked on it. At B, the diameter is extended by one radius to a point S. The points S and T are joined and the line TS intersects the circle at D, closest to T. Draw from D a perpendicular to AB at F. Denoting $\theta = AOD$, $\varphi = AST$ we find, from the

to the study of *infinity*, studying the infinitely large and the infinitely small. (He considered the circle as the limit of regular polygons.)

- Asserted that the truth can never be known in total, although it can be approached ever closer through scientific reasoning. God can be apprehended by intuition, i.e. an exalted state of the intellect in which all limitations disappear.

Nicholas became a great transitional figure between the worldview of the Middle Ages and that of the Renaissance. Like everyone in his time, he cast his thought as a continuation of tradition, yet his ideas initiated the fall of the entire cosmology and social outlook that held sway since Augustine. Nicholas' ideas were in truth a rebirth of ancient Greek learning, but not that of Plato and Aristotle, which had indeed never been rejected by the medieval thinkers. It was instead a revival of the Ionian methods of exactly 2000 years earlier.

In his work Nicholas returned to the central idea of **Anaxagoras** – an infinite, unlimited universe. In contrast to Ptolemy's finite cosmos circumscribed by concentric spheres with earth as their center, he argued that the universe has no limits in space, no beginning or ending in time, no center, and no single immobile place of rest, including the earth; God is not located outside the finite universe, he is everywhere and nowhere, transcending space and time.

Furthermore, since reality is infinite in its complexity, knowledge can only be a series of improved approximations, unifying ever expanding realms of experiences. In this sense learning will never lead to the *final* truth. There can be no "theory of everything". This open-ended theory of knowledge led Nicholas to the unavoidable conclusion that there is no final authority. While conservative in form, his ideas undercut the basic notions of hierarchy – social and cosmic – entrenched since the days of Plato.

He was born in the city of Cues (Latin: Cusa) on the Moselle, in the archbishopric of Trier (Treves), the son of a poor fisherman. He took his doctor's degree in law at the University of Padua in 1424. Failing his first case, he abandoned the legal profession and took the holy orders. He rose rapidly in the Church, finally becoming a Cardinal in 1448. In 1450 he was appointed bishop of Brixen in the Tyrol. In 1459 he acted as governor of Rome during the absence of his friend, Pope Pius II.

Although one of the great leaders in the reform movement of the 15^{th} century, Nicholas of Cusa's interest for later times lies in his philosophical

---

similarity of the triangles TAS and DFS, $\overline{AT} = \frac{3\sin\theta}{2+\cos\theta} = 3\tan\varphi$. For small θ, $\overline{AT} \approx \theta \approx 3\varphi$; the length $\overline{AT}$ of the tangent segment AT is approximately equal to the arclength $\widehat{AD}$, whose angle θ is thus approximately trisected by constructing the angle φ.

much more than in his political or ecclesiastical activity. The novel ideas mentioned above are propounded in his principal work *De docta ignorantia* (On learned ignorance, 1440). His chief philosophical doctrine was taken up and developed more than a century later by **Giordano Bruno** (1584).

1443–1482 CE **Paolo (dal Pozzo) Toscanelli** (1397–1482, Italy). Physician, mathematician, geographer, astronomer and philosopher. A Florentine savant who collected information and recorded data in the natural sciences and channeled it further to whoever sought his advice or seemed to him worthy of it. He sought out travelers and adventurers from distant part of the earth and ferreted out from their rodomontades some nuggets of truth.

As the leading geographer of Italy, he prepared new charts and maps for the Medici's sea captains. He recalculated the earth's diameter, as had the ancients, with the same goal of finding the length of a degree of latitude. Based on his calculations (which were wrong) he encouraged **Columbus** in the idea that China and India could be reached by sailing across the Atlantic.

Toscanelli recorded observations of comets; the one of 1456 was later named comet Halley. Proclaimed (1450) the feasibility of sailing from Europe to Asia across the Atlantic he estimated the distance between the two continents at roughly 4900 km. In 1468 he traced in the cathedral of Florence the famous meridian line, which was to serve for determining the dates of the movable feasts of the church.

He never left his native city of Florence. But in front of him in his study there stood a globe showing countries still unexplored, and oceans not yet traversed, and strange races of mankind. From the confusing mass of fantastic reports that reached him, and from his measurements, made with inadequate resources, he drew with increasing certainty the conclusion that it must be possible to reach India by a westward route. He could no longer search for that passage himself, but he wanted to see it found by bolder and younger men, and gave them maps and advice. When **Columbus** began to dream of the untraveled sea route to India, he sought the advice of Toscanelli who sent him (1482) a chart of the ocean with an accompanying letter including all the fragments of his knowledge. This information increased the confidence of Columbus in his ability to cover the distance that an experienced sea captain could easily traverse.

He collaborated with **Nicholas of Cusa** and disseminated the latter's new cosmology, linking it to the emerging observational science.

Toscanelli exercised decisive influence over the young **Leonardo da Vinci**. He turned Leonardo's gaze to the skies, explaining to him the nature of the heavenly bodies, according to the new worldview of Nicholas of Cusa, thus propagating through him a conception of science that was wholly secular.

1446–1454 CE **Johannes Gensfleish zur Laden zum Gutenberg** (1397–1468, Germany). Inventor. Perfected in Mainz a printing press from movable metal type and conducted the first large-scale printing-office in the modern sense. By 1448, at the latest, he was using accurate metal type through which he could produce in sufficient quantity the print of the Latin *Vulgate Bible*. By 1454, Gutenberg printed 300 copies of the so-called *Gutenberg Bible*. The names of **Johann Fust** (1400–1465) and his son in law **Peter Schöffer** (1425–1502), both from Mainz, recur in some sources as possible collaborators.

Gutenberg said: "With my 26 soldiers of lead I will conquer the world". And he did. He died blind and penniless.

Gutenberg did much more than invent the printing press, and much less than invent printing. He played a major practical and symbolic role in independently reinventing (in a greatly improved form and within more receptive society) a printing technique previously developed in Minoan Crete (ca 1700 BCE) and by 1041 CE in China[143] by **Pi Sheng**.

1450–1475 CE **Ali al-Qalasadi** (1412–1486, Spain). The last of the Moorish mathematicians of Spain. [The name al-Qalasadi means the Upright, or Versed in the Law.] Made original contributions to the theory of numbers. Introduced a new radical sign and a sign of equality, and proposed a system of ascending continued fractions. Computed $\sum n^2$, $\sum n^3$ and used the method of successive approximation to determine square roots. Although these were all known to be discovered earlier, some of these may have been discovered independently by al-Qalasadi. He wrote several books on arithmetic and one on algebra.

Al-Qalasadi was born in Basta, a Moorish city in Spain, and remained there until the Christians captured it. He then traveled through the Islam world and died in Tunisia.

---

143 By the year 858 CE, China was printing books. But most Chinese printers carved or otherwise wrote out a text on a wooden block instead of assembling it – letter by letter as Gutenberg did. Why did Gutenbergian printing take off while Minoan and Chinese did not? Coming up with an invention itself may be the easy part; the real, obstacle to progress may instead be a particular society's capability to utilize the invention. Other premature inventions include *wheels* in pre-Columbian Mexico (relegated to play toys because Mexican Indians had no draft animals!) and Cro-Magnon *pottery* from 25,000 BCE (what nomadic hunter-gatherer really wanted to carry pots?). The first made automobile driven with an internal-combustion engine was built in 1863, but no motor vehicle came along for decades, because the public was content with horses and railroads.

1450–1461 CE **Georg von Peurbach** (1423–1461, Austria). Mathematician and astronomer. Due to him (and Regiomontanus) European scholars became well acquainted with Arab trigonometry. Peurbach wrote on astronomy and gave tables of ecliptic calculations. He observed Halley's comet (June 1456) and wrote a report on his observation. He made further observations of comets and recorded the lunar eclipse of 1457. He published further tables checked by his own eclipse observations, and devised astronomical instruments.

Peurbach studied under Nicholas of Cusa. He became a professor of mathematics of Vienna, making this university the mathematical center of his generation.

1450–1600 CE The *Renaissance period* in music; The leading composers are:

- Josquin Despres 1440–1521
- Giovanni De Palestrina 1525–1594
- Orlando di Lassus 1532–1594
- Giovanni Gabrieli 1554–1612
- Claudo Monteverdi 1567–1643

1450–1850 CE 'Little Ice-Age' in Europe; advance and recession of glaciers.

Books and Guns

In the beginning there was only the spoken word. Then, to entrust his thoughts to a more lasting medium than mere memory, man took to drawing pictures representing things. Perhaps the oldest picture-script originated at 4000 BCE *in Mesopotamia. Its images – bird, ox, ear of barley – were scratched into soft clay tablets, then baked hard for preservation.*

But such writing was a cumbersome affair, mainly used for priestly documents and public records and literature depended almost totally on word-of-mouth transmission. The quick Mediterranean mind, awakening to a new culture, demanded a better way of harnessing the spoken language; shortly before 1000 BCE*, the* Phoenicians *– swift seafarers, sharp traders and good record keepers – began breaking spoken sound into their basic elements, and shuffling the resulting "letters" to form words – thus creating the world's oldest alphabetic writing. Soon the alphabet was seized upon by the* Greeks *who gave letters more convenient shapes and added the still-missing vowels.*

No sooner had man taught himself to spell then a new problem arose: what to write on? Leather, tree bark, leaves and wax tablets had all proved unsatisfactory.

In Egypt, for some 2500 BCE*, texts had been inscribed on brittle sheets made from the pith of a Nile Delta water plant,* papyrus*. The use of this material gradually spread through the Mediterranean world. Usually, several papyrus sheets were glued together to form a* scroll *that could accommodate a lengthy text (one* 40*-meter scroll containing the picture-script of Pharaoh Rameses II in still extant). But what a clumsy thing to read! The scroll, wrapped around a wooden stick, had to be held in the right hand, while the left slowly unwound it to reveal the next column of writing. Nevertheless, the royal library at* Alexandria *is believed to have had no fewer than* 700,000 *scrolls. Relatively fragile, papyrus invited rivalry.*

In wealthy Pergamum*, on the coast of Asia Minor, scribes wrote on specially prepared sheep, goat or calf skins. This fine pellucid stationary, tougher than papyrus and foldable, came to be known as* parchment*. Shortly after* 1 *CE, an unknown* Roman *scribe with a sense of compactness took a stack of thin parchment sheets, folded them, and fastened them together at the spine. Thus, the* book *was born. The earliest promoters of books were Roman Christians; to them it was essential to preserve the Scripture in the most lasting medium – and parchment did not wilt when handled. Moreover, when one wanted to hunt up a reference, chapter and verse, a book was a lot handier than a scroll.*

So it came about that, all through Europe's Dark Ages, an army of monks, ensconced behind monastery walls, hand-copied the torn and shredded writings of the past on sturdy parchment sheets. Without their toil, the literary and scientific glories of ancient Greek might have been lost forever; it frequently took years to finish copying a thick tome.

Meanwhile, in distant China, in the year 105 *CE an inventor by the name* **Tsai Lun** *devised paper, a writing surface that could be produced cheaply from wood, rags, or other substances containing cellulose. For* 600 *years this invention remained a closely guarded secret of the East. It was not until some Chinese papermakers were captured by the Arabs in the battle of Samarkand (7 CE) that the secret was divulged. Arab manuscripts written on paper survive from the* 9^{th} *century, and in the* 12^{th} *century the industry was established among the Moors in Spain, and also among the Moorish subjects of the Norman Kingdom of Sicily. From there it spread to the Christians in Spain and Italy, and in the* 14^{th} *century to Germany and elsewhere, though down to the close of the Middle Ages the most important paper-making centers were in north Italy.*

In 1439*, a stubbornly determined German craftsman,* **Johannes Gutenberg***, began experimenting with a substitute for handwriting; if he could cast the letters of the alphabet in reusable metal type, then arrange them, in a mirror pattern, into words, lines and columns on an even-surfaced plate, an imprint taken from this plate would make one page. In place of one painstakingly handwritten book, he would be able to run off on his "press" as many imprinted books – exact copies of each other – as he wished.*

Laboriously, Gutenberg put together his first page plates, each one composed of more than 3700 *signs and letters. With the help of a hand-worked wooden press that he had adapted from the wine press of his native Rhineland (and which remained unchanged for the next* 350 *years), he started printing in a rented workshop in Mainz. It took three years to turn out some* 190 *copies of the Gutenberg Bible (1454).*

With this remarkable invention, book prices dropped 80 *percent overnight, and learning to read became worthwhile among the Christians. A mere* 50 *years after Gutenberg's exploit, every major European country except Russia was printing its own books. It was as if floodgates had been opened. Some* $520,000$ *new titles were published in the* 16^{th} *century,* 1.25 *million in the* 17^{th}, 2 *million in the* 18^{th}*, and* 8 *million in the* 19^{th}*. Today, more than three billion titles come off the presses in a single year, adding up to an estimated* 5 *billion individual books.*

With the invention of printing came the invention of engraving: Woodcuts and copperplates did for the graphic arts exactly what printing did for letters. Works of art could be diffused and standardized. The two inventions, *printing and engraving, were of immense importance for the development of knowledge. Printing made possible the publication of mathematical and astronomical tables which could be depended upon; engraving, the publication of books with illustrations representing plants, animals, anatomical or surgical details, chemical apparatus, etc. One good figure is more revealing than many pages of text; the use of illustrations obliged the author to be more precise than he could have been, or wished to be, without them.*

The new technology was symbolized by the publication of illustrated treatise by ***Vannoccio Biringuccio of Siena*** *(1540),* ***Georgius Agricola*** *(1556),* ***Lazarus Ercker*** *(1574), all of which included a wealth of information on mining, metallurgy, chemistry, the founding of guns and bells, the making of weapons and gunpowder, the casting of alloys such as type metal, the coining of money, and many other arts and crafts. This suggested that, thanks to printing and engraving, the Renaissance was a vigorous age of stocktaking and encyclopedism as well as of invention. Every bit of knowledge could now be garnered and preserved forever. Words and images were immortalized.*

The Chinese gave us paper. Phoenicians brought forth our alphabet. To Rome we owe the format of the book; to Germany, the art of printing from movable type. Britain and the United States perfected book production. Today, 30,000 *finished books roll of high-speed presses in the U.S. alone in just one hour, and we find it hard to visualize the bookless world of our forebears.*

As is the case with many other inventions, it is impossible to determine the contribution of a particular individual to the development of typography and its commercial exploitation. This illustrates the fact that an invention is sometimes not the creation of an individual but a social product, multiple and cumulative.

The previous Chinese inventions of block printing and paper, are linked with the beginning of typographical printing in Western Europe. Xylography, or wooden block printing, originated in China in the early 8^{th} *century. Its transmission to the west [probably during the century from* 1250 *to 1350] suggested the next crucial step of cutting up an old block into constituent letters.*

When the art of writing, xylography, and all the subsidiary arts of illuminating, decorating and binding manuscripts, books, pictures etc., were at their apex (and had long passed out of the exclusive hands of the monasteries into the hands of students and artisans) – the art of typography was invented.

The invention of the movable type alone could not have brought about the 'printing revolution' in the absence of paper, ink and type. Printing on *parchments (sheep skin) or on vellum (calf skin) would require* 170 *calf skins or* 300 *sheep skins for a single copy of the Bible!*

Paper manufacture was introduced, as mentioned above, in Spain during the 12^{th} *century by the Arabs, who had themselves received the technique from China. It spread slowly during the next two centuries to much of Europe [to Germany by 1390]. In Europe, the chief raw material was old rags. By the time of Gutenberg's youth, paper was plentiful and sold for approximately one sixth of the price of parchment. The oil base for an* ink *suitable for metal type was used by Flemish artists in the early* 15^{th} *century.*

Finally, the type *[the mirror image of each of the letters of the alphabet] required skills connected with delicate forms of metallurgy, namely: those of the metal engraver and the designer of coins and medals, of the goldsmith adept at casting small objects, of craftsmen who made punches for stamping letters on bells, and of manufacturers of pewter vessels.*

We must imagine that in many places in Europe, ingenious artisans experimented with type, inks, papers and presses; that many parallel efforts were made to replace the scribe by a mechanical device. The actual invention of printing, namely, the dramatic fusion of familiar techniques into a workable process, probably occurred independently in several places, but first organized as an industry in Mainz by ***Gutenberg****,* ***Fust*** *and* ***Schöffer****. By* 1500 *the presses all over Europe had issued more than* 9 *million books representing over* 30,000 *titles.*

The immediate contribution of printing to learning was that it halted the propagation of error incurred by successive generations of scribes, and restored the great texts of the past to their original integrity. Printing gave scholars all over Europe identical texts to work with*, referring precisely to a particular word in a particular line on a particular page. Printing turned intellectual work as a whole into a cooperative instead of a solitary human activity; printing thus enlarged the amount of intellectual effort applied to individual problems.*

The effects of this novel concentration of brain power were noticeable, especially in the exact sciences. Thus, following Copernicus' publication of his book in 1543*, it gradually drew the best minds in Europe into a cooperative study of the controversial problem, and a solution was found* sooner *than it would have otherwise. Scientific research*[144] *acquired through this tool* a public forum*, a published exchange of novel results and ideas controlled by*

---

144 The *immediate* effect of printing on science was not especially favorable, for those works printed most often were old-fashioned. A publisher is more keenly aware of what men wish to read than of the obligation to supply them with what is best for them to read.

cooperative critical examination and the repetition of experiments. Printing made books easier to acquire, freed students from compiling their own dictionaries and reference books, and freed their minds from barren memorization. It accelerated the diffusion of ideas. The reformation spread with the same astonishing rapidity as printing itself; it could not have done so without it.

The printing press spread the news at a hitherto unthinkable speed, increased the range of human communication, broke down isolation. The broadsheets and brochures were not necessarily read by all the people on whom they exercised their influence; rather, each printed word of information acted like a pebble dropped into a pond, spreading its ripples of rumor and hearsay. The printing press was only the ultimate source of the dissemination of knowledge and culture; the process itself was complex and indirect, a process of dilution and diffusion and distortion, which affected ever increasing numbers of people, including the backward and illiterate.

Even three or four centuries later, the teaching of Marx and Darwin and the discoveries of Einstein and Freud, did not reach the vast majority of people in their original, printed text, but through second and third hand sources, through hearsay and echo.

Printing assumed a double role through its promise of enlightenment and popular education on the one hand, and being a weapon of revolution, hostile to the status quo, on the other. This is why the censorship *of books appeared very soon after the invention of printing, and was practiced by both secular and ecclesiastical authorities. Banning and* burning *of books were designed to maintain political as well as religious orthodoxy. By* 1560*, censorship of books of all forms was prevalent in Western Europe.*

No less important was the invention of the gun*. After the invention of the rocket in* 1232*, the Chinese performed some further experiments in the military use of explosive power. They put it into tubes of bamboo, making the first 'Roman candles'.*

Early Roman candles had alternate packing of loose and compressed powder, so that as the powder burned down from the muzzle, the solid lumps were thrown out and burned as they flew. This was as close as the Chinese came to the invention of the primitive gun, which probably took place in Germany not later than 1326*. Some of the earliest guns were made of wood strengthened by iron hoops, or of copper and leather.*

Guns soon evolved into cannon and hand guns. The latter were at first small cannons latched to poles, which the gunners held under their arms like lances at rest. Cannons evolved into long guns for direct fire and very short guns, called mortars, for high-angle fire. For a time, balls of iron or lead were used in hand guns and balls of stone in cannon. Iron cannon balls soon *replaced those of stone, carrying as they did more kinetic energy for a given bore. Now cannons had to be made stronger and of smaller bore.*

The gun soon brought the feudal system tumbling down. This was not accomplished by shooting holes in the armor of knights; the early hand-guns were not as effective as all that. They did not completely displace the crossbow until the 16^{th} *century, and they did not put the armor makers out of business until the* 17^{th} *century,* 300 *years after guns came into use. What the early gun did was to knock down the walls of the castles where the local lordlings had dominated the countryside and defied their king. By shattering the feudal castle, just as it had the walls of Constantinople, the cannon prepared the way for the era of sun-kings ruling by divine rights. The towering medieval fortresses with their draw-bridges and moats became mere relics.*

Meanwhile, the hand-gun in its turn improved until it outshone the cannon. As the flintlock musket, it became cheap enough for any citizen to own, simple enough for him to use, and deadly enough to enable him to face regulars. Then the stage was set for fall of kings and the setting up of republics.

1452 CE The University of Paris required that students must read the first 6 books of Euclid to get a master's degree.

1453 CE, May 29 *The Turks captured Constantinople*[145] to the sound of heavy gun salvo, used for the first time in history in a major war. The Sultan Mahomet II was able to deploy against the astonished Byzantines 14 batteries, each of several great bombards, plus 56 smaller cannons of various types. Most spectacular of all were two enormous guns which fired stone balls nearly 1 meter in diameter and weighing over 400 kg. The guns required two oxen each and more than 1000 men to drive them from Adrianople, where they were cast, to the Bosphorus. The great guns took 2 hours to load and could fire only few times a day. Many Greek-speaking scholars escaped to the West. They brought with them classical manuscripts in Greek along with the ability to translate it into Latin. This may be considered as the beginning

[145] Founded by Constantine the Great, through the enlargement of the old town of Byzantium in 328 CE. Famous in history as the capital of the Roman empire in the East for more than eleven centuries (330–1453) and as the capital of the Ottoman empire since 1453. Rivals only Athens, Rome and Jerusalem in respect of influence over the course of human affairs. The University of Constantinople was founded by Theodosius II (401–450) in 425.

of the *Renaissance in science*[146], which lagged behind the Italian Renaissance by some 150 years.

---

[146] The *Renaissance* may be divided into the *Humanistic period* (1453–1600, death of Giordano Bruno), and the *Natural Science period* (1600–1690, publication of Locke's *Essay on the Human Understanding*, which marked the beginning of the Enlightenment). Philosophy, during the Humanistic period was *man-centered*, emphasizing the place of man in the universe, while that during the Natural Science period was *cosmos-centered*. In both periods, philosophers turned their attention from theological studies of heaven, the life to come, God and Church, and supernatural things – to the study of man and nature, the earthly needs of man, nature's relationship to man and scientific methodology. Even the language of the Church, Latin, was discarded by the academic world for the various national languages, as the power of the Church declined. Rome was loosing mastery over the Church as new centers of religion appeared in Wittenberg (Martin Luther), Geneva (John Calvin), and London.

Scientific inquiry developed in all directions. While the universities of Paris and Oxford remained as great centers of learning, new institutions were established in Vienna, Heidelberg, Prague, and throughout Italy as well as Protestant Germany. During the 17^{th} century the scientific point of view became dominant in England, France, and the Netherlands. Both groups, the Humanists and the scientists, accepted new points of view – new methods of inquiry, new knowledge, new standards for the new man in his new Universe. There was a difference in their approach and emphasis, for the Humanists sought to revive Hellenic culture, while the scientists relied mainly upon empirical observation and rational methods of discovery.

Among the most influential philosophers adhering to the strictly scientific school were: **Galileo Galilei** (1564–1642), **Francis Bacon** (1561–1626), **Hugo Grotius** (1583–1620), **Thomas Hobbes** (1588–1679), and **Isaac Newton** (1642–1727). The approach of **René Descartes** (1596–1650) differed markedly from both Humanist and scientific philosophers.

The period of Renaissance philosophy (1453–1690) saw the rebirth of Greco-Roman culture, the revival of an independent spirit of learning, the renewal of interest in the humanities, and (with the downfall of Scholasticism) the termination of subserviency of philosophy to theology, and the authority of the Church. Philosophy developed in a natural progression free from the yoke of ecclesiastical dogmatism.

Men in the 15^{th} century developed an interest in nature, but most turned to the Greek writings rather than add new knowledge. It is true that **Leonardo da Vinci** (1452–1519) found that sound and light follow certain rules, but he did not publish his results and had little influence on his contemporaries.

1457–1503 CE **Itzhak ben Yehudah Abravanel (Abrabanel)** (1437–1508, Portugal, Spain, Italy). Jewish statesman, philosopher and biblical exegete. The last scholar-statesman who occupied an important position in the financial administration of both Spain and Portugal. Assisted in financing the Columbus first expedition and led Jewish exodus out of Spain (1492).

He was born in Lisbon of an ancient family which claimed descent form the royal house of David. Like many of the Spanish Jews he united scholarly tastes with political ability. He held a high place in the favor of King Alphonso V, who entrusted him with the management of important state affairs. On the death of Alphonso (1481), his counselor and favorites were harshly treated by his successor John II, and Abravanel was compelled to flee to Spain (with his son Yehudah), where he held for eight years (1484–1492) the post of a minister of state under Ferdinand and Isabella. When the Jews were banished from Spain in 1492, no exception was made in Abravanel's favor. He afterward resided in Naples, Corfu and Monopoli and in 1503 removed to Venice, where he held office as a minister of state till his death in 1508.

His repute as a commentator on the Scriptures is still high. He was one of the first to see that for Biblical exegesis it was necessary to reconstruct the social environment of olden times, and he skillfully applied his practical knowledge of statecraft to the elucidation of the books of *Samuel*, *Kings* and *Daniel*[147].

Abravanel rejected philosophical rationalism, drawing on contemporary social and political realities to elucidate Messianic Biblical passages. His political theory is expounded in his commentary on *Deuteronomy* and *Judges*: the monarchy, according to him is a human (not a divine) institution. He advocated Constitutional form of government, yet he denied right of subjects to rebel.

1457–1480 CE **Yehudah Ibn Verga** (ca 1430–1499, Spain and Portugal). Astronomer, mathematician, chronicler and Kabbalist. Wrote a number of books on astronomy and mathematics. Invented a new instrument to determine the Sun's meridian, described in his book *Kli-ha-Ofek*, (Lisbon, 1457).

---

147 In his commentary on the book of Daniel (1497) entitled "The Wells of Salvation" (Maa'yanot ha'Yeshuah), the author indulges in an *astrological* study, discussing in detail the significance attributed by the Jews to the periodic conjunctions of *Jupiter and Saturn* which occur about every 20 years. The sign of the zodiac in which they occur changes from one conjunction to another. This study was consulted by Juhannes Kepler (1603) and prompted him to advance the hypothesis that the 'Star of Bethlehem' was indeed a conjunction of Jupiter and Saturn in Pisces in 7 BCE.

Ibn Verga came from Seville and was a relative of Itzhak Abravanel. There he was active in maintaining an understanding between the Marranos and the Jews. When the Inquisition was introduced into Spain it desired him to betray the former. When Jews were expelled from Andalusia (1483) he moved to Northern Spain, but had to flee again to Lisbon (1492). He lived there for several years until he was imprisoned, perishing as a martyr in the Inquisition dungeons (1499).

Ibn Verga wrote a history of the persecution of the Jews; his work, in turn, was the basis of the historical work *Shevet Yehudah* (The Rod of Yehudah) compiled and published (1550) by his relatives **Shlomo Ibn Verga** (ca 1460–1524) and his son **Yosef Ibn Verga** (ca 1495–1559). This work has special importance in the annals of Jewish historical thought: it is one of the outstanding achievement of the Hebrew literature of the Renaissance.

1463–1476 CE **Johannes Müller**, or **Regiomontanus** (1436–1476, Germany). Astronomer and mathematician. Together with **Georg von Peurbach** (**Purbach**) (1423–1461) revived observational astronomy in the 15^{th} century[148]. His observations of the great comet of January 1472 and his major work on comets (published by Johannes Schöner in 1531) provided several techniques for determining a comet's parallax, as well as determining a comet's position and size[149].

Müller published *De Triangulis*, the first systematic European treatise on spherical trigonometry, from which Copernicus borrowed heavily (without acknowledgement!) in his own chapter on trigonometry. It was the earliest work treating trigonometry as a substantive science[150]. Müller made his own astro-

---

[148] They jointly undertook a reform of astronomical observations rendered necessary by the errors they detected in translations of Ptolemy's tables. This need arose in connection with navigation and the reform of the old Julian Calendar. From **Roger Bacon** in the 13^{th} century to **Petrus Ramus** in the 16^{th}, there have been outstanding individuals and schools who realized that Aristotelian physics and Ptolemaic astronomy had to be put out of the way before a new departure could be made. When Müller completed the commentaries on Ptolemy which Purbach had begun, he realized the need to put astronomy on a new basis by 'ridding posterity of ancient tradition'.

[149] Already **Levi ben Gershon** suggested in 1328 that Ptolemy's parallax method for the moon be applied to determine the distance to a comet.

[150] *Regiomontanus' problem* (1471): "*At what point on the earth's surface does a perpendicularly suspended rod appear largest*?" The point of this problem becomes obvious when phrased in the more vivid form: "*From what distance will a statue on a pedestal appear largest to the eye*?". Clearly this occurs when the angle α subtended at the eye is widest.

nomical observations and prepared a nautical almanac for the aid of Spanish and Portuguese navigation, including tables of trigonometric functions.

Müller was born at Königsberg, the son of a miller[151]. He was a child prodigy, who at the age of 12 published the best astronomical yearbook for 1448, and at 15 received a bachelors degree from the University of Vienna (and was asked by the Emperor Frederick III to cast a horoscope for the imperial bride). At 16 he became the pupil and associate of Peurbach in Vienna and was appointed to the faculty at 21 (his association with Peurbach lasted through 1452–1461). Upon Peurbach's death in 1461, he took over his teacher's condensation and explication of **Gerard of Cremona's** 12^{th} century translation of Ptolemy's *Almagest*. In 1462 he traveled to Italy with Cardinal Bessarion. At Rome he learned Greek and studied Ptolemy in the original. Although this work was completed sometime before 1463, it was not published until 1496.

He left Rome in 1468 to return to Vienna, and there was summoned to Buda by Matthias Corvinus, King of Hungary, for the purpose of collating Greek manuscripts at a handsome salary. But he convinced his royal patron that Ptolemy could no longer be relied on, and that it was necessary to put astronomy on new foundations by patient observations, making use of such recent inventions as the *corrected sundial* and the *mechanical clock*. Matthias agreed and in 1471, Regiomontanus left for Nuremberg where, under the patronage of Johann Bernard Walther (1430–1504) he installed the *first European observatory*, for which he partly invented the requisite instruments. In 1475 he was summoned to Rome by Pope Sixtus IV to aid the reform of the calendar (which was getting out of step with the solar year), and there he died within the year, most likely of the plague (some contemporary accounts attribute his death to poisoning).

If the events surrounding the death of Regiomontanus seem strange, the events surrounding the fate of his effects were even more peculiar. After his

---

Assume for simplicity that the x-axis goes through the foot of the pedestal $(0, 0)$ and the eye $(\xi, 0)$, while the ends of the statue $(0, h)$, $(0, h+L)$ lie on the y-axis. Simple geometrical considerations show that

$$f(\xi) = \sin\alpha = \xi L[\xi^2 + h^2]^{-1/2}\left[\xi^2 + (h+L)^2\right]^{-1/2}.$$

The extremum condition $f'(\xi) = 0$ then yields $\xi = \sqrt{h(h+L)}$, corresponding to $\sin\alpha = \frac{L}{L+2h}$. At this distance, the best view is guaranteed. It can be shown that the points $(0, h)$, $(0, h+L)$, $(\xi, 0)$ lie on a *circle* that is tangent to the x-axis at ξ.

151 Königsberg means 'King's Mountain' in German. In Latin, Regiomonte translates as 'from the royal mountain'.

death, his books, papers, and instruments were acquired by Walther. Walther used the instruments to continue the observations that he and Regiomontanus had started, but the books and papers were locked up and access to them denied to one and all. After Walther's death in 1504, the executors of Regiomontanus' estate apparently started selling his books, all the while denying that they were doing so. Several law suits were initiated over the remains of the estate. Finally, most of the remaining books and papers were acquired by Johannes Schöner, who published a few of them in the 1530's and the 1540's.

The manuscripts and notes of Regiomontanus' last years are lost, and there remain only scant indications of the reform of astronomy that he planned. But we know that he had paid special attention to **Aristarchos**' heliocentric system, as a note on one of his manuscripts shows. And much earlier he, too, had noted that the sun ruled the motion of the planets.

Towards the end of his life, he wrote on a piece of paper enclosed in a letter the words: "*It is necessary to alter the motion of the stars a little because of the motion of the earth*". The wording, seems to indicate that the '*motion of the earth*' here refers to its annual revolution round the sun. In other words, Regiomontanus has arrived at the same conclusion as Aristarchos and Copernicus, but was prevented from finalizing his work by his untimely death. He died at 40, when Copernicus was three years old.

1470–1494 CE **Itzhak ben Moshe Aramah** (1420–1494, Spain). Philosopher, mathematician and Talmudic scholar. First formulated the *statistical law of large numbers* (1470) in his book *Akedat Yitzhak* (Binding of Isaac); It was published in Salonici (1522), over two centuries ahead of **Jakob Bernoulli** (1770). Therein, Aramah stated:

> "Ordinary lots due to chance are without any tendency to one side or the other... They are not a 'sign', for matters of this kind are not established unless they are found many times... The casting of a lot indicates primarily a reference to chance."

Aramah was born in Zamorah, Spain and served as head of rabbinical academies in various Jewish learning centers. He was expelled from Spain (1492) and died in Naples, Italy. His philosophical system was influenced by Aristotle and Maimonides, and deals specifically with such major questions as faith and reason. Aramah became popular and influential, and his thinking represents the mainstream of Jewish medieval philosophy.

1473–1497 CE **Avraham ben Shmuel Zacuto** (1450–1515, Spain and Portugal). Astronomer, mathematician and historian. His astronomical tables, maritime charts and new astrolabe played an important role in the Spanish and Portuguese discoveries, especially in the voyages of Columbus and Vasco da Gama.

Zacuto's achievements in astronomy were many: his astrolabe of copper, the first of its kind (previously they had been made of wood), enabled sailors to determine the position of the sun with greater precision; his astronomical tables, based on the Alphonsine tables, were an improvement on the latter. They permitted sailors to ascertain latitudes without recourse to the meridian of the sun, and to calculate solar and lunar eclipses with greater accuracy.

Zacuto was born in Salamanca, Spain. His ancestors were Jewish exiles who had come to Castile from France in 1306. He attended the university of his native city, where he specialized in astronomy. Subsequently he became a professor at the universities of Salamanca and Saragossa. There he wrote his major astronomical work (1473–1478), and engaged in research and writing until 1480. He later removed to Gata, where he wrote a treatise on solar and lunar eclipses.

In 1492, when the Jews were expelled from Spain, Zacuto emigrated to Portugal, where he was appointed court astronomer to King John II and later to his successor Manuel I. Here he was engaged in fitting and instructing the expedition of Vasco da Gama. Gama himself consulted Zacuto in Lisbon before he set sail in 1497.

The great services rendered by Zacuto did not protect him, however, from the persecution inaugurated by Manuel at the instigation of the infamous royal couple Ferdinand and Isabella of Spain; he and his son were forced to seek safety in flight. He reached Tunis (1498), where he lived until the Spanish invasion in 1509. He then fled to Turkey, residing there for the remainder of his life.

The work of Zacuto was continued by his pupil and associate **Joseph Vecinho** (Vizino), who supplied Columbus with a translation of Zacuto's astronomical tables. Vecinho was later sent by king John II of Portugal to the coast of Guinea, there to measure the altitude of the sun by means of the astrolabe as improved by **Yaacov ben Machir Ibn Tibbon**.

1477–1514 CE **Donato Bramante** (1444–1514, Italy). Architect and painter. Evolved a style known as the *High Renaissance*. The greatest architect of his generation.

Bramante was born in Urbino and trained as a painter by **Francesca, Piero della**. Arrived in Rome (1499) to build the *Tempietto*[152] of St. Pietro in Montorio (1502). Worked in Milan (1477–1499) and Rome (1499–1514).

[152] So called because it has the aspect of a small pagan temple from antiquity.

Patronized by the Sforza family. Worked with **Leonardo da Vinci** on problems of the Milan Cathedral. Bramante designed the Basilica of St. Peter (begun 1506). He strongly influenced Pope Julius II city-plan for Rome (from ca 1508).

Even though Bramante was called unlettered (as were Leonardo), because he was ignorant of Latin and Greek, he must have acquired considerable learning, however fragmentary. His theoretical writings, have all been lost. His insatiable thirst for experiment and for new knowledge forced him away from convention in his works to a multiplicity of attitudes and expressions. Perhaps these characteristics indicate a certain dissatisfaction, an inner melancholy, or a deep sense of solitude. He apparently never married or had children. In unceasing experiments in his work, he may have been seeking a remedy for his incurable restlessness.

1481 CE **Meshullam ben Menahem of Volterra** (ca 1441–1500, Italy). Jewish goldsmith and traveler. Sailed from Naples, Italy (May 1481) via Rhodes[153] to Alexandria. Visited Cairo and went through the Sinai Desert to Gaza, Hebron, Jerusalem, Jaffa, Damascus and Beirut. From there he sailed back via Rhodes, Crete and Korfu to Venice (October 1481). His travelogue was first published in Vienna in 1882. The manuscript is an important historical document concerning the cultural and socio-political background of life in the Eastern Mediterranean and the Holy Land at the end of the 15^{th} century.

1480–1484 CE **Felix Fabri** (1441–1502, Germany). Dominican friar traveler and writer; one of the most distinguished learned writers of the 15^{th} century.

Fabri (Faber, Schmid) was born in Zürich and died in Ulm, Germany, where he spent most of his life. He made his early studies under the Dominicans at Basle and Ulm and graduated as master of sacred theology. He became head preacher of the Preaching Order at Ulm (1477–1478). Made two pilgrimages to the Holy Land (1480, 1483–1484) taking the route Ulm - Memmingen - Innsbruck - over the Alps into Italy - Venice - by ship to Corfu - Crete - Cyprus - Syria - Holy Land - Sinai - Egypt. Wrote two accounts of his travels , one in German and second in Latin. The Latin version is very complete and accurate in its description of places visited. The journal of his second pilgrimage made Fabri one of the most distinguished writers of his time. This work was reproduced by the Stuttgart Literary Society in three

[153] During 1428–1485, the Popes forbade all Italian ship owners to transport Jews to the Holy Land on board their vessels. This explains why Jewish travelers had to zigzag their way by hopping from port to port in different ships or go overland through Turkey.

octavo volumes (1843–1849) under the title: "*Fr. Felicis Fabri Evagatorium in Terrae Sanctae, Arabiae at Aegyptis peregrinationen*".

1482–1519 CE **Leonardo da Vinci**[154] (1452–1519, Italy). Painter, sculptor, architect, musician, civil and military engineer, inventor and philosopher. The father of modern aviation and anatomy. Student of the natural sciences (anatomy, botany, astronomy, geology, and physics), who sought to discover the mathematical laws governing all observable phenomena.

Through his teacher **Paolo Toscanelli**, his thinking developed towards the modern scientific method: a conception of science that was wholly secular and in no way based on religious doctrines or philosophy. In his thinking as in his actions, the gap between spirit and matter, theory and practice, was finally bridged in reality. While philosophers from Philoponus to **Nicholas of Cusa** had recognized the unity of the world, they had remained abstract thinkers. In Leonardo, the craftsman, scientist, and inventor are merged into one. Liberated philosophically by the new infinite cosmology, and liberated economically by widespread social change that had weakened the authoritarian hierarchy, he went far beyond his predecessors – he observed the *whole world*.

Leonardo put into practice Nicholas' idea that knowledge must derive from observations, and linked it with the necessity of mathematical description. He emphasized that "*there is no certainty in science where one of the mathematical sciences cannot be applied*". But he emphatically rejected the Platonic idea of mathematics as the master of science. In Leonardo's method, experiments lead to the hypothesis of 'rules of nature', mathematical rules whose utility is as an aid to human beings in their lives. He applied this method on a scale not equaled before him.

Leonardo recorded his ideas about art, engineering and science in his *notebooks*, which include about 4200 pages. He wrote his notes backwards, such that they can be read only with a mirror. Many of his ideas and designs were far ahead of their time, but because his writings remained largely uncirculated, and were extremely difficult to decipher[155], he exerted little or no

[154] For further reading, see:

- Vallentin, A., *Leonardo da Vinci, The Tragic Pursuit of Perfection*, Viking Press: New York, 1938, 561 pp.
- Hart, I.B., *The World of Leonardo da Vinci*: *Man of Science, Engineer and Dreamer of Flight*, Viking Press: New York, 1961, 374 pp.

[155] His method of mirror writing on little notes which he often inserted in any blank space that was available, had to do with a number of independent factors: First,

influence on subsequent generations of scientists. By the time Leonardo's scientific and technical investigations became widely known, other people had come up with many of the same ideas. Uneducated[156], incapable of adequate expression in words of the ideas flashing through his extraordinary mind, his notes are often incoherent and without conclusions. Thus he never developed his ideas systematically, seldom formulated scientific laws or principles, and did not make any notable scientific discoveries. He *did* however develop the empirical side of the scientific method[157], and must be credited with an impressive number of inventions, such as: *parachute*, *helicopter*, *construction crane*, the *wheelbarrow*, a *hodometer*, a *lens grinder and polisher*, a *flying machine*, a *compass*, *flexible chain or sprocket drive*, and *ball bearings*.

His wide variety of suggestions for the fields of *military engineering and hydraulics* is amazing: he could produce engines for offense and defense, and equipment for military excavations, mining, supply, and ordnance. *Projectile throwers*, *aerial bombs*, *catapults*, *mine detectors*, *military bridges*, *firearms* capable of imparting spin to bullets, are among his inventions or improvements on existing devices.

In hydraulics (a subject of endless fascination to him throughout his life) he was generations ahead of his time, especially in the field of *canal engineering*. He also devised innumerable ways of employing hydraulic power, such as *water lifts*, *ventilators*, *screws*, *pumps* and *water shells*. (Yet, there is no proof that all the machines he sketched were his own invention.) He stated that the sun does not move (some fifty years ahead of Copernicus), though savants of his day believed that the sun revolves around the earth.

Together with **Andreas Vesalius of Brussels** (1514–1564) he is the

---

paper was not as cheap then as it is now and people did not like to waste it as we do. Second, there was no patent office and secrecy was the only method of protection.

[156] The distinguished historian of science and longtime Leonardo scholar, **George Sarton**, remarks soberly that in comparison to his contemporaries, he quoted very little from the great minds of his day, and indeed seems, for all his natural brilliance, to have been comparatively unlettered.

[157] Leonardo studied various building problems experimentally. Using small-scale models, he investigated how the weight that vertical pillars and horizontal beams could support, varied with their thickness and their height or length. His experiments led him to the results that the carrying power of a pillar, of given material and height, varied as the cube of its diameter, and that the carrying power of a beam was directly proportional to its thickness and inversely proportional to its length.

The bones and joints of animals he considered to be lever systems operated by the forces of their muscles.

founder of modern anatomy. Leonardo was fearless in his research, at a time when ecclesiastical and magical taboos still intimidated his contemporaries. In his anatomical dissections his often restated belief in the primary value of observation, and his willingness to repeat his dissections rather than content himself with one single example, establish his drawings as important scientific documents. But again, his anatomical drawing and researches remained hidden for centuries.

Leonardo was born near the village of Vinci, near Florence, as the illegitimate son of Piero da Vinci (a legal specialist) and a peasant girl. During the late 1460's Leonardo became an apprentice to the painter and sculptor **Andrea del Verrocchio**. During 1478–1482, Leonardo had his own studio in Florence, and he left Florence in about 1482 to become court artist for Lodovico Sforza, the Duke of Milan. There Leonardo stayed for 17 years, being employed as a military and civil engineer and a sculptor. He painted *The Last Supper* in 1495. During his Milan years he began to produce scientific drawings.

In 1499, the French overthrew Sforza and forced him to flee Milan. Leonardo too left the city, and visited Mantua and Venice before returning to Florence. The Florentine government hired him and Michelangelo to decorate the new hall for the city council. While working on this project, Leonardo painted the *Mona Lisa*, a portrait of Lisa del Giocondo, the young wife of a Florentine merchant. The *Mona Lisa* became famous because of the mysterious smile of the subject[158]. In 1517 Leonardo settled in France at the invitation of King Francis I, and spent his final two years near Tours.

Leonardo was one of the greatest heroes of the Renaissance, whose activities marked a climax of the Italian Renaissance as well as the beginning of the French one. Leonardo moves us deeply, first because of the Oriental proclivities that are one of the aspects of his mysterious genius, and second because of his scientific tendencies. He was a man without academic learning, whose attention, therefore, was not focused on books but rather on nature. He was concerned with new discoveries, not with rediscoveries.

At the end of the 15^{th} century, a new way of thinking opened up great vistas of learning and beauty. The wonderful phenomenon of the Renaissance was not merely a revival of classical culture; it was a change in the whole outlook of thinking men, who demanded escape from the tyranny of dogmatism,

---

[158] "*Women did not arouse in him any feelings of desire. He was therefore all the more curious about the mysterious character of reproduction and generation. He could consider the sexual act as part of the endless flux of growth, decay and rebirth which formed for him the most fascinating and fundamental of all intellectual problems*". (Kenneth Clark).

from limitations of thought imposed by the Church. It was the Renaissance that finally broke the Church's stranglehold upon science and medicine.

1484 CE **Nicolas Chuquet** (ca 1445–1500, France). Mathematician. Published (1484) a manuscript treatise entitled *Triparty en la science des nombres*. Although the work was not printed until 1880, it had considerable contemporary influence. In the third part of his book Chuquet devised an exponential notation in which the power of the unknown is indicated by an exponent [e.g., $6x+12x^3+4+7x^{-2}$ were written in the form $.6.^1+.12.^3+.4.^0+.7.^{2.m}$]. Chuquet also produced what is, in effect, a small table of *logarithms* to base 2. In his work, *negative numbers* appear for the first time and *zero* is used.

Chuquet was born in Paris, qualified in medicine and practiced in Lyon.

Table 2.6 lists important Chinese, Hindu and Medieval mathematicians.

Eclipses, Occultations and Maps

If noon *(when the sun lies directly over the meridian on which one is located) at a place B on earth occurs y hours* after *noon at A, B is $15y$ degrees west of A. If noon occurs at B y hours* before *A, B is $15y$ degrees east of A. A difference in longitude is the* hour angle *difference between the local transits of the sun across the two* meridians *(the lines joining the north and south points of the horizon at the two locales).*

Simple as this may appear, it was a very difficult mental leap to make in ancient times! Until there were wheel-driven clocks, there were no portable devices with which to compare solar time at two different places. Although the later Alexandrians had very elaborate water-clocks *of much greater delicacy than the crude hour-glasses of earlier periods (and certainly no less accurate than the first medieval clocks which were driven by weights) they had no means of a maintaining a continuous record of time over a long journey.*

Yet, ***Eudoxos*** *(fl. 370 BCE),* ***Kiddinu*** *(fl. 367 BCE),* ***Aristarchos*** *(fl. 280 BCE),* ***Eratosthenes*** *(fl. 235 BCE),* ***Hipparchos*** *(fl. 150 BCE), and* ***Ptolemy*** *(fl. 150 CE) – all understood that certain astronomical events can be used in lieu of accurate clocks to determine longitude. Equipped with neither chronometers, nor radio signals, they offered a way of using natural*

I = Italian; J = Jewish; F = French; G = German *phenomena visible from many parts of the earth such as eclipses of the moon or the occultation of a planet or star by the moon's disk.*

The method, based on the lunar eclipse, works as follows. Let the moon enter the earth's shadow cone at local time t_1 *as reckoned at location* A_1 *(relative to the local noon as measured on a sun-dial, say), and let it likewise enter the same cone at local time* t_2 *as reckoned by the local timekeeping at location* A_2*. The longitude difference between the two locations is then* $15°(t_2 - t_1)$*. The mariner who possesses an almanac giving the local time at which an eclipse (or other astronomical event) will occur at one place, can therefore obtain his longitude by recording the local time of its occurrence where he is*[159]*.*

Aside from lunar eclipses, the moon's course displays other circumstances which were highly portentous; as it moves along its orbit, it may block the visibility of other heavenly bodies, in particular planets which move near the ecliptic and thus also near the moon's orbit. Thus, during an occultation of Mars, the planet will disappear behind the moon's disk.

People observed these occultations and were able to know when they would occur at a particular place. Anyone who possessed an hour-glass at another place could watch for them and record the interval which elapsed between an occultation (or an eclipse) and that day's local noon.

Latitude could be determined by either sighting the elevation of a star at night (with a sextant) or the sun at daytime. Thus true maps could in principle be constructed from the knowledge of both latitude and longitude of places.

Occultations and conjunctions of planets were reported by Greek, Chinese, Arab and European astronomers throughout history; some examples are:

- ***May 04, 357*** *BCE: Occultation of Mars visible in Greece during the lifetime of Aristotle, and one of the very few astronomical observations which Aristotle himself is known to have made. He renders a very careful description in De Caelo* ***2****, 12.*
- ***Sept. 04, 241*** *BCE: Close conjunction of Jupiter and the star* δ *Cnc (Ptolemy, Almagest* ***11****, 3).*

[159] **Columbus** used this technique to fix the longitude of *Jamaica* (1504), and was disappointed to find that it lay not as far west as he expected. Earlier, he looked out for a port of anchor at *Haiti* for observing the lunar eclipse on January 13, 1493. Allegedly, **Vespucci** found the difference of longitudes between Venezuela and Cadiz in 1499 by observation of a lunar eclipse.

- ***Feb. 12, 73*** *CE: Chinese report on occultation of β Sco by Jupiter (disappeared Feb. 12; reappeared Feb. 16).*
- ***Sept. 13, 1170*** *CE: Conjunction of Mars and Jupiter. During the night of* 12–13 *Sept. the planets passed within a minute of arc of one another, so that the unaided eye would not be able to resolve them.*
- ***July 18, 1273*** *CE: Mercury occulted by the moon. Observed in Egypt for half an hour.*
- ***Jan. 09, 1591*** *CE: Jupiter totally occulted by Mars. Observed by Kepler at Tübingen, Germany.*

Unfortunately, eclipses or occultations occur so rarely as to be almost useless for ships on the move. Nevertheless, ***Hipparchos*** *believed that an extensive series of observations should be carried out in order to ascertain, by mathematical and astronomical means alone, latitudes and longitudes of a large number of places. To facilitate such a survey, he prepared tables of lunar eclipses, and tables to aid in the determination of latitudes, but the practical difficulties of the undertaking were too great and the work was never completed. In fact, throughout antiquity the total number of places whose position had thus been accurately determined probably does not exceed half a dozen, if that*[160].

The navigators of ***Columbus*** *and* ***Magellan****, versed in Muslim astronomy, were able to define the position of America on the world's map. So knowing exactly where the planets are located was a matter of some practical importance in the period of the Great Navigations, when* ***Copernicus*** *and* ***Kepler*** *showed that their positions can be calculated more accurately and far more simply if we reject the commonsense-view of the priestly astronomers.*

1485–1488 CE **Ovadiah Yareh of Bertinoro** (ca 1435–1515, Italy). Traveler and Mishna commentator. Sailed (1485) from Naples to Sicily and

[160] **Pliny** speaks of an eclipse of the sun that was seen in *Campagnia* between the 7^{th} and 8^{th} hours and in *Armenia* between the 11^{th} and 12^{th}, indicating a difference in longitude of 4 hours, or 60°. The actual distance is no more than half of this. Much greater accuracy was attained by the Arabs in their calculations of longitude, and some of their figures were passed on to the Western world in astronomical tables during the 12^{th} and 13^{th} centuries.

from there to Egypt[161] (1487). Then went through the Sinai Desert to Jerusalem (1488). Described his perilous journey in a series of letters (1488–1490) to his family in Northern Italy. Composed his famous exegesis to the Mishna (1490–1505). Died in Jerusalem and was buried in a cave in the Mount of Olives.

1486–1489 CE **Johannes Widman** (1462–1498, Germany). Mathematician. Introduced the symbols (+) and (−) to denote addition and subtraction, respectively. Author of *Behennde und hüpsche Rechnung auf allen Kauffmanschafften* (1489). This marks the beginning of *algebraic symbolism*. He considered computation with irrational numbers and polynomials to be part of algebra.

Widman attended the University of Leipzig, graduating in 1482. His Masters Degree was awarded in 1485 and he then taught at the University of Leipzig on arithmetic and algebra.

Although the Germans did not enrich algebra during the Renaissance with great inventions, as did the Italians, they still cultivated it with great zeal.

1492 CE, Jan. 23 First printing of the Pentateuch.

1490–1520 CE **Yehudah Abravanel** (LEONE EBREO) (1460–1530, Portugal, Spain, Italy). One of the great philosophers of the Renaissance, physician, mathematics and astronomer. An outstanding figure of the period of transition between the Middle Ages and the Renaissance. He lived not only at the conjunction of two eras but was also in contact with three cultures – Jewish, Spanish and Italian.

Yehudah was born in Lisbon. He fled (with his father Itzhak) to Spain (1483) and practiced medicine there. After the expulsion (1492) he left with his father for Naples and worked there as a physician. Upon the conquest of Naples by the French (1496) he moved to Geneva, but returned to Naples and lived there (1503–1521) as court physician to the Spanish viceroy. He lectured on mathematics and astronomy at the Universities of Naples and Rome.

His most famous work *Dialoghi di Amore* (1535) is a landmark in the history of aesthetics, metaphysics and ethics. He maintained that true happiness is the union of human intellect with the Divine intelligence, and that it is directly connected to aesthetic enjoyment. There is a pantheistic strain in Abravanel's philosophy, but he always emphasized his orthodox Judaism, and tries to reconcile his pantheistic feelings with the biblical concept of God. The book was translated to most European languages and exerted great influence.

[161] When the ship reached Palermo, Ovadiah met (1487) with **Meshullam of Volterra**, who was on his second voyage to Egypt.

It was one of the most widely read books in Shakespeare's England. One of its heritages is the concept of *Platonic love*.

1492 CE, Aug. 3 **Christopher Columbus**[162] (Cristoforo Colombo, 1451–1506, Italy), *Admiral of the Ocean Sea*, sailed from the Spanish port of Palos with a crew of 89 men on board three small and fragile ships – the *Niña*, *Pinta* and the *Santa Maria* (a 24 meter long carrack of about 280 tons). On Oct. 12, he completed his first Atlantic crossing and landed on a Caribbean island that he named San Salvador, which he believed to be an island of the Indies, near Japan or China. He discovered Cuba (Oct. 27) and Hispaniola (Dec. 6). On March 4, 1493 he reached Lisbon after a tempestuous recrossing of the Atlantic.

Columbus' ambition was to find a short sea route to the Indies. He used a map given to him by the Florentine geographer **Paolo Toscanelli** (1397–1442, Italy), in which Japan lay only 4400 kilometers west of Lisbon.

Columbus navigated by dead reckoning: his navigators knew just enough celestial navigation to measure latitude from the North star. The navigation tools at his disposal were: compass needle, sandglass, quadrant and ephemerides (tables listing positions of stars and planets at given times). It was virtually impossible for him to use celestial navigation for the measurement of longitude (i.e. east-to-west distance) because there were no chronometers. To find latitude (i.e. north-to-south location) the height of the sun at its meridian (noon) was measured, or in the Northern hemisphere – the height of the North star. Sailors used an instrument called a *quadrant* for making these measurements; but the quadrant was so difficult to use on a rolling ship that reliable measurements could be made only through repeated land-based observations.

Given the primitive state of navigational instruments, the *ship's fix* in Columbus' day was usually only a rough approximation. It was necessary to know three elements: time, speed, direction. Based on these, the route

---

[162] Some historians believe that Columbus was of Jewish origin, possibly a marrano or secret Jew. Five of his crew, as well as his interpreter **Luis de Torres** (who knew Hebrew, Chaldaic and a little Arabic) were known to be *Marrano* Jews (among them **Maistre Bernal**, the official doctor of the expedition, and **Marco**, the surgeon), and he used the Alfonsine Tables compiled by Jews.
There is bitter irony to the fact that the wealth that Ferdinand and Isabella confiscated (1492–1497) from the expelled Jewish population (ca 200,000), was used to finance the journeys of discovery of Columbus, Magellan, Cabral, da Gama and others. Thus, both Jewish material and intellectual resources were instrumental in the discovery of the New World. (History repeated here what had previously occurred during the Crusades!).

taken from the point of departure could be marked on the chart. *Direction* was given by the compass: the horizon was divided into 32 points instead of 360°, which means that directions were measured roughly. Accuracy was further reduced by the fact that no account was taken either of declination (difference between geographic north and magnetic north which varied from place to place) or of the shifting of the needle caused by nearby metal objects. It was relatively easy to record successive changes in course, but much more difficult to calculate the effects of drifts or the movement of currents.

Speed was a matter of guesswork, estimating by looking at the flow of water along the hull.

Time was measured with a *sandglass* which was turned every half hour (every 8 turns of the sandglass – that is, every 4 hours – the old watch was replaced and fresh crewmen took their place. Each watch passed on the compass course to the next watch and a new helmsman began his work). Since the time of noon was essential, and since the hour of midday became progressively later as the ships sailed westward, it was necessary periodically to synchronize the sandglass with the sun. Columbus did this on a weekly basis, using a method that probably was accurate within a quarter of an hour.

It is estimated that Columbus' first voyage cost $14,000 in today's currency. (A few years after the voyage, the 'poorest' of Spain's 13 dukes had an annual income that was about 5 times greater than all the funds raised for Columbus' voyage.) This suggest that his expedition was, in modern terms, a relatively low-budget operation.

Columbus was born in Genoa. The family name was Colombo. He called himself Cristóbal Colón after he settled in Spain. His father, Domenico, was a wool weaver. Columbus was sent to the University of Pavia, where he devoted himself to mathematics, astronomy, geometry, and cosmography. He had settled in Lisbon about 1479, marrying the daughter of the governor of Porto Santo in Madeira Island. There he spent some time studying his late father-in-law's collection of navigational works, talking to sailors about their voyages and making charts.

Like Aristotle and Eratosthenes, who had successfully calculated the circumference of the earth more than 1600 years earlier, Columbus knew that the earth was a sphere. Most of his reading seems to have been medieval. It was Marco Polo's overestimation of the east-west extent of Asia, and of the distance of Japan from the Asian mainland, that led him to believe that the voyage westward from Europe to Japan would be less than 3000 nautical miles. Indeed, he called the natives of the Bahamas "Indians", certain that he had arrived in Asia, in the realm of the Great Khan.

On Sept. 25, 1493 he went on his *second voyage* with the objective of the colonization of Hispaniola (today's Haiti and the Dominican Republic). He set out with 3 great carracks, 14 caravels and 1200 men – soldiers, farmers, missionaries, civil servants, and assorted fortune hunters. During his voyage he discovered the Lesser Antilles – from Dominicana to the Virgin Islands, including Puerto Rico and Jamaica. He returned with his fleet to Cadiz on June 11, 1496.

He embarked again, on his *third voyage*, on May 30, 1498, with 6 ships, crewed by pressed men and released criminals, the only men who could be found. The new lands discovered during this expedition was Trinidad and what is now Venezuela (= little Venice). From this voyage he was sent home in chains, but later reinstated in the Queen's favor.

After this Columbus made his *last voyage*, sailing on March 9, 1502, once more presumably in search of a way to Asia, and en route discovered Martinique, the mainland of Honduras and Costa Rica.

He had no means of knowing that the Pacific was not more than 500 kilometers to the west![163] He reached Seville on September 7, 1504, only to die two years later, a disillusioned and broken man.

1492–1498 CE *The New Exodus*[164]: expulsion of the Jews from Spain un-

[163] Columbus drew most of his ideas about geography from books written in the 14^{th} and early 15^{th} centuries. The cosmography in these books was based on erroneous maps and imaginary concepts that propagated from Greek and Roman writings

[164] In the course of the years 1355–1482, about 60,000 Jews were killed in massacres and riots and 20,000 forcibly baptized into Christianity under Spanish rule. On the eve of the expulsion there still remained about 200,000 Jews in the Iberian Peninsula. Of these ca 25,000 perished while seeking a new home; ca 50,000 remained in Spain as Marranos and Conversos; about 55,000 eventually reached Turkey; some 35,000 finally settled in France and Holland; 10,000 went to Italy; 5,000 to South America, and 20,000 to North Africa and Egypt.
Jews played a leading part in the cultural and economic life of Spain during the Roman and Islamic periods. When the Christians wrestled Spain from the Moors (1212), the Jews brought the splendor of the Islamic civilization to Christian Spain. By virtue of their learning and sophistication they left an imprint of humanism on that country. They rose to great positions of power, many attaining high ranks of nobility. Resentment against "outsiders" as "insiders" smoldered for a century, then erupted into an anti-Jewish movement popularly known as the "*Second Reconquest*", a movement to force the Jews to "give" Spain back to the Christians. It climaxed in the great conversion drives (1391) when many thousands were forcibly baptized. Thus, these "*New Christians*", the flower of Jewish aristocracy and intelligentsia, entered the service of the Church (becoming bishops, archbishops, cardinals) and began to dominate

der complex and chilling circumstances which laid the foundation for modern racist holocausts in Europe.

1494–1509 CE **Luca Pacioli** (ca 1455–1517, Italy). Mathematician and Franciscan friar. Compiled an overview of most mathematical methods handed over from the Middle Ages in his book *Summa de arithmetica, geometria, proportioni et proportionalita* (1494). This work, freely compiled from many sources, purported to be a summary of the arithmetic, algebra and geometry of the time. It contains little of importance not found in Fibonacci's *Liber abaci* (1202), but does employ superior notation. Methods are presented for solving equations of the first and second degree, accompanied

---

Spanish intellectual life. It was this "Jew in Christian cloths" who became the villain, with disastrous results for the Jews and Spain. The cry was raised by the "Old Christians" that the "New Christians" were not loyal to the Church. They held that *limpieza de sangre* (purity of blood), not mere ability, should determine one's fitness for Church office. So persistent was that feeling that the Inquisition was introduced (1480) to determine blood purity; the stage was set for the Grand Inquisitor Tomas de Torquemada and the *Auto-da-fé* ("act of faith") – the rite of purification by being burned alive. [His grandfather, Alvar Fernandez de Torquemada married a recently baptized Jewess; this genealogical fact throws psychopathological light on the grandson's ruthlessness toward Jews.]

Torquemada asked for the expulsion of the all Jews. No charge was brought against them other than that they were not Catholic. The 50,000 Jews who chose to stay in Spain by conversion to Christianity became the new Marranos. But because the all-prevailing effects of *limpieza* they did not soar to intellectual eminence as the Jews and the Marranos of the two preceding centuries – the intellectual lights in Spain went out.

In the 2005 Internet text of the *Catholic Encyclopedia* we read the following lines under the item 'Tomas de Torquemada':

"During Torquemada's office (1493–1498) 8,800 suffered death by fire and 9,654 were punished by other ways. Whether Torquemada's ways of ferreting out and punishing heretics were justifiable is a matter that has to be decided by an inquiry into their necessity for preservation of *Christian* Spain." (sic!)

The contemporary Spanish chronicler, **Sebastian de Olmedo** calls Torquemada "the hammer of heretics, the light of Spain, the savior of his country, the honor of his order."

History tells us that after 1498, Spain sank back into the Middle Ages [see Science Progress Report No. 5]. The persecution by the Inquisition and the following expulsion of the Jews, stripped Spain of most of its intellectual, scientific and economic powers. It never recovered, and after Torquemada was not worth saving.

by many problems leading to such equations. It includes algorithms for multiplication of integral numbers written in Hindu-Arabic numerals, extraction of square roots, and the first printed description of *double entry bookkeeping*.

Pacioli's second book, *De Divina Proportione* (1509), included figures of regular solids on plates engraved by his friend **Leonardo da Vinci**.

Pacioli traveled extensively and taught at various places.

1495–1512 CE **Alesandro Achillini** (1463–1512, Italy). Philosopher, anatomist and surgeon. One of the first to dissect a human body. In his anatomical writings he described the veins of the arm, the seven bones of the tarsus, the fornix, ventricles, and infundibulum of the brain, and the trochlear nerve. He also described the ducts of the submaxillary gland before **Thomas Wharton** (1656), and two of the three ossicles of the ear (the malleus and incus).

Achillini was a lecturer both in medicine and in philosophy at Bologna and Padua.

1495 CE Epidemic of *syphilis* sweeps Europe.

1496–1500 CE The diseases of syphilis and cholera first identified or described with accuracy.

1497 CE **Amerigo Vespucci** (1451–1512, Italy). Merchant, pilot and adventurer, who gave his name of **Amerigo** to the new world as *America* although he had no share in the first discovery of the American continent. Yet, due to some odd combination of circumstances, America was named after him.

He was born at Florence. His father was notary, and his uncle, to whom he owed his education, was a scholarly Dominican and a friend of Savonarola. He studied natural philosophy, astronomy and geography and later was placed as a clerk in the great commercial house of the Medici, then the ruling family in Florence. He resided in Seville, Spain throughout the period 1492–1496 as an agent of the Medici, and certainly did not make the 1497 voyage, which he claimed he had made. Whether or not he took part in the expeditions of 1499 (for Spain), 1501 and 1503 (for Portugal) is yet an open question.

The connection of the new world with Vespucci, is derived from an alleged letter written by him from Lisbon (march of April 1503) to Lorenzo Piero Francesco di Medici, the head of the firm under which his business career had been mostly spent, describing his alleged Portuguese voyage of March 1501–September 1502. The original Italian text is lost, but a Latin translation is extant. According to this letter, Vespucci reached the mainland of America on a Spanish expedition 8 days before **Giovanni Gaboto** (John Gabot, June 16^{th} against June 24^{th}, 1497).

A second letter, written from Portugal (September 1504) to his old schoolmate Piero Sodorini, was made available in Latin translation to Martin Waldseemüller, professor of cosmography in St. Dié University. This man wrote a book *Cosmographiae Introductio* (St. Dié, 1507) in which he suggested that the newly discovered 4^{th} part of the world should be called "*America, because Americus discovered it*"[165]. His name was first accepted for South America, and gradually came into use for North America as well.

1498–1519 CE **Shmuel Zarfati**[166] (called **Gallo**, ca 1450–1519, Italy). One of the greatest physicians of his age; Pioneer of blood-transfusion in modern medicine. Originated from France. When the Jews were expelled from Provence (1493–1500), Shmuel was assured by King Louis XII that he personally would not be molested. He nevertheless preferred to emigrate (1498) and settled in Rome, where he became famous for his cures. There he was granted special privileges by Pope Alexander VI. He represented the Jewish community at the coronation of Pope Julius II (1503), and became the latter's personal physician (1504). His reputation was greatly enhanced (1511), when he successfully predicted the recovery of the Pope from a serious illness at a time when all the Pope's other physician had given up hope. He was permitted to treat Christian patients and was granted full rights of residence; He and his family were exempted from wearing the Jew badge. In 1515 he became physician of Giuliano de Medici.

Shmuel's son, **Joseph Zarfati** (called **Josiphon**, **Giosifante**, or **Giuseppe Gallo** by Christian writers, ca 1470–1527) was a physician, philosopher, poet, mathematician and an accomplished linguist (Latin, Greek,

---

[165] In 1492, **Christopher Columbus** had no idea that he reached the Western Hemisphere. He thought that the islands he explored were part of the Indies. He first set foot on the mainland of America on his third voyage in 1498. When Vespucci claimed that he had discovered the new continent, or the New World, as it was called in 1497, Columbus did not dispute his claim.

[166] **Zarfati, Zarefati, Sarfaty**: An illustrious group of families of rabbinic Talmudic scholars, originating from France, some of which descended from **RASHI** (1040–1105). For the next 700 years these families issued Rabbinic scholars, Talmudists, physicians, poets, mathematicians and linguists which spread from France to Spain, Netherlands, Italy, Turkey, Israel and North Africa.
Other famous physicians from this family were:

- **Yaacov ben Shlomo Zarfati** (ca 1365–1425, Avignon, France).
- **Itzhak Zarfati** (ca 1485–1550, Italy). Physician to Pope Clement VII.
- **David Zarfati de Pina** (ca 1630–1700, Amsterdam). Noted physician, poet and preacher.

Hebrew, Aramaic, Arabic). The Pope extended to him the privileges that had been accorded to his father; these were confirmed by Pope Leo X and Pope Clement VII (1524).

The latter part of his life was dogged with misfortune. An unfaithful servant ran off with his fortune, he was falsely accused of being a spy, he was beset by robbers, and he escaped the siege of Rome in 1527 only to fall victim of the plague and die outside of the city of Vicovaro.

1498–1510 CE **Gaspar da Gama** (1444–1510, India and Portugal). Jewish navigator and explorer. Participated in the Portuguese naval expedition of **Vasco da Gama**, **Cabral**, **Nicolau Coelho** and **Francisco d'Almeida**.

He was born in Posen, Poland and became a traveler. He made his way to Jerusalem and then Alexandria, was taken prisoner and sold as a slave in India, where he obtained his freedom and entered the service of the ruler of Goa. There, he took on the name Yusuf' Adil. We do not know what his original name was.

When the Portuguese explorer Vasco da Gama arrived off Angediva in 1498, he was greeted in a friendly fashion by this long-bearded European on behalf of his master. Vasco da Gama self-righteously seized the Jew and compelled him to embrace Christianity under the baptismal name of Gaspar da Gama. He was also known as Gaspar d'Almeida and Gaspar de las Indias.

As a Catholic, Gaspar da Gama became the pilot of Vasco da Gama's fleet. He successfully guided the ships through treacherous Indian waters and was brought back to Portugal.

In Lisbon, Gaspar was granted a pension by the King, who employed his linguistic ability in subsequent Portuguese naval expeditions. In 1500 he accompanied Cabral on his voyage in Western waters and was with Nicolau Coelho when he first stepped ashore in Brazil.

On the return voyage he met Amerigo Vespucci (the Tuscan explorer after whom America is named) at Cabo Verde and was consulted by him.

In 1502, he went to India once more with Vasco da Gama and again in 1505 with Francisco d'Almeida. He took part in the latter's expedition against Calicut in 1510, when he may have died.

1500 CE *Hindu-Arabic* numerals finally superseded Roman numerals for most computational purposes in Europe.

1500 CE The Portuguese navigator and explorer **Pedro Álvars Cabral** (1467–1520) discovered *Brazil*. After da Gama's return, King Manuel I of Portugal sent Cabral in command of a fleet of 13 vessels to establish trade with India. Taking a westward course, he was carried by wind and current to the coast of Brazil and took possession of it in name of Portugal. They named the country for the red dyewood, called *Brazilwood*, that they found there.

The 16th ***century:*** final collapse of the *cultural balance* of the Old World when Europe opened the Americas, and then explored the rest of the world's habitable coastlines, using the oceans as highways for their commerce and conquests. For the first time, one civilization gained such superiority as to upset the fourfold balance that existed since 1000 BCE between the four distinctive civilized traditions of Greece, the Middle East, India and China.

Those four major civilizations were set apart by different cultural traditions, and by distinctive religious and philosophical world views, all of which found their initial expressions before the end of the sixth century BCE.

The relationship between the four major civilizations may be thought of as an equilibrium. Any serious disorders might influence other parts of the system, but not until 1500 CE did any one civilization gain such superiority as to upset the fourfold balance of the whole. This balance did, however, encounter a number of jolts:

- First, **Alexander the Great** pushed Greek civilization far beyond its original borders.
- Then, *Hindu Buddhism* advanced along the silk road into the heart of China.
- But the *Hellenization of the Middle East*, like the *Indianization of China* did not last and was soon either repudiated or absorbed into native concepts.
- Next came the explosive conquest of *Islam*, first across the Middle East, North Africa and Spain, and then into India, Eastern Europe and Central Asia.

The Amateur Mathematicians of the Renaissance[167]

(1500–1600)

The Renaissance was a golden age of part-time naive mathematicians.

Before 1500*, the three components of modern scientific method – the logical, the experimental and the mathematical – developed in isolation. The underlying reason was that the aims, intellectual interests and social positions of the professional groups with which they were connected, were too diverse to permit fruitful communication among them.*

By 1500*, the gaps between these groups had narrowed rapidly due to printing: the cultural ideas of humanism influenced all educated men. Fashion forcefully imposed newly translated texts on their attention, while an increasing number of scholars learned Greek and began to study Greek science in its original source. An important phase of this reappropriation of Greek antiquity was the recovery of understanding of the works of* ***Pappos****,* ***Apollonios****,* ***Diophantos****,* ***Hero*** *and above all those of* ***Archimedes****, which appeared in Latin translation in* 1543*. With these came the growing emphasis on the cultural and scientific importance of mathematics. Humanist educational practice stressed mathematics at the expense of logic. The professional teaching of mathematics spread to the universities and there was hardly a Renaissance writer who did not remind his readers of the sentence inscribed over the door of the Platonic Academy: "Let no one unskilled in geometry enter here".*

In this atmosphere emerged persons who had skills in many fields of knowledge.

The artist-engineer ***Leonardo da Vinci*** *(1452–1519, Italy) was such a 'universal man', and being interested in everything, he was naturally interested in mathematics. Although he did not have much of a mathematical education, he tried to square the circle.*

Albrecht Dürer *(1471–1528, Germany), originated what we call today: 'descriptive geometry', because as an artist he was interested in perspective and the proportions of the human form.* ***Francois Vieta*** *(1540–1603 ,*

---

[167] To dig deeper, read:

- Coolidge, J.L., *The Mathematics of Great Amateurs*, Oxford University Press: London, 1949, 211 pp.
- Ore, O., *Cardano the Gambling Scholar*, Dover Publications: New York, 1965, 249 pp.

France) was a Royal Privy Counselor and mathematician. ***Joseph Scaliger*** *(1540–1609, Netherlands)was a philologist at the University of Leyden. He was an amateur mathematician whose name is associated with the Gregorian Calendar.*

The monk and Lutheran preacher ***Michael Stifel*** *(1487–1567), was for a time professor of mathematics at the University of Jena.* ***John Napier*** *(1550–1617, England) a Scottish nobleman and amateur mathematician invented logarithms, but also warlike machines for the defense of Britain against Spain. He promoted astrology and published a book in which he argued that the Pope was the Anti-Christ.* ***Jobst Bürgi****, a Swiss clockmaker working in Prague, invented the logarithms independently.*

It should be kept in mind that during 1494–1559, *Italy served as a victim of rivalries of the strong monarchies which were rising in Western Europe, all of which coveted the wealth of the peninsula. Spain was engaged in a series of wars against France to control Italy, which was politically divided into four major city-states (Venice, Milan, Florence, and Naples) and the Papal states. These units maintained a precarious balance among themselves and were constantly endeavoring to victimize each other, and ultimately reached the point of inviting in foreigners, with the result that Italy became the prey of French, German and Spanish ambitions.*

Nevertheless, the said period marked the apogee of the Renaissance and the intellectual and artistic primacy of Italy. It seemed as if all the armies of Europe could not stop the ideas whose time had come.

In the field of political science ***Niccolo Machiavelli*** *(1469–1527) was outstanding.* ***Ludovico Ariosto*** *(1474–1533) was a great epic poet. In the field of music* ***Giovanni Palestrina*** *(1525–1594) and* ***Orlando di Lassus*** *(1532–1594) were men of the first rank. Architects and painters of eminence were too numerous to be listed, and it will suffice to recall names like* ***Raffaelo Santi*** *(1483–1520),* ***Michelangelo Buonaroti*** *(1475–1564),* ***Titian*** *(Tiziono Vecelli, 1477–1576),* ***Tintoretto*** *(1512–1594),* ***Paolo Veronese*** *(1528–1588) etc.*

By 1559, *almost all of Italy was under the influence of Spain and so it remained until the early* 1700*'s.*

The most spectacular mathematical achievement of the 16^{th} *century was the discovery, by Italian mathematicians, of the algebraic solution of the cubic and quartic equations. The story of this discovery rivals any page ever written by Benevenuto Cellini:*

About 1515, ***Scipione del Ferro*** *(1465–1526), a professor of mathematics at the University of Bologna, algebraically solved the cubic equation* $x^3 + px = q$, *probably basing his work on earlier Arabic sources. [Bologna* *was at the time one of the oldest of the medieval universities, with a strong mathematical tradition.]*

Consider the identity $(a-b)^3+3ab(a-b) \equiv a^3-b^3$ *and denote* $a-b=x$. *The identity then reads* $x^3+3abx = a^3-b^3$. *Comparing this with the original equation* $x^3+px=q$, *we choose* $3ab=p$, $a^3-b^3=q$, *and solve this pair for* $\{a,b\}$ *in terms of* $\{p,q\}$. *The problem has thus been reduced to the level of the biquadratic equation,* $a^6-a^3q-\left(\frac{p}{3}\right)^3=0$. *A solution of this equation is:* $a^3=\frac{q}{2}+\sqrt{\left(\frac{q}{2}\right)^2+\left(\frac{p}{3}\right)^3}$ *and therefore* $b^3=a^3-q=-\frac{q}{2}+\sqrt{\left(\frac{q}{2}\right)^2+\left(\frac{p}{3}\right)^3}$. *Finally,* $x_1=\left\{\frac{q}{2}+\sqrt{\left(\frac{q}{2}\right)^2+\left(\frac{p}{3}\right)^3}\right\}^{1/3}-\left\{-\frac{q}{2}+\sqrt{\left(\frac{q}{2}\right)^2+\left(\frac{p}{3}\right)^3}\right\}^{1/3}$.

To obtain the other two solutions, one effects the factorization:

$$x^3+3abx+b^3-a^3=[x-a+b][x+\omega b-\omega^2 a][x+\omega^2 b-\omega a]$$

where $\omega=-\frac{1}{2}[1+i\sqrt{3}]$, $\omega^2=-\frac{1}{2}[1-i\sqrt{3}]$, *and finds:* $x_2=\omega^2 a-\omega b$, $x_3=\omega a-\omega^2 b$. *Note that the case of three distinct and real roots occurs only when* $(-a)^3$ *and* b^3 *are complex conjugate. For this "irreducible" case, the trigonometrical solution is adequate, and was first given by* ***Francois Viète*** *in ca* 1579.

Cardano's solution for the general cubic equation

$$a_0x^3+3a_1x^2+3a_2x+a_3=0$$

has the explicit algebraic form

$$x_1=-\frac{a_1}{a_0}-\frac{1}{a_0}\sqrt[3]{\frac{G}{2}+\frac{1}{2}\sqrt{G^2+4H^3}}-\frac{1}{a_0}\sqrt[3]{\frac{G}{2}-\frac{1}{2}\sqrt{G^2+4H^3}},$$

$$x_2=-\frac{a_1}{a_0}-\frac{\omega}{a_0}\sqrt[3]{\frac{G}{2}+\frac{1}{2}\sqrt{G^2+4H^3}}-\frac{\omega^2}{a_0}\sqrt[3]{\frac{G}{2}-\frac{1}{2}\sqrt{G^2+4H^3}},$$

$$x_3=-\frac{a_1}{a_0}-\frac{\omega^2}{a_0}\sqrt[3]{\frac{G}{2}+\frac{1}{2}\sqrt{G^2+4H^3}}-\frac{\omega}{a_0}\sqrt[3]{\frac{G}{2}-\frac{1}{2}\sqrt{G^2+4H^3}},$$

with

$$G=a_0^2a_3-3a_0a_1a_2+2a_1^3; \qquad H=a_0a_2-a_2^2$$

$$\omega = -\frac{1}{2} + \frac{1}{2}i\sqrt{3}$$

For example the equation $x^3 - 7x + 7 = 0$ *is solved by*

$$x_1 = -\sqrt[3]{\frac{7}{2} + \frac{7}{18}\sqrt{-3}} - \sqrt[3]{\frac{7}{2} - \frac{7}{18}\sqrt{-3}},$$

$$x_2 = -\omega\sqrt[3]{\frac{7}{2} + \frac{7}{18}\sqrt{-3}} - \omega^2\sqrt[3]{\frac{7}{2} - \frac{7}{18}\sqrt{-3}},$$

$$x_3 = -\omega^2\sqrt[3]{\frac{7}{2} + \frac{7}{18}\sqrt{-3}} - \omega\sqrt[3]{\frac{7}{2} - \frac{7}{18}\sqrt{-3}}.$$

This is the famous cubic formula which Cardano is reputed to have weaseled out of his fellow mathematician, Tartaglia, under the oath of secrecy.

Consider two examples: the equation $x^3+x = 2$, *has* $x = 1$ *as a solution. The above solution yields* $x = \left[1 + \sqrt{1 + \frac{1}{27}}\right]^{1/3} - \left[-1 + \sqrt{1 + \frac{1}{27}}\right]^{1/3} = 1.263,762,616 - 0.263,762,658$, *which is* $x = 1$ *within* 2×10^{-10}.

We then take the equation $x^3 - 15x = 4$, *which has* $x = 4$ *as a solution. Here, the formula yields:* $x = [2 + \sqrt{-121}]^{1/3} - [-2 + \sqrt{-121}]^{1/3}$, *where* x *is* real *although each of its two members is a complex number. In the year* 1545, *this was a meaningless expression: square roots of negative numbers had no legitimacy and the theory of complex numbers was nonexistent. Only* 255 *years later(!) (when complex numbers were interpreted as points in a coordinate plane) was the mystery lifted.*

Ferro did not publish his solution, but before his death he disclosed it to his pupil ***Antonio Maria Fior****, a mediocre mathematician. Through this intermediary, the solution (or part of it) leaked to Niccolo Fontana, known as* ***Niccolo Tartaglia*** *('the stammerer', 1499–1559) who claimed in* 1535 *to have found the solution of the cubic equation. He divulged his solution to* ***Girolamo (Jerome) Cardano*** *(1501–1576) in return for financial assistance. Although Cardano promised not to publish the solution, he did so in* 1545, *in his book 'Ars magna' which appeared at Nuremberg, Germany. Tartaglia's vehement protests were countered by* ***Lodovico Ferrari****, who argued that Cardano had received his information from* ***del Ferro*** *through a third party and accused Tartaglia of plagiarism from the same source. Since the actors in the above drama seem not always to have had the highest regard for truth, one finds a number of variations in the details of the plot.*

The solution of the cubic and quartic equations was perhaps the greatest contribution to algebra since the Babylonians (almost 4 millennia earlier) had learned how to complete the square for quadratic equations. No other discovery had quite the stimulus to algebraic development as those of Ferrari, Tartaglia and Cardano. It was natural that further study should take aim at the quintic and polynomial equations of higher order. Here mathematicians of the next 200 years would be faced with unsolvable problems, and their negative conclusions would yield much good mathematics.

The explicit solutions of the quadratic, cubic and quartic equations use only the four basic arithmetical operations and the extraction of roots. In the attempts to find general formulae for equations of higher degrees, using only these operations, mathematician after Ferrari have greatly overestimated the 'power of radicals' and were mislead by the fact one can very well find special equations whose solutions can be expressed by radicals (such equations are called 'soluble by radicals', where a radical is a solution of the equation of the n^{th} *degree* $x^n - a = 0$ *and is denoted*[168] *by* $\sqrt[n]{a}$*).*

Indeed, ***Abel*** *(1824) and* ***Galois*** *(1831) put an end to traditional algebra, Italian style, where one provides a neat formula in terms of coefficients, which is applicable to all polynomial equations of a certain degree.*

In the year named, Abel showed for the quintic equation, that even though ***Gauss*** *(1799) guaranteed a solution when coefficients are real or complex, it is impossible to express this solution using only a finite number of rational operations and root extractions on the coefficients. Galois gave a more elegant proof of the same fact, and then established a general theorem indicating the impossibility of finite algebraic formulation of solutions for polynomial equations of all degrees greater than four.*

1507 CE First outbreak of *smallpox* in the New World. By 1520 it spread into Mexico. Several million died.

[168] The n roots of the equation $x^n - 1 = 0$, where n is a positive integer, are given by $x_k = \cos\frac{2\pi k}{n} + i\sin\frac{2\pi k}{n}$, $k = 0, 1, 2, \dots, n-1$. They are known as the *roots of unity*. Clearly, $x_k = \alpha^k$ where $\alpha = \cos\frac{2\pi}{n} + i\sin\frac{2\pi}{n}$ (the n^{th} roots of unity) lie on the circumference of the unit circle and divide it into n equal parts.
The more general equation $x^n - \lambda = 0$, $\lambda > 0$ has the solutions $x_k = \lambda^{1/n}, \alpha\lambda^{1/n}, \alpha^2\lambda^{1/n}, \dots, \alpha^{n-1}\lambda^{1/n}$.
Since $x^n - 1$ contains the factor $x - 1$, it follows that $\alpha, \alpha^2, \dots, \alpha^{n-1}$ are the $n-1$ roots of $x^{n-1} + x^{n-2} + \cdots + x + 1 = 0$.

1510 CE Beginning of systematic importation of African black slaves into the West Indies.

1510–1528 CE **Albrecht Dürer** (1471–1528, Germany). Artist (painter, engraver) and mathematician. Laid the foundations of *descriptive geometry*[169]. It is expounded in Dürer's treatise on human proportion [*De symetria Partium in Rectis Formis Humanorum Corporum Libri*], published in Nuremberg after his death in 1528. His engraving *Melancholic* contains the first *magic square* to be seen in Europe. It contains the date 1514 as two entries in the middle of the bottom row. Dürer's geometry was the first printed work to consider the subject of *higher plane curves*, and the first to discuss scientifically the question of such approximate construction as that of the regular *heptagon*.

Dürer was born in the Imperial Free City of Nüremberg and became an apprentice painter and woodcut designer (1486). He traveled to Colmar (1490) and went to Strasbourg and Basel. He returned to Nüremberg (1494) and married Agnes Frey. Dürer visited Venice in 1494–1495 and again between 1505 and 1507. These visits strongly influenced his art. He was appointed court painter to Maximilian I, the Holy Roman emperor (1512) and again under Charles V (1520).

Dürer (and Rembrandt) are credited with the invention of the technique of *dry-point engraving*[170].

1513–1519 CE **Juan Ponce de Léon** (1474–1521, Spain). Explorer. First to describe the *Gulf Stream* (specifically, the Florida Current) in 1513. Sailing from Puerto Rico, he crossed the stream north of Cape Canaveral and then sailed south to Tortugas. The current was so swift that his three ships were frequently unable to stem it. (The island of Cuba was first circumnavigated in 1508, but the current was not reported until 1513.)

In 1515, **Peter Martyr of Anghiera** reported various conjectures about the Gulf Stream. He believed, however, that the North Equatorial Current is deflected by the mainland so as to flow back into the ocean. The westward flow of the Equatorial Current itself was attributed to the general westward motion of the celestial bodies across the sky that allegedly drew the water and air of the equatorial regions along with it (!)

---

[169] Later given a sound mathematical basis by **Monge** (1768).

[170] Made by cutting a design into a flat metal plate. The engraved plate is then used to print the design or picture. The artists uses a needle with a diamond or hard steel point. As the needle cuts into the plate (copper or zinc), it throws up a soft ridge of metal called a *burr*. This burr holds the ink and thus forms the lines that appear on the picture.

By 1519 the Gulf Stream was so well known that Spanish ships bound for America by way of the Equatorial Current, passed on their return through the Florida Straits, and followed the Gulf Stream to about the latitude of Cape Hatteras, and then sailed eastward to Spain. In this way they secured favorable winds and avoided contrary currents over the entire voyage.

Ponce de Léon went to America with **Columbus** on the second voyage (1493). He led the settlement of Spaniards in Puerto Rico (1508), and encountered the Gulf Stream while searching for *Bimini*, a fabled island on which was said to be located the Fountain of Youth. This search brought him to a new land at Easter time of 1513. Ponce de Léon claimed the region for Spain and named it *Florida* because of the many flowers he saw there. He returned to Florida in 1521 to start a colony, but was wounded and died on his return to Cuba. Ponce, Puerto Rico, is named in his honor.

1513–1525 CE **Niccolo Machiavelli** (1469–1527, Italy). Political philosopher and historian. A leading literary figure of the Renaissance.

Best known for his book *The Prince* (*Il Principe*, 1513, published 1532), which established Machiavelli as the father of modern political science. He also wrote *History of Florence* (1525), *The Art of War* (1520) and *Discourses upon the First Ten Books of Livy* (1517).

Machiavelli was born in Florence, the son of a jurist, and a member of an old Tuscan family. He became a leading figure in the Republic of Florence after the Medici family was driven out (1498). For 14 years, he served as first secretary of the council of the republic. His duties brought him in contact with the notorious Cesare Borgia. When the Medici regained power (1512), Machiavelli was dismissed from office, tortured and imprisoned, but finally released on order of Pope Leo X. He spent the next 14 years (1512–1526) in retirement near Florence. There he wrote his books on history and politics.

As an historian, he raised the study of history from mere chronicle to an evaluation of motives and causes. He was the first to come along and attack the Church and preach rebellion against the dictatorship of the clergy. Machiavelli's reputation as a diabolical apostle of intrigue, duplicity and power politics is a travesty of his actual work:

The Prince, apparently cynical exposition of a creed of treachery and tyranny, must be read in the context of his other political works, and of the circumstances of the time. The *Discourses* give his long-term views, and in this unconstrained context of security founded on law, he proclaims the superiority of government by people over government by princes. Thus, the precepts of *The Prince* must be taken to be applicable in times of crisis or in desperate circumstances that are comparatively rare.

Much of what he says in *The Prince* is a sardonic description of the political practices of his own day and not a recommendation of such practices. Machiavelli, in his own practice as a diplomat and minister, was hardly '*Machiavellian*': emphasizing power and how it is held, not what should be done to fulfill a providential scheme.

Machiavelli had serious doubts about the chances of long-term success. He maintained that humans tire even of stability and success, and crave novelty. They have a weakness, almost a flair, for corruption; and by the time it becomes visible, it has already taken hold in defiance of the old laws and measures. To restore the healthy political structure then requires extraordinary measures which very few are equal to carrying out.

The collapse of the Soviet Union (1989), the discrediting of Marxism and the defeat of reformist parliamentary socialism are striking examples of the political theory of Machiavelli.[171]

1516 CE **Franz von Taxis** (**Francesco Tassi**, 1460–1517, Italy and Germany). Established the first successful *regular public postal system* in the Habsburg Empire, which soon spread all over Europe. This organization of the Taxis family was in operation for 350 years. In 1867 it was incorporated into the Prussian postal system.

---

171 According to the political philosopher **Leo Strauss** (1899–1973), in his book *Thoughts on Machiavelli* (1958), Machiavelli is the key turning point that leads to modern political philosophy, and Machiavelli's sin was to speak esoteric truths openly. He told all within hearing that there is no certain God who punishes wrongdoing; the essence of Machiavellianism is that one can get away with things. Because of this, he turned his back on the Christian virtue that the belief in a retributive God had upheld. Pre-Machiavellian philosophy, be it Greco-Roman of Christian, had taught that the good political order must be based upon human virtues. Machiavelli believed that sufficient virtue was not attainable and therefore taught that the good political order must be based on men as they are, i.e. upon their mediocrity and vices. This is not just realism, or mere cynicism. It amounts to a deliberate choice as to how society should be organized and a decided de-emphasis on personal virtue. It leads to the new discipline of political science, which is concerned with coldly describing men as they actually are. It leads ultimately to Immanuel Kant's statement that, "We could devise a constitution for a race of devils, if only they were intelligent." The ancient view is that this will get you nowhere, because only men with civic virtue will obey a constitution. The modern view leads naturally to value-free social science and social policies that seek to solve social problems through technocratic manipulation that refrains from "imposing value judgements" on the objects of its concern.

1516 CE The first official *ghetto*[172], the street or quarter of a city in which Jews were compelled to live, established in *Venice*, Italy. Ghettos were enclosed by walls and gates which were locked each night. Haphazardly, without a master plan, the isolation of the Jews in the ghettos was achieved within a century of their expulsion from Spain. Out of sight, out of mind, out of influence, they would be expelled from the mainstream of Christianity (and later from Islam too), so as not to contaminate with heresy the minds of Jesus-loving Christians. Placing the Jews into *cordons sanitaires* (antiseptic enclaves) seemed an excellent solution.

The Jew, who for a millennium had been an integral part of the economic, social and intellectual history of Europe, was now relieved of all his rights and privileges. He was now neither essential for Christian salvation nor necessary for national economic survival – he has become the superfluous man in Europe.

During the Middle Ages the Jews were forbidden to leave the ghetto after sunset when the gates were locked, and they were also imprisoned on Sundays and all Christian holy days. By the middle of the 19^{th} century the ghetto system was moribund. It was reinstituted by the Germans during 1939–1945 as a transitory stage to the Jews on their trek to the gas-chambers.

1517–1546 CE **Elia Levita; Eliyahu ben Asher ha'levi Ashkenazi**[173] (1468–1549, Italy). Hebrew grammarian, philologist and lexicographer. Laid the foundation of the lexicography and etymology of the Yiddish language. Published many books on Hebrew Masorah and grammar, and composed the first comprehensive biblical concordance. Claimed that punctuation was established by the Masoretes in the 4^{th} century CE. Composed the first Hebrew–Yiddish dictionary.

Levita was born in the village of Ipsheim, near Nüremberg in Germany and moved to Italy at about 1490, settling in Padua. He lost all his property during the French conquest of Padua (1509) and eventually moved to Rome (1514), where he befriended Cardinal Edidio de Viterbo who later became his patron (1517–1527). In return, Levita taught the Cardinal (and other noted Christian, among them Martin Luther) the Hebrew language and its grammar[174].

172 Abbreviation of Italian *borghetto*, diminutive of borgo = a borough. According to another view it came from *gietto nuovo* = the new foundry, a location near an iron-foundry in the city of Venice. Temporary ghettos existed previously in London (1276), Capua (1375) and Bolonia (1417). The earliest regular ghettos were established in Italy in the 11^{th} century, though Prague is said to have had one already in the 10^{th} century.

173 Known also as the 'Bachur'.

174 The *Renaissance* made the study of Hebrew more popular, and this resulted in

In this sense Levita fulfilled the historic mission of endearing the Hebrew language to enlightened Christians and humanists.

When the Spanish and German mercenaries sacked Rome on May 06, 1527, Rome pre-eminence in the Renaissance ended. All of Levita's property (including some of his finished manuscripts) was lost and he removed to Venice, where he continued to publish his works, and spent the last years of his life.

1517–1546 CE **Girolamo Fracastoro** (**Hieronymus Fracastorius**) (1478–1553, Italy). Physician, astronomer and poet. Universal man of the Renaissance. Explained *fossils* as the remains of actual organisms (1517); Gave name and described symptoms and treatment of *Syphilis*[175] (1530); Prefigured a Copernican model of the solar system[176] in *Homocentrica sive de stellis liber* (1538); made first scientific statement on the nature of *contagion and transmission of diseases by germs* (1546).

Born at Verona and studied at Padua. Became (1502) professor of philosophy and colleague of Copernicus at the University of Padua. He was skilled not only in medicine and literature, but in most arts and sciences. Maintained private medical practice in Verona; studied epidemic diseases; medical consultant of Pope Paul III at the Council of Trent (1545 ff). Intimately acquainted with Julius Scaliger and most of the great man of his time.

1518–1536 CE **Hernando Cortés** (1485–1547, Spain). Spanish conqueror of Mexico. Discovered the peninsula of Lower California.

Cortés was born at Medellin, a small town of Estermadura. He belonged to a noble family of decayed fortune. Being destined for the law, he was sent (1499) to the University of Salamanca, but returned home (1501) resolved to enter upon a life of adventure. He set out (1504) as a soldier for San Domingo and remained there until 1511, when he accompanied **Diego Velasquez** in his expedition to the island of Cuba. Soon after the discovery of Mexico by **Juan Grijalva**, Velasquez entrusted the conquest of the newly discovered

---

an increasingly sympathetic attitude on the part of the cultured Europeans toward the literary treasures of the Jews. Italy became the Jewish printing center and Christian printers employed learned Jews to find the best manuscripts and to arrange them in the best manner. This 'honeymoon', however, did not last for long. With the rise of Pope Paulus IV, during the *Counter-Reformation*, the Inquisition in Italy burned Jews and their books (1553–1572) in great bonfires and locked the Jews up in ghettos all over Italy for the next two centuries. Interestingly enough, Levita's sons converted to Christianity and his renegade grandson Vitorio Aliano, urged the Inquisition to burn the Talmud.

[175] The name of a mythical young shepherd who developed the disease.

[176] His planetary system is close to Eudoxos' model; it contains 79 spheres.

country to Cortés. He landed there on the *4th* of March 1519. Coasting along Yucatan and Mexico to San Juan de Uhia (1519), he founded Veracruz and afterwards destroyed his fleet, showing his soldiers that they must either conquer or perish[177]. On march inland, he drew to his side some 6000 natives, hostile to Montezuma, the Aztec monarch.

Believing Cortés to be the god Quetzalcoatl, Montezuma sent him conciliatory gifts. Cortés entered the Aztec capital Tenochtitlan (Nov 8, 1519) as Montezuma's guest, but surrounded and outnumbered by hostile Aztecs he executed a most daring project of taking the monarch hostage in his own capital. The Aztec revolted but, after heavy losses and a long siege, Cortés took the capital and ended Aztec power (13^{th} Aug 1521). These successes were entirely owing to the military genius, valor and profound but unscrupulous policy of Cortés; and the account of them which he transmitted to Spain excited the admiration of his countrymen.

This, however, created for him powerful enemies in Spain and Mexico. Eventually, the King of Spain[178] alarmed by Cortés ambition, ousted him[179].

---

177 This moment was immortalized in John Keat's poem "On First Looking into Chapman's Homer" (Oct 1816)

"... Then felt I like some watcher of the skies
When a new planet swims into his ken;
Or like stout Cortez when with eagle eyes
He stared at the Pacific – and all his men
Looked at each other with a wild surmise –
Silent, upon a peak in Darien."

178 Emperor **Charles V** (1500–1558) was the King of Spain as **Charles I** (1516–1556) and also Holy Roman emperor (1519–1556). He was son of **Philip I** ("The Handsome") and the insane Joan who was the daughter of Ferdinand and Isabela. Charles ruled over the Netherlands, Austria, Milan, Naples, Sardinia, Sicily and all the Spanish possessions in America. He fought **Francis I** of France over their rival claims in Italy. He also fought the Turks who threatened central Europe and tried unsuccessfully to put down the Protestants. His troops sacked Rome (1527) and captured **Pope Clement VII**. The acquisition of Mexico and Peru by his intrepid conquistadors, afforded him the means of prosecuting his ambitious and most expensive enterprises; the stream of gold and silver from the New World surpassed all European dreams of wealth. As a result, Spain was to become the leading power in Europe in the 16^{th} century.

179 After the disastrous expedition to Algiers (1541), Cortés fell into neglect, and could scarcely obtain an audience. The story goes that, having forced his way through the crowd which surrounded the emperor's carriage, and mounted on the door-step. Charles, astonished at an act of such audacity, demanded to know who he was. "I am a man" replied the conqueror of Mexico proudly, "Who has

Nevertheless, in 1536, Cortés discovered the peninsula of Lower California, and surveyed part of the gulf which separated it from Mexico.

In 1541, Cortés withdrew from King's court and passed the remainder of his days in solitude on his estate near Seville.

1522–1555 CE **Joseph Caro** (1488–1575, Spain and Turkey). Codifier of Jewish law and Kabbalist. He began writing *Beit Yosef* (*House of Joseph*) in 1522 in Adrianpole and completed it in Safed, Israel (1542). Caro investigated the source of every practical law from its Talmudic origins, traced its development, mentioned divergent views, and recommended the appropriate practice. His *Shulhan Arukh* (*The Set Table*), a digest of *Beit Yosef*, was completed in 1555. It became the pillar of Orthodox Jewish observance.

Caro was born in Toledo, Spain. He was expelled with his family to Portugal (1492) and settled in Lisbon. Expelled again (1496) and reached Constantinople. He finally settled in Safed, Israel (1536) and died there.

Science Progress Report No. 3

The Conquistadors (1521–1548)

As the Spaniards on the Caribbeans began to hear exciting tales of wealthy, half-civilized empires they turned from exploration to conquest. From 1520 *to* 1550*, the Conquistadors of Spain carved out an empire in the West.*

The ***Aztecs of Mexico*** *began their history in* 1168*, when migratory tribes entered the valley of Anahuac. Later in* 1325 *they founded their capital Tenochtitlan (now Mexico City). They were fine architects, evolved a system of picture-writing, but the major thrust of their bizarre culture went into an extraordinary preoccupation with time and the calendar [it was similar in many ways to the Maya Calendar, and thus much more advanced than in either Egypt or Greece].*

---

given you more provinces than your ancestors left you cities."

For further reading, see:

- Von Hagen, V.W., *The Aztec*: *Man and Tribe*, Mentor Books: New York, 1962, 224 pp.

Their priest-astronomers had put great efforts into the elaboration of the calendar, which had a 52 *year cycle and "5 empty days" at the end of each year. They believed that during these critical periods, the very future of the world was at balance and might be destroyed. They responded to this issue with mass human sacrifice rituals, where the sacrifices had to be precisely timed so that it would benefit the particular god to whom they were appealing and thus propitiate the right god at the right time. So sacrifice was not mere butchery but rather a parade of elaborately conceived ritual with only one object in view: to preserve human existence.*

During the 'five empty days', fires were extinguished, fasting was general, sexual intercourse ceased, artists left their work, business lay idle. On the dawn of the fifth day, when the priest-astronomers observed the Pleiades rising in the heavens and knew that the world would not end, they slashed open the chest of the sacrificial victim, pulled out his heart, and in the freshly weeping wound kindled a new fire. From it the fires in the temples were rekindled, and people all over the kingdom gathered the new fire for the coming year[180].

Into this formidable empire, entered one ***Hernando Cortés*** *(1485–1547) in* 1519 *with* 600 *men,* 16 *horses, a few cannons and a secret weapon of which he was not aware – the smallpox virus.*[181]

"Thus[182]*, on Saint Hippolytus' Day, Aug.* 31, 1521, *amidst the acrid smoke of a thousand fires, the Spanish conquest was complete and Aztec civilization passed into cultural limbo."*

The Inca culture in and about the Peruvian Cuzco Valley started at about 1250. *By* 1500, *the Inca ruled an empire in the Andes of perhaps as many as* 7 *million people. They were fine architects, potters and metal workers with a well-organized government and superb roads.*

Nevertheless, ***Francisco Pizarro*** *(1471–1541), with* 180 *men and* 27 *horses subjugated the entire empire within three years (1532–1535)*[183]*. So passed the glory of the Incas, whose kingdom extended from Ecuador to as*

---

[180] In this connection, read the beautiful story of **D.H. Lawrence**: "The Woman who Rode Away".

[181] It was recently discovered that the epidemics of 1545 and 1576, which exterminated about 8 million Aztecs, were caused by the *Ebola* virus.

[182] Victor W. Von Hagen: "The Aztec: Man and Tribe" Mentor Books New York 1958

[183] At first, the Inca's King, Atahualpa, thought that the Spaniards were the gods themselves, coming to conduct him to Cuzco to his rightful heritage as Inca. But after he had reports that they raped his Virgins of the Sun at the village of Caxas, he knew by then that he dealt with no gods.

far as latitude 35°S in present day Chile, a distance of 3200 *km on a north-south line. With them vanished their great skill in engineering and architectural works, which they accomplished without the use of iron tools, mortar, the wheel, the keystone arch or the written word to help them in their plans and calculations [instead they used the 'quipo', a cord made up of different colored threads, which acted as a superior abacus].*

So vanished too their skill in working precious metals, and their system of education which was based on their credo that "science was not intended for the people, but for those of generous blood. Persons of low degree are only puffed up by it, and rendered vain and arrogant".

The discovery of the New World had disastrous consequences for the natives of South and Central America; during the century that followed the voyages of Columbus, about 40 *million* Indians *were methodically exterminated.*

Amerindians had spent millennia adapting to their microbial environment. The Americas were as untouched by Old World crowd diseases as any remote Pacific island. Therefore one person with even a mild case of smallpox, measles, or mumps could set of an epidemic that could destroy entire cities and that is what indeed happened.

Smallpox was probably introduced to Europe in Roman times, and perhaps reintroduced by returning Crusaders. By 1500, it had become endemic, chiefly a children's disease to which most adults were immune. When, however, the virus reached the New World with the Spaniards, it acted as epidemics had when they killed Romans by the hundred of thousands and drove Huns from the walls of Rome.

In 1520, reinforcement arrived to Cortés from smallpox – stricken Cuba. Among them was an African slave with a mild case of the disease. While the Spanish approached Tenochtitlan, smallpox spread among the natives, first outside the city and then within. In 1521, Cortés attacked with 300 Spaniards and some native allies. Three months later, when Tenochtitlan fell, Cortés learned that half of its people had died, including Montezuma and his successor. The canals were choked with corpses.

The surviving Aztecs were stunned and apathetic, and awed by the white men who went untouched among the dead and dying. Native social and political structures shattered. The terror of smallpox sent people fleeing. Because smallpox incubates for 10–14 days, an apparently healthy refugee could carry it hundreds of kilometers before showing symptoms. By 1530, smallpox had rushed ahead of the conquistadors, covering the Americas from the pampas to the Great Lakes.

South of the Aztec empire, lay the realm of the Mayas. Smallpox reached them before the Spaniards did, and it run through them with searing devas-

tation. It continued south toward the Inca empire. It outran Pizarro, killing hundreds of thousands, among them the chief Inca, his son and heir, and many nobles and generals. In 1533, when Pizarro finally entered Cuzco, the Incas were incapable of serious resistance.

The disease preceded the Spaniards as they ventured northward to the Mississippi valley. In 1539–1542, when ***Hernardo de Soto*** *made his way through the land of the Mound Builders, he found uninhabited towns where corpses were stacked in large houses – the pestilence had done the fighting for him.*

Measles followed smallpox, spread by troops, sailors, missionaries, colonists, messengers and fleeing natives. In 1529, a measles epidemic in Cuba killed two-thirds of the natives who survived smallpox. Two years later it had killed half of the people of Honduras, ravaged Mexico, spread through the Central Americas and attacked the Incas; whipping out whole cities and tribes, cultures and languages lost.

Throughout the 16^{th} *century and beyond, the "great fire" kept raking native peoples from Canada to Chile. Other Old World diseases followed – mumps, typhoid, typhus, influenza, diphtheria, and scarlet fever.*

However daring and resourceful Cortés and Pizarro were, it beggars imagination that each defeated an empire of millions with mere hundreds of soldiers. Their strongest ally was the Fourth Horseman – the Old World virus; It is estimated that the New World population of perhaps 100 million was reduced by about 90 percent. It was a bigger disaster than the Black Death, but spread over 300 years.

History of Geographical Theory (585 BCE–1524 CE)

Geography is the exact and organized knowledge of the distribution of phenomena on the surface of the earth. The fundamental conception of geography is form, including the figure of the earth and the varieties of crustal *relief. Hence* mathematical geography *comes first. It merges into* physical geography, *which takes account of the outer forms of the lithosphere (*geomorphology*), and also of the distribution of the hydrosphere and the rearrangements resulting from the working of solar energy throughout the hydrosphere and atmosphere (*oceanography *and* climatology*). Next follows the distribution of plants and animals (*biogeography*), and finally the distribution of mankind and the various artificial boundaries and redistributions (*anthropogeography*).*

The applications of this latter discipline to human uses, give rise to political *and* commercial geography*, in the elucidation of which all the earlier stages have to be considered, together with* historical *and other purely human conditions.*

The concepts of Darwinian evolution and the more recent Wegenerian plate-motions has revolutionized and unified geography as it did biology, breaking down the old partitions between the various departments and integrating it into one holistic science. The earliest conceptions of the earth were usually expressed in symbolic language, manifested in the old mythological cosmogonies.

The first definite geographical theories to affect the Western world were those first expressed by the Greeks*. The earliest theoretical problem of geography was the* form of the earth: *the natural supposition that the earth is a flat disk, circular or elliptical in outline, had in the time of Homer (ca 800 BCE) acquired a special definiteness by the introduction of the idea of the* ocean river *bounding the whole, an application of imperfectly understood observations.*

Thales of Miletos *(fl. 575 BCE) is claimed as the first exponent of the idea of a* spherical earth. *Although this idea was carried on by* ***Anaximander*** *(fl. 560 BCE), the Pythagorean school (535 BCE)* and ***Parmenides*** *(fl. 470 BCE), the Ionian philosophers (who preferred to deal with facts demonstrable by travel rather than with speculations) did not advance beyond the primitive conception of a circular disk.*

Thus ***Hecataeos of Miletos*** *[fl. 500 BCE, Greek traveler and historian] in his book* Periodos*, modeled the habitable world in the form of a land disk within the ring of ocean. His land mass consisted of* Europe *to the north, and* Asia *to the south, divided by a midland sea.*

Herodotos *(fl. 450 BCE), equally oblivious of the sphere, criticized and ridiculed the* circular *outline of the oceanic ring (which he knew to be longer in the east-west direction than in the north-south direction). He accepted a division of land into* three *continents Europe, Asia and Africa. Beyond the limits of his personal travels, Herodotos applied the Greek theory of* symmetry *to complete in the unknown, outlines of lands and rivers analogous to those* *which had been explored*[184].

Scientific geography was founded by **Aristotle** *(fl. 350 BCE). He demonstrated the sphericity of the earth by three arguments, two of which could be tested by observation:*

- *The tendency of matter to fall together towards a common center.*
- *Only a sphere could always throw a circular shadow on the moon during eclipse.*
- *The shifting of the horizon and the appearance of new constellations or the disappearance of familiar stars, as one traveled from north to south, could only be explained on the hypotheses that the earth was a sphere.*

The first approximately accurate measurement of the globe was made by **Eratosthenes** *(ca 235 BCE) who also was the first to introduce the word geography.*

Aristotle was certainly conversant with many facts, such as the formation of deltas, coast-erosion, and to a certain extent the dependence of plants and animals on their physical environment. He formed a comprehensive theory of the variations of climate with latitude and season, and was convinced of the necessity of a circulation of water between the sea and the rivers[185]*, though, like Plato, he held that this took place by water rising from the sea through crevices in the rocks, losing its dissolved salts in the process.*

Ptolemy *(fl. 110 CE) summarized in his writings all Greek geographical learning and passed it across the gulf of the Middle Ages by the hands of the Arabs, to form the starting-point of the science in modern times. His main sources were* **Marinos of Tyre** *(fl. 150 BCE), and his work was mainly cartographical in its aim, and theory was, as far as possible, excluded. It was the ambition of Ptolemy to describe and represent accurately the surface of the world ocean ("oekumene"), for which purpose he took immense trouble to collect all existing determinations of the latitude of places, all estimates of*

[184] *Symmetry* was in fact the first geographical theory, and the effect of Herodotos' hypothesis that the *Nile* must flow from west to east before turning north in order to balance the *Danube* running from west to east before turning south, lingered in maps of Africa down to the time of **Mungo Park** (1805)!

[185] If we believe that he discovered it himself, then this may put a bound (ca 350 BCE) on the date of composition of the book of *Ecclesiastes* ["*All the rivers run into the sea; yet the sea is not full; unto the place from whence the rivers come, thither they return again*", **1**, 7]. This however, will not be true if both Aristotle and the biblical author had an unknown common source.

longitude, and to make every possible rectification in the estimates of distances by land or sea.

The symmetrically placed hypothetical islands in the great continuous ocean disappeared and the oekumene *acquired a new form of the representation of the* Indian Ocean *as a larger Mediterranean completely cut off by land from the Atlantic. The* terra incognita *uniting* Africa *and* Farther Asia *was an unfortunate hypothesis which helped to retard exploration. In contradistinction to geography, Ptolemy introduced the word* topography *to signify the very detailed description of a small locality.*

The Arab astronomers, studying the Arab translation of Ptolemy's astronomical work (the Almagest*) measured a degree on the plains of Mesopotamia, thereby deducing a fair approximation to the size of the earth (ca 815 CE; in the time of the Caliph* ***al-Mamun****).*

The Middle Ages saw geographical knowledge die out in Christendom, although it retained, through the Arabic translations of Ptolemy, a certain vitality in Islam. The verbal interpretation of Scriptures led ***Lactantius*** *(ca 320 CE) and other ecclesiastics to denounce the spherical theory of the earth as heretical. The wretched subterfuge of* ***Cosmas*** *(ca 550 CE) to explain the phenomena of the apparent movements of the sun by means of a planar rectangular earth reverted geography to the primitive ignorance of the times of Homer.*

The journey of ***Marco Polo*** *(1274 CE), the increasing trade to the East and the voyages of the Arabs in the Indian Ocean prepared the way for the reacceptance of Ptolemy's ideas when the sealed books of the Greek original were translated into Latin by* ***Angelus*** *(1410 CE). The old arguments of Aristotle and the old measurements of Ptolemy were used by* ***Toscanelli*** *and* ***Columbus*** *in urging a westward voyage to India (1492 CE). But not until the voyage of* ***Magellan*** *shook the scales from the eyes of Europe (1522 CE) did modern geography begin to advance. Discovery had outrun theory; the rush of new facts made Ptolemy practically obsolete in a generation, after having been the fount and origin of all geography for a millennium.*

The earliest evidence of the reincarnation of a sound theoretical geography is to be found in a text-book by ***Peter Apian*** *(1524 CE). He based the whole science on mathematics and measurement, following Ptolemy closely.*

1524–1540 CE **Peter Apian** (**Peter Bennewitz**, **Peter Bienewitz**, **Peterus Apianus**) (1495–1552, Germany). Astronomer, mathematician and geographer. First to base the science of geography on mathematics and measurement. Born at Leising, Germany. Professor at Ingolstadt (1527–1552), where he died. *Pascal's triangle* appeared for the first time in one of his books (1527). In his *Cosmographicus liber* (1524) [subsequently edited and added to by **Gemma Frisius** under the title of *Cosmographia*] he created a map projection appropriate for large areas, with latitude circles appearing as parallel straight lines, a prime meridian as a straight line, and the other meridians of longitude as circles with curvature increasing away from the prime meridian. This book includes some of the earliest maps of America and is considered the first text-book on theoretical geography. In his *Instrumentum sinuum sive primi mobilis* (1534) he published a table of sines for every minute of arc. In *Astronomicon Caesareum* (1540), he included description of five comets [including the comet later known as *Comet Halley*], and stated that the tails of comets are pointed away from the sun[186].

1525 CE **Christoff Rudolff** (1500–1545, Germany). Mathematician. Introduced the radical sign $\sqrt{}$, because it resembles a small r, for radix. His book on algebra entitled *Die Coss* was very influential in Germany, and an improved edition was brought out by Michael Stifel (1553).

1528–1530 CE Typhus epidemic in Italy. Hundreds of thousands of lives were lost.

1528–1550 CE **Georg Bauer** (**Georgius Agricola**, 1490–1555, Germany). Mineralogist, Physician and scholar. The father of mineralogy and physical geology , and one of the first to base writings on observation and inquiry rather than received opinion.

He was born at Glauchau in Saxony. Studied philology, philosophy, physics, chemistry and medicine at Leipzig and Italy, and settled at Joachimstal (a center of mining and smelting works) as practicing physician (1527–1533), his object being to test what had been written about mineralogy by careful observation of ores and the method of their treatment. His thorough grounding in philology and philosophy accustomed him to systematic thinking, and this enabled him to construct out of his studies and observations of minerals a logical system which he began to publish in 1528. His *Bermannus, sive de re metallica dialogus*, was the first attempt to reduce to scientific order the knowledge won by practical work. In 1530 Prince Maurice of Saxony appointed him historiographer with an annual allowance, and he moved to Chemnitz (1530 to 1555), a center of mining industry, in order to widen the range of his observations.

---

[186] A fact known to the Chinese as early as 635 CE and perhaps earlier, but not known in Europe.

The citizens showed their appreciation of his learning by appointing him town physician and electing him mayor (bürgermeister) in 1546. His popularity was, however, short-lived. Chemnitz was a violent center of the Protestant movement, while Agricola never wavered in his allegiance to the old religion; he was forced to resign his office.

In 1544 he published the *De ortu et causis subterraneorum*, in which he laid the first foundations to a physical geology[187], and criticized the theories of the ancients. His most famous work, *De re metallica*, was published in 1556, though apparently completed several years before. It is a complete and systematic treatise on mining and metallurgy[188].

While all of Chemnitz had gone over to the Lutheran creed, Agricola remained to the end a staunch Catholic. His life ended by a fit of apoplexy brought on by a heated discussion with a Protestant priest. So violent was the theological feeling against him that his body was carried, amidst violent demonstrations, to Zeitz, 10 km from Chemnitz, and buried there.

1528–1554 CE **Jean Francois Fernel** (1497–1558, France). Astronomer and physician. The first man to improve on Eratosthenes' determination of the earth's circumference.

He measured a distance in the direction of the meridian near Paris, by counting the revolutions of his carriage wheels on a journey between Paris and Amiens. His astronomical observations were made with a triangle used as a quadrant. The resulting length of a degree were very near the true value.

Fernel was born at Clermont, and educated at Paris. At first he devoted himself to mathematical and astronomical studies. But from 1534 on he

---

[187] In his books, Agricola describes and classifies minerals according to the physical properties of color, luster, odor, shape, state, texture, transparency and weight. He also defines and explains mineral form, hardness, friability, smoothness, solubility, fusibility, brittleness, cleavage and combustibility.
He considered the origin of mountains, hypothesizing that mountains are produced by water erosion, atmospheric winds, earthquakes, and fire from the earth's interiors. He suggested that the subterranean heat apparent in volcanic eruptions is localized under the volcanic centers, and derives from combustion of beds of coal, bitumen, or sulfur, ignited by intensely heated vapors.

[188] This treatise was preceded by *Pirotechnia* (1540) by **Vannoccio Biringuccio of Siena** (1480–1539, Italy). The latter book describes a brass-foundry in Milan where 1200 small objects could be made in one mould – an interesting early example of *mass production*. It also informs us that 5 percent of brass and 8 percent of tin were added to copper to make bronze. Bronze has long been used for casting statues, bells and later also cannons.

gave himself up entirely to medicine, in which he graduated in 1530. His extraordinary general erudition, and the skill and success with which he sought to revive the study of the old Greek physicians, gained him great reputation, and ultimately the office of physician to the court.

In his book *Medicina* (1554) he included descriptions of appendicitis, endocarditis, peristalsis, the systole and diastole of the heart, and anatomical details such as the spinal canal. Fernel introduced the terms '*physiology*' and '*pathology*' into medicine. First to describe '*appendicitis*' and '*peristalsis*' (the waves of contraction in the digestive system that moves food through the alimentary canal).

Fernel was born in Montdidier, Somme, France.

1530 CE, Nov. 01 Dikes burst in Holland and flood the country; 400,000 people perish. Similar catastrophes occurred on: Dec. 4, 1287; Apr. 17, 1421; Nov. 1, 1570; Oct. 1–2, 1574; 1646; 1916; 1953.

1530 CE **Philippus Aureolus Paracelsus** (1493–1541, Switzerland). Alchemist, pioneering chemist and physician. One of the first to apply chemistry to medicine and introduce the use of prescription drugs. Described the properties of many substances. He was the first man who arrived at the conclusion that the processes in the body were of a chemical character, and that when disordered, they were to be put right by counter operations of like kind.

His real name was Theophrastus Bombast von Hohenheim. At the age of 16 he entered the University of Basel, but soon abandoned his chemistry studies in favor of practical medicine and the cure of diseases by means of natural substances made of minerals, ores and metals. He went to Tirol to study the mines and the health problems of the miners, believing that the positive knowledge of nature was not to be got in schools and universities, but only by going to nature herself, and to those who are constantly engaged with her. For ten years (1516–1526) he wandered over a part of Europe and acquired stores of facts, which it was impossible for him to have reduced to order, but which gave him an unquestionable superiority over his contemporaries.

In 1526 he returned to Basel and was appointed town physician and university lecturer. Thus, without a medical degree and against the accepted doctrines of Galen and Avicenna, he had great success in curing or mitigating diseases with his drugs (including the use of opium to deaden pain), for which the regular physicians could do nothing. However, using and advocating a pharmaceutical system of his own aroused the enmity and jealousy of his competitors, causing him to leave Basel in 1529 and wander around in destitution.

He finally settled in Salzburg (1541). Although he proclaimed that he had found the *philosopher's stone*[189] and would live forever, he died before he was 50 – in a fall which some attribute to drunkenness.

Paracelsus was a successful physician and scientist despite his belief in alchemy. His personality is typical of the transition period from the Middle Ages to modern times.

1530–1546 CE **Pedro Nuñes** (**Petrus Nonius**, 1492–1577, Portugal). Jewish mathematician, geographer and cartographer[190]. The father of modern cartography and a peak figure in Portuguese nautical science. He invented the '*nonius*' [an auxiliary movable ruler device for reading fine subdivisions on the scale of astronomical and other instruments which permits greater accuracy in length or arc measurements. The instrument is also called '*vernier*', after the Frenchman **Pierre Vernier** (1580–1637), who reinvented it in 1631]. It is described in his *De crepusculis* (1542). He discovered the *loxodromic curve* in his treatise *De arte atque ratione navigandi* (1546).

Nuñes (pronounced nü-nesh) was born in Portugal at Alcacer do Sal (southeast of Lisbon). He was professor of mathematics at Coimbra University, and in 1529 was appointed cosmographer to the crown, when Spain was disputing the position of the Spice Islands and maps did not agree in their longitude. He then devoted himself to such problems as well as to maps and map projections. This led him to discover (1533) the so-called Mercator-projection and the loxodorme course ahead of Mercator (1568). He published studies of the sphere and of the oceans and a copiously annotated translation of portions of Ptolemy. His clear statements on the scientific equipment of the early Portuguese explorers has become famous.

As the position of the Jews in Portugal became untenable[191] he left the country for Spain (1538). He returned in 1544 to become a leading authority

[189] He also claimed that he was successful in creating a *homunculus*, a living diminutive man *devoid of a soul*. He thus became a model for the *Faust* legend.

[190] For further reading, see:
- Bagrow, Leo, *History of Cartography*, Harvard University Press: Cambridge MA, 1966, 312 pp.

[191] **Nuñes** (also Nuñez) is the family name of Portuguese *Marranos*, which lost many members as martyrs to the Inquisition. Those who were fortunate enough to escape, became prominent physicians, scholars, poets, scientists and financiers during the past 400 years in England, Italy, Holland, South and Central America, and the United States. In fact, the fate of this family reflects, in a microcosmos, the history of the Jews in the Diaspora since the end of the Middle Ages.

The bonfires of the autos-da-fe were operating in Portugal from 1540 to 1791 on the new discoveries of Spain and Portugal. He died at Coimbra in 1577. A complete edition of all his writings appeared at Basel in 1592.

After Nuñes, little of importance for either fundamental or applied science appeared from the Iberian Peninsula.

1530–1576 CE *Botany breaks away from medicine*; plants which adorn the globe in most countries must necessarily have attracted the attention of mankind from the earliest times. The science that treats them dates back to the days of King Solomon (d. 927 BCE), who according to *I Kings* **5**, 13 "*spake of trees, from the cedar of Lebanon to the hyssop on the wall*". The Babylonians, Egyptians and Greeks were the early cultivators of science, and botany was not neglected, although its study was mixed up with crude speculations as to vegetable life, and as to the change of plants into animals.

Aristotle's student **Theophrastos of Eresos** (372–290 BCE, Athens) described over 500 plants in his *Natural history of plants* (ca 300 BCE), including cane sugar and the coconut palm, used for treatment of diseases. **Pliny the Elder** (23–79 CE, Rome) described about a 1000 plants, many of them famous for their medical virtues. Asiatic and Arabic writers also took up this subject.

Little, however, was done in the science of botany[192] until the 16^{th} century. Botany was then an essential part of medical teaching. While the ancient botanists had been satisfied mostly with names and enumeration of qualities and virtues there was now a growing desire to see and handle the plants themselves. Since 1545 (Padua, Italy) *botanical gardens* were attached to medical schools and dried plants were collected in *herbaria*.

One aspect of the Renaissance has often been described and emphasized: the publication of the Latin and Greek classics, many of which had been lost because they were represented by single manuscripts, which were buried and forgotten in the corners of neglected libraries. The discovery of such manuscripts was as thrilling as the discovery today of papyri or clay tablets. There were incunabula editions of the great botanical books of antiquity, those of Theophrastos and Discorides, but those early editions were not illustrated. The descriptions of plants, even when correct, were confusing, because they referred to another flora than that of Western Europe. In this case, the classics have to be rejected and the work of botanical description had to be done over. The pioneers, "the fathers of botany", were Germans:

---

and claimed the lives of about 1200 Jews. Among them were Pedro's descendants, Beatrice Nuñes, Fracesco Nuñes, Isabel Nuñes and Clara Nuñes – all burned at the stake on July 04, 1632.

[192] From the Greek $\beta o \tau \alpha \nu \eta$ = *plant*; $\beta o \sigma \kappa \epsilon \iota \nu$ = to *graze*. The science which includes everything relating to the plant kingdom.

- **Otto Brunfels** (1488–1534, Germany). Father of modern botany, a physician in Bern, has been looked upon as the restorer of the science of botany in Europe. In his *Herbarium* (1530–1536) he gave descriptions of a large number of plants, chiefly those of central Europe, accurately illustrated by beautiful woodcuts. He was followed by:

- **Leonhard Fuchs** (1501–1566, Germany), whose *Historia Stirpium* (Basel, 1542) summarized the accepted knowledge regarding some 500 plants. (He introduced European readers to pumpkin and Indian Corn of the Americas.)

- **Valerius Cordus** (1515–1544, Germany) wrote *Dispensatorium* (1535), one of the first pharmacopeias, describing drugs, chemicals and medical preparations. His *Historia Planetarum* (1544) includes description of 500 newly identified plant species. His is the first definite mention of ether and description of its preparation (1540).

- The physician **Hieronymus Bock** (1498–1554, Germany) is also regarded as one of the founders of the science of botany. Author of *Neu Kreutterbuch* (1539), pioneering classic in descriptive botany.

The descriptions in these early works were encumbered with much medical detail, including methods of preparing and administering extracts for medical purposes.

- **Charles de l'Ecluse** (1526–1609, France). Botanist. Introduced *potato* into Europe. Published *Rariorum Planetarum* (1601) on European and American plants.

- **John Ray** (1627–1705, England) did much to advance the sciences of botany and zoology. He promulgated a system of *classification* of plants into *orders* in his *Methodus Planetarum nova* (1682).

1531–1548 CE **The Pizarro brothers**: **Francisco** (1471–1541) and his three half-brothers (one father, three mothers): **Gonzalo** (1506–1548); **Hernando** (1501–1580); **Juan** (1505–1536). Explorers and adventurers. Led the conquest of Peru and its exploitation.

Francisco overcame Atahualpa[193] (1532) and executed him (1533) at Cajamarca for refusal to accept the Chritian faith; Captured Cuzco (1533)

---

[193] In the very same year, the great "boss" of Pizarro and Cortés, namely, emperor **Charles V**, held in his hands the fate of two men who offered him a Kingdom in the East:

David Reuveni (ca 1483–1538) arrived in Venice (1523) and later in Rome and secured immense amount of gold. Founded the new capital Lima (1535). Waged a civil was with Almagro (1537–1538) who was defeated and killed. He was slain by followers of Almagro in revenge (1541).

Gonzalo went with Francisco to Peru (1531) and became governor of Quito (1541–1546). After the Spanish government abridged their rights, the conquistadors revolted but were defeated (1546). The age of the conquistadors ended in Cuzco on 10 April 1548, when Gonzalo Pizarro was executed.

Hernando went with Francisco to Peru (1531) and returned to Spain with fifth of the Royal ransom of Atahualpa (1534). On his return to Peru (1537) he helped Francisco overcome Almagro. He was imprisoned in Spain (1540–1560) by Charles V.

Juan went with Francisco to Peru (1530) and became governor of Cuzco (1535), killed in fighting at Cuzco against the Inca Manco Capac.

Gonzalo Pizarro also explored much of northwestern South America. During 1539–1541 he made a perilous journey from Cuzco to Quito, a march of some 1600 km in hostile Indian territory.[194]

1533–1545 CE **Rainer Gemma Frisius** (1508–1555, The Netherlands). Geographer and astronomer. Invented the modern *triangulation* technique for surveying, replacing the pace-out of distances; After measuring a single *baseline*, other distances are calculated by means of *trigonometry*. In *De principis astronomiae et cosmographie* (1533) he pointed out that knowing the correct time according to a mechanical clock and comparing it with sun time, can be used to calculate *longitude*.

Gemma Frisius used Maurolycus' *camera obscura* for his observation of the solar eclipse of Jan. 1544 at Louvain, and fully described the methods he

---

(1525), claiming to be of the Lost Tribe of Reuben; for a while he was supported by Pope **Clement VII** and King **John III** of Portugal in a plan to lead a Jewish army against Turks in the Holy Land.

Shlomo Molcho (1500–1532), a Portuguese Marrano from Lisbon by the name Diego Pires, openly proclaimed Judaism. Fleeing the Inquisition, he traveled and preached in Turkey, Israel and Italy.

Reuveni and Molcho eventually joined forces and tried to persuade Charles V that they can help defeat the Turks (1532). The emperor, however turned them over to the Inquisition, who burned Molcho at the Stake in Mantua (1532) and imprisoned Reuveni in Spain where he probably died a few years later.

194 For further reading, see:

- Von Hagen, V.W., *Realm of the Incas*, Mentor Books: New York, 1961, 223 pp.

adopted for making measurements and provided drawings of the eclipsed sun in his *De Radio Astronomico et Geometrico* (1545). He recommended that these methods be used for observation of the moon and stars and also for longitude determination.

Gemma Frisius was born at Dokkum, Friesland, Holland. He was a pupil of **Maurolycus**; died at Louvain (Belgium).

1534–1563 CE **Garcia da Orta** (1500–1560, Goa). Botanist and physician. Made major pioneering contribution to medicine and botany by acquainting Europeans with Oriental medical plants and drugs. His monumental scientific work on which he spent some 30 years of his life in Goa appeared under the title "*Coloquios dos simples e drogos medicinais*" (1563).

Da Orta was born in Elvas, Portugal. Studied at Salamanca and Alcala (1515–1525). Practiced medicine for a while and then became a professor of logic at Lisbon. Being a *Marrano*, he endured great affliction and tribulation: various members of his family, among them a sister, were tried by the Inquisition and sentenced to be burned at the Stake. In 1534 he sailed to India on a voyage of 6 months and later established himself in Goa as a medical practitioner. There he carried out the studies and researches which enabled him to publish his treatise.

Since he lived in Goa as a Jew, he was convicted postmortem on charges of heresy (1580) and his body was exhumed and burned.

1535–1557 CE **Niccolò Fontana (Tartaglia)** (1499–1559, Italy). Amateur mathematician, self-taught engineer, surveyor and bookkeeper, who wrote on mathematics and mechanics. In 1535 he claimed to have discovered a general method of solving the cubic equation $x^3 + ax = b$, independently of **Scipione del Ferro** (1515). In 1537 and 1546 he published works dealing with military tactics, munitions, and ballistics, in which he stated that the impetus of projection and the force of gravity act together on a projectile throughout the course of its flight. Thus the path of the projectile is curved throughout its course. Tartaglia also found an empirical rule connecting the *range* of a cannon with its *angle of inclination*. The range is a maximum, he said, when the cannon is inclined at an angle of 45°, although he did not discover the parabolic shape of the trajectory, later discovered by **Galileo Galilei** (1638). Tartaglia was much concerned with the promotion of mathematics and mechanics. He made the first Italian translation of Euclid's geometry, and published the first edition of Archimedes' mechanics in 1543.

Tartaglia was born at Brecia. His childhood was passed in dire poverty. During the sack of Brecia in 1512 he was horribly mutilated by French soldiers. He slowly recovered from these injuries, but he long continued to stammer in his speech, whence the nickname, adopted by himself, of 'Tartaglia'. Save for the barest rudiments of reading and writing, he tells us that he had no master; yet we find him at Verona in 1521, an esteemed teacher of mathematics. In 1534 he went to Venice. In 1548 Tartaglia accepted the position of professor of Euclid at Brecia, but returned to Venice at the end of 18 months. He died at Venice.

1536–1559 CE **John Calvin (Jean Cauvin)** (1509–1564, France and Switzerland). Theologian and reformer. One of the chief leaders of the *Protestant Reformation*. Calvin's incisive mind, powerful preaching, many books and voluminous correspondence, and capacity for organization and administration made him a dominant figure of the Reformation. He was especially influential in Switzerland, England, Scotland and Colonial *North America*.

Calvin was born in Noyon, France and educated in Paris. He was never ordained as a priest and his education reflected the influence of the liberal and humanistic Renaissance. He adopted Protestantism (1533) and left Paris (1534) to settle in Basel where he published his *Institutes of the Christian Religion* (1536). From 1541 on, Calvin became the dominant personality in Geneva, though he held only the position of pastor.

By 1546, many Protestants in Germany, Switzerland and France were insisting that the people – not just kings and bishops – should share in political and religious policy–making. This idea influenced Calvin and his followers in France, England, Scotland and The Netherlands. Calvin's French followers were called *Huguenots*. The English Protestants whom he influenced were called *Puritans*.

Calvin developed political theories that supported *constitutional government*, *representative government*, the right of the people to change their government, and the separation of civil government from church government. (Calvinists of the 1500's intended these ideas to apply only to the aristocracy, but during the 1600's, further democratic concepts arose, especially in England and later in Colonial America).

Calvin set the *Bible* as the basis to all Christian teachings, and expanded the idea that Christianity was intended to reform all society. Indeed, no other reformer did so much to force people to think about *Christian social ethics*. From this ethical concern, Calvin developed the pattern of church government that today is called *Presbyterian*. He organized the church government distinct from civil government, so that an organized body of churchmen would work for social reform.

The syncretism of the Jewish and Hellenistic cultures that exist at the basis of Christianity, disintegrated at the time of the Reformation. This process enabled **Luther** and **Calvin** to adopt for themselves anew different elements from the various components of Christianity. Luther chose the mystic, Paulinian element, while Calvin chose the nomistic part, emphasizing those elements expressed in the Bible.

Calvin based his doctrine on the Scriptures, returning to the Jewish idea of *God's providence*. His dominant figure is that of God and not the Son. He believed in a world that is ordered, rational and manageable by man, while Luther believed that the visible world was dominated by the *devil*, and that laws were a superfluous devilish phenomena[195].

Calvin maintained, on the other hand, that even God's providence does not relieve man of *responsibility*. Paul and Luther held that man is too weak to save himself by his deeds and therefore not accountable for his sins. While Calvin returned to Jesus' original Christianity, Luther continued to negate the world leaving it under the Devil's control. For this reason, Germany lagged behind England and the United States both politically and spiritually. The devilishness of which Luther spoke so much, finally was realized in the national-socialist movement and the genocide of the Jews in Europe during 1940–1945 by the Germans.

1536–1561 CE **Amatus Lusitanus** (1511–1568, Portugal and Italy). Physician and medical scientist. Among the greatest researchers in medicine during the first half of the 16^{th} century.

Published *Index Dioscoridis* (1536) on medical botany and seven volumes (1549) including 700 medical case histories, which established his name as an original researcher in the fields of internal medicine, anatomy, surgery, skin diseases, etc. Although Lusitanus was associated with the traditions of Hippocrates, Galen and the medieval Arab writers, his accurate observations, examinations, and diagnoses led him to go beyond these authorities and make new discoveries. For example, he was first to describe the *venous valves* (1547).

Lusitanus was born in Castel Branco, Portugal, to a family of marranos under the name Joannus Rodericus. His Jewish name is unknown. He studied medicine, mathematics, Greek and logic at the University of Salamanca, Spain. He fled the Inquisition (1533) and moved to Antwerp where he returned openly to his Jewish faith. He then removed to Ferrara, Italy (1544) and later to Ancona (1547), where he became the physician of the papal court. When pope Paul IV began to prosecute the Jews of Ancona, Lusitanus fled to

[195] Through this, Luther returned to *Paulinian* Christianity, maintaining that since man is devoid of free will, he is incapable of fulfilling laws of any kind. This fact had disastrous consequences for the development of Germany; The Germans never developed their own constitution and that is the reason why Nazi ideology could and did flourish in Germany and not in a Catholic country, let alone in a country under Calvinist influence.

Ragusa and from there to Saloniki (1558), where he died in a local outbreak of the plague.

1537–1555 CE **Andreas Vesalius** (1514–1564, Brussels). One of the foremost anatomists of all times. His book *Fabrica* (1543) contains the first complete description of the human body. For this he is called the *father of anatomy*. He was first to break with the extravagant admiration of antiquity (with the excessive confidence in the writings of **Galen**), and the general practice of principally dissecting bodies of lower animals.

A native of Brussels, he began to study anatomy at the age of 14. The difficulties with which the practical pursuit of human anatomy was beset in France made him look for Italy as a suitable field for the cultivation of this science; in 1536 we find him at Venice, and later at Padua, where he became a professor at the age of 23. Because he dared to correct many of Galen's errors (based on animal dissection), the followers of Galen bitterly attacked him. Discouraged, he burned most of his writings and resigned from Padua in 1544. After teaching at the Universities of Bologna and Pisa he became physician to Philip II of Spain, and to the Holy Roman Emperor Charles V.

Vesalius departed from tradition by performing dissections himself while instructing his medical classes. Traditionally, the dissections were performed by barber-surgeons while the instructor read from the works of earlier writers.

Jewish Scholasticism – Contributions to the Scientific Method

According to the scientific method, science begins from systematic observation and measurement, but it does not stop there – it is not the mere collection of information about nature. The creative act is to generalize from the data, to hypothesize *a possible physical process and to describe the process in* mathematical form. *Mathematics describes a relationship observed in nature, rather than claiming to* be *the underlying reality (as in Platonism). Finally, the hypothesis is judged not on its intrinsic logic or by debate, but solely by its ability to* predict *further measurements.*

In spite of their ancient weakness in mathematics (which can be traced directly to their use of alphabetic notations), the Jewish scholars of the Talmudic era (70–470 CE), and the post Talmudic era (ca 500–1500 CE) must be *given credit for inventing a completely new way of thinking. In their concern to apply the scriptures to the minutest details of everyday life, they supplied not only the definitive method of interpreting the sacred text, but also a logical basis for the scientific method and the logical principles basic to the theory of probability, modern statistics and the inductive method in mathematics. Their achievements are summarized as follows:*

- *First to declare the* principle of economy *(later known as 'Ockham's Razor').*
- *Established the method of reasoning known as 'binyan av'. It is similar to* 'the method of agreement' *used in scientific reasoning to identify causes and effects. This method states that, when there is an invariable association between certain events which happen before the phenomenon, and an absence of the phenomenon when these events do not occur, then the events are related in a causal manner to the phenomenon.*
- *Developed the mode of proof known as 'en la-davar sof'. This is the* reductio ad absurdum *agreement, also attributed to such Greek thinkers as Theaetetos, Hippocrates, and Zeno. It tests some declared truth or opinion by drawing some conclusion from it which is known to be false. If this can be done, the opinion itself must be false.*
- *Introduced the mathematical method of* proof by induction.
- *Formulated the* statistical law of large numbers *some* 250 *years ahead of Jakob Bernoulli (1713). It was first declared by the philosopher* **Itzhak Aramah** *(1420–1494, Spain).*
- *Anticipated many of the laws of* probability *and of* statistical reasoning. *Extensive use of the method of casting lots and constant scrutiny of the system of fairness (because of the tendency of individual priests to manipulate the system for personal gain) was a strong motivation to study the operations of chance. Expressing the idea of the random principle led to the recognition that a number of repetitions of a process of choosing should result in an equal number of choices of the alternatives.*

  The fact that, in the short run, there might be a bias in the results of the draw but that this bias should disappear in the long run of repeated samplings, led them to an intuitive awareness of the law of large numbers (that equal probabilities yield equal frequencies as the draw is repeated more and more times). The recognition that 'counted majorities' yield numbers equal to the actual probabilities which operate in cases of unbiased sampling, was also established.

The factor that ensured the primacy of Jewish savants in pioneering modes of thinking about chance in practical situations, was that Orthodox Jews were forbidden to gamble. The Greek might have discovered probability, for they were addicted to dice-throwing. But the dice they used were made from the astragalus bones of sheep. These were very irregular in shape, so that dice were biased and there was no equal likelihood of each side falling uppermost. Because of the astragalus' imbalance, it was impossible for the statistical law of large numbers to manifest itself in any tractable way. By contrast, the elaborate system of casting lots used by Jewish priests did exactly what it was devised to do; that is, gave everyone an equal chance of being chosen[196].

The theory is virtually the same as was developed later in mathematical form by ***Cardano****,* ***de Moivre****,* ***Laplace****,* ***Gauss****, and* ***Pearson****. But in the religious context in which the rabbis worked, they naturally avoided abstract speculations as an end in itself, and concentrated their analysis on empirical relations. They worked on problems by means of an inductive logic quite foreign to the speculative urges of the Greek philosophers. In doing so, they helped (in the same way as Christian medieval theologians did with their analytic methods and dialectical disputation) to lay the theoretical foundations for the scientific revolution in Western Europe. They set out, albeit in rhetorical and not scientific terminology, the logical principles basic to the modern science of statistics.*

Solved problems pertaining to external geometrical areas and volumes. For example – finding a box of the shape of a cube (or a circular cylinder) with open top and fixed surface area, such that its volume be maximized. A problem of this kind arose, for example, in connection with Jewish dietary laws *which traditionally divide food into pure and impure [Talmud; Kelim]. The addition of a very small proportion of impure food does* not *make a pure food impure. Thus, a cooking vessel whose walls might have in the past absorbed some impurity, can be used safely, provided the ratio of its volume to the total area of its walls is sufficiently large.*

Consequently, many problems of relative area and volume were analyzed by the Talmudists[197].

---

[196] The historical origin of the lottery system is the annual choice of one of two goats to be the '*scapegoat*', carrying the heavy load of sin into the wilderness as the *Goat of Azazel*. The concept of an equal chance of being chosen in a 'fair' lottery would be the prime motivation of the whole system. In turn, the notion of equal probabilities, and the fact that such chances would be shown by equal numbers of votes for each participant over a period, could naturally emerge.

[197] **Shlomo ben–Moshe Ashkenazi–Rappoport** (1717–1781, Poland). Talmudic scholar and amateur mathematician, solved this problem in an ingenious way, bypassing the Newtonian calculus (unknown to him). In his book *Mirkevet–Mishne* (1751) he considered a vessel in the form of a box with square

1540 CE **Vannoccio Biringuccio** (1480–1539, Italy). Metallurgist. His *De pirotechnia* (1540), covers the technology of metallurgy of his time: practical aspects of mining, smelting of metals, casting of bells and cannons, and the preparation of chemicals for treating *ores*.

1542–1565 CE **Conrad Gesner** (1516–1565, Switzerland). Universalist and naturalist: physician, encyclopedist, botanist, zoologist, linguist and mountaineer. His compendium *Historiae animalium* (1551–1587) is the starting point of modern zoology. In his *Catalogus plantarum* (1542) he classified the plant genera on the basis of reproductive organs. Distinguished *genus* from *species* and *order* from *class* in his classification of plants. He also classified *fossils* into 15 different types.

Gesner was born in Zurich. He studied (1532–1541) at the Universities of Strasbourg, Bourges, Montpellier and Basel, where he took his degree in medicine (1541). He practiced medicine in Zurich and stayed at the city until his death from the plague.

In 1545 he published his remarkable *Bibliotheca universalis*, a catalogue (in Latin, Greek and Hebrew) of all writers who had ever lived, with the title of their works, etc. A second part, under the title *Pandeclarium sive partitionum universalium Conradi Gesneri Lingurini* appeared in 1548. In 1555 he put forth *Mithridates de differentiis linguis*, an account of about 130 known languages.

---

base of side a, and hight h. Then

$$S = \text{ total area } = 4ah + a^2 = 2ah + 2ah + a^2$$

$$V = \text{ volume } = ah^2 = \frac{1}{2}\sqrt{2ah \cdot 2ah \cdot a^2}$$

If we take the total area as constant, then $4V^2 = 2ah \cdot 2ah \cdot a^2$ is the product of three quantities whose sum is constant, and is therefore a maximum when they are all equal, which is when $h = \frac{1}{2}a$. The same argument holds for a cylindric box with a circular base of diameter d, namely $h = \frac{1}{2}d$. This result can be checked against the provable statement that of all *closed* rectangular boxes, the cube encloses the greatest volume for its surface area.

The Emergence of Modern Science

"In the year 1500 *Europe knew less than Archimedes who died in the year* 212 *BCE"*

Alfred North Whitehead, 1953 (1861–1947)

The growth of science was strongly affected by the historical events that shaped Western civilization. During the 130 *years between* 1559 *and* 1689*, Europe passed through a tumultuous and anarchic period of civil wars and rebellions. Each upheaval had its own distinct character, each had multiple causes. The one common denominator, which constantly recurred, was the Protestant-Catholic religious strife.*

Yet, amidst all bloodsheds and turmoil, an intellectual revolution in astronomy, physics and mathematics was steadily and quietly being accomplished. In no other period of history was there such a dense galaxy of brilliant thinkers as ***Copernicus****,* ***Francis Bacon****,* ***Galileo****,* ***Kepler****,* ***Descartes****,* ***Fermat****,* ***Pascal****,* ***Spinoza*** *and* ***Newton****. [This was also the age of* ***Cervantes*** *(1547–1616),* ***Shakespeare*** *(1564–1616),* ***Bernini*** *(1598–1680),* ***Velásquez*** *(1599–1660),* ***Rembrandt*** *(1606–1669),* ***Hobbes*** *(1588–1679),* ***Locke*** *(1632–1704),* ***Montaigne*** *(1533–1592)* and ***Moliere*** *(1622–1673)] – all men of creative genius, whose work still lives today.*

No 16^{th} *or* 17^{th} *century achievement is better remembered today than the accomplishments of this international brotherhood of fellow scientists. They obliterated the traditional view of nature and established scientific practice on an impressive new footing. This great breakthrough equipped the physical scientist with new methods and new standards which worked exceedingly well throughout the* 18^{th} *and* 19^{th} *centuries. So total was the victory, that it requires an effort of imagination to understand how any intelligent man could have taken the pre-Copernican view of nature seriously. Yet this traditional view was scientific within its own terms. For many centuries, thinking men had found it logical and empirical, as well as emotionally convincing.*

We must try to reconstitute this obliterated system in order to appreciate the magnitude of the scientific discoveries which swept it away.

The traditional view of the cosmos, accepted by almost every educated man until well into the 17^{th} *century, was an amalgam of Aristotelian mechanics, Ptolemaic astronomy, and Christian theology. It fitted all the preexisting views of a moral universe in which man occupied a middle place between*

Heaven above and Hell in the earth's core. Everyday experience would seem to indicate that Aristotle's theory of motion did indeed represent the way God operated the universe: All heavenly bodies, said Aristotle, naturally fell toward the center of the universe and rested there, unless propelled by a mover in some other direction. It followed that the round earth, obviously solid and weighty, stood motionless in the center of the universe.

Such teaching, accepted by all *Christians, harmonized nicely with Ptolemaic astronomy in which a concentric series of transparent crystalline spheres revolved around the earth: the moon, the sun, the planets, the fixed stars and the outermost sphere, which drives the entire system, all wheeled in perfect circles, going around the earth once every 24 hours. Beyond the outermost sphere lay God's heavenly abode. This theory coincided, as well as anyone could see, with the crude astronomical observations which stargazers were able to collect.*

There were of course major mysteries that were not written in Aristotle's philosophy, such as plagues, storms, floods, earthquakes, comet apparitions and other natural catastrophes. The fickleness of life seemed to show that God had delegated a role in nature to fate, fortune, or chance. This was the twilight zone in which astrologers and alchemists could thrive. It may also explain the need to believe in small-scale supernatural beings such as witches, fairies, pixies, evil spirits (fallen angels) or even the devil himself, who meddled in human affairs.

In the 14^{th}, 15^{th}, *and* 16^{th} *centuries, however, certain forces in European society were preparing the way for a change in the general view of Nature. Artisans and craftsmen were becoming more skilled in their techniques. The invention of the lens and the development of the glass industry, to take but one example, contained the promise of vastly extending man's power of observing natural processes. New techniques in shipbuilding led to voyages of discovery, which in turn stimulated interest in nature and turned men's attention to problems of navigation. The Renaissance, with its emphasis on literature and art, was in some ways anti-scientific. But humanism stimulated a passionate interest in man. Furthermore, humanistic study revealed conflicting opinions among the ancients on matters of science, just at the moment when the authority of Ptolemy was becoming shaky for other reasons: growing skill in mathematics exposed the clumsiness of Ptolemy's explanations. In the opening years of the* 16^{th} *century, conditions were ripe for change.*

The first thinker to challenge the traditional viewpoint was ***Nicolaus Copernicus****, as early as* 1514*. He was a quiet, conservative Polish cleric, who lived in an obscure East Prussian cathedral town. He had no quarrel with the Ptolemaic vision of concentric crystalline spheres wheeling in perfect circles around the central point in the universe. What troubled him was the fact that Ptolemy's spheres were not perfectly circular, and he therefore published* *his revision to the geocentric theory, hoping to bring Ptolemaic astronomy up to date. He then discovered that he could account for the irregularities in celestial motion by making a single elemental adjustment, namely, to put the sun, rather than the earth in the center of the universe. He could then simplify the Ptolemaic intricate network of 80 interlocking circles by replacing them with only 34 circles. It would then be superfluous to posit that the distant fixed stars wheeled daily around the earth.*

What we call the Copernican Revolution was not made by Canon Koppernigk. His book was not intended to cause a revolution. He knew that much of it was unsound, contrary to evidence, and its basic assumption unprovable. He only half believed in it, in the split-minded manner of the Middle Ages[198]*. Besides, he was denied the essential qualities of a prophet: awareness of mission, originality of vision, and the courage of conviction.*

The scientific revolution began at the medieval universities of ***Oxford*** *and* ***Paris*** *(Roger Bacon, William of Ockham),* ***Padua*** *(Copernicus, Galilei),* ***Tübingen*** *(Kepler) and* ***Cambridge*** *(Newton).*

Other universities such as Bologna, Prague, Vienna, Heidelberg, Leipzig, Uppsala, Königsberg, Jena, Salamanca, Edinburgh and Leyden (established 1158–1575) also participated in the West European movement of intellectual emancipation.

Europe Under the Reformation (1517–1648)

Reformation is the name given to a religious movement that gave birth to Protestantism. It had great impact on man's social, political and economic life

[198] A strange situation formed in astronomy after the Copernican Revolution: Ptolemy's epicycles could still fit the data. In fact, in some respect they did so better than Copernicus' calculations. Yet their forced complexity came to make them seem unconvincing when compared with the eventual attractions of the heliocentric system: There is a deep feeling among those who practice fundamental science, a feeling that has so far proved reliable, that the way to true understanding is the one that satisfies the canons of economy and elegance – the way which is *mathematically beautiful*.

and on the development of science. The Reformation began in 1517 *when the German monk* ***Martin Luther*** *(1483–1546) protested certain practices of the Roman Catholic church. About* 40 *years later, Protestantism was established in nearly half of Europe.*

Before the Reformation, Europe had been held together by the universalism of the Catholic church and by the claim of the Holy Roman Emperor to be the supreme secular *ruler. After the Reformation, Europe had several large Protestant churches and some smaller Protestant religious groups. All of them competed with the Catholic church – and with each other – for the faith and allegiance of men.*

The word Protestant ('one who protests') dates from the diet of Speyer, Germany, in 1529*. In* 1530*, the Lutherans presented the 'Augsburg Confession' to the diet of Augsburg, Germany, and it became the basic statement of Lutheran doctrine. In the 'peace of Augsburg', signed in* 1555*, the Holy Roman Empire officially recognized the Lutheran churches.*

One of the chief leaders of the Protestant Reformation was ***John Calvin*** *(1509–1564). From his center in Geneva he directed efforts to convert the people of France and other West European countries. His followers in France were called the Huguenots. In* 1571*, a moderate form of Protestantism, known as* Anglicanism*, was established in England.*

As a result of the Reformation, Europe was divided between Catholic countries in the south and Protestant in the north. The Protestant ethic encouraged industriousness and careful management of material things. It contributed to the development of industry and commerce during the 18^{th} *and* 19^{th} *centuries.*

Protestant leaders also emphasized education, promoted literacy, an educational curriculum based on ancient Greek and Roman literature and a high respect for teaching and learning. After 1640*, advances in science were promoted more energetically in Protestant lands.*

Science Progress Report No. 4

The Religious Wars (1562–1689)

Persecution compelled the French Protestants (Huguenots) to take up arms. At the same time they formed a political party. The ensuing struggles, therefore, did not constitute a purely religious war, but also civil war in which the leaders of both parties endeavored to exploit the weakness of the crown and secure control of the government. The Huguenots were recruited primarily from the nobility and from the new capitalist-artisan class. Paris and the northeast in general remained Catholic throughout. After the first three wars (1562–1569), the Huguenots, despite defeat, were given conditional freedom of worship.

On Aug. 24, 1572 (known as "Massacre of Saint Bartholomew"), the pro-Catholic party, with the approval of Queen Catherine dé Medici, murdered some 5000 *Huguenots in Paris and in the French provinces. Killing continued until October* 03. *Catholic Europe congratulated the Queen on her success and the Pope celebrated the event in Rome. The massacre led to the fourth of the religious wars (1562–1598) in which the Huguenots won.*

The wars ended with the Edict of Nant (1598) which gave the Huguenots equal political rights but did not secure them entire freedom of religious worship. The persecutions were resumed in 1620, *and especially after* 1685, *when the Nant Edict was canceled. Many of them (ca 250,000) fled to Switzerland, Netherlands, England, Germany and the U.S.A., where they contributed greatly to the cultures of these countries. Only in* 1789 *did they regain equal religious and social rights.*

The last of the great religious wars in Europe was the Thirty Year War (1618–1648). It involved most of the nations in Europe in a struggle for territory and political power. The underlying cause of the war was the old deep-seated hostility between the German Protestants and the German Catholics.

The war had three stages: The Bohemian period (1618–1620), The Danish period (1625–1629), and finally The Swedish-French period (1635–1648). During the entire duration of the war, the people of Germany suffered misery and hardships. In 1648, *the war ended with the peace of Westphalia. By this treaty, Calvinism was put on an equal footing with Catholicism and Lutheranism.*

By the time the war ended, Germany was in a pitiable condition. Third of its people were killed. Whole cities, villages and farms disappeared, and much property had been destroyed. Art, Science, trade and industry declined. It *took almost* 200 *years for Germany to recover from the effects of the Thirty Years War. Thousands of persons left Europe, especially Germany, and went to America to build a new life.*

The Golden Age of The Netherlands

The Reformation spread through the Netherlands during the early 1500*'s. However, in* 1516 *Charles of Burgundy also became King of Spain. In this way, the Netherlands came under Spanish control. In* 1519*, Charles became emperor of the Holy Roman Empire and tightened his control over the Low Countries. He tried to stop the Protestant threat to Roman Catholicism by persecuting them. His son Phillip II inherited the Netherlands in* 1555 *and tried to gain complete power over the country. In* 1568*, the Nobles there revolted under the leadership of William of Orange. In* 1581*, the northern provinces declared their independence from Spain. The revolt of the Netherlands lasted until 1648 (except for temporary peace from 1609–1621), when Spain finally recognized Dutch independence.*

The first half of the 17^{th} *century, during which the Dutch provinces were still at war with Spain to secure their independence, was nevertheless a period of unexampled flowering in art, science and literature. This was primarily due to an unprecedented expansion of the Dutch commerce which resulted from the closing of Lisbon to Dutch trade and the annexation of Portugal to Spain. The Dutch were obliged to find their own way to the East, and within a remarkably short time they were disputing the command of the Indies with the Portuguese, whom they soon displaced.*

The Dutch 'East India Company' (founded 1602) was given extensive political and military authority and became one of the chief organs of Dutch imperialism. In 1652 *the Dutch established themselves at the Cape of Good Hope, and in* 1667 *they took Sumatra. The 'Dutch West India Company'* *(founded 1621) had the same extensive control over the American and African coast trade.*

In 1623 *the Dutch began extensive conquests in Brazil, until* 1661. *They took the islands of St. Eustace and Curacao (1634–5), Saba (1644) and St. Martin (1648). With this far-flung colonial empire, the Dutch provinces became the commercial center of Europe, Amsterdam easily holding the lead as the financial center.*

Thus, a million and a half people fought, against great odds, the whole might of the Spanish Empire. At the end the Dutchmen not only were able to hold their own, but actually turned the tables on their enemies to such an extent that Spain never recovered from the blow.

The prodigious energy necessary to accomplish such a stupendous victory could not suddenly be subdued the moment peace was signed. Carried forward by its own momentum, this desire to achieve manifested itself in almost every other phase of life. Almost overnight Holland was turned into an economical, intellectual, and artistic beehive.

Never before or since has Holland been the world power it was then – a small country, forced to live by its wits. Because of its tolerance for unorthodox opinions and its tradition of encouraging freedom of thought, it was a haven for intellectuals, who were refugees from censorship and thought-control elsewhere in Europe.

It is therefore not by sheer chance that ***Descartes*** *created most of his philosophy and mathematical writings (1628–1649) in Holland. It was the home of the great Jewish philosopher* ***Baruch Spinoza*** *(1632–1677) and the political scientist* ***John Locke*** *(1632–1704). It was the cradle of the developments of the microscope [****Leeuwenhoek*** *(1632–1723)] and the telescope [****Huygens*** *(1629–1695)], the extensions of human visions to the realms of the very small and the very large, respectively.*

The fundamental studies of ***Snellius*** *(1580–1626) on the refraction of light and* ***Huygens****' wave theory of light are among the remarkable achievements of this golden age.*

This was also the time of ***Rembrandt*** *(1606–1669),* ***Vermeer*** *(1632–1675) and* ***Hals*** *(1580–1666).*

Is there a common denominator to Descartes' 'frame of reference', and the obsession with light and vision of Vermeer, Rembrandt, Huygens, Snellius and Leeuwenhoek? ***Hendrik van Loon*** *(1882–1944, U.S.A.) replied to that in the affirmative:*

"The Low Countries are one of the few parts of the world where every window becomes the frame for a very definite and exceedingly paintable little

landscape, while inside the house that strange light that sweeps across a sky washed clean by everlasting rainstorms, has a clarity and harsh brightness which turns even the most ordinary article of daily usage into mysterious objects that lose their commonplace character and begin to vibrate with all the colors of the rainbow."

ca 1543 CE **Nicolaus Copernicus** (Nicolas Koppernigk, 1473–1543, Poland). Astronomer, physician and Canon of Law. First to revive the heliocentric theory of Aristarchos. Broke away from the Ptolemaic doctrine and put the center of the universe near the sun, with the earth and all the planets revolving about it (1514). This heliocentric model was revolutionary in that it challenged the previous dogma of scientific authority of Aristotle, and caused a complete scientific and philosophical upheaval.

The Ptolemaic system formed the basis of all the writings of the Arab and Jewish astronomers of the Middle Ages, including Maimonides, Avraham bar Hiyya, Levi ben Gershon and others.

Martin Luther (1483–1546) ridiculed the Copernican hypothesis, that the earth revolves around the sun, and appealed to a literal interpretation of scripture to support his arguments. He pointed out that Joshua had made the sun – not the earth – stand still! For half a century after Copernicus' death, his heliocentric theory gained few adherents. It was taught at only one university (Salamanca, Spain) and the general public was unaware of it. **Montaigne** (1533–1592) lightly dismissed it and **Tycho Brahe** (1546–1601) did not accept it either. All this was however quite irrelevant to science; the important thing was that **Kepler** was a Copernican.

Nicolas Koppernigk was born on the 19^{th} of February 1473, at Torun on the Vistula in Prussian Poland, a trading post between East and West. There his father, a native of Cracow, had settled as a dealer in copper (the family business, from which the Koppernigks derived their name). His mother, Barbara Watzelrode, belonged to a family of high mercantile and civic standing. After the death of his father in 1483, Nicolas was virtually adopted by his uncle Lucas Watzelrode, later Bishop of Ermeland.

Placed at the University of Cracow in 1491, he devoted himself during the next four years to mathematical science, but did not take any degree. In 1495 he came to the University of Bologna, where he studied Canon law and astronomy. In 1497 he was nominated a canon of the cathedral chapter of Frauenburg[199] (some 85 km east of Danzig, on the Baltic Sea), but the chapter gave him permission to continue his education in Italy. In 1501, Nicolas entered the medical school of Padua, where he remained until 1505, having taken meanwhile a doctor's degree in canon law at Ferrara in 1503. After his return to his native country in 1506 he resided at the episcopal palace of Heilsberg as his uncle's physician until the latter's death in 1512. He then retired to Frauenburg and attended to his capitular duties. His work was mainly administrative, though he had occasionally to practice medicine. In his spare time he pursued astronomical researches.

The main lines of his work were laid down at Heilsberg and at Frauenburg from 1513 until its completion in 1530. In it he sought, with scant instrumental means, to test by observations the truth of the heliocentric doctrine. In 1530 he circulated a brief popular account, the *Commentariolus*. His disciple **George Joachim Rheticus** (1514–1576) printed in 1540, in Danzig, a preliminary account of the Copernican theory, and simultaneously sent to the press at Nuremberg his master's complete exposition of it in a treatise entitled *De Revolutionibus Orbium Coelestium* (concerning Revolutions of Celestial Spheres). But the final printed copy reached Frauenburg barely in time to be laid on the writer's death-bed. The book was marred by an anonymous preface, addressed to the reader, slipt in by **Andreas Osiander** (1498–1552). It insisted upon the purely hypothetical character of the reasoning it introduced, and explained that the ideas of the book need not be taken too seriously. The trigonometrical section of the book had been issued as a separate book (1542) under the care of Rheticus.

The first edition, Nuremberg 1543, numbered ca 1000 copies, which were never sold out. It had altogether 4 reprints in 400 years: Basle 1566, Amsterdam 1617, Warsaw 1854, and Torun 1873. It is a remarkable negative record, and quite unique among books which made history.

The Copernican system met with very determined opposition, and the Christian Church as well as the Jewish Rabbis denounced it as heretical because the Bible said that the earth was fixed and the sun was moving (*Eccles* **1**, 3–4).

---

[199] His uncle was anxious to secure him this post because the economic future of the Baltic Sea ports of the Hanseatic league became uncertain due to the alleged opening of new sea routes to the Orient by Columbus. He drew his prebend, but he neither took holy orders nor was his physical presence at Frauenburg required for the next 15 years. However, the income from this position supported him for the rest of his life. From the age of 22 to 32, the young canon spent his time in Italy, at the Universities of Bologna, Padua and Ferrara on a series of extended leaves of absence. Toward the end of his Italian studies, the heliocentric system began to take shape in Nicolas' mind (ca 1505).

The Copernican Revolution (1543)

In 1543 CE, **Nicolas Koppernigk** *(1473–1543) [now known as* **Nicolas Copernicus***], astronomer, physician and Canon of Law, first revived the heliocentric theory of* **Aristarchos***. He broke away from the Ptolemaic doctrine and put the center of the universe near the sun, with the earth and all the planets revolving about it (1514). This heliocentric model was revolutionary in that it challenged the previous dogma of scientific authority of Aristotle, and caused a complete scientific and philosophical upheaval.*

In his book 'De Revolutionibus', published as late as 1543, he put forward the kinematic explanation to the precession of the equinoxes. Imagining himself as an observer outside *the solar system, he stated that the earth's axis, although it always keeps the same inclination ($66\frac{1}{2}^\circ$) to the plane of the earth's orbit (ecliptic), nevertheless traces out a cone of semiangle $23\frac{1}{2}^\circ$ with respect to the normal to this plane. Copernicus also concluded that the average precessional rate is 50.2″ per year, corresponding to a complete precessional period of about 26,000 years.*

The cause *of this precession remained a mystery until Newton [Principia, Book III, Proposition 39, 1687] gave a quantitative dynamical explanation: the wandering of the earth's axis round the pole of the ecliptic depends upon the same principle as the corresponding motion of a spinning top under the action of terrestrial gravitation. The equatorial bulge of the earth is attracted towards the plane of the ecliptic by the Moon and the Sun. Their turning moment acts upon the earth's angular momentum vector, causing it to precess.*

Although Copernicus is hailed as the harbinger of a new era in natural science, we encounter in his writings Pythagorean-Platonic mysticism and scientific reasoning in a combination which, from a modern standpoint, appear strange to us: he regarded the cosmos as spherical, a 'divine body' endowed with the perfection of its creator, and rejoices in the regularity and order of the world. Circular motion was supposed to be proper to all complete objects, and the state of rest to be more noble than that of motion.

The question arises as to how did Copernicus figured out the sidereal periods of the planets and the sizes of their orbit?

The observed retrograde *motion of the planets inspired* **Aristarchos** *(ca 270 BCE) to suggest a heliocentric cosmology. In Aristarchos' day, however, the idea of a moving earth seemed incompatible with explanation of other phenomena at the earth's surface. About 1800 years elapsed before someone had the insight and the determination to work out the details of a sun-centered cosmology.*

Table 2.7: The synodic and sidereal periods of the planets (in earth time units)

Planet	Synodic Period	Sidereal Period
Mercury	116 days	88.0 days
Venus	584 days	224,7 days
Earth	–	365.2 days
Mars	780 days	687.0 days
Jupiter	399 days	11.9 years
Saturn	378 days	28.6 years

Copernicus realized that, using a heliocentric perspective, he could determine which planets are closer to the sun than the earth and which are further away. Because Mercury and Venus are always observed fairly near the sun in the sky, he concluded that their orbits are smaller than earth's (inferior planets). The other visible planets: Mars, Jupiter and Saturn can be seen in the middle of the night, when the sun is far below the horizon, which can occur only if the earth comes between the sun and the planet. Thus Copernicus concluded that the orbits of Mars, Jupiter and Saturn are larger than that of the earth[200] *(superior planets).*

Since the earth, sun and other planets are all in relative motion w.r.t the distant fixed stars, Copernicus was careful to distinguish between two characteristic time-intervals, or periods, of each planet. Whereas the synodic period[201] *of a planet can be determined by observing the sky, the* sidereal period[202] *must be calculated.*

He derived the relation

$$\frac{1}{P} = \frac{1}{E} \pm \frac{1}{S},$$

where

[200] Other, dimmer superior planets - *Uranus*, *Neptune* and *Plato* - were discovered after the telescope came into use.

[201] Time that elapses between successive identical configurations (as seen from earth from one *opposition* to the next, for example, or from one *conjunction* to the next).

[202] The time it takes the planet to complete one orbit of the sun - the true orbital period.

$$\begin{array}{lcl} P & = & \textit{sidereal period of the planet (in earth years)} \\ E & = & \textit{sidereal period of the earth, which Copernicus} \\ & & \textit{knew to be equal to } 365\tfrac{1}{4} \textit{ days} = 1 \textit{ earth year} \\ S & = & \textit{synodic period of the planet (in earth years)} \end{array}$$

and $(+/-)$ *refers to inferior/superior planets, respectively.*

For example, taking the synodic period of Jupiter to be 398.88 *days* = 1.092 *earth years, and* $E = 1$, *we set:*

$$\frac{1}{P} = 1 - \frac{1}{1.092} = 0.084 = \frac{1}{11.9}$$

It thus takes Jupiter to complete one full orbit of the sun in 11.9 *earth years. Table 2.7 renders the values obtained by the method of Copernicus.*

To determine the size of an inferior planet's orbits, Copernicus measured the angle α *between the sun and the planet when this angle (known as elongation) is maximal. This occurs when the triangle formed by earth, the inferior planet, and the sun is a right angle. The hypotenuse of the triangle has a length of one astronomical unit (1 AU), and hence the radius of the inferior planet's orbit is equal to* $\sin\alpha$, *also measured in AU.*

Determining the size of the superior planet is somewhat more complicated. Here Copernicus used a triangle formed by the sun, earth and the planet at quadrature[203]*, which again contains a right angle at the earth. Simple trigonometry shows that in this configuration, the radius of the superior planet's orbit is equal to* $\frac{1}{\cos(\beta-\gamma)}$ *(measured in AU), where* β *is the angle the earth has spanned from its initial fiducial position at an approximate rate of* 1° *per day. The angle* γ *is that spanned by the planet from the earth's initial fiducial position and can be calculated knowing the sidereal period of the planet.*

Copernicus compiled his ideas and calculations into his book De Revolutionibus Orbium Celestium ("On the Revolutions of the Celestial Spheres") that was published in 1543, the year of his death. Although he assumed that the earth travels around the sun along the circular path, he found that perfectly circular orbits cannot accurately describe the paths of the other planets. He therefore had to add an epicycle to each planet *to account for the slight variation in speed along the orbit. Thus, according to Copernicus, each planet revolves around a small epicycle, which in turn orbits the sun along a circular path. Table 2.8 compares the average distances of the planets from the sun calculated by Copernicus with modern values.*

---

[203] In this position, the planet's elongation is 90°.

Table 2.8: Average distances of the planets from the sun (in AU)

Planet	Copernicus	Modern
Mercury	0.38	0.39
Venus	0.72	0.72
Earth	1.00	1.00
Mars	1.52	1.52
Jupiter	5.22	5.20
Saturn	9.07	9.54

Tycho Brahe *tried to test Copernicus' ideas with detailed observations of the sky. We know that, when we walk from one place to another, nearby objects appear to shift their position against the background of more distant objects. Tycho argued that, if Copernicus was correct, nearby stars should shift against the background stars as the earth orbits the sun.*

Tycho spent his lifetime making accurate observations of the positions of the stars and planets. Yet he could not detect any shifting of star positions. He therefore concluded that Copernicus was wrong. Actually, the stars are so far away that naked-eye observations could not possibly detect any tiny shifting of star positions. That has now been confirmed with telescoping observations.

Nevertheless, Tycho Brahe's astronomical records were destined to play an important role in the development of heliocentric cosmology. Upon his death (1601), many of Tycho's charts and books fell into the hands of his gifted assistant, ***Johannes Kepler****.*

Could you prove today that Copernicus was right?

Any school-boy knows that the earth revolves about the sun and not the other way round. But most people, among them, no doubt, some professors of physics would be hard pressed to explain why they are so sure of this.

The solar system is much smaller then the distance between the sun and the nearest star. That the universe is such a big place was only understood once it was realized that the parallax (as viewed from earth in, say, winter *and summer) of even the nearest star is minuscule, even with a base-line of* 3×10^8 *km (2 AU). Nonetheless, such parallaxes have been measured*[204].

Together with optical measurements of stellar aberrations, Doppler shifts and inertial effects caused by the earth's revolution, this provides evidence for the earth's relative *orbital motion w.r.t the sun and fixed stars.*

While none of these arguments can distinguish between the Copernican theory and, say, the Tycho Brahe's approach[205]*, the immense stellar distances revealed by parallax measurements to the nearest stars has rendered the Tycho interpretation unlikely in the extreme. It is simply unreasonable to believe that such huge numerous and distant objects conspire to rotate in unison around the earth.*

Another powerful argument for the correctness of the pure Copernican interpretation follows from a judicious combination of empirical facts and theoretical principles. Once one is armed with Newton's Second law of motion *and his* Law of Universal gravitation *can the issue be resolved in several steps as follows:*

- *Use* Kepler's third law *to compare the lunar orbital elements with those of the earth's revolution in order to deduce the mass ratio of earth and sun. This requires at least two parallax measurements from two different points on the earth's surface in order to relate one AU and the lunar-earth distance to the earth's radius.*
- *Use Newton's Law of Universal gravitation and his second law of motion to show that the earth and the sun must both revolve around a common center of mass which is inside the sun.*

The problem with this "proof" is that it is somewhat indirect. A better way is to directly measure the centrifugal acceleration *due to earth's circumsolar revolution. This can, in fact, be done with sensitive Eotvös-type experiment.*

Additionally, if the center of the earth's mass were really stationary relative to an inertial frame, there would be no way of understanding why there are

[204] The vastness of the universe, as revealed by conjoining the Copernican hypothesis with the minute value of stellar parallaxes, intimidated the minds of scholars and tended to prejudice many against the Copernican theory. Little did they know that the discovery of the extragalactic nature of many nebulae in the 1920's would once again vastly expand the scale of man's universe by many order of magnitudes.

[205] Namely, the compromise view that non-terrestrial planets revolve around the sun, which in turn revolves around the earth!

solar and/or lunar tides *when the respective heavenly bodies were on the other side of the earth. Incidentally, the earth's rotation about an axis is also easy to demonstrate: it partly accounts for, via the centrifugal force, for the reduced weight of objects (and the acceleration of gravity) on the equator relative to higher latitudes.*

The following four effects demonstrate that the earth rotates relative to the sun and the fixed stars:

1. Triangulation *of nearest stars.*

2. Doppler-shifts *of all stars with period of one earth-year.*

3. Stellar aberration *of light from all stars, with the same period and 90° out of phase with the Doppler-shift oscillation.*

4. Inertial forces *observed in Eotvös-type experiments that are due to orbital acceleration.*

None of these four effects can settle the question of whether the earth acceleration relative to sun and fixed stars, or the other way round. Even effects no. 4 cannot resolve this because of the Lenz-Thirring-Brill-Cohen-Mach effect. However, since effect no. 1 shows the immense distance of even the nearest stars, the Tycho interpretation appears unlikely in the extreme.

On Copernicus

"It is necessary to alter the motion of the stars a little because of the (annual) motion of the earth"

Aristarchos, ca 280 BCE (310–230 BCE)

"The Ptolemaic astronomy is nothing so far as existence is concerned; but it is convenient for computing the non-existent"

Muhammad Ibn Rushd, ca 1170 (1126–1198)

"Since, then, the earth cannot be the center, it cannot be entirely devoid of motion... It is clear to us that the earth is really in motion though this may not be apparent to us, since we do not perceive motion except by comparison with something fixed... Moreover, neither the sun, nor the moon, though to us it seems otherwise, can in its motion describe a true circle, because they do not move around a fixed base...".

Nicolas of Cusa, 1440 (1401–1464)

"... I cannot get over my amazement at the mental inertia of our astronomers in general who, like credulous women, believe what they read in the books, tables, and commentaries as if it were the divine and unalterable truth; they believe the authors and neglect the truth".

Regiomontanus, 1464 (1436–1476)

"There is talk of a new astrologer who wants to prove that the earth moves and goes round instead of the sky, the sun, and moon... The fool wants to turn the whole art of astronomy upside-down...".

Martin Luther, 1533 (1483–1546)

"... I have been informed that you have... created a new theory of the Universe according to which the Earth moves and the Sun occupies central position...; moreover, that you have written a treatise on this entirely new theory of astronomy, and also computed the movement of the planets and set them out in tables, to the greatest admiration of all.
Therefore, learned man, I beg you most emphatically to communicate your discovery to the learned world...".

From a letter of Nicolaus Schoenberg, Cardinal of Capua, written to Copernicus on Nov. 1, 1536, at the initiative of Pope Paul III.

"Copernicus had opened the eyes of the most intelligent to the fact that the best way to get a clear grasp of the apparent movements of the planets in the heavens was to regard them as movements round the sun conceived as stationary. If the planets moved uniformly in a circle round the sun, it would have been comparatively easy to discover how these movements must look from the earth".

Albert Einstein, 1930 (1879–1955)

"In philosophy proper, the 15^{th} *and* 16^{th} *centuries are on the whole not very spectacular. On the other hand, the spread of the new learning, the dissemination of books, and, above all, the renewed vigor of the ancient traditions of Pythagoras and Plato, paved the way for the great philosophic systems of the* 17^{th} *century.*
It was in the wake of this revival of ancient modes of thought that the great scientific revolution began. Starting from a more or less orthodox Pythagoreanism, it gradually overthrew the established notions of Aristotelian physics and astronomy, to finish by going right behind the appearances and discovering an immensely general and powerful hypothesis. In all this, the men who furthered such inquiries knew that they stood directly in the Platonic tradition...
The theory as Copernicus propounded it was not free from difficulties, and in some ways was dictated by preconceived notions going back to Pythagoras. That the planets must move steadily in circles seemed to Copernicus a forgone conclusion, because the circle is a symbol of perfection, and uniform motion is the only kind becoming to a heavenly body. Within the scope of the observations available, the heliocentric view with circular orbits was, however, much superior to the epicycles of Ptolemy. For here, at last, was a simple hypothesis that by itself alone saved all appearances".

Bertrand Russell, '*Wisdom of the West*' (1892–1970)

"It is a strange paradox that at every time when man was beginning to conquer nature he was obliged to drive himself away from the center of things; in proportion as he grew wiser he had to make himself smaller."

George Sarton

"Copernicus was a poor observer and it had been easier for him (as it was for Aristarchos) to formulate his new theory, because he was not embarrassed by good observations."

George Sarton

"The notion of limitlessness or infinity, which the Copernican system implied, was bound to devour the space reserved for God on the medieval astronomer's charts. They had taken it for granted that the realms of astronomy and theology were contiguous, separated only by the thickness of the ninth crystal sphere. Henceforth, the space-and-spirit continuum would be replaced by a space-time continuum. This meant, among other things the end of intimacy between man and God. Homo sapiens *had dwelt in a universe enveloped by divinity as by a womb; now he was being expelled from the womb.*

During the remainder of the sixteenth century, the new system of the universe went, like an infectious disease, through a period of incubation. Only at the beginning of seventeenth did it burst into the open and caused the greatest revolution in human thought since the heroic age of Greece.

1600 CE is probably the most important turning point in human destiny after 600 BCE. Astride that milestone, born almost exactly a hundred years after Copernicus, with one foot in the sixteenth, the other in the seventeenth century, stands the founder of modern astronomy, a tortured genius in whom all the contradictions of his age seem to have become incarnate: Johannes Kepler".

Arthur Koestler, 'The sleepwalkers', 1959

1543 CE The works of Archimedes appeared in Latin translation. **Vesalius** published *Des Humani Corporis Fabrica*.

1543–1555 CE **Petrus Ramus** (**Pierre de La Rameé**, 1515–1572, France). Humanist, philosopher, mathematician and logician[206]. Published (1543) *Aristotelicae Animadversiones* – an attack on Aristotelian logic and physics. It represented a break with the authority of medieval tradition.

Ramus defended the audacious thesis that "*Everything Aristotle taught was false*". This iconoclastic attitude was not so much an attack on Aristotle as on the medieval Peripatetic tradition which had become embedded in Scholasticism. One can therefore justly choose the year 1543 to mark the separation of medieval from modern times.

In his second book *Dialecticae partitiones* (1543), Ramus criticized university curriculum and argued for return to teaching of the seven liberal arts:

His works were suppressed and he was forbidden to teach logic (1544–1547). However, the ban was lifted by Henry II (1547) through the influence of the Cardinal of Lorraine. He was then appointed professor of philosophy at the College de France (1551) and embraced Calvinism (1561). Persecuted thereafter by academic and ecclesiastic enemies, he was assassinated in the Massacre of St. Bartholomew.

His system of logic, known as *Ramism*, emphasized logic as method of disputation and had influence in the 16^{th} and 17^{th} centuries.

Ramus was born at the village of Cuth in Picardy, a member of a noble but impoverished family. His father was a charcoal–burner. He gained admission to the college of Navare, working by day and carrying his studies at night. On taking his degree (1536) he actually took as his thesis: "Everything Aristotle taught was false". At the College de France he lectured, for a considerable time, before audiences numbering as many as 2000. He published 50 works in his lifetime and nine appeared after his death.

1544 CE **Lodovico Ferrari** (1522–1565, Italy). Mathematician. A pupil of **Cardano**. Solved the quartic equation by reducing it to a cubic

[206] Ramus was obsessed by the *Tree of Porphyry* and applied the binary tree to so many topics that it was thereafter known as the *Tree of Ramus*. Ramus coined the term *radius* (1569) saying: "*Radius est recta a centro ad perimetrum*".

equation[207]. Ferrari was taken into Cardan's house as a servant at the age

[207] His method, summarized in modern notation, is as follows: First, the general quartic is reduced to a canonical form

$$x^4 + px^2 + qx + r = 0,$$

which is recast into:

$$(x^2 + p)^2 = px^2 - qx + (p^2 - r).$$

Using this, one obtains for *arbitrary* y:

$$(x^2 + p + y)^2 = (p + 2y)x^2 - qx + (p^2 - r + 2py + y^2).$$

Then, y is chosen such that the r.h.s. of the last equation is a square. This occurs when a *cubic in* y is satisfied, namely

$$4(p + 2y)(p^2 - r + 2py + y^2) - q^2 = 0.$$

Once this is solved and y is known in terms of (p, q, r), we are left with a quadratic equation in x.
An alternative procedure consists of expressing the original quartic

$$x^4 + ax^3 + 3x^2 + cx + d = 0 \quad (1)$$

as a product of two quadratic factors:

$$(x^2 + p_1x + q_1)(x^2 + p_2x + q_2) = 0 \quad (2)$$

To find the coefficients (p_1, q_1, p_2, q_2), one carries out the multiplication of the two quadratic factors and equates its coefficients with (1), obtaining the simultaneous equations

$$p_1 + p_2 = a; \quad p_1p_2 + q_1 + q_2 = b; \quad p_1q_2 + p_2q_1 = c; \quad q_1q_2 = d \quad (3)$$

Introducing the notation

$$m = q_1 + q_2 \quad (4)$$

we eliminate the four unknown (p_1, q_1, p_2, q_2) from the five relations (3) and (4), obtaining the eliminant

$$m^3 - bm^2 + (ac - 4d)m + (4bd - c^2 - a^2d) = 0 \quad (5)$$

Assuming m to be solvable explicitly, the equations $q_1q_2 = d$ and $q_1 + q_2 = m$ yield a quadratic equation for the roots q_1 and q_2

$$q^2 - mq + d = 0 \quad (6)$$

of 14. Cardan taught him Latin, Greek and mathematics. Ferrari became

After this, we find p_1 and p_2 from (3) via

$$p_1 = \frac{aq_1 - c}{q_1 - q_2}; \qquad p_2 = a - p_1 \tag{7}$$

Thus, the solution of a 4^{th} -order equation to a solution of a cubic equation (5) and of three quadratic equations (6) and (2).
The explicit algebraic solution of the *general quartic equation*

$$a_0x^4 + 4a_1x^3 + 6a_2x^2 + 4a_3x + a_4 = 0,$$

then hinges on the solution of the *resolvent cubic*

$$u^3 - g_2u + 2g_3 = 0,$$

where

$$g_2 = a_0a_4 - 4a_1a_3 + 3a_2^2$$
$$g_3 = a_0a_2a_4 - a_0a_3^2 + 2a_1a_2a_3 - a_1^2a_4 - a_2^3$$

Denoting the roots of the cubic by $u_1, \quad u_2, \quad u_3$ (using Cardan formula), the roots of the cubic are

$$-\frac{a_1}{a_2}+\frac{1}{a_0}\sqrt{\frac{1}{2}a_0u_1 - a_0a_2 + a_1^2}+\frac{1}{a_0}\sqrt{\frac{1}{2}a_0u_2 - a_0a_2 + a_1^2}+\frac{1}{a_0}\sqrt{\frac{1}{2}a_0u_3 - a_0u_2 + a_1^2}$$

The four possible combination of the signs of the square roots are being chosen so that their product equals $-\frac{1}{2}(a_0^2a_3 - 3a_0a_1a_2 + 2a_1^3)$.

For example, the equation $x^4 + 4x^2 - 24x - 24 = 0$ is solved by

$$x_1 = -1 + \sqrt{1 + \sqrt[3]{3}} + \sqrt{1 + \omega\sqrt[3]{3}} + \sqrt{1 + \omega^2\sqrt[3]{3}},$$
$$x_1 = -1 + \sqrt{1 + \sqrt[3]{3}} - \sqrt{1 + \omega\sqrt[3]{3}} - \sqrt{1 + \omega^2\sqrt[3]{3}},$$
$$x_1 = -1 - \sqrt{1 + \sqrt[3]{3}} + \sqrt{1 + \omega\sqrt[3]{3}} - \sqrt{1 + \omega^2\sqrt[3]{3}},$$
$$x_1 = -1 - \sqrt{1 + \sqrt[3]{3}} + \sqrt{1 + \omega\sqrt[3]{3}} + \sqrt{1 + \omega^2\sqrt[3]{3}},$$

where

$$w = -\frac{1}{2} + \frac{1}{2}i\sqrt{3}$$
$$w^2 = -\frac{1}{2} - \frac{1}{2}i\sqrt{3} = w^*.$$

Cardan's personal secretary and succeeded him (1540) as public lecturer on mathematics in Milan. On Aug 10, 1548 Ferarri defended Cardan in a debate with Nicolo Tartaglia in Milan before a large and distinguished gathering. In 1565, Ferrari became professor of mathematics at the University of Bologna. It is claimed that he died of arsenic poisoning, administered by his own sister!

1544 CE **Michael Stifel** (1486–1567, Germany). The greatest German algebraist of the 16^{th} century, was born in Esslingen and died in Jena. He was educated in the monastery of his native town, and afterwards became a Protestant minister. The study of the significance of mystic numbers in the book of Daniel drew him to mathematics. He then studied German and Italian works and published (1544) in Latin, a book entitled *Arithmetica integra*. Its three parts treat respectively rational numbers, irrational numbers, and algebra. Stifel gave a table containing the numerical values of the binomial coefficients for powers below the 18^{th}. He made early steps towards logarithmic computations, and used alphabet letters to designate unknowns.

Stifel was one of the oddest personalities in the history of mathematics. Converted by Martin Luther, he became a fanatical reformer. His erratic mind led him to indulge in number mysticism. From an analysis of Biblical writings, he prophesied the end of the world on October 3, 1533 and was forced to take refuge in a prison after ruining the lives of many believing peasants who had abandoned work and property to accompany him to heaven.

An extreme example of Stifel's mystical reasoning is his proof, by arithmography, that Pope Leo X was the "beast" mentioned in the *Book of Revelation*[208] (**13**, 18).

1545 CE **Girolamo Cardano** (1501–1576, Italy), also known as Jerome Cardan. The most celebrated mathematician of the age. Physician, astrologer and a Professor of mathematics at the universities of Bologna and Milan. Was first to appreciate complex numbers and use them in computations. In his influential treatise 'Ars Magna', he put the complete solution of a general cubic equation in terms of square roots of numbers that may be positive *or* negative. In his book he admits quite candidly that he was not the original discoverer of the solution. Cardano initiated the study of probability theory in his gambler's manual "Liber de Ludo Aleae" (Book on Games of Chance) published in 1663. He discovered the p^n law for the probability of n successes in n independent repetitions of an event with probability p.

Cardano was one of the most extraordinary characters in the history of mathematics: a physician by trade, an inveterate gambler, heretic and a caster

[208] Others throughout history had claimed the "number of the beast" (616) must be interpreted as Nero, the Pope of Rome (by Napier), Martin Luther, Kaiser Wilhelm, and finally the Nazi Führer.

of horoscopes [he was imprisoned for a time for heresy because he published a horoscope of Christ's life], and undoubtedly an eccentric talent.

His contemporary fame was very largely medical and philosophical. He studied medicine in Pavia and Padua and obtained his doctorate in 1526, but was not admitted into the College of Physicians of Milan because of his illegitimate birth. He settled down as a country doctor in Sacco (near Padua) and married. According to his own recollections, the years he spent there (1526–1532) were the happiest of his life. In 1532 he was able to return to Milan as a lecturer in mathematics; but his first published book was medical (1536). In 1517 he was appointed professor of medicine in Pavia.

The celebrity which Cardan had acquired led in 1551 to his journey to Scotland as a medical advisor of Archbishop Hamilton of St. Andrews. At this point Cardan attained the summit of his prosperity, and the rest of his life was little but a series of disasters: one of his sons was a scoundrel and the other was executed for poisoning his wife. Cardan's reputation and practice waned, and crushed by the blows he addicted himself to gambling.

He was ultimately banished from Milan on some unspecified accusation and he found it advisable to accept a professorship at Bologna (1562). There he was suddenly arrested on a charge of heresy. Through the intervention of some influential cardinals Cardan was released, but was deprived of his professorship, prohibited from teaching and publishing any further. Resigning his chair in Bologna, he moved to Rome and became a distinguished astrologer, receiving a pension as astrologer to the Papal court.

1545–1563 CE **Ambroise Paré** (1510–1590, France). Surgeon. Introduced many medical innovations in the field of surgery: use of artificial limbs and tying severed arteries to stop bleeding after amputation. Instead of treating gunshot wounds with hot oil, according to the practice of the day, he had the temerity to trust a simple bandage. In 1545 he published at Paris *La Méthode de traicter les playes*. His next book was *Anatomy* (1550) and *Cinq livres de chirurgie* (1563).

He began life as apprentice to a barber-surgeon in Paris. His earliest opportunities were in military surgery during the campaign of Francis I in Piedmont. Paré was adored by the army and greatly esteemed by successive French kings; but his innovations were opposed, as usual, by the faculty, and he had to justify it as well as he could by quotations from **Galen** and other ancients.

1547–1570 CE **Andrea Palladio** (di Pietro della Gondola, 1508–1580, Italy). Architect. One of the most influential figures in Western architecture. His palaces and villas were imitated for 400 years all over the Western world; He was the first architect to systematize the plan of a house and consistently to use the ancient Greco-Roman temple front as a portico (roofed perch supported by columns). The influence of Palladio's buildings and publications reached its climax in the architecture of the 18^{th} century, particularly in England, Ireland, the United States and Italy, creating a style known as Palladianism, which is turn spread to all quarters of the world.

Palladio was born in Padua. As a youth he was apprenticed to a sculptor in Padua and at the age of 16 enrolled in Vicenza in the guild of the bricklayers and stonemasons. In 1538, he was discovered by the humanist and scholar Gian Giorgio Trissino. The name Palladio was then added by Trissino to Andrea as an allusion to the mythological figure Pallas Athena, the Greek goddess of wisdom. Palladio then turned to architecture (the ancient literature on architectural engineering and military science) and was influenced by Alberti and Bramante. He adopted principles of Roman architecture, revolting against ornamentalism. He built large palaces, churches and numerous country villas (most of them are near Vicenza, Rome, Venice and various parts of the countryside of Northern Italy). In Venice he built the facade of the churches of *San Giorgio Maggiore* (1566) and *Ill Redentore* (1576).

1550–1700 CE Leading European poets and novelists during the periods of Late Renaissance-Reformation-Baroque:

- Torquato Tasso 1544–1595
- Miguel de Cervantes Saavedra 1547–1616
- Christopher Marlowe 1564–1593
- William Shakespeare 1564–1616
- John Donne 1572–1631
- John Milton 1608–1674

1551–1555 CE **Pierre Belon** (1517–1564, France). Author of *Histoire naturelle des éstranges poisson marins* (1551) and *L'Histoire de la nature de oysseaux* (1555), containing pioneering work in *comparative anatomy* and *embryology*. He also wrote *Les Observations de plusieurs singularitez et choses memorables* (1553) on his tour of the Eastern Mediterranean.

Belon was born near Le Mans. He studied medicine at Paris, where he took the degree of a doctor, and then became a pupil of the botanist Valerius Cordus (1515–1544) at Wittenberg, with whom he traveled in Germany. During 1546–1549 he traveled through Greece, Asia Minor, Egypt, Arabia and Israel.

Belon was assassinated at Paris one evening when coming through the Bois de Boulogne.

1551–1563 CE **George Joachim** (**von Lauchen**) **Rheticus** (1514–1567, Germany). Astronomer, mathematician and physician. Latinized his name into Rheticus since his birthplace, Feldkirch in Tyrol, was anciently the territory of Rhaetica. As a young man he studied at the Universities of Zürich, Nuremberg and Göttingen. At the age of 22, he was appointed professor of mathematics and astronomy at the young University of Wittenberg, center and glory of Protestant learning.

Being greatly attracted by the new Copernican theory, he resigned the professorship in 1539 and went to Frauenburg with a determined purpose to set in motion the Copernican Revolution which Copernicus himself tried to suppress. Soon, a most peculiar situation arose in which Rheticus was pressing for publication of 'De Revolutionibus', while Copernicus maintaining his stubborn opposition. Eventually, he prepared his master's work for publication in 1542, but afterwards lost all interest in the subject – because Copernicus failed to mention his name anywhere in the text.

Rheticus survived his master by more than 30 years, leading a restless and hectic life in Leipzig, Italy, Cracow and Cassovia in Hungary. During 1551–1563 he completed a monumental work on trigonometry which secured him an honorable place in the history of mathematics: he was first to define the trigonometric functions in a right triangle and prepare tables of these functions to seven decimal places at intervals of 10 arcseconds. These were published posthumously by his pupil **Valentinus Otho** (ca 1550–1605).

1552–1553 CE **Thomas Gresham** (1519–1579, England). The financial adviser to Queen Elizabeth I. Developed methods to raise the value of the pound sterling by operations that involved actuarial problems in probability, however rudimentary. Bequeathed his property for the foundation of the first chair of geometry in London's Gresham College in 1596, founded by him. **Henry Briggs** was the first incumbent, to be followed later by **John Wallis**, **Edmund Halley** (1656–1742) and **Christopher Wren** (1632–1723).

Established the economic law (known as: *Gresham's Law*): bad coin drives out good coin.

1553 CE *Burning of the Talmud* by **Pope Julius III** on September 9 (Jewish New-Year day) at Plazza Campo de Fiori in Rome [at the same place they burned Giordano Bruno in 1600]. On September 12, the head of the Inquisition, **Giovanni Pietro Caraffe** ordered the Talmud to be burned throughout Italy. When this man was elected **Pope Paul IV**[209] (1555), he issued a decree which, for ferocious anti-Jewishness, was not equaled until the coming of Hitler in modern Germany. During his terrible reign, Jews and their books kept burning. When he died (18^{th} Aug. 1559) Romans vented their hatred by demolishing his statue, liberating the prisoners of the Inquisition and scattering its papers.

209 Paul's want of political wisdom and ignorance of human nature were fatal to the Christian Church; he joined with France (1555) in order to drive the Spaniards out of Italy. But the victory of Philip II at St. Quentin (1557) and the threatening advance of Alva upon Rome forced him to abandon his French alliance. He denounced the peace of Augsburg as a pact of heresy; nor would he recognize the abduction of Charles V and the election of Ferdinand. By insisting upon the restitution of the confiscated church-lands, regarding England as a papal fief, requiring Elizabeth (whose legitimacy he aspersed) to submit her claims to him, he brought about the final break of England with the Church of Rome.

Science Progress Report No. 5

The "Marranos" – Or how Portugal and Spain sank back into the Middle Ages (1498–1615)

The banishment or forcible conversion of the Jews deprived Portugal of its middle class and of its most scientific traders and financiers. Though the Jews had always been compelled to reside in Ghettos, they had been protected by the earlier Portuguese kings. Before 1223 *their courts had received autonomy in civil and criminal jurisdiction; their chief rabbi was appointed by the king and entitled to use the royal arms on his seal.*

Alphonso V even permitted his Jewish subjects to live outside the Ghetto, relieved them from the obligation to wear a distinctive costume (enforced 1325), and nominated a Jew, ***Itzhak Abravanel*** *(1437–1508) as his minister of finance. In all cultural disciplines, the Portuguese Jews surpassed their rulers. Many of them were well versed in Aristotelian and Arabic philosophy, astronomy, mathematics, cartography, nautical science, and especially in medicine. Three Jewish printing presses were established between* 1487 *and* 1495*; both John II, and Emanuel I, employed Jewish physicians. It was a Jew –* ***Avraham ben Shmuel Zacuto*** *(1450–1515) – who supplied Vasco da Gama with nautical instruments; and it was another Jew,* ***Pedro Nuñes*** *(1492–1577) who invented the* nonius*, the Mercator projection and as a peak figure in Portuguese science became the cartographer Royal in* 1529*. Moreover, the Jews were employed in the overland journeys by which the Portuguese court first endeavored to obtain information on Far Eastern affairs.*

However, while protected by the kings and tolerated by the lower classes, the other orders – the ecclesiastics and nobles resented their religious exclusiveness or envied their wealth, and gradually fostered the growth of popular prejudice against them. In 1449 *the Lisbon Ghettos were stormed and sacked, and between* 1450 *and* 1481 *the Cortes four times petitioned the Crown to enforce the anti-Jewish provisions of the canon law. John II gave asylum to* 90,000 *Jewish refugees from Castile* (1492)*, in return for heavy poll-tax and on condition that they leave the country within* 8 *months, in ships furnished by himself. These ships were not provided in time, and the Jews who were thus unable to depart were enslaved, while their children were deported to the island of St. Thomas and there perished.*

In 1496 *Emanuel I desired to wed Isabella*[210]*, daughter of Ferdinand and Isabella, but found that he was first required to purify his kingdom of the*

[210] She died, anyway, one year after the wedding, leaving Emanuel with neither wife nor Jews.

Jews, who were accordingly commanded to leave Portugal before the end of October 1497*. But in order to avoid the economic dangers threatened by such an exodus, every Jew and Jewess between the ages of* 4 *and* 24 *was seized and forcibly baptized (March 19, 1497): "Christians" were not required to emigrate.*

In October 1497*,* 20,000 *adults were treated in the same way. These "New Christians" or "Marranos"*[211] *as they were called, were forbidden to leave the country between* 1497 *and* 1507*. In April* 1506*, most of the Marranos who resided in Lisbon were massacred during a riot. The rest were permitted to emigrate – an opportunity of which the majority took advantage. Large numbers settled in Holland where their scientific, commercial, and financial skills greatly assisted the Dutch in their rivalry with the Portuguese.*

After the main body of Jews had been banished from Spain and had fled from Portugal, the Inquisition was turned against converted Moors and eventually upon the Christians themselves.

The Reformation never reached Portugal, but even here the critical tendencies which elsewhere preceded Reform, were already at work. Their origin is to be sought not so much in the Revival of Learning as in the fact that the Portuguese had learned, on their voyages of discovery, to see and think for themselves. This interest in the physical world and the true scientific spirit was seen by orthodox churchmen as a threat to religious doctrines previously regarded as beyond criticism.

To check this "dangerous" trend, the Holly Office *was established in Lisbon in* 1536*, where the first* auto-da-fe *was held in* 1540*. The worst vices of the Inquisition were the widespread system of delation it encouraged by paying informers out of the property of the condemned. Quite as serious, in their effects upon national life, were the severe censorship to which all printed matter was liable before publication and the control of education by the Jesuits.*

Portuguese education centered in the national University of Coimbra*, which had long shown itself ready to assimilate new ideas. By* 1555 *The Jesuits had secured control over Coimbra – a control which lasted for two centuries and extended to the whole educational system of the country. The effects of this change upon the national character were serious and permanent. Portugal sank back into the Middle Ages. The old initiative and self-reliance of the nation, already shaken by the brain-drain of the Jews and years of disaster, were now completely undermined, and the people submitted without show of resistance to a theocracy disguised as absolute monarchy.*

In Spain, the harassment of the Marranos became unbearable as time went on. Those who possessed the means sought to escape from the country.

[211] Meaning *pigs* in Spanish.

Unfortunately, the great majority of Marranos had become desperately poor. They saw little hope of cutting themselves loose from the fatal net of their double loyalty: as Christians openly, and as Jews secretly. Many resigned themselves to the hopelessness of their lot, and went over completely to the Church.

But eventually the power of Spain started to crumble. First came the successes of the Dutch in their struggle to gain independence from Spanish rule, which was marked by the Union of Utrecht *in* 1579*. This was followed by the crushing defeat the Great Armada by the English navy* (1588) *– the prison walls of Spain and Portugal finally fell down. In* 1593 *the Iberian* Marranos *began to move to the free Protestant Netherlands. Official permission was granted to them to settle in Amsterdam in* 1615*. The Dutch never had occasion to regret their settlement in their country; from their activities prosperity and energy flowed to Amsterdam. With their help the city became one of the principal maritime centers of Europe. By and large, the* Marranos *were enterprising merchants and traders. They were fluent in many tongues and were thus ideally suited for carrying on international commerce.*

Moreover, they had world-wide connections with the dispersed communities of Spanish and Portuguese Jews and Marranos*, especially in the countries of North Africa, in Arab lands, Turkey, Greece, Persia and India. They also established important shipping branches in such strategic trade ports as Livorno, Genoa, Venice and Naples.*

Finding a ready and unrestricted field for their energies, the ex-Marranos of Amsterdam founded new factories and industries. They also did an effective banking business; at one time they controlled more than a quarter of the stock of the East India Company which played such a decisive role in the history of New York. The prosperity and the relative freedom they enjoyed in Amsterdam drew more and more Marranos *from Spain and Portugal to the city.*

The exceptional vitality and capability of the freedom-seeking Marranos exemplified itself in the story of The House of Nasi, The Duke of Naxos*. Operating from Muhammedan Turkey, the family played an important role in European politics during 1553–1569. The main characters in the drama was* ***Donna Gracia (Hanna) Mendez-Nasi*** *(ca 1510–1569) and her nephew* ***Yosef Nasi*** *(ca 1524–1579).*

The compulsory baptism in Portugal (1497) left the Mendez family [Francisco and Diego Mendez and their wives Beatrics and Reyna] residing in Lisbon. They were bankers with wide connections, with branch offices in Holland and debts due them from the kings of France. After the death of Francisco (1536) and Diego (1543) the clever and gracious Donna Beatrics took over, with the Inquisition always at her heels, she managed to move her business *through Antwerp and Venice to Turkey (1553), where, under the protection of the powerful sultans Suleimen and Selim, her business flourished to such a degree that she had her own private navy.*

In Turkey she openly returned to Judaism and resumed her original name of Donna Gracia Nasi. Her nephew, Joã Migues followed her there, married her daughter and adopted his Jewish name, Yosef Nasi. He rose high in the favor of the Sultan, who created him duke of Naxos. Yosef exerted great influence on the foreign affairs of the Turkish empire at its height and for a while was among the most powerful statesmen in Europe; he had conquered Cyprus for the Sultans and negotiated with the Emperor of Germany, Maximillian II, William of Orange and Sigismund August II, King of Poland. His career was one of the tokens of the new era that was to dawn for the Jews as trusted public officials and as members of the state.

Everywhere they went, the Marranos *brought with them to Amsterdam their superior culture. Even under the oppression of the Holy Office they had functioned in Spain and Portugal as doctors, lawyers, scholars, writers, university professors, army officers, and even as statesmen, diplomats and landed* hidalgos*. In* New Jerusalem *(as Amsterdam was called by the Jews) they picked up the threads of their past callings and many achieved great distinction in them. They helped advance both Jewish and Dutch cultures in all branches.*

Fore and foremost in eminence is the philosopher ***Baruch Spinoza*** *(1632–1677) whose grandfather came from Portugal in* 1579*. Among the physicians,* ***Avraham Zacuto II*** *(1575–1641) [*known as ***Zacutus Lusitanus****] was the foremost Jewish doctor in Holland in the days of Rembrandt and a pioneer in medical history. He came to Amsterdam from Lisbon* (1625)*, where his great grandfather was a famous astronomer. Zacuto II published important books in which he foreshadowed later medical discoveries. In France,* ***Eliyahu Montalto*** *(1550–1616) was a member of the large group of Marranos who distinguished themselves in medicine.*

Itzhak Cardoso *(1610–1685), studied medicine at Salamanca and settled (1632) in Vallabolid. Became chief physician to the Court in Madrid, but was forced to flee the Inquisition and settled in Verona, Italy. There he reverted to Judaism, taking the name Itzhak. Published a number of books on medicine, the natural sciences and philosophy. His brother* ***Michael Avraham Cardoso*** *(1627–1706), also a physician, became one of the ardent followers of Shabetai Zvi.*

Immanuel Rosales *(1593–1668) was a mathematician, astronomer and a famous physician. His family originated from the town Castallvi de Rosanes near Barcelona. Upon the expulsion of the Jews from Spain (1492), the family fled to Lisbon, where they became Marranos. Rosales studied mathematics* *and medicine at Montpelier and became a famous physician. Fleeing from the Inquisition he reached Rome (1625) and then practiced medicine in Amsterdam, where he reverted openly to Judaism. The Rosales (Rosanes) family spread from Spain to North Africa, Europe and the Near East.*

Ludovico Mercato *(1525–1611) from Vallaboild, Spain, became physician to Kings Phillip II and Phillip III.*

The Marrano family **de Castro** *issued a number of famous physicians who escaped the jaws of the Inquisition;* ***Roderigo*** *(1546–1627) was one of the foremost physicians to establish gynecology in the Renaissance period and a prolific medical writer. He received his education in Pisa and became a professor of medicine. Died in Hamburg*[212]*;* ***Itzhak*** *(1620–1687) was also a prolific medical writer. Died in Amsterdam.*

The physician ***Garcia da Orta*** *(1500–1560) fled Portugal as far as Goa and during 1534–1563, prepared singlehandedly a unique encyclopedia of medical plants. But the long hand of the Inquisition reached sentenced and burned his "heretic" body, twenty years after his death.*

The Portuguese Marrano family **Teixeira** *(also known by the name Teixeira de Mattos or Teixeira de Sampayo) became noted in Western Europe and Brazil during the past four centuries for their philanthropy as well as their financial, diplomatic and scientific achievements:*

Benito Teixeira *(ca 1545–1600) was an author and martyr. He lived in Brazil for 30 years and described his travels in books. The Inquisition arrested him in Bahia, sent him to Lisbon where he was burned at the Stake.*

Pedro Teixeira *(1570–1650) became one of the greatest explorers of the* 17^{th} *century, and reverted to Judaism in Antwerp.*

Diego Teixeira Sampayo *(Avraham Senior Teixeira, 1581–1666) became the diplomatic representative of Queen Christina (of Sweden) in Hamburg. He left Portugal (1643) and openly acknowledged Judaism (1647).*

His son ***Manuel Teixeira*** *(Itzhak Hayyim Senior Teixeira, 1625–1705) continued the diplomatic and financial career of his father and became the leader of the Spanish–Portuguese community in Amsterdam. In the* 18^{th} *century we find members of his family as educators, writers, statesmen and scientists in Brazil, Italy, Holland, England, Austria and Germany. Among them:* ***Gomes Teixeira*** *(1860–1941) was the president of Portugal (1923–1925); the poet and writer* ***Teixeira de Pascoais***[213] *(1877–1952); the mathematician* ***F.G. Teixeira*** *who extended Bürmann's theorem (1900);* ***Anisio Spinola***

[212] His son **Benedict** (1597–1684), also a physician at Hamburg, became the personal physician of Queen **Christina** of Sweden.

[213] Pseud. of Joaquim Pereira de Vasconcelos

Teixeira, *a Brazilian educator;* ***Mario Teixeira de Carvalho*** *(b. 1906), a Brazilian physician and writer.*

Among the Marranos lost to Judaism were the Spanish writer ***Fernando de Rojas*** *(1465–1541, Spain), the French philosopher* ***Michel de Montaigne***[214] *(1533–1592) and* ***Mario Soares***, *former prime minister of Portugal.*

1553–1572 CE **Moshe Isserles** ("REMA"[215], ca 1525–1572, Poland). Jewish scholar, Talmudist, codifier and philosopher. One of the great halakhic authorities and one of the founders of rabbinic learning in Poland and Germany. He was recognized as the authority not only in rabbinic law but also in philosophy, Kabbalah, astronomy and the secular sciences. Wrote ten books on halakhic, philosophical, exegetical and scientific subjects[216]. These works contain Biblical exegesis and commentaries, codification of religious laws, responsa and philosophical matters. In his philosophical system he followed Maimonides to which he can be compared in his universal outlook, manner of study, character and his attachment to both Talmudic and secular knowledge. His philosophy of Judaism is expounded in his book *Torat ha-Olah* (Prague, 1570).

Isserles was born in Cracow, Poland, a son of a wealthy and influential Talmudic scholar. He studied in Lublin and in 1553 built a synagogue in Cracow (called 'the synagogue of the Rema'), which still exists today. He died in Cracow and was buried next to his synagogue. Until WW II, thousands of Jews from all over Poland made a pilgrimage to his grave every year on the anniversary of his death.

1555 CE The Age of the Jewish *Ghetto* began officially when compulsory segregation was imposed by Pope Paul IV. By the end of the 16^{th} century the ghetto had become an accepted institution in Italy, from Rome to the Alps. All ghettos were locked at night. Jews who went outside the ghetto were required to wear a distinguished badge on their garments. They could not enter a profession except (with severe restrictions) that of medicine. To

[214] His mother Antoinette de Louppes (Lopez) was of Spanish Marrano origin.

[215] Acronym of Rabbi Moshe Isserles. His full name Israel–Eliezer was shortened to Isserles

[216] E.g. he wrote a commentary on the *Theorica of George Peurbach*.

travel out of town they required special permits. Almost everywhere they were compelled to attend conversionist sermons. The police gave adequate protection to the ghetto from concerted attacks, but only reluctantly in cases of individual molestation. There were about 30,000 Jews living in Italy in the 17^{th} and 18^{th} centuries.

When the French armies entered Italy (1796–1798), the new revolutionary spirit momentarily triumphed: the walls of the ghetto were demolished and the Jews received equal rights. However, in 1815, the restoration resulted in a complete and almost general renewal of the old conditions.

1556 CE, Jan. 23 An *earthquake* in Shansi Province, China caused the death of ca 830,000 persons. No higher death toll from a natural disaster has ever been recorded (ca 700,000 people perished on July 27, 1976 during a major earthquake in the Hopeh Province, China).

1557 CE **Robert Recorde** (ca 1510–1558, England). Welsh physician and mathematician. Lived at a time of social change, economic expansion and religious strife in England. An active participant in the turbulent life of his times, Recorde rose to a position of great trust and responsibility, becoming a physician to Edward VI and Queen Mary. A courageous man with the rare gift of loyalty and compassion, the span of his life was not without its tragedy.

He entered the University of Oxford in 1525. He went later to Cambridge to study medicine and received his M.D. there in 1545. Recorde introduced the equality sign (=) into algebra and systematized its notation. He justified his adoption of a pair of equal parallel line segments for the symbol of equality, as follows: "*bicause noe 2 thynges can be moare equalle*".

Recorde virtually established the English school of mathematics and was first to introduce algebra in England.

Recorde died in King's Bench prison, South Wark, where he was confined for debt.

1558 CE **Luigi Cornaro** (1475–1566, Italy). Dietician. Established theories on the relationship between food and health. A member of the powerful Cornaro family of Venice, he spent the first 40 years of his life indulging his passion for food and drink. After a period of serious ill health, he was threatened by his physician with death if he continued to indulge himself. He then resolved to restrict his diet drastically, eventually reducing it to a single egg a day. His *Discorsi sulla vita sobria* (1558) includes some of the first systematic accounts of diet. It enjoyed great popularity and was widely translated, largely because Cornaro himself lived to the age of 91.

1558–1565 CE **Federigo Commandino** (1509–1575, Italy). Mathematician. Rendered a new translation (1558) of the works of Archimedes into

Latin, thus stimulating subsequent interest in integration techniques. In his work *De centro gravitatis solidorum* (1565) he established a theorem (may have been known to the ancient Greeks), bearing his name and stating that: *The four medians of a tetrahedron* (lines joining vertices to centroid of opposite faces) *are concurrent in a point that quadrisects each median*. In this book he also applied integration techniques of Archimedes to the determination of *centers of gravity*.

1559 CE **Matteo Realdo Colombo** (1516–1559, Italy). Anatomist. Demonstrated pulmonary circulation, the process of blood circulating from the heart to the lungs and back. This showed that Galen's teachings were wrong[217], and was of help to William Harvey (1628).

Colombo was born at Cremona. He was a pupil of **Andreas Vesalius** and became his successor at the University of Padua. Colombo is also remembered for his 'discovery' of the *clitoris*.

1560 CE *Smallpox* epidemic sweeped Brazil; millions died.

1560–1667 CE '**Accademia Secretorum Naturae**' (Academy of the Secrets of Nature) established in Naples. It was the oldest scientific society in modern times. This organization was dissolved after several years following charges of witchcraft practice. Another society, in Rome, '**Accademia dei Lincei**', was established in 1601 and included Galileo. It was closed in 1630 due to pressure from the Church. A third society was established in Florence in 1650, named '**Accademia dei Cimento**' (Academy of the Experiments) and included Torricelli. It dispersed in 1667 when its patron, Leopold Medici was appointed cardinal. Its last member fell into the hands of the Inquisition and committed suicide.

1560–1572 CE **Rafael Bombelli** (1526–1572, Italy). Mathematician, engineer and architect. Inventor of *complex numbers*. In a work entitled 'L'Algebra', he extended Cardano's work and initiated the actual algebra of complex numbers. Improved algebraic notation, including the earliest approach to *index notation*. The first person to write down the rules for addition

---

[217] His *De re anatomica* (1559) claims that blood circulates from the right chamber of the heart to the lungs and then to the left chamber. **Galen** thought that the blood passes directly between the two chambers.

Michael Servetus' anonymously published book on theology contains (1553) his view (to be demonstrated by Colombo in 1559), that blood circulates from the heart to the lungs and back. When his authorship was discovered, his unorthodox theological views resulted in Servetus being burned at the Stake (1553) in Geneva by **John Calvin**.

and multiplication of complex numbers. He showed that using his methods, correct real solutions could be obtained from the Cardan–Tartaglia formula for the solution of the cubic equation even when the formula gave an expression involving the square roots of negative numbers.

Presented the first explicit use of imaginary numbers in solving the cubic equation $x^3 = 15x + 4$. Employed continued fractions to approximate square roots. In our modern symbolism he showed that $\sqrt{a^2+b} = a + \frac{b}{2a+}\frac{b}{2a+}\cdots$. A similar result appeared in 1613 in a treatise published by **Pietro Antonio Cataldi** (1548–1626, Italy).

Rafael Bombelli was born in January 1526 in Bologna, Italy, the eldest son of Antonio Mazzioli, a wool merchant, and Diamante Scudieri, the daughter of a tailor. Sometime early in the sixteenth century, the Mazzioli family changed its surname to Bombelli, perhaps due to political difficulties surrounding the family's support of a failed coup. The young Rafael always went by the Bombelli name.

Little is known about Bombelli's early life. He was a student of the engineer-architect, Pier Francesco Clementi of Corinaldo, and it was thus under Clementi that Rafael learned this trade. Throughout most of his working life, Bombelli worked in the employ of Monsignor Alessandro Ruffini, a Roman nobleman and later bishop of Melfi. Most notably, Bombelli helped engineer the reclamation of the marshes of the Val di Chiana which began, under Ruffini's patronage, some time prior to 1549. This project was suspended for some years between 1555 and 1560, and it was during part of this hiatus (1557–1560) that Bombelli did much of the algebraic work that ultimately became his book, *Algebra*, part of which was published in 1572.

Bombelli traveled repeatedly to Rome, working as a consultant to Pope Pius IV on the proposed reclamation of the Pontine marshes. It was during one of Bombelli's Roman sojourns in the 1560s that he met and began working with Antonio Maria Pazzi on the newly found manuscript of Diophantus' *Arithmetica*.

Bombelli died in 1572. At the time of his death, only the algebraic books, Books I–III, of the *Algebra* had been published. The geometrical part, Books IV–V, were discovered in manuscript form in 1923 and were published for the first time only in 1929.

Evolution of Algebraic Notation

Some of the symbols encountered by a student of mathematics, such as $>$, $<$, $=$, $+$, $-$, $\times$, $:$, $\{\ \}$, $[\ ]$, $(\ )$, $::$, $!$, $\sqrt{\ }$, $\sqrt[3]{\ }$, ∞, Σ, π, e, i, a^x, a^n, log, sin, cos, tan, a_n, $a, b, c, d, e, \ldots, m, n, \ldots, x, y, z$, $f(x)$, $\Gamma(x)$, *are little more than* 400 *years old. Yet we know that already the ancient mathematicians of Babylonia, India and Greece, communicated via comprehensible algebraic statements. How did they do it?*

We can discern three stages in the historical evolution of algebraic symbolism:

(1) Rhetorical algebra. Prior to Diophantos of Alexandria (ca 250 CE), solutions to problems were written, without any abbreviations or symbolism, as pure prose statements.

(2) Syncopated algebra. A method by which stenographic abbreviations were adopted for some of the frequently recurring entities, relations and operations.
One of Diophantos' significant contributions to algebraic development was his syncopation of Greek algebra. In the rest of the world (with the exception of India) rhetorical algebra persisted for many hundreds of years. Specifically, in Western Europe algebra remained essentially rhetorical until the 15^{th} *century.*

(3) Symbolic algebra. Solutions to problems appear largely in a mathematical shorthand made up of symbols having little apparent connections with entities and ideas they represent. Symbolic algebra made its first appearance in Western Europe in the 16^{th} *century, but developed so slowly that it did not become widespread until about 1650.*

In his book Arithmetica [arithmos = number, techne = science], ***Diophantos*** *used the following method of syncopation: Greek letters were given numerical values:*

$$\alpha(1), \beta(2), \ldots, \iota(10), \kappa(20), \ldots, \rho(100), \sigma(200), \ldots, \omega(800)$$

[thus $13 = \iota\gamma$, $31 = \lambda\alpha$, $742 = \psi\mu\beta$*]. Unknowns were denoted by a final sigma* (ς)*, unknown square by* Δ^{Υ} *[first two letters of the Greek word dunamis (ΔΥΝΑΜΙΣ)], unknown cube by* K^{Υ} *[first two letters of the word kubos (ΚΥΒΟΣ),* 4^{th} *power by* $\Delta^{\Upsilon}\Delta$, 5^{th} *power by* ΔK^{Υ} *and* 6^{th} *power by* $K^{\Upsilon}K$*. The symol* $\wedge$ *stood for the minus sign. Thus*

$$x^3 - 8x^2 + 2x - 3$$

would appear as

$$K^{\Upsilon}\alpha\varsigma\beta \wedge \Delta^{\Upsilon}\epsilon\mathring{M}\gamma$$

and read literally as (unknown cubed 1*, unknown 2) minus (unknown squared 8, units 3). Here,* $\mathring{M}$ *is an abbreviation of the Greek word monades (MONAΔΕΣ) for 'units'.*

The Hindus had their own syncopation. Addition was indicated by juxtaposition, subtraction by placing a dot over the subtrahend, multiplication by writing bha (the first syllable of the word bhavita, "the product"), division by writing the divisor beneath the dividend, square root by writing ka (from the work karana, "irrational") before the quantity. ***Brahmagupta*** *(628) indicated the unknown by* $y\bar{a}$*, known integers by* $r\bar{u}$ *and a second unknown by* $k\bar{a}$*. In this notation*

$$5xy + \sqrt{13} - 4$$

appears as

$$y\bar{a}\ k\bar{a}\ 5\ bha\ ka\ 13\ r\bar{u}\ \dot{4}.$$

The symbolic stage may have began in 1486*, when* ***Johannes Widman*** *introduced the* $+$ *and* $-$ *signs. It was followed with the radical sign* ($\sqrt{\ }$) *in* 1525 *by* ***Christoff Rudolff*** *and the equality sign* (=) *of* ***Robert Recorde*** *in 1557.* ***Rafael Bombelli*** *(1572) denoted square root by Rq and cubic root by Rc. The compound expression* $\sqrt{7 + \sqrt{14}}$ *would have been written by him as* $R[7pR14]$*, whereas the expression* $\sqrt[3]{4 + \sqrt{-11}} + \sqrt[3]{4 - \sqrt{-11}}$ *would be cast as* $Rc[4p\ dim\ Rq\ 11]p\ Rc[4m\ dim\ Rq\ 11]$.

The following table demonstrates the notation of Bombelli:

Modern notation	*Bombelli printed*	*Bombelli wrote*
$5x$	$\overset{\overset{1}{\smile}}{5}$	$\overset{\overset{1}{\smile}}{5}$
$5x^2$	$\overset{\overset{2}{\smile}}{5}$	$\overset{\overset{2}{\smile}}{5}$
$\sqrt{4 + \sqrt{6}}$	$Rq\lfloor 4pRq6\rfloor$	$R\lvert\underline{4pR6}\rvert$
$\sqrt[3]{2 + \sqrt{0 - 121}}$	$Rc\lfloor 2pRq\lfloor 0m121\rfloor\rfloor$	$R^3\lvert\underline{2pR\lvert\underline{0m121}}\rvert\rvert$

Although authors such as ***Pacioli*** *had made limited use of notation, others such as* ***Cardano*** *had used no symbols at all. Bombelli, however, used quite* *sophisticated notation. It is worth remarking that the printed version of his book uses a slightly different notation from his manuscript, and this is not really surprising for there were problems associated with the printing of mathematical notation which to some extent limited the type of notation which could be used in print.*

***Francois Viète** (1579), the greatest French mathematician of the* 16^{th} *century, did much for the development of algebraic symbolism. He used vowels to represent unknown quantities and consonants to represent known ones, but had no symbol for equality. He would have written*

$$5BA^2 - 2CA + A^3 = 0$$

as:

$B5$ *in* A *quad* $- C$ *plano* 2 *in* $A + A$ *cub aequatur* D *solido.*

In 1586, ***Simon Stevin** introduced a notation of encircled numerals to denote mere exponents, e.g.*

$$9 \textcircled{4} -14 \textcircled{3} +6 \textcircled{1} -5$$

meant

$$9x^4 - 14x^3 + 6x - 5.$$

Through this notation he did not avoid fractional exponents, and was ignorant only of negative exponents.

***René Descartes** (1637) introduced our present custom of using the latter letters of the alphabet for unknowns and the early letters for knowns. He also introduced the present system of indices* x, x^2, x^3, *etc.* ***Thomas Harriot** (1588) gave us our present inequality signs* $>$ *and* $<$ *and* ***William Oughtred** (1631) left us the cross* ($\times$) *for multiplication, and the four dots* (::) *used in a proportion.* ***John Wallis** (1655) introduced negative and fractional exponents and the symbol* ∞ *for infinity.* ***William Jones** was first to use* π *for the ratio (perimeter/diameter) of a circle, in* 1706.

*We owe to **Euler** the symbols* $f(x)$ *for functional dependence,* Σ *for the summation sign,* $\iota = \sqrt{-1}$, e *and the adoption of* π *in* 1737. *The factorial symbol* $n!$ *was introduced in* 1808 *by **Christian Kramp** of Strasbourg.*

Table 2.9 exhibits milestones in the history of symbolic algebra. Once introduced, the symbols did not become popular overnight. On the contrary, often fifty years or more elapsed before anything resembling a unanimous adoption of the symbol was achieved.[218]

[218] Additional material on this subject can be found in:
- Cajori, F., *A History of Mathematical Notation*, Dover publications, Inc: New York, 1993, volume I (451 pp.) and volume II (365 pp.).

Table 2.9: Milestones in the History of Symbolic Algebra

Symbol	Meaning or Name	Date Introduced	Inventor
$+$	Plus	1486	Johannes Wideman
$-$	Minus	1486	Johannes Wideman
$\sqrt{\ }$	Square root	1525	Christoff Rudolff
$()$	Parentheses	1556	Nicolo Fontana (Tartaglia)
$=$	Equals	1557	Robert Recorde
.	Decimal point	1617	John Napier
$a > b$	a greater than b	1631	Thomas Harriot
$a < b$	a less than b	1631	Thomas Harriot
$\times$	Multiplication	1631	William Oughtred
$\cdot$	Multiplication	1631p	Thomas Harriot
AB	Multiplication by juxtaposition	1637	René Descartes
x, y, z	Letters near the end of the alphabet for unknown quantities	1637	René Descartes
a, b, c	Letters near the beginning of the alphabet for known quantities	1637	René Descartes
$a^1, a^2, a^3 \ldots$	positive integer powers	1637	René Descartes
$a^{-1}, a^{\frac{1}{2}}, \ldots$	negative integer or a fractional powers	1656	John Wallis
∞	Infinity	1656	John Wallis
$\div$	Division	1659	John Rahn
a^n	n any real number	1676	Isaac Newton
π	The ratio of circumference to diameter in a circle	1706	William Jones
$a \leqq b$	a less than or equal to b	1734	Pierre Bouguer
$a \geqq b$	a greater than or equal to b	1734	Pierre Bouguer
$\neq$	Not equal	1740	Leonhard Euler

p = posthumously

1565 CE **Bernardino Telesio** (1509–1588, Italy). Natural philosopher. Proposed the first system of physics to rival that of Aristotle. In it he sowed the seeds from which sprang the scientific methods of Bacon and Descartes, with their rich and manifold results. He therefore abandoned the purely intellectual sphere and proposed an inquiry into the data gathered by the senses, from which he held that all true knowledge really comes.

Telesio was born of noble parentage near Naples and was educated at Milan by his uncle, himself a scholar of eminence. His studies included a wide range of subjects: classics, science and philosophy, which constituted the curriculum of the Renaissance savants. He lectured at Naples and finally founded the Academy of Cosenza. His ideas were expounded in his work *De Rerum Natura*. The heterodox views which he maintained aroused the anger of the Church, and a short time after his death his books were placed on the Index.

1566 CE **Aldus Manutius (Manuzio) the Younger** (1547–1597, Venice). Publisher and erudite; defined the *full stop sign* as a dot at the end of the sentence, in his punctuation handbook "*Interpungendi ratio*". Here he described, for the first time, its ultimate role and aspect. He thought he was offering a manual for typographers; he could not have known that he was granting all future writers and readers, the gifts of sense and music in all the literature to come.

The need to indicate the end of a written phrase is probably as old as writing itself, but the solution, brief and wonderful, was not set down until the Italian Renaissance.

"No iron", **Isaac Babel** wrote, "can stab the heart with such force as a full stop put just at the right place".

Aldus was a member of an Italian family , famous in the history of printing as organizers of the *Aldine Press*. He became head of the Aldine press (1574). Appointed professor of literature to the Cancellaria at Venice; Occupied the chair of eloquence at the University of Bologna (1585).

1568 CE **Gerhardus Mercator** (**Gerhard Kremer, Gerard de Cremere**, 1512–1594, Netherlands). Cartographer. Published a projection for world maps ('Mercator Projection')[219] suited for navigation, with a grid of

[219] **Pedro Nuñez** employed the same projection already in 1533 and described it in his treatise *De arte atque ratione navigandi* (1546). He also discovered the *loxodromic curves* before Mercator, in 1533.

Mercator's projection – in which a spherical surface (representing the earth) is straight parallel lines representing longitudes and latitudes. It was one of the first attempts to base cartography upon solid mathematical principles. His chart facilitated both dead reckoning and the problem of rhumb-line sailing.

Mercator was born at Rupelmonde, in Flanders (now Belgium). He studied at Louvain and independently under the mathematician **Gemma Frisius** from whom he derived much of his inclination to cartography and scientific geography. He started to produce maps in 1537. In 1538 appeared Mercator's map of the world in hemispheres (north and south). In 1541 he issued the celebrated *terrestrial globe*. In 1551 a *celestial globe* followed.

Mercator was inclined toward Protestantism; in 1533 he had retired for a time from Louvain to Antwerp, partly to avoid inquiry into his religious beliefs; in 1544 he was arrested and prosecuted for heresy, but escaped serious consequences (two of the 42 arrested with him were burnt, one beheaded, two buried alive). Consequently, he was released and emigrated to Germany to become cosmographer to the Duke of Cleve (1564). He spent the rest of his life issuing regional maps of Europe, using his own projection. He did excellent service in helping to free the 16^{th} century geography from the tyranny of Ptolemy.

---

projected from the sphere's center onto the circumscribing cylinder tangent to it at the equator – is a particular case of the *conical orthomorphic* group. The introduction of this type of projection is due to the fact that for navigation it is very desirable to possess charts which yield correct *local* outlines (orthomorphic) and at the same time represent by a straight line any line which cuts the meridians at a constant angle (conformal). The latter condition clearly necessitates parallel meridians, and the former – a continuous increase of scale as the equator is departed from, i.e., the scale at any point must be equal to the scale at the equator times a function of the latitude angle θ – which turns out to be $\sec\theta$ for the Mercator projection.

In early days the calculations were made by assuming that for a small increase of latitude, say $1'$, the scale was constant, then summing up the small lengths so obtained. Nowadays (assuming for simplicity that the earth is spherical) we say that an infinitesimal length of a meridian is represented in this projection as $a\, sec\theta d\theta$, and the length of the meridian in the projection between the equator and latitude θ is $\int_0^\theta a\, sec\theta d\theta = a \log_e \tan\left(\frac{\theta}{2} + \frac{\pi}{4}\right)$. The projection mapping is therefore: $x = \varphi$; $y = \log_e \tan\left(\frac{\theta}{2} + \frac{\pi}{4}\right)$. This is a conformal representation of the sphere on the plane, in which $\varphi = 0$, $\theta = 0$ corresponds to $x = 0$, $y = 0$; the equator $\theta = 0$ is mapped onto the x-axis and equally spaced parallels $\theta =$ constant correspond to lines parallel to the x-axis at ever increasing distance when θ increases, until North and South poles are mapped at infinity. Mercator's projection, although indispensable at sea, is of little value for land maps.

The early Greeks had mostly imagined the earth to be a flat disc, surrounded by an ocean and vaulted by the heavens. However, ***Pythagoras*** *(ca 540 BCE) had taught that the earth was spherical in shape and* ***Aristotle*** *(ca 354 BCE) and* ***Archimedes*** *(ca 250 BCE) tried to prove this fact.* ***Eratosthenes*** *(ca 200 BCE) derived a fairly accurate value for the circumference of our planet. The spherical shape of the earth was certainly common knowledge to the educated in ancient Greece; yet, in late Roman times, this geographical knowledge was rarely remembered. Most of the Church Fathers inferred from the Bible that the earth must be a flat disc. Accordingly it was described as a wheel having Jerusalem as its center. During the Renaissance, the old Greek writings were rediscovered, and science revived. In 1492, when Columbus discovered America,* ***Martin Behaim*** *(1459–1507, Germany) constructed the first globe since antiquity. With the increase of trade and navigation, the preparation of accurate maps became a major scientific, technological and commercial task.*

Portuguese cartographers and theoretical writers on navigation seem to have been the first to recognize the errors of plane charts, which ignored the earth's curvature and the convergence of meridians. From about 1520, *graduation in longitude began to appear, usually along the equator. Latitude graduation has been introduced somewhat earlier than this* (1500). *The earliest surviving printed sea-chart intended for use on board a ship was the map of the eastern Mediterranean, published in Venice in* 1539.

1569–1572 CE **Itzhak Luria Ashkenazi** (**ha-Ari**, 1534–1572, Israel). Philosopher and Kabbalist. Gave rise to a new and influential form of Jewish mysticism.

Luria, a man of German Jewish ancestry, was born in Jerusalem and raised and educated in Egypt. He settled in Safed, Israel, and lived the life of an ascetic. Although he wrote nothing down and merely taught, the Kabbalistic teachings by Luria's disciples and apostles made a tremendous impact not only on Jewish life throughout the communities in Europe but also on Christian thought.

Lurianic Cosmology (1572) ***and modern physics*** (1979)

Western philosophy and science, which had died with the Greco-Roman Hellenistic culture in the first several centuries CE, was reborn in the 16^{th} *and* 17^{th} *centuries. A 1400 year philosophical and scientific dark age lies between Epictetos and Marcus Aurelius on the one hand and Bacon, Descartes, Leibnitz, Copernicus, Kepler, Galileo, and Newton on the other. Something must have sparked this rebirth, but what? Did perhaps the Kabbalistic*[220] *metaphysical speculations of such Jewish and Christian scholars as* ***Avraham Ibn Latif*** *(1220–1290),* ***Raymond Lully*** *(1235–1316),* ***Pico della Mirandola*** *(1470–1533),* ***Johannes Reuchlin*** *(1455–1522), and the contributions of such Jewish scientists as* ***Avraham bar Hiyya*** *(1065–1136),* ***Levi ben Gershon*** *(1288–1344) and* ***Immanuel Bonfils*** *(fl. 1340–1377) have something to do with laying the intellectual foundations for the* 17^{th} *century rebirth of philosophy and the establishment of scientific methodology in Western Europe?*

Indeed, the burst of Christian scientific and philosophical activity did not take place in the centuries between 1100 and 1500, nor did it take place in Eastern Europe[221]*. It took place in the* 17^{th} *century, in Western Europe, in the area where Jewish Kabbalists and scientists had flourished for 400 years. There is no reason to doubt that Copernicus, Kepler, Galileo, Newton, Bacon, Descartes, Locke, Leibnitz and others were familiar both with Kabbalistic thought and the scientific writings of the Jews. In the* 17^{th} *century all these writings were available in Latin and widely distributed in the libraries and universities of Europe.*

One outstanding fact about the Scientific Revolution is that its initial (and in a sense most important) stages were carried through before *the invention of the new measuring instruments – the telescope, microscope, thermometer and accurate clock which were later to become indispensable for setting scientific answers to the questions at the forefront of science. In its initial stages, in fact, the Scientific Revolution came about rather by a* systematic change in the intellectual outlook*, in the type of questions asked, than by an increase in technical equipment. Such a revolution in methods of thoughts was stimulated and inspired by the preexisting* ideas *prevailing in Jewish occult philosophy.*

220 The word *Kabbalah* comes from the Hebrew verb *Kabeil*, meaning 'to receive' - hence 'tradition' or 'revelation'. It was the name given to Jewish mystic philosophy.

221 In Eastern Europe, Kabbalah was put in the service of alleviating the misery of the Jewish people; with its doctrine of the imminence of the Messiah, the Kabbalah held out hope for the Jews.

Throughout the centuries, this mystical undercurrent was present alongside the Torah and the Talmud. It fed on noncanonized prophecy, Zoroastrian resurrection mythology, Greek science, numerology, gnostic heresies. This was the material Jewish scholars worked on for centuries, distilling it, shaping it, blowing life into it.

Not until the 8^{th} century CE, did the first of these undercurrents of mysticism break through the surface with the publication of the Book of Formation, *compiled in southern Italy. In the thirteenth century, the second undercurrent emerged into medieval Jewish civilization with the appearance of the* Zohar *("Glow" in Hebrew), written and compiled in Spain. The* Book of Formation *is concerned mainly with the ecstatic experience of God. The* Zohar *can best be described as an encyclopedia of occultism and metaphysical speculations on God, universe, and science. These two books combined, constitute the Kabbalah, a body of mystic and occult thought, a distinctly Jewish metaphysical philosophy.*

With the appearance of the Zohar, *Kabbalism did not continue for long to course through Jewish life as a unified current, but branched out into two streams. One stream sought out the rational and the scientific and became metaphysical in its orientation. This current led to* **Spinoza** *and the rationalist school of Western philosophers and scientists, finding adherents among both Jewish and Christian scholars. The other stream had its source in Germany and coursed for centuries through Eastern Europe. It began with mysticism and degenerated into superstition as its central theme.*

Both the Zohar *and the* Book of Formation *were translated into Latin and other Western tongues, and the writings of Jewish and Christian scholars, humanists, and scientists, based on or inspired by the Kabbalah, were widely disseminated throughout the universities. This body of Kabbalistic work may even have had a large share in the sudden efflorescence of science in the seventeenth century. This was the century when Kabbalism reached the height of its influence and also saw the beginnings of its demise, perhaps because it was no longer needed after science was reborn.*

Because logic alone could not explain their doctrine of the "exalted experience of God", the Kabbalists introduced symbolic thinking and symbolic language into their speculations. They abandoned the ordinary meanings of words, gave numerical values to letters, and attributed mystical properties to both letters and numbers. This symbolic language consisted of the first ten numbers and all the letters in the Hebrew alphabet, and together they formed the Kabbalistic thirty-two avenues to wisdom. With this abstract shorthand the Kabbalists developed a fantastic metaphysical world where one element was transformed into another, where numbers stood for properties possessed by objects, and the world revolved around its own axis. These Kabbalists also *had an ear for language and a flair for style. They wrote great poetry which survived in Hebrew liturgy and literature.*

A scholar who coupled Kabbalism and science was the Spanish Jew ***Avraham ibn Latif*** *(1220–1290). He wove Kabbalism, Aristotelianism, mathematics, and natural science into a unified system. His works were translated into Latin and caught the attention of* ***Raymond Lully****, a Christian scholar, and the outstanding scientist of thirteenth-century Spain. Lully, searching for a way to break through the stranglehold which Scholasticism had upon science, used the Kabbalah and the works of ibn Latif as the basis for his book on logic, Ars Magna, which was widely used in the medieval European universities. The Muhammedans stoned him to death for preaching the gospel in North Africa.*

It was in the fifteenth and sixteenth centuries, however, that Kabbalism received its greatest dispersal in the Christian world. In the late fifteenth century, for instance, ***Pico della Mirandola****, a Renaissance humanist and philosopher, translated the Zohar into Latin. But the Christian scholar who did the most to popularize Kabbalism was, of course,* ***Johannes Reuchlin****, who, early in the sixteenth century, freely asserted that his theological philosophy was based on the Kabbalah.*

A new metaphysical philosophy was injected into Kabbalism in the sixteenth century by one of the greatest Kabbalistic scholars, ***Itzhak Luria****.*

A strange parallel exist between his Kabbalistic cosmology and the recent reformulation of the 'big bang' theory via so-called 'inflationary models' of cosmic creation and expansion.

Luria stated that all cosmic energy passed through a cosmic drama of three stages:

Stage 1 *'Tzimtzum' (= 'contraction'). God ushered in all the world's dissident elements into a tiny region, while at the same time withdrew Himself from that which he has created.*

Stage 2 *'Shevirat ha-Keilim' (= 'breaking of the vessels'). Everything that has been brought together in the first stage was expanded and shattered.*

Stage 3 *'Tikkun' (= 'restoration'). All that had been shattered is unified into a new final totality.*

In this process, the Ein-Sof (= infinity) contracted unto itself, forming a 'tehiru' (= false vacuum), while the Ein-Sof then expanded outwards, and out of it matter and light were later to emerge. Luria's cosmos is not a static one, but the world for him emanated out of a dynamic interplay of archetypical forces, unlike the cold rigidity of earlier Greek models of the universe.

According to the Lurianic cosmology, the cosmos was created ex-nihilo (out of nothing) which parallels a central idea of modern cosmology — that the universe emerged out of the vacuum state.

Present day cosmologists picture the universe beginning around 14 billion years ago in the "Big Bang". The energy densities involved in this explosion of space-time, matter and energy out of nothing were enormous. However, in the past several decades particle accelerators have allowed scientists to explore some of these energy densities in their laboratories (corresponding to the state of the universe on trillionth of a second after the Big Bang), and the theories that have emerged about the Big Bang are to some extent supported by experimental evidence and not merely upon speculation.

As the universe emerged out of the initial singularity, the causally connected space it occupied rapidly expanded until it engulfed the vast expanses explored by astronomers. During epochs close to the Big Bang, all the energy and matter of the universe must therefore have been packed into a much smaller space, and therefore the universe had a much larger energy density, pressure and temperature. The earlier we go back in time, closer to the event of creation – to 1 second after the Big Bang, to 10^{-3} *sec, to* 10^{-9} *sec, and so on – the smaller a volume of space the currently-observable universe occupies.*

The simplest of Big Bang models thus assume that at the instant of creation the universe had infinite density and temperature. The idea was that the universe emerged out of a naked space-time singularity, a kind of a knot or foam of space-time, like a black hole in reverse. This model of an explosive expansion from a point of nothingness (which had infinite density), raised more questions than it answered. In particular it is still far from clear why the various physical constants and relationships between different particles have the values and patterns they do; for example, the ratio of particles of matter to photons of light, or the relative strength of the four fundamental forces of nature – gravity, electromagnetism, weak interactions, and the strong nuclear force. If the value of some of these constants had been different by a minuscule amount, the universe would have taken a radically different course.

On the macro scale, stars and planets would not have come into being, or would have lasted a much shorter time, or been too hot or cold, etc., while on the smaller scale, the long-chained carbon-based molecules that are the building blocks of living cells could not have come about unless the physical constants which constrain the nature of chemical bonding had adopted the values they have, or unless the stars had the right temperatures and lifetimes, or unless the nuclear and electromagnetic forces would have strengths whose ratios are fine-tuned to enable carbon nuclei to form from three helium nuclei.

Some philosophers and theologians saw the possibility of invoking the hand of God acting to adjust these various values to create the particular special conditions that gave rise to the universe we know today.

This period of theorizing about the Big Bang, which began in the 60's and 70's of the 20th *century, is to some extent akin to the earlier Kabbalistic cosmology, in which God had to play an active formative role in structuring the chain of events. There arose the further problem of what existed before the Big Bang singularity, and what caused it to happen. God could again be called upon for assistance.*

***Luria** realized that if God played a formative role in the structuring of the cosmos, then the cosmos would be a direct manifestation of Him. God would not have been able to separate Himself from his creation, and therefore our created world would in fact be part of God's body.*

In a similar way present day cosmologists did not feel inwardly happy with creation theories in which some factor, outside the equations and mechanics of creation, set the critical values of the constants of nature that determined the form and contents of our universe as we know it.

*In 1980 **Allan Guth**, an American physicist, devised a theory which seems to have solved many of the technical problems inherent in the simplistic Big Bang theory.*

He considered a very early stage in the development of the universe; At around 10^{-43} *seconds after the Big Bang (the 'Planck era'), when the strength of the gravitation forces comes to equal that of other fundamental forces — quantum gravitational events dominated the emerging universe, its dense bubble of space-time being subject to quantum fluctuation in its very geometry. The universe itself could indeed be described at that early epoch as a quantum fluctuation in the vacuum. The energy that the vacuum contained was bound up in various fields and thus (highly symmetric) vacuum configuration could have been unstable (a so-called* false vacuum*) even when the universe was much older than* 10^{-43} *sec (say,* 10^{-30} *or* 10^{-20} *sec old), and its space-time manifold already quite smooth.*

Once the temperature fell sufficiently, Guth's "inflationary" scenario became possible. In inflationary models, the field energy of the initial vacuum is released *by a phase transition triggered by the cooling. The released energy influences space-time geometry via GTR, causing a* 10^{50}*-fold,* faster-than-light expansion *of the universe within a fraction of a second; part of the released energy is dissipated into heat, which becomes the matter and radiation observed in the present epoch by astronomers. The new, "true" vacuum is* stable*, but is* less symmetric *in its field-configuration than the original* false vacuum *— much as a* ferromagnetic domain *below the Curie temperature is less symmetrical, yet more stable, than a microscopically-disordered magnetic phase. Such a breaking of symmetries is called* spontaneous symmetry breaking.

We can see a parallel here between the inflation-precipitating fields and the vessels (Keilim) of the sephiroth, which were unable to hold the light energy that poured through them. The matter and light in the universe arose out of the breaking of the symmetries of the fields to which the Lurianic Kabbalah parallel would be the "breaking of the vessels", and the falling down through the worlds of the husks or shells (Kelipoth).

The inflationary model resolves various problems with the naive Big Bang models, – such as the problem of the large scale uniformity and near-flatness of the universe; the non-observation of arcane particles called magnetic monopoles; and other difficult and paradoxical aspects of the earlier theory.

As indicated above, cosmologists have been speculating about even earlier periods in the life of the universe, before the inflationary period, in which the universe was a foam of space-time emerging out of quantum fluctuations in an even earlier false vacuum state.

One speculation which has received some credence is that the universe began as a quantum fluctuation in an eleven dimensional space. This resulted in four of the dimensions expanding (these being the three dimensions of the space and one of the time), while the other seven became wrapped up into a seventh dimensional sphere of extremely small size. These seven "compact" dimensions remain hidden from our universe on the macro scale (or even currently-observable subnuclear scales) which only know the four outer space-time dimensions, though the compact dimensions do participate in the inner structure of particles of matter.

This idea is strangely paralleled in the Lurianic doctrine of the Ein-Sof contracting unto itself and forming a tehiru or vacuum while its Ein-Sof expands outwards. The Tsimtsum of the Kabbalists and folding up of seven of the eleven dimensions of space-time seem similar. Both of these cosmologies place this contraction before the formation of the false vacuum out of which the matter and light particles of the universe were later to emerge.

Nobody would claim, of course, that Luria foresaw the problems of 20^{th} *century physics, or that cosmologists and particle physicists are secretly adept in obscure areas of Kabbalah.*

It seems, though, that both disciplines were addressing the same cosmological problem, though using different set of ideas. What these parallels do reveal is the way in which the human mind formulates and pictures an event as vast and awesome as the creation of the cosmos.

The simplistic archetype of the cosmos emerging from a single source or event, in a straightforward way, does not satisfy the patterning of our minds; and both these cosmologies found ways of introducing a 'falling into matter' *which harmoniously touches some archetype within our being. So, although the formulations of these two cosmologies was separated by some 400 years, we can recognize that they addressed the same problem - that of the emanation of our cosmos out of nothing.*

In a strange way the physicists of today have come to retrace the philosophical and theosophical steps taken by Kabbalists 400 years ago.

Incidentally, the sources of the Lurianic cosmology are to be found in the works of the great Jewish philosopher ***Shlomo Ibn-Gabirol*** *(1021–1058, Spain), who described what might be construed as the "Big Bang" and the subsequent inflation in these words:*

> *"Calling unto the void and it was cleft,*
> *And unto existence and it was urged,*
> *And to the universe and it was spread out".*

1570 CE, Nov. 2 *Flood in the Netherlands*[222]: the great cities flooded, possibly as many as 400,000 drowned. Flood extended from Northern France to Northwestern Germany.

1570–1587 CE **Avraham Ortelius**, **Ortels**, **Wortels** (1527–1598, Antwerp). Scientific geographer, cartographer and publisher of maps. One of the founders of historical geography. Issued the first modern systematic atlas, *Theatrum Orbis Terrarum*[223] (Theatre of the World, 1570) which consists of 53 maps. Published 20 historical maps and a geographic dictionary (*Thesaurus Geographicus*, 1587) in which he laid the basis for critical treatment of ancient geography.

[222] This event marks the beginning of the general advance of glaciers in what is known as the "Little Ice-Age" in Europe. It was preceded by the floods of April 17, 1421 (100,000 victims) and Nov. 1, 1530 (50,000 victims) and followed by the flood of 1646 (110,000 victims). Similar events, though of lesser magnitude, occurred in the 20^{th} century: Jan. 14, 1916 (10,000 victims) and Jan. 31, 1953 (2000 victims).

[223] Errors, of course, abound, both in general conceptions and in detail. Thus, South America is very faulty in outline, but taken as a whole, this atlas, with its accompanying text was a monument of rare erudition and industry.

Ortelius came from Augsburg, Germany. He traveled extensively in Western Europe and was a friend of Gerhard Kremer (Mercator). He was appointed (1575) geographer to Philip II of Spain.

Antwerp and Amsterdam became great centers of cartographic activity, and they maintained their pre-eminence until the beginning of the 18^{th} century.

1571 CE, Oct. 7 *Battle of Lepanto* (off Greece) for the domination of the Mediterranean; combined papal and Venetial fleet under Don John of Austria defeated the Ottoman Turks under Ali Pasha. Lepanto was the end to the Turkish threat to Europe from the sea. (**Cervantes** lost his arm in this battle.) It marks the first stage of the second unsuccessful drive of Islam to dominate Western civilization.

1571–1578 CE **Azariah** (**Bonainto**) **dei Rossi** (1511–1578, Italy). Physician and scholar. One of the greatest Hebrew savants of the Renaissance. Published *Me'or Einayim* (Light of the Eyes), a series of historical essays. Using classical Greek, Latin and Jewish sources, dei Rossi's work is the first since antiquity to deal with the Hellenistic-Jewish cultural encounter and to subject the Jewish calendar to historical scrutiny. On account of his critical method and refusal to accept rabbinic legend as literal truth, the work was banned in many Jewish communities. Die Rossi described in detail the great earthquake of 1561.

1571–1588 CE **Michel-Eyquem de Montaigne** (1533–1592, France). Influential skeptic and humanist philosopher. In his main work, the "*Essais*" (1588), he used the self as a subject to study the basic features of human nature. It is "the dialogue of the mind with itself."

The Renaissance was a period of expanding horizons, and one in which there was a vast increase in knowledge of the world and its inhabitants. At the same time Europeans were recovering Latin culture and a much more complete grasp of Greek literature. Science was developing. New horizons made previous truths seem wrong or parochial. These discoveries provided Montaigne and other skeptics with a treasure chest of new facts which they used to increase our sense of relativity of all man's beliefs about himself and the world in which he lives.

The practical and self-centered world-view of the Renaissance was manifested in the autobiographical writings of **Cellini** and **Montaigne**, the historical analyses of **Machiavelli**, and **Leonardo**'s drawing of the Vitruvian man. Montaigne was the first to use the term "essay" to describe the literary form to which he had devoted himself.

Montaigne's *Essais* had great influence not only in France, but also in England, where his works were quoted by **William Shakespeare** and imitated by **Francis Bacon**. No real models existed for Montaigne's essays. His literary apprenticeship had been slight: his only early noteworthy publication had been a work of translation. Montaigne's purpose in his essays was self-knowledge: "The greatest thing in the world is to know how to be oneself." But the self one finds in his writings is not narcissistic, although he admitted: "Painting myself for others, I represent myself in a better coloring than my own natural complexion." Montaigne gives room for dialogue, addressing his thoughts to the potential reader, and combining the form of a letter with the form of a dialogue with an ideal friend. Later the French philosopher **René Descartes** (1596–1650) developed Montaigne's unsystematic thoughts into their logical conclusion in his famous "Cogito; ergo sum" (Je pense, donc je suis; I think, therefore I am).

Montaigne was born at his family estate in Château de Montaigne, near Bordeaux, in southwest France. His grandfather, Ramon Eyquem, had bought the estate of Montaigne in 1477, and thus gained the right to its name. Montaigne's father, a lawyer, had served as a soldier in Italy and adopted advanced views about education, which benefited his son. He had married (1533) Antoniette de Lopez (or Louppes) of a wealthy Spanish-Portuguese Jewish family from Toulouse. Montaigne was sent to a small cottage with a peasant family and a tutor until he was six, and while he lived there he spoke exclusively in *Latin*, the language of the educated class.

He received his early education at the Collège de Guyenne in Bordeaux, and then studied law at Bordeaux and Toulouse (1546). He was a counselor of the Court des Aides of Périgueaux, in 1557 he was appointed councilor of the Bordeaux Parliament, and from 1561 to 1563 he was at the court of Charles IX. When his friend Etienne de la Boëtie died in 1563 at thirty-two, Montaigne suffered the most severe emotional experience of his life. Thereafter he never had a close relationship.

In 1564 he married Francoise de la Chassaigne and had five daughters, but only one survived childhood. In 1570 at the age of 37 he sold his post of counselor, and in the following year retired to the Château de Montaigne. There, from 1571 to 1580 he wrote his "Essais."

The first edition of this work contained only two books. He then set out on a journey which lasted a year and a half, of which he has written in his "Journal." He went to Lorraine and Alsace, started for Switzerland, crossed Bavaria and came down to the Tyrol, saw Venice and reached Rome, the end of his journey, where he received letters of citizenship. During his absence he had been made mayor of *Bordeaux*, which office he held for four years (1581–85), his duties coming to an end when the pest broke out. Montaigne being absent from the town did not feel obliged to return to it. In 1588 he published a new edition of his "Essays," corrected and augmented by a third book. He continued to revise his work until his death.

The "Essais" reflected his wide interests and erudition. It is the result of his personal experience and very extensive reading. He writes about his disgust with the religious conflicts of his time, his belief that humans are not able to attain true certainty (*skepticism*), and even alludes to *cultural relativism*, all rather modern notions.

Montaigne considered *marriage* necessary for the raising of children, but disliked the strong feelings of *romantic love* as being detrimental to true freedom. In education, he favored concrete examples and experience over the teaching of abstract knowledge that has to be accepted uncritically.

He argued that the beliefs of different cultures should be respected, and covered in his texts a huge range of subjects, including how to converse properly, how to endure pain, how to prepare for death, how to read well, how to bring up children, and how to deal with the sexual urge. Even his cat did not escape his watchful attention: "When I play with my cat, who knows whether she isn't amusing herself with me more than I am with her?" Montaigne's voice is skeptical and sincere; "I am myself the subject of my book; it is not reasonable to expect you to waste your leisure on a matter so frivolous and empty."

Worldview VI: Michel de Montaigne

* * *

Let us permit nature to have her way. She understands her business better than we do.

* * *

Love to his soul gave eyes; he knew things are not as they seem. The dream is his real life; the world around him is the dream.

* * *

Make your educational laws strict and your criminal ones can be gentle; but if you leave youth its liberty you will have to dig dungeons for ages.

* * *

Marriage is like a cage; one sees the birds outside desperate to get in, and those inside equally desperate to get out.

* * *

My life has been full of terrible misfortunes most of which never happened.

* * *

My trade and art is to live.

* * *

No man is exempt from saying silly things; the mischief is to say them deliberately.

* * *

No wind serves him who addresses his voyage to no certain port.

* * *

Not being able to govern events, I govern myself.

* * *

Nothing fixes a thing so intensely in the memory as the wish to forget it.

* * *

Nothing is so firmly believed as that which we least know.

* * *

Lend yourself to others, but give yourself to yourself.

* * *

I prefer the company of peasants because they have not been educated sufficiently to reason incorrectly.

* * *

He who establishes his argument by noise and command shows that his reason is weak.

* * *

Rejoice in the things that are present; all else is beyond thee.

* * *

The world is all a carcass and vanity, The shadow of a shadow, a play. And in one word, just nothing.

* * *

If you don't know how to die, don't worry; Nature will tell you what to do on the spot, fully and adequately. She will do this job perfectly for you; don't bother your head about it.

* * *

It should be noted that children at play are not playing about; their games should be seen as their most serious-minded activity.

* * *

If you press me to say why I loved him, I can say no more than because he was he, and I was I.

* * *

Fashion is the science of appearances, and it inspires one with the desire to seem rather than to be.

* * *

It is not death, it is dying that alarms me.

* * *

Fame and tranquility can never be bedfellows.

* * *

A man of understanding has lost nothing, if he has himself.

* * *

The way of the world is to make laws, but follow custom.

* * *

It is good to rub and polish our brain against that of others.

* * *

I have no more made my book than my book has made me.

* * *

We can be Knowledgeable with other men's knowledge, but we cannot be wise with other men's wisdom.

* * *

There is no conversation more boring than the one where everybody agrees.

* * *

There are some defeats more triumphant than victories.

* * *

Death, they say, acquits us of all obligations.

* * *

An untempted woman cannot boast of her chastity.

* * *

When I am attacked by gloomy thoughts, nothing helps me so much as running to my books. They quickly absorb me and banish the clouds from my mind.

* * *

When I play with my cat, who knows whether she is not amusing herself with me more than I with her.

* * *

Even on the most exalted throne in the world we are only sitting on our own bottom.

* * *

The most profound joy has more of gravity than of gaiety in it.

* * *

A wise man sees as much as he ought, not as much as he can.

* * *

1572–1601 CE **Tycho Brahe** (1546–1601, Denmark). The first modern astronomical observer. His series of planetary observations made possible Kepler's study of the laws of planetary motion, the basis of our modern view of the solar system.

He constructed the most accurate instruments that were possible at his time and took great precautions in making masses of astronomical observations that reached the limits of naked-eye accuracy, being thoroughly modern in his attempts to avoid errors. Brahe did *not* believe in the Copernican heliocentric theory and clung to the geocentric theory. For, he argued, if the earth rotated and revolved, a stone dropped from a high tower would fall to the *west*, which in fact did *not* happen.

In science-fiction parlance, Tycho Brahe was something like a mad scientist. On a Danish island he built and operated the fantastic castle of Uraniborg, equipped with outside instruments, observatories, and laboratories where he also conducted astrological and alchemical studies.

1572–1604 CE New stars (actually supernova explosions) were seen in the sky and interpreted as portents of imminent destruction. When astronomers observed sunspots through the new telescopes, it was taken as evidence that the sun was decaying too. Previously, the constellations had been thought to be changeless, but when the Protestant Reformation got under way, belief in Biblical chronology strengthened.

1573 CE **Valentinus Otho** (ca 1550–1605, Germany). Mathematician. A pupil of the early table maker **Rheticus**. Rediscovered the ancient Chinese ratio $\pi = 355/113 = 3.1415929$. In 1585 **Adrian Anthoniszoon** (1527–1607, Netherlands) rediscovered it independently.

1574–1608 CE **Christoph Clavius** (1537–1612, Germany and Italy). Mathematician and astronomer. Contributed to algebraic notation (1608) and developed the proposal adopted as the Gregorian calendar reform (1582). Author of an extended commentary on Euclid's *Elements* (1574). In his book *Astrolabium* (1593), he used the identity[224]

$$2\sin A\sin B = \cos(A-B) - \cos(A+B)$$

to shorten calculations by replacing products by sums ("*prosthaphaeresis*"). Clavius was born in Bamberg, Germany, and entered the Jesuit order (1555); professor at the Collegio Romano, Rome (1565–1612).

[224] Proved by **Ibn Yunus** around 975 CE in Cairo and first used by the German astronomer **Johann Werner** (1468–1522). as an aid to calculations. This was used by **Rheticus** and **Brahe** up to the invention of logarithms.

1575–1580 CE **Bernard Palissy** (1514–1589, France). Potter, ceramist and naturalist. Made important contributions to both science and art. His views are set forth in his work (1580): *Discours Admirables de la Nature des Eaux at Fonteines, tant naturelles qu'artificielles, de metaux, de sels et salines, des pierces, des terres, du feu et des emaux*. In it he covered a wide range of chemical and geological ideas. He was first to recognize that rain and melting snow were the source from which springs and rivers derived their waters. Recognized for the first time that *fossils* are remains of *living* organisms. Rediscovered the enameling of pottery (1575).

Palissy, a true son of the Renaissance, was born of humble parents in Aquitaine. He first studied drawing and modeling. He served as an apprentice to a glass-painter and later practiced the art of glass-painting. He endeavored unsuccessfully to discover the secret of Chinese porcelain. He had recourse to the alchemists and apothecaries in order to learn the nature and properties of materials (in an age where chemistry had not yet developed into a science).

While gaining from them useful information, he found in their teachings a large element of imposture and fraud. He then broke away completely from the speculative attitude of the medieval writers and based his whole treatment of the subject on the facts of nature which he had *observed*. His opponents pointed a finger of scorn at him because he knew neither Latin nor Greek, a fact which he did not attempt to deny.

After a long period of poverty and disappointment he achieved success: his pseudo-chemical knowledge gained from the alchemists, aided him in the preparation of fine glazes for the adornment of pottery.

Later, when in danger of his life because he had embraced the reformed religion, he was taken under the protection of the King and Court. He lectured to large audiences in Paris on natural history, illustrating his remarks by specimens from collections which he had made and insisting that the *direct study of nature and experiment* was the true path to knowledge.

Palissy was eventually thrown into the Bastille because he was a Calvinist, and died in one of its dungeons.

1576–1578 CE **Martin Frobisher** (1535–1594, England). Navigator and explorer. Commanded an expedition (1576) in search of the *Northwest Passage* to India and China and discovered Frobisher Bay in the Eastern Arctic. The discovery of such a route was the motive of most of the Arctic voyages undertaken at that period and for long after, but Frobisher's special merit was in being the first to give to this enterprise a national character. For fifteen years he solicited in vain the necessary means to carry his project into execution. Finally, with the help of the earl of Warwick, he was put in command of an expedition consisting of two tiny ships, the 'Gabriel' and 'Michael' of about 20 tons each with a crew of 35.

He returned to the same region in search for gold, which was not there (1577, 1578). He then became vice admiral under Drake in the West Indian expedition (1586); Commanded the *Triumph* against the Spanish Armada (1588); Vice admiral under Hawkins (1590). Died fighting a Spanish force off French Coast

Frobisher was one of the greatest seamen in the reign of Queen Elizabeth I. His three attempts to reach Asia by sailing west extended geographical knowledge. On the first voyage (1576), he rounded the Southern end of Greenland, visited Labrador, and became the first European to sail into the bay in Baffin Island.

Frobisher took back to England a rock that some persons thought to be gold ore. On his next two voyages (1577, 1578) he brought back some 1200 tons of the rock. But it proved valueless. Yet, in spite of this and his failure to find the Northwest Passage, Frobisher changed the coarse of English imperialism and world's history by making possible 300 years of British colonialism in North America.

1576–1589 CE **Thomas Digges** (ca 1546–1595, England). Mathematician and astronomer. The first Copernican to claim that space is *unbounded* and that stars were scattered through this infinite space. He became the first to popularize Copernicus' ideas to a broad audience, and wrote a book about it in English, instead of scholarly Latin (1576). Already in 1572, Digges and other astronomers had studied the supernova of that year, showing that the heavens do in fact change, contrary to tradition – a sight visible to all.

Digges synthesized the works of **Copernicus** and **Nicholas of Cusa**, proclaiming the universe to be infinite, populated with innumerable suns and worlds.

Thomas Digges was a Member of Parliament (1582, 1585) and served as mustermaster general of English forces in the Netherlands (1586–1594). His father, **Leonard Digges** (d. 1571), also a mathematician, experimented with magnifying effects from combination of lenses, and was said to have anticipated the invention of the *telescope*.

1576–1600 CE **Robert Norman**. English pioneer in accurate magnetic work. Published in 1581 his book 'The New Attractive' in which he stated the fundamental law that unlike poles attract while like poles repel. Found that the magnetic needle dips with the vertical and a freely suspended needle in a horizontal plane orients itself in the north-south direction. The downward tendency of the north-pole magnet, pivoted on a horizontal axis, had been observed by **G. Hartmann** of Nüremberg in 1544, but his observations were not published till much later.

Up to that time, only two magnetic phenomena of importance, besides that of attraction, had been observed: (1) the north seeking property of a horizontal magnet; (2) the magnetization of a piece of iron, when brought into contact with a magnet. The first known magnets were hard black stones, known as 'lodestones'. No one knows when or by whom they were discovered, but the ancient Greek knew their power to attract iron. Throughout the middle ages, many people believed that the 'lodestone' had medical powers.

1577 CE, Oct. 27–Nov. 10 An extraordinary apparition of a *comet*, known thereafter as "*The Great Comet of* 1577". Contemporary descriptions noted that it was seen through the clouds like the moon and rivaled Venus is brightness. It was first recorded on November 01, 1577 in Peru and last recorded January 26, 1578 by **Tycho Brahe** (1546–1601). The comet reached perihelion on Oct. 27, 1577 when it was 0.18 AU from the sun, well inside the orbit of Mercury. The comet's nearly *parabolic* motion around the sun was opposite to that of the earth and planets (retrograde), and it approached closest to earth, at 0.63 AU, on November 10, 1577.

The works published on this comet by the German astronomer **Michael Mästlin** (1550–1631) and Tycho Brahe form a turning point in the history of astronomy because precise observations were used to demonstrate that Aristotle's view that comets occur in the earth's atmosphere (like rainbow), were wrong[225]. Thus, belief in Aristotle's perfect celestial system was shaken by the appearance of the Great Comet.

[225] The comet was shown to be well above the moon: Tycho and his colleagues observed the comet from two different locations on the earth's surface. If the comet was below the moon and close to the earth, each observer would see it appearing against an entirely different stellar background. Since each observer noted the comet appearing against nearly the *same* background stars, the comet must have been quite distant and beyond the lunar sphere. Tycho found however that the comet was much closer to earth than the supernova of 1572, since its motion (relative to distant stars) across the sky was greater.

The placement of the comet of 1577 above the moon by Tycho Brahe and his colleagues was about one step in the eventual discarding of the Aristotelian cosmology. Since Tycho still believed in the geocentric system, he faced a serious problem: on one hand he had the earth at the center of the universe with the moon orbiting around it; on the other hand he had the sun circling the earth, with the interior planets Mercury, Venus, Mars and the Great Comet, all circling the moving sun. There was thus an imminent danger that the crystalline sphere of the comet would smash into that of the moon or that of Mars. By 1583, Tycho accepted as possible the intersection of the planetary and lunar orbits, thus casting aside the notion of solid crystalline spheres for the planetary orbs.

1577–1580 CE *The second circumnavigation of the world* accomplished by the English explorer **Francis Drake** (1540–1596). On Dec. 13, 1577 Drake sailed from Plymouth aboard the *Gololen Hind* (a 100 ton gun-boat, 33 meters long). After passing the Straits of Magellan, Drake cruised along the western coasts of South and Central America and then sailed north to what is now San Francisco Bay. He then crossed the Pacific Ocean, stopping for water at the Philippine Islands. After crossing the Indian Ocean, he sailed around the Cape of Good Hope and reached Plymouth on Sept. 26, 1580.

Drake's voyage broadened English knowledge about the world and paved the way for later explorations.

1579 CE **Francois Viète** (**Franciscus Vieta**), Seigneur de la Bigotière (1540–1603, France). French mathematician. A lawyer by profession, in Poitiers. Being a Huguenot, persecution forced him to flee his native town for several years. He spent this period (1567–1580) largely on mathematics. With the accession of Henry of Navarre to the throne of France, Viète filled in 1589 the position of Royal Privy Counselor, and remained in that post till his death. He endeared himself to the King by breaking the Spanish code, consisting of more than 500 characters, thus enabling the French to read all secret enemy dispatches. His fame, however, rests entirely upon his achievements in mathematics.

Viète introduced the algebraic notation in which letters represented unknowns. To be sure, **Regiomontanus** and **Stifel** in Germany and **Cardano** in Italy, had used letters before him, but Viète extended the idea and was first to make it an essential part of algebra. The new algebra was called by him *logistica speciosa* in contradistinction to the old *logistica numerosa*.

In 1579 Viète published his *Canon mathematicus seu ad triangula cum appendicibus* in which he systematically applied algebra to trigonometry and discovered new trigonometric identities. It gave first systematic elaboration in the Occident of the methods of computing plane and spherical triangles with the aid of the six trigonometric functions. He paid special attention also to trigonometry, developing such relations as

$$\sin\alpha = \sin(60+\alpha) - \sin(60-\alpha),$$

and

$$\tan\frac{\alpha}{2} = \frac{1-\cos\alpha}{\sin\alpha},$$

with the aid of which he could compute the functions of angles below 30° or 45°. Letting $x = 2\cos\alpha$ he expressed $\cos n\alpha$ as a function of x for all integers $n < 11$.

An ambassador from the Netherlands once told Henry IV that France did not possesses a single geometer capable of solving a problem by a Belgian mathematician, **Adrianus Romanus**. It was the solution of the equation of the 45^{th} degree:

$$y^{45} - 45y^{43} + 945y^{41} + \cdots + 9563y^5 - 3795y^3 + 45y = C.$$

Henry IV called Viète, who saw at once that this awe-inspiring problem was simply the equation by which $C = 2\sin\phi$ was expressed in terms of $y = 2\sin\{\frac{\phi}{45}\}$. Since $45 = 3 \cdot 3 \cdot 5$, it was necessary only to divide an angle once into 5 equal parts, and then twice into 3, a division which could be effected by corresponding equations of the 5^{th} and 3^{rd} degrees. Thus Viète brilliantly discovered that the above equation has 23 roots (the remaining ones involve negative sines, which were unitelligible to him!)

Detailed investigations on the famous old problem of the section of an angle into an odd number of equal parts, led Viète to the discovery of a trigonometrical solution of Cardano's irreducible case (3 distinct real roots) of the cubic equation. To this end he applied the identity

$$\left(2\cos\frac{1}{3}\phi\right)^3 - 3\left(2\cos\frac{1}{3}\phi\right) = 2\cos\phi$$

to the solution of the equation $x^3 - 3a^2x = a^2b$ when $a > \frac{1}{2}b$, by placing[226] $x = 2a\cos\left(\frac{1}{3}\phi\right)$ and determining ϕ from $b = 2a\cos\phi$.

In 1593 he found the representation of π as an infinite irrational product:

$$\frac{2}{\pi} = \frac{\sqrt{2}}{2}\frac{\sqrt{2+\sqrt{2}}}{2}\frac{\sqrt{2+\sqrt{2+\sqrt{2}}}}{2}\cdots.$$

The value of π itself was calculated by him to 9 significant figures, using the Archimedean method by taking a polygon of 393,216 sides obtained by 16 successive doubling of the original hexagon. This enabled him to improve the Archimedean bounds to $3.1415926535 < \pi < 3.1415926537$.

[226] The solutions of the equation

$$x^3 + a_1x^2 + a_2x + a_3 = 0$$

then assume the forms given in his book *De Emendatione*: $x_1 = -2\sqrt{Q}\cos\frac{\phi}{3} - \frac{a_1}{3}$; $x_2 = -2\sqrt{Q}\cos\left(\frac{\phi+2\pi}{3}\right) - \frac{a_1}{3}$; $x_3 = -2\sqrt{Q}\cos\left(\frac{\phi+4\pi}{3}\right) - \frac{a_1}{3}$ where $Q = \frac{1}{9}(a_1^2 - 3a_2)$,

$$R = \frac{1}{54}(2a_1^3 - 9a_1a_2 + 27a_3); \quad Q^3 - R^2 \geq 0; \quad \phi = \arccos\left\{\frac{R}{\sqrt{Q^3}}\right\}.$$

Table 2.10: PROMINENT EUROPEAN MATHEMATICIANS OF THE 16^{th} CENTURY

NAME	N	LIFE-SPAN	MAJOR CONTRIBUTION
Scipione del Ferro	I	1465–1526	Algebraic solution of the cubic equation
Albrecht Dürer	G	1471–1528	Descriptive Geometry (1514)
Michael Stifel	G	1486–1567	Arithmetic and Geometric series; Algebraic notation
Nicolo Fontana (Tartaglia)	I	1499–1559	Algebraic solution of the cubic equation; The idea of logarithms (1544)
Christoff Rudolff	G	1500–1545	Algebraic notation
Girolamo Cardano	I	1501–1576	The cubic equation: probability calculations
Pedro Nuñes	J	1502–1577	The 'Nonius' calculator
R.Gemma Frisius	D	1508–1555	Trigonometric surveying (1533): Triangulation; Finding longitude at sea (1534); First terrestrial and celestial globe
Robert Recorde	E	1510–1558	Algebraic notation and terminology
Gerhardus Mercator	G	1512–1594	Map projection
George Joachim (Rheticus)	G	1514–1576	Trigonometric functions as ratios of sides of a right triangle; Sine tables
Jacques Peletier	F	1517–1582	Geometry
Lodovico Ferrari	I	1522-1565	Quartic equations; Binomial coefficients
Rafael Bombelli	I	1526–1572	Algebra of complex numbers; Algebraic notation
Adrian Anthoniszoon	D	1527–1607	$\pi \sim \frac{355}{113} = 3.141592\ldots$ (1573)
Christopher Clavius	G	1537–1626	Continued fractions; Gregorian Calendar

Ludolph van Ceulen (1596)	G	1540–1610	$\pi = 3.14159\ 26535\ 89793\ 23846\ 26433\ 8327950$
Simon Stevin	D	1546–1620	Vector decomposition; Use of decimal fractions
Thomas Digges	E	1546–1595	Mathematical Astronomy
Antonio Cataldi	I	1548–1626	Continued fractions
Thomas Finck(e)	S	1561–1656	Trigonometry: Law of tangents
Bartholomew Pitiscus	G	1561–1613	Calendar Reform; Trigonometric tables
Galileo Galilei	I	1564–1620	Cycloid (1599); Idea of equivalence of infinite classes (future set theory)
Paul H. Guldin	SW	1577–1643	Center of gravity

N = Nationality

(I = Italian; G = German; D = Dutch; E = English; F = French;

J = Jewish; S = Swiss; SW = Swedish)

1580 CE **Gaspare Tagliacozzi** (1546–1599, Italy). Surgeon. Pioneered in *plastic surgery*. He was the first to repair noses lost in duels or through syphilis. He also repaired ears. His method involved taking flaps of skin from the arm and grafting them into place.

ca 1580 CE **Itzhak ben Avraham ha-Rofeh of Troky** (1533–1594, Lithuania). Karaite philosopher and physician; Wrote *Hizuk Emunah* (Fortification of Faith) – a polemic in defense of Judaism against the repeated attempts of the Christian Church to establish its faith via a slanted and tendentious interpretation of the Old Testament. The author refutes the linkage of the Christian Biblical references and aims a thorough discussion at vulnerable points of the Christian tradition by exposing the internal contradictions and inconsistencies of the books of the New Testament and misinterpretation of texts of the Old Treatment by Paul and the other authors of the Evangelions. The book was translated into many languages and was highly praised by anticlerical authors of the 18^{th} century, such as **Voltaire**.

1580–1600 CE **Yehudah Liwa ben Bezaleel**, MAHARAL[227] OF PRAGUE (1512–1609, Posen and Prague). Humanist, scholar, Talmudist and philosopher. The greatest Jewish savant of the Renaissance era. A philosopher of history[228] whose original ideas on the evolution of national cultures stand out in their uniqueness on the background of the teachings of his contemporaries **Machiavelli** (1469–1527), **Calvin** (1509–1564) and **Grotius** (1583–1645). Foreshadowed the systems of **Vico** (1668–1743) and **Hegel** (1770–1831).

The Maharal lived in a time of great changes in European history, at the cross-roads of the Middle Ages and the Modern Era. The violent collision of Judaism and Christianity in the 13^{th} and 14^{th} centuries with all its tragical consequences[229] on one hand, and the collapse of the Medieval World (as a result of the Copernican revolution, geographic explorations, Gutenberg's invention and the wars of the Reformation) on the other – place him forcibly at the center of all ideological currents of his age.

Equipped with the scholastic tools of a Talmudic erudite, a deep knowledge in the history of Judaism and Christianity, and the keen understanding of the philosophical and sociological problems of the age of humanism, the Maharal

---

227 Hebrew acronym: MORENU HARAV LIWA.

228 B. Gross, "*L'Eternite d'Israel*" *du Maharal de Prague*, Editions Klincksieck, Paris, 1969.

229 Burning of the Talmud (1242); expulsions from England (1290), France (1306), Germany (1336), Spain (1492); Black Death (1348); Disputations (1263, 1240, 1413–14); Inquisition etc.

laid out a new outlook of the significance of the history of Israel and its fate on the *universal level*, and addressed the confrontation of Judaism with the humanistic trends in Europe.

In his trilogy *Gevurot Hashem* (1582), *Tifeeret Israel* (1599) and *Netzah Israel* (1600), the Maharal rendered, for the first time, a daring synthesis that was aimed to bridge the gap between the dualistic *inevitable opposition* and the *necessary tie* between Israel and the rest of the world. Reading correctly the internal dynamics of Jewish history and its overall message and mission in the annals of Western civilization, he proposed a wide Jewish *educational reform* aimed at the peaceful coexistence of all different cultures, each keeping its own uniqueness, and all striving together toward a universal messianic revelation.

Being deeply versed in the new scientific trends of his age, he was entirely in favor of *scientific research* in so far as the latter did not contradict divine revelation. His message, however, fell on deaf ears; during the 350 years that followed Jews were busy seeking other solutions: prior to the *emancipation* of Jews (after the French Revolution), the horizon of most Jews did not venture beyond the world of the Talmud. Their interaction with their environment were limited on account of their being locked inside the ghetto and their special vernacular. The constant humiliation and brutality to which they were subjected, encouraged conservative trends and led to derisive indifference regarding the cultural achievements of the outside world. All their spiritual energy was introverted. When the emancipation finally arrived, Jews were blinded by the European culture, and their eagerness to conform led them on the sure road to *assimilation*, and the voice of the Maharal was lost in the void.

The Maharal was born in *Posen*, Poland, whither his family had fled from persecution in *Worms*, Germany, toward the end of the 15^{th} century. Following his rabbinical studies in his home town and his marriage (1544), he was appointed rabbi at Nikolsburg, Moravia (1553–1573). He then moved to Prague, where he established a private academy (1573–1584). On account of his unconventional ideas his bid for the chief rabbinate of Prague was rejected and he returned to Nikolsburg. His repeated effort (1592) to gain the rabbinate of Prague met again with failure and he took the rabbinate of Posen (1592–1598). Finally, at the age of 86, he became the chief rabbi of Prague, and there his life-work ended.

The Maharal was greatly influenced by the teachings of **Yehudah Halevi** in the latter's book *Ha'Kuzari* (1139). Both rejected the application of the Aristotelian rationalistic system in matters that concern religion, as taught by **Maimonides**. According to Maharal, the laws of nature were created by God *arbitrarily* (in "reply" to **Einstein**'s famous question – God indeed *had* a choice!) and all deviations from the apparent laws of physics (miracles) have their origin in another universe, which he called the "upper universe"[230].

1581 CE *The Dutch Republic was begun.* The history of The Netherlands began with Caesar's conquest (58 BCE) of much of the Low Countries, including what is now *The Netherlands*[231].

During ca 400–800 CE, the Franks controlled the region. In 870 CE The Netherlands became part of the East Frankish Kingdom (now Germany). During the 1300's – 1400's the French dukes of Burgundy united most of the Low Countries. In 1516 Duke Charles of Burgundy, ruler of the Low Countries, also became the King of Spain.

In 1648, Spain recognized Dutch independence. France controlled The Netherlands during 1795–1813. In 1815 The Netherlands became an independent kingdom united with Belgium (Belgium was an independent country during 1598 – 1621), but in 1830 Belgium declared its independence from The Netherlands.

1581 CE, Mar. 30 The fruitful epoch of Jews in medicine, which had lasted uninterruptedly for some 800 years, came ingloriously to an end with the severe repression that was initiated by the Church in Rome during the Counter-Reformation.

Contra Medicos Hebreos, a Bull issued by Pope Gregory XIII, which forbade Christians to receive medical treatments from Jewish doctors, on the ground that this involved danger to the patient's *soul*. This, however, did not stop the Christians from calling on Jewish medical experts. In the late Middle Ages the popes themselves used Jewish physicians. The very fact that

230 Paradoxically, while the Maharal became a legendary figure already in his lifetime, and Jewish folk-legend ascribed to him the fashioning of the *Golem* in the attic of the Gothic-styled Altneuschul – his philosophy remained totally unknown and was, in fact, ignored by philosophers and historians alike until the second half of the 20^{th} century. The actuality of his teachings became very acute after the genocide of the Jews in WWII and the consequential establishment of the State of Israel.

231 The Netherlands is often called *Holland*, though this name actually refers to only one part of the country. The people of The Netherlands call themselves *Hollanders* or *Netherlanders*, but in English speaking countries they are known as *Dutch*. "God created the world, but the Dutch created Holland", according to an old Dutch saying. More than $\frac{3}{5}$ of the country's land was covered by the sea, or by lakes, or by swamps. The Dutch "crated" this land by pumping out the water.

the Jewish physicians were so skillful and popular made their Christian competitors the more anti-Jewish. Indeed, there was no group, with the possible exceptions of monks, throughout the history of the Jews in Europe, more bitterly anti-Jewish than the Christian members of the medical profession. Eventually they succeeded in reducing the number of Jewish physician to insignificance. Nevertheless, when a Jewish physician was available, he always found Christian patients, especially among the higher nobility and the upper ranks of the clergy.

Challenging the Pope's Bull, the Jewish physician **David de Pomis**[232] (1525–1595) from Spoleta, bravely defended the integrity of the Jewish doctors in his publication *De Medico Hebraeo enarratio apologetica* (1581).

Jews and Medicine

"... therefore choose life..."

(Deutronomy *30*, 19)

* * *

"Two of the greatest hygienic thoughts of mankind owe their origins to the Hebrews... the weekly day of rest and the direct prophylaxis of disease. Had Judaism given nothing more to mankind than the establishment of a weekly day of rest, we should still be forced to proclaim her one of the greatest benefactors of humanity.
It is most interesting fact that, despite its theory of natural causation, Greek medicine was blind to the fact of contagion, or direct transmission of disease. But in the Old Testament we have a methodical inspection of a leper by the priest who, according to the diagnosis, isolated the patient temporarily or permanently, and admitted him again to free intercourse only after indubitable convalescence or cure."

Karl Sudhoff

[232] One of the greatest physicians in Italy at that time. Descended from the families exiled by the Roman Emperor Titus from Jerusalem to Rome ('de Pomis' = from the apples). Received his M.D. in 1552 and settled in Venice.

The science of healing has an intensely revered tradition among Jews, with an unbroken continuity of more than 2000 years. To be a doctor was generally considered as the most exalted moral and worldly calling a Jew could aspire to. The doctor could claim great humanitarian and social usefulness – all the more important to a Jew because of the religious belief that the alleviation of human suffering is one of the most meritorious pursuits of righteousness. In any case, the medical profession always had enormous appeal for Jews. Centuries of social idealization have fixed for them its tradition and pattern to this day. They have been producing more doctors in proportion to their number than any other ethnic or cultural group. For a thousand years Jews were among the most honored healers in Europe.

Throughout the ages the Jew has shown a remarkable predilection for the healthy art and in all epochs his skill has been recognized. Indeed there are significant points of encounter between the history of the Jewish people and the history of medicine. Jewish physicians always had special interest in medical ethics and the Hebrew language played an important role in the history of medical writing.

The Hebrews' medical concepts and practices were influenced by the surrounding nations, whose knowledge was highly developed. However, the uniqueness of Biblical "medicine" lies in its prophylactic nature, regulations of hygiene and the weekly day of rest.

Talmudic writings emphasize the sanctity of human life, the importance of health and the saving of life (Piku'ah Nefesh). Patients, are required, not merely permitted, to seek medical help and all restrictions should be set aside.

The Karaites, opponents of Rabbinical Judaism, held that "God alone should be sought as a physician and no human medicine should be resorted to". But the Talmud does not regard calling upon a physician for medical aid as a failure to rely upon God: "Whoever is in pain, let him go to a physician", (Baba Kamma 46b). A physician had to receive adequate fees, since "a physician who takes nothing is worth nothing" (Baba Kamma 85a). At the same time, Jewish physicians had to show special consideration for the poor and the needy - a tradition that was maintained throughout the centuries.

Beginning with the 9^{th} century they helped found the finest medical colleges. Those in Tarentum, Palermo, Salerno and Bari; a little later, those in Rome and Montpellier, furnished Europe for centuries with its best doctors:

***Zedakiah** (fl. ca 1000 CE) was court physician to the Carolingian Kings, Louis 'the Meek' and Charles 'the Bold'*

*The three great figures in 10^{th} century medicine were **Haroun of Cordova**, **Yehudah Hayyuj of Fez** and **Amram of Toledo**.*

The study of medicine was introduced as part of the regular curriculum in rabbinic academies about the year 1000 CE. A long and distinguished line of rabbi-physicians were graduated from them and served caliphs, emperors, popes, kings, bishops and princes.

In the Middle Ages, half of the best known Jewish scientists, scholars, philosophers and litterateurs - men like ***Maimonides***, ***Yehudah ha-Levi***, ***Immanuel of Rome****, and so on - were physicians by profession; a striking illustration of the respect in which that calling was generally held. The bibliographer* ***Moritz Steinschneider***[233] *(1816–1907), who devoted much of his life to a study of Jewish contributions to medieval science and mathematics was able to enumerate no less than 2168 Jewish physicians who were of sufficient eminence to be recorded and who flourished between the Dark Ages and the* 18^{th} *century.*

The contribution of Jewish doctors in the Middle Ages lay mainly in their work as translators. They constituted an important link in the transmission of Arab medicine to Europe, thus enhancing the emergence of modern science. This period is also marked by a revival of Hebrew as the language of scientific writing. Hebrew medical works were important in preserving and spreading knowledge until the beginning of the 16^{th} *century.*

Knowledge of Hebrew was considered extremely important in the study of medicine. In 1518 the rector of the University of Leipzig, ***Mosellanus****, said in his inauguration speech: "In the libraries of the Jews a treasure of medical science lies hidden, a treasure as scarce as is to be found in any other language. Nobody ... will be able to get access to this treasure without intimate knowledge of Hebrew grammar".*

One of the outstanding features of this period was the constant emphasis on ethical and social behavior. Medical aphorisms concerning ethical conduct were composed by every major medical writer from ***Asaf*** *to* ***Maimonides****. An interesting glimpse into this world is given in the ethical will of* ***Yehudah ibn Tibbon*** *(ca 1120–1190), an eminent physician and translator, to his son:*

"My son, let thy countenance shine upon the sins of man: visit the sick, and let thy tongue be a cure to them; if thou receive payment from the rich, attend gratuitously on the poor".

The most important aspect of the physician's activity, however, was the care of the sick. In the Middle Ages and until the late 18^{th} *century, sick people were usually treated at home. And the commandment of visiting the sick and of strengthening family ties was kept religiously. This explains why the necessity for a hospital was not felt in Jewish communities. The Hekdesh*

[233] The father of modern Jewish bibliography. Melvina, the daughter of his cousin Sigmund, married the philosopher **Edmund Husserl** (1859–1938).

was a hospice of sorts and served as a shelter for wandering peddlers and for poor sick Jews. It was administered by the Hevra Kaddisha, a brotherhood that cared for the sick and the dead. Servants had a right to special status as a kind of social insurance.

As merchants and travelers, the Jews met the best scholars of their time and became acquainted with drugs, plants and remedies from many parts of the world. The large number of Jewish physicians during the Middle Ages may be explained by the fact that scholars could turn to the practice of medicine to earn their living, and indeed many Jewish physicians were also rabbis, authors or poets. As men of wide general knowledge, they attained high positions in the countries in which they lived. In spite of renewed ecclesiastical opposition, bishops and popes, kings and sultans - all summoned Jewish physicians to their courts.

With the possible exception of ***Itzhak Israeli****, the most renowned Jewish physician in the Middle Ages, who was also a distinguished rabbi and philosopher, was* ***Moshe Maimonides*** *(the RAMBAM 1137–1204). Born in Cordova, he fled to Fez and later moved to Israel and then to Cairo, where he became court physician of Saladin and his sons. Maimonides had a prodigious literary output, including extensive writing on medical matters. These were written at the end of his life, after his monumental Halakhic and philosophical works.*

Maimonides strongly believed in prophylactic medicine. He wrote:

"Among a thousand persons only one dies a natural death: the rest succumb early in life owing to ignorant or irregular behavior".

Guide To The Perplexed

"Medicine teaches man to restrict his boundless lust which undermines his health and to choose the manner of living. It helps to maintain the fitness of the body and enables him to purify and raise his strength to an uplifted ethical plane."

Mishne Tora

The ***ibn Alfakhar*** *family of Christian Spain (12^{th}, 13^{th} and 14^{th} centuries) is known for its distinguished scholars, diplomats and physicians.* ***Yosef ibn Alfakhar*** *was court physician to Alfonso VIII and his son* ***Yehudah ibn Alfakhar*** *served as physician to Ferdinand III of Castile during the first part of the 13^{th} century.*

*The **ibn Shoshan** family was very influential in Toledo during the* 12^{th} *and* 13^{th} *centuries. The family included physicians, scholars, Kabbalists, poets, grammarians, philosophers, diplomats and rabbis. Through their political work the family became wealthy and powerful.*

The 16^{th} *century was a period of immense exploration, discovery and progress - the century of **Paracelsus**, **Servetus** and **Fallopius**. In 1543 **Andreas Vesalius**, the 29 year old Flemish professor of anatomy in Padua, published De Humani Corporis Fabrica (The fabric of the human body). His great work showed for the first time how nerves penetrated muscles, the relationship between the abdominal organs and the structure of the brain. Vesalius gave Hebrew names together with Greek and Latin equivalents for the anatomical structures.*

The beginning of the medical renaissance had tragic consequences for the Jews of Europe. At the Church Council of Basel (1437–1447) a catalogue of restrictions was drawn, including a decree prohibiting Jews to receive a university degree. Those Jews that were admitted to universities, were subject to special rules, charged special fees and forced to listen to conversional lectures. After graduation they were generally forbidden to treat Christian patients.

At the end of the 15^{th} *century, Spain and Portugal compelled the Jews to embrace Christianity. Many became Marranos, and other emigrated. As a result, during the* 16^{th}, 17^{th} *and* 18^{th} *centuries a very high proportion of noted physicians, scientists and scholars in Europe were of Spanish and Portuguese origin. The Marranos continued to practice medicine in Spain and Portugal until the* 18^{th} *century despite their precarious position and the continual persecution by the Inquisition.*

*Ranking high on the seemingly endless list of eminent Jewish doctors and medical scientists who flourished in Europe as the modern era approached were **Amatus Lusitanus** (1511–1568), **Eliyahu Montalto** (1550–1616) and **Roderigo Lopes** (1525–1594). Lopes was physician to Queen Elizabeth I of England since 1586 and one of about 80 Marranos to live in London during her reign. He was executed on a false charge of attempting to poison the Queen. His fate caused the Marrano community to dwindle away.*

*A particularly horrifying example is that of **Garcia da Orta**, a physician who had left Portugal for Goa, India (then a Portuguese colony) in 1534. There he completed a pioneer scientific work on Oriental medicinal plants, Coloquios dos simples e drogas e cousas medicinaes da India (1563). Da Orta died in 1568 but his work had already attracted great attention. But da Orta was a Marrano and various members of his family, among them his sister, were tried by the Inquisition and sentenced to be burned at the stake. In 1580, following da Orta's posthumous conviction on the charge of having lived as a Jew, his body was exhumed and burned.*

In spite of the limitations and continuous persecution, many Jewish physicians who distinguished themselves in medical practice and literature were also concerned with the moral responsibility which their profession required.

In Renaissance Italy there was evidence of a more liberal spirit. Some Italian universities, mainly those of Padua and Perugia were among the few that allowed Jews to enter the medical faculties. Relative tolerance was only one aspect of their life in that period. In the extensive anti-Semitic literature published at the time, physicians were not spared. Successful Jewish physicians aroused the jealousy of their Christian counterparts, and thus became subject to bitter attacks and innumerable calumnies. It is not surprising therefore, that Jewish physicians published several books containing scholarly defenses. Among them were ***David de Pomis****,* ***Benedict (Baruch) de Castro (1597–1684)*** *and* ***Itzhak Cardoso*** *(1604–1681).*

Cardoso, at the age of 29, after studying medicine and philosophy, became court physician to Philip IV in Madrid, and published several medical works. Persecuted by the Inquisition, he fled to Italy and worked as a physician of the poor Sephardic community. There he published his apologia, Las Excelencias Y Caluminias De Los Hebreos. In ten chapters he emphasized the distinguishing features of the Jews, their selection by God, their separation from all other peoples by special laws, and their compassion for the suffering of others; on ten other chapters he refuted the calumnies brought against them.

The famous Jewish physician in the 17^{th} *century were:*

- ***Benjamin Mussafia*** *(1606–1675), an ex-marrano who practiced in Hamburg (1634), Denmark (1635–1647; private physician of Christian, King of Denmark) and Amsterdam (from 1648).*
- ***Tuvia ha-Rofeh*** *(1652–1729). Physician and Talmudic scholar. Born in Metz, Germany and died in Jerusalem. Descended from* ***Ezra the Scribe*** *through the* ***Maniscriba*** *family. His family flew Poland following the 1648 persecutions of the Jews. Studied medicine in Padua, and became a chief physician to the Turkish Sultan.*

The 18^{th} *century marked the beginning of the Haskalah (Enlightenment), whose aspirations matched those of educated gentiles, for the moral and social betterment of Jews and the abolishment of all social and legal discrimination. This period marked the beginning of the movement of Jews into German universities and the increase in the number of Jewish physicians.*

Marcus Herz *represents the change which took place in the status of Jewish physicians in the Modern Era. Born in Berlin, he studied in Halle* *and was a favorite pupil of Kant. After graduation, Herz lectured on Kantian philosophy and physics. At the same time he worked at the Jewish Hospital in Berlin and was reputed to be one of the best doctors of his time. As his illustrious predecessors, Herz was concerned with the ethical aspects of his profession and in 1783 published "The Physicians' Prayer". It was similar to those which had come before, but Herz added a section about the thirst for knowledge, which reflected the spirit of his times:*

"May I be moderate in everything except in the pursuit of the knowledge of science. Grant me the strength and opportunity always to correct what I have learned... for knowledge is boundless".

The first half of the 19^{th} *century was characterized by a progressively increasing interest in the natural sciences. This period coincided with the Emancipation and the opening of universities, hospitals and scientific research institutes to Central European Jews. Jewish physicians were thus able to take an active part in the development, and there is scarcely an area in the broad domain of medicine in which they were not prominent as pioneers.*

Nevertheless, for many years Jewish physicians were not accepted as university professors unless they converted. They were not welcomed in the fields of surgery and internal medicine. Consequently, they worked primarily in private clinics and hospitals, where they did their research. They developed new fields of medicine that did not attract their non-Jewish colleagues, such as dermatology, venereology, hematology and psychiatry. Freud who was not only a physician but a gifted writer, formulated the reason for this trend with great perceptiveness:

"Soon there was the insight that I had only my Jewish nature to thank for two of the qualities that had become indispensable of my difficult path through life. Because I was a Jew, I found myself free from my prejudices that limit others in the use of their intellect; as a Jew I was prepared to go into opposition and forgo the acceptance of the 'compact majority'".

Emancipation brought with it many changes, among them the pattern of sick care within the community. With the improvement of the general hospital, the Jewish hospital too changed its character from a social institution to a medical one. The acceleration in the creation of modern Jewish hospitals continued in the 20^{th} *century, and by 1933 there were in Poland alone 48 such institutions. Some of them continued their activity in the ghettos even after the German occupation.*

The racial laws introduced into Germany at the beginning of the 1930s and, subsequently, into all of occupied Europe, severed the careers of Jewish physicians. Many emigrated, mainly to the US, where a center of Jewish medical activity was emerging, coinciding with the rise of American medicine.

*The motto taken from Deuteronomy, "*Therefore choose life...*" establishes the basis of the Jewish attitude towards medicine,– yet there has never been a "Jewish Medicine" per se. Jews have always adopted the medical teaching of cultures in which they lived, and enhanced them through their own contribution.*

History of Biology and Medicine, II – The Middle Ages and the Renaissance

The history of biology traces man's understanding of the living world from the earliest recorded history to modern times. Though the concept of biology as a single coherent field of knowledge only arose in the 19th century, the biological sciences emerged from traditions of medicine and natural history reaching back to the ancient Greeks (particularly ***Galen*** *and* ***Aristotle****, respectively).*

Whereas evolutionary ideas more or less died out in Europe after the fall of the Roman Empire, they continued to be propounded in the Islamic world. For example ***Al-Jahiz*** *considered the effects of the environment on the likelihood of an animal to survive, and* ***Ibn al-Haitham*** *went even further, writing a book in which he argued explicitly for evolutionism (although not, of course, natural selection), and numerous other Islamic scholars and scientists (including* ***Nasir al-Din Tusi****) discussed these ideas. Translated into Latin, these works began to appear in the West after the Renaissance and probably had a large (though subterranean) impact on Western science.*

The decline of the Roman Empire led to the disappearance or destruction of much knowledge. However, some people who dealt with medical issues still studied plants and animals as well. In Byzantium and the Islamic world, natural philosophy was kept alive. Many of the Greek works were translated into Arabic and many of the works of Aristotle were preserved. Of the Arab biologists, al-Jahiz, who died about 868, is particularly noteworthy. He wrote Kitab *al Hayawan (Book of animals). In the 1200's the German scholar named* ***Albertus Magnus*** *wrote De vegetabilibus, seven books, and De animalibus, 26 books. He was particularly interested in plant propagation and reproduction and discussed in some detail the sexuality of plants and animals.*

Persia and other Islamic areas became important in the development of science. Based on Greeks and Indian science and connected to Europe they were in a good position to help science develop. There were also Arab and Turkish scientists but the most important ones were Persians. ***Avicenna*** *(commemorated in the genus Avicenna) recorded many findings. He is sometimes regarded among the fathers of modern medicine.*

Interestingly, as many visual artists were interested in the bodies of animals and humans, they studied the physiology in detail. Such comparisons as that between a horse leg and a human leg were made. ***Otto Brunfels****,* ***Hieronymus Bock*** *and* ***Leonhard Fuchs*** *were three men who wrote books about wild plants; they have been referred to as the fathers of German botany. Books about animals were also made, such as those by* ***Conrad Gesner****, illustrated by, among others,* ***Albrecht Dürer****.*

Medieval medicine was an evolving mixture of the scientific and the spiritual. In the early Middle Ages, following the fall of the Roman Empire, standard medical knowledge was based chiefly upon surviving Greek and Roman texts, preserved in monasteries and elsewhere. Ideas about the origin and cure of disease were not, however, purely secular, but were also based on a spiritual world view, in which factors such as destiny, sin, and astral influences played as great a part as any physical cause.

In this era, there was no clear tradition of scientific medicine, and accurate observations went hand-in-hand with spiritual beliefs as part of the practice of medicine.

This idea of personalized medicine was challenged in Europe by the rise of experimental investigation, principally in dissection, examining bodies in a manner alien to other cultures. The work of ***Andreas Vesalius*** *and* ***William Harvey*** *challenged accepted folklore with scientific evidence. Understanding and diagnosis improved but with little direct benefit to health. Few effective drugs existed, beyond opium and quinine, folklore cures and almost or actually poisonous metal-based compounds were popular, if useless, treatments.*

Table 2.11 lists the most influential contributors to the Life-Sciences and Medicine throughout the Middle Ages and the European Renaissance.

The Gregorian Calendar[234]

In 1582 CE, Pope Gregory XIII (1502–1585, Italy) ordered a calendar reform. The Julian year, with average length $365\frac{1}{4}$ *days, is* 11^m14^s *longer than*

[234] For further reading, see:

- Reingold E.M. and H. Dershowitz, *Calendrical Calculations*, Cambridge University Press, 2001, 422 pp.

the tropical year (length $365^d5^h48^m46^s$*). This slight discrepancy accumulates at a rate of one day in 128 years. Thus, between 46* BCE *and 325 CE, the date of the vernal equinox had slipped back from March 25 to March 21. In the year 730, the medieval scholar* ***Bede*** *(672–735, England; known as the 'Venerable Bede'), showed that the deviation was more than 3 days.* ***Roger Bacon****, in 1200, found an error of 7 or 8 days.* ***Dante****, soon after 1300, was well aware of the need of calendar reform. In 1474 Pope Sixtus IV invited the astronomer* ***Regiomontanus****, to revise the calendar and bring it into line. The premature death of the scientist interrupted the plan. In the following century, numerous memoirs appeared on the subject by mathematicians of note.*

By 1582, the 11 minutes and 14 seconds per year had added up such that the first day of spring was occurring on March 11. If the trend were allowed to continue, eventually Easter and the related days of observance would be occurring in early winter. Therefore, Pope Gregory XIII undertook the long-desired reformation. The author of the adopted system was ***Luigi Lillio Ghiraldi****, a learned astronomer and physician of Naples, who died, however, before the introduction of the reform. The calculations were continued by* ***Christoph Clavius*** *(1537–1612, Germany).*

The Gregorian calendar reform consisted of two steps. First, 10 days were dropped out of the calendar in October to bring the vernal equinox back to March 21, where it was at the time of the Council of Nicaea. This step was expeditiously accomplished. By proclamation, the day following October 4, 1582, became October 15. The second feature of the new Gregorian calendar was that the rule for leap year was changed so that the average length of the year would more closely approximate the tropical year.

In the Julian calendar, every year divisible by 4 was a leap year, so that the average year was 365.250000 *mean solar days in length. The error between this and the tropical year of* 365.242199 *mean solar days accumulated to a full day every 128 years. Ideally, therefore, one leap year should be made a common year, thus dropping one day, every 128 years. Such a rule, however, is cumbersome. Instead, Gregory decreed that in 3 out of every 4 century-years, all leap years under the Julian calendar, would be common years henceforth. The rule was that only century-years divisible by 400 should be leap years. Thus 1700, 1800 and 1900, all divisible by 4 (and thus leap years in the old Julian calendar), were* not *leap years in the Gregorian calendar. On the other hand, the years 1600, and 2000, both divisible by 400, are leap years under both systems.*

Among those who objected to this reform was ***Viète****. The reform was devised so that religious ceremonies could be performed on the correct dates. The Julian calendar was promptly adopted throughout the Roman Empire,* *which comprised the whole civilized Western world. But the Gregorian calendar was formulated after the Reformation, and the Pope's decision was not immediately accepted everywhere.*

The Catholic nations adopted it at once, but the Protestant nations fell in line only gradually: Germany in 1700, England in 1751. By this time, the two calendars were out of step by 11 days, and there was rioting in England with the slogan: "Give us back our eleven days". Notwithstanding, England and its colonies (North America included) jumped directly from 02 Sept. 1752 into 14 Sept. 1752. Russia adopted the Gregorian calendar only on 31 Jan. 1918, which was succeeded by 14 Feb. 1919.

As the Gregorian method of intercalation has been adopted in all Christian countries, it is of interest to examine to what degree of accuracy it reconciles the civil year (365^d) *with the tropical year* ($365.2422^d = 365^d : 5^h : 48^m : 46^s$)*. The Gregorian rule gives 97 intercalations in 400 years; Thus, 400 years contain* $365 \times 400 + 97$, *that is 146,097 days. Consequently, an average year contains 365.2425 days or* $365^d : 5^h : 49^m : 12^s$. *This exceeds the true solar year by 26 seconds, which amount to a day in 3323 years. It is perhaps unnecessary to make any formal provision against an error which will only happen after so long a period of time; but as 3323 differs little from 4000, it has been proposed to correct the Gregorian rule by making the year 4000 and all its multiples common years. With this correction, the commencement of the year would not vary more than a day from its present place in 200 centuries.*

One would prefer, however, a different method of intercalation by which the coincidence of the civil and solar year could be restored in shorter periods (since people in the year 3322 would presumably feel uncomfortable with a discrepancy of 24 hours!). To find this method, the decimal fraction 0.2422 is converted into the continued fraction

$$\cfrac{1}{4+\cfrac{1}{7+\cfrac{1}{1+\cfrac{1}{3+\cfrac{1}{4+\frac{1}{1+\cdots}}}}}}$$

which gives the series of approximating fractions $\frac{1}{4}, \frac{7}{29}, \frac{8}{33}, \frac{31}{128}, \frac{132}{545}, \frac{163}{673}$, *etc. The first of these,* $\frac{1}{4}$, *gives the Julian intercalation of one day in 4 years, and is significantly too big. It supposes the year to contain* $365^d : 6^h$.

The second, $\frac{7}{29}$, *gives 7 intercalary days in 29 years, and errs in defect, as it supposes a year of* $365^d : 5^h : 47^m : 35^s$.

The third, $\frac{8}{33}$, *gives 8 intercalations in 33 years, or 7 successive intercalations at the end of 4 years, and the* 8^{th} *at the end of 5 years. This supposes* *the year to contain* $365^d : 5^h : 49^m : 5.45^s$. *It implies a year exceeding the true year by* 19.45^s, *while the Gregorian year is too long by 26 sec.*

Thus, the above method produces a much nearer coincidence between the civil and solar years than does the Gregorian method; and by reason of its shortness of period, confines the evagations of the mean from the true equinox within much narrower limits. The discovery of the period of 33 years is ascribed to ***Omar Khayyam*** *(1079* CE*).*

Better yet is the fourth convergent

$$\frac{31}{128} = \frac{3 \times 8 + 7}{3 \times 33 + 29},$$

which combines 3 periods of 33 years with one of 29 and would be very convenient in application. It supposes the year to consist of $365^d : 5^h : 48^m : 45^s$, *and is practically exact.*

To determine the day of the week corresponding to the day of the month in any year, one uses the formula

$$S = Y + D + \frac{Y-1}{4} - \frac{Y-1}{100} + \frac{Y-1}{400}.$$

Here Y *is the year of the Gregorian calendar, and* D *is the day of the year (after February 28 of a leap year,* $D \to D+1$ *relative to a non-leap year). Also, in dividing* $Y-1$ *by 4, by 100 and by 400, the remainder gives the day of the week, 0 indicating Saturday, 1 Sunday etc. The corresponding formula for the Julian calendar is*

$$S = Y + D + \frac{Y-1}{4} - 2.$$

Thus, Columbus discovered America on Oct. 12, 1492 which was a Friday.

The Gregorian calendar, for all its sophistication, is not quite as accurate as that devised by the Maya priests of Central America. The Gregorian year is slightly too long, the error amounting to three days in 10,000 years. The length of the year according to the Maya astronomers was too short, but the defect amounted only to two days in 10,000 years.

In the same year (1582), the scholar ***Joseph Justus Scaliger*** *(1540–1609, Netherlands) suggested that all dates be referred to an arbitrary fiducial date, Jan. 1, 4713* BCE *(he may have believed this to be the day of creation). The date thus reckoned is known as the Julian day (JD), in honor of his father* ***Julius Caesar Scaliger*** *(1484–1558) (no connection to the Julian calendar). Julian days are now used for expressing the times of most astronomical ob-*

servations. They are reckoned from noon, and parts of a day are expressed in decimals to the necessary degree of precision[235].

The basis of modern Western science

Modern science started at the end of the Renaissance (ca 1550) with ***Copernicus***, ***Kepler*** *and* ***Galileo***. *All efforts prior to this date did not produce any significant corpus of scientific and technological knowledge and thus did not lead to the uncovering of the great code of natural laws. Neither the Greeks, nor the Chinese or the Hebrews succeeded in revolutionizing human thought in spite of their great respective advances in astronomy, geometry, logic, philosophy, technology and ethics. Why?*

The ancient Hebrews fostered a belief that nature is governed by the decrees of an omnipotent and divine law-giver. This created an advantageous environment for the emergence of a firm belief in laws of nature, and in the rationality and ordered character of the world: a firm belief that there exists something worth investigating. It emphasizes a common factor behind nature, and establishes nature's universality. Moreover, it establishes the invariance of some elements of nature in the face of the flux of events.

This biblical view exerted a powerful influence during much of the period when science grew into its modern form[236]. *The Old Testament picture of God fashioning the World out of a formless void and ordering it in special ways was quite different to beliefs elsewhere in the ancient world, and to the*

[235] The system has since been modified slightly. Modified Julian Date (MJD) is simply $JD - 2,400,000$ days and 12 hours, putting the zero hour at midnight on November 17, 1858.

[236] The majority of leading British scientists until the beginning of the 20^{th} century were devout Christians, and this had a particular influence upon their scientific work.

earlier magical *view of nature. However, this philosophy, while being* necessary *for the development of scientific thought, was* not sufficient*; The instruction against graven images (Exodus 30, 4-5) forbids the representation of the one true God and therein is ingrained a perpetual contentment with an* abstract *view of things, and a distrust of having useful or symbolic representation of things. Thus, nature was seen primarily as a sign and symbol of its creator, rather then as a puzzle to be solved or a source of power to be harnessed.*

Moreover, although the natural world was acknowledged to be the handiwork of the Creator, it was not held that a knowledge of the works of creation led necessarily to a deeper understanding of God. Deep understanding, or 'wisdom', was to be found in the moral world, and came not through the earthquake, wind or fire, but through the 'still small voice' of the Spirit of God. Science, therefore, could not develop directly within such a world-view. Indeed, the ancient Hebrews never developed any seafaring tradition (avoiding the need to study the heavens for the purpose of navigation) and had motivation for neither architecture nor industry - life remained tied to agriculture and tradition.

In the blundering progress of scientific and technical achievements in the Middle Ages, the Jews of Europe did not fail to contribute their part. Throughout the period one finds mention of them - now translating a fundamental scientific work, now introducing a new process from one country to another, now referred to as authorities, now making their original contribution to mathematics, logic, astronomy, philosophy, philology, physics, chemistry and engineering.

An impressive lot of Jewish inventors and scientists of the Middle Ages could be compiled. Many other instances may be adduced, serving to indicate that, in the gradual, anonymous, development of technical progress before the 19^{th} *century, Jews collaborated with other sections of the European population. This same intellectual alertness was given a fresh outlet after the breakdown of the Ghetto.*

In the course of the 19^{th} *century, the energy and inventiveness which had previously been almost confined to Talmudical studies (with their philosophical and mathematical corollaries), or to the difficult task of earning a living through menial occupations (under adverse conditions of hardships and persecutions), began to be turned to science in its wider sense. Jews now not only earned distinction but produced a few scholars who are the unchallenged leaders in their particular branches of research.*

The idea of a single supreme Deity was foreign to the early Chinese *and as a consequence the fate of natural science in that culture was a curious stillbirth. For the Chinese there existed no concept of a divine being whose decrees formed inviolate 'laws of nature', and who underwrote the scientific enterprise.*

Despite sophisticated technological development in rocketry, printing, and the widespread use of magnetic compasses in their sailing ships, these inventions provoked no urge to explore natural regularities or the geography of the globe.

A central idea of Chinese thought from earliest times until the mid 20th century appears to be that of spontaneous development of order in the world. This notion could have had its roots in observations of the natural world, for example the organized collective behavior of insect colonies, where there arises a mysterious harmony between many separate parts without external human interference.

Alternatively, we might find its roots in the gradual appearance of social order within small peasant groups who found themselves evolving a stable and organized way of life within their communities, without the imposition of rules by some external central government. Rules arose by negotiation and compromise rather than dictatorial decree.

This view eventually evolved in the 6th *century BCE into Confucianism - a world view that did not seek rules for the behavior of nature in logical analysis or through systematic observational studies, but looked instead to the analogy with the harmonious social customs that evolve out of* collective human activity. *Thus, order in nature was sought in social behavior, known as Li. Li operated across the entire spectrum of life; it was the reason for the motions of the moon and the stars, for the successful exercise of self-control in human dealings, and for the social divisions of rich and poor.*

Another Chinese philosophy, known as the Tao (the 'way') opposed this search for order of nature in social behavior. They believed that only by being one with nature could the order within be understood. This holistic view also denies a notion of an external world of physical reality. Thus, despite their technology, the Taoist philosophers never framed any statement that we might call laws of nature. They had no confidence in the ability of reason to unravel the universe. *Their theology of pantheistic naturalism, ran counter to the entire concept of God controlling the universe. They believed that everything had the ability to bring itself into being, and so there was no psychological desire to introduce a personal Creator.*

Thus, whether through Li or Tao, the early Chinese had no reason to believe in an underlying rationality in nature that might be uncovered and understood by detailed observation and codification. The Universe was believed to be far too complex for such an enterprise to be even considered.

The idea of order never carried with it any implication that there must inevitably exist constraining laws and an ordering law-giver. Despite their early technological superiority, the scientific altitude faded and died unfulfilled in ancient China.

It remains to ask why the intellectual atmosphere of Greek *culture, with its stable government and highly developed systems of civil law, did not lead to uncovering of the great code of natural laws.*

At first sight it appears that many trends in Greek thought were taking the perfect coarse toward a scientific revolution: a faith in the intelligibility and rationality of the world, a desire to seek out and comprehend the truth for its own sake and a desire to amass a vast panoply of facts. None the less, the following trends created a barrier through which their thinking about the natural world could not pass:

- *The Greek philosophical schools begun with theories about the nature of* everything *but were too vague and diluted to tell us very much about particular things. Science only began to make dramatic progress during the late Renaissance when it limited its objectives and started to address the particular as the necessary prerequisite to any understanding of the general. Greek philosophers preferred to argue about the meaning of the idea rather then observe what happened in the world. Even the Greek materialist philosophers applied their logic to problems beyond the reach of observation (origin of life, origin of all things, etc.).*
