During evolution, many plant species have adapted to life in seasonally dry and arid environments by developing the ability to store water in their stems, leaves, and/or underground organs – this phenomenon is called “succulence.” Succulent plants can be found in more than 70 plant families. The *Illustrated Handbook of Succulent Plants* (excluding cacti and orchids) was first published in six volumes in 2001–2003. A second revised edition, of which the first volume (treating the family Aizoaceae) was published in 2017, provides a taxonomical treatment of all estimated 11,000 taxa of succulents (excluding orchids). In addition to the volumes on Monocotyledons and Dicotyledons, separate volumes are devoted to those families with an especially great diversity of succulent species, namely, Aizoaceae, Apocynaceae, Cactaceae, and Crassulaceae.

Each volume is organized by alphabet of families, genera, and species, with comprehensive synonymies added at all levels. Detailed descriptions are given for all accepted taxa, together with data on the distribution and typification, and references to the most important literature. Where necessary, information on ecology, ethnobotany, history, etc. is added, and in many places, proposed relationships are critically discussed. Over 2000 superb colour photographs complete this inventory of succulent plants.

## Preface to the Second Edition

Succulents are an attractive group of plants that have for centuries attracted the interest of botanists and gardeners alike, both professionals and hobbyists. During this time, a vast body of specialized books and especially journal papers has accumulated that contains our knowledge of these fascinating plants.

Over time, there were several efforts to collate the existing knowledge and information into lexica devoted to succulent plants and thus allow an ordered presentation of the diversity of succulents. The publication of the first edition of the present series of *Illustrated Handbook of Succulent Plants* in the years 2001–2003 in six volumes marked a milestone in this field, even though coverage remained incomplete since the families *Bromeliaceae* and *Cactaceae* were not included.

The past more than 15 years have seen a continued, and in many fields, revived interest in all aspects of succulent plant biology, and the handbook series soon became a widely accepted taxonomic reference for ordering the biodiversity of succulents. Fifteen years is a long stretch of time for any lexicon, and much new data have been generated by recent research in all fields of botany. During this time, especially molecular studies have led to an improved understanding of the living diversity of plants, and a firm phylogenetic backbone is now in place for most major groups. The past more than 20 years have also seen an important change in the way taxonomical studies are conducted, that is, an increasingly common replacement (or at least support) of intuition-based interpretations with data-derived conclusions. We are now well aware that many of the characters traditionally used to define taxonomical units are homoplasious (i.e., have evolved repeatedly in parallel) and thus are of limited or no value to understand evolutionary pathways.

Such increase in knowledge has led to important changes in the circumscription or affiliation of many groups. Such changes often meet with considerable antipathy from many user groups, but when they are based on firm data derived from adequate sampling depth, they will become the accepted standards in the future. For this handbook series, a phylogenetic approach, based on the most recent available standard phylogenetic framework, has been selected. In cases where the available data is inconclusive, or contradictory, established classifications are usually followed, with the necessary cautious comments (see, e.g., the genus *Aloe*).

For this second edition, the existing entries from the first edition have been thoroughly checked and updated, including revised classifications and new taxa. Especially the discussions of classifications have been expanded considerably within a phylogenetic context but also new data, for example, on ecology or ethnobotany, have been added. For most groups, the original authors have been able to provide these updated treatments, and we are most grateful to our colleagues for their continued support of the project. For some groups, new contributors had to be sought, and we are delighted about the willingness of the respective authors to accept this task. In contrast to the first edition of this volume, the succulent taxa of the pineapple family (*Bromeliaceae*) are now also included, thanks to the energetic help of a group of specialists of that family. With this addition, this volume now covers the monocotyledonous succulents in full with the notable exception of the orchids – the sheer number of possible succulent species makes their inclusion unfeasible.

The overall layout of the volume has changed considerably in comparison with the original edition, while the sequence of information presented for each taxon has largely remained the same. We hope that the new layout, which places the illustrations near the text to which they belong, will prove helpful for the users.

## From the Preface to the First Edition

Handbooks devoted to succulent plants (including cacti) have a long-standing tradition, and the demand for updated editions is a good indication of the high degree of interest that exists in this fascinating group of plants.

While the first handbooks devoted to the family *Cactaceae* were already published in the nineteenth century, the first handbook dealing with the so-called other succulents was authored by Hermann Jacobsen and published in 1954–1955, then called *Handbuch der sukkulenten Pflanzen*. A revised and enlarged English edition was made available in 1959 and was repeatedly reprinted in the following years.

A major step towards a compact handbook including short descriptions, full synonymy, and hundreds of illustrations was the publication of the first edition of Hermann Jacobsen's celebrated *Sukkulentenlexikon* in 1970, followed by the English edition in 1975, and a revised German edition in 1981, finished by Klaus Hesselbarth following Hermann Jacobsen's death in August 1978.

The demand for updated compact information on succulent plants has not diminished since then, and contrary to Hermann Jacobsen's opinion (preface to the German edition 1970) that the number of papers dealing with succulent plants was on the decline, the interest in succulent plants was growing, both among hobbyists and among botanists. The results are numerous new taxa in many families, and many monographs of previously little-known groups have been published over the years. Accordingly, a need for a "New Lexicon" was beginning to be felt, both for "other" succulents and for cacti.

After some informal initial discussions held among various botanists and interested specialist collectors, and faced with the desire of Gustav Fischer Verlag Jena, the publisher of both Backeberg's *Kakteenlexikon* and Jacobsen's *Sukkulentenlexikon*, to prepare revised editions, a meeting was called for during the 1990 congress of the International Organization for Succulent Plant Study (IOS) in Zürich. There was a general feeling that the situation presented a unique occasion to produce a set of authoritative volumes embracing *all* succulent plants (except orchids), and produced according to a rigid set of common standards adopted to suit all families involved. It was planned that the project, informally termed the "New IOS Succulent Plant Lexicon," should consist of three volumes, one devoted to the *Cactaceae*, one to the *Aizoaceae*, and one to the remaining succulent taxa from various families.

For various reasons, the Lexicon project took much longer to be completed than anticipated. The *Cactaceae* part had not become available in time for

inclusion in the first handbook edition. In the case of the *Aizoaceae*, time permitted a much more complete treatment of the family, which was published in two volumes. Moreover, it soon became apparent that a single volume will not be sufficient to cover the vast array of the “remaining succulents.” Accordingly, they were split into four volumes (Monocotyledons, Dicotyledons, *Asclepiadaceae* (= *Apocynaceae* in the revised edition), and *Crassulaceae*).

---

# General Introduction to the Series

---

## Setup of the Handbook Series

The present series of handbooks is devoted to a lexicographic treatment of the known diversity of succulent plants (excluding pteridophytes and orchids, see below). The APG III classification (APG 2016) is used as the phylogenetic framework at the rank of order and supraordinal taxa, while the slightly modified APG III classification (APG 2009) as defined by Nyffeler and Egli (2010a) is used at the rank of family.

---

## What Is a Succulent?

It is a continuing challenge to define what constitutes a *succulent plant* – at least in view of the several competing definitions (see Egli and Nyffeler 2009 for a review and a modern definition). For the purpose of this handbook, a pragmatic approach has been selected. Apart from the multitude of unambiguous succulents, borderline cases are included as well, especially when they occur sympatrically with undisputed succulents in more or less semiarid regions, and consequently show some degree of xerophytic adaptation, and more so when the species in question are encountered in cultivation together with other succulents. This, then, includes many of the so-called caudex and pachycaul plants popular in cultivation in public and private collections alike.

Other borderline cases included are a number of bulbous and rhizomatous groups, where examples from several genera are covered, as well as some weakly developed leaf succulents from, for example, the *Commelinaceae* and *Gesneriaceae* (e.g., *Columnnea*), and several other families.

Purely halophytic succulents (such as *Salicornia*) are omitted from this series of handbooks since they are as a whole neither adapted to climatically arid or semiarid conditions (see Ogburn and Edwards 2010 for an explanation) nor encountered in collections devoted to succulent plants.

Finally, the family *Orchidaceae* is excluded (apart from a short general overview), despite the uncontested claim to succulence of many taxa. A preliminary count (Nyffeler and Egli 2010a) showed some 2200 succulent species for this family, and a more detailed census (see the family treatment in this volume) arrives at a minimum count of 4500 succulent species – this

makes the *Orchidaceae* the most important family containing succulents in term of species number.

Fortunately, vast specialist literature covering orchids exists, numerous specialist societies are in existence, and the available lexicographic efforts (e.g., Pridgeon & al. 1999, 2001, 2003, 2005, 2009, 2014) do not need to be duplicated here. Also omitted from the series are the pteridophytes, as insufficient knowledge on the – possibly few – marginally succulent taxa is available.

---

## Succulence Among Flowering Plants

Succulence, without any doubt, has evolved repeatedly and independently in many clades of the angiosperms. Succulence thus illustrates in an exemplary manner how adaptations to a given set of ecological conditions appear time and again throughout the evolution of the Plant Kingdom (and likely has disappeared again in numerous cases, but as no macrofossils of succulents are known, this will be difficult to prove). Figure 1 illustrates the occurrence of succulence throughout the clades of the angiosperms. Succulent plants are known to occur in 31 out of a total of 64 orders accepted. While some orders only count with a small number of succulent representatives, succulence is a more prevailing character in others. A notable concentration of succulents is to be found in the order Caryophyllales, and its suborder Portulacineae embraces almost exclusively succulent taxa (Nyffeler and Egli 2010b).

---

## Division of the Handbook into Individual Volumes

The handbook is divided into individual volumes that either cover an entire individual family or a coherent group of families. The planned breakdown into volumes is as follows (see also Fig. 1):

- Monocots: Egli, U. & Nyffeler, R. (eds.): Illustrated Handbook of Succulent Plants. Monocotyledons. **This volume.**
- Dicots A: Egli, U. (ed.): Illustrated Handbook of Succulent Plants. Magnoliids and Dicotyledons (excluding Rosids).
- Dicots B: Egli, U. (ed.): Illustrated Handbook of Succulent Plants: Dicotyledons: Rosids.
- *Aizoaceae*: Hartmann, H. E. K. (ed.): Illustrated Handbook of Succulent Plants: *Aizoaceae*. Volumes 1 and 2. **Published 2017.**
- *Apocynaceae*: Meve, U. & Egli, U. (eds.) Illustrated Handbook of Succulent Plants: *Apocynaceae*.
- *Cactaceae*: NN. (ed.): Illustrated Handbook of Succulent Plants: Cactaceae.
- *Crassulaceae*: U. Egli (ed.): Illustrated Handbook of Succulent Plants: *Crassulaceae*.

For ease of reference, an alphabetical list of families, together with the orders to which they belong and the volume of the series which covers them, is also supplied (Table 1).

**Fig. 1** Summary phylogeny of the angiosperms, based on APG IV (2016), Moore & al. (2010), and Soltis & al. (2011). The estimated number of succulent species (modified from Nyffeler and Eggli 2010) is indicated to the right of the order names. Supraordinal names follow Soltis & al. (2011) and Chase and Reveal (2009); their

Lilianae conform to the Monocotyledoneae of Soltis & al., their Rosanae to the Superrosidae, and their Asteranae to the Superasteridae). **MAG** = Magnolianae. The division of the handbook series into individual volumes is shown on the right of the cladogram. (Diagram by Urs Eggli) rats

# How to Use This Handbook

---

## Sequence of Information

All information is presented in strictly alphabetical sequence of families, genera, and species within each volume. It is therefore easy to directly find the entry for a given species as long as its family placement is known.

An alternative way is to use the taxonomic cross-reference index supplied at the end of each volume. This index contains all the names covered in the volume and indicates the page where a treatment can be found, or in the case of synonyms gives the page reference where the accepted name is treated.

For each family, the handbook supplies keys to the genera with succulent representatives. Please note that these keys are designed to work for the *succulent* taxa treated and do not account for the total variation encountered in a genus. If the family is not known, the reader is referred to general botanical books that include keys to plant families. Rowley (1980) and Egli (2008) provided keys for flowering and nonflowering succulents, and Geesink & al. (1981) produced a well-known book of keys to all flowering plants worldwide.

---

## Scope of Information Presented

### Families

The family names adopted are always conforming to the standard form (ending in *-aceae*); alternative names (such as *Compositae* for *Asteraceae*) are not used. Important synonyms at family rank are indicated, especially when the synonymous names include succulents. The order to which the family belongs is also given.

Within each family, the genera are treated in alphabetical sequence and the same applies to the sequence of species within genera. Some genera of minimal importance or with borderline succulence are only mentioned or at the most described, but no individual species are treated.

The family description characterizes the family as a whole, which often includes much more variation than that observed among its succulent representatives. This is supplemented by notes on the distribution, phylogeny, classification, and economic importance of the family and the occurrence of

succulence if this is not a general feature of the family as a whole. Also, a key to genera with succulents is included, and special terminology used for genera and species descriptions is discussed. The family concept adopted more or less follows APG III and APG IV, but with the modifications for Asparagales proposed by Nyffeler and Eggli (2010a).

## **Genera and Species**

The entries for genera and species are structured in the following way: names of authors are given in full, with initials added where necessary according to Brummitt and Powell (1992) and IPNI. The literature reference of the original description or combination is followed by information on typification (where available, see below). In the case of genera, important taxonomic literature is then cited. This is followed by information on geographical distribution (including notes on ecology where available) and an explanation of the etymology for generic names. For genera of larger families, their placement within the family is also indicated.

The main part of the entry is made up by the diagnostic description of the taxon, followed by a discussion of its variability, circumscription, and/or application where necessary. It should be noted that the descriptions reflect major variability only but do not usually include all the reported minor variations.

For larger genera, an outline of the accepted formal or informal classification is also given, with individual taxa or groups numbered in sequence. These sequence numbers are subsequently given at the start of each species description to indicate its placement within the genus.

If recent conflicting classifications are available for a given group, this is shortly discussed and the classification adopted is indicated. Further data, for example, on population biology, pollination, and seed dispersal or ethnobotany, are also included. Minor spelling variants of epithets are not indicated; instead, the “corrected” spelling is used throughout for accepted names and synonyms. Major spelling variants are treated as synonyms and are listed accordingly.

## **Infraspecific Taxa**

Infraspecific taxa are given in strict alphabetic order of rank and name (i.e., ranks in the sequence cultivar, forma, subspecies, variety). The typical infraspecific taxon (i.e., the one repeating the species name) is thus not treated first as in many handbooks but in its appropriate alphabetical sequence.

## **Cultivars, Hybrids**

Cultivars (rank indicated by placing the epithet in simple quotes) are not included on an exhaustive base; only cultivars of exceptional horticultural merit or botanical interest are covered. Cultivars not associated with a species are enumerated immediately following the entry for the genus. Cultivars

associated with a species name are included under that species, either as an entry of their own (and in the same form as subspecies, etc.) or, in the case of cultivars of minor importance, in the form of a short mention in the species discussion. Cultivar nomenclature follows the guidelines of the ICBN/ICN.

Formally named hybrid genera (nothogenera) are covered as genera of their own in the proper alphabetical sequence. The same applies to formally named hybrid species (nothospecies) and infraspecific nothotaxa. Hybrids only known with their hybrid formula are either discussed in the generic entry or mentioned under one or the other of their parent species. Formally named naturally occurring hybrids are usually covered in full including a description. No attempt has been made, however, to include all the numerous named artificial hybrids that originated in cultivation.

### **Phylogenetic Diagrams**

Phylogenetic summary cladograms are provided for all major families as well as for larger genera with a well-established infrageneric phylogeny. The width of the triangles in these cladograms is always proportional to the number of species of the clade, and the proportion of succulent taxa per clade is indicated with a darker shade. The length of the branches leading to each terminal clade has no phylogenetic meaning, that is, branch length does not indicate “phylogenetic distance” and thus is not indicative of the degree of relationships between clades. An asterisk (\*) accompanying a clade name indicates that the entity is paraphyletic.

### **Descriptions**

The descriptions are as compact, concise, and diagnostic as possible. Characters that do not vary for the group concerned are usually not repeated from the family or genus descriptions. In the case of genera further subdivided, information already presented in the group definitions is also not normally repeated in the descriptions of individual taxa.

### **Measurements**

All measurements are given in metric units. Measurements without further qualification *always refer to the long axis* of the organ described (i.e., length, height, etc.); two measurements united with the ×-sign stand for length × width.

### **Terminology**

Special terms used in descriptions are explained when first used; other botanical terminology is not further explained, and the readers are referred to the numerous botanical glossaries, of which Stearn (1992) is cited by way of a most important and useful example.

## Typification

An attempt is made to include typification data (including lecto- and neotypifications) for all accepted names. The type citations include the country and major administrative unit where the type was collected, the collector and collection number, and the herbaria where material is said or known to be deposited. The herbarium acronyms conform to *Index Herbariorum*, Ed. 8 (Holmgren & al. 1990) and its current later electronic version. Where more than one herbarium acronym is given, the first relates to the holotype and the others to isotypes (and similarly to lectotype or neotype and isolectotypes or isoneotypes). Additional information on typification is sometimes added, especially in the case of lecto- or neotypes, but epitypes are usually not cited.

## Nomenclatural Status of Names

For all taxa treated, every attempt has been made to use only valid and legitimate names, but this was not achievable in a small number of cases. In the synonym lists, the nomenclatural status (invalid, illegitimate, rejected, incorrect) is indicated by citing the ICBN or ICN articles violated. In many of these cases, the numbering still follows the “Vienna Code” (McNeill & al. 2006), but for more recent names, the numbering in the “Melbourne Code” (McNeill & al. 2012) is used; this is indicated by preceding the violated articles by “ICN.” Spelling variants are considered as invalidly published according to ICBN/ICN Art. 61.

While invalid names are, strictly speaking, not considered as names in ICBN/ICN (see Art. 6.3), they are nonetheless listed (and flagged accordingly with the violated articles of ICBN/ICN) in the synonymies in this handbook to draw attention to the fact that they are invalid.

## Synonymies

The synonymies given for genera and especially species are as complete as possible and include all names recognized as synonyms. The first synonym(s) – if applicable – is/are the basionym(s) and/or later combination(s) for the accepted name of the entry. All combinations of the same basionym are given in sequence of publication year and are united with the  $\equiv$ -sign to indicate that these are homotypic (nomenclatural) synonyms. Please note that the  $\equiv$ -sign is only used for *combinations* based on the same basionym and does not indicate other homotypic synonyms (e.g., *nomina nova*, which are by definition based on the type of the replaced name). All other synonyms are headed with “incl.” to indicate that they are, with the exception of *nomina nova* as just discussed, taxonomic synonyms (= heterotypic synonyms). Again, groups of combinations based on the same basionym are united with  $\equiv$ -signs. Basionyms are given first and in chronological order.

## Geographical Names

Country names are listed roughly in a North to South and West to East sequence. Every attempt has been made to standardize geographical names (of countries, administrative units, regions, etc.) as far as possible, but there is a

surprising amount of change relating to such names. This is specifically the case for the names of the provinces of the Republic of South Africa, which have changed considerably in the 1990s, especially affecting the former Cape Province, which has been split up into four units (North-West Province, Northern Cape, Western Cape, Eastern Cape). We tried as best as we could to provide the modern names in the distribution information included in the handbook, but it has been impossible to adjust all the data for type localities, where the name “Cape Prov.” is still used in a small number of cases.

Some difficulties were also encountered in a few cases where countries have been amalgamated (as in the case of the former North Yemen and South Yemen) or divided (e.g., Eritrea, formerly part of Ethiopia, or the nations that formerly made up Yugoslavia). Full consistency in all these cases was impossible to achieve.

In order to save space, geographical directions such as North, South, etc., are *always* abbreviated (N, S, etc.). Please note that *SW Africa* indicates “southwestern Africa” and *not* the former Southwest Africa (now Namibia). Similarly, *S Africa* indicates “southern Africa” and *not* the Republic of South Africa, for which the abbreviation RSA is always used.

## Literature References

Literature references are given for all accepted names. Normally, the publication is cited with a full abbreviation according to the standards defined in BPH2 (Bridson & al. 2004) for periodicals (supplemented with those of Eggle (1985) and Eggle (1998) for specialist succulent plant periodicals), while TL2 of Stafleu and Cowan (1976–1988) and supplements (Stafleu and Mennega 1992–2000, Dorr and Nicolson 2008–2009) are followed for book abbreviations (in both cases with some minor exceptions to conserve uniformity). In the running text, literature is cited in the usual way (author(s) and year, sometimes supplemented by a page reference), and full details can be found in the list of references at the end of each family or genus.

## Illustrations

An attempt has been made to cite at least one readily accessible illustration for each species or infraspecific taxon when no illustrations are included in the literature reference for the accepted name. If the name used in the cited publication differs from the accepted name in the handbook, it is indicated (genus name abbreviated to first letter if identical, specific or infraspecific epithet omitted if identical to the accepted name).

## Indication of Authorships of the Handbook Texts

For each family and genus, the authorship of the handbook text is indicated at the start of the entry. If more than one author has contributed species entries for a genus, each species entry has its own indication of authorship when this differs from the authorship of the genus as a whole.

# List of Abbreviations and Symbols

---

## Symbols

- ≡ Mathematical “equal,” used for homotypic synonyms  
† Dagger symbol, used for lost type specimens and to indicate death dates  
∅ Diameter symbol, used in descriptions  
× Mathematical multiplication symbol, used to connect measurements of length × width and used to indicate hybrid status  
± Plus-minus symbol, used to indicate approximate values  
\* (Beneath a taxon name) indication of a paraphyletic taxon

---

## General Abbreviations

Art.	Article of ICBN/ICN
BG	Botanical Garden
C	central
clono	clonotype, i.e., a herbarium specimen derived from the type gathering after the publication of the protologue, and not a “true” type in the sense of botanical nomenclature
cult.	cultivated
cv.	cultivar
<b>Distr</b>	distribution
Distr.	District
E	East, eastern
e.g.	for example
epi	epitype (nomenclatural type)
esp.	especially
<b>Etym</b>	etymology
excl.	excluding
fa.	forma (botanical rank)
fig., figs.	figure, figures
fl.	“floruit,” i.e., lived
Gr.	Greek
Herb.	herbarium
holo	holotype (nomenclatural type)
Hort., hort.	garden, of gardens

<b>I</b>	Illustration
ICBN	International Code of Botanical Nomenclature (“Vienna Code,” 2006)
ICN	International Code of Nomenclature for Algae, Fungi, and Plants (“Melbourne Code,” 2012)
ill., ills.	illustration, illustrations; illustrated
illeg.	illegitimate (nomenclatural concept)
in sched.	“in schedis,” i.e., in the herbarium
incl.	including
ING	Index Nominorum Genericorum
inval.	invalid (nomenclatural concept)
KG, KGW	Karoo Garden, Worcester, RSA
l.c.	“loco citato,” i.e., at the place cited
lecto	lectotype (nomenclatural type)
<b>Lit</b>	literature
ms.	manuscript
Mt., Mts.	mountain, mountains
mybp	million years before present
N	North, northern
NBG	National Botanical Garden, RSA
NE	North-East, north-eastern
neo	neotype (nomenclatural type)
nom.	“nomen,” i.e., botanical name
NW	North-West, north-western
p., pp.	page, pages
p.a.	“per annum,” i.e., per year
p.p.	“pro parte,” i.e., partly
pers. comm.	personal communication
pl.	plate
pp.	pages
Prov.	Province
publ.	published
q.v.	“quod vide,” i.e., which see
RSA	Republic of South Africa
S	South, southern
s.a.	“sine anno,” i.e., without year
s.l.	“sensu lato,” i.e., in a wide sense
s.n.	“sine numero,” i.e., without (collection) number
s.s.	“sensu stricto,” i.e., in the strict/narrow sense
SE	South-East, south-eastern
Sect.	section (botanical rank)
SEM	Scanning electron microscope
Ser.	series (botanical rank)
spp.	several species
ssp.	subspecies (botanical rank)
Subgen.	subgenus (botanical rank)
Subsect.	subsection (botanical rank)

Subser.	subseries (botanical rank)
SUG	Stellenbosch University Botanical Garden
SW	South-West, south-western
syn	syntype (nomenclatural type)
t., tt.	“tabula,” i.e., illustration plate/plates
unpubl.	unpublished
USA	United States
var.	variety (botanical rank)
W	West, western
WCSP	World Checklist of Selected Plant Families. Facilitated by the Royal Botanic Gardens, Kew. Published on the Internet: <a href="http://apps.kew.org/wcsp/">http://apps.kew.org/wcsp/</a>

### Abbreviations in Plant Descriptions

<b>Anth</b>	Anther, anthers
<b>Ar</b>	Areole, areoles
<b>Ax</b>	Axil, axils
<b>Bo</b>	Body, i.e., the plant body of a cactus, etc.
<b>Br</b>	Branch, branches
<b>Bra</b>	Bract, bracts
<b>Bri</b>	Bristle, bristles
<b>Ca</b>	Carpel, carpels
<b>Cal</b>	Calyx
<b>Cap</b>	Capitulum (of Asteraceae)
<b>Ci</b>	Interstaminal corona (of Apocynaceae)
<b>Cn</b>	corona
<b>Cs</b>	Staminal corona (of Apocynaceae)
<b>Cy</b>	Cyathium (of Euphorbiaceae)
<b>Fil</b>	Filament, filaments
<b>Fl</b>	Flower, flowers
<b>Fr</b>	Fruit, fruits
<b>Gl</b>	Gland, glands
<b>Gy</b>	Gynostegium (of Apocynaceae)
<b>Ha</b>	Hair, hairs
<b>Inf</b>	Inflorescence, inflorescences
<b>Int</b>	Internode, internodes
<b>ITep</b>	Inner tepal, inner tepals
<b>L</b>	Leaf, leaves
<b>Nec</b>	Nectary, nectaries
<b>NGl</b>	Nectary gland, nectary glands
<b>NSc</b>	Nectary scale, nectary scales
<b>OTep</b>	Outer tepal, outer tepals
<b>Ov</b>	Ovary, ovaries
<b>Pc</b>	pericarpel
<b>Ped</b>	Pedicel, pedicels

<b>Per</b>	Perianth
<b>Pet</b>	Petal, petals
<b>Phy</b>	Phyllaries (of Asteraceae capitula)
<b>Poll</b>	Pollinia
<b>R</b>	Root, roots
<b>Rec</b>	receptacle
<b>Ri</b>	Rib, ribs
<b>Ros</b>	Rosette, rosettes
<b>Sc</b>	Scale, scales
<b>Se</b>	Seed, seeds
<b>Sep</b>	Sepal, sepals
<b>Sp</b>	Spine, spines
<b>SpS</b>	Spine shield (in Euphorbiaceae)
<b>St</b>	Stamen, stamens
<b>Sti</b>	stigma
<b>Sty</b>	Style, styles
<b>Tep</b>	Tepal, tepals
<b>Tu</b>	Tubercle, tubercles (of cactus bodies, etc.)

---

## About the Editors

**Dr. Urs Eggli** studied botany at the University of Zürich and produced a monographic study of the genus *Rosularia* (*Crassulaceae*) for his Ph.D. Subsequently he became scientific assistant at the Sukkulenten-Sammlung Zürich, Switzerland, where he continues to curate the herbarium and is responsible for public education, special exhibits, and all aspects of information dissemination. His main focus of interest is the diverse biological aspects of succulent plants. Dr. Eggli is an expert in the classification of succulents, especially of the families *Crassulaceae* and *Cactaceae*, and a specialist of nomenclature. He traveled widely to study succulent plants in habitat, especially in Latin America. His numerous publications cover a diversity of aspects of the biology of succulent plants. Since 1995 he is editor of the annual *Repertorium Plantarum Succulentarum*. During 2001–2003 he edited four volumes of the first edition of the present series, and in 2005 he translated and revised a monograph of the *Cactaceae*. Dr. Eggli was awarded the Cactus d'Or by the International Organization for Succulent Plant Study in 2015.

**Dr. Reto Nyffeler** studied biology at the University of Zürich. In 1997 he received a doctor's degree with a Ph.D. thesis on the systematics of the tribe *Notocactae* (*Cactaceae*) from South America. Subsequently, he spent 4 years as a postdoctoral student at Harvard University and Stanford University and conducted during that stay the first comprehensive molecular phylogenetic study of *Cactaceae*. Since 2002 he is curator for the vascular plant collections at the United Herbaria of the University and ETH Zurich, and he is a lecturer for plant systematics at the

Department of Systematic and Evolutionary Botany, University of Zurich. His research focuses on the systematics of succulent plants and on the history of botany. During the past two decades he published several papers on succulents from different plant families in collaboration with Dr. Urs Egli.

# Introduction to the Classification of Monocotyledons

R. Nyffeler and U. Eggli

## General Remarks

Succulents of the Monocotyledons (“monocots”, subclass Liliidae or superorder Lilianae) contribute in an important manner to the overall plant diversity in many arid and semi-arid regions. Generally, they are easily recognized on the basis of their characteristic parallel-veined leaves often in rosettes or as geophytic bulbs. Prominent and landscape-dominating representatives are shrubby to arborescent monocots such as the “kokerboom” (*Aloe dichotoma*, Asphodelaceae) in the Namib desert of SW Africa, or tall-growing and branched *Yucca* species, e.g. the “Joshua tree” (*Yucca brevifolia*, Agavaceae), which form open forests in parts of the Mojave desert and surroundings in California, United States.

The Monocotyledons comprise almost 25% of the total existing vascular plant biodiversity, i.e. c. 70,000 species. Overall, about 10%, i.e. ±6460 monocot species, are recognized as succulents, present in five of the eleven orders commonly recognized today (APG 2009, 2016, Christenhusz et al. 2016). Molecular phylogenetic studies of the

past three decades have provided a well-founded “backbone” of relationships among the distinct clades recognized as orders (e.g., Givnish & al. 2006, Moore & al. 2010, Soltis & al. 2011). Our current knowledge on the phylogenetic relationships among the monocot orders and their share of succulent representatives is illustrated in Fig. 1.

## Family Classification in the Order Asparagales

There is unanimous agreement about the circumscription of the monophyletic order Asparagales in all recent phylogenetic studies (Chase & al. 2000, Fay & al. 2000). This order, comprising in total some 36,000 species of which some 16% are succulent, includes several species-rich distinct succulent lineages. However, their classification into families is still dealt with controversially, as they include most of the former “Liliaceae” and relatives as recognized by Cronquist (1981) and other authors in the era before molecular phylogenetic studies. Relationships among lineages in the order Asparagales are reconstructed in rather stable form (Bogler & al. 2006, Pires & al. 2006, Seberg & al. 2012, Steele & al. 2012) and consensus is reached (e.g., Judd & al. 2016) concerning relative relationships among the major clades, similar to the relationships illustrated in Fig. 2. The order includes a grade of families referred to as “lower Asparagales”, including Orchidaceae and

**Fig. 1** Summary phylogeny of the monocot orders following APG (2009, 2016). The numbers to the right of the ordinal names are the total species number and the number of succulent species. The widths of the triangles are proportional to the number of species per order. The proportion of succulents is illustrated by the black part of each triangle.

Except for the order Asparagales, all other orders only comprise a few dozen succulent species, with the only exception of the Poales where the bromeliads (family Bromeliaceae) contribute almost 500 species of succulents. (Copyright: U. Eggli)

Iridaceae, and a well-supported clade of “higher Asparagales” consisting of the broadly circumscribed families Asphodelaceae s.l. (changed for nomenclatural reasons from the previously used

Xanthorrhoeaceae s.l.), Amaryllidaceae s.l. and Asparagaceae s.l. However, no final consensus has been reached for the classification into families, largely due to different concepts of

**Fig. 2** Summary phylogeny of the Asparagales (data from Judd & al. 2007, Mabberley 2008, Nyffeler & Eggli 2010, and Stevens (2001 onwards, accessed Dec. 2017). Family

concepts of APG (2016) are indicated to the right of the shaded boxes. The shading of the boxes relates to the proportion of succulent species in the families. (Copyright: U. Eggli)

**Table 1** Comparison of family names used in this series (based on Nyffeler & Eggli 2010) with the family names proposed by APG (2009, 2016), and the subfamily names proposed by Chase & al. (2009)

Nyffeler & Eggli 2010, used in this Handbook	AGP IV (2016), Christenhusz & al. (2016)	Subfamilies following Chase & al. (2009)
Asphodelaceae s.s. (1)	Asphodelaceae s.l. (3)	Asphodeloideae
Amaryllidaceae s.s.	Amaryllidaceae s.l.	Amaryllidoideae
Agavaceae	Asparagaceae s.l.	Agavoideae
Anthericaceae	Asparagaceae s.l.	Agavoideae
Asparagaceae s.s.	Asparagaceae s.l.	Asparagoideae
Eriospermaceae	Asparagaceae s.l.	Nolinoideae
Hyacinthaceae	Asparagaceae s.l.	Scilloideae
Ruscaceae (2)	Asparagaceae s.l.	Nolinoideae

Notes: (1) incl. Aloaceae; (2) incl. Dracaenaceae, Nolinaceae; (3) previously, e.g. APG (2009) Xanthorrhoeaceae s.l.

inclusiveness at the rank of subfamilies versus families in this order. Hence, we identify the different concepts of inclusiveness relative to each other as *sensu lato* (s.l.) versus *sensu stricto* (s.s.).

Nyffeler & Eggli (2010) have discussed the different options at length, and the situation has not changed during the past half decade (see Nordal & Sletten BJORÅ 2016). The main point for discussion remains the number of families to accept, and their diagnostic circumscriptions. Traditional concepts such as the vast family Liliaceae s.l., or the utilization of superior versus inferior ovaries as basis for classificatory decisions, have been found to be not congruent with inferred phylogenetic relationships and these characters are no longer considered as providing valid concepts. While APG (1998) recognized almost 30 families for the Asparagales as a whole, subsequent discussions about the practicability of having so many families for the “higher Asparagales” led to a “lumping” proposal to recognize only the three widely circumscribed families Asphodelaceae (previously called Xanthorrhoeaceae), Amaryllidaceae and Asparagaceae (APG 2003, 2009, repeated by APG 2016; see Christenhusz & al. 2015 for a history of the APG process and the rationale for the preferred lumping). Hence, and applying these circumscriptions, APG recognizes today 14 families for the order Asparagales. Adherents of this reduction in the number of families and the concomitant wide circumscriptions claim that this results in a gain in practicability, esp. for teaching purposes. On the other side, the proposed radical changes in family circumscriptions are disruptive

in comparison with the traditional “splitting” concepts. It should be noted that the discussion does not concern neither the topology of the phylogenetic backbone, nor accepting non-monophyletic taxa above the rank of species, but merely affects at what level family names are attached to clades. Since the “lumping” approach of APG (2009, 2016) does not result in a gain of information, and because the alleged gains in practicability remain to be clearly identified, we here follow the traditional (splitting) concept, in line with the considerations of Schmid (2013), and in parallel with the recently updated edition of “Plant systematics: a phylogenetic approach” by Judd & al. (2016; Eriospermaceae not covered). Additional support for the recognition of at least some of the traditionally accepted families is discussed by Seberg & al. (2012) and Nordal & Sletten BJORÅ (2016). Our decision keeps all links to previous literature and concepts intact, without concessions to phylogenetic relationships. For clarity, Table 1 lists the two classificatory approaches side-by-side, and also provides the subfamily names suggested by Chase & al. (2009).

**Part I**

**The Family Agavaceae**

# Agavaceae

J. Thiede and U. Eggli

**Including** *Funkiaceae* Horaninov (*nom. illeg.*, Art. 18.3).

**Including** *Yuccaceae* J. Agardh.

**Including** *Hesperocallidaceae* Traub.

**Including** *Hostaceae* B. Mathew.

**Including** *Chlorogalaceae* Doweld & Reveal.

Small to often large perennial **Ros** plants or (sometimes bulbous) herbs, or shrubs or trees, **Ros** monocarpic, either unbranched and plant monocarpic, or branched and whole plant polycarpic, terrestrial, very rarely epiphytic; stems none or short (then not rarely caespitose), or  $\pm$  arborescent (then mostly  $\pm$  branching), in part with secondary thickening growth (*Furcraea*, *Yucca*), partly with spreading or thick and upright rhizomes (*Yucca* p.p., *Agave* Subgen. *Manfreda* p.p., herbaceous non-succulent taxa); **L** spirally arranged in **Ros**, dorsiventral, lanceolate, linear or subulate, often broadest near the base or the middle and gradually tapering towards the tip, deciduous or more commonly evergreen and then usually thick and succulent, tough and fibrous or  $\pm$  thin and weak (*Agave* Subgen. *Manfreda*,

herbaceous non-succulent taxa), tip often a hard pungent spine (*Yucca*, *Agave* s.s.) or a  $\pm$  soft (more rarely hard) point (*Beschorneria*, *Furcraea*, *Agave* Subgen. *Manfreda*) or not differentiated, margins entire, hardened in most perennial taxa but soft in herbaceous taxa, or with horny marginal teeth (these often on prominences), or filiferous; **Inf** terminal, mostly large, 0.5–13 m, with few or numerous bracts, determinate and mostly complex much-branched panicles with cymose lateral part-**Inf** consisting of monochasial units; peduncle mostly present, more rarely short to nearly none; peduncular **Bra** mostly  $\pm$  similar to rosette leaves, diminishing in size upwards; floral **Bra** present; **Ped** normally present; **Fl** bisexual, 3-merous, actinomorphic or slightly zygomorphic, pendent or spreading, or  $\pm$  upright (*Agave*), anthesis diurnal and / or nocturnal; **Tep** 3 + 3, mostly whitish to yellow or greenish, rarely  $\pm$  reddish, pinkish or brownish, or lavender or blue, **Tep**  $\pm$  spreading or connivent to form a tube-like structure (*Beschorneria*, *Hesperaloe* p.p.), or fused for part of their length and forming a tubular to campanulate tube (*Agave*), sometimes abruptly widened or urceolate in the upper part; **St** 3 + 3, inserted at or somewhat above the base of the free tepals or within the perianth tube; **Fil** mostly long and slender-filiform, rarely short, sometimes widened basally (*Furcraea*) or apically (*Yucca*), mostly glabrous, sometimes puberulent (*Yucca* p.p.); **Anth** dorsifixed, 2-theccous, small to large, sagittate to hastate (*Yucca*, etc.) or oblong to linear (*Agave*, etc.), long or short,

dehiscing introrsely with longitudinal slits; pollen primarily sulcate, rarely bisulcate (*Agave* Subgen. *Manfreda* p.p.), mainly released in monads, rarely also in tetrads (*Beschorneria*, *Furcraea*); **Ov** inferior (*Agaveae*) or superior (all other clades), 3-locular, each locule with 2 to several to mostly many ovules; **Nec** septal; **Sty** rather long and simple or apically with 3 free and short branches (*Yucca*); **Sti** mostly single and either capitate or 3-lobed or on 3 style branches (*Yucca*), surface dry or wet; **Fr** mostly loculicidal capsules, rarely septicidal capsules or berry-like (*Yucca* p.p.), with several to many seeds; **Se** various but mostly flat and plate-like, crescent-shaped or semicircular, but sometimes less compressed (*Yucca*), or globose, ovoid or pear-shaped (*Chlorogaleae*, *Schoenolirion*), black (due to phytomelans). — **Cytology**:  $x = 30$  in the *Agavoideae* (bimodal, with 25 short and 5 long chromosomes) and *Hosta* (bimodal, with 4 large, 2 medium and 24 small chromosomes), or variable ( $n = 12, 15, 16, 17, 18, 26, 30, 48?$ ) in the other clades (chromosomes all of equal length, or bimodal in *Hesperocallis*).

**Order:** Asparagales

**Important Literature:** Krause (1930: outdated synopsis); Schulze (1984: palynology, classification); Dahlgren & al. (1985: classification); Eguiarte & al. (1994: classification); Bogler & Simpson (1995: molecular phylogeny); Bogler & Simpson (1996: molecular phylogeny); Verhoek-Williams (1998: synopsis); Bogler & al. (2006: molecular phylogeny); Givnish & al. (2006: molecular phylogeny); Good-Avila & al. (2006: molecular phylogeny); Graham & al. (2006: molecular phylogeny); Rocha & al. (2006: molecular phylogeny & pollination); Smith & al. (2008: molecular phylogeny); Kim & al. (2010: molecular phylogeny); Seberg & al. (2012: molecular phylogeny); Steele & al. (2012: molecular phylogeny); Matiz & al. (2013: photosynthesis); Halpin & Fishbein (2013: molecular phylogeny *Chlorogaloideae*); Archibald & al. (2015: molecular phylogeny *Chlorogaloideae*); Heyduk & al. (2016: molecular phylogeny & photosynthesis); McKain & al. (2016: molecular phylogeny).

**Distribution:** S Canada, USA, Mexico (= distribution centre), C America to Panama, Caribbean Region, Colombia, Venezuela, Peru, Bolivia, E Asia (*Hosta*); widely cultivated throughout the world in suitable climates and often also naturalized.

The *Agavaceae* s.l. are a family of 12 genera and some 445 species. Most are adapted to semi-arid or arid conditions, and the majority are xeromorphic and somewhat to distinctly succulent rosette plants of semidesertic regions and drylands.

**Classification:** The genera placed in *Agavaceae* s.s. have a complicated classification history (Nyffeler & Eggli 2010). Up to the 1950ies, *Agave* and the closely related genera with inferior ovaries were placed in *Amaryllidaceae*, while *Yucca* and superficially similar genera with superior ovaries were classified in *Liliaceae*. At times, superficially similar xeromorphic taxa such as *Dracaena* or *Nolina* (now placed in *Ruscaceae* s.l.) were also included in *Agavaceae*, e.g. by Hutchinson (1934), Matuda & Piña Luján (1980), Rowley (1987) or Verhoek-Williams & Hess (2002).

In traditional classifications (e.g. Verhoek-Williams (1998)), *Agavaceae* s.s. are composed of 8 genera of mostly xerophytic to succulent species. In contrast to this narrow circumscription, already the early molecular phylogenies of Eguiarte & al. (1994), Bogler & Simpson (1995), Eguiarte (1995) and Bogler & Simpson (1996) showed a close relationship of *Agavaceae* s.s. with *Hosta* (traditionally classified as monogeneric *Hostaceae*; not succulent, Kubitzki (1998)), either as sister group, in a basal unresolved position, or nested within.

The inclusion of *Hosta* is also supported by cytological data (Tamura 1995) as well as embryological (Cave 1948), serological (Chupov & Kutivina 1981) and palynological data (Schulze 1984). *Hesperocallis* (monotypic *Hesperocalidaceae*; not succulent, from North America, treated as anomalous genus in *Hostaceae* by Kubitzki (1998: 260)) and *Chlorogalum* and related genera (traditionally classified as *Hyacinthaceae* subfam. *Chlorogaloideae*, Speta (1998)) are also associated with *Agavaceae* s.l. in various recent molecular phylogenies. According to the molecular phylogenies of

Seberg & al. (2012) and Steele & al. (2012). *Agavaceae* should be treated in a wide sense and include not only *Hosta*, but also *Anemarrhena* (monotypic *Anemarrheneaceae*; not succulent, from China and Korea, see Conran & Rudall (1998)), *Behnia* (monotypic *Behniaceae*; not succulent, from SE Africa, see Conran (1998a)) and *Herreria* (bitypic *Herreriaceae*; not succulent, from S America and Madagascar, see Conran (1998b)), although support for the various topologies is low. The most recent well-sampled study is that of Archibald & al. (2015). These authors found the *Chlorogaloideae* as unambiguous (though not monophyletic in the traditional circumscription) part of *Agavaceae*, confirming the earlier expressed views as well as the results of Pfosser & Speta (1999). *Behnia* and *Herreria*, however, remain unplaced in that phylogeny, and for the time being should either be included in an expanded *Anthericaceae*, or probably best be accepted as separate families in sister-group position (Petersen & al. 2006: Fig. 2).

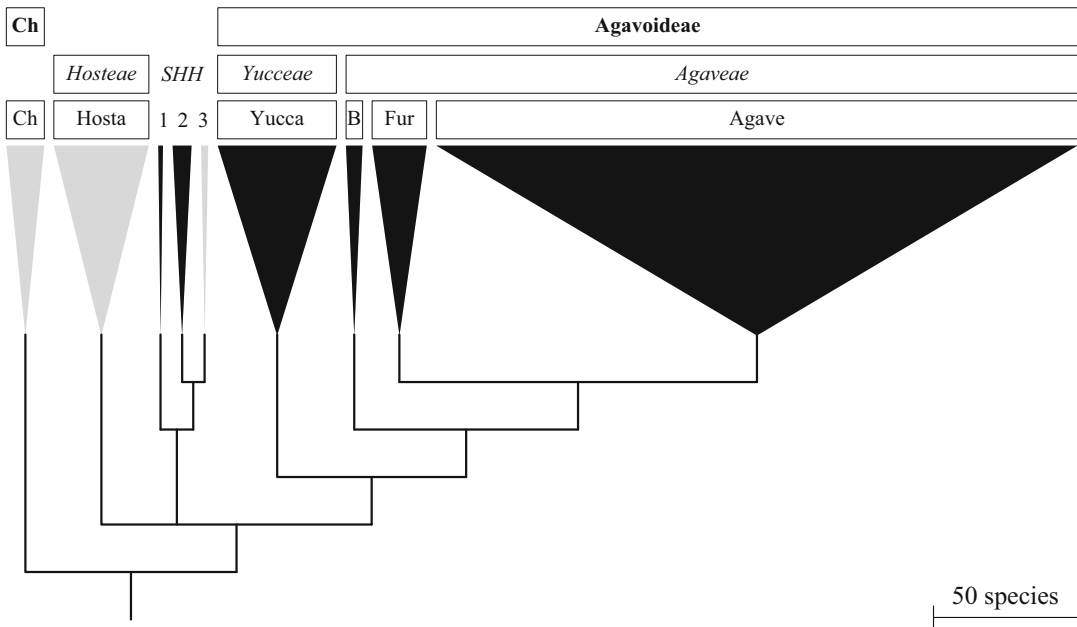

Whether the *Anthericaceae* should also be treated as part of *Agavaceae* s.l. has not yet been fully clarified. While Graham & al. (2006), Givnish & al. (2006) and Kim & al. (2010) prefer to include them in a further enlarged *Agavaceae* s.l., Pfosser & Speta (1999), Good-Avila & al. (2006), Bogler & al. (2006) and Smith & al. (2008) stress the lack of support for this and prefer to treat the *Anthericaceae* as separate family in sister-group position to *Agavaceae* s.l. This is also the position followed in this handbook.

There is no doubt that the *Agavaceae* s.l. belong to the higher core Asparagales, together with *Asparagaceae* s.s., *Anthericaceae*, *Hyacinthaceae* and *Ruscaceae*, to name just the families with succulent representatives. The families of the higher core Asparagales have recently been merged and treated as *Asparagaceae* s.l. (Janssen & Bremer 2004, Graham & al. 2006), and this classification is that advocated by APG (2009), and confirmed by APG (2016). *Asparagaceae* s.l. in that circumscription would be diagnostically circumscribed by racemose inflorescences (vs. umbellate inflorescences in the lower core Asparagales). Within the framework of such a classification, *Agavaceae* s.l. would be classified at the rank of subfamily as

*Agavoideae*. However, support for some of the proposed relationships is either low or unconfirmed in recent molecular phylogenies (e.g. Kim & al. (2010)). Moreover, accepting *Asparagaceae* in the very broad sense of APG does not provide improved insights into the phylogeny of the order, but is unnecessarily disruptive to established traditional classifications (Nyffeler & Egli 2010). Therefore, and in line with these authors and the recent textbook by Judd & al. (2016), *Agavaceae* in their new expanded circumscription is here treated as independent family. While Judd & al. (2016) also include the *Anthericaceae*, we maintain that support for this placement is insufficient, and accept *Anthericaceae* as separate family in this Handbook.

*Agavaceae* s.l. is sister to *Aphyllanthaceae* + *Themidaceae* according to Seberg & al. (2012), while Steele & al. (2012) found just *Aphyllanthaceae* (monotypic, not succulent, W Mediterranean) as the more likely sister group. This is confirmed by the plastid phylogenomic study of Givnish & al. (2018) who also found *Aphyllanthes* as most likely sister of *Agavaceae* (as *Agavoideae*, including *Anthericaceae*), but support is low. The clade age of the expanded *Agavaceae* has been estimated at a mere  $\pm 14.5$  mybp but could also be  $23.7 \pm 9.7$  mybp (Smith & al. 2008a). The monocot-wide plastid phylogenomic study of Givnish & al. (2018) found an age of 24.51 mybp for the split of the expanded *Agavaceae* from *Anthericaceae* (including *Herreria*). This is much younger than the age of  $\pm 35$  mybp given by Wikström & al. (2001) for the split of *Agave* from (*Behniaceae* + *Anthericaceae*). The major radiations in *Agave* (starting 7.8–10.1 mybp) and *Yucca* (starting 13–18 mybp) of crown-group *Agavaceae* (Good-Avila & al. 2006, Rocha & al. 2006) fall into a time of increasing desertification of North America. The origin of the family in its presently wide circumscription is supposed to have been in W North America (Bogler & al. 2006).

**Classification of crown group *Agavaceae*:** The crown group of *Agavaceae* is co-extensive with the “Agave+”-clade of Archibald & al. (2015) and is largely congruent with *Agavaceae* s.s. as covered in the first edition of this Handbook.

**Fig. 1** Summary phylogeny of *Agavaceae* s.l. mainly based on Archibald & al. (2015) (445 species total). Ch = *Chlorogaloideae*, 1 = *Hesperoyucca*, 2 = *Hesperaloe*;

3 = *Schoenolirion*; B = *Beschorneria*, Fur = *Furcraea*; SHH = SHH clade. (Copyright: U. Eggli)

Archibald & al. (2015) show this clade in a trichotomy with *Hosta* on the one hand, and their SHH-clade (*Hesperaloe* and *Hesperoyucca* plus the non-succulent *Schoenolirion*). – Fig. 1.

Although the various molecular phylogenies cited above are not in full agreement about the topology of the genera that make up the “Agave+”-clade, there are good indications that *Yucca* is the sister of an *Agave*-clade that is composed of *Beschorneria* as sister to *Agave* + *Furcraea*. The remaining genera traditionally accepted in *Agavaceae*, i.e. *Manfreda*, *Polianthes* and *Prochnyanthes*, are all derived from within *Agave* s.s. (Bogler & al. 2006, Rocha & al. 2006). They cannot be separated from *Agave* s.s. on molecular grounds, and if they were accepted as separate genera, several clades within *Agave* s.s. would have to be recognized as separate genera as well to attain a monophyletic classification. Such a classification appears clearly unwarranted before the background of the frustratingly low sequence variation for *Agave* (Bogler & al. 2006) and the segregate *Manfreda* (Ritchie 2014, almost no variation at all amongst 19 specimens studied).

In addition, *Manfreda* can be successfully hybridized with *Agave* (= ×*Mangave*) (Klein 2010) and *Polianthes* (= ×*Polifreda*) (Lindstrom 2006a, Lindstrom 2006b, Ritchie & Lindstrom 2014). We interpret this as additional support for subsuming these genera under *Agave*. The mesomorphic characters exhibited by the species of *Manfreda*, *Polianthes* and *Prochnyanthes* have thus evolved secondarily from more arid-adapted evergreen taxa. The study of McKain & al. (2016) arrives at the same topology, but is overall of limited value since only single terminals were analyzed.

*Agavaceae* s.l. can thus conveniently be classified into the following monophyletic clades – Fig. 1:

- **Chlorogaloideae** Lotsy 1911 (= “core Chlorogaloideae” of Archibald & al. (2015); incl. *Hesperocallidaceae* Moore & Reveal 2012); Bulbous herbs; **L** keeled; **Inf** (double) racemes; **Tep** white, greenish or blue; **Ov** superior, with 2 or numerous (*Hesperocallis*) ovules per locule; **Sti** 3-lobed; **Se** pear-shaped to globose or ovoid; n = 15, 17, 18, 24 (*Hesperocallis*), 26, 30, bimodal in

*Hesperocallis* (5–6 large, 18–19 small chromosomes). — 16 species (not succulent) in the 4 genera *Camassia*, *Chlorogalum*, *Hastingsia* and *Hesperocallis* from N America.

- **Hosta-clade** (= *Hosteae* Traub 1972; = *Hostaceae* B. Mathew 1988): Rhizomatous, usually deciduous herbs; **L** linear-lanceolate to cordate-ovate, often long-petiolate, distinctly veined; **Inf** bracteate racemes, often  $\pm$  secund; **Tep** white, lavender or blue; **Fil** declinate; **Ov** superior; **Se** flattened, winged;  $x = 30$ , bimodal with 4 large, 2 medium and 24 small chromosomes. — Only genus *Hosta* ( $\pm 40$  species, not succulent) from Japan, China, Korea and Russia.
- **SHH-clade** (Archibald & al. 2015): **Ov** superior; **Sti**  $\pm$  capitate to slightly lobed. — This clade is morphologically heterogeneous:
  - *Schoenolirion*: Perennial shortly rhizomatous herbs with or without bulb; **L** grass-like, flat, without keel; **Inf** to 1.5 m; **Tep** white or yellow; **Se**  $\pm$  globose;  $x = 12, 15, 16, 24(?)$ . — 3 species (not succulent) from N America.
  - *Hesperaloe* + *Hesperoyucca*: Perennial xerophytes with or without (*Hesperoyucca*) rhizomes and with monocarpic rosettes; **L** few to very numerous, tough, more or less to distinctly succulent, fibrous, rounded or keeled on both faces; **Inf** to 4.5 m, racemose-paniculate; **Tep** greenish-white, white, red to salmon or yellow; **Se** flat;  $x = 30$ , bimodal. — Composed of the genera *Hesperaloe* and *Hesperoyucca*, treated below in this Handbook.
- **Agavoideae** = “*Agave* + clade” of Archibald & al. (2015): Mostly evergreen and **L** mostly fibrous and succulent, rarely hardly succulent and xerophytic, or herbaceous-succulent and  $\pm$  deciduous; **Ov** superior or inferior. — Divisible in 2 subclades:
  - Tribe *Yuceae* Bartlett 1930 (incl. subfam. *Yuccoideae* Kosteletzky 1831; incl. *Yuccaceae* J. Agardh 1858): **L** xeromorphic, fibrous, not strongly succulent (except *Y. endlichiana*); **L** margins mostly filiferous, rarely serrulate; **Fl** pendent, actinomorphic; **Tep** free; **Ov** superior; **Anth** sagittate to

hastate. — Only genus: *Yucca*, treated below in this Handbook.

- Tribe *Agaveae* (incl. tribe *Poliantheae* Hutchinson 1934): **L** mostly xerophytic, evergreen and succulent, rarely deciduous and herbaceous and soft; **L** margins entire and often with teeth, or rarely filiferous; **Fl** pendent or  $\pm$  upright, actinomorphic or slightly zygomorphic; **Tep** free or  $\pm$  fused to form a tube; **Ov** inferior; **Anth** oblong to linear. — Consists of the genera *Agave*, *Beschorneria* and *Furcraea*, all treated below in this Handbook.

**Cytology:** The striking bimodal karyotype (McKelvey & Sax 1933) with  $x = 30$  represents a major distinguishing feature for *Agavaceae* s.s. Similar, but less pronounced bimodal karyotypes are present in *Hesperocallis* ( $x = 24$ ) and *Hosta* ( $x = 30$ ), but not in the other members of the *Agavaceae* s.l. According to McKain & al. (2012) the bimodal karyotype is due to two independent palaeopolyploidization events (identified as whole-genome duplication by McKain & al. (2016)), one predating the last common ancestor of *Agave* and *Hosta*, the other in the lineage that includes *Anthericaceae*. Subsequently, the bimodal karyotype was lost twice independently, once in the *Hesperocallis* - *Chlorogalum* - *Camassia* clade, once in *Schoenolirion*. Polyploidy is common esp. in species of *Agave* subgen. *Agave*. Ploidy ranges from diploid to octoploid, including (sterile) triploids (e.g. *A. angustifolia* var. *letonae*) and pentaploids (e.g. *A. sisalana*) (Robert & al. 2008). Polyploidization, at least in *Agave*, is likely of a comparatively young age (Robert & al. 2008) and probably linked to increased vegetative propagation and/or selected for by the conditions of an increasingly arid and harsh environment. Robert & al. (2008) did not find any dysploid changes, and early chromosome counts that deviate from the basal  $x = 30$  are likely observation errors.

**Succulence:** Leaf succulence in varying degrees prevails in the family, but stem succulence in the form of thickened rhizomes, pachycaulous stems, or subterranean corms, also occurs. The strongly succulent leaves of many *Agave* species show

well-developed tissue succulence, visible in cross sections as a narrow peripheral band of chlorenchyma, and voluminous chlorophyll-free water storage parenchyma (hydrenchyma) with interspersed scattered fibrous vascular bundles (see Müller (1909) for illustrations). The demarcation between chlorenchyma and hydrenchyma is not very strict. Already Bray (1903) found the hydrenchyma to contain air spaces, which cause the whitish colour of this tissue.

The massive trunks of stem-forming *Yucca* species such as *Y. gigantea* are reminiscent in architecture to those of *Beaucarnea* (*Ruscaceae*) and consist of numerous vascular bundles dispersed in a matrix of ground tissue. Within the outer cortex, a secondary thickening meristem develops (Fisher 1975, Stevenson 1980, Carlquist 2012: 113).

**Physiology:** Crassulacean Acid Metabolism (CAM) is almost always present in *Agave* s.s., *Furcraea* and *Hesperaloe*. *Yucca* is heterogenous with respect to photosynthetic pathway, with constitutive CAM in the species of sect. *Yucca*, and C3 in the species of the other sections (Nobel 1988, Gibson 1996: 118, Sayed 2001, Heyduk & al. 2016). *Agave amica* (*Polianthes tuberosa*) and *Beschorneria* appear to use the C3 pathway (Heyduk & al. 2016). Data for *Hesperoyucca* is ambiguous: Winter & Smith (1996) report CAM, but Heyduk & al. (2016) indicate C3. The non-succulent species of the former *Chlorogaloideae*, *Hosta* and the SHH-clade also use the C3 pathway (Heyduk & al. 2016). Heyduk & al. (2016) argue for 3 independent origins of CAM. Olivares & Medina (1990) report that CAM signature varies over the length of the leaves as well as between the leaves of a rosette in *Furcraea acaulis* (as *F. humboldtiana*); CAM is least pronounced in the vertically upright youngest leaves, and in the leaf base of older leaves.

**Chemistry:** Steroidal saponins are probably universally present throughout the *Agavaceae* s.l., sometimes in considerable concentrations. Simmons-Boyce & Tinto (2007) and Sidana & al. (2016) present an overview of steroidal saponins and saponinins found in species of *Agave*,

*Furcraea* and *Yucca*. The most common compound classes are furastanes, furospirostanes, and spirostanes. Some of these compounds show considerable biological activity, including anti-cancer effects, and some are used as starting material for the biosynthesis of steroidal hormones.

**Ecology:** Many species of *Agave* and *Yucca* as well as *Hesperoyucca* are landscape-dominating elements throughout the arid and semi-arid regions of Mexico and the SW, S, and SE USA. Some species form vast populations locally and these are a spectacular sight when mass flowering occurs.

Pollination systems vary from very specialized to generalist. The most striking specialized pollination system is found in *Yucca* and *Hesperoyucca*, with a closely knit mutualistic relationship between the pollinating yucca moths and *Yucca*, sometimes described as “nursery pollination” (Svensson & al. 2011). Althoff (2016) and the chapter on *Yucca* in this Handbook provide overviews of extant knowledge.

In *Agave*, bats and hawkmoths during the night as well as hummingbirds and other birds and/or bees during the day are known as pollinators, depending on the species. The floral syndromes displayed are not always predictive of the main pollinators (e.g. Silva-Montellano & Eguiarte (2003a) for *A. lechuguilla*, Riffell & al. (2008a) and Riffell & al. (2008b) for the generalist pollination systems of *A. palmeri* and *A. chrysantha*). Flowering *A. palmeri* form a veritable “nectar corridor” and its geographical range closely overlaps the range of its migratory bat pollinators. In C Mexico, *Agave* and bats appear to mutualistically depend on each other, while in N Mexico and SW USA, the interdependence is less strict (Riffell & al. 2008b).

**Ethnobotany:** Many species esp. of *Agave* and to a lesser extent of *Yucca* have been used for food, beverage and fibre since prehistoric times by numerous local ethnic groups. The use of these plants can be dated back for at least 9000 years (Gentry 1982: 5) and has continued for centuries among many different and unrelated cultures (Hodgson 2001: 14–51).

Gentry (1982: 3–24) termed the intimate relationship between these cultures and the plants “man-*Agave* symbiosis”.

There is evidence that some species of *Agave* (e.g. *A. parryi*) were extensively cultivated in prehistorical times for both food and fibre (Parker & al. 2014), leading to domestication of selected variants. Indeed, many relict populations continue to exist at ancient dwelling sites, and domestication of *Agave* probably started several 1000 years BCE. *A. murphyi* is one of several ancient cultigens, and clones persist at prehistorically inhabited sites as “living archaeological assemblages preserved in their cultural landscape for more than five centuries after their presumed cultivation” (Hodgson 2001).

Several species of *Agave* are used to manufacture distilled alcoholic beverages, and are the basis of the Mexican pulque, mezcal and tequila industries. Enormous areas are devoted to this purpose: Chagoya-Méndez (2004) (cited from Martínez-Gutiérrez & al. (2013)) report an area of 15.500 hectares just for the Mexican state of

Oaxaca, planted with *A. angustifolia* and yielding an annual 2.9 million litres of mezcal.

A number of species of *Agave* and *Furcraea* continue to be important sources of fibre, and are cultivated in large-scale plantations up to today in suitable climates throughout the world. Another commodity obtained from species of *Agave* is agave syrup.

**Horticulture:** Numerous taxa of *Agavaceae* s.s. have considerable horticultural potential (see Starr (2012) and Moore (2016) for *Agave*, Boeuf (2007) and Ondrovic & Ondrovic (2016) for *Yucca*, as well as the more general works on the horticultural use of perennial succulent monocots by Irish & Irish (2000) or Jacquemin (2000) and Jacquemin (2001)). Many species such as *A. americana* are frequently planted as ornamentals in broad-scale landscaping in suitable frost-free regions, esp. with Mediterranean climates. Numerous cultivars are available in the trade, including variously variegated forms (for *Yucca*, see, e.g. Boeuf & al. (2010)). Numerous species

**Key to the genera with succulents**

<b>1a</b>	<b>L</b> margins often filiferous, rarely serrulate but never toothed; <b>Fl</b> pendent, actinomorphic; <b>Tep</b> free; <b>Anth</b> sagittate to hastate; <b>Ov</b> superior	2
<b>1b</b>	<b>L</b> margins entire and without or with (often strong) teeth, rarely filiferous; <b>Fl</b> pendent or ± upright, actinomorphic or slightly zygomorphic; <b>Tep</b> free or usually forming a ± long tube; <b>Anth</b> oblong to linear; <b>Ov</b> inferior	4
<b>2a</b>	<b>Ros</b> stemless or with short to massive stem and then arborescent; <b>L</b> margins entire or filiferous, <b>L</b> epidermis without papillate cells; <b>Fl</b> usually white or whitish and wax-like; <b>Fil</b> free, apically swollen and outcurved, sometimes puberulent; <b>Sty</b> thickened with 3 short branches; <b>Sti</b> 3 with 2 lobes each (S Canada to Guatemala)	<i>Yucca</i>
<b>2b</b>	<b>Ros</b> stemless; <b>L</b> margins filiferous or finely serrulate, <b>L</b> epidermis with papillate cells over the veins; <b>Fil</b> adnate to the base or lower parts of the tepals, not swollen, straight, glabrous; <b>Sty</b> short and slender; <b>Sti</b> distinctly capitate and fringed with papillae	3
<b>3a</b>	Habit ± grass-like with succulent leaves; <b>Ros</b> few-leaved; <b>L</b> margins filiferous; <b>Tep</b> connivent and <b>Fl</b> therefore narrowly campanulate, whitish to reddish (S USA (Texas), N and C Mexico)	<i>Hesperaloe</i>
<b>3b</b>	Habit <i>Yucca</i> -like; <b>Ros</b> many-leaved; <b>L</b> margins finely serrulate; <b>Tep</b> openly spreading, whitish (SW USA, NW Mexico)	<i>Hesperoyucca</i>
<b>4a</b>	<b>L</b> margins entire or toothed; <b>Fl</b> pendent, actinomorphic; <b>Tep</b> (almost) free; <b>Fil</b> filiform or basally swollen; <b>Sty</b> swollen and with 3 basal ridges, distally abruptly narrowed	5
<b>4b</b>	<b>L</b> margins entire or toothed, or filiferous; <b>Fl</b> ± upright, actinomorphic or slightly zygomorphic; <b>Tep</b> basally fused to form a ± long tube; <b>Fil</b> filiform; <b>Sty</b> basally not swollen (S USA to Colombia and Venezuela, Caribbean region)	<i>Agave</i>
<b>5a</b>	Plants polycarpic; <b>L</b> margins entire or minutely denticulate; <b>Tep</b> free but connivent and forming a tube-like structure, reddish to yellowish; <b>Fil</b> filiform (Mexico)	<i>Beschorneria</i>
<b>5b</b>	Plants monocarpic or polycarpic when branched; <b>L</b> margins mostly toothed; <b>Tep</b> openly spreading, whitish to greenish; <b>Fil</b> basally swollen (Mexico to Bolivia, Caribbean region)	<i>Furcraea</i>

have become naturalized outside their native occurrence, and today form an important feature of the landscape, often together with species of *Opuntia* (esp. *O. ficus-indica*, *Cactaceae*), which has a similar New-World origin.

## Agave AGAVACEAE

J. Thiede

**Agave** Linné (Spec. Pl. [ed. 1], 323, 1753). **Type:** *Agave americana* Linné [lectotype, designated by Britton & P. Wilson, Sci. Survey Puerto Rico, 5: 156, 1923 (fide ING)]. — **Agavoideae** — **Lit:** Trelease (1913: synopsis West Indies); Trelease (1915: synopsis Guatemala); Berger (1915: general synopsis); Hummelinck (1936: synopsis Caribbean); Hummelinck (1938: synopsis Caribbean); Gentry (1972: monograph Sonora); Verhoek-Williams (1975: revision Subgen. *Manfreda*); Gentry (1982: monograph USA, Mexico, C America); Piña Luján (1985: synopsis Subgen. *Manfreda*); Piña Luján (1986: synopsis Subgen. *Manfreda*); McVaugh (1989: Fl. Novo Galiciana); Hummelinck (1993: synopsis Caribbean); Lott & García-Mendoza (1994: Fl. Meso-america); Solano Camacho (2002: revision *Polianthes*); Heller (2006: ill. synopsis cultivated taxa); Castillejos-Cruz (2009: revision *Manfreda*); Solano & Ríos-Gómez (2011: key to Sect. *Polianthes* in Jalisco); Solano & al. (2014: anatomy *Polianthes*); Castro-Castro & al. (2015: key to Sect. *Polianthes* in Nueva Galicia); Guillot Ortiz (2015: key to naturalized taxa in Spain); Mottram (2015: nomenclature infrageneric names); Sidana & al. (2016: review steroidal saponins); Castro-Castro & al. (2016: key to *Polianthes*, flower ills.); Boeuf & al. (2017: ill. synopsis); Thiede &

al. (2019: sectional classification). **Distr:** S USA, Mexico, C America to Panama, whole Caribbean region, Colombia, Venezuela; cultivated worldwide in tropical and subtropical to frost-free temperate climates and often naturalized. **Etym:** Gr. ‘Agave’, daughter of Kadmos and sister of Semele in Gr. mythology, also the mother of Pentheus, who she murdered in an outburst of fury; also Gr. ‘agavos’, stately, noble, illustrious; for the stately nature of many species, but also for the ferocious leaf margin teeth present in many species.

**Incl.** *Polianthes* Linné (1753). **Type:** *Polianthes tuberosa* Linné [typification by inference, only element included].

**Incl.** *Pothos* Adanson (1763) (*nom. illeg.*, Art. 53.1). **Type:** not typified.

**Incl.** *Tuberosa* Heister ex Fabricius (1769) (*nom. illeg.*, Art. 52.1). **Type:** *Polianthes tuberosa* Linné.

**Incl.** *Bonapartea* Willdenow (1814) (*nom. illeg.*, Art. 53.1). **Type:** *Bonapartea juncea* Willdenow.

**Incl.** *Littaea* Tagliabue (1816). **Type:** *Littaea geminiflora* Tagliabue.

**Incl.** *Bravoia* Lexarza (1824). **Type:** *Bravoia geminiflora* Lexarza [typification by inference, only element included].

**Incl.** *Coetocapnia* Link & Otto (1828). **Type:** *Coetocapnia geminiflora* Link & Otto [typification by inference, only element included].

**Incl.** *Robynsia* Drapiez (1841) (*nomen rejiciendum*, Art. 56.1). **Type:** *Robynsia geminiflora* Drapiez

Hamburg, Germany  
e-mail: joachim\_thiede@gmx.de

[typification by inference, only element included].

**Incl.** *Ghiesbreghtia* Roezl (1861) (*nom. illeg.*, Art. 53.1). **Type:** not typified.

**Incl.** *Manfreda* Salisbury (1866). **Type:** *Agave virginica* Linné.

**Incl.** *Allibertia* Marion (1882) (*nom. illeg.*, Art. 53.1). **Type:** *Allibertia intermedia* Marion [typification by inference, only element included].

**Incl.** *Prochnyanthes* S. Watson (1887). **Type:** *Prochnyanthes viridescens* S. Watson.

**Incl.** *Leichtlinia* H. Ross (1893). **Type:** *Agave protuberans* Engelm ex Baker [typification by inference, only element included].

**Incl.** *Delpinoa* Ross (1897). **Type:** *Delpinoa gracillima* Ross [typification by inference, only element included].

**Incl.** *Pseudobravoa* Rose (1899). **Type:** *Bravoa densiflora* B. L. Robinson & Fernald.

**Incl.** *Runyonia* Rose (1922). **Type:** *Runyonia longiflora* Rose [typification by inference, only element included].

**Incl.** ×*Mangave* D. Klein (2010). **Type:** not typified.

**Incl.** ×*Polifreda* W. Ritchie (2014). **Type:** *Polyfreda* ‘Lindstrom’.

Perennial xerophytic **Ros** plants, mostly **L** succulents, mono- or polycarpic but individual rosettes always monocarpic, terrestrial (very rarely epiphytic); **R** tough and fibrous, sometimes fusiformly thickened (Subgen. *Manfreda*), shallowly radiating; **Ros** acaulescent or stems short, rarely elongated (e.g. *A. attenuata* ssp. *dentata*), mostly thick, solitary or branched, sometimes rhizomatous (esp. in Subgen. *Manfreda*); **Ros** small to very large; **L** mostly long-lived, predominantly succulent and xeromorphic, more rarely ± soft and annual (Subgen. *Manfreda* p.p.), ± thick and fibrous, linear to lanceolate to ovate, usually rich in steroidal sapogenins, tip a terminal ± strongly developed **Sp** or a soft point (Subgen. *Manfreda*); **L** margins entire, minutely to strongly toothed (then teeth partly on prominences of the **L** margin), or filiferous; **Inf** paniculate, small to up to 12 m tall (= complete **Inf**, i.e. peduncle and floriferous part); part-**Inf** cymose, consisting of monochasial units, either ± short-stalked and

mostly with few (often paired) flowers (Subgen. *Littaea*), or long-stalked, often several times compound, with many ± densely arranged flowers (Subgen. *Agave*), or without a stalk and paired to single flowers (Subgen. *Manfreda*); **Inf** sometimes bulbiferous, esp. in species of anthropogenic origin; peduncular **Bra** ± similar to rosette leaves, diminishing in size upwards; **Ped** long to short or nearly none (esp. Subgen. *Manfreda*); **Fl** diurnal and/or nocturnal, actinomorphic or (slightly) zygomorphic (Subgen. *Manfreda* p.p., rarely in Subgen. *Littaea*), nearly always proterandrous (proterogynous in *A. polianthiflora*); **Per** tubular to campanulate, usually yellow or greenish to brownish, more rarely reddish, rarely white or pink (Subgen. *Manfreda* p.p.); **Tep** basally usually fused and forming a perianth tube, much varying in length, lobes of varying length; **St** usually exerted, but included in Sect. *Polianthes*; **Fil** usually filiform, normally ± long, rarely ± short, inserted in the tube or at the mouth of the tube or at the tepal base; **Anth** versatile, oblong, pollen released in monads, sulcate (rarely bisulcate); **Ov** inferior, thick-walled, 3-locular, with numerous axile ovules in 2 rows per locule, often constricted above to a ± conspicuous neck; septal **Nec** present; **Sty** elongate, filiform, tubular, not yet fully expanded at anthesis; **Sti** 3-lobed, papillate-glandular; **Fr** dehiscent loculicidal capsules, apically often beaked (i.e. narrowly elongated); **Se** flattened, black. — **Cytology:** x = 30, with multiples present.

The genus includes ±265 species (plus several naturally occurring or artificial hybrids) of leaf succulents (only some species of Subgen. *Manfreda* are weakly succulent) of considerable ethnobotanical, economical, ecological, and horticultural importance. Many of its species are landscape-dominating elements esp. in the Mexican semi-arid and arid biomes.

**Classification History:** *Agave* taxonomy is difficult due to the complex nomenclature with many old names of uncertain application and many poorly or even undocumented names of horticultural origin. Additional difficulties are caused by the pronounced variability and plasticity of

many taxa, including possible hybridization and introgression.

Haworth (1812: 70–72) published a first rudimentary infrageneric classification of *Agave* based on leaf colour with 2 groups “*Foliis glaucis*” vs. “*Foliis viridibus, vel virescentibus*”. Salm-Dyck (1834: 7–8) classified *Agave* into 3 informal groups: *Caulescentes*, *Acaules*, and *Herbaceae* (which includes 2 species of Subgen. *Manfreda*) and later (Salm-Dyck 1859: 86–87) recognized 5 unranked taxa (“§”) based on leaf characters. In a subsequent publication, Salm-Dyck (1861) amended the classification and used the rank of section for these groupings, which is apparently the first formally ranked classification of the genus. Jacobi (1864: 498–501) proposed a classification based on leaf characters into 4 major unranked groupings (“Hauptgruppen”), the largest of which (*Keratacanthae*) is subdivided into 7 subgroups. Koch (1865) was apparently the first to use inflorescence types and proposed an informal classification into 2 divisions (“Abtheilungen”) (“*Agavae paniculatae*” and “*Agavae spicatae*”), subdivided into groups (“Gruppen”) based on leaf characters.

Engelmann (1875: 296–297) provided apparently the first formal classification of *Agave* based on inflorescence types, proposing 3 sections: *A. Sect. Singuliflorae* with solitary flowers (conforming to the modern Subgen. *Manfreda*), *A. Sect. Geminiflorae* with long and narrow ‘subspicate’ panicles (conforming to Subgen. *Littaea*), and *A. Sect. Paniculatae* with broad panicles (conforming to Subgen. *Agave*). Baker (1877a: 171), Baker (1877b: 808), and Baker (1888a: 164) subdivided *Agave* into 3 subgenera based on inflorescence types corresponding to Engelmann’s 3 sections: *A. Subgen. Euagave* (= *Agave*), *A. Subgen. Littaea*, and *A. Subgen. Manfreda*. In a simultaneous alternative classification based on leaf characters, he (Baker 1877b: 808, Baker 1888a: 164–166) divided *Agave* into 4 series, 3 of which are subdivided into 13 informal groups. Terracciano (1885) recognized 2 subgenera, *Cladagave* (conforming to Subgen. *Agave*), and *Aplagave* (conforming to Subgen. *Manfreda* + Subgen. *Littaea*), the latter further subdivided into Engelmann’s *Sect. Singuliflorae*

and *Sect. Geminiflorae*, both further divided into subsections.

Berger (1898) first largely followed Baker’s classification. In his later monograph, Berger (1915) recognised 3 subgenera (*Manfreda*, *Littaea*, *Euagave* (= *Agave*)) and subdivided Subgen. *Littaea* into 7 formal sections, while Subgen. *Euagave* was divided into 18 informal “Reihen”. Berger’s classification became rather influential because it was adopted in Jacobsen’s handbooks (e.g., Jacobsen 1954: 78–89). Trelease (1913), in his monograph of the Caribbean species, established 7 informal groups widely used up to today.

The highly influential monograph of the continental North American species of the genus by Gentry (1982) recognized 2 subgenera only (*Littaea* and *Agave*), thus excluding *Manfreda* from *Agave* s.s. Both subgenera are subdivided into informal groups “tantamount to sections” (Gentry 1982: xi); these were mainly taken from Baker and Trelease or also established as new, and were and are widely used. Several of these informal groups were formalized at sectional rank e.g. by Ullrich (1993b: 53, 56: *Sect. Crenatae*) and Starr & Webb (2015).

For the treatment of *Agave* in the first edition of this handbook, the present author converted molecular phylogenetic results that showed *Manfreda*, *Polianthes* and *Prochnyanthes* to be nested within *Agave* s.s. into a revised, monophyletic circumscription of *Agave* s.l. that included *Manfreda*, *Polianthes* and *Prochnyanthes* in *Agave*, together classified as *A. Subgen. Manfreda*. Hochstätter (2015), in his *Agave* (s.s.) compilation, published many new names at sectional, series and subseries rank (many of the latter seem superfluous when there is only one series within a section or one subseries within a series). Mottram (2015) provided an annotated checklist of the infrageneric taxa of *Agave*.

**Classification:** The circumscription of the infrageneric groupings applied in the first edition of this handbook is largely retained, but names at formal sectional rank for all infrageneric taxa are used. This classification applies, whenever available, names at sectional rank published earlier by

Salm-Dyck (1861), Engelmann (1875), Bentham in Bentham & Hooker (1883), Berger (1915), Ullrich (1992), Ullrich (1993b), Webb & Starr (2015), and Hochstätter (2015), including 3 sectional names recently published as new (Sect. *Conicae*, Sect. *Intermediae*, Sect. *Hibernicae*). Thiede & al. (2019) provide the necessary new combinations for those groupings for which no formal name at sectional rank has previously been published, and also provides typifications and a synopsis of the infrageneric classification of *Agave*.

[1] Subgen. *Littaea* (Tagliabue) Baker 1888 (≡ *Littaea* Tagliabue 1816): **Inf** with ± short-stalked to nearly sessile part-**Inf** mostly with few, mostly geminate (= paired) **Fl**, or **Fl** 3–4 (–8), rarely more or rarely single ('spicate' **Inf**):

[A] 'Weakly armed group'; **L** margins entire, serrulate, filiferous or with weak teeth:

[a] **L** margins firm, not filiferous, **L** surface without white marks left by the central bud, striate, not soft, **L** margins finely serrulate; **Tep** tube well-developed; **Ov** without neck:

[1a] Sect. *Juncineae* Salm-Dyck 1861 (≡ Group *Striatae* Baker 1877 ≡ Subsect. *Striatae* (Baker) A. Terracciano 1885 ≡ Sect. *Schoenagave* A. Berger 1915; incl. Abteilung *Loriformes* Jacobi 1864 ≡ Sect. *Chonanthagave* A. Berger 1915): Plants perennial, often forming large clumps; **L** numerous, narrow, linear, hard, not softly succulent, usually striate, margins finely serrulate; **Fl** geminate; **Tep** forming a well-developed tube often longer than the lobes; **Ov** half-inferior, without neck, merging into a well-developed tepal tube; **Fil** usually inserted in the middle of the tube, rarely higher up, frequently at 2 levels. — 9 species in NE, C and S Mexico.

Some species appear to flower repeatedly from "lateral" inflorescences which are actually likely terminal on rudimentary lateral rosettes. Molecular data (Bogler & Simpson 1996, Bogler & al. 2006, Gil-Vega & al. 2007) show

that Sect. *Juncineae* is the earliest branch-off in *Agave* s.l. and sister to the remainder of the genus. Such a basal position coincides with its plesiomorphic morphological features, esp. as seen in *A. dasyliroides* (see the section on the phylogeny below, and under *A. dasyliroides*).

[b] **L** not striate, margins firm, not filiferous, softly succulent, surface without white marks left by the central bud, margins smooth or irregularly serrulate; **Tep** tube short or none; **Ov** with a neck:

[1b] Sect. *Inermes* Salm-Dyck 1861 (≡ Sect. *Anoplagave* A. Berger 1915 ≡ Group *Amolae* Gentry 1982 (*nom. inval.*, ICN Art. 37.1); incl. Abteilung *Margine integerrimae* Jacobi 1864 (*nom. inval.*, ICN Art. 21.2 Ex. 2 & 32.1c); incl. Ser. *Yuccifoliae* A. Terracciano 1885 ≡ Sect. *Yuccifoliae* (A. Terracciano) B. Ullrich 1996; incl. Group *Serrulatae* Baker 1877; incl. Ser. *Nizandensae* B. Ullrich 1991 ≡ Sect. *Nizandensae* (B. Ullrich) B. Ullrich 1991): **L** soft, margins entire, unarmed, **terminal Sp** usually present, rarely soft or absent; **Inf** with densely arranged **Fl**; **Tep** tube shallow, much shorter than the lobes; **Fil** usually inserted at the mouth of the tepal tube. — 10 species in N, C and S Mexico (mainly Sierra Madre Occidental).

[1c] Sect. *Choritepalae* Hochstätter 2015 (incl. Group *Choritepalae* Gentry 1982 (*nom. inval.*, ICN Art. 37.1)): **L** soft to fleshy-leathery, without (*A. bracteosa*, *A. ellemeetiana*) or with **terminal Sp** (*A. guiengolensis*, *A. gypsicola*); **Inf** dense; **Tep** tube (nearly) lacking and **Tep** arising from a discoid receptacle, or very short; **Fil** inserted on the receptacle or at the base of the tube. — 4 species from N and S Mexico (Oaxaca).

Regarded as artificial by Ullrich (1990b), and this is corroborated by the AFLP data of Gil-Vega & al. (2007) where the 3 studied taxa are not forming a monophyletic group.

[c] **L** margins filiferous (i.e. decomposing into white threads), **L** surface with white marks left by the central bud:

[1d] Sect. *Littaea* (Tagliabue) Bentham 1883 (≡ *Littaea* Tagliabue 1816; ≡ Sect. *Xysmagave* A. Berger 1915; incl. Group *Filiferae* Baker 1877 ≡ Subsect. *Filiferae* (Baker) A. Terracciano 1885): **Ros** small to medium-sized, 20–50 (–200) cm Ø; **L** numerous, narrow, unarmed, filiferous; **Fl** usually geminate, campanulate, 30–55 mm, **Tep** tube usually much (rarely slightly) shorter than the lobes; **Fil** usually inserted at the rim of the tube (rarely slightly below). — 8 species in N and C Mexico (mainly Sierra Madre Occidental).

[1e] Sect. *Parviflorae* Hochstätter 2015 (≡ Group *Parviflorae* Gentry 1982 (*nom. inval.*, ICN Art. 37.1)): **Ros** mostly small, compact, 12–60 (–80) cm Ø, solitary or freely suckering; **L** numerous, short (6–15 to very rarely exceeding 30 cm), narrow, unarmed, filiferous; **Fl** small, 13–42 (–50) mm; **Tep** forming a distinct tube; **Fil** shortly exerted, inserted usually deep in the tube. — 4 species from the N Sierra Madre Occidental (Mexico) and adjacent Arizona (USA). Starr & Devender (2011) supply a key to the species of the group.

[B] ‘Strongly armed group’: **L** margins generally with large teeth (except some species of Sect. *Micracanthae* and Sect. *Heteracanthae*):

[a] Plants mainly polycarpic; stems branched; **Tep** tube deep, lobes 1–2× as long as the tube:

[1f] Sect. *Micracanthae* Salm-Dyck 1861 (incl. Abtheilung *Subcarinatae* Jacobi 1864; ≡ Abtheilung *Aloideae* Jacobi 1868; ≡ Sect. *Anacamptagave* A. Berger 1915; incl. Group *Polycephalae* Gentry 1982 (*nom. inval.*, ICN Art. 37.1)): **Ros** usually surculose; **L** few, 13–36, broad, softly succulent, fleshy, margins usually with small, weak and closely set teeth or denticles; **terminal Sp** weak and flexible to strong; **Tep** tube often ±3-angled

and ± grooved, lobes 1–3× as long as the tube; **Ov** often ±3-angled and ± grooved. — 9 species from NE to E-C and S Mexico. A mostly mesophytic and predominantly tropical group. Many (or even all) species appear to flower repeatedly from “lateral” inflorescences which are actually likely terminal on rudimentary lateral rosettes. See Cházaro Basáñez & Vázquez-García (2013: 59) for a key.

[b] Plants mainly monocarpic; stems simple; **Ros** often surculose; **Tep** tube shallow, lobes 2–6× as long as the tube (except *A. pelona*):

[1g] Sect. *Heteracanthae* Salm-Dyck 1861 (≡ Sect. *Geminiflorae* Engelman 1875; incl. Abtheilung *Marginatae* Jacobi 1864 ≡ Group *Marginatae* Baker 1877 ≡ Subsect. *Marginatae* (Baker) Terracciano 1885 ≡ Sect. *Pericamptagave* A. Berger 1915; incl. Sect. *Brachysolenagave* A. Berger 1915; incl. Sect. *Becholdiae* Hochstätter 2015): **L** stiff and straight, usually with conspicuous and continuous horny margins and with conspicuous marginal teeth; **Fl** usually small with short, ± openly funnel-shaped **Tep** tube, lobes 3–8 (–10) × as long as the shallow tube, frequently involute around the filaments during or only after anthesis. — 25 species from the S USA (S New Mexico, S Texas), Mexico and Guatemala.

[1h] Sect. *Urceolatae* Hochstätter 2015 (≡ Group *Urceolatae* Gentry 1982 (*nom. inval.*, ICN Art. 37.1)): **L** with small or weakly attached **marginal teeth**; **Ros** usually small and in small tight clusters; **Tep** lobes broadly overlapping, ± 2.5–3× as long as the short, broadly funnel-shaped **Tep** tube. — 1 species (*A. utahensis*) in the USA (NW Arizona, S Utah, Nevada, S California).

[2] Subgen. *Agave*: **Inf** with long-stalked, often several times compound part-**Inf** with many ± densely arranged flowers (‘umbellate’ part-**Inf**).

[A] ‘Large-sized group’: Plants medium-sized to (very) large; **Ros**  $\pm 1$ –2.5 m tall; **L**  $\pm 1$ –2.5 m. — Continental Species:

[a] **L** generally not ensiform but lanceolate to ovate, much less than 10 $\times$  longer than wide; **Fr**  $\pm$  oblong:

[2a] Sect. *Agave* ( $\equiv$  Sect. *Macracanthae* Salm-Dyck 1861 (*nom. inval.*, ICN Art. 22.1 & Ex. 2)  $\equiv$  Abteilung *Carnosae* Jacobi 1864 (*nom. inval.*, ICN Art. 22.1 & Ex. 2)  $\equiv$  Sect. *Paniculatae* Engelmann 1875 (*nom. inval.*, ICN Art. 22.1 & Ex. 2)  $\equiv$  Group *Americanae* Baker 1877 (*nom. inval.*, ICN Art. 22.1 & Ex. 2)  $\equiv$  Subsect. *Americanae* (Baker) A. Terracciano 1885 (*nom. inval.*, ICN Art. 22.1 & Ex. 2)  $\equiv$  Reihe *Americanae* A. Berger 1915 (*nom. inval.*, ICN Art. 22.1 & Ex. 2); incl. Abteilung *Subcoriaceae* Jacobi 1864): **Ros** medium-sized to large, (freely) surculose; stems short; **L** light glaucous-grey to pale green, **marginal teeth** well-developed; **Inf** axis with smaller chartaceous **Bra**; fertile part of the **Inf** usually linear to long-oval in outline, part-**Inf** several times compound, not crowded; **Fl** yellow, rather slender; **Tep** tube furrowed, lobes (much) longer than the tube, not wilting until after anthesis; **Fil** inserted mostly at or near mid-tube, rarely at the mouth. — 7 mainly cultivated species.

[2b] Sect. *Salmianae* (A. Berger) Verloove & Thiede in Thiede & al. 2019 ( $\equiv$  Reihe *Salmianae* A. Berger 1915;  $\equiv$  Group *Salmianae* Gentry 1982 (*nom. inval.*, ICN Art. 37.1)): **Ros** large, massive, usually closely and freely surculose; stems short, thick; **L** light green to green, mostly very large, very thick towards the base; **Inf** axis with large appressed imbricate fleshy **Bra**; **Inf** pyramidal to ellipsoid in outline, part-**Inf** widely branching, several times compound; **Fl** large, succulent; **Tep** tube broad, thick-walled, lobes longer than or  $\pm$  as long as the tube,

dimorphic, becoming incurved when wilting after anthesis; **Fil** inserted at, above or below mid-tube, usually at 2 levels. — 3 mainly cultivated species.

[2c] Sect. *Sisalanae* Thiede & Gideon F. Smith 2019 ( $\equiv$  Unterreihe *Sisalanae* A. Berger 1915 (*nom. illeg.*, ICN Art. 53.1)): **Ros** medium to large, usually freely surculose; stems short to elongate; **L** without marginal teeth, or teeth reduced to prickles or irregularly arranged; **terminal Sp** small and weak; **Inf** lax, frequently bulbiferous; **Tep** tube as long as wide,  $\frac{2}{3}$  as long as to equalling the lobes; **Fil** inserted at or near mid-tube. — 3 cultivated species. Ullrich (1990) abandoned this group in the sense of Gentry (1982) as an artificial assemblage and rearranged its species in other groups. This is not followed here.

[2d] Sect. *Crenatae* (A. Berger) B. Ullrich 1993 ( $\equiv$  Unterreihe *Crenatae* A. Berger 1915; incl. Group *Crenatae* Gentry 1982 (*nom. illeg.*, ICN Art. 53.3, and *nom. inval.*, ICN Art. 37.1)): **Ros** medium-sized to large, usually solitary, rarely surculose; stems short; **L** green to yellowish-green, young pruinose, usually with clearly visible marks left by the central bud, **L** margins deeply crenate and undulate, **marginal teeth** large, irregular in size and spacing, frequently with small interstitial teeth, on distinct prominences; **Inf** tall, narrow; **Tep** red or purple in bud, yellow at anthesis, lobes 2.5–5 $\times$  as long as the tube; **Fil** inserted at, above or below mid-tube. — 7 species mainly from the Mexican Sierra Madre Occidental and the Trans-Mexican Volcanic Belt.

[2e] Sect. *Campaniflorae* (Trelease) R. H. Webb & G. D. Starr 2015 ( $\equiv$  Group *Campaniflorae* Trellease 1912b  $\equiv$  Reihe *Campaniflorae* A. Berger 1915): **Ros** small to large, rather open, mostly solitary (except var. *capensis*); stems short; **L** rather softly succulent, 35–150 cm, green,

margins not horny, **marginal teeth** usually 4–7 mm, uniform in size and spacing; **Fl** campanulate; **Tep** tube thin-walled, deep, broad (15–22 mm), **Tep** red to purplish in bud, opening (orange-) yellow, lobes 1.5–2× as long as the tube; **Fil** deeply attached in the tube. — 1 species (*A. aurea*) from Baja California (Mexico).

[2f] Sect. *Umbelliflorae* (Trelease) R. H. Webb & G. D. Starr 2015 (≡ Group *Umbelliflorae* Trellease 1912 ≡ Reihe *Umbelliflorae* A. Berger 1915): Stems commonly branching from **L** axils, frequently developing long branching stems resulting in fragmented clones; **L** broad and short (<70 cm), mostly bright (glaucous) green; **Inf** stout and broad, compact, part-**Inf** large, ± globular ('umbellate'), subtended by large succulent sheathing **Bra**; **Fl** large, fleshy. — 2 species in the USA (SW California) and Mexico (N Baja California).

[b] **L** ensiform, linear, patulous, 10–20× as long as wide; **Tep** lobes drying reflexed on the tube; **Fr** broadly ovoid:

[2g] Sect. *Rigidae* (Baker) R. H. Webb & G. D. Starr 2015 (≡ Group *Rigidae* Baker 1877 ≡ Subsect. *Rigidae* (Baker) A. Terracciano 1885 ≡ Reihe *Rigidae* A. Berger 1915; incl. Abteilung *Canaliculatae* Jacobi 1864; incl. Group *Sisalanae* Trellease 1913; incl. Group *Tequilanae* Trellease 1916): **Ros** small to large, surculose; stems short to elongate; **L** linear, ensiform, narrow, rigid, usually patulous, 10–20× as long as wide, margins nearly straight; **Inf** with relatively few part-**Inf**, open, frequently bulbiferous; **Fl** greenish to yellow, lobes ±2× as long as the tube; **Fr** broadly ovoid. — 14 species, mainly in Mexico, 1 in the S USA (Florida), 1 also in C America, some cultivated only.

In the first edition of this handbook, this group was treated as *Viviparae* for nomenclatural reasons (see under *A. vivipara*) and was merged with Group *Sisalanae* following Ullrich (1990d).

Here, Sect. *Rigidae* and Sect. *Sisalanae* are re-instated in the sense of Gentry (1982: 551, 619) (as Groups).

[B] 'Small-sized group': Plants mostly small to medium-sized; **Ros** ±0.4–1 m tall; **L** ±0.2–1 m. — Continental species:

[a] Plants generally surculose; flowering period spring to summer; **Tep** tube deep, lobes short, strongly dimorphic, outer lobes conspicuously larger; **Fil** usually inserted at 2 levels:

[2h] Sect. *Ditepalae* Hochstätter 2015 (≡ Group *Ditepalae* Gentry 1982 (*nom. inval.*, ICN Art. 37.1); incl. Group *Applanatae* Trellease 1912b; incl. Sect. *Hodgsoniae* Hochstätter 2015): **Ros** small to large, single or sparingly surculose; **L** mostly light glaucous, **marginal teeth** well-developed; **Inf** open; **Bra** scarious, reflexing, persistent; **Tep** leathery, usually yellow or orange, often reddish in bud; **Tep** tube deep, mostly ± as long as or longer than the lobes, rarely shorter, lobes dimorphic, usually short, tips usually red, rarely yellow; **Fil** usually inserted unequally at ± mid-tube; **Fr** long oblong. — 17 species in N, C and S Mexico and the S USA (Arizona, New Mexico).

This section includes many pre-Columbian cultivar species, mainly from Arizona.

[b] As in [a], but **Tep** tube shallow or deep, lobes much longer than the tube, subequal; **Fil** generally inserted all on the same level:

[2i] Sect. *Deserticolae* (Trellease) R. H. Webb & G. D. Starr 2015 (≡ Group *Deserticolae* Trellease 1912b ≡ Reihe *Deserticolae* A. Berger 1915): **Ros** small to medium-sized, usually ± caespitose; stems none or short; **L** glaucous-grey to greenish-yellow; **marginal teeth** weak and easily detached; **Inf** narrow, part-**Inf** short; **Fl** small, 30–60 mm, yellow(ish) to green(ish); **Tep** tube very short and broad to long, lobes 1–5× as long as the tube. — 7 species from the

- USA (SE California, Arizona) and Mexico (mainly Baja California, also Sonora) (Sonoran Desert Region).
- Without close relationship to any other Group except Sect. *Conicae* and Sect. *Intermediae*.
- [2j] Sect. *Conicae* R. H. Webb & G. D. Starr 2015: **Ros** medium-sized, solitary; **Ros** solitary; **L** green or grey-green; **Inf** conical, part-**Inf** conspicuous. — 4 species from Mexico (Baja California and Baja California Sur) (Sonoran Desert Region). Formerly placed in Sect. *Deserticolae* but differing in the shape of the inflorescences.
- [2k] Sect. *Intermediae* R. H. Webb & G. D. Starr 2015: **Ros** medium-sized, solitary or caespitose; **L** dark grey-green to blue-green; **Inf** short, cylindrical, rather broad, part-**Inf** conspicuous; **Fl** with long tepal tube. — 2 species from Mexico (Baja California Sur) (Sonoran Desert Region). Considered intermediate between Sect. *Deserticolae* and Sect. *Umbelliflorae*.
- [2l] Sect. *Parryanae* Hochstätter 2015 (≡ Group *Parryanae* Gentry 1982 (*nom. inval.*, ICN Art. 37.1)): **Ros** small to medium-sized, compact, suckering sparingly or prolifically with vigorous rhizomes; **L** short, broad, closely imbricate, glaucous-grey to green, **marginal teeth** conspicuously larger towards the leaf tip; **Inf** peduncle strong, with large, irregularly reflexing bracts, fertile part usually deep, with 15–40 part-**Inf**; **Tep** red to purplish in bud, tube well-developed, shorter than the lobes; **Fr** rather small, strong-walled, ovoid to oblong. — 4 species from the S USA (California to SW Texas) and Mexico (Central Mexican Plateau to Guanajuato).
- [2m] Sect. *Hibernicae* Hochstätter 2015 (incl. Group *Parrasanae* Alsemgeest & Roosbroeck 2012 (*nom. inval.*, ICN Art. 29.1)): Plants medium-sized; **Ros** compact, mostly solitary, or clustering; **L** broad, yellowish-green to glaucous-green; **Inf** developing during winter, protected by large bracts clasping the young inflorescence, flowers in spring. — 3 species from N & C Mexico. Formerly included in Sect. *Parryanae*.
- [c] Plants not surculose; flowering period winter to early spring:
- [2n] Sect. *Marmoratae* (A. Berger) Thiede & Gideon F. Smith 2019 (≡ Reihe *Marmoratae* A. Berger 1915; ≡ Group *Marmoratae* Gentry 1982 (*nom. inval.*, ICN Art. 37.1)): **Ros** small to large, usually solitary; **L** few, usually grey-green, often cross-zoned and scabrous, margins often repand, **terminal Sp** small; **Fl** mostly small, 28–50 (–70) mm, bright yellow or orange-yellow to orange, tube short. — 9 species from C and S Mexico and Sonora.
- [2o] Sect. *Guatemalenses* (Trelease) B. Ullrich 1992 (≡ Group *Guatemalenses* Trellease 1916; incl. Group *Atravirentes* Trellease 1916; incl. Reihe *Scolymoides* A. Berger 1915; incl. Group *Hiemiflorae* Gentry 1982 (*nom. inval.*, ICN Art. 37.1) ≡ Sect. *Hiemiflorae* Hochstätter 2015): **Ros** small to medium-sized, rarely gigantic, generally solitary; **Inf** narrow, part-**Inf** on short to medium-sized stalks; **Fl** small to medium-sized, in lax or mostly tightly ball-like clusters; **Tep** lobes longer than the tube; **Fl** inserted above mid-tube. — 13 species from E-C and S Mexico and C America (Guatemala to Costa Rica).
- Gentry's group name '*Hiemiflorae*' alludes to its flowering period in winter (Lat. 'hiems, hiemis', winter).
- [C] Caribbean and S American species (the sectional characteristics are in need of revision, and many species are insufficiently known):
- [2p] Sect. *Antillanae* (Trelease) Thiede & Gideon F. Smith 2019 (≡ Group *Antillanae* Trellease 1913 ≡ Reihe *Antillanae* A. Berger 1915): **Ros** suckering; **L** fleshy, usually curved, usually green, **marginal teeth** usually rather large, **terminal Sp** usually elongated; panicles several times compound,

freely fruiting, sometimes bulbiferous; **Fl** rather large (40–80 mm); **Se** rather large (6–9 × 4–6 mm). — 16 species mainly from the Greater Antilles.

- [2q] Sect. *Antillares* (Trelease) Thiede & Gideon F. Smith 2019 (≡ Group *Antillares* Trelise 1913 ≡ Reihe *Antillares* A. Berger 1915): **Ros** suckering; **L** fleshy, usually curved, usually green, **marginal teeth** small, **terminal Sp** usually elongated; panicle **Br** rather simple; **Fl** rather small (30–45 mm); **Se** small (5–6 × 4–5 mm). — 7 species: 5 from Cuba, 1 from Puerto, 1 cultivated only. — Not to be confused with Sect. *Antillanae*.
- [2r] Sect. *Bahamanae* (Trelise) Thiede & Gideon F. Smith 2019 (≡ Group *Bahamanae* Trelise 1913 ≡ Reihe *Bahamanae* A. Berger 1915): **Ros** rarely suckering; **L** usually grey, **terminal Sp** elongated; panicles several times compound; **Fl** rather large (40–60 mm); **Se** rather large (7–8 × 4–6 mm). — 6 species from the Bahamas.
- [2s] Sect. *Caribaeae* (Trelise) Thiede & Gideon F. Smith 2019 (≡ Group *Caribaeae* Trelise 1913; incl. Reihe *Caribaeae* A. Berger 1915): **Ros** solitary and not suckering; **L** fleshy, usually curved, usually green, marginal teeth usually small, **terminal Sp** with stout involutely slitted base, above usually short and oblique; panicles several times compound, freely bulbiferous, not always fruiting; **Fl** rather large (40–80 mm); **Se** rather large (6–9 × 4–6 mm). — 2 species from the Lesser Antilles.
- [2t] Sect. *Inaguenses* (Trelise) Hochstätter 2015 (≡ Group *Inaguenses* Trelise 1913 ≡ Reihe *Inaguensis* A. Berger 1915): **Ros** freely suckering; **L** hard and straight, grey; **Fl** rather small (35–50 mm); **Se** small (5 × 4 mm). — 2 species from the Bahamas.
- [2u] Sect. *Viviparae* (Baker) Verloove & Thiede in Thiede & al. 2019 (≡ Group *Viviparae* Baker 1877 ≡ Subsect. *Viviparae* (Baker) A. Terracciano 1885; incl. Group *Vicinae* Thiede 2001 (*nom. inval.*, ICN Art. 37.1)): **Ros** suckering; **L** fleshy, usually curved, usually green, **marginal teeth** usually small, **terminal Sp** elongated, slender;

panicles several times compound, freely bulbiferous, not always fruiting; **Fl** rather large (40–80 mm); **Se** rather large (6–9 × 4–6 mm). — 8 species from the Leeward Antilles, Trinidad, and N South America (Colombia, Venezuela).

In the first edition of this handbook, Trelise's Group *Viviparae* was renamed Group *Vicinae* for nomenclatural reasons (see under *A. cocui*), but it is here re-established in the original sense of Trelise (1913).

- [2v] Sect. *Columbianae* (A. Berger) Thiede & Gideon F. Smith 2019 (≡ Reihe *Columbianae* A. Berger 1915): **Ros** (always?) solitary and not suckering; **L** ± lanceolate, large, curved, **marginal teeth** small. — 2 species from N South America. Possibly closest to Sect. *Caribaeae*.
- [3] Subgen. *Manfreda* (Salisbury) Baker (1888) (≡ *Manfreda* Salisbury 1866; incl. *Polianthes* Linné 1753; incl. *Bravoa* Lexarza 1824; incl. *Allibertia* Marion 1882; incl. *Delpinoa* Ross 1887; incl. *Prochnyanthes* S. Watson 1887; incl. *Leichtlinia* Ross 1893; incl. *Pseudobravoa* Rose 1899; incl. *Runyonia* Rose 1922):
- [A] Rhizomes upright, fleshy, with basal corm and apical bulb; **R** fleshy and fibrous, arising from the base of the rhizome; **L** chartaceous to fleshy, green for one season or slightly longer, ending in a soft point, margins often hyaline, entire, denticulate to papillate, or with soft teeth; **Inf** 'racemes' or 'spikes' with solitary or paired **Fl** at the nodes. — S USA, Mexico, N-C America.
- [3a] Sect. *Herbaceae* Salm-Dyck 1861 (incl. *Manfreda* Salisbury 1866 ≡ Sect. *Singuliflorae* Engelmann 1875; ≡ Sect. *Manfreda* (Salisbury) Bentham 1883 ≡ *Manfreda* Subgen. *Eumanfreda* Rose 1899 (*nom. inval.*, ICN Art. 21.3) ≡ Group *Manfreda* Thiede 2001 (*nom. inval.*, ICN Art. 37.1); incl. *Manfreda* Subgen. *Pseudomanfreda* Rose 1899): Rhizome globose or oblong, large; **Fl** usually solitary at the nodes (paired only in aberrant specimens), scent sweet or unpleasant; **TeP** mostly greenish or brownish (rarely white or pink), tube

short to long; **St** and **Sty** long-exserted; **Sti** trigonous or rarely 3-lobed. — S USA, Mexico, N-C America.

Solano & al. (2017) describe the comparative anatomy of roots, shoots, leaves and peduncle base.

[3a1] Ser. *Brunneae* (Hochstätter) Thiede & Gideon F. Smith 2019 (≡ *Manfreda* Ser. *Brunneae* Hochstätter 2016 (as ‘*Brunneaea*’) ≡ *Manfreda* Sect. *Brunneae* Hochstätter 2016 (as ‘*Brunneaea*’) ≡ *A. brunnea* Subgroup Thiede 2001 (*nom. inval.*, ICN Art. 37.1)): **L** succulent, evergreen, not dying back at the end of the growing season, tip with a short soft point; **L** margins with large to small teeth  $\pm \geq 1$  mm, spaced apart from each other (**L** not fleshy and with a long pungent apical point in *A. hauniensis*). — 9 species in the USA (Texas) and N Mexico.

[3a2] Ser. *Scabraea* (Hochstätter) Thiede & Gideon F. Smith 2019 ≡ *Manfreda* Ser. *Scabraea* Hochstätter 2016 ≡ *Manfreda* Sect. *Scabraea* Hochstätter 2016 ≡ *A. scabra* subgroup Thiede 2001 (*nom. inval.*, ICN Art. 37.1)): **L** thin to semi-succulent, dying back at the end of the growing season; **L** margins entire or minutely papillate; **Ov** not protruding into the tepal tube; **Tep** tube inserted at the tip of the ovary, funnel-shaped, narrowed above the ovary. — 10 species in C and S Mexico. This subgroup is possibly an artificial paraphyletic hold-all of the least specialized species.

[3a3] Ser. *Guttatae* (Hochstätter) Thiede & Gideon F. Smith 2019 (≡ *Manfreda* Ser. *Guttatae* Hochstätter 2016 (as ‘*Guttataea*’) ≡ *Manfreda* Sect. *Guttatae* Hochstätter 2016 (as ‘*Guttataea*’) ≡ *A. guttata* Subgroup Thiede 2001 (*nom. inval.*, ICN Art. 37.1)): **L** thin to semisucculent, dying back at the end of the growing season; **L** margins hyaline, usually minutely erose-denticulate and thus rough to the touch; **Ov** protruding into the tepal tube; **Tep** tube cylindrical, not narrowed

above the ovary; **Fr** with a scar from the tepals in a ring around the shoulder. — 15 species from C and S Mexico and Guatemala.

[3a4] Ser. *Virginicae* (Hochstätter) Thiede & Gideon F. Smith 2019 (≡ *Manfreda* Ser. *Virginicae* Hochstätter 2016 (as ‘*Virginicaea*’) ≡ *Manfreda* Sect. *Virginicae* Hochstätter 2016 (as ‘*Virginicaea*’) ≡ *A. virginica* Subgroup Thiede 2001 (*nom. inval.*, ICN Art. 37.1)): **L** thin to semisucculent, dying back at the end of the growing season; **Fl** slender; **Tep** lobes erect; **Sty** markedly shorter than the stamens; **Sti** 3-lobed, lobes reflexed at maturity. — Only *A. virginica* from the C and SE USA.

[3a5] Ser. *Yucatanae* Thiede & Gideon F. Smith 2019: **Ros** 30–100 cm Ø; **L** with **terminal Sp**; **Inf** panicles or less often racemes (*A. petskinil* p.p.), with 1–5 branches; **Fl** pedicellate, solitary, subtended by a single bracteole. — Only *A. paniculata* and *A. petskinil* from the N Yucatán Peninsula (Mexico).

[B] Rhizomes small or large, upright, fleshy, with basal corm and apical bulb; **R** fleshy and fibrous, arising from the base of the rhizome; **Fl** usually paired at the nodes (solitary in *A. confertiflora*), scent sweet or absent; **Tep** white (sometimes tinged with green) to reddish, tube long; **St** and **Sty** included; **Sti** 3-lobed, lobes reflexed at maturity.

[3b] Sect. *Polianthes* (Linné) Thiede & Gideon F. Smith 2019 (≡ *Polianthes* Linné 1753): Plants medium-sized to small; **L** linear to lanceolate, herbaceous; **Tep** white, pink, red or coral-pink, tube straight or usually with a wide curve, narrow, usually gradually widening above. — 21 species from Mexico.

Feria-Arroyo & al. (2010) assessed the conservation status and extinction risk for 5 species. Castro-Castro & al. (2015) indicate the distributions by state for all species. Solano & al. (2014) describe the comparative anatomy of shoots, leaves and peduncle base.

[3b1] Ser. *Polianthes* (Linné) Thiede & Gideon F. Smith 2019 (≡ *Polianthes* Linné

1753  $\equiv$  *Polianthes* Group Thiede 2001 (*nom. inval.*, ICN Art. 37.1): **Inf** with (2–) 3–8 (–15) flowering nodes; **Fl** sweet-scented; **Ov** erect or spreading; **Tep** white to pink, sometimes pink to red at senescence, with a long, narrow tube, usually ascending at the base and curved outwards to downwards at about the middle, or also curved near the base, usually widening above the curvature up to the  $\pm$  oblique mouth, lobes erect or reflexed to revolute; **St** included, inserted near the mouth of the tepal tube. — 10 species from N and C Mexico.

[3b2] Ser. *Bravoa* (Lexarza) Thiede & Gideon F. Smith 2019 ( $\equiv$  *Bravoa* Lexarza 1824  $\equiv$  *Polianthes* Subgen. *Bravoa* (Lexarza) M. Roemer 1847  $\equiv$  Group *Bravoa* Thiede 2001 (*nom. inval.*, ICN Art. 37.1); incl. *Prochnyanthes* S. Watson 1887): **Inf** with (3–) 4–22 or more flowering nodes; **Fl** unscented (fragrant in *A. bicolor* and *A. multicolor*); **Ov** horizontal or curved downwards; **Tep** pink, pinkish-red, red, or coral-coloured (yellowish-green in *A. bicolor*, white tinged with grey-green or dull green and red in *A. bulliana*, cream to nearly red in *A. multicolor*), with a narrow tube usually ascending at the base and curved downwards at about the middle or lower so that the flowers are  $\pm$  pendent, tube usually widening above the curvature up to the straight to oblique mouth, lobes short, erect or flaring; **St** included (rarely slightly exserted), inserted from near the base of the tube up to near the throat. — 11 species from C and S Mexico.

**Terminology and measurement conventions:**

Leaf margin characters have widely been employed as diagnostic characters, but the terminology used by different authors is often not directly comparable, and lacks standardization even within major works. Here, the leaf margin is described as straight, concave or repand (rather than undulate, which refers to the structure of the leaf along its long axis). The marginal

extensions (“prickles”) are, in accordance with most current literature, termed teeth, and if they are situated on drawn-out parts of the margins, these parts are termed prominences. The teeth itself can show a specially broadened or otherwise characteristic base, and can be straight or curved, etc.

The inflorescences of Agaves are often termed spikes or panicles with umbels, e.g. by Gentry (1982), but as explained in the opening paragraphs, all inflorescences have basically a paniculate architecture, and have cymose-monochasial part-inflorescences. Accordingly, the terms “spike” and “umbel” should be avoided because they are morphologically inappropriate. Measurements for flower length include the ovary, but not the pedicel.

**Phylogeny:** The first molecular phylogenetic sequencing studies of *Agave* (Bogler & Simpson 1996, Bogler & al. 2006, Good-Avila & al. 2006) as well as a phylogeny based on structural features (Hernández-Sandoval 1995) showed that the genera *Manfreda*, *Polianthes* and *Prochnyanthes*, widely recognized in recent treatments (e.g. Verhoek-Williams 1978a, McVaugh 1989, Castro-Castro & al. 2010), are nested within *Agave*, thus rendering *Agave* s.s. paraphyletic. Recent studies (Archibald & al. 2015, Heyduk & al. 2016, Scheinvar & al. 2016, Flores-Abreu & al. 2019) confirm this pattern. The sole study in which *Manfreda*, *Polianthes* and *Prochnyanthes* grouped separate from rather than nested within *Agave* is the molecular AFLP study of Gil-Vega & al. (2007). However, in all phylogenies thus far published, the support values for the nodes are often wanting to moderate only, and none of the studies is based on a broad sampling of taxa and loci.

The samples of Subgen. *Manfreda* show different placements and either together form a clade (Bogler & Simpson 1996, Archibald & al. 2015) or are dispersed over the tree of *Agave* (Good-Avila & al. 2006, Flores-Abreu & al. 2019). In Flores-Abreu & al. (2019), the samples of the *Bravoa* and the *Polianthes* group of Sect. *Polianthes* both form monophyletic clades, but place separate suggesting polyphyly of Sect.

*Polianthes*; the same is true for the samples of Sect. *Manfreda*.

*Agave* [Subgen. *Littaea*] Sect. *Juncineae* (= Group *Striatae* of Gentry (1982)) is the earliest branch-off in *Agave* s.l. and sister to the remainder of *Agave* in the studies of Bogler & Simpson (1996), Bogler & al. (2006) and Archibald & al. (2015), thus principally confirming an earlier hypothesis of Gentry (1982: 241–242) who suggested a basal position for *A. dasylirioides* (of Sect. *Juncineae*).

Eguiarte & al. (2013) summarize available studies on the population genetics of single species or species groups.

**Biogeography:** Distribution patterns of *Agave* (s.s.) are dealt with by Reichenbacher (1985), García-Mendoza (1995), García-Mendoza & Galván (1995), and García-Mendoza (2002). The natural range of *Agave* (s.l.) ranges from the E-C USA (*A. virginica*) and the S USA throughout Mexico, Mesoamerica and the Caribbean to N South America (Colombia and Venezuela). Highest species richness in *Agave* (s.s.) is found in the border region of Puebla and Oaxaca (Tehuacán-Cuicatlán valley), further concentrations are found along the mountains of E and S Mexico (Sierra Madre Oriental, Trans-Mexican Volcanic Belt, Sierra Madre del Sur), in W Durango (Mazatlán-Durango, highway 40), SE Sonora and SW Chihuahua (Hermosillo-Chihuahua, highway 15), W Mexico (Nueva Galicia) and in S-most Baja California. Subgen *Agave* is more diverse in S Mexico, and Subgen. *Littaea* in E Mexico (Reichenbacher 1985, García-Mendoza 1995). Most species occur at altitudes between (500–) 1000 and 2000 (–2500) m, esp. in desert scrub/chaparral and pine-oak forests (García-Mendoza 2002). Subgen. *Manfreda* is most diverse in W Mexico (Nueva Galicia), along the Trans-Mexican Volcanic Belt, and in N Oaxaca (García-Mendoza 1995) (as *Manfreda*, *Polianthes*, *Prochnyanthes*).

**Cytology:** *Agave* has a bimodal karyotype with  $x = 30$  (McKelvey & Sax 1933, Robert & al. 2008). Ploidy ranges from diploid to octoploid, including (sterile) triploids (e.g. *A. angustifolia* var. *letonae*, *A. cantala*) and pentaploids (e.g.

*A. mapisaga*, *A. sisalana*) (Robert & al. 2008). Polyploidy is common in Subgen *Littaea* and even more so in Subgen. *Agave* (Pinkava & Baker 1985). Some species include several ploidy levels (e.g., *A. americana*  $2\times-8\times$ , *A. angustifolia*  $2\times-6\times$ ). The few counts for Subgen. *Manfreda* show di- or tetraploidy (Verhoek-Williams 1975: 78). Polyploidization is probably linked to increased vegetative propagation and/or selected for by an increasingly arid environment (Robert & al. 2008). The same authors argue that polyploidization is of comparatively recent age since genome structure is completely additive.

Robert & al. (2008) did not find any dysploid changes — the early dysploid counts (e.g. Sató 1935) are thus likely observation errors. Many chromosome numbers are reported by Granick (1944), Cave (1964), Pinkava & Baker (1985), Zonneveld (2003), Lv & al. (2009), and Simpson & al. (2011).

**Natural hybridization:** Natural hybrids are common in co-occurring species, and e.g. Gentry (1982) reports many putative hybrids which are usually more or less intermediate between the putative parents. Introgression is assumed in *A. americana* ssp. *protoamericana*, *A. asperrima* ssp. *asperrima*, ssp. *potosiensis* and ssp. *zarcensis*, *A. chrysantha*, and *A. palmeri*, but in *A. pringlei*, the “introgression” hypothesis of Gentry is dismissed. *A. ×saltilloensis* is an introgressive hybrid swarm connecting both parental species (see there). *A. ×arizonica*, *A. ×glomeruliflora*, and *A. ×peacockii* are natural hybrids originally published as new species. *A. doctorensis* and *A. montium-sancticaroli*, both published as new species, appear to represent natural inter-subgeneric hybrids between species of Subgen. *Littaea* and Subgen. *Agave*. *A. ×ajoensis* is a sterile triploid natural hybrid. Several taxa (*A. cerulata* var. *nelsonii*, *A. hauniensis*, *A. nunsaviorum* (both ssp.), *A. ornithobroma*) might have arisen as allopolyploids of hybrid origin, but more evidence is needed.

**Evolution:** The origin of *Agave* s.l. is dated at 7.9–9.8 mybp (Good-Avila & al. 2006), 9.07 mybp (Smith & al. 2008a), and, respectively,

8.67 mybp (Scheinvar & al. 2016). Speciation rates appear to have been significantly elevated between 8 and 6 mybp coincident with an increase of dry conditions in C Mexico, and between 3 and 2.5 mybp, probably driven by the emergence of the bat pollination syndrome (Good-Avila & al. 2006). Possible driving factors in the radiation of and high diversification rate in *Agave* s.l. may be the evolution of monocarpy, changes in physiology and morphology such as funnel-shaped rosettes, etc., and the evolution of a generalist pollination system largely dependent on nectarivorous bats. Flores-Abreu & al. (2019) calculated a younger age of 5–8 mybp, which coincides with the age of the 3 main genera of nectarivorous bats, suggests a shared evolutionary history between plants and pollinators, and gives further support for a potential *Agave*–bat coevolution.

**Succulence:** Species of Subgen. *Littaea* and Subgen. *Agave* mostly have rather tough, rigid, very fibrous leaves with a well-developed voluminous parenchymatous central water-storage tissue; this tissue is undifferentiated or differentiated into palisade-like cells and a spongy mesophyll that frequently contains groups of elongated water-storage cells (Blunden & al. 1973, Nobel 1988: 41). Bray (1903) found the storage tissue of *A. lechuguilla* to contain air spaces. The water storage tissue is usually not strictly delimited from the photosynthetic tissue (Metzler 1924: 58).

Thickened rhizomes are present in many species, and some species have a well-developed trunk with a secondary thickening meristem (Carlquist 2012: 112).

**Physiology:** Crassulacean Acid Metabolism (CAM) is almost always present and constitutive in Subgen. *Agave* and Subgen. *Littaea*; *A. vilmoriniana* exhibits substantial diurnal CO<sub>2</sub> uptake esp. at lower temperatures (Nobel 1988: 46, 99–100) and appears to be the sole exception. Data for Subgen. *Manfreda* are sparse; *A. scabra* and *A. virginica* (as *Manfreda*) both have CAM, whereas *A. amica* (*Polianthes tuberosa*) appears to use the C<sub>3</sub> pathway (Heyduk & al. 2016). CAM originated in the most recent common ancestor of

*Agave* s.l., and *A. amica* exhibits a reversal to the C<sub>3</sub> pathway, which should be confirmed with physiological measurements to rule out an intermediate form of CAM (Heyduk & al. 2016).

Similar as in *Yucca*, roots near the stem (“rain roots”) and at shallow soil depth play an important role in rapid water uptake after rainfalls (Nobel 1988: 38, 67 & seq., North & Baker 2007), likely based on the fact that the internal anatomy continues to appear more reminiscent of young roots with living cortical cells, despite the suberization of the external root tissues (North & Baker 2007). Rapid water uptake occurs close to the stem and in the distal parts of the root system, while the mid-root sections rapidly lose water uptake abilities (North & al. 2004).

64% of the examined species had contractile roots close to the stem (North & al. 2008), 85% in Subgen. *Agave* but only 47% in Subgen. *Littaea*. Contraction is achieved by radial expansion and longitudinal shortening of the cells of the inner and/or middle cortex, accompanied by a lack of suberization (North & al. 2008). Root contraction occurs already in young seedlings, which may be pulled into the soil for up to nearly 60 mm/year (average 34.7 mm/year in the 16 species studied; North & al. 2008).

**Inflorescence development:** Depending on the species, the vegetative phase may last 6–55 years, during which water and carbohydrates are accumulated in stems and leaves (Slauson 2002a: 10). In *A. deserti*, the percentage of flowering rosettes in a population varied from 3.8% in a peak year to only 0.08% in the subsequent year (Nobel 1992) and depends on the number of wet days in the previous 2 years (Nobel 1988: 92). 68% of the energy stored by the plant is diverted into inflorescence development, and the water required by the inflorescence is fully provided by the leaf water reserves (Nobel 1988: 91). The inflorescences may grow over 10 cm per day (Nobel 1988: 91; *A. lechuguilla* inflorescences may grow up to 20 cm per day and may attain full height in 3–4 weeks).

Scattered reports of polycarpic rosettes flowering repeatedly from leaf axils are discussed by Zona (2018), and are dismissed as relating to

aberrant specimens. Some species (from Sect. *Juncineae* and Sect. *Micracanthae*) are described as “polycarpic” or with “lateral” inflorescences, but such inflorescences are in fact likely in a terminal position on underdeveloped rudimentary lateral rosettes. Lev-Yadun (2017) discusses the proper use of the term monocarpic in relation to clonal species that are polycarpic, but with individual monocarpic rosettes.

**Pollination biology:** *Agave* has a broad variation in floral morphology, colour and size. In general, a broad spectrum of diurnal (hummingbirds and other birds, bees and other hymenoptera, other insects) as well as nocturnal flower visitors (nectar- and pollen-feeding bats, sphingids and moths) has been observed. Many studies were carried out on species in the S USA and Mexico; data on Caribbean and Mesoamerican species and for species of Subgen. *Manfreda* are sparse. For further information and references, see the following paragraphs. Reviews are provided by Slauson (2002a) and Rocha & al. (2006).

Subgen. *Agave*: The flowers are robust, of pale colour, pollen (with high protein content) is abundant, and nectar (abundant, with low sugar concentration) is produced mainly at night, which, together with proterandrous flowers and often a smell of ripening fruit, suggests adaptation to bat pollination (chiropterophily; Slauson 2002a: 14, Rocha & al. 2006: 335). First studies suggested that species of Subgen. *Agave* are mainly pollinated by bats (Rocha & al. 2006: 335), but recent studies showed many species to exhibit a broader range of floral visitors (birds, bees, bats, moths; Rocha & al. 2006: 335), suggesting that diurnal and other nocturnal pollinators are more important than previously thought (Slauson 2002a: 18). Several species are assumed to provide, when in bloom, a “nectar corridor” for migrating nectarivorous bats (Slauson 2002a: 16). Some species (e.g. *A. havardiana*, *A. subsimplex*) have a multiple pollinator syndrome with diurnal and nocturnal nectar production and stigma receptivity, and diurnal and nocturnal visitors that may be equally effective. *A. palmeri* and *A. chrysantha* both show floral shifts from nocturnal bat to diurnal pollination, allowing for multiple pollinators where bats are

infrequent and not important for pollination. *A. mckelveyana* occurs outside the range of nectar-feeding bats and is pollinated by hummingbirds and diurnal insects. For Caribbean species, few casual observations are reported only. *A. braceana* and *A. caymanensis* flowers are visited at day by birds, *A. grisea* nectar is exploited and *A. cajalbanensis* is pollinated by a bat.

Subgen. *Littaea*: Floral traits in Subgen. *Littaea* such as smaller floral tubes in a horizontal position, less abundant nectar with high sugar concentration, more attractive flower colours, and a sweet smell are associated with an insect pollination syndrome (Slauson 2002a: 15). Bees are indeed the most common and important pollinators, but bats, hummingbirds, and hawkmoths are also major visitors (Rocha & al. 2006: 335). Most species have a broader pollinator spectrum ensuring fruit set when the main pollinator fails. *A. parviflora* exhibits largely diurnal anther dehiscence and nectar production and is primarily visited by bumblebees. Nectar-feeding bats are the most important flower visitors in *A. difformis*, *A. garciae-mendozae*, *A. horrida* and *A. mitis*, but other pollinators (bees, hummingbirds, or hawkmoths) also occur. In *A. colimana*, bats are the sole observed visitors. *A. schottii* with mainly nocturnal nectar production favouring bat pollination, but a sweet fragrance, low protein content of the pollen, and yellow flowers favouring bee pollination, is possibly undergoing a shift from bat to bee pollination. *A. lechuguilla*, which is mainly pollinated by bees and hawkmoths, shows a latitudinal pattern in flower shape, colour and flower visitors: Flowers tend to be shorter, more open, and colourful in the N part of the range where the number of flower visits and fruit set decreases significantly.

Subgen. *Manfreda*: Species of Subgen. *Manfreda* remain sparsely studied. In Sect. *Manfreda*, seed set in *A. virginica* is mainly effected by nocturnal moths and hawkmoths, less so by bees. *A. scabra* is mainly pollinated by a long-nosed bat, minor pollinators are other bats, hawkmoths, and hummingbirds. In Sect. *Polianthes*, *A. coetocapnia* is visited by insects and hummingbirds; hummingbirds were also observed in *A. neocernua* and might be the usual

flower visitors also in other red-flowering species. For species with fragrant whitish flowers such as the Tuberose *A. amica*, hawkmoth pollination is assumed (Rocha & al. 2006: 334).

**Flowering and fruiting ecology:** Almost all Agaves are proterandrous: During the male phase on the first day(s), the anthers open and shed pollen; during the female phase in the last days, the style elongates, the stigma opens, and copious nectar is produced mainly during the night. *A. polianthiflora* appears to be the sole proterogynous species. Most species are self-incompatible (outbreeding). Only few species are reported to be self-compatible (e.g. *A. garciae-mendozae*, *A. horrida*), but cross-pollination is most effective for fruit set. In *A. colorata*, flowers pollinated by natural pollinators showed a much higher fruit set, more viable seeds and a higher germination rate compared to fruits obtained from self-pollination.

In Subgen. *Littaea*, inflorescences may have between 740 (*A. difformis*) and 3623 flowers (*A. garciae-mendozae*) of which 43.9% (*A. mitis*) to 60% (*A. garciae-mendozae*) develop into fruits. Inflorescences in Subgen. *Littaea* may release from 4000 (*A. striata*) to 142,725 viable seeds (*A. garciae-mendozae*); the seed production in *A. chrysoglossa* is estimated as 500,000–750,000 seeds per plant. In *A. palmeri*, flowering, nectar and pollen production, sugar concentration, and fruit and seed set in burn-damaged plants are as high as in unburned rosettes (Slauson 2002b). Fruit formation in *A. mckelveyana* appears to be resource- (nutrient) limited rather than pollinator- or pollen-limited.

**Seed dispersal and establishment:** In *Agave*, wind dispersal of the light-weight seeds seems to be the primary dispersal mechanism. Field studies showed that successful seedling establishment in *A. deserti* occurred only in 2 out of 29 years; from only 17 seedlings observed in an area with  $\pm 2900$  rosettes, 14 may reach maturity (Nobel 1992). The length of the first drought period is the limiting factor for establishment, with water-stress in the seedling stage as the single most important factor. Most successful seedlings are associated with

protective nurse plants (Nobel 1988: 87–88, 130). For a summary of many further ecological and ecophysiological studies on *A. deserti* see Nobel (1988). Seeds germinate both under light and dark conditions (Pavliscaak & al. 2015: for *A. palmeri*). A germination temperature of 30 °C produces optimal seedling emergence for *A. tequilana* and *A. mapisaga* (Ramírez-Tobías & al. 2016), while optimal germination temperatures of 25 °C were found for 8 further Mexican species (Ramírez-Tobías & al. 2012).

In *A. durangensis*, the seed morphology, germinability and phenolic profiles varied among 3 natural populations, and in *A. potatorum*, seeds from different localities show significant differences in size, weight, and germinability decreases with age.

**Ethnobotany:** The genus *Agave* is of considerable ethnobotanical importance due to its many-fold human uses on a household to industrial level. Agaves were consumed by humans at least 9000 years ago, and artefacts of *Agave* fibre and tools from *Agave* date from the same time (Gentry 1982: 5, 6). Cultivation of *Agave* began at least 6000 years ago (Nobel 1988: 4).

A summary of pre-hispanic culture of *Agave* in Mesoamerica and NW Mexico is provided by Radding (2012); Castetter & al. (1938) review its uses by native Americans in the SW USA, and Stewart (2015) gives an overview of past and possible future uses as beverage, food, sweetener, bioenergy and for fibres. Many data on the uses of single species are given by Bye & al. (1975: SW Chihuahua), Martin & al. (1998: NW Mexico: Río Mayo area), Hodgson (2001b: Sonoran Desert), and Delgado-Lemus & al. (2014: Tehuacán Valley). Colunga-García Marín & al. (2007) list vernacular names for 102 taxa used in Mexico.

The Mescalero Apaches were so named due to their use of *A. parryi* ssp. *neomexicana* for food (as “mescal”). Five species from Arizona (*A. delamateri*, *A. phillipsiana*, *A. sanpedroensis*, *A. verdensis*, *A. yavapaiensis*) occur always or predominantly associated with pre-Columbian living sites of native Americans, and apparently represent cultivars developed by pre-Columbian

people for food or fibre. *A. americana* var. *expansa*, *A. decipiens* and *A. murpheyi* are further pre-Columbian cultigens. *A. parryi* ssp. *parryi* and var. *huachucensis* include ancient anthropogenic populations planted by native Americans that persisted for up to 600 years.

**Domestication:** Uses of *Agave* range from harvesting wild populations or its management to cultivation on a household to plantation (industrial) level. Several species show domestication gradients, such as the different cultivars subsumed under *A. fourcroydes* that show different degrees of similarity with its wild progenitor *A. angustifolia*, and *A. inaequidens* (wild and cultivated) apparently gave rise to *A. hookeri*, which is exclusively cultivated. The domestication syndrome (direction of human selection) includes gigantism (larger leaves and rosettes), greater fibrosity (in fibre plants) or higher sugar contents (in *A. tequilana* landraces), less pronounced thominess, and reduced sexual reproductive capacity (often even sterility) (Colunga-García Marín & al. 1996, Colunga-García Marín & May-Pat 1997, Ramírez-Tobías & al. 2016). *A. tequilana* (used for tequila), *A. fourcroydes* and *A. sisalana* (both used for fibre) are domesticated “species” derived from *A. angustifolia* (*A. tequilana*, *A. fourcroydes*) or of possible hybrid origin involving *A. angustifolia* or *A. kewensis* (*A. sisalana*).

**Alcoholic beverages:** Alcoholic beverages from Agaves include those produced from the sap of living plants, consumed fresh as aguamiel or fermented as pulque, and distilled liquors known as mescal (alternative spelling mezcal) or tequila. Pulque was developed from aguamiel by the Aztecs at the end of the twelfth century and incorporated into religious and mystical ceremonies which were associated with several gods, including Mayahuel, the Aztec goddess of pulque (Gentry 1982: 8). Many *Agave* species are harvested for pulque from natural populations or are cultivated (e.g. *A. americana* s.l., *A. atrovirens* var. *mirabilis*, *A. hookeri*, *A. marmorata*, *A. salmiana* ssp. *salmiana*, *A. weberi*). Further fermented beverages are produced regionally, e.g., “sugui”, a strong alcoholic beverage from baked stems and leaf bases of *A. bovicornuta*, *A. multiflifera* or *A. wocomahi* in NW Mexico. Torres & al. (2015)

provide a list of 37 species that are extracted from natural populations for mescal production. The increased demand for *Agave*-derived alcoholic beverages results in intensified development of agricultural use, which diminishes food availability for pollinators, and concurrently negatively impacts genetic diversity (Trejo-Salazar & al. 2016). According to these authors, a bat-friendly approach would be to allow 5% of the plants to flower — applying such an approach to the whole current total population of *A. tequilana* would feed 2.3 million bats per month. For *A. cupreata*, Torres & al. (2015) suggest to conserve at least 30% of the reproductive plants of a population to ensure natural or assisted population recovery.

The distilled beverage mescal may be produced from any species of *Agave* and is officially produced mainly in Oaxaca and also in Tamaulipas, Durango, Zacatecas, San Luis Potosí, Guanajuato, Guerrero, Puebla and Oaxaca. It includes regional variants such as bacanora in Sonora. Species used include *A. angustifolia*, *A. cupreata*, *A. durangensis*, *A. inaequidens*, *A. lyobaa*, *A. marmorata*, *A. montium-sancticaroli*, *A. potatorum*, and *A. salmiana* ssp. *crassispina*. According to Mexican law, tequila can only be produced in Jalisco from the cultivar ‘Azul’ of *A. tequilana* (see there for details). The landscape around the town of Tequila (Jalisco, Mexico) where *A. tequilana* ‘Azul’ is cultivated in large plantations was declared as UNESCO World Heritage “Agave Landscape and Ancient Industrial Facilities of Tequila” in 2006.

Enormous areas are planted with *Agave* species to meet the demand of the beverage industry – Fig. 1. Alone for Oaxaca, an area of 15,500 hectares is planted with mostly *A. angustifolia*, resulting in a primary production of 2.9 million litres of mescal per year (Chagoya-Méndez 2004 cited in Martínez-Gutiérrez & al. 2013). The stupendous amount of bagass waste of the mescal industry is currently underused but could be employed for soil-less vegetable production (Martínez-Gutiérrez & al. 2013).

**Fibre:** Many *Agave* species are used locally for fibre, e.g. *A. cocui*, *A. ghiesbreghtii*, *A. multiflifera*, and *A. quiotepensis*. For large-scale

**Fig. 1** Enormous areas are devoted to commercial plantations with species and cultivars of *Agave*, such as *Agave* ‘Azul’ for tequila production. (Source: Flickr/Sergio Niebla, CC BY-SA)

fibre production, *A. lechuguilla* is harvested from wild populations, and *A. fourcroydes* and *A. sisalana* are cultivated on industrial level in plantations (see under these species). Fibres and textiles traded in Morocco under the name of “Agave silk” (or “cactus silk”) have nothing to do with *Agave* fibres, and have been found to consist of viscose fibres (U. Egli, pers. comm.).

**Food:** Stems (hearts) are eaten cooked or pit-baked (*A. americana* var. *expansa*, *A. jaiboli*, *A. marmorata*, *A. multiflifera*, *A. pelona*) or made into mescal bread (“mesagoli”, *A. americana* var. *expansa*, *A. multiflifera*, *A. wocomahi*) or sweet food (*A. polianthiflora*). *A. kerchovei* plants are used as food for humans. Flower buds (“cacayas”) are prepared boiled and cooked in various stews (*A. bovicornuta*, *A. durangensis*, *A. graciellae*, *A. gypsicola*, *A. maximiliana* var. *maximiliana*, *A. quioatepecensis*), or also eaten dried (*A. gypsicola*) or in the form of tortillas (*A. bovicornuta*), sometimes washed to remove the bitterness (*A. bovicornuta*). Sometimes, flowers are eaten, too (*A. gypsicola*). (Young) inflorescences (“quiotes”) are cooked and eaten as stew or sweets (*A. graciellae*, *A. gypsicola*, *A. jaiboli*, *A. marmorata*). In recent years, unfermented concentrated juice

(“Agave syrup”) has gained some importance as sweetener.

Giant bugs feeding on inflorescences of *A. triangularis* are also used as food item. Leaf cuticles (“mixiote”) from *Agave* leaves are used to envelop food (Delgado-Lemus & al. 2014: 7), and the illegal removal from leaves of plantation plants negatively affects growth rates (José Jacinto & García Moya 2001). In order to prevent thefts of cuticles, small holes are made into the central leaf bud, which renders the cuticles useless for “mixiote” production, but does not affect leaf unfolding rates (García-Moya & Nobel 1990).

**Animal fodder:** Young or also old plants and inflorescences are used as fodder mainly for cattle and goats (Delgado-Lemus & al. 2014: 7; see also under *A. kerchovei*, *A. quioatepecensis*), sometimes also the flowers (*A. kerchovei*).

**Medicine and poison:** Roasted leaves, leaf infusions, tonics and tinctures are used as anti-inflammatory, analgesic and anticoagulant treatments, and to relieve luxation pains, stomach ache, cold, fever, bronchitis, and for whetting appetite and treating rheumatic and traumatic pains (Delgado-Lemus & al. 2014: 7). *A. paniculata* and *A. petskinil* are used against headache,

species of Sect. *Manfreda* (*A. brunnea*, *A. maculosa*, *A. variegata*, *A. virginica* ssp. *virginica*) are used as antidote against snakebites, and *A. vilmoriniana* is used to stupefy fish.

**Fencing and construction:** Agaves may be used as live fences or hedges (*A. americana* var. *expansa*, *A. ghiesbreghtii*, *A. hurteri*, *A. karatto*, *A. striata* ssp. *striata*, *A. tecta*), also on rock walls (*A. hurteri*), and dried inflorescences may also be used (*A. gypsicola*).

Several species are used as wooden material for supporting roofs, walls and fences. Peduncles are employed as water pipes, leaves for thatching, and fibre cords for tiding house structures (Delgado-Lemus & al. 2014: 7). Large peduncles are used for manufacturing ladders, and thinner, longer peduncles as pole vaults for collecting fruits (Delgado-Lemus & al. 2014: 7). Inflorescence stalks may be used as arrow shafts (*A. polianthiflora*).

**Ritual and religious:** Several species are used for decorating altars (Delgado-Lemus & al. 2014: 7; see also *A. marmorata*) or for curing and death ceremonies (*A. shrevei*). Dried inflorescences of *A. missionum* are used as Christmas tree.

**Ornamental:** Many species are locally planted as ornamentals (Delgado-Lemus & al. 2014: 7). Species of sect. *Polianthes* are locally used as ornamentals (*A. neonelsonii*, *A. rosei*) or harvested for the cut-flower trade (*A. dolichantha*). The “Tuberose” (*A. amica*) has attracted considerable interest from the cut-flower trade.

**Biofuel:** Remains of dead adult large-sized species are used locally as firewood (Delgado-Lemus & al. 2014: 7). For the industrial use for biomass and biofuel production, see Garcia-Moya & al. (2011) and Davis & al. (2011). Under optimal conditions, productivity of *Agave* plantations attains 40 tons dry weight per hectare per year. Mechanized large-scale production is a challenge, however (Stewart 2015). Industrial ethanol production using *Agave* is more costly than using corn or sugar cane as basis (Núñez & al. 2011).

**Chemistry:** Due to high saponin contents, species esp. of Sect. *Manfreda* (*A. brunnea*, *A. hauniensis*, *A. maculosa*, *A. paniculata*, *A. petskinil*), but also *A. cocui* and *A. vilmoriniana*

are used as soap, bath, laundry and shampoo. The chemistry and bioactivities of the steroidal saponins of *Agave* are reviewed by Sidana & al. (2016); for the industrial potential as source of saponins as antinutritional factors and anticancer, antifungal, and anti-inflammatory agents, see Santos-Zea & al. (2012).

For the industrial potential of Agaves as source of polyphenols with anticancer, antioxidant, anti-diabetic, anti-inflammatory, antiparasitical, antimicrobial, and prebiotic activities, see Santos-Zea & al. (2012) and Almaraz-Abarca & al. (2013a).

**Horticulture:** Many *Agave* species are cultivated world-wide esp. in Mediterranean climates, in the arid S USA also for “desert landscaping” (see Starr 2012). Many species are naturalized world-wide; naturalized species near Valencia, Spain, are listed by Guillot Ortiz & Meer (2003a), at the central W coast and SE coast of Portugal by Silva & al. (2015) and Smith & Figueiredo (2008), and in the Cape Floristic Region, RSA, by Smith & Klopper (2007). Species cultivated in (sub-)tropical regions might be threatened by the Agave Snout Weevil (*Scyphophorus acupunctatus*) (see Smith & al. 2012). Control of neophytic *A. americana* on the Canary Islands was most effective combining removal of adults with herbicide spraying of juveniles, but with significant recovery 4 years after the treatment (Arévalo & al. 2015).

In cultivation, variegated cultivars are increasingly popular. Early listings of known variegates are given by Koch (1862) and Trelease (1908b). Many named cultivars and also unnamed examples are shown by Starr (2012), Pilbeam (2013), Starr (2014), and Moore (2016). Keys to variegated and other cultivars grown in Spain are provided by Guillot Ortiz & Meer (2003a) and Guillot Ortiz & al. (2008). In *A. americana*, cultivars with various degrees of variegation are common, and sometimes also naturalized, e.g. in Spain (Guillot Ortiz & Meer 2003a, Guillot Ortiz & al. 2012: as *A. ingens*) or Portugal (Smith & Figueiredo 2008). The origin and genetics of variegated cultivars is dealt with by Zonneveld (2007). Methods for large-scale propagations of

useful *Agave* species are described by Binh & al. (1990).

Artificial *Agave* hybridisation started in 1865 with *A.* × *hybrida* (see there). Trelease (1914) listed the interspecific hybrids known at that time. Hybrids between species of Subgen. *Agave* and Subgen. *Littaea* and with and between species of the former genera *Manfreda*, *Polianthes* and *Prochnyanthes* show that crossing barriers within *Agave* s.l. are weak or absent: Examples for crosses of Subgen. *Agave* × Subgen. *Littaea* are *A.* × *engelmannii*, *A.* × *guignardii*, *A.* ‘Blue Flame’ (see under *A. attenuata* ssp. *attenuata*), and *A.* ‘Royal Spine’ (see under *A. macroacantha*), examples for crosses of *Manfreda* × *A.* Subgen. *Agave* or Subgen. *Littaea* (= × *Mangave*) are *A.* × *gonzaloii*, *A.* ‘Bloodspot’ (see under *A. macroacantha* and *A. maculosa*), *A.* ‘Macho Mocha’ (see under *A. variegata*), and *A. spicata* (?). Crosses also exist for *Manfreda* × *Polianthes* (= × *Polifreda*; Lindstrom (2006), Ritchie & Lindstrom (2014); see under *A. virginica* ssp. *virginica*), and *Polianthes* × *Prochnyanthes* (*A.* × *neokewensis*). In the white-flowered Tuberose *A. amica*, modern hybrids were obtained from crossings with other species of Sect. *Polianthes* with other flower colours (see there).

The following species may be hardy outdoors in C Europe in mild climates and/or with rain protection: *A. havardiana*, *A. parryi* and ssp. *neomexicana* (as *A. neomexicana*), *A. utahensis* (Boeuf 2007), and *A.* × *glomeruliflora* (see there).

The following names are of unresolved application but are referred to this genus: *Agave abortiva* A. Terracciano (1885); *Agave aloides* Jacobi (1866); *Agave americana* Grisebach (1864) (*nom. illeg.*, ICN Art. 53.1); *Agave aspera* A. Terracciano (1885) (*nom. illeg.*, ICN Art. 53.1); *Agave attenuata* var. *subdenudata* hort. ex Trelease (1892); *Agave banlan* Perrotet (1824); *Agave baxteri* Baker (1888); *Agave bennetii* hort. ex A. Berger (1915); *Agave bernhardii* Jacobi (1868); *Agave bonnetii* hort. ex A. Berger (1915); *Agave calderonii* Trelease (1923); *Agave caribaea* Verschaffelt (1873); *Agave chloracantha* Salm-Dyck (1842) (*nom. inval.*, ICN Art. 38.1a); *Agave concinna* Lemaire in Hort. Vanhoutte

(1846); *Agave cookei* Woodrow (1899); *Agave cucullata* Lemaire ex Jacobi (1865); *Agave davillonii* Baker (1892); *Agave deamiana* Trelease (1915); *Agave decaisneana* Jacobi (1868); *Agave diacantha* Royle (1855); *Agave elizae* A. Berger (1915); *Agave entea* Hartwich (1897); *Agave erosa* A. Berger (1915); *Agave flaccida* Jacobi (1866) (*nom. illeg.*, ICN Art. 53.1); *Agave fourcroydes* Jacobi (1865) (*nom. illeg.*, ICN Art. 53.1); *Agave fragrantissima* Jacquin (1762); *Agave* × *franzosinii* Hort. Hanbury ex W. Watson (1889) (*nom. inval.*, ICN Art. 32.1c?); *Agave friderici* A. Berger (1912); *Agave galeottei* Baker (1877); *Agave glabra* Karwinsky in M. Roemer (1847); *Agave glaucescens* Otto in M. Roemer (1847) (*nom. inval.*, ICN Art. 32.1c?); *Agave grandibracteata* Ross (1892); *Agave granulosa* Scheidweiler ex K. Koch (1861); *Agave guedeneiryi* Houlllet (1875); *Agave gutierreziana* Trelease (1920); *Agave henriquesii* Baker (1887); *Agave heteracantha* A. Berger (1898) (*nom. illeg.*, ICN Art. 53.1); *Agave horizontalis* Jacobi (1868); *Agave horizontinalis* Baker (1887) (*nom. inval.*, ICN Art. 61.1); *Agave humboldtiana* Jacobi (1866); *Agave inghamii* hort. ex Verschaffelt (1872) (*nom. inval.*, ICN Art. 38.1a?); *Agave inghamii* [?] *longissima* Hort. Whitacker ex A. Berger (1915); *Agave ixtli* K. Koch (1860) (*nom. illeg.*, ICN Art. 53.1); *Agave kellermaniana* Trelease (1915); *Agave killischea* Rafarin (1874); *Agave lamprochlora* Jacobi (1868); *Agave laticincta* Verschaffelt (1868); *Agave leguayana* Baker (1877) (*nom. illeg.*, ICN Art. 53.1); *Agave leguayana* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); *Agave lemairei* Hort. Verschaffelt ex Ill. Hort. (1864); *Agave lempana* Trelease (1925); *Agave lindleyi* Jacobi (1868); *Agave littaeoides* Pampanini (1909); *Agave longisepala* Todaro (1878); *Agave maculata* Regel (1856); *Agave maculata* hort. ex A. Berger (1915) (*nom. illeg.*, ICN Art. 53.1); *Agave malinczii* Hort. Tonel ex K. Koch (1862); *Agave maximowicziana* Regel (1890); *Agave milleri* Salm-Dyck (1834) (*nom. illeg.*, ICN Art. 53.1); *Agave minarum* Trelease (1915); *Agave monostachya* Sessé & Moçño (1894); *Agave monstrosa* Rafarin (1874); *Agave mooreana*

Masters & T. Moore (1874) (*nom. inval.*, ICN Art. 36.1a); *Agave muelleriana* A. Berger (1915); *Agave multiflora* Todaro (1890); *Agave nigra* Bassols (1870) (*nom. inval.*, ICN Art. 38.1a); *Agave nigromarginata* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); *Agave nirvana* Herbin & Robins (1968) (*nom. inval.*, ICN Art. 39.1, 40.1); *Agave nissonii* Baker (1874); *Agave ortgiesiana* Todaro (s.a.) (*nom. illeg.*, ICN Art. 53.1)  $\equiv$  *Agave filifera* fa. *ortgiesiana* (Todaro) H. Jacobsen (1954) (*nom. inval.*, ICN Art. 41.4); *Agave pallida* Sartorius ex Jacobi (1865) (*nom. illeg.*, ICN Art. 53.1); *Agave pampaniniana* A. Berger (1915); *Agave paupera* A. Berger (1915); *Agave pavoliniana* Pampanini (1910); *Agave perlucida* Jacobi (1868); *Agave perringea* Rafarin (1874); *Agave planera* Fasio (1903) (*nom. inval.*, ICN Art. 32.1c); *Agave polyacantha* Haworth (1821); *Agave polyacantha* Jacobi (1865) (*nom. illeg.*, ICN Art. 53.1); *Agave potatorum* K. Koch (1860) (*nom. illeg.*, ICN Art. 53.1); *Agave pringlei* hort. ex A. Berger (1912); *Agave prostrata* Martius ex Dragendorff (1898) (*nom. inval.*, ICN Art. 32.1c); *Agave pulcherrima* Otto in M. Roemer (1847); *Agave pulverulenta* Verschaaffelt (1863); *Agave pumila* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); *Agave purpurea* Souza Novelo (1941) (*nom. inval.*, ICN Art. 39.1); *Agave ragusae* Todaro (1897); *Agave regia* Baker (1877); *Agave robusta* Rafarin (1874); *Agave rohanii* hort. ex A. Berger (1915) (*nom. illeg.*, ICN Art. 53.1); *Agave rudis* Lemaire ex Jacobi (1865); *Agave saponifera* H. Grothe (1880); *Agave scolymus* D. Dietrich (1843) (*nom. illeg.*, ICN Art. 53.1); *Agave scolymus* Kunth (1850) (*nom. illeg.*, ICN Art. 53.1); *Agave serrata* Hort. Tonel ex K. Koch (1862); *Agave serrulata* Steudel (1841); *Agave silvestris* hort. ex A. Berger (1915); *Agave smithiana* Jacobi (1866); *Agave sordida* A. Berger (1915); *Agave subinermis* M. Roemer (1847); *Agave taeniata* Hort. Tonel ex K. Koch (1862); *Agave teoxomuliana* Karwinsky ex M. Roemer (1847); *Agave thomsoniana* Jacobi (1866); *Agave toeniata* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); *Agave toneliana* Hort. Tonel ex K. Koch (1862);

*Agave toneliana* Baker (1881) (*nom. illeg.*, ICN Art. 53.1); *Agave toneliana* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); *Agave troubetskoyana* Baker (1892); *Agave vandervinnenii* Lemaire (1864); *Agave viridissima* Baker (1877); *Agave vivipara* Salm-Dyck (1859) (*nom. illeg.*, ICN Art. 53.1); *Agave washingtonensis* Rose (1898); *Agave watsonii* J. R. Drummond & C. H. Wright (1907); *Agave weissenburgensis* Wittmack ex Baker (1889) (*nom. inval.*, ICN Art. 61.1?); *Agave wercklei* Trelease (1920); *Agave wiesenburgensis* Wittmack (1885); *Agave wiesenburgensis* Wittmack (1885) (*nom. inval.*, ICN Art. 61.1); *Agave wildringii* Britton (1911); *Agave zuccarinii* Otto (1842); *Polianthes ensifolia* hort. ex Steudel (1840); *Polianthes purpurea* Dean (1874); *Polianthes pygmaea* Jacquin (1793).

**A. abisaii** A. Vázquez & Nieves (Syst. Bot. 38 (2): 321–323, ills., 2013). **Type:** Mexico, Jalisco (*García-Mendoza & al.* 6414 [MEXU, IBUG, MEXU]). — **Distr:** Mexico (S Jalisco); limestone outcrops in tropical dry forests, 640–800 m; flowers February to March. **I:** Vázquez-García & al. (2007b: figs. M5–M8, as *A. gypsophila*); Hochstätter (2015: VI: 25); Meer (2016d).

[2n] **Ros** 0.95–1 × 1.5 m, surculose; **L** 9–11, linear to narrowly lanceolate to obtrullate, generally arching, firm but brittle, guttered, wider above the base, abaxially with a transversal or longitudinal wrinkle at the base, smooth, 80–90 × 9–13 cm, to 7 cm wide and to 3.5 cm thick at the base, light to dark green, not evidently cross-banded, abaxially glaucous at the base; **marginal teeth** firm, closely set, on prominences 3–4 × 2.5–3 mm, teeth mostly curved, 1–3 mm from a broad base 2–5 mm wide, 6–17 mm apart in the middle of the leaf, regularly spaced, dark brown, intervening margin concave, involute, with few denticles; **terminal Sp** conical, firm, 4–5 mm, dark brown, not decurrent; **Inf** 2.5–3 m, paniculate, peduncle with triangular **Bra** to 7.5 cm long at the base, fertile **Inf** part oblong, occasionally with numerous red bulbils, part-**Inf** 13 in the upper 1/3, with 30–38 flowers; **Fl** 28.5–35.5 mm; **Tip** tube funnellform, 2.5–3.5 × 6–8 mm (at the mouth), green, lobes triangular, erect, fleshy, 14–16

**Fig. 2** *Agave acicularis*  
(Etter & Kristen 4130:  
Cuba, ± 40 km SE of  
Cienfuegos, 20 m).

M. Kristen)

× 2.5–4 mm, orange, apex galeate; **Fil** 18–25 mm, inserted 1 mm above the tube base; **Anth** centric, 8–10 mm, yellow; **Ov** 12–16 × 2–3 mm; **Sty** shorter than the filaments; **Sti** capitate; **Fr** oblong, slender, 22 × 10 mm, shortly stipitate, apiculate; **Se** crescent-shaped, thin, flat, membranous, 3–4 × 2–3 mm, black.

The recent study of the *A. gypsophila* group by Vázquez-García & al. (2013) has led to a narrower re-circumscription of *A. gypsophila* and the description of this and 3 further new species (*A. andreae*, *A. kristenii*, *A. pablocarrilloi*). According to the protologue, *A. abisaii* is most similar to *A. gypsophila* s.s. in having rosettes with few smooth green leaves, but differs by having suckering rosettes, linear to narrowly obtrullate leaves with a glaucous base and with transversal or longitudinal wrinkles at the abaxial base, regularly spaced marginal teeth at mid-leaf, orange flowers, red bulbils on the inflorescence, smaller inflorescences with fewer branches, and smaller capsules. Material belonging to *A. abisaii* was formerly placed in *A. gypsophila* by Gentry (1982). Newton (2004: as *A. gypsophila*) provides photographs of the rosette, inflorescence, flowers and bulbils.

**A. acicularis** Trelease (Mem. Nation. Acad. Sci. 11: 34, t. 52, 1913). **Type:** Cuba, Santa Clara (*Britton & al.* 5926 [MO, MEXU, NY]). — **Lit:** Berger (1915: 208); Álvarez de Zayas (1996: 119–121, with ills.); Guillot Ortiz & Meer

(2011: with ill.). **Distr:** C Cuba (Matanzas: Rio San Juan) rocky cliffs and quartzite outcrops in tropical dry forests, 250 m; flowers January to March. **I:** Etter & Kristen (1997+: accessed 2016). – Fig. 2.

[2p] Acaulescent, **Ros** solitary; **L** lanceolate, 90–105 × 8–14 (–16) cm, green to slightly greyish, dull; **marginal teeth** gently upcurved, triangular from a somewhat lenticular base, 1–4 × 1–3 mm, chestnut-brown, 8–20 mm apart, more distant (to 25 mm) in the lower leaf parts and larger (4 mm) and reflexed, occasionally with outcurved point, intervening margin slightly repand; **terminal Sp** stoutly acicular, straight, subtriangularly grooved below the middle, smooth, (5–) 9–20 (–25) × 1.5–3 mm, grey-brown, slightly glossy, not decurrent; **Inf** paniculate, 3–6 m, peduncle with narrow triangular **Bra**, fertile part oblong, part-**Inf** ±25, in the upper ¾ of the inflorescence, 29–33 cm, not known to be bulbiferous; **Ped** 5–11 mm; **Fl** (35–) 38–47 mm; **Tep** yellow, wilting golden-yellow, tube open, 4–6 × 7–8 mm, lobes 11–16 × 4 mm, about ½ as long as the ovary; **Fil** 25–35 mm, inserted slightly below the throat; **Anth** 10–13 mm; **Ov** oblong-fusiform, 25 mm; **Sty** longer than the filaments; **Sti** capitate; **Fr** cylindrical, 35–43 × 15–17 mm, stipitate, apex rostrate; **Se** triangular, 6–7 × 4–5 mm.

Differs from *A. brittoniana* esp. in its narrower lanceolate leaves with non-decurrent terminal spine, and from *A. grisea* in its smaller leaves. Known from one population at the bank of the Río

San Juan only (Álvarez de Zayas 1996) and classified as “Endangered” (Berazaín & al. 2005).

**A. acklinicola** Trelease (Mem. Nation. Acad. Sci. 11: 41, t. 91, 1913). **Type** [syn]: Bahamas, Acklin Island (*Brace* 4442 & s.n. [NY, MO]). — **Lit**: Berger (1915: 204–205); Britton & Millspaugh (1920: 75–76); Correll & Correll (1982: 309); Freid & al. (2014: 210–211, 217). **Distr**: Bahamas (Acklins, Crooked and Mayaguana Island); tropical dry forests. **I**: Hochstätter (2015: VII: 82).

[2r] Acaulescent, **Ros** solitary; **L** rather narrowly lanceolate, fleshy, curved, concave, occasionally somewhat guttered, 180–300 × 15 cm, dull greyish; **marginal teeth** straight or gently curved, rather acuminate deltoid, often from oblique green prominences or with lenticular bases, 1–1.5 mm, 5–10 mm apart, intervening margin nearly straight; **terminal Sp** conical, somewhat flexuously recurved, involutely grooved to or beyond the middle, smooth, 20–25 × 4–6 mm, red-brown, becoming grey, glossy, decurrent; **Inf** paniculate, peduncle thick, with triangular **Bra**, fertile part broadly ovoid; part-**Inf** ±20 in the upper  $\frac{2}{3}$  of the inflorescence, not known to be bulbiferous; **Fl** bright yellow, not further known; **Fr** and **Se** not known.

According to the protologue with the “aspect of *A. bahamana*” (see also the note there).

**A. ×ajoensis** W. C. Hodgson (Novon 11(4): 414–415, ills., 2001). **Type**: USA, Arizona (*Hodgson & al.* 4478 [DES, ORPI]). — **Lit**: Parker (2018a: 21, with ill.). **Distr**: USA (S Arizona); rocky slopes in desert scrub and grasslands, 900–1100 m; flowers late spring to summer. **I**: Pilbeam (2013: 17); Hochstätter (2015: VIII: 65–66).

[1e × 2i] This is the sterile hybrid *A. deserti* ssp. *simplex* × *A. schottii* var. *schottii*. It is known in nature from 1 population with 28 clones in the Ajo Mts. within the Organ Pipe Cactus National Monument in S Arizona only and was first misidentified as *A. schottii* var. *atricha* (= *A. schottii* var. *treleasei*), but differs in being much lighter in colour (Parker 2018a). The hybrid is triploid (2n = 90), while sympatric ssp. *simplex* is diploid (2n = 60) and var. *schottii* is tetraploid (2n = 120) (protologue and Reveal & Hodgson (2002)).

**A. aktites** Gentry (US Dept. Agric. Handb. 399: 148–150, ill., 1972). **Type**: Mexico, Sinaloa (*Gentry* 11470 [US, ARIZ, ASU, MEXU, MICH]). — **Lit**: Gentry (1982: 555–559, with ills.). **Distr**: Mexico (Sonora, N Sinaloa); sand dunes with coastal thorn forests; flowers February to April. **I**: Richter (2011: 76); Pilbeam (2013: 18); Hochstätter (2015: VII: 28).

[2g] Stems broadly globose; **Ros** 40–70 × 60–110 cm, surculose; **L** linear, straight, patulous, unequal within a rosette, broadly clasping at the base, convex below, nearly flat above, smooth or asperous, 40–60 × 2–4 cm, bluish-glaucous-grey, sometimes with transverse zonal pattern; **marginal teeth** generally antrorse, with slender flexuous tips, 3–5 mm, irregularly spaced, 10–30 or 40–50 mm apart; **terminal Sp** abruptly subulate, usually broad at the base and flattened above, 12–20 mm, dark brown to greyish; **Inf** 1.8–4 m, paniculate, narrow, part-**Inf** 10–15 in the upper  $\frac{1}{4}$ – $\frac{1}{3}$  of the inflorescence, short, small; **Fl** 64–70 mm; **Tep** pale greenish (Gentry) or light yellow (Etter & Kristen 1997+), sticking together and not opening properly, quickly wilting, tube cylindrical to globose, narrowly grooved, 14–16 × 12–16 mm, thick-walled below the filaments, lobes long-linear, soon infolding and becoming spatulate with broadly rounded hooded tips, unequal, the outer larger, closely overlapping the inner, 21–25 mm; **Fil** 40–50 mm, inserted at wide angles 8–10 mm above the base of the tube; **Anth** slender, extremely excentric, 23–29 mm; **Ov** angulate-cylindrical, 26–31 mm, neck constricted, tapering to the pedicel; **Sty** longer than the stamens after anthesis; **Sti** capitate; **Fr** linear-oblong when still unripe; **Se** unknown. — **Cytology**: 2n = 60 (Palomino & al. 2010).

This is the only Mexican *Agave* growing naturally and regularly in the maritime zone of beach dunes, to which habitat it appears to be narrowly endemic. The widespread *A. angustifolia* is common in the same region, but *A. aktites* can usually be distinguished from it by its smaller size and narrow bluish leaves (Gentry 1982: 558). Palomino & al. (2010) found some evidence for spontaneous heterozygous chromosomal exchange in 2 studied populations, indicating an actively differentiating genome.

**A. albescens** Trelease (Mem. Nation. Acad. Sci. 11: 44, tt. 53, 116, 1913). **Type:** Cuba (Britton 2085 [MO, NY, US]). — **Lit:** Berger (1915: 273); Greulich (2010: with ills.); Kunte (2013: with ills.). **Distr:** SE Cuba; calcareous soils in coastal and near-coastal xerophytic scrub. **I:** Pfendbach (2005: 76); Richter (2010: 39); Richter (2011: 92–93); Kattermann (2012: 12); Pilbeam (2013: 19–21); Rigerszki & al. (2013: 257); Hochstätter (2015: VII: 89, 96); Lodé (2015).

[2q] Acaulescent, **Ros** solitary, rarely suckering at the base; **L**  $\pm$ 30–40, oblong-lanceolate, flattish, slightly rough,  $\pm$ 45  $\times$  15 cm, light grey, dull, passing to glaucous, sometimes transversely banded, margins nearly straight; **marginal teeth** usually straight or gently curved, broadly triangular or acuminate deltoid, 2–3 mm, dark brown,  $\pm$ 10 mm apart, from broad deltoid prominences; **terminal Sp** conical, somewhat recurved, shallowly grooved or involute below the middle, dull, sometimes roughened except at the tip, 15  $\times$  4 mm, blackish chestnut-brown, very shortly decurrent; **Inf** paniculate, 5 m, with  $\pm$ 30 ascending part **Inf** in the upper  $\frac{3}{4}$ ; **Ped** slender, 10 mm; **Fl** 30–35 mm; **Tep** golden-yellow, tube open, 5–6 mm, lobes 12–14  $\times$  4 mm; **Fil** 35 mm, inserted somewhat below the throat of the tube; **Ov** fusiform, 15 mm; **Sty** longer than the filaments; **Fr** and **Se** unknown.

A small species variable in leaf characters. According to the protologue, it differs from the few other grey-leaved Cuban species in the granular roughening of the leaves and the finally purplish-black colour of the terminal spine and marginal teeth. Habitat photographs and cultivated plants indicate that the rosettes are likely surculose (Greulich 2010, Richter 2010, Richter 2011), whereas the protologue describes them as solitary. The species may form natural hybrids with *A. underwoodii* (Richter 2010: 41). It is classified as “Least Concern” in the Cuban Red List (Berazain & al. 2005).

**A. alboaustralis** (E. Solano & Ríos-Gómez) Thiede (Bradleya 33: 83, 2015). **Type:** Mexico, Oaxaca (Solano & Ríos 2516 [MEXU, CHAPA, FEZA, IAMIZ, IEB, OAX]). — **Lit:** Solano &

Ríos-Gómez (2014: as *Polianthes*, with ills.). **Distr:** Mexico (W Oaxaca); in disturbed habitats in black or brown loamy to clayey soils, in juniper, pine-oak and montane cloud forests, 1945–2130 m; flowers August to September. **I:** Hochstätter (2016: II: 5).

$\equiv$  *Polianthes alboaustralis* E. Solano & Ríos-Gómez (2014).

[3b1] Herbaceous; corm cylindrical, 1.5–3.6  $\times$  1–2.2 cm, bulb ovoid, 1.7–4 (–6)  $\times$  1.3–3.5 cm, covered with dry leaf bases; **R** contractile, thickened; **L** 2–6, linear, cartilaginous, apex acute, thickened, 36–63  $\times$  0.4–0.7 cm, upper and lower surface with papillae unevenly distributed over the veins, margins papillose-toothed; **Inf** 94–160 cm, ‘spicate’, internodes becoming shorter towards the distal portion, peduncle with first **Bra** linear, 29–56  $\times$  0.3–0.8 cm, fertile part with 3–7 floral nodes, 7–25 cm; **Ped** none; **Fl** geminate, diffuse to divaricate at anthesis, fragrant, at the base with two bracteoles; **Tep** white at anthesis, white-pink at senescence, tube curved  $\pm$  in the middle, infundibular above the curve and widening to the base of the lobes, broadest part usually with extrafloral nectaries, 40–60  $\times$  4–8 (at the tip) mm, throat symmetrical, lobes extended, broadly ovate, papillose on both faces, margins hyaline, almost equal, 2–6  $\times$  2–3.7 mm, apex cucullate, obtuse to rounded, papillose, pink, purplish, or reddish; **St** included; **Fil** filiform, white, 2–10 mm, inserted  $\pm$ 30–60 mm above the tip of the ovary; **Anth** linear, 5–10  $\times$  1–2 mm, yellow to green-yellowish; **Ov** cylindrical, 4–10  $\times$  1.5–3 mm; **Sty** filiform, 39–45 mm, included at anthesis, white; **Sti** 3-lobate, papillose; **Fr** globose, 16–23  $\times$  10–21 mm, with persisting perianth remains; **Se** ovate-depressed, flat, 5–6  $\times$  4–5 mm, black, dull.

According to the protologue most similar to *A. neonelsonii* (as *Polianthes nelsonii*) and *A. palustris* (as *P. palustris*), but differing by its longer leaves, longer sterile primary bract, and its much longer inflorescence. The species is remarkable for its extrafloral nectaries which are reported for the first time for Sect. *Polianthes*. It is the only species of the section with fragrant white flowers from S of the Trans-Mexican Volcanic Belt.

**A. albomarginata** Gentry (Agaves Cont. North Amer., 129–131, ill., 1982). **Type:** Ex cult. (Gentry 19811 [US 2601938, ARIZ 265547]). — **Lit:** Irish & Irish (2000: 93–94); Puche & Meer (2014: with ills.). **Distr:** Mexico (W & N-C Querétaro); ecology not recorded, presumably desert scrub, 1300–2100 m; flowers June to July; neophyte in Spain. **I:** Hochstätter (2015: IX: 23); Hernández-Sandoval & al. (2016: 203); Martínez & al. (2017: 188).

[1g] Stems short; **Ros** open, freely suckering; **L** 16–30, long lanceolate-linear, straightly ascending, rigid to sinuous, apex long acuminate, convex below, nearly flat above, somewhat keeled towards the base, 100–125 × 4 (near the base)/2.5 cm (in the middle), greyish-green, often with paler mid-stripe, margins thin, horny, somewhat friable, easily separable, white to grey, rarely brown; **marginal teeth** at mid-leaf white like the margin with tips sometimes reddish or light grey, thin, deltoid, recurved, 2–4 mm, remote, 30–50 mm apart, towards the leaf base blunt, 10–20 mm apart, distal 1/3 of the leaf toothless; **terminal Sp** subulate, with a rounded groove above, 15 mm, white or sometimes light grey with dark tip, thinly decurrent; **Inf** 2–4.5 m, ‘spicate’, peduncle with narrowly deltoid chartaceous **Bra**, fertile part slender, laxly flowered, part-**Inf** with 2 or 3 flowers; **Ped** short, thick, bracteolate; **Fl** 30–35 (–40) mm; **Tep** yellow or greenish-yellow, tube broadly funnel-shaped, forming a marked angle relative to the tepal base, 4–5 × 9 mm, lobes strictly erect, equal, 13–14 × 3 mm, pale yellow,

clasping the filaments; **Fil** dorsiventrally flattened, to ±30 mm, greenish-yellow to reddish, inserted at the tube rim; **Anth** excentric, 16–17 mm; **Ov** fusiform, 18–22 mm, neck thick, grooved; **Fr** oblong or obpyriform, 20–30 × 12–14 mm, brown; **Se** semicircular, thickened esp. at the curved rough side, shiny black.

In the protologue, Gentry (1982) cited the specimen at US (2 cross-labelled sheets) as holotype, but the isotype at ARIZ bears the stamp “Gentry Herbarium” and his handwriting “type collection”. According to the protologue perhaps better treated as a var. or ssp. of the closely related *A. lechuguilla*, but more extreme in morphological characters than other variants of the taxon, esp. in its elongate leaves with conspicuous, white, friable margins and a toothless terminal third. Known to Gentry (1982) from cultivation only, the species was subsequently rediscovered in habitat in Querétaro (Magallán Hernández & Hernández Sandoval 2001). Gómez-Bellver & al. (2019: 24–25) report the taxon as local neophyte from Spain.

**A. albopilosa** I. Cabral & al. (Acta Bot. Mex. 80: 52–55, ills., 2007). **Type:** Mexico, Nuevo León (Cabral 1612 [MEXU, ANSM, CFNL, CIIDIR, ENCB, UNL]). — **Lit:** Starr (2012: 40–43, with ills.). **Distr:** Mexico (Nuevo León); steep nearly vertical limestone rocks, 1000–1500 m. **I:** Etter & Kristen (2009a); Richter (2011: 56); Lodé (2011); Janeba (2013); Alsemgeest (2013); Pilbeam (2013: 22); Hochstätter (2015: VII: 5, 15). – Fig. 3.

**Fig. 3** *Agave albopilosa* (Etter & Kristen 4282: Mexico; Nuevo León, Huasteca Canyon, 1600 m). (Copyright: J. Etter & M. Kristen)

[1a] Stems decumbent, with woody rootstock up to  $20 \times 2\text{--}2.5$  cm; **Ros** symmetrical, semi-globose,  $20\text{--}40 \times 15\text{--}36$  cm, caespitose; **L** 100–180, in 15–25 spiral rows, linear-triangular, broadened at the base, narrowing at the apex, slightly concave with dorsal keel, striate on both faces, glabrous,  $14\text{--}23 \times 0.8\text{--}1.4$  (in the middle) cm, yellowish-green to slightly glaucous, margins rigid, slightly curved, serrate; **marginal teeth** none; **terminal Sp** straight to sigmoid, sub-conical,  $3\text{--}6 \times 0.7\text{--}0.9$  (at the base) mm, blackish, 4–6 mm below its base with a ring of white hairs 4–7 mm long; **Inf** straight to inclined, 45–80 cm, ‘spicate’, peduncle  $30\text{--}50$  cm  $\times$  6–9 mm, with linear-triangular **Bra**  $3\text{--}5 \times 0.3\text{--}0.5$  cm, fertile part cylindrical, dense,  $15\text{--}30 \times 4\text{--}8$  cm, with 70–120 flowers; **Fl** usually geminate, slightly campanulate, 22–36 mm; **Top** greenish, with purple tinge, buds greenish-purple, tube 8–10 mm, lobes erect, slightly incurved, 4–5 mm; **St** exserted; **Fil** flattened, 25–30 mm, greenish-yellow according to the protologue but with purple tinge according to photographs, inserted in the middle of the of tube; **Anth** 8–10 mm, yellow; **Ov** shortly oblong, 8–10 mm, green, neck constricted; **Sty** cylindrical, 26–32 mm, greenish; **Sti** slightly 3-lobate; **Fr** oblong, with transversal stripes,  $10\text{--}12 \times 8\text{--}10$  mm, coffee-brown; **Se** semicircular, flattened, thickened at the curved side,  $3\text{--}3.5 \times 1.5\text{--}2$  mm, black, shiny.

Morphologically similar to *A. stricta*, but with fewer leaves with an apical ring of hairs, and smaller flowers and fruits. *A. rzedowskiana* is also similar but lacks the ring of hairs, and has larger flowers. The ring of hairs near the leaf tip just below the terminal spine is unique.

**A. americana** Linné (Spec. Pl. [ed. 1], 1: 323, 1753). **Type:** LINN 443.1 [lecto]. — **Distr:** USA, Mexico; cultivated worldwide in frost-free climates, and locally naturalized.

The lectotype cited above was designated by Howard & Thompson-Mills (1979: 486).

**A. americana** ssp. **americana** — **Lit:** Gentry (1982: 276, 278–281, with ills.); Lott & García-Mendoza (1994: online with ills.); Smith & Mössmer (1996: with ills.); Hodgson (1999a: 3–4); Reveal & Hodgson (2002); Guillot Ortiz &

Meer (2006a: key to cultivars grown in Spain); González-Elizondo & al. (2009: 43–46, with ills.); Hurrell & Delucchi (2009: with ills.); García-Mendoza (2011a: 7–10); Guillot Ortiz & al. (2012: with ills., as *A. ingens*). **Distr:** USA (SE Texas), E Mexico; sandy places in desert scrub, 20–1830 m; flowers June to September; widely cultivated and naturalized in suitable climates. **I:** Curtis’s Bot. Mag. 65: t. 3654, 1938–1939; Irish & Irish (2000: t. 2); Reveal & Hodgson (2002: 18, 19, 60–62); Richter (2011: 70, 120); Pilbeam (2013: 23); Hochstätter (2015: VII: 4).

Valenzuela & Nabhan (2004); **incl.** *Agave subzonata* Trelease (1920); **incl.** *Agave americana* [?] *nairobensis* Herbin & Robins (1968) (*nom. inval.*, ICN Art. 39.1, 40.1); **incl.** *Agave cordillerensis* Lodé & Pino (2008).

[2a] Stems none or short, trunks <2 m; **Ros** open or dense, 1–2.5  $\times$  2–3.7 m, freely suckering; **L** 40–70, lanceolate, erect, ascending, or frequently reflexed above the middle, narrowed above the thickened base, usually acuminate, convex below near the base, flat above and somewhat guttered near the base, smooth to slightly asperous, mostly 100–200  $\times$  15–30 cm, 6–10 $\times$  longer than wide, light green to green or glaucous-grey, sometimes variegated yellow or whitish, especially in cultivated forms, sometimes cross-zoned, margins straight or repand to crenate; **marginal teeth** variable, larger teeth (5–) 7–10  $\times$  6–12 mm, brown to pruinose-grey, 20–65 mm apart, from broad low bases, tips slender, straight to flexuous or curved; **terminal Sp** conical or subulate, 20–50  $\times$  4–5 mm, shiny brown to pruinose-grey; **Inf** 5–9 m, paniculate, peduncle green, with triangular chartaceous **Bra** 30–60 cm, fertile part slender, straight, long-oval in outline, rather open, part-**Inf** 15–35, 1.-order stalks 1–1.2 m, in the upper  $\frac{1}{3}$ – $\frac{1}{2}$  of the inflorescence, spreading; **Fl** long-pedicellate, slender, 70–100 mm; **Tep** yellow, tube funnel-shaped, 8–20  $\times$  12–20 mm, lobes oblong unequal, 25–35  $\times$  3–5 mm; **ITep** 2–3 mm shorter than the **OTep**, tip cucullate; **Fil** somewhat flattened, long tapering, 60–90 mm, inserted  $\pm$ 5–10 mm above the tube base, yellowish-green; **Anth** centric to excentric, 30–36 mm, yellow; **Ov** fusiform, 30–45  $\times$  5 mm, greenish, neck grooved, tapering to the narrower base; **Sty**  $\pm$ 90 mm, longer than the stamens after anthesis; **Sti** 3-lobate; **Fr** oblong, 40–80  $\times$  20–25 mm, beak short, shortly stipitate;

**Se** crescent- to tear-shaped, winged for 2 mm, 7–10  $\times$  5–8 mm, shiny. — **Cytology**: 2n = 60, 120, 180, 240; also 20, 44, 96, 81–104, 110, 115, 118, 119, 125, 134, 226 (see esp. Granick (1944), Satô 1935, Lv & al. 2009, Simpson & al. 2011).

The leaves are often reflexed above the middle, and this is a characteristic feature of the species. The flowers exhibit a short tapering ovary that is shorter than the tepals. *A. americana* ssp. *americana* is a very polymorphic taxon cultivated worldwide in many variants, especially in winter-rainfall climates (Gentry 1982: 278). Ssp. *americana* differs from its assumed wild progenitor ssp. *protoamericana* esp. in its longer leaves 6–10 $\times$  longer than wide, and its larger capsules.

Asensi & al. (2016) report the taxon as naturalized in Spain (where it may invade natural communities), Smith & Klopper (2007) for RSA, and Smith & Figueiredo (2008) for Portugal, but it is also naturalized in C & S America, N Africa, Asia, Australia, New Zealand, and on the islands of the Pacific (see references in Hurrell & Delucchi (2009), who also list many uses of the plant). The experimental management control of naturalized plants on the Canary Islands is described by Arévalo & al. (2015).

Cultivars with various degrees of variegation are common, and sometimes also naturalized, e.g. in Spain (Guillot Ortiz & Meer 2003b, Guillot Ortiz & al. 2012: as *A. ingens*) or Portugal (Smith & Figueiredo 2008). The origin and genetics of variegated cultivars is dealt with by Zonneveld (2007). A key to variegated and other cultivars grown in Spain is provided by Guillot Ortiz & Meer (2003b) and Guillot Ortiz & al. (2012).

A review of *A. americana* in American ancient cultures based on earliest Spanish chronicles is given by Pardo (2007). Meer (2011) summarized early European literature on flowering cultivated plants. European historical illustrations of flowering *A. americana* published before 1800 were reviewed by Ullrich (1993d). The very first illustration of an *Agave* was published in 1574 by Rembert Dodoens.

*A. cordillerensis* is a cross-zoned variant recently described from Peru. It represents hardly more than a locally cultivated variant and is therefore synonymized according to Govaerts (2014+).

**A. americana** ssp. **protoamericana** Gentry (Agaves Cont. North Amer., 287–290, ills., 1982). **Type:** Mexico, Nuevo León (*Gentry & Barclay* 20156 [US, ARIZ, MEXU]). — **Lit:** Reveal & Hodgson (2002). **Distr:** USA (Texas); Mexico (Nuevo León, Tamaulipas, San Luis Potosí); sandy places and open slopes in tropical deciduous and thorn forests or desert scrub, 200–1400 m; flowers early spring to early summer. **I:** Richter (2011: 99, 116); Pilbeam (2013: 25); Hochstätter (2015: VII: 7).

[2a] Differs from ssp. *americana*: **L** generally shorter, shortly narrowed above the thick and fleshy base, 80–135 × 17–22 cm, 4–6× longer than wide, light glaucous-grey to pale green, sometimes cross-zoned; **Inf** generally with fewer (15–20) part-**Inf**; **Tep** tube deeply funnel-shaped, longer, 15–20 mm; **Fr** 35–40 mm.

Regarded as the wild progenitor of the many cultivated types of *A. americana* ssp. *americana* according to the protologue. In Mexico, it shows apparent introgression with *A. asperrima* (as *A. scabra*; Gentry 1982: 289). Plants from Starr County, Texas, are smaller than Mexican material but appear to belong here (Reveal & Hodgson 2002).

‘Silver Surfer’ is a cultivar selected from seedlings (Starr 2014: 220, with ill.).

**A. americana** var. **expansa** (Jacobi) Gentry (US Dept. Agric. Handb. 399: 80, 1972). **Type:** not typified. — **Lit:** Bye & al. (1975: 93–94); Gentry (1982: 276, 283–284, with ills.); McVaugh (1989: 132); Reveal & Hodgson (2002); Vázquez-García & al. (2007b: 40–41); Smith & Figueiredo (2011: with ills.). **Distr:** Cultivated only (USA [California, Arizona], Mexico [SW Chihuahua, Jalisco]); sandy places in desert scrub and grasslands, 500–1300 m; flowers late spring to early summer; naturalized in RSA **I:** Pilbeam (2013: 24); Hochstätter (2015: VII: 6, as ssp.).

≡ *Agave expansa* Jacobi (1868) ≡ *Agave americana* ssp. *expansa* (Jacobi) Hochstätter (2015); **incl.** *Agave abrupta* Trelease (1920).

[2a] Differs from ssp. *americana*: Stems forming a short trunk in age, to 60 cm; **L** erect to stiffly spreading, deeply channelled above, glaucous-grey, frequently cross-zoned, margins crenate; **marginal teeth** along the middle of the lamina on several sharply angled low prominences; **terminal Sp** 20–30 mm; **Fl** 70–85 mm; **Fr** and **Se** unknown. — **Cytology:** 2n = 119 (Granick 1944, Simpson & al. 2011).

The wild forms of var. *expansa* are classified as a variant of ssp. *americana* (Reveal & Hodgson 2002). Known only as a cultivar (and better to be named as such) used for the pulque industry, first introduced into W Europe where it was described by Jacobi (Gentry 1982: 283). Var. *expansa* is occasionally cultivated in the warmer regions of the USA and is not naturalized. It has never been found in fruit and reproduction is strictly vegetative. Var. *expansa* likely is an early cultivar developed by pre-Columbian people who established it far to the west of the species’ range in E Mexico (Reveal & Hodgson 2002). It differs from ssp./var. *americana* esp. in its erect, non-reflexed leaves with a shorter terminal spine. In Chihuahua, leaf-bases are eaten pit-baked or prepared as mescal bread (Bye & al. 1975), and in Jalisco, it is used as living fence and for the production of aguamiel and pulque (Vázquez-García & al. 2007b). It is naturalized in RSA (Smith & Figueiredo 2011, Walters & al. 2011: 40–41).

**A. americana** var. **oaxacensis** Gentry (Agaves Cont. North Amer., 285–287, ills., 1982). **Type:** Mexico, Oaxaca (*Gentry & Arguelles* 12260 [US, ARIZ, DES, MEXU]). — **Lit:** García-Mendoza (2011a: 9–10). **Distr:** Cultivated only (Mexico: Oaxaca). **I:** Pilbeam (2013: 26); Hochstätter (2015: VII: 8, as ssp.).

≡ *Agave americana* ssp. *oaxacensis* (Gentry) Hochstätter (2015).

[2a] Differs from ssp. *americana*: **L** not reflexed, spreading, very large, 120–250 × 10–24 cm, glaucous-white, margins nearly straight, without distinct prominences; **marginal teeth** closely set; **Inf** large, 6–10 m; **Fl** large, 95–105 mm.

According to the protologue observed in cultivation only (and thus better treated as a cultivar), esp. in the Oaxaca Valley, but similar plants were also observed elsewhere. Formerly grown for fibre and pulque, but later abandoned (Gentry 1982: 287). Guillot Ortiz & Meer (2004) interpret an old illustration from Valentini (1719) as representing this taxon.

**A. amica** (Medikus) Thiede & Govaerts (Phytotaxa 306(3): 237, 2017). **Type:** BM [Herb. Hermann 3: 34, No. 125]. — **Lit:** McVaugh (1989); Ullrich (1993e: with ills.); both as *Polianthes*. **Distr:** Cultivated only. **I:** Bot. Reg. 1: t. 63, 1815; Curtis's Bot. Mag. 43: t. 1817, 1815–1816; Hochstätter (2016: II: 24); all as *Polianthes tuberosa*.

≡ *Tuberosa amica* Medikus (1790); **incl.** *Polianthes tuberosa* Linné (1753) ≡ *Agave tuberosa* (Linné) Thiede & Eggli (1999) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Crinum angustifolium* Houttuyn (1780); **incl.** *Polianthes gracilis* Link (1821) ≡ *Polianthes tuberosa* var. *gracilis* (Link & Otto) Beurling (1856); **incl.** *Polianthes tuberosa* fa. *plena* Moldenke (1948); **incl.** *Agave polianthes* Thiede & Eggli (2001) (*nom. illeg.*, ICN Art. 52.1).

[3b1] Herbaceous; corm cylindrical, mostly short and broad,  $\pm 1\text{--}1.5 \times 2\text{--}3$  cm, bulb ovoid to conical, to 5–6 cm, covered with dry leaf bases; **R** contractile, thickened; **L** 6–10 in a basal **Ros** from a bulbous base, linear, soft, deeply channelled in the basal  $\frac{1}{2}$ , to  $30\text{--}60 \times 1\text{--}1.5$  cm, bright green, sometimes reddish near the base, sometimes with brown spots on the lower face; **Inf** 60–100 cm, 'spicate', fertile part 14–28 cm, laxly flowered, with up to 15 flowering nodes; **Fl** geminate, mostly sessile, fragrant, 25–40 mm; **Tep** waxy white, base upright or strongly ascending, tube smoothly outcurved from below the middle, funnel-shaped above the curvature, expanding to the very slightly oblique mouth, there 7–8 mm  $\varnothing$ , lobes subequal, elliptic-ovate, obtusely pointed, often  $15\text{--}25 \times 5\text{--}10$  mm; **St** included; **Sty** included, with 3 oblong-ovate recurved lobes 2.5 mm long; **Fr** not described; **Se** poorly produced, not further known. — **Cytology:**  $2n = 60$ ,

120;  $2n = 50$  in double-flowered cultivars (Whitaker 1934, Satô 1935, Verhoek-Williams 1998, Tapia-Campos & al. 2013).

This is the "Tuberosa" or "Nardo", one of the most important cut flowers in (sub-)tropical areas, grown commercially for its fragrant flowers in India, New Zealand, Japan and Mexico, and for the perfume industry in India and France (Barba-Gonzalez & al. 2012). It was already cherished and cultivated as a perfume flower named "Omixochitl" (bone flower) by the Aztecs in pre-conquest times (Trueblood 1973). In Europe, the tuberosa is known since 1594 when Clusius received a specimen which he illustrated in 1601 (Sims 1816). Old European illustrations are discussed by Ullrich (1993e). Especially common is a form with double ('filled') flowers, *Polianthes tuberosa* fa. *plena* Moldenke 1948, which should better be treated as cultivar 'Plena'. The species is at present not known from the wild and already Linné based his description on cultivated material from India. It is most probably of Mexican origin and possibly native to the region around Guadalajara (Jalisco), where its putative ally *A. dolichantha* has recently been rediscovered in the wild (see note there).

Unfortunately, the original species name is pre-occupied in *Agave*, and the replacement name *A. polianthes* unfortunately is predated by *Tuberosa amica*, whose epithet must be taken up for priority reasons.

Modern hybrids with pink, reddish-purple, purple, orange and yellow flowers, obtained from crossings with other species of Sect. *Polianthes*, were bred during the last years in North America, Europe and Asia and are now commercially offered (Huang & al. 2001: with ills., Guillot Ortiz & al. 2006: with ills., Barba-Gonzalez & al. 2012, Datta 2017).

**A. andreae** Sahagún & A. Vázquez (Syst. Bot. 38(2): 323–326, ills., 2013). **Type:** Mexico, Michoacán (*Muñiz-Castro & Padilla-Lepe* 862 [IBUG, GUADA, IEB, MEXU, MICH, MO, WIS]). — **Distr:** Mexico (W Michoacán: Sierra de Coalcomán); limestone outcrops in tropical dry forests, 1400–1435 m; flowers January to

March. **I:** Cházaro Basáñez & al. (2006a); Vázquez-García & al. (2007b: figs. M1, M3); both as *A. gypsophila*; Hochstätter (2016: VI: 26).

[2n] **Ros** 0.8–2.3 × 1.5–3.6 m, solitary or rarely surculose; **L** 20–40, narrowly lanceolate, firm but brittle, concave to channelled with the sides almost perpendicular, smooth on both faces, 90–150 (–210) × 12–14 (–23) cm, to 11.5–15 cm wide and to 4–5.5 cm thick at the base, light green and slightly darker above, glaucous below at the base, not evidently cross-zoned on both faces, margins slightly repand; **marginal teeth** flattened, on prominences 3–4 × 4–5 mm, mostly ascending and curved, mostly 3–5 mm, 30–38 mm apart at mid-leaf, 5–11 mm at the base, dark brown, from broad bases 3–4 mm wide, intervening margin repand with few or no teeth; **terminal Sp** usually short and conical, firm, 15–26 mm, dark brown, not decurrent; **Inf** 5–7.3 m, paniculate, with triangular **Bra** to 15 cm long at the peduncle base, fertile part oblong, occasionally with numerous red bulbils, part-**Inf** 27–36, compact, in the upper 2/3 of the inflorescence; **Fl** 34–40 mm; **Tep** orange, tube somewhat funnel-form, 5–6 × 11–12 mm, lobes triangular, erect, fleshy, 11–13 × 5–7 mm, yellow at the base, orange at the galeate apex; **Fil** firm, 32–36 mm, inserted 2–3 mm above the tube base, orange; **Anth** centric, 14–15 mm, yellow; **Ov** 18–21 × ±4 mm, neck constricted, green; **Sty** shorter than the filaments; **Sti** capitate; **Fr** oblongoid, 32–39 (–45) × 18–19 mm, stipitate, apiculate; **Se** crescent-shaped but curved on one side, flat, membranous, 5–6 × 4 mm, black.

Part of the *A. gypsophila* species group, and recently (together with *A. abisaii*, *A. kristenii* and *A. pablocarrilloi*) separated from a more narrowly circumscribed *A. gypsophila* (Vázquez-García & al. 2013). This is the largest-growing species in the group, and differs from the most similar *A. gypsophila* s.s. by more numerous and ascending leaves, more robust inflorescences, larger flowers, and by occurring at higher elevation.

**A. angustiarum** Trelease (Contr. US Nation. Herb. 23: 139, 1920). **Type** [syn]: Mexico, Guerrero (*Trelease* 17 + 77 [MO, ARIZ [para]]). — **Lit:**

Gentry (1982: 134–135, with ill.); Vázquez-García & al. (2007b: 41–42, t. B [excl. B1–B4 = *A. garciaruii*]); Greulich (2012a: with ill.); Hernández-Vera & al. (2019). **Distr:** Mexico (SE Jalisco, Michoacán, México, Morelos, Puebla, Guerrero, Oaxaca); limestone rock abutments and cliffs in tropical deciduous forests and desert scrub, 600–2300 m; flowers March and October. **I:** Richter (2011: 111); Pilbeam (2013: 27); Hochstätter (2015: IX: 24).

[1g] Stems short; **Ros** open, (0.5–) 0.8–1.2 × <1–2.2 m, mostly solitary, rarely with basal offsets; **L** 20–50, linear to lanceolate, openly spreading, straight, thick, firm, long acuminate, flat to concave above, thickened below, 50–120 × 6–13 cm, olive-green or glaucous-green (both forms occur sympatrically), mostly with a conspicuous light green median stripe above, margins horny, continuous; **marginal teeth** straight or slanted downwards but commonly upcurved, rather slender, flattened, largest somewhat scattered, mostly 2–7 mm, brown to grey, 10–40 mm apart, 3–7 teeth per 10 cm, teeth absent from the topmost 1/4–1/3 of the leaf, intervening margin nearly straight, scarcely 1 mm broad; **terminal Sp** acicular, rounded, very slender, narrowly grooved above, with a conspicuous median protrusion below, 25–45 mm, long decurrent to the upper teeth; **Inf** 1.5–5 m, ‘spicate’, slender, fertile part in the upper 50–60%, rarely bulbiferous; **Ped** 9–11 mm; **Fl** 35–40 mm; **Tep** glaucous greenish-white, cream-yellow, yellow, yellowish-green or reddish, tube very short, 4–5 × 6–7 mm, lobes 16 × 3 mm, clasping the filaments; **Fil** 40–45 mm; **Anth** 14–15 mm, usually yellow, rarely reddish; **Ov** 15 mm, neck narrow; **Sty** slightly shorter than the filaments; **Sti** capitate; **Fr** 8–25 × 5–15 mm, fruit valves straight, apically rounded; **Se** 3–5 × 2–3 mm.

Distinguished by its simple rosettes with long, narrow leaves that are toothless along the long-tapering apex, and the long-protruding spine-base. The taxon may be confused with some forms of *A. kerchovei*, but the latter has larger rosettes with more leaves which are longer, narrowly lanceolate, and more sword-shaped (Gentry 1982). The description by Gentry (1982: 134) is inadequate and omits the variation given in Trelease’s protologue (Greulich 2012a);

Hernández-Vera & al. (2019) provide additional data. Plants of *A. angustiarum* from Nizanda (Oaxaca) placed here by Greulich (2012a) are placed in *A. ghiesbreghtii* by Mexican botanists (e.g. Pérez-García & al. (2001)). The recently published *A. arcedianoensis* from C Jalisco with purple-reddish flowers appears closely related (see there). For differences from the closely related *A. garciaruii* see there. The complex *A. angustiarum* — *A. arcedianoensis* — *A. kerchovi* is in need of a critical study.

**A. angustifolia** Haworth (Synops. Pl. Succ., 72, 1812). **Type** [neo]: Mexico, Oaxaca (*García-Mendoza & Palma* 5654 [MEXU]). — **Distr:** N Mexico to Panama, widespread.

García-Mendoza & Chiang (2003: 86) designated the neotype cited above.

**A. angustifolia** var. **angustifolia** — **Lit:** Trelease (1908a: with ills.); Gentry (1972: 143–148, with ills., as *A. pacifica*); Gentry (1982: 559–564, with ills.); McVaugh (1989: 133–134); Lott & García-Mendoza (1994: online version with ills.); Turner & al. (1995: 41–43, with ills.); García-Mendoza & Chiang (2003: with ills.); Vázquez-García & al. (2007b: 42–44, t. C); González-Elizondo & al. (2009: 45–47, with ills.); García-Mendoza (2011a: 12–14); Franck (2012: 3–6, with ills.). **Distr:** Mexico (widespread from Sonora and Chihuahua to the S), Belize, Costa Rica, Honduras, Nicaragua, El Salvador, Panama; mainly tropical savannas, thorn forests, and tropical deciduous forests at low to middle elevations (to 1500 m, rarely more); flowers March to November; naturalized in Spain and RSA. **I:** Curtis’s Bot. Mag. 85: t. 5097, 1859, as *A. jacquiniana*; Curtis’s Bot. Mag. 97: t. 5893, 1871, as *A. ixtlioides*; Heller (2006: 147, as *A. vivipara*); Richter (2011: 20–21, 119, 123); Pilbeam (2013: 28); Hochstätter (2015: VII: 28, 29). — Fig. 4.

Johnston (1924); **incl.** *Agave prolifera* Schott ex Standley (1930); **incl.** *Agave costaricana* Gentry (1949); **incl.** *Agave breedlovei* Gentry (1982) (*nom. inval.*, ICN Art. 36.1a); **incl.** *Agave vivipara* var. *bermejo* A. Valenzuela & Nabhan (2003) (*nom. inval.*, ICN Art. 39.1, 40.1).

[2g] Nearly acaulescent or stems to 20–60 (–90) cm; **Ros** radiately spreading, 1–1.5 (–2)  $\times$  1.5–2 m, surculose; **L** 40–70, linear to (very broadly) lanceolate, ascending to horizontal, mostly rigid, hard-fleshy, fibrous, narrowed and thickened towards the base, convex below, flat to concave above, full-grown generally (40–) 60–100 (–130)  $\times$  3.5–5 (–10, larger in cultivation) cm, light green to glaucous-grey, margins straight to repand,

sometimes thinly cartilaginous; **marginal teeth** generally small, (0.5–) 2–5  $\times$  (0.5–) 2–5 mm, rarely longer, commonly reddish-brown or dark brown, evenly and closely spaced or remote, from low narrow bases, tips slender,  $\pm$  curved, 10–35 mm apart; **terminal Sp** variable, conical to subulate, flat to shallowly grooved above, (15–) 20–35 mm, dark brown to blackish, greying with age, not or thinly decurrent; **Inf** 2.5–5 m, paniculate, open, peduncle green to brownish, somewhat waxy, with quick-drying narrow triangular **Bra** 7–15 cm, fertile part in the upper  $\frac{1}{2}$ – $\frac{1}{3}$ , oblong, with 9–15 (–20) horizontally spreading to ascending part–**Inf** 25–35 cm long, sometimes (freely) bulbiferous, bulbils leafy; **Ped** 2–3 mm; **Fl** (40–) 50–65 (–80) mm; **Tep** green, brownish-green, yellowish-green to yellow, tube funnellform to slightly urceolate, grooved, (4–) 7–16 (–20)  $\times$  8–10 mm, lobes oblong, unequal, (15–) 18–25  $\times$  2–5 mm, rapidly infolding, at first erect, soon wilting, drying reflexed against the tube, outer broadly overlapping the inner at the base, obtuse to rounded, tip slightly cucullate; **Fil** slender, flattened, 35–45 (–50) mm, inserted in the middle to the upper  $\frac{1}{4}$  of the tube, yellowish or with purple dots; **Anth** centric or excentric, (15–) 20–30 mm, yellow(ish); **Ov** small, angulate-cylindrical, somewhat ribbed, tapering at the base, 20–30  $\times$  3–5 mm, neck short, slightly grooved; **Sty** 50–60 mm, longer than the stamens after anthesis; **Sti** capitate; **Fr** broadly ovoid to oblong, 50–60  $\times$  20–30 mm, dark brown, raggedly beaked, shortly stipitate; **Se** 7–12  $\times$  5–8 mm, hilar notch a long cleft, not winged, dull. — **Cytology**: 2n = 60, 90, 120, 180 (esp. Castorena Sanchez & al. 1991, Palomino & al. 2005, Robert & al. 2008, Simpson & al. 2011: p.p., as *A. rigida*, Gomez-Rodriguez & al. 2013).

According to Wijnands (1983), *A. vivipara* is the oldest name for the widespread continental taxon previously referred to as *A. angustifolia* by Gentry (1982: 559) and others, which was followed in the first edition of this handbook. However, García-Mendoza & Chiang (2003) showed that Wijnands' interpretation is incorrect, and that *A. angustifolia* and *A. vivipara* are distinct species. Consequently, *A. angustifolia* is re-established as circumscribed by Gentry (1982),

and *A. vivipara* is applied to the Caribbean species previously known under that name.

The plants from Panama separated as *A. panamana* (Cseh 1993) merely represent the S-most element in the complex (Lott & García-Mendoza 1994). Smith & Figueiredo (2017) re-studied the taxon and argue that it could be accepted at specific rank, pointing out differences from *A. angustifolia*. *A. angustifolia* var. *rubescens* apparently represents a superfluous separate name for a depauperate form with narrower leaves and shorter narrower teeth, occurring irregularly in shady habitats within the species' range in Mexico (Gentry 1982: 567, García-Mendoza 2011a). Since the leaf and other measurements given by both authors fall well into the range of var. *angustifolia*, it is included in the synonymy here. *A. angustifolia* var. *deweyana* merely represents a "not well marked" (Gentry 1982: 564) cultivar cultivated in Tamaulipas and Veracruz. It is included in the synonymy of var. *angustifolia* by García-Mendoza (2011a) which is followed here, but it might warrant cultivar status. *A. spectabilis* Todaro is placed in the synonymy here based on Gentry (1982: 559) and the original plate, in contrast to its placement in the synonymy of *A. appianata* by Govaerts (2014+).

*A. angustifolia* is by far the most wide-ranging species of the genus and exhibits an extensive range of variation esp. in vegetative features. It is a sun-loving taxon (although also not rarely found with etiolated growth in light shade) occurring in nearly all vegetation types (albeit mainly in the 'tierra caliente') (Gentry 1982: 561).

Zizumbo-Villarreal & al. (2013) report on the local sustainable management of sylvicultural populations of *A. angustifolia* for mescal production in S Jalisco. The genetic variability of wild populations in Sonora was studied by Barraza Morales & al. (2006) and Sánchez-Teyer & al. (2009), and that of landraces in Jalisco by Vargas-Ponce & al. (2009). *A. angustifolia* is the wild progenitor of the cultivated *A. tequilana* (mainly used for alcoholic beverages) and *A. fourcroydes* (mainly used for fibre) (see there).

Variiegated and non-variiegated varieties cultivated in Spain are presented by Guillot Ortiz & Meer (2016b). *A. angustifolia* is naturalized in the

Balearic Islands (Sáez & al. 2016: 103) and in RSA (Steyn & Smith 2000: as *A. vivipara*, Walters & al. 2011: 43–45).

**A. angustifolia** var. **letonae** (F. W. Taylor ex Trelease) Gentry (Agaves Cont. North Amer., 564, ill. (p. 565), 1982). **Type:** El Salvador (*Milner* s.n. [US, ILL]). — **Lit:** Trelease (1925: 393–395, with ills.). **Distr:** Cultivated only (for fibre): Guatemala, El Salvador. **I:** Heller (2006: 153).

≡ *Agave letonae* F. W. Taylor ex Trelease (1925) ≡ *Agave vivipara* var. *letonae* (F. W. Taylor ex Trelease) P. I. Forster (1992) ≡ *Agave angustifolia* ssp. *letonae* (F. W. Taylor ex Trelease) Hochstätter (2015); **incl.** *Agave letonae* var. *marginata* Trelease (1925).

[2g] Differs from var. *angustifolia*: Stems broad; **Ros** robust; **L** nearly white. — **Cytology:** 2n = 120 (Robert & al. 2008).

A robust, nearly white-leaved plant which develops a broad trunk over several years of leaf-cutting. It has been of considerable economic importance for fibre production in El Salvador and has been in minor cultivation in Guatemala (Gentry 1982: 564). It apparently merely represents cultivated selections and should better be named as cultivar. In a molecular study, var. *letonae* clustered independently from *A. angustifolia*, but the result should be viewed with some caution, as the studied plants of *A. angustifolia* and *A. fourcroydes* likewise did not form a common clade (Infante 2006).

**A. angustifolia** var. **marginata** Trelease (in Linsbauer, Wiesner-Festschrift, 343, t. viii, 1908). **Type:** not typified. — **Lit:** Trelease (1908a: 286–287, t. 35). **Distr:** Cultivated only. **I:** Irish & Irish (2000: t. 4); Heller (2006: 147, as *A. vivipara* var. *marginata*); Sáez & al. (2014).

**Incl.** *Agave vivipara* 'Marginata' Hort. ex Gentry ex P. I. Forster (1992).

[2g] Differs from var. *angustifolia*: Stems 30–60 cm; **L** numerous, with narrow white or yellow margins. — **Cytology:** 2n = 60 (Castorena Sanchez & al. 1991, Lv & al. 2009).

This variety is merely a horticultural selection, now widely distributed around the World as an ornamental (Gentry 1982: 564), and sometimes

naturalized (e.g. in Spain, Sáez & al. (2014)). Probably better recognized as cultivar. In a molecular study (Infante 2006), var. *marginata* did not cluster with *A. angustifolia* s.s. (see var. *letonae* above for more details).

**A. angustifolia** var. **nivea** (Trelease) Gentry (Agaves Cont. North Amer., 566, 1982). **Type:** Guatemala, Progreso Dept. (*Trelease* 11 [ILL 00009808]). — **Lit:** *Trelease* (1915: 143–144, t. 22); Standley & Steyermark (1952: 114). **Distr:** Cultivated only (for fibre and fences): Guatemala. **I:** Guillot Ortiz & Meer (2016b: 65).

≡ *Agave nivea* *Trelease* (1915) ≡ *Agave vivipara* var. *nivea* (*Trelease*) P. I. Forster (1992).

[2g] Differs from var. *angustifolia*: Stems short; **L** 130–140 (–200) × 9–10 (–15) cm, characteristically dull bluish-grey, somewhat transversely green-banded; **Inf** unknown.

A long-leaved and short-stemmed plant with characteristic dull bluish-grey leaves, still present at its type locality in Guatemala in 1965 (Gentry 1982: 566), but also cultivated elsewhere (Standley & Steyermark 1952). Possibly better treated as cultivar.

**A. angustifolia** var. **sargentii** *Trelease* (Annual Rep. Missouri Bot. Gard. 22: 99, tt. 100–101, 1912). **Type:** [lecto — icono]: Annual Rep. Missouri Bot. Gard., 22: tt. 100–101, 1912. — **Lit:** Gentry (1982: 567). **Distr:** Cultivated only: Mexico (México, Puebla).

≡ *Agave vivipara* var. *sargentii* (*Trelease*) P. I. Forster (1992) ≡ *Agave angustifolia* ssp. *sargentii* (*Trelease*) Hochstätter (2015).

[2g] Differs from var. *angustifolia*: Stems ±25 cm; **Ros** dwarf; **L** numerous, narrowly oblong-lanceolate, minutely roughened, 25–30 × 2.5–3 cm, greyish-green; **marginal teeth** 1–2 mm, nearly black, glossy; **Inf** ±1 m, part-**Inf** few, bulbiferous; **Fl** 40 mm.

Gentry (1982) designated the lectotype cited above (as “Type”), which makes the later designation by Smith & Figueiredo (2014e: 228) unnecessary.

**A. angustifolia** var. **variegata** *Trelease* (Annual Rep. Missouri Bot. Gard. 19: 287, 1908). **Type:** not

typified. — **Lit:** *Watson* (1899b: as *A. woodrowii*). **Distr:** Cultivated only.

≡ *Agave vivipara* cv. *Variegata* (*Trelease*) P. I. Forster (1992); **incl.** *Agave woodrowii* W. Watson (1899) ≡ *Agave vivipara* var. *woodrowii* (W. Watson) A. Berger (1915) (*nom. inval.*, ICN Art. 41.4) ≡ *Agave angustifolia* fa. *woodrowii* (W. Watson) D. Guillot & P. Van der Meer (2016) (*nom. inval.*, ICN Art. 41.5).

[2g] Differs from var. *angustifolia*: **L** with unusual broad marginal white stripe, remainder of the leaf silvery-grey or milky.

A horticultural selection only, which is reported to have arisen in the Botanical Garden of the College of Science at Poona, India, around 1895 (*Trelease* 1908a: 287, Gentry 1982: 567). Better to be treated as cultivar.

**A. anomala** *Trelease* (Mem. Nation. Acad. Sci. 11: 36, t. 66, 1913). **Type:** Cuba (*Shafer* 1409 [MO, K, US]). — **Lit:** Berger (1915: 211–212); Correll & Correll (1982: 310). **Distr:** Bahamas (Rum Cay and San Salvador [Watling] Island), E Cuba (Holguín: N Holguín, Mayabe [Myabe]); beach coppices (Bahamas) and limestone outcrops (Cuba); flowers December to April. **I:** Richter (2011: 88); Pilbeam (2013: 29); Hochstätter (2015: VII: 66).

[2p] Acaulescent; **Ros** to 1 × 1 m, solitary; **L** ±40, elongate-lanceolate, spreading and arching, guttered, rather gradually pointed, 75–100 × 10 cm, green, not cross-zoned, margins straight; **marginal teeth** none or few and very small towards the base; **terminal Sp** conically subulate, unguicately recurved, smooth, rather dull, openly grooved to ± the middle, 10–30 × 3 mm, reddish to dark brown, shortly decurrent and dorsally immersed into the green tissue; **Inf** at least 4 m, paniculate, fertile part in the upper ½, narrowly oblong, part-**Inf** ascending, not known to be bulbiferous; **Ped** ±10 mm and slender or 40 mm and much stouter; **Fl** 55–60 (–70) mm; **Tep** yellow, tube conical, 8–10 mm, lobes 15–20 × 3–5 mm; **Fil** 25–40 mm, inserted nearly in the throat; **Ov** oblong-fusiform, 25–40 mm; **Sty** longer than the filaments; **Sti** capitate; **Fr** broadly ellipsoid, 30–40 × 15–20 mm, beaked, somewhat stipitate; **Se** 6 × 4 mm.

The species was described based on the type collection only and is the only native Caribbean species that lacks marginal teeth (Trelease 1913: 36). It has apparently hardly ever been recollected, but Richter (2011: 88) shows a plant cultivated in Germany. Pilbeam (2013: 29) and Hochstätter (2015: VII: 66) publish the first habitat photographs. Ullrich (1990d: 107) suggests that it might be identical with the Mexican *A. desmetiana* (see also there); photographs of both species by Pilbeam (2013: 29, 75) and elsewhere are indeed hardly different. Since *A. desmetiana* is placed in Sect. *Sisalanae* (as Group), *A. anomala* is probably better placed in that section. It is classified as “Least Concern” in the Cuban Red List (Berazaín & al. 2005).

**A. antillarum** Descourtilz (Fl. Méd. Antilles 4: 239, t. 284, 1827). **Type:** not typified. — **Lit:** Engelm. (1875: 313–314); Petersen (1893: with ill.); Trel. (1913: 31–32, tt. 41–43 [leaf margin of t. 43 probably of *A. intermixta*]); Berger (1915: 206–207); Álvarez de Zayas (1995: 41). **Distr:** Hispaniola (Haiti, Dominican Republic).

This is the earliest named species of Sect. *Antillaranae*, but the protologue is short and indicates orange flowers. Engelm. (1875) equated it with the short- and red-orange-flowered *Agave* of S Haiti, and he was followed by later authors (Petersen 1893, Trel. 1913: 31). According to Álvarez de Zayas (1995), the differences of the other *Agaves* from Hispaniola (*A. brevipedata*, *A. brevispina*, *A. intermixta*) are very subtle and need a critical revision, since they might be conspecific.

**A. antillarum** var. **antillarum** — **Distr:** Hispaniola (Haiti, Dominican Republic); hillsides, limestone rock outcrops and steep cliff sides, S-exposed places, 340–1400 m; flowers in February and November. **I:** Richter (2011: 15, 89, 90); Pilbeam (2013: 30); Hochstätter (2015: VII: 67).

**Incl.** *Agave vivipara* Lamarck (1783) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave americana* Schomburgk (1835) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave dominicensis* Ruse (1893) (*nom.*

*inval.*, ICN Art. 32.1c); **incl.** *Agave americana* Urban (1903) (*nom. illeg.*, ICN Art. 53.1).

[2p] Acaulescent; **Ros** solitary; **L** lanceolate, gradually acute, somewhat concave, 75–100 × 6–11 cm, bright green, margins typically nearly straight; **marginal teeth** straight or upcurved, narrowly triangular from lenticular bases or acuminate deltoid, hard, sharp, 2–4 mm, deep brown to reddish-brown, 10–30 mm apart; **terminal Sp** conical, nearly straight, involutely grooved near the base, smooth, 15–20 × 3 mm, brown or reddish-brown, dull, decurrent; **Inf** 2.5–5 m, paniculate, peduncle with acute green **Bra**, fertile part narrowly oblong, part-**Inf** ascending, in the upper ¼–½ of the inflorescence, the middle ones longest, to 30 cm, with up to nearly 100 densely clustered flowers, not known to be bulbiferous; **Ped** 5–10 (–25) mm; **Fl** 40–50 mm, fragrant; **Tep** deep orange, tube open, 5–10 mm (Petersen 1893: almost none), yellowish-green, lobes linear-lanceolate, erect-patent, 15–25 (–28) × 4 mm, orange; **Fil** 25–30 mm, inserted in the throat of the tube or a little below; **Anth** ±20 mm, orange before dehiscence; **Ov** oblong-fusiform, triquetrous, 25–40 (–46) mm; **Sty** as long as the filaments; **Fr** narrowly oblong, 38–45 × 15–20 mm, beaked, stipitate; **Se** 5–7 × 3–4 mm, shiny, black.

**A. antillarum** var. **grammontensis** Trel. (Repert. Spec. Nov. Regni Veg. 23: 362, 1927). **Type:** Hispaniola, Haiti (*Ekman* 3355 [US, B, ILL, S]). — **Distr:** Hispaniola (Haiti); hard limestone rocks.

≡ *Agave antillarum* ssp. *grammontensis* (Trel.) Hochstätter (2015).

[2p] Differs from var. *antillarum*: **L** glaucous; **marginal teeth** in the middle of the leaf broadly triangular, larger, 5 mm, 5–10 mm apart, margins between the teeth concave; **Tep** orange, almost cochineal-red within; **Fr** and **Se** unknown.

Apparently never recollected.

**A. apedicellata** Thiede & Egli (Kakt. and Sukk. 50(5): 111, 1999). **Type:** Mexico, San Luis Potosí (*Parry & Palmer* 867 [K, GH, NY, US]). — **Lit:** Rose (1903a: 9, as *Polianthes durangensis*, 10, as *P. sessiliflora* & *P. pringlei*);

McVaugh (1989: 255–258, as *P. pringlei*); Solano & Feria (2007: as *P. sessiliflora*); Cházaro Basáñez & al. (2014: with ills., as *P. pringlei*); Cházaro Basáñez & al. (2015: with ills., as *P. pringlei*). **Distr:** Mexico (Durango, Zacatecas, Aguascalientes, San Luis Potosí, Nayarit, Jalisco, Guanajuato, Michoacán); grasslands, grassy openings and hillsides in oak or pine-oak forest regions, wet meadows and pastures, 800–2470 m; flowers July to October. **I:** Hemsley (1879–1888: t. 86, as *Bravoa sessiliflora*); Barba-Gonzalez & al. (2012: 124, as *P. pringlei* & *P. sessiliflora*); Hochstätter (2016: II: 23, as *P. sessiliflora*); Castro-Castro & al. (2016: 721, as *P. sessiliflora*).

≡ *Bravoa sessiliflora* Hemsley (1880) ≡ *Polianthes sessiliflora* (Hemsley) Rose (1903a); **incl.** *Polianthes durangensis* Rose (1903a); **incl.** *Polianthes pringlei* Rose (1903a); **incl.** *Agave neopringlei* Thiede & Egli (1999).

[3b1] Herbaceous; corm ± (1–) 2.2–3.2 × 1.5–2.5 cm, oblong, bulb 4–6 × 1.2–2.5 cm, narrowly ovoid to conical, completely covered with dried fibrous leaf bases; **R** fleshy, thickened, contractile; **L** drought-deciduous, (1–) 5–15, erect or nearly so, linear to linear-attenuate, grass-like, sometimes 1–6 additional ones a few cm above the peduncle base, upper ones much reduced, sometimes papillose on the veins on the lower face, 10–25 (–45) × (0.1–) 0.3–0.7 (–1) cm, green, margins ± papillose; **Inf** (20–) 25–45 (–65) cm, erect, ‘spicate’, green, peduncle with 2–4 **Bra**, lanceolate-subulate, 1–4 cm, internodes decreasing in size distally, fertile part 8–17 (–20) cm, very lax, with 2–7 remote floral nodes; floral **Bra** ± 0.8–1.2 × 0.2 cm, broadly ovate, acute or shortly acuminate; **Ped** none; **Fl** geminate, fragrant, 54–75 mm; **Tep** white, sometimes (pale) pink, or white inside and pink outside, or sometimes red, or drying purplish, forming a slender tube, ascending from the base, commonly curved outwards in the middle or below, narrowly funnel-shaped above, tube 30–70 × 2.5–4 mm at the base of the lobes, mouth strongly oblique, lobes elliptic to oblong or broadly ovate, subequal, ascending-spreading or finally recurved, erect or finally recurved, (3–) 10–15 × (2.5–) 3–6 mm, apex obtuse or subacute, tip cucullate; **Fil** filiform, 1–2 mm, included, inserted 4–6 mm below the

mouth of the tube; **Anth** linear, (5–) 7–9.5 mm, apex reaching the tip of the lobes; **Ov** fusiform, erect, ± 5–6 × 2–3 mm; **Sty** filiform, not exerted; **Sti** 3-lobed, included; **Fr** broadly ellipsoid, 10–13 × 8–10 mm, weakly stipitate; **Se** flat, 3.5–4 mm.

The second-most widely distributed species of Sect. *Polianthes* and recorded from 64 localities by Solano & Feria (2007). It is characterized by its narrow leaves and white flowers with a long tube curved outwards. *A. neopringlei* (≡ *Polianthes pringlei*) and *Polianthes durangensis* are both placed in the synonymy of this species following A. Castro-Castro (pers. comm. to author, Nov. 2018). *A. dolichantha* has similar white flowers with an oblique mouth, but differs in its longer flowers with much longer filaments. The record from the Balsas basin (Fernández Nava & al. 1998: 2, as *P. pringlei*) needs confirmation. — The original epithet of *Polianthes sessiliflora* is pre-occupied under *Agave*, necessitating the new name published by Thiede & Egli (1999).

**A. applanata** Hort. Tonel *ex* K. Koch (Wochenschr. Vereines Beförd. Gartenbaues Königl. Preuss. Staaten 5: 198, 1862). **Type** [neo]: Mexico, Veracruz (*Trelease* 1 [MO]). — **Lit:** *Trelease* (1912b: 86–88, with ills.); Gentry (1982: 421–425, with ills.); Alsemgeest & al. (2005: with ills.); García-Mendoza (2011a: 15, 17, 21); Starr (2012: 44–49, with ills.); Smith & Figueiredo (2013: 54–55). **Distr:** Mexico (Chihuahua, Durango, Zacatecas, Guanajuato, Querétaro, Hidalgo, México, Puebla, Veracruz, Oaxaca). **I:** Alsemgeest & al. (2005); Heller (2006: 63); Klopper & al. (2010: 54); Richter (2011: 14); Pilbeam (2013: 31); Hochstätter (2015: IV: 5). – Fig. 5.

**Incl.** *Agave cinerascens* Jacobi (1864); **incl.** *Agave applanata* var. *major* Jacobi (1866); **incl.** *Agave applanata* var. *subnivea* Jacobi (1866); **incl.** *Agave applanata* var. *spectabilis* A. Terracciano (1885); **incl.** *Agave spatularia* hort. *ex* Alsemgeest & Roosbroeck (2010) (*nom. inval.*, ICN Art. 38.1a).

[2h] Stems short; **Ros** 0.5–1 × 1–2 m (in cultivars 1.2–2 × 2.5–3.5 m), solitary or

**Fig. 5** *Agave applanata*

(Etter & Kristen 3648: Mexico; Querétaro, along the road to Cerro Zamorano, 2600 m). (Copyright: J. Etter & M. Kristen)

sparingly caespitose; **L** 100–200, linear-lanceolate, stiffly erect-spreading, very rigid, hard-fleshy with coarse, abundant fibres, gradually acute, usually widest at or near the base, very openly concave, smooth, 40–60 × 7–10 cm (cultivated material 100–160 × 10–15 cm), mostly glaucous-grey, mature leaves much longer than earlier stages, margins horny throughout or not differentiated in the middle of the lamina; **marginal teeth** nearly straight or frequently curved downwards, very strong, sharp, larger teeth (middle of the leaf) 8–15 mm, dark brown becoming light waxy pruinose, mostly 25–60 (–75) mm apart, smaller (5–8 mm) and more closely spaced (25–35 (–50) mm) in wild forms, abruptly lenticularly widened to 20–30 mm at the base, or confluent throughout to form a slightly concave horny margin ±1 mm wide, which is, like the teeth, sparsely granular; **terminal Sp** very strong, flat or broadly guttered, often somewhat flexuous, 30–70 × 6–14 (at the base) mm, dark reddish-brown becoming greyish with age, long-decurrent along the margin; **Inf** 3.5–8 (–14) m, paniculate, peduncle glaucous-green, with reflexed triangular **Bra** 20–25 cm long, fertile part narrowly oblong, in the upper ½, part-**Inf** numerous, horizontal or slightly ascending, (40–) 65–80 cm; **Ped** 15–20 mm; **Fl** 55–70 (–85) mm, foetid; **Tep** yellow to greenish-yellow, sometimes with brownish or reddish tinge, tube cylindrical, thick-walled,

deeply furrowed from the tepal sinuses, 12–22 × 10–15 mm, lobes linear-lanceolate, thick, unequal, 15–22 × 4–8 mm, **ITep** shorter and narrower, with a narrow prominent keel, apex cucullate, brown; **Fil** flattened, 45–65 mm, inserted in 2 ranks at mid-tube or ± in the upper ½, yellowish-green; **Anth** centric or excentric, 20–30 mm, yellow; **Ov** angularly cylindrical, tapering towards the base, 35–38 mm, greenish; **Sty** 70 mm; **Sti** 3-lobate; **Fr** oblong, 40–50 × 20–25 mm; **Se** 6–7 × 5–7 mm, shiny, with inconspicuous wing.

See Smith & Figueiredo (2013) for the place of valid publication. The neotype cited above was designated by Gentry (1982: 422). This taxon appears to be truly native to Veracruz and adjacent Puebla and is cultivated as a cottage plant elsewhere. It was possibly disseminated to the North by men in (pre-) historic times (Gentry 1982: 424–425). For plants from Guanajuato with rosettes of few broad leaves with especially long terminal spines, resembling *A. applanata*, the invalid name “*A. spatularia*” is used (Alsemgeest & Roosbroeck 2010: 74); Richter (2011: 57, 119, ill.) places these plants under *A. parryi*. In habitat, plants are very similar to some forms of *A. flexispina*. ‘Cream Spike’ is a variegated cultivar (Starr 2012: 49, with ill.); Alsemgeest & al. (2005: 248) show unarmed variegated plants. See also the notes under *A. angustifolia* var. *angustifolia* and *A. potatorum*.

**Fig. 6** *Agave arcedianoensis* (Etter & Kristen 3514; Mexico; Jalisco, Río Santiago Canyon, 1220 m). (Copyright: J. Etter & M. Kristen)

**A. arcedianoensis** Cházaro & al. (in Vázquez-García & al. (eds.), *Agaves Occid. Méx.*, 45–46, ills. (t. EE, pp. lxxiv–lxxv), 2007). **Type:** Mexico, Jalisco (*Vázquez-García & Cházaro Basáñez* s.n. [IBUG]). — **Lit:** Cházaro Basáñez & Valencia (2003: with ills., as *A. impressa*); Greulich (2012a: 32–35); Hernández-Vera & al. (2019: with ills.). **Distr:** Mexico (C Jalisco: endemic to the Santiago Canyon N of Guadalajara); volcanic rock cliffs and ridges in tropical deciduous forests, 1250–1440 m; flowers May to July; only known from the type locality. **I:** Etter & Kristen (2012: 91); Pilbeam (2013: 32); Hochstätter (2015: IX: 25). – Fig. 6.

**Incl.** *Agave colimillensis* hort. (s.a.) (*nom. inval.*, ICN Art. 29.1).

[lg] **Ros** stemless, solitary, symmetrical, to  $0.9 \times 1.5$  m  $\varnothing$ ; **L** many, lanceolate, rigid, fleshy,  $60\text{--}70 \times 10\text{--}12$  cm, dark green, with a

conspicuous yellowish-green mid-stripe above along the whole length, with inconspicuous marks left by the central bud, margins horn-grey; **marginal teeth** numerous, straight or variously curved, size not described, with broad base, greyish to silvery, 20–25 mm apart, partly absent from the upper leaf parts; **terminal Sp** 20–40 mm, dark brown, long-decurrent; **Inf** 1.8–2 m, ‘spicate’, peduncle with many filiform  $\pm$  horizontal **Bra**, fertile part in the upper 70–80%, 15–18 cm  $\varnothing$ ; **Ped** 3–6 mm, thick; **Fl** geminate; **Tep** reddish-purple above, greenish below, tube very short, lobes greenish below, upper  $\frac{2}{3}$  reddish-purple, tips slight recurved; **Fil** long exerted, reddish-purple; **Anth** 14–15 mm, reddish-purple; **Ov** 17–18 mm, greenish, neck with a longer constriction; **Fr** oblong,  $30\text{--}40 \times 16\text{--}22$  mm, beaked, fruit valves spreading, infructescence 18–25 cm  $\varnothing$ ; **Se** unknown.

The protologue description is incomplete, and information taken from published photographs is here added. Similar to *A. angustiarum* according to the protologue but differing in smaller rosettes, more widely spaced marginal teeth, and reddish flowers. The comparison is based on the inadequate data for *A. angustiarum* in Gentry (1982: 134), however, which did not include the complete variation given in Trelease’s protologue. Based on this data, rosette and leaf sizes of *A. arcedianoensis* fall within the range of *A. angustiarum* (see there), and the same is true for the arrangement of the marginal teeth. The reddish-purple flowers therefore appear to remain as sole distinguishing character, as pointed out by Greulich (2012a); reddish flowers are rarely also reported for *A. angustiarum* (Velasco Gutiérrez & al. 1904, MEXU 1375574: “tépalos rojizos”). Hernández-Vera & al. (2019) provide additional morphological data and photographs, pointing out differences from *A. angustiarum* esp. in the inconspicuous marks left by the central bud (vs. lacking), shorter pedicels, much larger diameter of the infructescences, and beaked fruits with spreading valves (vs. straight fruit valves apically rounded). Sterile plants of this taxon were first erroneously reported as *A. impressa* (Cházaro Basáñez & Valencia 2003). For differences from the closely related *A. garciaruii* see there.

**A. ×arizonica** Gentry & J. H. Weber *pro sp.* (Cact. Succ. J. (US) 42(5): 223–225, ill., 1970). **Type**: USA, Arizona (Weber s.n. [US, ASU, DES]). — **Lit**: Gentry (1977a: 40–41, with ill.); Gentry (1982: 254–257, with ill.); both as *A. arizonica*; Hodgson (1999a: 4, 18, with ill.); Reveal & Hodgson (2002); Parker (2018a: 20–21, with ill.). **Distr**: USA (Arizona); open rocky slopes in chaparral vegetation or juniper-dominated grasslands, 900–1800 m; flowers May to July. **I**: Pilbeam (2013: 33); Hochstätter (2015: IX: 20).

[1e × 2h] Identified as the diploid natural hybrid *A. toumeyana* ssp. *bella* × *A. chrysantha* by Reichenbacher (1985), Pinkava & Baker (1985) and others. The taxon is of conservation concern since only about 50–60 clones are known (Hodgson 1999a, Reveal & Hodgson 2002). Parker (2018a) knows of only two living plants in habitat and reports a natural hybrid with *A. toumeyana* ssp. *bella* (as var. *bella*). — For the in vitro propagation, see Powers & Backhaus (1989).

**A. arubensis** Hummelinck (Recueil Trav. Bot. Néerl. 33: 236–237, 248, figs. 14–15, tt. 3a, 4, 1936). **Type** [syn]: Aruba (Hummelinck 17a + b [U]). — **Lit**: Hummelinck (1938: 19, 27); Hummelinck (1993: 104–105, 108, 219, 223, with ill.); Thomson (2014: with ill.). **Distr**: Leeward Islands (Aruba: Fontein and vicinity); debris of coral rocks, calcareous terraces, 30–550 m; flowers in June. **I**: Pilbeam (2013: 34); Hochstätter (2015: VIII: 33).

[2u] Acaulescent, **Ros** 1.3–1.6 m Ø, suckering (?); **L** rather few, broadly lanceolate, slightly S-curved, flat, margins upcurved and infolded during drought, widest somewhat below or in the middle, usually slightly acuminate, usually guttered and lower face round, 60–80 × 13–14 cm, 4.25–6 × as long as broad; **marginal teeth** usually pointing downwards somewhat below the middle of the leaves, often upcurved farther up, slenderly acicular, usually rough at the base, 4–6 (–7) mm, 8–12 per 10 cm, on rather weakly to strongly developed green or hardening prominences; **terminal Sp** acicular, straight or very slightly upcurved at the tip, sometimes slightly flexuous, narrowly to broadly grooved basally or to the

middle, margin blunt or rather sharp, usually rough, covered with many minute tubercles, 27–32 × 2.5–4 mm, shortly decurrent, dorsally at most very slightly intruding into the leaf tissue; **Inf** 3.5–5 m, paniculate, narrowly oblong, peduncle with 6–13 **Bra** (4–) 6–12 (–14) cm long, part-**Inf** rather many, on slightly S-curved ± ascending **Br**, in the upper ½–⅔ of the **Inf**, forming few fruits but freely bulbiferous; **Ped** 4–7 mm; general **Fl** shape and **Ov** not described; **Tep** tube 7–8 mm, lobes 19–21 mm; **Fil** 30–35 mm, inserted 2–4 mm below the throat; **Anth** 14–19 mm; **Sty** 35–40 mm; **Fr** narrowly oblong, 33–40 × 12–15 mm, long-beaked, long-stipitate; **Se** 4.5–5 × 4–4.5 mm.

According to the protologue hardly different from *A. vicina* (as *A. vivipara*) in vegetative characters, but clearly differing in generative parts (small number of bracts, long tube with filaments inserted low down, form of capsules). The species was recently re-studied in habitat by Thomson (2014).

**A. asperrima** Jacobi (Hamburg. Gart.- & Blumenzeit. 20: 561, 1864). **Type** [neo]: USA, Texas (Gentry & Barclay 20012 [US, DES]). — **Lit**: Gentry (1975: with ill., as *A. scabra*); Gentry (1982: 296–303, with ill., as *A. scabra*); Ullrich (1992j: with ill.); Reveal & Hodgson (2002); Villarreal & al. (2005); González-Elizondo & al. (2009: 54–57, with ill.); Starr (2012: 50–55, with ill.). **Distr**: USA (Texas), Mexico (Chihuahua, Coahuila, Nuevo León, Durango, Zacatecas, San Luis Potosí, Querétaro).

The nomenclature of this taxon was discussed controversially. Gentry (1982: 296) used the name *A. scabra* Salm-Dyck (1859) for this taxon, but this is an illegitimate later homonym of *A. scabra* Ortega (1797), as shown by Ullrich (1992j). Ullrich consequently re-established the oldest synonym *A. asperrima* Jacobi (1864) as correct name for *A. scabra* sensu Gentry, and he was followed by later authors. The neotype cited above was designated by Ullrich (1992j: 253). *A. wislizeni* Engelman (1875) received alternative interpretations (see Villarreal & al. (2005)) as *A. parryi* (Ullrich 1992j), *A. parrasana* (Gentry 1975), or *A. ovatifolia* (Villarreal & al. 2003, Villarreal & al. 2005), but all these interpretations are flawed

since *A. wislizeni* was published as a legitimate replacement name for the illegitimate *A. scabra* Salm-Dyck and must thus be typified by the type of the latter (Villarreal & al. 2005). Gentry (1982: 296) designated one of his own collections (*Gentry & Engard* 23268) as neotype for *A. scabra* Salm-Dyck, which he equated with *A. asperrima*. Ullrich (1992j) seemingly rejected Gentry's neotypification as a misinterpretation of *A. scabra*, but did not propose a replacement type. Since Gentry's neotype is not in serious conflict with Salm-Dyck's protologue of *A. scabra*, there are no grounds for superseding Gentry's neotypification, and the type for *A. scabra* is also the type of *A. wislizeni*, which then also becomes a synonym of *A. asperrima* (Villarreal & al. 2005).

**A. asperrima** ssp. **asperrima** — **Lit:** Gentry (1982: 276, 296–299, with ill., as *A. scabra*); González-Elizondo & al. (2009: 54–56, with ill.); Starr (2012: 51–55, with ill.). **Distr:** USA (Texas), Mexico (SE Chihuahua, C & S Coahuila, C & S Nuevo León, NE & E Durango, N & C Zacatecas, Guanajuato); dry, sandy to gravelly, often calcareous places in desert scrub, 500–1500 (–1900) m; flowers April to December. **I:** Irish & Irish (2000: t. 36, as *A. scabra*); Heller (2006: 64); Richter (2011: 115, 117–118); Pilbeam (2013: 35); Hochstätter (2015: VII: 10).

**Incl.** *Agave scabra* Salm-Dyck (1859) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave wislizeni* Engelm (1875); **incl.** *Agave caecilians* A. Berger (1915).

[2a] Acaulescent, **Ros** frequently suckering with new rosettes appearing at some distance, rather open, 0.7–1 × 1.5–2 m; **L** 30–40, lanceolate, rigid, spreading to recurved and mostly reflexed, very broad at the base and constricted just above, long-acuminate, convex below, flat above but deeply guttering in the lower ½, scabrous, generally 60–110 × 12–16 cm, light green to glaucous-grey, without imprints from the central bud, margins sometimes horny along the upper ½; **marginal teeth** generally deflected below the middle of the leaves, larger teeth 8–15 mm, brown to pruinose-grey, from broadly rounded bases; **terminal Sp** subulate to acicular, very narrowly grooved above, base scabrous,

30–60 mm, dark brown to blackish, long decurrent on the involute leaf margin; **Inf** mostly 4–7 m, paniculate, peduncle with persistent triangular **Bra** 3–10 cm long, part-**Inf** 8–12 in the upper ⅓ of the inflorescence, small, compact, slightly ascending, >10 cm, with 14–18 flowers; **Fl** erect, 60–80 mm; **Tep** yellow, tube cylindrical, 13–18 × 14–16 mm, lobes erect, lanceolate-linear, involute, subequal, 18–26 × 4–6 mm, outer 2 mm longer, inner broadening at the base, with narrow, prominent keel, both cucullate; **St** long-exserted; **Fil** erect, slender, tapering, 50–65 mm, yellow, inserted just above mid-tube; **Anth** centric, 24–30 mm, yellow; **Ov** slender, 30–40 mm, greenish, neck constricted, 4–6 mm; **Sty** longer than the stamens after anthesis, broadly clavate towards the apex; **Sti** 3-lobate; **Fr** oblong, 40–50 × 17–20 mm, beaked, shortly stipitate; **Se** crescent-shaped, 6–7 × 5 mm, margin with wavy wing. — **Cytology:** 2n = 60, 87, 174–180, 148–186 (2×, 6×; Cave 1964, Simpson & al. 2011).

This is the most widespread and common *Agave* in the Chihuahuan Desert of N Mexico, with the exception of *A. lechuguilla*. In contrast to most other species, it inhabits the broad valleys and plains as well as the stony slopes of the mountains (Gentry 1982: 296). It is related to *A. americana* and distinguished by its more scabrous and shorter leaves, less branched inflorescences, a longer flower tube, and smaller tepal lobes (Gentry 1982: 296). Cave (1964) gave chromosome counts of n = 74–93, but according to Gentry (1982: 273), only the count n = 87 applies to ssp. *asperrima*. It shows introgressive hybridization with *A. americana* and *A. nickelsiae* (= *A. ×santilloensis*; see there) (Gentry 1982: 299).

**A. asperrima** ssp. **maderensis** (Gentry) B. Ullrich (*Sida* 15(2): 254, 1992). **Type:** Mexico, Coahuila (*Gentry & Engard* 23251 [DES, ARIZ, CAS, MEXU, US]). — **Lit:** Gentry (1982: 301–302, with ill., as *A. scabra* ssp.); Starr (2012: 55). **Distr:** Mexico (Coahuila); local endemic in (limestone) canyons of desert mountains in pine-oak forests or oak-chaparral vegetation, 1850–2000 m; flowers June to July. **I:** Hochstätter (2015: VII: 11).

≡ *Agave scabra* ssp. *maderensis* Gentry (1982) (*incorrect name*, Art. 11.4).

[2a] Differs from ssp. *asperrima*: Stems short, thick; **Ros** solitary; **L** triangularly linear-lanceolate, relatively smooth, 50–60 × 7–12 cm, green to yellow-green; **marginal teeth** slender, larger teeth 5–8 mm, mostly 20–30 mm apart; **Inf** with >11 large spreading part-**Inf**, each several times compound; **Fl** 65–70 mm; **Tep** tube 11–16 × 12–15 mm, lobes linear, 15–20 mm.

A local endemic of the Chihuahuan Desert mountains, well characterized by its (always?) solitary rosettes, short thick stems, and smooth green leaves (Gentry 1982).

**A. asperrima** ssp. **potosiensis** (Gentry) B. Ullrich (Sida 15(2): 254, 1992). **Type**: Mexico, San Luis Potosí (Gentry & al. 20162 [US, ARIZ, MEXU]). — **Lit**: Gentry (1982: 301–302, with ills., as *A. scabra* ssp.); Starr (2012: 50–51, 55, with ill.). **Distr**: Mexico (San Luis Potosí, Querétaro); rocky slopes and desert plains with limestone, in desert scrub or pine-oak forests, 1130–2070 m; flowers in July. **I**: Etter & Kristen (2007b: 177); Richter (2011: 120); Pilbeam (2013: 35).

≡ *Agave scabra* ssp. *potosiensis* Gentry (1982) (*incorrect name*, Art. 11.4).

[2a] Differs from ssp. *asperrima*: **Ros** more open, spreading, sparingly surculose; **L** broadly lanceolate, tip outcurving and sigmoid, asperous to nearly smooth, 65–110 × 14–20 cm, glaucous-grey to nearly white, frequently cross-zoned; **marginal teeth** sometimes on tuberculate elevations; **Inf** with 10–18 small part-**Inf**; **Tep** tube large, 15–22 mm; **Ov** slender, 32–50 mm.

Best distinguished by its more open and spreading graceful rosettes with broad and less rigid, lightly glaucous leaves, flowers with slender ovaries and a large tube, but often difficult to separate due to apparent introgression with *A. americana* ssp. *protoamericana* (Gentry 1982: 301–302). Zamudio & Galván Villanueva (2011: as *A. scabra*) provide a new record of “*A. scabra*” from Guanajuato which, due to geographical proximity, must represent ssp. *potosiensis*.

**A. asperrima** ssp. **zarcensis** (Gentry) B. Ullrich (Sida 15(2): 254, 1992). **Type**: Mexico, Durango (Gentry & Arguelles 22084 [US, ARIZ, ASU, MEXU, MICH]). — **Lit**: Gentry (1982: 302–303, with ills., as *A. scabra* ssp.); González-Elizondo & al. (2009: 56–57, with ills.); Starr (2012: 55). **Distr**: Mexico (Durango); sunny rocky slopes with limestone in transition between desert and grama grasslands, 1120–1675 m; flowers in June and July. **I**: Pilbeam (2013: 36); Hochstätter (2015: VII: 13).

≡ *Agave scabra* ssp. *zarcensis* Gentry (1982) (*incorrect name*, Art. 11.4).

[2a] Differs from ssp. *asperrima*: **Ros** surculose, forming large clumps; **L** linear-ovate, guttered, 55–60 × 15–20 cm, greyish-green; **marginal teeth** mostly reflexed, moderate, larger 5–7 mm, 10–20 mm apart; part-**Inf** 8–14, in the upper 1/3 of the **Inf**, on sigmoid branches; **Fl** 68–92 mm; **Tep** tube deeply furrowed, thickly 12-ridged within; **Ov** 3-angled and 6-grooved, 35–50 mm.

A highland ecotype within *A. asperrima*, distinguished best by its short broad leaves with moderate teeth, large flowers, 2-level insertion of filaments, and large woody fruits. The insertion of the filaments at 2 levels suggests an affinity with *A. havardiana* where this character sporadically occurs, as well as in ssp. *asperrima* — the character is thus not exclusive to Sect. *Ditepalae* (as Group), where it is so prominent (Gentry 1982: 302–303). González-Elizondo & al. (2009) show plants from Durango with introgression of *A. salmiana* and *A. ×gracilipes*.

**A. atrovirens** Karwinsky ex Salm-Dyck (Hort. Dyck., 7: 302, 1834). **Type** [neo]: Mexico, Oaxaca (Gentry 22377 [US, ARIZ, MEXU]). — **Distr**: S Mexico.

The neotype cited above was designated by Gentry (1982: 469).

**A. atrovirens** var. **atrovirens** — **Lit**: Gentry (1982: 468–476, with ills.); Ullrich (1990a: with ill.); Piña Luján (1994: with ill.); García-Mendoza (2011a: 17–21, with ills.). **Distr**: Mexico (C Guerrero, Oaxaca); strictly high-montane in

oak forests, 1850–3400 m; flowers October to March. **I**: Cact. Suc. Mex. 39(3): front cover, 1994; García-Mendoza (2002: 178); Heller (2006: 65); Richter (2011: 41–42); Greulich (2012c: 39); Pilbeam (2013: 37); Hochstätter (2015: VI: 5); Moore (2016: 238).

**Incl.** *Agave coccinea* Roez l ex K. Koch (1862); **incl.** *Agave schlehtendahl ii* Jacobi (1864); **incl.** *Agave coccinea* Roez l ex Jacobi (1865) (*nom. illeg.*, ICN Art. 53.1)  $\equiv$  *Agave americana* var. *coccinea* (Roez l ex Jacobi) A. Terracciano (1885); **incl.** *Agave ottonis* Jacobi (1866); **incl.** *Agave canartiana* Jacobi (1868); **incl.** *Agave canartiana* var. *laevior* Jacobi (1868); **incl.** *Agave deflexispina* Jacobi (1870); **incl.** *Agave gracilis* Jacobi (1870); **incl.** *Agave macroculmis* Todaro (1878); **incl.** *Agave coccinea* hort. ex A. Berger (1898) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave atrovirens* var. *cochlearis* Trelease (1914); **incl.** *Agave atrovirens* var. *marginata* Trelease (1914); **incl.** *Agave atrovirens* var. *sigmatophylla* A. Berger (1915).

[2o] Acaulescent, **Ros** openly spreading, large to very large, 1.5–2.5  $\times$  3–4 m, solitary or caespitose; **L** 40–70, erect to recurved, broadly lanceolate, thick at the base (to 25 cm), usually narrowed below the middle, convex below, openly concave above, mostly 150–200 (–220)  $\times$  20–40 cm, dark to blackish-green to light glaucous or glaucous-variegated, margins  $\pm$  straight or slightly wavy; **marginal teeth** regular, straight, antrorse, 4–8 (–12)  $\times$  10–13 (–17) mm (mid-leaf), dark brown, greyish-brown or reddish, with low broad bases, 10–20 (–40) mm apart, sometimes bases fused into a continuous band; **terminal Sp** straight, conical, strong, broad at the base, widely openly grooved above, (30–) 60–70 mm, decurrent for 10–20 cm, keel rounded below and markedly intruding into the leaf tip for 1.5–2.5 cm, dark brown; **Inf** 6–12 m, paniculate, peduncle with long triangular dark brown **Bra** 40–50 cm long, fertile part narrow, oblong, part-**Inf** congested in the upper  $\frac{1}{3}$ – $\frac{1}{2}$  of the **Inf**, globose, (18–) 35–60, 20–30 cm long, with >600 flowers, axis reddish; **Fl** thickly fleshy, (70–) 80–90 (–100) mm; **Ped** 10–20 mm; **Tep** red to purple in bud, at anthesis yellowish to yellowish-green within, tip reddish, tube deeply furrowed, thick-walled, 10–15  $\times$

10–20 mm, bulging at the insertion of the stamens, lobes triangular or oblong, erect, conduplicate-revolute, thickly fleshy, unequal, 30–40  $\times$  4–6 (–9) mm, incurved at the tips; **OTep** slightly larger; **ITep** with very thick keel and thin margins, red with paler margins; **Fil** large, flattened, 70–80 (–90) mm, purplish or red-spotted, inserted in the middle or at the mouth of the tube, yellowish or with purple dots; **Anth** excentric, straight to sinuous, (25–) 30–43 mm, yellow(ish) to bronze; **Ov** cylindrical, tapering at the base, 3- to 6-angled, 30–50  $\times$  (4–) 6–8 mm, neck thick, furrowed, 4–7 mm; **Sty** 80–110 mm, much longer than the stamens after anthesis; **Sti** clavate, 4–5 mm  $\varnothing$ ; **Fr** ovoid, ellipsoid or clavate, 40–50 (–65)  $\times$  20–30 mm, 5–12 mm stipitate, tapering from the apex; **Se** crescent-shaped, 7–9  $\times$  4–6 mm, shiny, with inconspicuous wing. — **Cytology**: 2n = 180 (Simpson & al. 2011).

A very large species with affinities to species of Sect. *Guatemalenses* (as Group *Hiemiflorae*) from Chiapas and Guatemala, which flower in winter, produce straight and strong peduncles, and with tightly arranged flowers in bracteolate globose purplish clusters in narrow panicles (Gentry 1982: 468–476). Karwinski's type locality "Monte Tanga" (see Piña Luján (1994)) was re-named as Monte Fiscal-Santos and is located W of Ciudad Oaxaca (David 2009), and this is supported by Karwinski's letters (Phillips 2013). Earlier authors (Baker, Berger, Trelease) confused the species with *A. salmiana* (Gentry 1982). Gentry's records from NE Puebla and C Veracruz apparently refer to cultivated plants of var. *mirabilis* (see there). Ullrich (1990a) reports on a new locality from Guerrero. The records from México state (Ávila-Akerberg & al. 2008: 617) (specimens *Castañeda Rojas* 27, MEXU 1047763 & 1047765) need verification. *A. macroculmis* is a synonym to be placed here (Ullrich 1990i), and was misinterpreted by Gentry (1982: 598) for plants later described as *A. gentryi* and *A. montana* (see there). Leaves frequently show necrotic spots caused by a herbivorous fly whose larvae develop inside the leaves of *A. atrovirens* and *A. salmiana* (Brunel & Rull 2010).

**A. atrovirens** var. **mirabilis** (Trelease) Gentry (Agaves Cont. North Amer., 473, ill. (p. 476), 1982). **Type:** Mexico, Veracruz (*Trelease* 7 p.p. [MO, DES]). — **Lit:** García-Mendoza (2011a: 20–21, with ills.). **Distr:** Mexico (NE & S Puebla, C Veracruz, N Oaxaca); cool montane habitats, in pine-oak forests and cultivated, 2150–2480 m. **I:** García-Mendoza (2002: 179); Richter (2011: 83); Spracklin (2014); Hochstätter (2015: VI: 6).

≡ *Agave mirabilis* Trellease (1920) ≡ *Agave atrovirens* ssp. *mirabilis* (Trellease) Hochstätter (2015).

[2o] Differs from var. *atrovirens*: **L** broadly lanceolate, consistently light grey-glaucous; **Fl** smaller, 60–80 mm, without large bracteoles; **Ov** 25–30 mm.

A light glaucous form cultivated for pulque and as fences about Las Vigas, Veracruz, without confirmed occurrence elsewhere according to Gentry (1982: 473). Photographs from the type locality were published on the web by Spracklin (2014). Gentry's records for var. *mirabilis* from NE Puebla and C Veracruz apparently belong here according to García-Mendoza (2011a), who also reports the taxon from Oaxaca.

**A. attenuata** Salm-Dyck (Hort. Dyck., 303, 1834). **Type:** [neo — icon]: Curtis's Bot. Mag. 88: t. 5333, 1862. — **Distr:** Mexico (Sinaloa, SW Durango, Nayarit, Jalisco, Colima, Michoacán, México, Guerrero, Oaxaca).

The neotype cited above was designated by Gentry (1982: 68).

**A. attenuata** ssp. **attenuata** — **Lit:** Gentry (1982: 66–68); Ullrich (1990h); Cházaro Basáñez & al. (1998); Vázquez-García & al. (2007b: 47, t. F); Ullrich (2007); all with ills. **Distr:** Mexico (Jalisco, Colima, Michoacán, México); rocky outcrops in pine forests, 1900–2500 m; flowers November to December. **I:** Curtis's Bot. Mag. 88: t. 5333, 1862, as *A. glaucescens*; Irish & Irish (2000: t. 5); Heller (2006: 21, 37, 41, 66, 67); Etter & Kristen (2012: 87); Pilbeam (2013: 38); Meer (2014: as *A. cernua*); Hochstätter (2015: VIII: 38); Moore (2016: 246). — Fig. 7.

**Fig. 7** *Agave attenuata* ssp. *attenuata* (Etter & Kristen 1569; Mexico; Michoacán, between Morelia and Ciudad Hidalgo, 2260 m). (Copyright: J. Etter & M. Kristen)

**Incl.** *Ghiesbreghtia mollis* Roehl (1861) (*incorrect name*, Art. 11.4); **incl.** *Agave glaucescens* Hooker (1862) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave attenuata* var. *compacta* Jacobi (1865); **incl.** *Agave attenuata* var. *subundulata* Jacobi (1866); **incl.** *Agave attenuata* var. *coarctata* Jacobi (1866) (*nom. inval.*, ICN Art. 38.1a); **incl.** *Agave ghiesbreghtii* [?] *mollis* Hort. Belg. ex Jacobi (1866) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Agave attenuata* var. *elliptica* Jacobi (1868) (*nom. inval.*, ICN Art. 38.1a); **incl.** *Agave spectabilis* Roehl ex Baker (1877) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Agave attenuata* var. *glauca* Carrière (1879) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Agave attenuata* var. *latifolia* Salm-Dyck ex A. Terracciano (1885); **incl.** *Agave attenuata* var. *brevifolia* Jacobi ex A. Besauccèle ex

*A. Berger* (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave elliptica* Hort. Besaucèle *ex A. Berger* (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave spectabilis* Hort. Besaucèle *ex A. Berger* (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave virens* Hort. Besaucèle *ex A. Berger* (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave attenuata* ‘Nova’ Kimmach & Trager (1990) (*nom. inval.*, Art. ICNCP 17.9); **incl.** *Agave attenuata* ‘Boutin Blue’ C. C. Walker (2000).

[1b] Stems 1 to several, usually ascending-curved, 0.5–1.5 m, becoming naked in age; **L** relatively short-lived, ovate-acuminate, softly succulent, broadest in the middle, flat to concave, 50–70 × 12–16 cm, light glaucous-grey to pale yellowish-green, margins smooth, straight, without teeth, leaf tip finely tapered, soon fraying, soft; **Inf** 2–3.5 m, ‘spicate’, densely flowered, part-**Inf** shortly pedunculate ‘fascicles’ with 3–8 flowers in the axils of chartaceous **Bra**; **Fl** 35–50 mm; **Tep** greenish-yellow, tube shallowly funnel-shaped, 3–5 mm, lobes linear-oblong, thin, recurving, equal, 16–24 mm, inner frequently broader, with broad low keel, mucronate with white-floccose tips; **Fil** slender, flattened, tapered, 35–45 mm, whitish, inserted on the rim of the tube; **Anth** centric, 15–20 mm, greenish-yellow; **Ov** fusiform, 15–25 mm, green, neck constricted; **Fr** oblong, 20–30 × 10 mm or smaller, shortly beaked, stipitate; **Se** crescent-shaped to deltoid, 3–3.5 × 2–2.5 mm, marginal wing low. — **Cytology**: 2n = 45–62 (Lv & al. 2009).

The presence of a flower tube groups this species in Sect. *Inermes* (Group *Amolae*) and not in Sect. *Choritepalae*, where the otherwise similar *A. bracteosa* and *A. ellemeetiana* are placed. It is closely related to *A. gilbertii* (Gentry 1982: 70). For relationships, see also under ssp. *dentata*. Cházaro Basáñez & al. (1998) provide a new record for Colima.

*A. attenuata* ‘Boutin Blue’ (Walker 2000: 97–98), first invalidly named *A. attenuata* ‘Nova’, differs in its leaves with an extremely blue colouration and its erect inflorescence; it was collected in 1970 as *Kimmach & Boutin* 3019 (ARIZ, DES, HNT) in the Sierra de Manantlán (Jalisco). *A. attenuata* ‘Emery Stripy’ (Walker 2000) and

‘Myron’s Magic’ (Smith 2004) are variegated cultivars (Alsemgeest 2006), and ‘Blue Flame’ is a hybrid with *A. shawii* (Trager 2005, Mays 2005: 44, Starr 2014: 219). The latter and further cultivars are illustrated by Guillot Ortiz & Meer (2009b). ‘Blue Glow’ is a hybrid with *A. ocahui* (Starr 2012: 56–58, with ills.), and ‘Snow Glow’ (Starr 2014: 224, with ill.) is a variegated sport selected from it.

The taxon is reported as casually naturalized in Gran Canaria (Canary Islands) (Verloove 2013: 80) and in Portugal (Silva & al. 2015: 73), and introduced in Madeira and Libya (Euro+Med 2006+: accessed Jan. 2019).

**A. attenuata** ssp. **dentata** (Roezl) B. Ullrich (Haseltonia 12: 27, ills. (pp. 23–27), 2007). **Type** [neo]: Mexico, Guerrero (*Rzedowski & McVaugh* 289 [ENCB, MICH]). — **Lit**: Gentry (1982: 79–82, with ills.); McVaugh (1989); Cházaro Basáñez & al. (1998); Vázquez-García & al. (2007b: 47, t. V-W); González-Elizondo & al. (2009: 58–60, with ill.); all as *A. pedunculifera*. **Distr**: Mexico (Sinaloa, SW Durango, Nayarit, Jalisco, Michoacán, Guerrero, Oaxaca); mountain slopes in tropical deciduous or pine-oak forests, 300–2200 m; flowers November to February. **I**: Richter (2011: 10, 61, 111, as *A. pedunculifera*); Etter & Kristen (2012: 88); Pilbeam (2013: 166–167, as *A. pedunculifera*); Hochstätter (2015: VIII: 39).

≡ *Ghiesbreghtia dentata* Roezl (1861) (*incorrect name*, Art. 11.4); **incl.** *Agave pruinosa* Lemaire *ex Jacobi* (1865); **incl.** *Agave debaryana* Jacobi (1868); **incl.** *Agave kellockii* Jacobi (1868); **incl.** *Agave ghiesbreghtii* [?] *dentata* Hort. Belg. *ex Jacobi* (1868) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Agave attenuata* [?] *dentata* J. Verschaffelt (1876); **incl.** *Agave dentata* hort. *ex Baker* (1877) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave attenuata* var. *subdentata* Cels *ex Carrière* (1879); **incl.** *Agave attenuata* var. *serrulata* A. Terracciano (1885) ≡ *Agave cernua* var. *serrulata* (A. Terracciano) A. Berger (1915); **incl.** *Agave pedunculifera* Trelease (1920).

[1b] Differs from ssp. *attenuata*: Stems short; **L** mostly ovate-acuminate and 50–70 × 15–18 cm, or lanceolate and 80–90 × 11–15 cm,

pale green to glaucous-white, margins narrowly lined with brown or white, with closely set denticles 0.5–2 mm, otherwise smooth; **terminal Sp** acicular, weak,  $\pm 10$  mm; **Inf** erect or recurving (on cliffs), part-**Inf** with 2 or 4 flowers; **Ped** 20–30 mm; **Tep** lobes 12–22  $\times$  5–6 mm; **Fil** 30–35 mm; **Fr** 15–20 mm; **Se** 2.5  $\times$  2 mm.

Known since Trelease (1920) as *A. pedunculifera*. Gentry (1982) considered it closely related to *A. attenuata* based on leaf and flower characters, but distinguished by being nearly stemless throughout all observed populations. The subspecies exhibits considerable variability in leaf form and size and depth of the flower tube, but the different forms are linked by intermediates (Gentry 1982: 80). González-Elizondo & al. (2009) provide a new record from Durango. The recently described blue-leaved *A. manantlanicola* from Jalisco is closely related (see there). There has been some argument which name is the correct basionym for this taxon. Since *Ghiesbreghtia dentata* is merely incorrect, rather than invalid, its use as basionym is not precluded.

**A. aurea** Brandegee (Proc. Calif. Acad. Sci., ser. 2, 2: 207, 1889). **Type** [lecto]: Mexico, Baja California Sur (Brandegee s.n. [UC, CAS, MO]). — **Lit**: Trelease (1912b: 44, 49–51, tt. 32–37); Berger (1915: 168–170); Gentry (1978: 70–83, tt. 3–4); Gentry (1982: 309–322, with ills.); Webb & Starr (2015: 68–71, 97–98, with ills.). **Distr**: Mexico (C & S Baja California Sur).

Gentry (1978) and Gentry (1982) recognized 3 species (*A. aurea*, *A. capensis* and *A. promontorii*) within Sect. *Campaniflorae* (as Group), which, at the latitude of Todos Santos, become similar to each other, suggesting interfertility (Gentry 1982: 313). Based on detailed field studies, Webb & Starr (2015) recognized a single species only and reduced *A. promontorii* to subspecific and *A. capensis* to varietal status. Brandegee's protologue does not indicate a type, but according to Trelease (1912a: 50), the type is "Brandegee, Feb. 13, 1889". The designation of "Brandegee s.n." at UC by Gentry (1972: 78) represents a lectotypification.

**A. aurea** ssp. **aurea** — **Lit**: Trelease (1912b: 49–50, tt. 32–34); Berger (1915: 168–169); Gentry (1978: 71, 74, 77–81, t. 4); Gentry (1982: 311–315, with ills.); Turner & al. (1995: 43–44); all as *A. aurea*; Webb & Starr (2015: 68–70, 97–98, with ills.). **Distr**: Mexico (Baja California Sur: Sierra de la Giganta and Cape district); lava fields and granitic or volcanic slopes, mostly 300–1070 m; flowers September to April. **I**: Heller (2006: 20); Richter (2011: 74); Pilbeam (2013: 39); Hochstätter (2015: V: 4); all as *A. aurea*.

**Incl.** *Agave campaniflora* Trelease (1912).

[2e] Stems short; **Ros** rather open, 1–1.2  $\times$  1–2 m, solitary; **L** linear to long-lanceolate, widely arching, pliable, guttered, rounded below, thickly fleshy towards the base, 60–110  $\times$  7–12 cm, green to yellow-green, somewhat glaucous, margins straight to wavy; **marginal teeth** moderate, mostly 4–7 mm from low angular bases, regularly spaced, 10–20 mm apart, dark to light brown; **terminal Sp** subulate, 25–35 mm, dark brown or greyish-red, shortly decurrent or decurrent as dark horny margin through the uppermost 8–10 tooth bases; **Inf** 2.5–5 m, paniculate, peduncle with remote lanceolate **Bra**, reddish, fertile part broad, part-**Inf** broad, congested, 15–25, in the upper  $\frac{1}{2}$  of the inflorescence, red to purplish in bud and fruit; **Fil** campanulate, 43–70 mm; **Tep** red to purplish in bud, opening yellow to orange-yellow, tube evenly grooved from the lobe sinuses, 8–14  $\times$  14–18 mm, lobes lanceolate, acute, incurved, 16–19 mm, outer larger, with tufts of white papillae below the distinctly hooded tip, inner ones with a distinct long keel and yellow, the thin margin involute; **Fil** stout, 35–45 mm, those in front of the outer tepals inserted 5–10 mm above the tube base, slightly higher than those in front of the inner tepals; **Anth** 19–23 mm; **Ov** slender, angular-cylindrical, 25–35 mm, reddish, neck constricted, furrowed, 6–10 mm; **Sty** somewhat longer than the tepals; **Sti** capitate; **Fr** oblong, 35–45  $\times$  15–17 mm, reddish, drying light brown, rounded-apiculate, not stipitate; **Se** irregularly crescent-shaped, 7–8  $\times$  5–5.5 mm, dull.

The most widespread and common taxon in Sect. *Campaniflorae* (as Group), easily

recognized by its long, narrow, green leaves arching out to form an open, spreading rosette, its broad, rather diffuse, reddish inflorescences, and its bright yellow flowers from reddish buds and ovaries (Gentry 1982: 313, Webb & Starr 2015). N of Todos Santos, it intergrades with both ssp. *promontorii* and var. *capensis* in the colour and shape of the leaves (Gentry 1982: 313 (as *A. promontorii* and *A. capensis*), Webb & Starr 2015: 69), and lower elevation populations of ssp. *aurea* in the Sierra de la Giganta are very similar to ssp. *promontorii* (Webb & Starr 2015: 69).

**A. aurea** ssp. **promontorii** (Trelease) R. H. Webb & G. D. Starr (Haseltonia 20: 70, ill. (p. 71), 2015). **Type:** Mexico, Baja California (*Nelson & Goldman* 7437 [US]). — **Lit:** Trellease (1912b: 50–51, tt. 35–37); Berger (1915: 169–170); Gentry (1978: 71, 74, 80–83, t. 3); Gentry (1982: 319–321, with ill.); all as *A. promontorii*; Webb & Starr (2015: 70–71, 98, with ills.). **Distr:** Mexico (S Baja California Sur: Sierra La Laguna, Cape District); slopes and summits of granitic mountains, 720–1800 m; flowers January and April to May. **I:** Goldman (1916: t. 111B); Richter (2011: 74); Pilbeam (2013: 178); Hochstätter (2015: V: 6); all as *A. promontorii*.

≡ *Agave promontorii* Trellease (1912a).

[2e] Differs from ssp. *aurea*: **Ros** larger, 1–2 × 2–2.5 m; **L** larger, 100–150 × 11–17 cm, margins straight; **marginal teeth** curved, 5–10 mm apart, reddish-brown; **terminal Sp** longer, 30–50 mm, dark brown; **Inf** larger, 5–9 m, peduncle with deltoid **Bra**, fertile part with 25–30 part-**Inf**; **Fl** 60–75 mm, larger in nearly all parts.

This subspecies is larger and occurs at higher elevations than ssp. *aurea*. Since the 2 taxa intergrade, subspecies status (Webb & Starr 2015) is more appropriate than species status (Gentry 1978, Gentry 1982).

**A. aurea** var. **capensis** (Gentry) R. H. Webb & G. D. Starr (Haseltonia 20: 70, ill., 2015). **Type:** Mexico, Baja California Sur (*Gentry & Fox* 11247 [US, ARIZ, MEXU]). — **Lit:** Gentry (1978: 72–78); Gentry (1982: 310, 316–318); both with

ills. and as *A. capensis*; Webb & Starr (2015: 70–71, 98, with ills.). **Distr:** Mexico (Baja California Sur: Cape District); arid slopes, ± sea-level to >300 m. **I:** Heller (2006: 71); Richter (2011: 74); Pilbeam (2013: 49); Hochstätter (2015: V: 5); all as *A. capensis*.

≡ *Agave capensis* Gentry (1978).

[2e] Differs from ssp. *aurea*: **Ros** smaller, 0.6–0.8 × 0.8–1.2 m, caespitose by axillary budding, eventually in large clusters; **L** smaller, mostly 35–60 × 4–7 cm, grey-green with a light glaucous covering, margins wavy; **marginal teeth** reddish-brown to greyish, on short mamillate prominences; **terminal Sp** short, 15–30 mm, dark brown; **Inf** mostly 2.5–3.5 m, fertile part relatively narrow; **Fl** 50–65 mm; **Fil** with an apical gland at the point of anther attachment. — **Cytology:** 2n = 60 (Pinkava & Baker 1985: as *A. capensis*).

Differs from the other 2 taxa primarily in its prolifically offsetting growth leading to large clusters of rosettes (Webb & Starr 2015: 70). The varietal status is warranted because of its distribution, which overlaps with that of ssp. *aurea*.

**A. avellanidens** Trellease (Annual Rep. Missouri Bot. Gard. 22: 60, tt. 61–62, 1912). **Type:** Mexico, Baja California (*Brandeggee* 6 [UC]). — **Lit:** Berger (1915: 267); Gentry (1978: 61–64, with ills.); Gentry (1982: 361–363, with ills.); Heim (2014: 8–11, with ills.); Webb & Starr (2015: 71–73, 98, with ills.). **Distr:** Mexico (S Baja California: Sierra La Libertad); desert scrub, to 325 m; flowers April to May. **I:** Irish & Irish (2000: t. 6); Richter (2011: 104); Pilbeam (2013: 40); Hochstätter (2015: V: 24). — Fig. 8.

[2j] Stems to 0.5 m; **Ros** 0.6–1.2 × 1–1.5 m, solitary; **L** many, broadly linear-lanceolate to ovate, thickly fleshy, rigid, little or not narrowed at the base, shortly acuminate, smooth, 40–70 × 9–14 cm, yellow-green, green or blue-green, margins straight, frequently horny; **marginal teeth** straight or variously curved, variable in size and curvature, flattened, 5–15 mm, grey to brown, mostly 10–30 mm apart, rather regularly spaced, on small to large, broadened bases; **terminal Sp** conical, strong, broadly grooved above, 25–45 mm, brown to greyish, strongly decurrent as horny margin; **Inf** 4–6 m,

**Fig. 8** *Agave avellanidens* (cult.: USA; Arizona, Desert Botanical Garden Phoenix). (Copyright: J. Thiede)

paniculate, peduncle with small **Bra**, fertile part in the upper  $\frac{1}{2}$  of the inflorescence, conical, with 25–35 dense large globose part-**Inf**; **Fl** slender, 40–70 mm; **Tep** pale greenish-yellow, drying orange-yellow, tube flaring, ridged within and grooved on the outside from overlapping lobe sinuses, 4–6  $\times$  13–15 mm, lobes  $\pm$  equal, 16–24 mm; **Ov** fusiform, tapering to the base, 20–40 mm, pale yellow, neck sometimes constricted; **Sty** somewhat shorter than the filaments; **Sti** capitate; **Fr** broadly oblong, 35  $\times$  20 mm, not stipitate, scarcely beaked, dark brown; **Se** unknown. — **Cytology**:  $2n = 60$  (Bennett & Leitch 1995, Simpson & al. 2011).

According to Gentry (1982: 354, 394), *A. avellanidens*, *A. gigantensis* and *A. moranii* form a separate group within Sect. *Deserticolae* (as Group), differing from other members in non-surculose rosettes with broader and greener leaves. Webb & Starr (2015) formalized this group as Sect. *Conicae*, named after its characteristic conical inflorescences, and added the greyish-leaved *A. turneri* to it. Within Sect. *Conicae*, *A. avellanidens* is differentiated by its short green broadly linear-lanceolate leaves not or scarcely narrowed towards the base (Webb & Starr 2015). — *A. avellanidens* resembles *A. shawii* ssp. *goldmaniana* from Sect. *Umbelliflorae* (as Group) in habit, and they appear to hybridize near Rosarito where their ranges overlap (Gentry 1982, Webb & Starr 2015).

**A. azurea** R. H. Webb & G. D. Starr (Haseltonia 19: 90–92, ills., 2014). **Type**: Mexico, Baja California Sur (Webb & Starr 20130418-1 [HCIB]). — **Lit**: Webb & Starr (2015: 88–89, with ills.). **Distr**: Mexico (Baja California Sur: Picachos de Santa Clara); rocky colluvial hillslopes and alluvial fans, 295–360 m, in desert scrub; flowers in April, but appearing opportunistically.

[2k] Acaulescent, **Ros** 0.8–0.9  $\times$  1–1.5 m, solitary; **L** 13–32, obovate to oblanceolate, flat to slightly guttered, attenuate at the tip, slightly rough and waxy above, smooth to slightly rough below, 55–76  $\times$  14–22 cm, widest just above the middle, 10–17 cm broad at the narrowest point below the middle, glaucous blue-green, faintly to moderately banded, with light imprints from the central bud, margins straight to rarely repand; **marginal teeth** deflexed, 10–15 mm, orange-yellow, reddish-purple or brownish-red, aging to whitish-grey, 40–50 mm apart, sessile or on small prominences; **terminal Sp** 40–70 mm, decurrent to the first 1–2 pair(s) of teeth; **Inf** 2–4.5 m, paniculate, peduncle 0.7–3 m; primary **Bra** triangular, 14–17  $\times$  2–3 (at the base) cm, fertile part 1.3–1.5 m, **Bra** 7  $\times$  4 cm, without terminal **Sp**, with 6–9 part-**Inf** with 6–8 stalked ‘umbels’ with 8–14 flowers each; **Ped** 6–30 mm; **Fl** 79–85 mm; **Tep** yellow-orange, tube 9–22  $\times$  15–22 mm, lobes slightly unequal, outer 22–30  $\times$  9–13 mm, inner 21–29  $\times$  10–13 mm; **Fil** 43–65 mm, inserted on the rim of the tube or 14–15 mm above the base of the tube; **Anth** 16–28 mm; **Ov** 30–40 mm, neck 6–10 mm;

**Sty** 85–90 mm when fully exerted; **Fr** oblong, 35–60 × 16–19 mm, with transverse lineations on the locules, beaked for 1–5 mm; **Se** crescent-shaped to ovate, 5–7 × 4–5 mm, shiny black.

Plants from the Picachos de Santa Clara were included in, but recognized as different from, *A. vizcainoensis* by Gentry (1982: 407) and were also identified by him as *A. sebastiana* or *A. gigantensis* according to the protologue, but have now been named *A. azurea*. *A. azurea* differs from *A. vizcainoensis* in its mostly solitary habit, larger size of most characters, leaves with significantly different shape and margins, and smaller fruits. It also resembles *A. turneri* of Sect. *Conicae* in habit, but the latter has a different inflorescence. Webb & Starr (2015) placed *A. azurea* and *A. vizcainoensis* — both characterized by long tepal tubes — in a separate Sect. *Intermediae*, which is considered intermediate between Sect. *Deserticolae* and Sect. *Umbelliflorae* (see under *A. vizcainoensis*).

**A. bahamana** Trelease (Mem. Nation. Acad. Sci. 11: 40, tt. 84–86, 1913). **Type:** Bahamas (Britton & Millspaugh 2340 [MO, NY, F]). — **Lit:** Berger (1915: 203); Britton & Millspaugh (1920: 74–75); Gillis (1976); Correll & Correll (1982: 310). **Distr:** Bahamas (Andros, Berry Islands, Cat, Cave Cay, Eleuthera, Exuma, Grand Bahamas, San Salvador [Watling] Island); open rocky plains and ridges, open coppices and pinelands, and sandy beach dunes, in dry broad-leaf evergreen wood- or scrubland; flowers mostly January to May. **I:** Hochstätter (2015: VII: 79, 82).

**Incl.** *Agave sobolifera* Hitchcock (1893) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave rigida* Northrop (1902) (*nom. illeg.*, ICN Art. 53.1).

[2r] Acaulescent; **Ros** solitary; **L** rather narrowly lanceolate, fleshy, curved, concave, occasionally somewhat conduplicate, 200–300 × 15–20 cm, dull greyish to greyish-green, margins nearly straight; **marginal teeth** straight or the longer teeth appressed-recurved, triangular, scarcely lenticular at the base, 3–5 mm, usually 5–10 mm apart, reduced near base and tip of the leaf or rarely greatly reduced throughout or nearly lacking, sometimes on small green tubercles;

**terminal Sp** slightly recurved, stoutly conical, usually becoming involutely grooved below the middle, smooth, 10–15 × 4–5 mm, brownish becoming grey, dull, decurrent; **Inf** to ±10 m, paniculate, peduncle with deltoid non-overlapping **Bra**, fertile part ovoid, part-**Inf** on slightly ascending **Br**, ± in the upper 1/3 of the **Inf**; **Ped** ±10 mm; **Fl** 50–60 mm; **Tep** ±15 × 4 mm, golden-yellow, tube conical, ±7 mm, lobes 15 × 4 mm; **Fil** 30–35 mm, inserted almost in the tube throat; **Ov** oblong-fusiform, 30–35 mm; **Sti** ± as long as the filaments; **Fr** oblong, 40–50 × 20–25 mm, shortly stipitate and beaked; **Se** 8 × 6 mm.

The most widespread *Agave* species on the Bahamas. Its area covers all larger islands of the N Bahamas. — Britton & Millspaugh (1920) suggested that *A. acklinicola*, *A. cacozela*, *A. indagatorum* and *A. millspaughii* “may be but races of *A. bahamana*”. Gillis (1976) included these four species as well as *A. braceana* (i.e., all other members of Sect. *Bahamaneae*) in the synonymy of *A. bahamana*, but this concept was not followed by subsequent authors. The recent accounts by Álvarez de Zayas (1995), Acevedo-Rodríguez & Strong (2012), and Freid & al. (2014) recognize all six species as distinct, pending a detailed study of the group.

**A. ×bedinghausii** Rebut (Suppl. Cat. Cact., 3, 1893). **Type:** not typified. — **Lit:** Koch (1865: 112); Ladenburg (1893: 74). **Distr:** Cultivated only.

[1g × 3a] According to the protologue (not seen) reported as the artificial hybrid between *A. ghiesbreghtii* (of Subgen. *Littaea*) and *A. maculata* (of Subgen. *Manfreda*) (= ×*Mangave*). *A. ×bedinghausii* was first mentioned by Koch (1865: 112) as mere name in the catalogue of “van Sweet in Gent”, most probably an error for L. de Smet, Gent, Belgium. The plant was exhibited by the private nursery of M. Bedinghaus, Gent (Ladenburg 1893: 74). Trelease (1920: 123) listed an *A. bedinghausii* as a mere form in the synonymy of the strong-toothed *A. verschaaffeltii* (= *A. potatorum*), which thus must have been a different plant.

**A. ×beguinii** hort. ex A. Berger (Agaven, 61, 1915). **Type:** not typified. — **Lit:** Ullrich

(1993b: 27, 31–32, as *A. beguinii*). **Distr:** Cultivated only.

[1] This is a garden hybrid of unknown parentage that was probably raised in the “Jardin Botanique au Parc de la Tête d’Or” at Lyon (France) and named and distributed by P. Rébut at Chazey-d’Azerognes (France). It was given to La Mórtoia via M. le Chanoine Béguin (Brignoles, France) in 1899 and flowered there in 1905 (Berger 1912: 357, Berger 1915: 61). Apparently lost from cultivation.

**A. bicolor** (Solano & García-Mendoza) Thiede & Egli (Kakt. and. Sukk. 52(6): 166, 2001). **Type:** Mexico, Oaxaca (García-Mendoza & al. 2403 [MEXU, BRIT, FEZA, SMU]). — **Lit:** Solano Camacho & García-Mendoza (1998); García-Mendoza (2011a: 83–86); both as *Polianthes* and with ill. **Distr:** Mexico (NW Oaxaca); grasslands and in pine and pine-oak forests, 2300–2500 m, flowers July to August. **I:** Castro-Castro & al. (2015: 145); Hochstätter (2016: II: 6); Castro-Castro & al. (2016: 721); all as *Polianthes*.

≡ *Polianthes bicolor* Solano & García-Mendoza (1998).

[3b2] Herbaceous; corm cylindrical, 4–6 × 2–2.5 cm, bulb ovoid, (2–) 3–5 × (1–) 1.5–2.5 cm, covered with dry leaf bases; **R** contractile, thickened; basal **L** (3–) 4–6 (–12), lanceolate, semi-succulent, generally undulate, smooth to papillose, apex acute, (5–) 8–15 × (0.6–) 1–4 cm, shiny green, margins papillose, hyaline, usually repand; **Inf** erect, 24–40 (–54) cm, peduncle with lanceolate **Bra**, lower **Bra** 3–5 (–7.5) × 0.2–0.5 cm, upper **Bra** progressively smaller, fertile part with 3–5 (–9) flowering nodes; **Ped** 6–13 mm, reddish; **Fl** geminate, (20–) 23–29 mm, fragrant; **Tep** yellowish-green, tube funnel-shaped, abruptly widened at the base, basal part erect, abruptly curved outwards just above the ovary, horizontal or down-curved at anthesis, (1.6–) 2.4–3 (–5.5) mm Ø at the mouth; **Tep** lobes orbicular to transversally elliptic, apiculate, subequal, outer 2–3 (–4) × (1.7–) 2–3 (–4) mm, inner with cucullate apex and pilose tips; **Fil** filiform, inserted somewhat above mid-tube 11–18 (–19) mm above the ovary, free part 4 (–15) mm,

included, green; **Anth** oblong, 4–5 (–9) × 1–1.5 (–2.5) mm, yellowish-green; **Ov** cylindrical, ±10 × 3–4 mm; **Sty** (10–) 19–26 (–32) mm; **Sti** 3-lobate; **Fr** globose, 11–13 × 10–11 mm, with persistent perianth remains; **Se** semicircular, one face straight, 4.5 × 2.4 mm, black.

According to the protologue characterized by its semisucculent undulate leaves with repand margins, flowers with the tube abruptly widened above its base, green tepal lobes, and included stamens. The species belongs to Ser. *Bravoia* of Sect. *Polianthes* and is morphologically closest to *A. coetocapnia* and *A. graminifolia*. *A. bicolor*, *A. alboaustralis* and *A. oaxacana* represent the S-most species of Sect. *Polianthes* and its sole representatives in Oaxaca (key in Solano & Ríos-Gómez (2014)).

**A. ×blissii** (Worsley) Thiede & Egli (Kakt. and. Sukk. 50(5): 111, 1999). — **Lit:** Worsley (1911: with ill.); Howard (1977); both as *Polianthes*. **Distr:** Cultivated only. **I:** Howard (2001: 9).

≡ *Polianthes ×blissii* Worsley (1911).

[3b1 × 3b2] This is the garden hybrid *A. coetocapnia* (as *Bravoia geminiflora*) × *A. amica* (as *Polianthes tuberosa*) first raised in 1911, but still extant in cultivation (Howard 2001).

**A. boldinghiana** Trelease (Mem. Nation. Acad. Sci. 11: 21, tt. 11–13, 1913). **Type** [syn]: Curaçao (*Boldingh* A2 [MO [6 sheets]]). — **Lit:** Berger (1915: 225–226); Hummelinck (1936: 239–240, 248–249, tt. VI, VIIIc, figs. 19–20); Hummelinck (1938: 20–21); Hummelinck (1993: 107–109, 219, with ill.). **Distr:** Leeward Antilles (Aruba, Bonaire, Curaçao), NE Colombia (?); coral rocks and coral debris, 2–50 m; flowers in May. **I:** Heller (2006: 68); Pilbeam (2013: 42–43); Hochstätter (2015: VIII: 87).

[2u] Stems almost none; **Ros** ±2 m Ø, suckering; **L** rather many to rather few, narrowly oblanceolate, subacuminate, rather slightly S-curved, apex slightly curved upwards, openly concave, 90–125 × ±15 cm, green, passing into somewhat glaucous, margins rather straight; **marginal teeth** often irregularly upcurved above and recurved below, heavily triangular or from crescent-shaped

bases, mostly 4–5 (–7) mm, scarlet becoming chestnut-brown, mostly 10–15 mm apart, on rather well to strongly developed hardening or partly green prominences; **terminal Sp** acicular, (very) slightly upcurved at the tip, somewhat flexuous, grooved and usually involute towards the base, smooth, polished towards the tip, 15–30 × 2–4 mm, red-brown, shortly or not decurrent, dorsally rather slightly intruding into the leaf tissue; **Inf** ±5 m, paniculate, peduncle with rather distant, narrowly triangular, appressed **Bra**, fertile part narrowly oblong, part-**Inf** few, distant, on ascending **Br** in the upper ½ or less of the **Inf**, freely bulbiferous; **Ped** 4–7 mm; **Fl** 45–46 mm; **Tep** golden-yellow, tube conical, 5–7 mm, lobes 15–20 × 4 mm; **Fil** 34–35 mm, inserted 0–1 mm below the tube throat; **Anth** 18–21 mm; **Ov** broadly fusiform or oblong, 20–25 mm; **Sty** length unknown; **Fr** 33–36 mm, beaked, stipitate; **Se** unknown.

Always distinguishable from all other species in its geographical range, but less well defined compared with certain forms of *A. cocui* and *A. vicina* (as *A. vivipara*) from other regions (Hummelinck 1938). The species appears not to belong to the indigenous flora (Hummelinck 1993) and was designated as “cultivated” already by Boldingh (1914: 17). Records from coastal NE Colombia (Bernal & al. 2015: 794) need verification against *A. cocui*. Trelease’s “type” at MO consists of 6 specimens that represent syntypes (Smith & Figueiredo 2014e: 229).

**A. bovicornuta** Gentry (Publ. Carnegie Inst. Washington 527: 92, 1942). **Type** [syn]: Mexico, Sonora (Gentry 3672 [CAS [2 sheets], ARIZ [2 sheets]]). — **Lit**: Gentry (1982: 328–332); González-Elizondo & al. (2009: 61–64); Starr (2012: 22, 59–63); all with ills. **Distr**: Mexico (S Sonora, SW Chihuahua, S Durango, N Sinaloa); rocky open slopes in oak woodlands and pine-oak forests, 930–1850 m; flowers December to May. **I**: Irish & Irish (2000: t. 7); Heller (2006: 69); Richter (2011: 73, 108); Pilbeam (2013: 44–45); Greulich (2014a: 56); Hochstätter (2015: IV: 19); Moore (2016: 270). – Figs. 9 and 10.

≡ *Agave maximiliana* var. *bovicornuta* (Gentry) González-Elizondo & al. (2009) (*nom. inval.*, ICN Art. 36.1b).

[2d] Acaulescent, **Ros** 0.6–1 × 1.5–2 m but often smaller, solitary; **L** lanceolate to spatulate, much narrowed towards the base, widest at or above the middle, smooth, 45–80 × 10–17 cm, yellowish-green to light or deep green, younger **L** frequently shining glaucous, with conspicuous imprints from the central bud, margins crenate; **marginal teeth** dimorphic, larger teeth mostly 8–12 mm, flexuous and slender above a broad base, mostly 20–40 mm apart, on prominent prominences, smaller teeth mostly 2–5 mm, 1 to several between the larger teeth, all chestnut-brown or dark brown to greyish-brown with age; **terminal Sp** strong, 30–50 mm; **Inf** 2.5–7 m, paniculate, peduncle short, with triangular-

**Fig. 9** *Agave bovicornuta* (Etter & Kristen 561: Mexico; Sonora, near San Bernardo, Río Mayo, 1700 m). (Copyright: J. Etter & M. Kristen)

**Fig. 10** *Agave bovicornuta* (Cultivated material without known wild origin). (Copyright: U. Eggli)

acuminate reflexed **Bra** 20–30 cm long, fertile part narrow, part-**Inf** short, compact, 20–30 in the upper  $\frac{1}{2}$  of the inflorescence; **Ped** 5–10 mm; **Fl** 55–65 mm; **Tep** greenish-yellow, tube 6–9  $\times$  12–14 mm, lobes linear-lanceolate, ascending-spreading, conduplicate, involute, sinuses broadly overlapping, 15–21  $\times$  4–7 mm, **ITep** broader and 2-costate within, yellow; **Fil** 30–45 mm, yellow, inserted (3–) 4–5 mm above the tube base; **Anth** 18–24 mm, yellow; **Ov** 26–29 mm, pale green, neck constricted, 4–6 mm; **Sty** hardly longer than the tepals; **Sti** capitate, 3-lobate; **Fr** oblong, 40–50  $\times$  15–20 mm, stipitate, valves thin; **Se** finely punctate, 15  $\times$  7 mm, curved side with a flange or wing, hilar notch shallow.

Gentry's protologue does not indicate a holotype so that all specimens represent syntypes. The designation of "Holotype DS" (Gentry 1982: 329) is a lectotypification which is ineffective under ICN Art. 8.1, since the 2 sheets at DS (now at CAS) are not cross-labelled (ICN Art. 8.3).

Distinguished within Sect. *Crenatae* by light to yellowish-green leaves with narrow bases, relatively small flowers, and the low insertion of the filaments in the middle of the tube. *A. bovicornuta* is common and widespread in the N Sierra Madre Occidental, but with usually local populations with a limited number of individuals. Its nearest relative appear to be the populations of *A. maximiliana* from Durango and Nayarit, but these have more glaucous, pale-coloured rosettes with more pronouncedly heteromorphic teeth and a mostly shorter terminal spine (Gentry 1982). González-Elizondo & al. (2009)

provide a new record from Durango and provisionally suggest to treat the species as variety of *A. maximiliana*. Etter & Kristen (2003a: 9) mention and depict a putative natural hybrid with *A. angustifolia* (as *A. vivipara*). The flowers, washed to remove the bitterness, are eaten cooked or in the form of tortillas, and the "hearts" are baked for preparing a strong alcoholic beverage "suguí" (Bye & al. 1975: 94). — 'Reggae Time' is a cultivar with bluish-green leaves, and 'Holstein' and 'Heifer's Cream' are variegated cultivars (Starr 2012).

**A. braceana** Trelease (Mem. Nation. Acad. Sci. 11: 40, t. 83, 1913). **Type:** Bahamas (*Brace* 1982 [MO, F, NY]). — **Lit:** Berger (1915: 203); Britton & Millspaugh (1920: 74); Correll & Correll (1982: 310–311, with ill.); Freid & al. (2014: 217). **Distr:** Bahamas (Abaco, Andros, Great Bahama); rocky or sandy soils in open pine-lands or coastal coppices; flowers mostly October to February. **I:** Hochstätter (2015: VII: 83).

**Incl.** *Agave mexicana* Dolley & al. (1889) (*nom. illeg.*, ICN Art. 53.1).

[2r] Acaulescent; **Ros** solitary; **L** broadly oblanceolate, fleshy, curved, nearly flat, 65–70  $\times$  19–20 cm,  $\pm$  3  $\times$  as long as broad, grey, margins between the teeth straight or concave when the teeth are raised on low green prominences; **marginal teeth** straight or the lower teeth gently recurved, triangular, 2–3 mm, scarcely lenticular at the base, usually 5–10 mm apart; **terminal Sp** conical, straight or gently curved, flat or roundly grooved to about the middle or becoming

involute, smooth, 10–15 × 3 mm, brownish becoming grey, dull, slightly decurrent; **Inf** 4–7 m, paniculate, not known to be bulbiferous; **Ped** ±10 mm; **Fl** 40–45 mm; **Tep** golden-yellow, tube conical, ±7 mm, lobes 15–17 × 3–4 mm; **Fil** 35 mm, inserted almost at the tube throat; **Ov** oblong-fusiform, 20 mm; **Sty** longer than the filaments; **Sti** capitate; **Fr** broadly oblong, 20–35 × 20 mm, beaked, shortly stipitate; **Se** 8 × 6 mm.

The flowers are visited at day by birds (hummingbirds, warblers (*Dendroica* spp.) and others). Wintering warblers show temporal territorial aggression against conspecifics and hummingbirds (Emlen 1973). Documented from the islands Abaco and Great Bahama in the protologue; Freid & al. (2014: 217) add Andros. — See also the note under *A. bahamana*.

**A. bracteosa** S. Watson *ex* Engelm (Gard. Chron., ser. nov. 18: 776, ills., 1882). **Type**: [lecto — icono]: l.c. figs. 138–139. — **Lit**: Gentry

**Fig. 11** *Agave bracteosa* (Etter & Kristen 696: Mexico; Coahuila, between Saltillo and Monterrey, 1370 m). (Copyright: J. Etter & M. Kristen)

(1982: 90–93); Ullrich (1990b); García-Mendoza (2003); Starr (2012: 64–68); all with ills. **Distr**: Mexico (SE Coahuila, W-C Nuevo León); scattered on limestone cliffs and rocky slopes of the N Sierra Madre Oriental, 900–1750 m; flowers May to July. **I**: Curtis’s Bot. Mag. 140: t. 8581, 1914; Irish & Irish (2000: t. 8); Heller (2006: 70, 154); Richter (2011: 62, 116); Pilbeam (2013: 46–47); Hochstätter (2015: VII: 35). — Fig. 11.

[l.c.] **Ros** open, small to medium-sized, forming caespitose mounds by above-ground axillary budding; **L** relatively few, ±30, long-lanceolate, arching and recurving, with weak fibres, widest near the base, convex in the basal 1/3, flat above, asperous, (40–) 50–70 × 3–5 cm, yellow-green, margins minutely serrulate, without teeth; **terminal Sp** absent, leaf tip drying early, friable, wind-scuffed, yellowish; **Inf** ascending to erect, 1.2–1.7 m, ‘spicate’, peduncle with erect triangular-acuminate **Bra**, fertile part densely flowered in the upper 1/2 of the inflorescence; **Fl** geminate, 22–26 mm; **Tep** white to pale yellow, tube virtually none, reduced to a short receptacle, lobes ovate, spreading, hyaline, distinct, 11 mm, the outer overlapping the inner, lanceolate, acute, the inner broadly ovate, obtuse, all floccose at the tips; **Fil** long-exserted, 50–60 mm, white, inserted on the receptacle, persisting, elongating after anthesis; **Anth** sagittate, 7–8 mm, yellow; **Ov** fusiform, 12–14 mm, virtually without neck; **Sty** eventually exceeding the stamens; **Fr** ovoid-oblong, obtuse, 18–20 × 8–10 mm, stipitate; **Se** deltoid to semicircular, 3–3.5 × 2–2.3 mm.

Very distinctive on account of its unarmed curling leaves and white flowers, so that is has never been confused with other species (Gentry 1982). Its distinctiveness prompted Ullrich (1990b) to place it within a reconsidered monotypic Group *Serrulatae* Baker. Gentry (1982) reports the inflorescences to emerge laterally from upper leaf axils so one and the same rosette may flower repeatedly, but this was dismissed as erroneous by Zona (2018). — The neotypification by Gentry (1982: 91) was superseded with a lectotype by Ullrich (1990b) as given above. ‘Monterrey Frost’ (Starr 2012: 68, with ill.), ‘Stingray’ (Starr 2014: 221, with ill.), and ‘Medio-Picta Alba’ (Greulich

2017c: 161, with ill.) are variegated cultivars. A plant cultivated outdoors on a protected site in Switzerland withstood temperatures of  $-12\text{ }^{\circ}\text{C}$  to  $-18\text{ }^{\circ}\text{C}$  (Bolliger 2014).

**A. brevipedata** Trelease (Repert. Spec. Nov. Regni Veg. 23: 362, 1927). **Type:** Hispaniola, Haiti (*Ekman* 1604 [US [2 sheets], B, G, GH, ILL, S]). — **Distr:** Hispaniola (Haiti: Massif de La Selle, top of Morne Cabaio), 2350 m; flowers in August.

[2p] Acaulescent; **Ros** solitary; **L** broadly lanceolate,  $\geq 100$  cm, green, rather dull; **marginal teeth** broadly triangular, variously curved, with lenticular bases, 5–10 mm but apical and basal teeth smaller, glossy chestnut-brown, 10–15 mm apart, teeth at mid-leaf clasping the green marginal prominences below them, intervening margin straight; **terminal Sp** smooth, curved, subterete, involutely narrowly grooved,  $20\text{--}25 \times 6$  mm, rather glossy chestnut-brown, decurrent for some 10 cm and connecting to the small upper teeth; **Inf** paniculate, part-**Inf** with densely clustered flowers at their tips, not known to be bulbiferous; **Ped**  $\pm 5$  mm; **Fl**  $\pm 35$  mm; **Tep** colour unknown, drying dark, tube 5 mm, lobes 10 mm; **Fil** 25 mm, inserted towards the tube throat; **Ov** thick, oblong, 20 mm; **Fr** and **Se** unknown.

Described on the base of the dried type material only. According to Álvarez de Zayas (1995) possibly conspecific with *A. antillarum* (see there). See also the note for *A. brevispina*.

**A. brevispina** Trelease (Repert. Spec. Nov. Regni Veg. 23: 363, 1927). **Type:** Hispaniola, Haiti (*Ekman* 5371 [US [2 sheets], B, GH, ILL, S]). — **Distr:** Hispaniola (Haiti: Croix-des-Bouquets, Plaine Cul de Sac); limestone, 150 m; flowers in December.

[2p] Acaulescent; **Ros** solitary; **L** broadly lanceolate,  $\geq 100 \times 10$  cm, dark green, rather dull; **marginal teeth** straight or some of the lower teeth recurved, rather narrowly triangular, with lenticular base, 1–3 mm, 5–15 mm apart, intervening margin almost straight; **terminal Sp** straight, somewhat flattened, involutely narrowly grooved, slightly granular,  $10 \times 3$  mm, rather dull hazel-

brown, tip darker, decurrent for  $2 \times$  its length; **Inf** 4 m, ‘paniculate’, part-**Inf** rather slender, recurving, shortly few-flowered at the tips and flowers densely clustered, not known to be bulbiferous; **Ped** slender, 10–15 mm; **Fl**  $\pm 40$  mm; **Tep** yellow, tube 5 mm, lobes  $12 \times 5$  mm; **Fil** 25 mm, inserted almost at the tube throat; **Ov** oblong-fusiform, 25 mm; **Fr** and **Se** unknown. — **Cytology:**  $2n = 60$  (Granick 1944: identity doubtful).

Described on the base of the dried type material only. The sample studied cytologically by Granick (1944) is of unknown origin. Trelease left this species and *A. brevipedata* unplaced, which was followed in the first edition of this handbook. According to Álvarez de Zayas (1995), both are possibly conspecific with *A. antillarum* (see there) and belong to Sect. *Antillanae*.

**A. brittoniana** Trelease (Mem. Nation. Acad. Sci. 11: 44–45, tt. 98–99, 1913). **Type:** Cuba, Santa Clara (*Britton & al.* 4776 [MO [3 sheets, cross-labelled later], NY [4 sheets], MEXU]). — **Lit:** Berger (1915: 273–274); Álvarez de Zayas (1996: 121–125, with ills.). **Distr:** C Cuba.

A polymorphic species, which occurs abundantly and prolifically at anthropogenic sites. It differs from *A. acicularis* esp. in its broadly lanceolate leaves with decurrent terminal spine, and from *A. grisea* in its shorter leaves. Álvarez de Zayas (1995: 41) and Álvarez de Zayas (1996), and the first edition of this handbook recognize 2 heterotypic subspecies, while Acevedo-Rodríguez & Strong (2012: 85) and Govaerts (2014+) place both in the synonymy of the species.

**A. brittoniana** ssp. **brachypus** (Trelease) A. Álvarez (Fontqueria 44: 121, 1996). **Type:** Cuba (*Britton & al.* 6183 [MO, NY [2 sheets]]). — **Lit:** Trelease (1913: 45, t. 99: 1, as var.); Álvarez de Zayas (1996: 121–125, with ills.). **Distr:** C Cuba (Alturas de Santa Clara); on skeletal soils and serpentine rocks in xeromorphic shrublands and derived secondary formations.

≡ *Agave brittoniana* var. *brachypus* Trelease (1913).

[2q] Differs from ssp. *brittoniana*: **L** tip canalicate, normally with small denticles at the

inner margin; **Inf** somewhat laxer; **Fl** smaller; **Fr** more cylindrical.

The shorter pedicels given as diagnostic in the protologue are not a constant feature (Álvarez de Zayas 1996). — The basionym could be regarded as a provisional and hence invalid (ICN Art. 36.1b) name, but Trelease's illustration and the adjacent caption leaves no doubt that he fully accepted the taxon. The lectotypification proposed by Álvarez de Zayas (1996: 121) is unnecessary and moreover erroneous, since an element not originally included by Trelease is selected.

**A. brittoniana** ssp. **brittoniana** — **Lit:** Trelease (1913: 44–45, tt. 98–99); Berger (1915: 273–274); Álvarez de Zayas (1996: 121–124, with ills.). **Distr:** C Cuba; on limestone, shale and slate, in evergreen forests and montane rain forests, primarily abundant in secondary formations and heavily disturbed sites, 100 to >1000 m; flowers January to March. **I:** Richter (2011: 92, 137); Hochstätter (2015: VII: 90); both as *A. brittoniana*.

[2q] Acaulescent, **Ros** solitary; **L** broadly lanceolate, abruptly acute towards the tip, (70–) 80–100 (–110) × (13–) 15–20 (–24) cm, green, sometimes somewhat greyish, slightly glossy, margins often concave between the teeth; **marginal teeth** variously curved, 4–6 (–8) × 3–6 (–7) mm at mid-leaf, (6–) 8–10 (–15) mm apart, slender-tipped from lenticular or voluminous bases, bases sometimes on retrorse green prominences in the lower 1/3 of the lamina; **terminal Sp** unguiculately curved, subconical or involutely much thickened in the basal parts, openly grooved to the middle or involute, smooth, somewhat polished, (10–) 15–20 (–25) × 4–6 mm, brown, dotted with white, ± decurrent; **Inf** (4–) 5–8 m, paniculate, peduncle very short or nearly none, part-**Inf** ascending, (11–) 15–30 cm, not bulbiferous; **Ped** slender, 5–10 mm; **Fl** 25–35 (–45) mm; **Tep** yellow, tube conical, sometimes very open, 3–6 × 5–8 (–10) mm, lobes 9–14 (–16) × 3–5 mm, dorsally greenish; **Fil** 18–25 mm, inserted nearly in the tube throat; **Anth** 9–15 mm; **Ov** fusiform, 15–20 (–25) mm; **Sty** longer than the filaments; **Sti** capitate; **Fr** oblong, sometimes nearly cylindrical, 23–40 (–45) × 11–15 (–17)

mm, dark chestnut-brown, tip slightly beaked, basally strongly stipitate; **Se** semicircular to subtriangular, 5–6 × 3–4 mm.

Occurs at least sometimes in regions with a predominance of ophiolitic soils (López Almira 2013).

**A. brittoniana** ssp. **sancti-spirituensis** A. Álvarez (Fontqueria 44: 125, ill. (p. 122), 1996). **Type:** Cuba, Sancti Spiritus (*Jiménez & al.* 69532 [HAJB]). — **Distr:** C Cuba (Montañas de Sancti Spiritus); on calcareous and shale rocks in montane rain forests and derived secondary formations; flowers in February.

[2q] Differs from ssp. *brittoniana*: **L** much shorter, more broadly oblong and less lanceolate; **Fl** 36–46 mm, with longer tepals and anthers.

**A. brunnea** S. Watson (Proc. Amer. Acad. Arts 26: 156, 1891). **Type:** Mexico, Coahuila (“Tamaulipas”) (*Pringle* 2218 [GH, US [photo]]). — **Lit:** Rose (1903c: 19); Berger (1915: 31–32); Verhoek-Williams (1975: 187–191); Piña Luján (1985: 28–29, 59–61, with ills.); García-Mendoza (2003: with ill.); Castillejos-Cruz (2009: [109]–[114], with ills.); all as *Manfreda* except Berger. **Distr:** Mexico (SE Chihuahua, N, NW, W & C Coahuila, N, NE & E Durango); dry hills or desert plains, volcanic or alluvial alkaline soils (sandy or gravelly clay), in desert scrub, grasslands, and low pine forests, 1000–1700 m; flowers late June to July. **I:** Hochstätter (2016: I: 15, as *Manfreda*).

≡ *Manfreda brunnea* (S. Watson) Rose (1903) ≡ *Polianthes brunnea* (S. Watson) Shinnars (1966).

[3a1] Herbaceous, robust; corm (1–) 2–5.5 × 0.9–2.5 cm, reproducing vegetatively by buds below the leaf bases; bulb cylindrical to ovoid, 3–7.5 × 1.5–4 (at the base) cm, completely covered with membranous dry leaf bases fraying into fine fibres at the tip, (4.5–) 5.5–9.5 cm; **R** fleshy and fibrous, contractile, with filiform ramifications; **L** evergreen, succulent, 4–8, linear-lanceolate to broadly lanceolate, erect to semi-erect, recurved to undulate, channelled above, tip acute, with a long point, smooth, 10–33 × 1.2–2.9 (–4) cm, light green to glaucous, intensely mottled with

purple to red above, both faces verrucose, margins with scattered, broad, hooked, cartilaginous teeth, usually large, deltoid or truncate-bipartite,  $\pm 2.5$  mm, 3–11 mm apart, with narrow pale hyaline band on the leaf margin between the teeth; **Inf** 0.7–1.3 m, ‘spicate’, green with purplish tinge, peduncle with lanceolate, narrowly attenuate **Bra** shorter than the internodes, fertile part (5–) 14–25 (–29) cm, dense, with 9–30 solitary flowers; **Fl**  $\pm 30$ –60 (–75) mm, sessile, ascending to appressed to the axis; **Tep** membranous to semisucculent, tube narrowly funnel-shaped, straight, gradually constricted above the ovary, 30–45  $\times$  5–6 mm, outer face yellowish-green, inner face brown, lobes oblong to narrowly oblong, spreading to revolute, tip obtuse, cucullate, with a tuft of short hairs, 8–18  $\times$  4–6 mm, greenish-red to brown with purple tinge; **St** much exerted; **Fl** 45–65 (–70) mm, exceeding the tube for 40–60 mm, inserted at  $\frac{3}{4}$  near the mouth of the tube, greenish-red to cherry-red; **Anth** 11–17 mm, reddish to yellowish-green; **Ov** cylindrical to long-ellipsoid, 10–20 (–23)  $\times$  4–6 mm; **Sty** (50–) 70–100 mm, exerted for 35–53 (–65) mm; **Sti** clavate, 3-lobate, deeply furrowed, yellowish-green with small purple dots; **Fr** ellipsoid to subcylindrical, 18–30 (–36)  $\times$  12–16 mm, without scar; **Se** deltoid, plano-concave, 4–5  $\times$  3–4 mm, shiny, somewhat rough.

Easily distinguished from the other species in Ser. *Brunneae* of Sect. *Polianthes* by its long narrow tepal tube with exerted stamens and styles and by the coarse teeth on the leaf margins (Verhoek-Williams 1975: 190). The corm is used as soap and shampoo, and the leaves, corm and bulb were formerly used as antidote against snakebites (Castillejos-Cruz 2009). “One of the most attractive manfredas” which “definitely requires a dry winter—early spring rest” (Hannon 2002: 251).

**A. bulbulifera** (Castillejos & E. Solano) Thiede (Haseltonia 17: 94, 2012). **Type:** Mexico, Guerrero (Castillejos & al. 1807 [MEXU, CHAPA, FEZA, IEB, MICH, NY, US]). — **Lit:** Castillejos-Cruz & Solano (2008); Castillejos-Cruz (2009: [115]–[120]); both with ill. as *Manfreda*. **Distr:** Mexico (Guerrero); slightly

inclined, somewhat rocky slopes rich in organic material, in pine-oak forests, 1200–1260 m; flowers June to July; only known from the type locality. **I:** Hochstätter (2016: I: 16, as *Manfreda*).

$\equiv$  *Manfreda bulbulifera* Castillejos & E. Solano (2008).

[3a3] Herbaceous; corm compressed, 0.5–0.7 cm, forming bulbils 0.5–1.5 cm long at its distal part, bulb ovoid, 3–5  $\times$  2.5–3 cm, covered with dry leaf bases 4.5–6 cm long, membranous below and fibrous above; **R** fleshy, fibrous, contractile; **L** drought-deciduous?, 2–4, prostrate or semi-erect, linear to lanceolate, attenuate, channelled, glabrous, tip acute, 12–25  $\times$  0.3–0.6 cm, green-yellowish to dark green, surface often slightly rough, margins hyaline, narrow, entire, partly microscopically papillose; **Inf** erect, 0.7–0.8 (–0.86) m, ‘spicate’, peduncle 0.63–0.74 m, with 5–7 **Bra** similar to the leaves, fertile part 7–8.5 (–12) cm, with 7–10 solitary, laxly arranged flowers; **Ped** 1–3 mm; **Fl** 25–32 mm; **Tep** green-yellowish to green-whitish, tube minute, 0.5–1  $\times$  2–3 mm, lobes linear, erect or revolute, 25–30 (–35)  $\times$  15–30 mm, apex thickened, cucullate, with a bundle of whitish hairs; **St** 50–60 mm, reddish; **Ov** obclavate, 12  $\times$  2.3 mm, green-yellowish; **Sty** 50–68 mm; **Sti** 3-lobate, green-yellowish; **Fr** subglobose, triquetrous, 10–12  $\times$  11–12 mm, apex without scar; **Se** 3–4  $\times$  3 mm, black, dull.

Belonging to Ser. *Guttatae* of Sect. *Manfreda* and most similar to *A. guttata*, *A. littoralis* and *A. pratensis* according to the protologue (as *Manfreda*). It differs from these in its compressed corms forming bulblets at their distal portion, its very short tepal tube, filiform tepal lobes, stamens and style by far exceeding the perianth in length, and an obclavate ovary.

**A. bulliana** (Baker) Thiede & Eggli (Kakt. and. Sukk. 50(5): 112, 1999). **Type:** Mexico (*Karwinsky* s.n. [not preserved]). — **Lit:** Rose (1903b: as *Prochnyanthes*); McVaugh (1989: 260–263, as *P. mexicana*); Castro-Castro & al. (2010: as *P. mexicana*); Thiede (2012a); all with ill. **Distr:** Mexico (Durango, Zacatecas, Nayarit, Aguascalientes, Jalisco, Guanajuato, Querétaro, Michoacán); dry rocky slopes or roadcuts, in

pine-oak grasslands, or in shaded moist ravines, 1150–3100 m; flowers late June to early September. **I:** Curtis's Bot. Mag. 121: t. 7427, 1895, as *Prochnyanthes*; Howard (2001: 13, as *P. mexicana*); Hannon (2002: as *P. mexicana*); Etter & Kristen (2012: 85); Hochstätter (2016: II: 31–32, as *P. mexicana*); Castro-Castro (2017: 139, as *P. mexicana*). – Figs. 12 and 13.

≡ *Bravoa bulliana* Baker (1884) ≡ *Prochnyanthes bulliana* (Baker) Baker (1895); **incl.** *Polianthes mexicana* Zuccarini (1837) ≡ *Prochnyanthes mexicana* (Zuccarini) Rose (1903); **incl.** *Prochnyanthes viridescens* S. Watson (1887).

[3b2] Herbaceous, large (for Subgen. *Manfreda*), usually single; corm cylindrical, 1–3 × 1.5–2.5 cm, bulb oblong, covered with fibrous

dried leaf bases 7–10 (–12.5) cm long; **R** fusiform, semifleshy with a wiry core, contractile; **L** few, deciduous, (1–) 2–3 (–7), the larger in a basal **Ros**, upwards diminishing up to the small **Bra**, chartaceous, thin, fibrous, erect or occasionally curved backwards from about the middle, often twisted, with a distinct midrib, shallowly channelled over the midrib, lamina flat, broadly undulate, or revolute, linear-lanceolate to oblanceolate, narrowed towards the base, (8–) 20–47 (–65) × (0.7–) 1.3–5.2 (–8) cm, light or dark green, dull, often speckled with magenta towards the base, spotted or not, veins slightly prominent on both surfaces, papillate, margins very narrow, hyaline, papillate to erose-papillate or papillate-denticulate, tip a soft **Sp**; **Inf** (0.6–) 0.9–2 (–2.8)

m and more, 'spicate', fertile part elongate, (9–) 17.5–47 (–83.5) cm, with (2–) 4–22 (–25) flowering nodes with geminate flowers; **Ped** (0.2–) 25–40 (–90) mm; **Fl** functionally pendent by an abrupt curve in the tepal tube; **Tep** white tinged with grey-green or dull green and red, white or creamy within, tube curved near the middle or at  $\frac{1}{3}$  from the ovary, narrow below, 5–17.5  $\times$  3–8 mm, abruptly widened above the bend, upper part (11–) 15–27  $\times$  5–20 mm, lobes flaring, broadly deltoid, (3–) 4–9 (–15)  $\times$  3–12 mm, tips pubescent; **Fil** 8–20 mm, inserted near the base of the bend of the tube; **Anth** linear, 3–15 mm; **Ov** ellipsoid, 4–8 (–12) mm; **Sty** filiform, 12–32 mm, finally equalling the tube or longer, white; **Sti** 0.7–4 mm, 3-lobate; **Fr** globose to oblong, 8–25  $\times$  10–17 mm; **Se** deltoid to semi-circular, 3.5–6  $\times$  2.5–3, black.

For some time recognized as monotypic genus *Prochnyanthes*, separated from *Polianthes* on account of the downward-curved perianth tube widening above the bend. The detailed morphometric studies of Castro-Castro & al. (2010) confirmed that *Prochnyanthes* consists of a single species only with a considerable variability in floral and other features. When treating *Prochnyanthes mexicana* as *Agave*, a change of name was necessary to avoid homonymy with the earlier *A. mexicana* Lamarck 1783. Therefore, the second-oldest epithet (*Prochnyanthes bulliana*) had to be chosen (Thiede & Egli 1999).

In the first edition of this handbook, the former genera *Prochnyanthes* and *Polianthes* were placed as distinct informal groups within Subgen. *Manfreda*, but the recently described *Agave (Polianthes) oaxacana* is morphologically intermediate, and *Prochnyanthes* was also included in *Polianthes* by García-Mendoza & Solano (2007: 115–116).

The history, introduction, horticulture, biology and taxonomy of *A. bulliana* was summarized by Thiede (2012a). Guillot Ortiz & Meer (2006b) erroneously stated that they introduced the species for the first time into European horticulture, but it was in fact cultivated much earlier at Munich in 1837 and at Kew in 1884 (Thiede 2012b). The ethnobotany and uses of the species are dealt with by Verhoek-Williams (1978b).

**A.  $\times$  bundrantii** (T. M. Howard) Thiede & Egli (Kakt. and. Sukk. 50(5): 111, 1999). **Type:** not typified. — **Lit:** Howard (1978: with ill.). **Distr:** Cultivated only. **I:** Hochstätter (2016: II: 27).

$\equiv$  *Polianthes  $\times$  bundrantii* T. M. Howard (1978).

[3b1  $\times$  3b2] This is the garden hybrid *A. amica* (as *Polianthes tuberosa*)  $\times$  *A. howardii* (as *Polianthes howardii*), still extant in cultivation. Solano Camacho (2002: 55, as *Polianthes*) erroneously lists the hybrid (as "*P. brundrantii*") in the synonymy of *P. howardii*. 'Chirp', 'Opal Eyes' and 'Mexican Firecracker' are commercially offered cultivars (Guillot Ortiz & al. 2006, Hochstätter 2016: II: 27, both with ill.).

**A. cacozela** Trelease (Mem. Nation. Acad. Sci. 11: 41, tt. 89–91, 1913). **Type:** Bahamas, New Providence (*Cunningham* s.n. [not located]). — **Lit:** Berger (1915: 204); Britton & Millspaugh (1920: 75); Correll & Correll (1982: 312). **Distr:** Bahamas (New Providence); rocky margins of salt marshes; flowers mostly January to March. **I:** Hochstätter (2015: VII: 83).

[2r] Acaulescent; **Ros** solitary; **L** lanceolate, fleshy, curved, deeply guttered, typically roughish, 150–200  $\times$  20 cm, yellowish-green, somewhat overcast with grey; **marginal teeth** nearly straight or the larger teeth appressed-recurved, narrowly triangular, rarely lenticular at the base, 2–5 mm (middle of the lamina), usually 10–15 mm apart, intervening margin straight or somewhat concave; **terminal Sp** triquetrously conical, straight or the tip slightly curved, openly grooved below the middle, smooth, 15–20  $\times$  3–5 mm, brownish becoming grey, dull, decurrent; **Inf** 6–7 m, paniculate, peduncle with broadly triangular non-imbricate **Bra**, fertile part dense, ovoid, part-**Inf** on horizontal or slightly ascending **Br**, in the upper  $\frac{1}{3}$  of the inflorescence, reportedly sometimes bulbiferous; **Ped**  $\pm$  10 mm; **Fl** 50–60 mm; **Tep** golden-yellow, tube rather open,  $\pm$  7 mm, lobes  $\pm$  20  $\times$  4–5 mm; **Fil** 40–45 mm, inserted nearly in the tube throat; **Ov** oblong-fusiform, 35–40 mm; **Sty** longer than the filaments; **Fr** narrowly oblong, 35–45  $\times$  15 mm, beaked, shortly conical-stipitate; **Se** 6–7  $\times$  4 mm.

According to the protologue, the leaves of seedlings of the type collection were decidedly papillate-roughened on both faces. See also the note under *A. bahamana*.

**A. cajalbanensis** A. Álvarez (Revista Jard. Bot. Nac. Univ. Habana 1(2–3): 33–39, ill., 1981). **Type:** Cuba, Pinar del Río (*Bisse & Álvarez* 32466 [HAJB [4 sheets]]). — **Lit:** Álvarez de Zayas (1985: 9, 13); Urquiola Cruz & al. (2010: 35, with ill.); González-Oliva & al. (2014: 11). **Distr:** W Cuba (Pinar del Río: Sierra de Cajálbana); denuded slopes of ultrabasic rocks, in pine forests and xeromorphic thorn scrubs; 100–400 m. **I:** Pilbeam (2013: 48); Hochstätter (2015: VII: 68).

[2p] Stems short; **Ros** solitary, semiglobose, to 1.2 m Ø; **L** many, oblanceolate in the lower  $\frac{2}{3}$ , straight, fleshy, coriaceous, only slightly concave, 50–100 × 8–10 cm, grey-green, somewhat dull, margins with asymmetrical slightly recurved prominences, these 3 × 4–5 mm, intervening margin nearly straight; **marginal teeth** basally slightly recurving, 2–4 mm, dark chestnut-brown to nearly black, 10–20 mm apart; **terminal Sp** conical, straight, basally flattened, 10–15 mm, dark chestnut-brown, not lustrous, not decurrent; **Inf** 3–6 m, paniculate, part-**Inf** 3-parted, broad, slightly incurved, 30–40 cm; **Ped** 18–25 (–35) mm; **Fl** 40–45 mm; **Tep** orange or yellow, tube open, 5–6 mm, lobes with broad margins, 12–15 mm, inner membranous, outer dorsally sulcate; **Fil** 15–20 mm, filiform, inserted near the base of the tube; **Anth** 10–12 mm; **Ov** fusiform, trigonous, basally constricted, 15–20 × 5–7 mm; **Fr** oblong, apically acute or apiculate, 20–25 × 15 mm; **Se** unknown.

Easily identifiable by its somewhat lobed leaf margins, the recurved marginal teeth, its orange (or yellow) flowers and small fruits. It is closest to *A. grisea*, but the leaves and inflorescences are only  $\frac{1}{2}$  as large according to the protologue. It differs from *A. legrelliana* (another species with broad panicles and orange flowers from W Cuba) by its greyish leaves < 1 m long (Álvarez de Zayas 1985: 9). Known only from the Sierra de Cajálbana where it occurs on ophiolitic soils (López Almira 2013), and categorized as “Vulnerable” by

Berazaín & al. (2005). Pollinated by the bat *Mono-phyllus redmani* (González-Oliva & al. 2014: 11).

**A. calodonta** A. Berger (Hort. Mortol. 364, 1912). **Type** [neo]: Ex cult. La Mortola (*Berger* s.n. [US 1023798]). — **Lit:** Berger (1898: 603, with ill., as *A. scolymus*); Berger (1915: 195–196, with ill.); Gentry (1982: 332–335, ill.). **Distr:** Only known from cultivation.

**Incl.** *Agave scolymus* A. Berger (1898) (*nom. illeg.*, ICN Art. 53.1).

[2d] Acaulescent; **Ros** semiglobose, 1.5–1.6 m Ø, solitary, with thick conical central bud; **L** many, spatulate, ± erect, older **L** many, spreading, the oldest prostrate, fleshy, narrowed towards the base (7.5–8 cm), upwards markedly thin, shortly acuminate, basally convex on both faces, upper face shallowly guttered, somewhat keeled on the back under the apex,  $\geq 80 \times 20$ –21 (upper  $\frac{1}{3}$ ) cm, light green, with light grey bloom, both faces with imprints of the central bud, margins sinuous in the middle of the lamina; **marginal teeth** irregular, 10–13 mm, 25–35 mm apart, with broad horny bases and deltoid antrorsely or retrorsely hooked tips, on broad fleshy prominences, intervening margins with much smaller intermittent teeth, teeth in the lower  $\frac{1}{2}$  of the leaf much smaller, straight or reflexed, all teeth light brown; **terminal Sp** broadly deeply grooved above, keeled on the back and with a deltoid protrusion, 30–40 mm, decurrent to the upper 3–4 teeth; **Inf** tall, paniculate, peduncle strong, at the base with numerous, deltoid, reflexed **Bra**, the lowest leaf-like but with pale broad horny margins with small teeth and a strong terminal spine, fertile part long pyramidal; **Ped** to 10 mm; **Fl** 85 mm excl. filaments (dried); **Tep** yellow, tube broadly funnel-shaped, ± 10 mm, lobes linear, acute, 35–40 mm, yellow-green, green at the tip, the inner with a broad keel; **Fil** 60 mm, inserted above mid-tube; **Anth** 28–32 mm; **Ov** narrow, 35–40 mm, both ends strongly constricted; **Sti** thick, blunt, 3-lobed; **Fr** and **Se** unknown.

Berger (1898) showed a photograph of the rosette of the only plant known up to now, first misidentified as *A. scolymus* Karwinsky. This plant flowered in La Mortola in 1897 and died without producing seeds or offsets. It was later

described as *A. calodonta* by Berger (1912) which is considered closest to *A. crenata* (Berger 1915). The neotype designated by Gentry (1982: 335) (as “type”) consists of bracts and flowers and was prepared by Berger (s.n., erroneously given as “Berger 603” in the database of US, referring to the page number of the prologue of *A. scolymus* that was added to the sheet) from the original plant; a second specimen (Berger s.n., US 1023799) consists of flowers only. The identity of the plant illustrated under this name by Hochstätter (2015: IV: 20) is doubtful.

**A. cantala** Roxburgh ex Salm-Dyck (Index Pl. Succ. Hort. Dyck, 1, 1822). **Type:** not typified. — **Lit:** Gentry (1982: 568–571, with ills.). **Distr:** Known from cultivation only.

≡ *Furcraea cantala* (Roxburgh) Voigt (1845); **incl.** *Agave cantula* Roxburgh (1832) (*nom. inval.*, ICN Art. 61.1).

**A. cantala** var. **acuispina** (Trelease) Gentry (Agaves Cont. North Amer., 569, ill. (p. 555), 1982). **Type:** El Salvador, San Miguel Dept. (Calderón 2084 [US [2 syntype sheets]]). — **Lit:** Lott & García-Mendoza (1994: & online version). **Distr:** Known from cultivation only (S Mexico, Honduras, El Salvador).

≡ *Agave acuispina* Trellease (1925) ≡ *Agave cantala* ssp. *acuispina* (Trellease) Hochstätter (2015).

[2g] Differs from var. *cantala*: **L** sturdier, shorter, mature leaves 120–170 × 6–9 cm, margins straight to repand; terminal **Sp** 3–5 mm broad at the base, longer, >15 mm; **Inf** with 20–35 part-**Inf**; **Fl** shorter, 45–63 mm; **Ov** shorter, 25–30 mm, neck short; **Tep** green, lobes subequal, 15–21 mm, light greenish-yellow.

Gentry (1982: 569) identified a cultivar from El Salvador as Trellease’s *A. acuispina* and placed it here.

**A. cantala** var. **cantala** — **Lit:** Berger (1915: 236–237); Trellease (1920: 119); Gentry (1982: 568–570, with ills.); McVaugh (1989: 146). **Distr:** Cultivated worldwide, esp. in SE Asia; not known from the wild. **I:** Todaro (1876–92: t. 15, as *A. candelabrum*); Morris (1889: as *A.*

*candelabrum*); Richter (2011: 77); Hochstätter (2015: VII: 34).

**Incl.** *Agave bulbifera* Salm-Dyck (1834); **incl.** *Agave laxa* Karwinsky ex Otto (1842) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave rumphii* Hasskarl (1843); **incl.** *Agave vivipara* Dalzell & A. Gibson (1861) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave candelabrum* Todaro (1878).

[2g] Stems 30–60 cm; **Ros** tall, slender, laxly leafy, 2–2.5 m Ø, surculose; **L** linear, long-acuminate, thin, frequently reflexing, guttered, roundly keeled below towards the base, rough below, smooth above, 150–200 × 7–9 cm, light or dark green, margins straight; **marginal teeth** antrorsely curved, larger teeth 3–4 mm, brown, mostly 20–30 mm apart, reduced or lacking towards the leaf tip; **terminal Sp** very small, 5–15 mm; **Inf** 6–8 m, paniculate, peduncle slender, with narrow chartaceous **Bra** soon becoming reflexed, part-**Inf** ascending to recurved, lax, ±20, on slender stalks, in the upper ½ of the inflorescence, freely bulbiferous; **Fl** slender, 70–85 mm; **Tep** greenish tinged purple or reddish, tube cylindrical-funnelform, grooved, 14–17 × 15 mm, lobes subequal, linear-spatulate, rapidly involute-conduplicate, 25–28 mm, apex rounded-cucullate, inner with narrow keel; **Fil** stout, abruptly outcurving from the tube wall, 50–55 mm, inserted 11–14 mm above the tube bottom; **Anth** excentric, slender, slightly curved, slatey purple; **Ov** fusiform, tapering below to a basal rim, roundly 6-ribbed, 32–42 mm, shortly constricted above but virtually neckless; **Sty** stout, shorter than the filaments; **Sti** capitate; **Fr** and **Se** unknown. — **Cytology:** 2n = 77–97 (3×) (Lv & al. 2009, Simpson & al. 2011).

Recognizable by the thin, long, narrow, weak leaves which are frequently reflexed above the middle, and by small teeth and large purplish-green flowers in broad, diffuse, slender-peduncled panicles which are only rarely produced (Gentry 1982). Roxburg published it from India whereto it was most certainly brought from North America by European traders. It has apparently been cultivated since long for fibre in SE Asia from the Philippines to India and is still hardly known in the Americas, where it remained unrecognized for long (Gentry 1982). Gentry (1982) collected

offsets from a plant at Villa Guerrero, Jalisco, very much looking like *A. cantala* and said to be spontaneous there. No plants from W-C Mexico were known to McVaugh (1989), and Hernández-Vera & al. (2007a) could not find *A. cantala* near Villa Guerrero.

The triploid chromosome number explains the sterility of the species. According to Trelease (1920) it is related to *A. tequilana* (which originated from *A. angustifolia*) and according to Valenzuela-Zapata & Nabhan (2003) it is merely a domesticated taxon obtained from *A. angustifolia*, for both of which triploid cultivars are known.

**A. ×cavanillesii** D. Guillot & P. Van der Meer (Flora Montiber. 28: 73–74, ill., 2004). **Type:** Spain, Valencia (Guillot s.n. [VAL]). — **Lit:** Guillot Ortiz & al. (2008: 81, with ill.). **Distr:** Cultivated only. **I:** Hochstätter (2015: VII: 101).

[2g × 2g] A spontaneous hybrid *A. decipiens* × *A. fourcroydes* found among its naturalized parental species in Spain.

**A. caymanensis** Proctor (Fl. Cayman Islands, ed. 2, 183, fig. 71, t. 7, 2012). **Type:** Cayman Islands (Proctor 52171 [IJ]). — **Lit:** Proctor (1984: 241–242); Hummelinck (1984: 208–212, 226–228); both with ills., as *A. sobolifera*. **Distr:** Cayman Islands (Grand Cayman, Little Cayman, Cayman Brac); dominant in dry rocky situations, semi-deciduous forests and deciduous shrublands with *Bursera* and *Pilosocereus*. **I:** Burton (2005: 168, 170, 174); Hochstätter (2015: VII: 69, 78).

[2p] Acaulescent when young, at maturity commonly with woody stems to 1 m clothed by dead leaves; **Ros** solitary; **L** ±30, elliptic-oblancoate to (narrowly) lanceolate, fleshy, massive, somewhat S-shaped, guttered, sometimes folded, narrowed at the base, acuminate at the apex, to 125–150 × 20–25 cm (above the middle), ± 5 × as long as broad, medium to dark green; **marginal teeth** curved or reflexed-triangular (rarely straight), 1–7 mm, glossy dark brown, 5–15 mm apart, usually 6–9 per 10 cm at mid-leaf, often from green prominences of the margin 1.5–3 mm high, very small below the terminal spine, intervening margin concave; **terminal Sp** slenderly conical to subulate, lower ½ usually clearly grooved between the

converging leaf margins, 17–23 × 2.5–4 (at the base) mm, decurrent only in outer leaves; **Inf** to 6 m or more, paniculate, peduncle ±3.5 m, with ±30 **Bra**, fertile part densely paniculate towards the apex, ±2 m, 2.5 × as long as broad, with up to ±15 part-**Inf**, longest 40 cm, main one 24 cm, freely bulbiferous; **Ped** 5–10 mm; **Fl** 41–51 mm; **Tep** bright yellow, tube 3–5.5 mm, lobes expanded at the base, narrowing to an elongate apex, 12–20 mm; **Fil** 30–41 mm, inserted 0.5–2.5 mm below the mouth of the tube; **Ov** narrowly fusiform, 25–40 × 7–8 mm; **Sty** 30–35 mm, almost as long as the filaments; **Sti** expanded; **Fr** ovoid, ±28 × 17 mm, stipitate for ±6 mm, very shortly apiculate; **Se** crescent-shaped, ±6–7 × 4–4.5 mm.

Plants now placed here were included in the Jamaican *A. sobolifera* by earlier authors such as Adams (1972), Proctor (1984) and Hummelinck (1984). *A. caymanensis* differs, according to the protologue, by forming woody stems at maturity, broader leaves in relation to their length, and by flowers with a much longer ovary (30–40 mm vs. 15–25 mm), shorter tepal lobes, and a longer, exerted style. Fruits and seeds were not described in the protologue, and data is here added from the published figure. Hummelinck (1984) carried out a detailed field study of *Agave* in the Cayman Islands. His detailed descriptions and many photographs supplement the short protologue and leave the purported differences less clear: The ovary is given as 25–32 mm (vs. 25–35 mm in Jamaican *A. sobolifera*), the lobes as 13–20 mm (vs. 20–25 mm), and the style as 30–35 mm (vs. 39–55 mm). Thus, the distinction of *A. caymanensis* is in need of re-study against more ample Jamaican material of *A. sobolifera*. Burton (2005) published 3 habitat photographs and used the name *A. caymanensis* 7 years before it was formally published. The Vitelline Warbler (*Setophaga vitellina*) feeds on nectar from the flowers (Bradley & Rey-Millet 2013: 236).

**A. cerulata** Trelease (Annual Rep. Missouri Bot. Gard. 22: 55, 1912). **Type:** Mexico, Baja California (Nelson & Goldman 7180 [US]). — **Lit:** Berger (1915: 262, 264); Gentry (1978: 35–48, with ill.); Gentry (1982: 363–375, with

ills.); Turner & al. (1995: 44–45, with ills.); Navarro-Quezada & al. (2003); Starr (2012: 69–73, with ills.); Webb & Starr (2015: 77–81, with ills.). **Distr:** Mexico (Baja California, Baja California Sur).

Molecular population studies including 5 samples of all 4 subspecies of *A. cerulata* showed a clade that also includes one sample of *A. deserti*, and which is nested within further clades with *A. deserti* and *A. subsimplex*, thus questioning the separation of these species (Navarro-Quezada & al. 2003). — The leaf shape of *A. cerulata* changes geographically with climate, and the leaf size decreases with increasing aridity (Burgess 1986).

**A. cerulata** ssp. **cerulata** — **Lit:** Trelease (1912b: 45, 55, tt. 45–47); Berger (1915: 264); Gentry (1978: 35–43, with ills.); Gentry (1982: 363–369, with ills.); Turner & al. (1995: 44–45); Starr (2012: 69–73, with ills.); Webb & Starr (2015: 77–78, with ill.). **Distr:** Mexico (C & S Baja California, N-most Baja California Sur); on hills and rocky mountain sides, in desert scrub with frequent fog and sea breezes, 25–640 m; flowers April to June. **I:** Irish & Irish (2000: t. 10); Heller (2006: 72); Richter (2011: 102); Pilbeam (2013: 51); Hochstätter (2015: V: 1, 14).

[2i] **Ros** 0.2–0.5 × 0.4–0.75 m, abundantly surculose or rarely solitary; **L** few, narrowly lanceolate to triangular-lanceolate, long-acuminate, mostly 25–50 × 4–7 cm and 5–12× as long as broad, yellow to light green, sometimes cross-zoned, rarely light glaucous-grey, margins nearly straight to shallowly repand; **marginal teeth** weakly attached, 1–4 mm, greyish-brown, bordered with a brown ring at the base, irregularly spaced, on low tubercles, sometimes lacking through much of the leaf length; **terminal Sp** acicular, 30–60 mm, light to dark grey, decurrent only to the uppermost teeth or less; **Inf** 2–3.5 m, paniculate, peduncle with small scarious triangular **Bra**, fertile part slender, narrow, part-**Inf** small, mostly 6–12, all white waxy-glaucous at bud stage; **Fl** mostly 45–60 mm; **Tep** in bud white waxy-glaucous, at anthesis pale yellow, tube broadly funnel-shaped or discoid, with thick **Nec** and bulges opposite the filament insertions, 3–5 × 11–14 mm, lobes

ascending to spreading, elliptic, equal, 16–22 mm, the inner wide with low broad keel and broadly overlapped at the base by the outer lobes; **Fl** usually incurved at anthesis, variable in length, 30–40 mm, inserted at the base of the lobes on the rim of the nectary; **Anth** centric to excentric, 15–20 mm; **Ov** fusiform, narrowly tapering towards the base, 22–32 mm; **Sty** shorter than the filaments; **Sti** capitate; **Fr** narrowly oblong, 30–50 × 12–13 mm, waxy light grey, bluntly apiculate, narrowly stipitate; **Se** crescent-shaped, hilar notch open or obscure, marginal wings pronounced on both sides around the curvature, 5 × 3 mm, sooty black.

Mostly characterized by slender, yellow, long-acuminate, lanceolate leaves with a brown ring at the weakly attached, moderate to small teeth, small narrow panicles with a conspicuous waxy bloom on peduncle, pedicels and fruits, and light-yellow, spreading tepal lobes. *A. cerulata* may be confused with the closely related *A. deserti*, but the latter is more robust, has grey-green (rather than yellow-green) leaves 4–7× longer than broad (vs. 5–12× longer than broad) and generally without the distinctive brown rings at the base of the teeth, and the capsules are generally broader and without waxy white bloom (Gentry 1982) (see *A. deserti* for further notes). Breslin (2015) provides a new record from Isla Cedros.

**A. cerulata** ssp. **dentiens** (Trelease) Gentry (Occas. Pap. Calif. Acad. Sci. 130: 43, 1978). **Type:** Mexico, Baja California (*Rose* 16819 [MO, NY, US]). — **Lit:** Trelease (1912b: 45, 51, tt. 38–40, as *A. dentiens*); Berger (1915: 264, as *A. dentiens*); Gentry (1978: 43–44, tt. 2–3); Gentry (1982: 369–371, with ills.); Turner & al. (1995: 45, with ill.); Wilder & al. (2008: 135–136, ill. p. 140); Guillot Ortiz & Meer (2008b: 24, ill. p. 30); Starr (2012: 70, 73); Webb & Starr (2015: 77–80, with ill.). **Distr:** Mexico (Baja California: Isla San Esteban); hillsides and arroyos; budding in April. **I:** Heller (2006: 73); Pilbeam (2013: 52); Hochstätter (2015: V: 15);

≡ *Agave dentiens* Trelease (1912).

[2i] Differs from ssp. *cerulata*: **Ros** 0.5–0.7 × 0.8–1.5 m; **L** long-acuminate, 40–55 (–70) cm,

**Fig. 14** *Agave cerulata* ssp. *subcerulata* (Etter & Kristen 383: Mexico; Baja California Sur, Vizcaino Desert, 170 m). (Copyright: J. Etter & M. Kristen)

light glaucous-grey, margins straight; **marginal teeth** friable, 1–2 mm, or nearly toothless; **terminal Sp** acicular, 30–50 mm, brown to grey; **Inf** broad, part-**Inf** 8–18 in the upper ½ of the inflorescence, on 30–40 cm long **Br**.

An isolated island population closely related to typical *A. cerulata*. With its broad inflorescences, it could bridge the gap between Sect. *Deserticolae* and Sect. *Conicae* (Webb & Starr 2015: 80). — Naturalized at one locality in Spain (Guillot Ortiz & Meer 2008b).

**A. cerulata** ssp. *subcerulata* Gentry (Occas. Pap. Calif. Acad. Sci. 130: 44–48, ills. (pp. 46–47, 49), 1978). **Type:** Mexico, Baja California Sur (Gentry 10330 [US, ARIZ, MEXU]). — **Lit:** Trelease (1912b: 45, 51, 55, tt. 30–40, 45–47); Gentry (1978: 44–48, with ills.); Gentry (1982: 371–374, with ills.); Turner & al. (1995: 45); Starr (2012: 70); Webb & Starr (2015: 81, with ills.). **Distr:** Mexico (S-most Baja California, N Baja California Sur); volcanic or gypsum slopes in desert scrub; flowers April to May. **I:** Heller (2006: 72); Richter (2011: 80, 141); Pilbeam (2013: 54); Hochstätter (2015: V: 17). — Fig. 14.

[2i] Differs from ssp. *cerulata*: **Ros** 0.15–0.3 × 0.3–0.5 m; **L** short-acuminate, 15–30 × 2.5–7 cm, mostly 3–6× as long as broad, mostly light grey to bluish-glaucous over green, margins conspicuously crenate with prominent tubercles; **marginal teeth** well developed, weakly attached, larger,

3–8 mm in the middle of the lamina; **terminal Sp** subulate, usually sinuous, 20–40 mm.

The S-most element in the *A. cerulata* complex, resembling *A. subsimplex* from the opposite Sonoran coast in habit (Gentry 1982). It might represent a genetic connection to the more southern *A. sobria* (Webb & Starr 2015).

**A. cerulata** var. *nelsonii* (Trelease) R. H. Webb & G. D. Starr (Haseltonia 20: 80, ill., 2015). **Type:** Mexico, Baja California (*Nelson & Goldman* 7111 [MO]). — **Lit:** Trelease (1912b: 45, 61, tt. 65–67, as *A. nelsonii*); Gentry (1978: 44–46, with ills.); Gentry (1982: 371–373, with ills.); Turner & al. (1995: 45, with ill.); Starr (2012: 70–71, ill.); the last 4 as ssp. *nelsonii*; Webb & Starr (2015: 78–81, with ill.). **Distr:** Mexico (C Baja California); igneous highlands in desert scrub or chapparal vegetation, 140–1120 m; flowers June to September. **I:** Goldman (1916: t. 111D, as *A. nelsonii*); Heller (2006: 73); Richter (2011: 102, 103); Pilbeam (2013: 53); Hochstätter (2015: V: 16). — Fig. 15.

≡ *Agave nelsonii* Trelease (1912) ≡ *Agave cerulata* ssp. *nelsonii* (Trelease) Gentry (1978); **incl.** *Agave shawii* E. C. Nelson (1911) (*nom. illeg.*, ICN Art. 53.1).

[2i] Differs from ssp. *cerulata*: **Ros** 0.5–0.75 m Ø; **L** short-acuminate, 20–35 × 6–8 cm, mostly 3–6× as long as broad, mostly light grey to bluish-glaucous over green, margins either repand and with small prominences, or nearly straight;

**Fig. 15** *Agave cerulata* var. *nelsonii* (cult.: USA; Arizona, Arizona-Sonora Desert Museum Tucson). (Copyright: J. Thiede)

**marginal teeth** firmly attached, larger, 3–9 mm, frequently on small tubercles; **terminal Sp** strongly subulate, 20–40 mm; **Inf** with 15–20 part-**Inf**.

The N-most element in the *A. cerulata* complex. Recognized at subspecies rank by Gentry, but reduced to varietal status by Webb & Starr (2015) since its distribution shows substantial geographical overlap with ssp. *cerulata* at its S end. Webb & Starr speculate that the taxon might represent a stabilized hybrid between *A. cerulata* and *A. shawii* ssp. *goldmaniana*. Hochstätter (2015: V: 16) depicts a natural hybrid with the latter.

**A. chamelensis** (E. J. Lott & Verhoek-Williams) Thiede & Eggli (Kakt. and. Sukk. 50 (5): 110, 1999). **Type:** Mexico, Jalisco (Lott & Wendt 1663 [MICH, BH, CAS, MEXU]). — **Lit:** Lott & Verhoek-Williams (1991); Castillejos-Cruz (2009: [121]–[126]); both with ills., both as *Manfreda*. **Distr:** Mexico (Jalisco, Oaxaca); uncommon along arroyos in tropical (semi-) deciduous and oak forests, 25–75 (–1170) m; flowers December to February. **I:** Hochstätter (2016: I: 17); Castro-Castro & al. (2017: 62); both as *Manfreda*.

≡ *Manfreda chamelensis* E. J. Lott & Verhoek-Williams (1991).

[3a2] Herbaceous; corm 3–15 × 2–3 cm, reproducing vegetatively by buds from the corm, bulb shortly cylindrical, 2–3.5 × 1.5–3 cm,

covered with membranous dry leaf bases 2.5–3.5 cm long and not separating into fibres; **R** fleshy and fibrous, with filiform ramifications, contractile; **L** drought-deciduous, 9–12, linear-lanceolate, spreading, brittle, herbaceous to somewhat fleshy, narrowly channelled, nearly conduplicate near the narrow base, tip acute, veins papillate on both faces, 37–77 (–91) × (1–) 1.6–4.8 (–6.5) cm, margins with a narrow yellowish cartilaginous band, minutely denticulate, teeth regular; **Inf** 0.75–1.2 (–2) m, ‘spicate’, fertile part 10–20 cm, with 10–25 (–35) sessile flowers; **Fl** nearly erect at anthesis; **Tep** green, tube funnel-shaped, 6–13 × 4–5 mm, lobes oblong, reflexed to tightly revolute, tip obtuse, with a tuft of short hairs, 8–11 × 4–5 mm; **Fil** erect, filiform, 21–32 mm, inserted in the middle of the tube, greenish-yellow with many purple dots; **Ov** oblong to ovoid, not constricted, not protruding into the tepal tube, 5–10 mm; **Sty** 25–35 mm, exserted; **Sti** clavate, trigonous; **Fr** globose, 12–16 × 10–15 mm; **Se** deltoid, plane-concave, 5–6 × 4–5 mm, shiny.

This species appears to be closest to *A. scabra* and *A. jaliscana*. It differs from both by shorter floral bracts, filaments curved near the tip at bud opening, and by the absence of coarse fibrous remains of old leaves, from the first-named by its shorter floral tube and globose beakless capsules, and from the last-named by its wider leaves and shorter styles and filaments (Lott & Verhoek-

Williams 1991, as *Manfreda*). The tropical lowland habitat is untypical and apparently not known for other species of Subgen. *Manfreda* except *A. littoralis*, *A. petskinil* and *A. paniculata*.

**A. chazaroi** A. Vázquez & O. Valencia (in Vázquez-García & al. (eds.), *Agaves Occid. Méx.*, 48–49, ills. (tt. CC-DD, pp. lxx-lxxiii), 2007). **Type**: Mexico, Jalisco (*Cházaro Basáñez & al.* 8161 [IBUG]). — **Distr**: Mexico (N Jalisco); basaltic cliffs in tropical deciduous forests, 900–1200 m; flowers January to February. **I**: Richter (2011: 56); Etter & Kristen (2012: 91–92); Pilbeam (2013: 55); Hochstätter (2015: IX: 26).

[1b] Acaulescent; **Ros** 1.45 × 0.8 m, solitary, not surculose; **L** up to 20, rigid, convex below, concave to flat above, to 80 × to 20 (mid-leaf) cm, yellowish-green, margins entire and horny dark brown all along; **marginal teeth** none; **terminal Sp** thin, large, canaliculate, 30–50 mm, dark brown; **Inf** erect, to 2.5 m, ‘spicate’, peduncle with filiform **Bra**, these 20–30 × 0.5 mm; **Ped** 10–15 mm; **Fl** 20–30 mm, geminate, densely arranged in the upper ½ of the inflorescence, funnel-shaped; **Tep** ivory-white, tube, lobes, **Fil** and **Anth** not described; **Ov** cylindrical, 10 mm incl. neck, cream-white; **Fr** oblong, 20 mm, glaucous when unripe, turning green (?) when ripe; **Se** unknown.

Based on the inadequately short protologue appearing close to *A. pelona* from Sonora, which differs esp. by the dark reddish flowers. It differs from other species of Sect. *Heteracanthae* (as Group *Marginatae*) in having few and broad leaves, and is better placed in Sect. *Inermes* (as Group *Amolae*) (Cuevas Guzmán & al. 2012). Here, it appears to be closest to *A. gilbertii* from which it differs by its stemless habit, and broader leaves without paler median stripe and with a much longer terminal spine. The tube length is not given in the protologue, but it appears to be very short (cf. t. CC-3), in contrast to 11–12 mm in *A. gilbertii* and 8–9 mm in *A. pelona*.

**A. chiapensis** Jacobi (Hamburg. Gart.- & Blumenzeit. 22: 213, 1866). **Type** [neo]:

Mexico, Chiapas (*Gentry* 12178 [US, ARIZ, MEXU, MICH]). — **Lit**: Jacobi (1871: 80–82); Berger (1915: 44–46, with ill.); Gentry (1982: 224–226, with ills.); Lott & García-Mendoza (1994: online version with ills.); García-Mendoza (2003: with ill.); García-Mendoza (2011a: 22–24). **Distr**: Mexico (N Oaxaca, Chiapas), Guatemala; limestone cliffs in the Montañas del Oriente, in humid oak, pine, pine-oak or pine-juniper forests or desert scrub-oak forest ecotones, 1400–3000 m; flowers March to April. **I**: Irish & Irish (2000: t. 11); Hils (2001); García-Mendoza (2002: 179); Heller (2006: 74); Lochner (2010); Richter (2011: 114); Pilbeam (2013: 56); Hochstätter (2015: IX: 4).

**Incl.** *Agave chiapensis* var. *major* hort. ex A. Berger (1915); **incl.** *Agave teopiscana* Matuda (1974).

[1f] Stems short or none; **Ros** openly spreading, robust, 0.5–0.8 × 1.3–1.5 m, mostly caespitose, rarely solitary; **L** 25–36, ovate, rarely lanceolate, soft, ascending, narrowed near the base, shortly acuminate, rounded below, flat to slightly hollowed above and upcurving, smooth, (20–) 30–50 (–65) × 7–17 cm, light shiny grey-green or grey-green to glaucous, lower face with imprints from the central bud, margins slightly repand to crenate, sometimes reddish or glaucous; **marginal teeth** deltoid, straight or upcurved, (1–) 2–4 × 2–4 mm, closely spaced and (1–) 4–5 (–10) mm apart, blackish or dark brown to greying, sometimes reddish; **terminal Sp** subulate, straight to sinuous, strong, rigid, ± openly grooved above, rounded to broadly keeled below, (15–) 25–40 × 3–4 mm, blackish or reddish, decurrent for (20–) 25–30 (–40) cm; **Inf** 2–3.5 m, ‘spicate’, peduncle long, green, closely bracteate with **Bra** to 13–22 × 2.5–4 cm, greenish-red or purple, fertile part dense, in the terminal ½–⅓; **Ped** 1–2 mm; **Fl** geminate, trigonous, fleshy, funnel-shaped, (40–) 60–70 (–85) mm, obscured in large tufts of broad-based bracts, the longer bracts equaling the flowers, reddish; **Tep** yellowish, whitish or green, sometimes tinged reddish or purple, tube funnel-shaped, thick-walled, 3-angled, grooved, 8–12 × 9–10 mm, lobes oblong or

linear-elongate, divaricate to recurved, fleshy, thick, unequal, 25–32 × 4–8 mm, the outer slightly longer, the inner with a prominent keel and involute, all cucullate and glandular at the tip, copiously papillate on and below the hood; **Fil** very broad at the base, (45–) 65–80 mm, reddish to dark purple-brown, inserted at the tube mouth; **Anth** (15–) 20–25 (–30) mm, yellow; **Ov** cylindrical to trigonous, truncate at base and apex, grooved to the base, (10–) 20–25 (–30) × 3–4 mm, neck 4 mm, sulcate; **Sty** very robust, 85–90 (–110) mm, dark purple-brown, thickened below the stigma; **Sti** weakly 3-lobed; **Fr** oblong to obovoid, rounded-truncate at the base, shortly apiculate at the apex, 30–40 × 10–15 mm, thin-walled; **Se** hemispherical, with regular complete marginal wing, 4–5 × 3–4 mm, black.

Gentry (1982: 226) designated the neotype cited above. The species is characterized by forming large caespitose clones and its ovate leaves with small teeth to 4 mm long, its dense inflorescences with large greenish-red or purple bracts, and its yellowish, whitish or green flowers with reddish to purple filaments (García-Mendoza 2011a). It appears to be closely related to *A. warelliana*, which differs in its brown (Gentry in error “red”) leaf margins with denticles 1–3 mm apart (Gentry 1982: 226). García-Mendoza (2011a) provides a new record from Oaxaca.

**A. chrysantha** Peebles (Proc. Biol. Soc. Wash. 48(4): 139, 1935). **Type:** USA, Arizona (Peebles & Harrison 5543 [US]). — **Lit:** Gentry (1982: 426–431, with ills.); Ullrich (1992i); Turner & al. (1995: 45–47); Hodgson (1999a: 4–5); Reveal & Hodgson (2002); Klopper & al. (2010: 56, 57, 59, with ills.); Parker (2017: 256, 258, with ills.). **Distr:** USA (C & S-C Arizona); very common on sandy to gravelly places on granitic or volcanic soils in desert scrub, grasslands, pinyon-juniper and oak woodlands, 700–2100 m; flowers June to July (to August). **I:** Irish & Irish (2000: t. 12); Heller (2006: 65); Richter (2011: 127); Pilbeam (2013: 57); Hochstätter (2015: IV: 6).

≡ *Agave palmeri* var. *chrysantha* (Peebles) Little ex L. D. Benson (1943) ≡ *Agave palmeri* ssp. *chrysantha* (Peebles) B. Ullrich (1992).

[2h] Acaulescent, **Ros** rather open to somewhat dense, 0.5–1.2 × 0.8–1 m, usually solitary, infrequently caespitose; **L** linear-lanceolate to lanceolate, spreading to ascending, straight, rigid, usually only a little narrowed below the middle, deeply guttered, 40–75 (–82) × (4–) 8–10 (–11) cm, pale to glaucous-green or yellowish-green to green, not cross-zoned, margins repand to wavy; larger **marginal teeth** straight or flexed, 4–10 mm, (8–) 10–30 (–40) mm apart, smaller towards the leaf base, intermittent teeth lacking or 1–3 (–5), mostly in the distal ⅓ of the leaves; **terminal Sp** slender, acicular, openly grooved above, 25–45 mm, reddish-brown or brown to grey, decurrent for 5–15 cm to the upper teeth; **Inf** 4–7 m, narrowly to broadly paniculate, open, peduncle with persistent triangular **Bra** 1–5 cm long, fertile **Inf** part narrowly to broadly paniculate, open, part-**Inf** slightly ascending, small, congested, (6–) 8–18 in the upper ¼–⅓ of the inflorescence, >10 cm, 12- to 21-flowered; **Fl** erect, 35–65 (–67) mm; **Tep** golden-yellow, rarely red-tipped, tube campanulate, 6–18 × (7–) 10–21 (–26) mm, lobes erect, persistent and often leathery during and after anthesis, strongly unequal, (6–) 9–15 (–18) mm; **St** long-exserted; **Fil** erect, (32–) 35–50 mm, pale yellow, inserted at 2 levels ± at mid-tube; **Anth** 7–20 mm, yellow; **Ov** slender, (14–) 22–30 (–33) mm, neck slightly constricted, (0.5–) 4–6 (–8) mm; **Sty** slightly longer than the tepals; **Sti** capitate; **Fr** narrowly oblong to obovoid, 35–50 mm, sessile or short-stipitate, apex shortly beaked; **Se** 6–7 mm. — **Cytology:** 2n = 60 (Pinkava & Baker 1985).

The closest relative is clearly the largely allopatric *A. palmeri* with often broader leaves with shorter and less distant teeth, and a very similar flower structure, but the latter differs consistently in its clear yellow flowers with tepal lobes conspicuously red to brownish at the tips, its more congested ‘umbels’, and its shorter panicles (Gentry 1982, Klopper & al. 2010). Benson (1943) and Ullrich (1992i) both suggest infraspecific ranks under *A. palmeri*, with which it shows introgression where they meet (Gentry 1982: 429, 446). *A. chrysantha* hybridizes with *A. delamateri*, *A. mckelveyana*, *A. murpheyi*, *A. palmeri*, *A. parryi* var. *couesii*, *A. schottii*, and *A. toumeyana* (Hodgson 1999a, Reveal & Hodgson 2002, Parker 2017).

**Fig. 16** *Agave chrysoglossa* (Etter & Kristen 548: Mexico; Sonora, Nacapule Canyon, 280 m). (Copyright: J. Etter & M. Kristen)

*A. chrysantha* appears to have developed minor shifts in several floral characters that enhance diurnal pollination; bats were not recorded as important pollinators (Slauson 2000).

**A. chrysoglossa** I. M. Johnston (Proc. Calif. Acad. Sci., ser. 4, 12: 998–999, 1924). **Type:** Mexico, Sonora (*Johnston* 3123 [CAS, ARIZ, GH, US]). — **Lit:** Gentry (1982: 71–75); Ullrich (1994a); Turner & al. (1995); Wilder & al. (2008); Felger & al. (2011); all with ill. **Distr:** Mexico (C & S Sonora: coastal and San Pedro Nolasco & Tiburón islands); slopes or often bare rocks in hot coastal and lowland regions, in desert and thorn scrub, 300–760 m; flowers mid-March to mid-May. **I:** Etter & Kristen (2001: 172–173); Richter (2011: 60); Pilbeam (2013: 58–59); Hochstätter (2015: VIII: 20). — Fig. 16.

[1b] Stems short; **Ros** openly spreading, 1–1.3 × 2–2.4 m, mostly solitary, sometimes suckering

profusely; **L** few, linear-lanceolate, straight or slightly curved, deflexed at maturity, convex below, flat above, smooth, 70–120 × 4–7 cm, widened at the base, light green, margins fragile, 1 mm wide, brown; **marginal teeth** none; **terminal Sp** acicular, with a short fine groove at the base above, 20–40 mm, brown, aging greyish; **Inf** mostly 2–4 m, ‘spicate’, peduncle with dry chartaceous **Bra**, lower **Bra** longer than the flowers, fertile part densely flowered, in the upper ¾ of the inflorescence; **Ped** bifurcate, 10–15 mm; **Fl** geminate, 35–45 mm; **Tep** yellow, tube shallow, 4–4.5 × 9 mm, lobes ovate, flat, outcurving at anthesis, clasping the filaments after anthesis, thin, ± equal, outer 14–16 × 6 mm, keeled, the inner wider (8 mm) and unkeeled; **Fil** 40–45 mm, inserted on the rim of the tube at the base of the lobes; **Anth** 14–18 mm; **Ov** slender, scarcely grooved, 16–20 mm incl. a 3–5 mm long neck; **Fr** mostly oblong, 20 × 10 mm, shortly apiculate, parallel-veined and slightly cross-ridged; **Se** crescent-shaped, with 1 to several wrinkles on the faces, marginal wing low, firm, the hilar notch sharply angled, mostly 4–4.3 × 2.5–2.8 mm.

Closely related to *A. vilmoriniana*, but distinguished by straight narrow flat leaves (vs. deeply guttered and arching in *A. vilmoriniana*) and without bulbils in the inflorescence. Gentry (1982) considers the inland populations at Río Yaqui as showing introgression from *A. vilmoriniana*; Turner & al. (1995) map these as *A. chrysoglossa*. The Sierra Seri populations of *A. chrysoglossa* appear to bridge a morphological gap to *A. pelona* (Turner & al. 1995). Specimens by R. Felger cited by Gentry (1982: 87) seem closer to *A. pelona* and are placed there by Turner & al. (1995). See also under *A. ocahui*. For the habitats on the Gulf Islands, see Wilder & al. (2008) and Felger & al. (2011). The seed production is estimated as 500,000–750,000 seeds per plant. The flowers are visited by numerous insects, hummingbirds, and other birds (Gentry 1982).

**A. cocui** Trelease (Mem. Nation. Acad. Sci. 11: 19, tt. 5–7, 1913). **Type:** Venezuela (*Zuloaga* s.n. [MO [syn, 4 sheets]]). — **Lit:** Berger (1915: 224–225); Hummelinck (1936: 244–247, 249, tt. VII, VIIIa); Hummelinck (1938: 21–23, tt. Ib,

IVb); Figueredo (2010: with ill.). **Distr:** Venezuela (incl. Isla Margarita), Colombia; mainly coastal, but also extending into inter-Andean valleys, 400–1000 m; flowers January to May. **I:** Hoyos F. (1985: fig. 83); Mostul (2005: 70); Figueredo (2010); Richter (2011: 96); Pilbeam (2013: 60); Hochstätter (2015: VII: 36).

**Incl.** *Agave americana* Humboldt (1808) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave cocui* var. *cucutensis* Hummelinck (1936); **incl.** *Agave cocui* var. *laguayrensis* Hummelinck (1936).

[2u] Acaulescent or sometimes subcaulescent; **Ros** to 2.5 m Ø, suckering; **L** rather many, lanceolate to elliptic, sometimes sub-oblong, rarely oblanceolate, guttered, often slightly S-curved, tip often slightly upcurved, sharply acute or subacuminate, (80–) 100–120 (–140) × 20–30 cm, (3.5–) 4–5 (–6) × as long as broad, glaucous, soon green and glossy; **marginal teeth** mostly upcurved above and recurved below, acuminately triangular or from crescent-shaped bases on green or later hardening prominences, (2–) 2.5–6 (7) mm, reddish chestnut-brown, (6–) 10–14 (–22) per 10 cm, intervening margin concave; **terminal Sp** conical or rarely acicular, sometimes triquetrous, rather often distinctly laterally flattened, very rarely flexuous, often recurved near the tip, shallowly grooved below the middle and involute below, smooth, sometimes rough, (10–) 12–22 (–30) × (2–) 3–5 (–6) mm, red-brown, slightly or not decurrent, dorsally very slightly immersed into the leaf tissue; **Inf** (5–) 6–8 (–10) m, paniculate, peduncle with 15–25 **Bra**, **Bra** serrate towards the tips, narrowly triangular, at length recurved, fertile part in the upper ½ of the inflorescence, narrowly oblong, part-**Inf** on nearly horizontal branches, freely bulbiferous; **Ped** (3–) 4–8 (–12) mm; **Fl** (40–) 45–55 (–65) mm; **Tep** yellow, tube openly conical, (3–) 4–6 (–7) mm, lobes (18–) 20–24 (–25) × 5–7 mm; **Fil** (30–) 35–45 (–55) mm, inserted 1 mm above to 0–1 (–1.5) mm below the throat; **Anth** (15–) 18–23 (–25) mm; **Ov** 25–40 × 7–8 mm; **Sty** (38–) 44–50 (–55) mm; **Fr** oblong, (35–) 40–50 × 20–25 mm, usually very slightly beaked, shortly stipitate; **Se** 7–9 × 5–6 mm. — **Cytology:** 2n = 60 (Mata-Sucre & al. 2017).

The type at MO consists of 4 sheets which are not cross-labelled and thus represent syntypes

(Smith & Figueiredo 2014e: 231). Not always clearly separated from *A. vicina* (Hummelinck 1938: as *A. vivipara*). Hummelinck's concept of *A. cocui* included plants from Curaçao and neighbouring islands here separated as *A. vivipara* (see there). The species is not restricted to coastal regions and extends into inter-Andean valleys as far as Táchira (Venezuela) and Santander (Colombia; Hummelinck (1938: 21)).

*A. cocui* is an important crop in Venezuela, used from wild plants in traditional production systems esp. for liquor, soap, fibres, and preserves (Salazar & al. 2009, Figueredo 2010). Flowering starts mainly with the onset of the dry period in January or later and is highly synchronized among the populations (Figueredo & Nassar 2011). Molecular populational studies showed that *A. cocui* has one of the lowest estimates of genetic diversity as yet reported, which is esp. low in its centre of economic use, suggesting that human impact represents a significant threat to its gene pool (Figueredo & Nassar 2011), but 3 populations could be separated with AFLP data (Yépez & al. 2008). For the in vitro propagation, see Salazar & al. (2009). See also under *A. boldinghiana*.

**A. coetocapnia** (M. Roemer) Govaerts & Thiede (Willdenowia 43(2): 331, 2013). **Type:** Mexico (*Deppe* s.n. [†; [lecto — icono]: Link & Otto, Icon. Pl. Rar., t. 18, 1828, as '*Zetocapnia*'). — **Lit:** McVaugh (1989: 248–252); Solano & García-Mendoza (2013: with ills.); both as *Polianthes geminiflora*. **Distr:** N and C Mexico.

≡ *Bravoa coetocapnia* M. Roemer (1847); **incl.** *Bravoa geminiflora* Lexarza (1824) ≡ *Polianthes geminiflora* (Lexarza) Rose (1903); **incl.** *Coetocapnia geminiflora* Link & Otto (1828); **incl.** *Robynsia geminiflora* Drapiez (1841); **incl.** *Bravoa graminiflora* Hemsley (1884) (*nom. inval.*, Art. 61.1); **incl.** *Polianthes americana* Sessé & Moçino (1888); **incl.** *Polianthes tubulata* Sessé & Moçino (1894); **incl.** *Agave duplicata* Thiede & Eggl (1999) (*nom. illeg.*, ICN Art. 52.1).

This is the most widespread and well-known species of Sect. *Polianthes*. It is rather variable in the size of the plant, leaves, bracts, inflorescences, and the number of flowering nodes (McVaugh 1989, Solano & García-Mendoza 2013).

When transferring *Polianthes geminiflora* to *Agave*, Thiede & Eggli (1999) published the new name *A. duplicata* due to the earlier *A. geminiflora* (Tagliabue) Ker Gawler (1817), but were unaware of the prioritable epithet available as *Bravoa coetocapnia* (Govaerts & Thiede 2013). Solano & García-Mendoza (2013) provided a taxonomic treatment (as *Polianthes geminiflora*) and neotypification. The hybrid of this species with *A. bulliana* is known as *A. ×kewensis* (see there).

**A. coetocapnia** ssp. **clivicola** (McVaugh) Govaerts & Thiede (Willdenowia 43(2): 332, 2013). **Type:** Mexico, Jalisco (*Wilbur & Wilbur* 2133 [MICH, IEB]). — **Lit:** McVaugh (1989: 250); Solano & García-Mendoza (2013); Castro-Castro & al. (2015: with ill.); all as *Polianthes geminiflora* var. **Distr:** Mexico (NW, SW, C & S Jalisco, W Michoacán); mostly on steep shaded slopes, barrancas, gullies, in oak, pine, and pine-oak forests, grasslands, or ecotones with tropical subdeciduous forests, (900–) 1200–2560 m; flowers June to September (to October). **I:** Guillot Ortiz & al. (2006: 67); Castro-Castro & al. (2015); Hochstätter (2016: II: 12); Castro-Castro & al. (2016: 721); all as *Polianthes geminiflora* var./ssp.

≡ *Polianthes geminiflora* var. *clivicola* McVaugh (1989) ≡ *Agave duplicata* ssp. *clivicola* (McVaugh) Thiede & Eggli (1999) (*incorrect name*, ICN Art. 11.4) ≡ *Polianthes geminiflora* ssp. *clivicola* (McVaugh) Hochstätter (2016).

[3b2] Differs from ssp. *coetocapnia*: **L** margins usually very narrowly revolute, with very thin pale scarious or hyaline edge, smooth and entire, rarely obscurely roughened.

This is the W element within *A. coetocapnia*, differing in leaf margin characters.

**A. coetocapnia** ssp. **coetocapnia** — **Lit:** McVaugh (1989: 248–252); Solano & García-Mendoza (2013: with ills.); Guillot Ortiz & Meer (2016a: 72–74); all as *Polianthes geminiflora*. **Distr:** Mexico (Durango, Nayarit, Jalisco, Guanajuato, Querétaro, Hidalgo, Michoacán, México, Tlaxcala, Distrito Federal, Morelos, Guerrero, Puebla); mainly on rocky slopes in oak, pine or cloud forests, mainly in the Trans-Mexican

**Fig. 17** *Agave coetocapnia* ssp. *coetocapnia* (Etter & Kristen 2835: Mexico; Jalisco, ± 20 km S of San Cristóbal de la Barranca, 1470 m). (Copyright: J. Etter & M. Kristen)

Volcanic Belt, 900–2800 m; flowers June to August (to November). **I:** Guillot Ortiz & al. (2006: 67, as *P. geminiflora*); García-Mendoza & Esparza Alvarado (2010: 62–63, as *P. geminiflora*); Etter & Kristen (2012: 85, as *A. duplicata*); Castro-Castro & al. (2015: 145, as *P. geminiflora* var.); Hochstätter (2016: II: 11, as *P. geminiflora* var.); Castro-Castro & al. (2016: 721, as *P. geminiflora* var.). – Fig. 17.

≡ *Agave duplicata* ssp. *duplicata*.

[3b2] Herbaceous; corm cylindrical, 1.5–2.7 × 1–2 cm, bulb ovoid, 1.8–4 × 1.3–3 cm, covered with dry leaf bases; **R** contractile, fleshy and fibrous; **L** 2–6 (–8), linear-lanceolate to broadly attenuate towards the acute tip, (8–) 12–35 (–50) × 0.1–2.5 (–3.7) cm, glaucous, plain green or spotted with small or large and confluent green or dark brown spots, lower face slightly papillose on the veins, margins entire, denticulate, papillose to erose; **Inf** 35–100 (–154) cm, ‘racemose’,

peduncle with linear to lanceolate **Bra** 4.5–31 × 0.1–2.3 (–2.8) cm, fertile part lax, denser towards the tip, 10–40 (–60) cm; **Ped** strongly ascending, (3–) 10–18 mm; **Fl** geminate, but often only 1 developing, pendent, unscented; **Tep** red, orange or coral-red, tube slender and terete at the base, broadened above, 14–21 × 1–3 (–5) (at the tip) mm, throat straight or slightly oblique, lobes erect, ovate, (sub-)orbicular to transversally elliptic, subequal, 2–3 (–5) × 1–2.5 mm, cucullate, apex obtuse to rounded, with a tuft of short white hairs; **St** included; **Fil** filiform, (5–) 10–21 (–24) mm, white, inserted 2–5 mm above the tip of the ovary; **Anth** linear, 3–6 mm, yellow; **Ov** erect, ellipsoid; **Sty** filiform, 10–25 mm, sometimes as long as the tepal tube, white; **Sti** 3-lobate; **Fr** shortly oblong or almost globose, 7–17 × 5–12 mm; **Se** semicircular, flat, 2–4 (–5) × 2–3 mm, black, shiny or dull.

Zamudio & Galván Villanueva (2011: 87) provide a new record for Guanajuato. The flowers attract hummingbirds and insects (Etter & Kristen 2012).

**A. coetocapnia** ssp. **pueblensis** (E. Solano & García-Mendoza) Govaerts & Thiede (Willdenowia 43(2): 332, 2013). **Type:** Mexico, Puebla (Solano & al. 849 [MEXU, CHAPA, ENCB, FEZA, HUAP, HUMO, IEB, US]). — **Lit:** Solano & García-Mendoza (2013: as *Polianthes geminiflora* var.). **Distr:** Mexico (W & SW Puebla); open spots on calcareous soils, in oak and juniper forests, desert scrub, grasslands and corn fields, 2160–2220 m; flowers July to August. **I:** Hochstätter (2016: II: 13, as *P. geminiflora* ssp.).

≡ *Polianthes geminiflora* var. *pueblensis* E. Solano & García-Mendoza (2007) ≡ *Agave duplicata* ssp. *pueblensis* (E. Solano & García-Mendoza) Thiede (2012) (*incorrect name*, ICN Art. 11.4) ≡ *Polianthes geminiflora* ssp. *pueblensis* (E. Solano & García-Mendoza) Hochstätter (2016).

[3b2] Differs from ssp. *coetocapnia*: **L** very narrow, 1–2 mm broad, papillose on the lower face, margins regularly denticulate.

This is the SE element within *A. coetocapnia*, differing in its leaf margin and very narrow leaves.

**A. colimana** Gentry (Cact. Succ. J. (US) 40: 212–213, ills., 1968). **Type:** Mexico, Colima (Gentry 18325 [US, ARIZ, DES, MEXU]). — **Lit:** Gentry (1982: 102–107, with ills.); McVaugh (1989); Ullrich (1991a: with ills.); Vázquez-García & al. (2007b: 49–50, t. G). **Distr:** Mexico (W, SW & S Jalisco, Colima, Michoacán); primarily coastal on rocky sites, or more inland in tropical deciduous forests, 0–1000 m; flowers November to March. **I:** Etter & Kristen (2012: 95); Pilbeam (2013: 61).

**Incl.** *Agave ortgiesiana* Roez (1871) (*nom. inval.*, ICN Art. 36.1b?); **incl.** *Agave schidigera* var. *ortgiesiana* Baker (1877) ≡ *Agave ortgiesiana* (Baker) Trelease (1914) (*nom. illeg.*, ICN Art. 53.1) ≡ *Agave angustissima* var. *ortgiesiana* (Baker) Trelease (1920); **incl.** *Agave maritima* Rose ex Hort. Kew (1897) (*nom. inval.*, ICN Art. 38.1a); **incl.** *Agave ortgiesiana* var. *brevifolia* Hort. Besauccèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a).

[1d] Shortly caulescent; **Ros** 0.4–0.6 × 1–1.2 m, solitary; **L** many, linear, straight, slightly narrowed above the base, widest near the middle, thin and flat above, smooth, 40–70 × 1–2.5 cm, green, with light green mid-stripe, margins narrow, brown, filiferous with fine, long, brown threads; **marginal teeth** none; **terminal Sp** weak, short, broadly rounded below, flattened or somewhat hollowed above, 5–8 mm, greyish-brown to dark brown, decurrent into the leaf margin; **Inf** 2–3 m, ‘spicate’, peduncle with linear-acicular dark brown or purplish **Bra**, lower **Bra** longer than the flowers, the upper somewhat shorter, fertile part of the inflorescence slender, from ±1 m above the base, part-**Inf** not crowded; **Ped** 10–15 mm; **Fl** geminate, 40–50 mm; **Tep** pale yellow or lavender, tube slightly 6-furrowed, narrow, 9–17 × 5–9 mm, lobes recurved at anthesis, subequal, 14–19 × 4–6 mm, outer 1 mm longer, thin, obtuse, with thickened papillate tip; **Fil** 30–40 mm, pale reddish, inserted 8–11 mm above the tube base and 1–2 mm below the lobe sinuses; **Anth** 17–21 mm, yellow; **Ov** round, 14–20 mm, greenish-yellow, neck 4–7 mm, slightly constricted; **Sti** contiguous with the style and not clavate, roundly trigonous, with papillae decurrent on the angles below the tip; **Fr** oblong,

20–25 mm, conspicuously constricted at the base, beaked, stipe stout, to 10 mm; **Se** small, hemispherical, rugulose, 2–3 × 3.5–4 mm.

Typical plants are distinctive with their elongate leaves and deep narrow flower tube, but sometimes approach *A. schidigera* in flower tube length and *A. multiflifera* in leaf characters and are then hard to distinguish without complete material (Gentry 1982). There has been a long dispute about the correct name for this species: McVaugh (1989: 135) regards the earlier name *A. ortgiesiana* Roezl (1871) as invalid since it was published in an excerpt of a letter only. Ullrich (1991a), in contrast, accepts *A. ortgiesiana* Roezl as validly published and thus as the correct name for the taxon. Govaerts (WCSP, April 2014) does not cite the Roezl name, but instead accepts *A. ortgiesiana* (Baker) Trelease (1914). Here, the established name *A. colimana* is retained for the time being, pending a formal proposal to conserve it over the earlier *A. ortgiesiana* (Baker) Trelease.

Tschapka & al. (2008) observed a highly specialized nectar-feeding bat on this species, *Ceiba pentandra*, *Pachycereus pecten-aboriginum* and *Pseudobombax ellipticum*; another species of migratory nectar-feeding bat was traced by Stoner & al. (2003).

**A. collina** Greenman (Contr. Gray Herb. 11: 296, 1897). **Type:** Mexico, Morelos (*Pringle* 6349 [MO, AC, BR, CAS, CM, ENCB, F, G, GH, GOET, JE, K, MEXU, MICH, MIN, MSC, NDG, NY, P, PH, S, US, VT]). — **Lit:** Berger (1915: 253); Trelease (1920: 116); Gentry (1982: 586). **Distr:** Mexico (Morelos, Guerrero); ±1500 m; flowers in June.

[2g] Acaulescent, unknown whether **Ros** solitary or offsetting; **L** 30–40, linear-attenuate, gradually narrowing towards the apex, convex below, concave above, 60–80 × 5–8 cm (in the middle, narrowing to 2 cm just above the base), bluish-green, somewhat green-banded below, margins narrowly cartilaginous; **marginal teeth** straight or upcurved, 3–5 mm, reddish-brown, on broad lenticular bases, 8–25 mm apart, intervening margin straight or very slightly emarginate, with a fine, brown or yellowish, horny line; **terminal Sp** conical, broadly and somewhat crookedly

canaliculate, 20–30 × 3–5 mm, reddish- or purplish-brown, somewhat decurrent; **Inf** 3–4 m, paniculate, fertile part 60–80 cm, lower part **Inf** ±30 cm; **Fl** ±60 mm (90 mm incl. the exerted stamens); **Tep** greenish-yellow, tube funnel-shaped, 15–16 mm, lobes linear-oblong, obtuse, thickened at the apex, 19–20 mm; **Fil** flattened, glabrous, ±50 mm; **Anth** 25–30 mm; **Ov** 25 mm, neck constricted; **Sty** slightly shorter or ± as long as the filaments; **Sti** capitate; **Fr** 45–50 × 25–30 mm, shortly beaked; **Se** crescent-shaped to obliquely triangular, 8–10 × 6–8 mm.

Listed by Gentry (1982: 586) under “incertae sedis”, but accepted as species by Espejo Serna & López Ferrari (1993), Govaerts (2014+), and Portal Datos Abiertos UNAM (2018+: accessed Jan. 2019). According to the protologue it is probably identical with *A. serrulata* (as “serratula”), a synonym of *A. angustifolia*. The measurements of the protologue fall well within the range of the variable *A. angustifolia*, and *A. collina* may belong to that complex as suggested by Gentry (1982: 586). Gentry deviates in part from the protologue, and describes the species as “a stout, short-stemmed plant with nearly white glaucous to pale green leaves with nearly black teeth and spine” and as “frequent in middle elevations from Morelos to Guerrero”. Fernández Nava & al. (1998: 2) list the species for the Balsas basin (Guerrero).

**A. colorata** Gentry (Publ. Carnegie Inst. Washington 527: 93–94, t. 14: fig. 2, 1942). **Type:** Mexico, Sonora (*Gentry* 3050 [CAS, ARIZ]). — **Lit:** Gentry (1972: 117–119, ills.); Gentry (1982: 431–433, ills.); Ullrich (1993f: with ills.); Turner & al. (1995: 48–49); Starr (2012: 78–83, 320–321, ills.). **Distr:** Mexico (S Sonora, N Sinaloa); foothills or coastal regions, open rocky sites in thorn or pine-oak forests, on volcanic or white limestone rocks, 60–200 m; flowers March to June. **I:** Irish & Irish (2000: t. 13); Heller (2006: 76); Klopper & al. (2010); Richter (2011: 131); Pilbeam (2013: 62–63); Hochstätter (2015: IV: 7); Moore (2016: 271). – Fig. 18.

[2h] Stems short; **Ros** compact, 0.45–0.9 × 0.45–1.2 m, tapered at the base or hemispherical, solitary or sparingly suckering; **L** few, ovate, shortly acuminate to lanceolate, thick, firm,

**Fig. 18** *Agave colorata*  
(Etter & Kristen 562:  
Mexico; Sonora, near  
Aquihuiquichi, 200 m).  
(Copyright: J. Etter &  
M. Kristen)

convex below towards the base, flat to concave above, asperous, 25–60 (–100) × 12–18 cm, light grey, glaucous, frequently cross-zoned and red-tinted, margins prominently crenate or with prominences; **marginal teeth** straight or flexuous, mostly 5–10 mm (in the middle of the lamina), brown to greyish, 15–30 mm apart, smaller below; **terminal Sp** subulate, straight or flexuous, narrowly grooved above in the lower ½, mostly 30–50 mm, brown to grey; **Inf** 2–3 m, paniculate, lower **Bra** leaf-like, the others soon drying, appressed at the base, reflexed above, 10–15 cm, reddish, fertile part of the inflorescence narrow, **part-Inf** densely flowered, 15–20 in the upper ⅓–½ of the inflorescence; **Fl** 53–73 mm; **Tep** yellow, reddish in bud, apex usually remaining reddish, tube cylindrical, thick-walled, narrowly grooved, 15–20 × 12–14 mm, lobes linear, strictly erect, thickly fleshy, unequal, outer larger, overlapping, 12–16 × 5–7 mm, inner shorter, thickly keeled; **Fil** stout, flattened, tapered, 45–65 mm, inserted at 2 levels at mid-tube, yellow or pink; **Anth** 21–26 mm; **Ov** 25–40 mm, pale green, neck short, not constricted; **Sty** thick, sometimes pink, exceeding the stamens after anthesis; **Sti** capitate; **Fr** oblong to clavate, 45–55 × 15–17 mm, thickly and shortly stipitate or sessile; **Se** tear-shaped, 6 × 5 mm, hilar notch frequently obscure, marginal wing narrow. — **Cytology**: 2n = 60 (Simpson & al. 2011).

The closest relative, both morphologically and geographically, is *A. shrevei*, from which

*A. colorata* differs in its broader cross-zoned leaves with deeply crenate to repand margins, more densely flowered panicles with closely set ‘umbels’, and its shorter, wider tepal tube and thicker ovary. The species is uncommon in nature. Its compact size and bright glaucous leaves with pinkish cross zones make it an attractive ornamental (Gentry 1982). Plants from near Guaymas and San Carlos Bay (Sonora) have longer and narrower leaves with smaller marginal teeth (Gentry 1982: 432–433, Starr 2012); these were first misplaced in *A. fortiflora* (Gentry 1972: 125). Bats and possibly also hummingbirds are the assumed pollinators (Gentry 1982). Flowers pollinated by the likely main pollinator, the bat *Leptonycteris yerbabuena*, show much higher fruit set, higher numbers of viable seeds, and a higher germination rate compared to fruits and seeds obtained from self-pollination (Borbón-Palomares & al. 2018).

**A. confertiflora** Thiede & Egli (Kakt. and Sukk. 50(5): 111, 1999). **Type**: Mexico, Chihuahua (*Hartman* 536 [US, MEXU, UC]). — **Lit**: Rose (1899: 155, t. 18, as *Pseudobravoa densiflora*); García-Mendoza (2003); Solano & Feria (2007); Feria-Arroyo & al. (2010: with ill.); all as *Polianthes densiflora*. **Distr**: Mexico (SW Chihuahua); open sites on calcareous soils, in pine or pine-oak forests, 2190–2500 m. **I**: Hochstätter (2016: II: 9).

≡ *Bravoia densiflora* B. L. Robinson & Fernald (1895) ≡ *Pseudobravoia densiflora* (B. L. Robinson & Fernald) Rose (1899) ≡ *Polianthes densiflora* (B. L. Robinson & Fernald) Shinnors (1966).

[3b1] Herbaceous, small, 7–15 cm; corm cylindrical, to  $\pm 1 \times 1$  cm, bulb oblong, to  $\pm 1 \times 1.5$  cm, covered with dry leaf bases; **R** many, contractile, thickened; **L** 4–10, linear, attenuate, apex acute, 7.5–11  $\times$  0.2–0.3 cm, green, margins entire, or partly papillose; **Inf** ‘spicate’, short; peduncle with **Bra** 2.5–5 cm, with broad scarious and attenuate tips; fertile part dense, with (2–) 4–6 floral nodes, 7.5–13 cm; **Ped** none; **Fl** solitary, slenderly tubular, spreading, curved, 43–55 mm; **Te**p pulverulent-tomentose on the outer face, dull yellow, tube narrow, scarcely widened, 21–44  $\times$  3–4 mm, throat oblique, lobes erect, ovate, obtuse, equal, 2.5–4 mm, tip with a tuft of short white hairs; **St** included; **Fil** filiform, inserted in the tube; **Anth** linear, 5–10  $\times$  1–2 mm, yellow to green-yellowish, at anthesis surrounding the throat; **Ov** cylindrical; **Sty** filiform, as long as the tube, included at anthesis; **Sti** 3-lobate; **Fr** globose, 8–12  $\times$  7–10 mm; **Se** deltoid or semicircular, flat, 3–4  $\times$  2.4–3.3 mm, shiny or dull.

A hardly known but seemingly very distinct species. Long known from the type collection only, but Solano & Feria (2007: 1888) mention 13 records from 5 localities. The geographical distribution, niche modelling and extinction risk of the species are dealt with by Solano & Feria (2007) and Feria-Arroyo & al. (2010). The type locality is incorrectly cited as “Varogachic” in the protologue, but is Norogachi, a Tarahumara community in the town of Guachochi (database note for GH 00030302!), and the type is “Hartman, 5 July, 1892 (no. 536)” (US, MEXU, UC) and not Hartman 546, 6 July 1892 (GH, K, MEXU), partly labelled as “Type”. — When *Polianthes densiflora* is transferred to *Agave*, a new name is necessary to avoid homonymy with *A. densiflora* Hooker.

**A. congesta** Gentry (Agaves Cont. North Amer., 476–479, ills., 1982). **Type:** Mexico, Chiapas (Gentry 23651 [US [2 sheets], ARIZ, DES, MEXU, MICH]). — **Lit:** Lott & García-Mendoza

(1994: online version with ills.); García-Mendoza (2003: with ill.). **Distr:** Mexico (Chiapas); widely scattered in pine-oak forests and pine woodlands in the Montañas del Oriente, on calcareous rocks, (930–) 2100–2500 m; flowers December to February. **I:** García-Mendoza (2002: 187); Richter (2011: 114); Pilbeam (2013: 64); Hochstätter (2015: VI: 6).

[2o] Stems short; **Ros** compact, 0.5–1  $\times$  1–2 m, solitary; **L** many, lanceolate to lanceolate-spatulate, at first curved-ascending, then horizontally spreading, thick, narrowed at the base, (shortly) acuminate, flat, (40–) 50–120  $\times$  10–22 cm, green to yellow-green, sometimes faintly glaucous or pruinose, margins straight in the lower  $\frac{1}{2}$ , repand to crenate in the upper  $\frac{1}{2}$ ; **marginal teeth** straight to variously curved, moderate to rather large, dark to greyish-brown, usually remote, 20–50 mm apart, mostly on variously shaped prominences, 5–10 mm, base broad and low; **terminal Sp** stout, base very broad, widely flatly grooved above, 30–70 mm, grey to chestnut-brown, sharply decurrent to the upper teeth; **Inf** 6–8 m, paniculate (“racemose” in the protologue), peduncle with prominent **Bra**, fertile part straight, slender, with 40–50 part-**Inf** as congested rounded clusters, subsessile or on short lateral branches 2–10 cm long, in the upper  $\frac{1}{2}$  or more of the inflorescence; **Ped** closely subtended by small purplish bracts, 3–10 (–20) mm; **Fl** (45–) 55–70 mm; **Te**p orange to reddish or purplish in bud, yellow at anthesis, softly fleshy, tube deeply funnel-shaped to tubular, thick-walled, grooved, knobby, 10–13 mm, lobes linear-lanceolate to narrowly triangular, involute, thickly rounded-cucullate, unequal, 17–30 mm, the outer larger, dark-coloured apically, the inner shorter, with a thick prominent keel; **Fil** slender, 40–60 mm, purplish, inserted at 2 levels near the throat of the tube; **Anth** centric, irregularly curved to sinuous, 20–30 mm, bronze-coloured; **Ov** angular-fusiform, (25–) 30–40 mm, neck short; **Sty** stout, lengthening after anthesis, somewhat longer than the filaments; **Sti** capitate; **Fr** oblong, 50  $\times$  20 mm; **Se** unknown.

The species name alludes to the congested flowers in the dense globose ‘umbels’. It is further distinguished by the dimorphic dark-coloured

tepals and the filaments inserted at 2 levels. The closely related *A. hiemiflora* has the same but less pronounced characteristics, and is distinguished by smaller rosettes with fewer leaves, and paler tepals (Gentry 1982: 479). Gentry's "holotype" at US consists of 2 sheets which appear to have been cross-labelled later.

**A. convallis** Trelease (Contr. US Nation. Herb. 23: 138, 1920). **Type** [lecto]: Mexico, Oaxaca (Trelease 4 [MO [1128755 + 1256267]]). — **Lit**: García-Mendoza (2010); García-Mendoza (2011a: 23–26); León Vázquez & al. (2013). **Dist**: Mexico (S Puebla, NW & C Oaxaca); desert scrub and pine forests, in soils of volcanic origin, 1610–2640 m; flowers August to January.

**Incl.** *Agave dissimulans* Trelease (1920).

[lg] Acaulescent; **Ros** dense, 1–1.2 × 1.5–2 m, solitary or rarely caespitose; **L** (40–) 50–80, broadly lanceolate to lanceolate, erect, stiff, succulent, leathery, fibrous, thick and flat at the base, flat to slightly guttered towards the apex, (50–) 70–100 × 10–16 (in the middle) cm, dark green, yellow-green or purple, sometimes with a weak yellowish mid-stripe, margins straight, horny, continuous, white; **marginal teeth** broadly triangular, sometimes bifid, present towards the base, absent in the uppermost 5–15 (–35) cm, straight to variously curved, 9–15 (–20) × (4–) 7–10 mm, (10–) 25–45 (–70) mm apart, grey-white or brown, sometimes with a lenticular broadening beneath each tooth, sometimes with small intermittent teeth; **terminal Sp** conical, deeply channelled above, 30–55 × 5–8 mm, greyish-white, decurrent on the lower face for 4–15 mm; **Inf** 3–6 (–8) m, 'spicate', peduncle green, with linear chartaceous deciduous **Bra** 11–15 cm long, fertile part in the upper ½–⅓; **Ped** 3–4 (–10) mm; **Fl** geminate, campanulate, (34–) 38–43 mm; **Tep** yellowish-green outside, dark reddish inside, tube 4–6 × 4–6 (–10) mm, lobes oblong, 17–20 × 4–6 (–10) mm, inner ones keeled, outer ones larger; **Fil** (30–) 35–40 mm, red, inserted in the mouth of the tube; **Anth** 15–20 mm, reddish; **Ov** cylindrical, 16–20 × 4–6 mm, neck 2–4 mm, constricted; **Sty** 40–50 mm, yellowish; **Fr** obovoid, 24–25 × 12–16 mm; **Se** 5–6.5 × 3–4 mm, with inconspicuous wing, black.

Previously placed in the synonymy of *A. kerchovei* (Gentry 1982: 149), but recently re-established as a species of its own (García-Mendoza 2010, García-Mendoza 2011a, Govaerts 2014+). The species differs from *A. kerchovei* in its larger number of shorter, relatively broader, broadly lanceolate to lanceolate leaves per rosette, the lack of teeth in the uppermost 5–15 (–35) cm of the margins, its more closely placed teeth, its oblong tepals, and its obovoid capsules and larger seeds. Furthermore, *A. convallis* occurs at higher altitudes mainly on igneous soils (García-Mendoza 2011a). This author also provides a new record for Puebla. Smith & al. (2018b) designated the lectotype cited above.

**A. cundinamarcensis** A. Berger (Agaven, 222, 1915). **Type**: Colombia, Cundinamarca (*Wercklé* s.n. [not indicated]). — **Lit**: Bernal & al. (2015: 794). **Dist**: Colombia (Cundinamarca: Río Cuja valley S of Bogotá); ±1250 m. **I**: Hochstätter (2015: VII: 59).

[2v] **Ros** solitary, not suckering; **L** very thick above the base but only 15 cm broad, straightly spreading, then curved upwards and rapidly becoming broader, above the middle 45 cm broad and then again curved outwards, but the last 15 cm again curved upwards, 200 × 45 cm, lead-grey on yellowish-green base colour; **marginal teeth** flat and broad, nearly blunt, very short, hardly pungent; **terminal Sp** rather short; **Inf** paniculate, sparingly bulbiferous, not further described; **Fl**, **Fr** and **Se** not described.

Possibly first mentioned by Wercklé (1907: 122) as *Agave* "vom westlichen Cundinamarca", and still insufficiently known. Plants studied by J. Etter and M. Kristen in March 2019 near the type locality of *A. cundinamarcensis* largely match the protologue and appear to represent the true species. This and the second species from Colombia, *A. wallisii*, were both placed in his Reihe *Columbianae* by Berger (1915: 222), which he regarded as possibly closest to the *Caribaeae*. Neither of these 2 species appears close to the geographically adjacent Colombian-Venezuelan *A. cocui* from Sect. *Viviparae*. Xhonneux (2004), Greulich (2012b), and Hochstätter (2015: VII: 59) show plants placed here from habitats

**Fig. 19** *Agave cupreata*  
(Martinez & Eggli 188b:  
Mexico; Guerrero, between  
Mazatlán and  
Chilpancingo, 1350 m).  
(Copyright: U. Eggli)

W and N of Bogotá and variegated plants with broad yellow margins cultivated at Bogotá and in Europe, which differ clearly from the protologue in having smaller, less curved, green leaves much less broadened in the middle. The variegated plants were given the cultivar name ‘Condor’. According to P. van der Meer (pers. comm. Nov. 2018/Feb. 2019), these plants, including the variegated ones, are misnamed and belong to an undescribed species provisionally named “*A. bogotensis*”.

The variegated plant may be the same as the medium-sized plant with dark green leaves with broad yellow margins cultivated at Bogotá reported earlier by Wercklé (Berger 1915: 222). Wercklé (in Berger 1915) and P. van der Meer (pers. comm. Feb. 2019) both report further undescribed species from Colombia.

**A. cupreata** Trelease & A. Berger (Agaven, 197, 1915). **Type** [lecto]: Mexico, Michoacán/Guerrero (*Langlassé* 867 [B, GH, K, MEXU, MPU, P, US]). — **Lit:** Gentry (1982: 335–337, ill.). **Distr:** Mexico (E Michoacán, Guerrero); mountain slopes, dry hills and rocky ledges, in tropical dry and oak forests and grasslands, 1220–2100 m; flowers November to March. **I:** García-Mendoza (2002: 183); Smith (2002: 225); Heller (2006: 77); Etter & Kristen (2007b: 178); Richter (2011: 48, 73); Pilbeam (2013: 65); Greulich (2014a: 56). – Fig. 19.

[2d] Caulescent, **Ros** openly spreading, 0.8–1.6 m Ø, solitary; **L** broadly lanceolate or ovate, thickly fleshy, strongly narrowed at the base, flat to slightly concave above, 40–80 × 18–20 cm, bright shiny green, with conspicuous patterns from the central bud, margins deeply crenate-mamillate; **marginal teeth** straight to curved, strongly flattened, dimorphic, larger teeth 10–15 mm on distinct prominences, 30–60 mm apart, with smaller intermittent teeth of varying sizes, copper-coloured to grey; **terminal Sp** slender, sinuous, openly grooved above, 30–50 mm, light brown to greyish, with a sharp border decurrent to the upper teeth; **Inf** 4–7 m, paniculate, fertile part rather broad, part-**Inf** lax diffuse ‘umbels’, 14–25 in the upper ½ of the inflorescence, branches with dark small bracts; **Fl** 55–60 mm; **Tep** brown-red in bud, at anthesis orange-yellow, tube broadly funnel-shaped, 6–7 × 14–15 mm, lobes erect, linear-lanceolate, acute, subequal, outer 20–21 mm, apex rust-coloured, broader and thicker than the inner, inner with narrow keel and thin involute margins; **Fil** thickened towards the base, 35–40 mm, inserted at mid-tube; **Anth** excentric, curved, 23–24 mm, yellow; **Ov** fusiform, knobby, grooved, thick-walled, 30–35 mm, olive-green, neck constricted, doubly 3-grooved; **Sty** hardly longer than the tepals; **Sti** capitate; **Fr** and **Se** unknown. — **Cytology:** 2n = 60, 120, 150, 180 (Palomino & al. 2012, Gomez-Rodriguez & al. 2013).

A beautiful plant from the Río Balsas basin, distinguished by the broad, shiny green leaves with tall marginal prominences and conspicuous patterns from the central bud, and brightly copper-coloured marginal teeth (Gentry 1982: 335). Material of the type collection is present in several herbaria, and Gentry (1982: 352) lists the specimen at B as “holotype”, which is interpreted as unintentional lectotypification. See also under *A. potatorum*.

A morphological characterization of populations in Guerrero is provided by Avendaño-Arrazate & al. (2015), and a study of wild populations in Michoacán by Martínez Castro & al. (2015). *A. cupreata* regenerates successfully by seed in different habitats, but the population density is reduced by cattle trampling and grazing on seedlings and floral stalks (Martin & al. 2011). Martínez-Palacios & al. (2011) studied the genetic diversity and its implications for conservation. The continued extraction of reproductive individuals from wild populations does not produce a decline in genetic diversity in 5 studied populations (Aguirre-Dugua & Eguiarte 2013). The species (vernacular name “Agave papalote”) is locally semi-domesticated with only sexual reproduction, and used for mescal production (Illsley & al. 2007). Molecular populational data do not clearly separate *A. cupreata* from *A. potatorum*, and both are seen to represent one species only with two lineages: One in lower areas of the Balsas basin (*A. cupreata*), and another one in the highest forests and open areas (*A. potatorum*) (Eguiarte & al. 2013: 495–496).

**A. dasyliroides** Jacobi & C. D. Bouché (Hamburg. Gart.- & Blumenzeit. 21: 344, 1865). **Type** [neo]: Cult. BG Berlin (*Anonymous* s.n. [B]). — **Lit**: Baker (1877b: 556–557, with ill.); Berger (1915: 83–85); Standley & Steyermark (1952: 110–111); Gentry (1982: 237–240, with ill.); García-Mendoza (2003: with ill.); Thiede (2014a); Thiede (2017a). **Distr**: Mexico (Morelos, México); igneous rock cliffs on mountain slopes, in mixed pine and hardwood forests, 1500–2200 m; flowers in December. **I**: Curtis’s Bot. Mag. 94: t. 5716, 1868; Kemble (2002); Heller (2006: 78); Richter (2011:

36, 58); Pilbeam (2013: 66–67); Hochstätter (2015: VIII: 6).

**Incl.** *Agave dealbata* E. Morren ex K. Koch (1862); **incl.** *Agave dealbata* Lemaire ex Jacobi (1865) (*nom. illeg.*, ICN Art. 53.1)  $\equiv$  *Agave dasyliroides* var. *dealbata* (Lemaire ex Jacobi) A. Terracciano (1885); **incl.** *Agave dealbata* var. *nana* K. Koch (1869) (*nom. inval.*, ICN Art. 35.1); **incl.** *Agave dealbata* [?] *angustifolia* Hort. (1871) (*nom. inval.*, ICN Art. 38.1a); **incl.** *Agave dealbata* [?] *compacta* Hort. (1871) (*nom. inval.*, ICN Art. 38.1a); **incl.** *Agave dealbata* [?] *compacta angustifolia* Hort. (1871) (*nom. inval.*, ICN Art. 24.2, 38.1a); **incl.** *Agave intrepida* Greenman (1899).

[1a] **Ros** symmetrical, 0.3–0.5  $\times$  0.6–1 m, generally solitary; **L** 70–100, linear-lanceolate, straightly spreading, pliable, relatively thin, scarcely succulent, flat above, mostly 40–60  $\times$  2–3 cm, glaucous-green, smoothly striate below and above, margins 1 mm wide, pale yellowish-white, minutely serrulate; **marginal teeth** none; **terminal Sp** acicular, rounded below, flat near the base above, 5–15 mm, reddish-brown; **Inf** 1.5–2 m, ‘spicate’, arching, peduncle greenish to pale reddish, with conspicuous greenish to pale reddish persistent **Bra** 10–15 cm long, fertile part in the upper  $\frac{1}{3}$ – $\frac{1}{2}$  of the inflorescence, **part-Inf** with 1–4 flowers; **Fl** 26–35 mm, persistent after anthesis; **Tep** pale green to greenish-yellow, tube funnel-shaped, 8–12  $\times$  8–12 mm, shallowly grooved below the lobe sinuses, lobes spreading, ovate to oblong, mucronate, equal, 9–11  $\times$  6–7 mm, sometimes with dark midstripe, the outer flat, the inner with a broad keel and convergent ribs within; **Fil** 35–50 mm, whitish-green to pink, inserted at mid-tube; **Anth** centrally affixed, 12–15 mm, yellow to brownish, persistent; **Ov** linear-tapered, 3-angulate, truncate at the base, 9–12 mm, neckless intruding the tepal tube; **Sty** whitish, sometimes pale reddish apically; **Fr** ovoid,  $\pm 20 \times 10$  mm, without beak, pale grey to brown; **Se** 4  $\times$  3 mm.

The name *A. dealbata* is commonly ascribed to Jacobi (who used it in the same publication where *A. dasyliroides* was described 1865), but it was in fact first used by K. Koch in 1862. Because of priority, it would displace the universally used

name *A. dasylirioides*, and a conservation proposal is envisaged to avoid this (Thiede 2014a). *A. dealbata* var. *nana* is a long-forgotten name for a small-growing form.

The species is best known from Morelos esp. around Cuernavaca, but was recently also collected in the State of México (García-Mendoza 2003, Thiede 2014a). Gentry (1982: 249) cited one collection from San Luis Potosí (*Rzedowski* 7128a), but this most probably belongs to *A. graciellae* (Galván & Zamudio 2013). Plants in habitat near Yosondua in Oaxaca depicted as “*A. dasylirioides*” by Ullrich (1990f) and Polka (2006) and a cultivated flowering plant depicted by Brand (2012) belong to the close relative *A. kavandivi* (see there for differences). See also the comment for *A. petrophila*.

The type of *A. dasylirioides* was erroneously said to have been collected in Guatemala. Gentry (1982: 241) assumed this species to hold a very basal position in the genus based on its ‘primitive’ (plesiomorphic) features (leaves serrulate and scarcely succulent, inflorescences relatively simple, ovary incompletely inferior, tepals all equal, lobes nearly of equal length), and this assumption is principally confirmed by molecular data insofar as Sect. *Juncineae* (as Group *Striatae*) represents the sister group to the remainder of the genus (Bogler & Simpson 1996, Bogler & al. 2006, Gil-Vega & al. 2007; see also introduction to the genus).

**A. datylio** Simon ex F. A. C. Weber (Bull. Mus. Hist. Nat. (Paris) 8: 224, 1902). **Type** [neo]: Mexico, Baja California (*Gentry & Arguelles* 11200 [US, ARIZ, MEXU, MICH]). — **Lit**: Trelease (1912b: 45, 61–62, tt. 68–71, also as *A. vexans*); Berger (1915: 259–260, also as *A. vexans*); Gentry (1978: 97–99, also as var. *vexans*); Gentry (1982: 571–572, also as var. *vexans*); Turner & al. (1995: 49–50, also as var. *vexans*); Webb & Starr (2015: 90–91); all with ill. except Berger. **Distr**: Mexico (C & S Baja California Sur); sandy plains and rocky granitic slopes to 730 m; flowers September to December. **I**: Goldman (1916: t. 111C, as *A. vexans*); Richter (2011); Pilbeam (2013: 68–69); Hochstätter (2015: VII: 37–38, also as ssp. *vexans*).

**Incl.** *Agave vexans* Trelease (1912) ≡ *Agave datylio* var. *vexans* (Trelease) I. M. Johnston (1924) ≡ *Agave datylio* ssp. *vexans* (Trelease) Hochstätter (2015).

[2g] Acaulescent; **Ros** 0.3–1 × 0.6–1.5 m, suckering freely, rhizomes frequently elongate; **L** radiately spreading, lanceolate-linear, nearly straight, rather rigid, rounded below, guttered above, 20–80 × 3–4 cm, green to yellow-green or glaucous-green, young somewhat glaucous, margins nearly straight; **marginal teeth** deltoid, mostly recurved, triangular, flattened, rather blunt, mostly 2–5 mm, dark brown, 15–60 mm apart, more closely spaced below, often on broad or lenticular bases; **terminal Sp** conical to subulate, scarcely or flatly grooved above, 20–40 × 3–6 mm, dark brown to greyish, shortly decurrent; **Inf** 1.2–5 m, paniculate, part-**Inf** small ‘umbels’, 8–15 in the upper ½ of the inflorescence; **Ped** < 5 mm; **Fl** 40–55 mm; **Top** greenish-yellow, tube funnel-shaped, 5–15 × 3–4 mm, lobes erect to ascending, 12–20 × 3–4 mm; **Fil** 25–45 mm, inserted 4–6 mm above the tube base; **Anth** 15–30 mm, yellow; **Ov** fusiform or flask-shaped, 20–30 mm, glaucous; **Sty** shorter than the filaments; **Sti** capitate; **Fr** (broadly) oblong to pear-shaped, 35–45 × 15–20 mm, shortly stipitate, conspicuously beaked; **Se** 6–7 × 5–6 mm. — **Cytology**: 2n = 87, 90, 174 (3×, 6×; Cave (1964), Simpson & al. (2011: as *A. vexans*)).

Widely scattered in the Cape region of Baja California Sur. This is the only species of Sect. *Rigidae* (as Group) in Baja California, and is without close relatives (Gentry 1982). It belongs to the “sword-leaved group” within Sect. *Rigidae* whose geographically nearest member is *A. aktites* from the opposite Sonoran-Sinaloa coast. *A. aktites* differs clearly by narrower bluish leaves with sharply cuspid teeth, and larger flowers with a deep bulging tube (Gentry 1982). Var. *vexans* was differentiated by Gentry (1978) and Berger (1915) by its smaller rosettes and leaves, but Webb & Starr (2015) consider the size differences as resulting from edaphic conditions and refer it to the synonymy. The triploid chromosome number of the former var. *vexans* suggests that parts of it may have arisen as hybrid between a di- and a tetraploid parent.

**A. debilis** A. Berger (Agaven, 33, 1915). **Type** [lecto]: Mexico, Oaxaca (*Pringle* 4745 [US, BM, BR, CM, ENCB, G, GH, JE, LE, M, MEXU, MSC, NDG, P, S, VT]). — **Lit:** Rose (1903c: 19); Verhoek-Williams (1975: 248–254); Piña Luján (1985: 86–89); McVaugh (1989: 233); Castillejos-Cruz (2009: [238]–[247], with ill.); García-Mendoza (2011a: 79–79, 81); all as *Manfreda pringlei*. **Distr:** Mexico (Nayarit, Jalisco, Hidalgo, Michoacán, México, D.F., Tlaxcala, Morelos, Guerrero, Puebla, Veracruz, Oaxaca); moist forests or pine-oak ericaceous woods, in cloud, pine-oak, pine, oak, thorn and tropical deciduous forests, desert scrub and grasslands, (1000–) 1500–3000 m; flowers mid-July to November. **I:** Hochstätter (2016: I: 37, as *Manfreda pringlei*).

≡ *Manfreda pringlei* Rose (1903) ≡ *Polianthes debilis* (A. Berger) Shinnery (1966); **incl.** *Manfreda angustifolia* Rose in sched. (s.a.) (*nom. inval.*, ICN Art. 29.1).

[3a3] Herbaceous, of moderate size (for Subgen. *Manfreda*), reproducing vegetatively by stoloniferous horizontal rhizomes with plantlets at the tips; corm 3–5 × (1–) 1.5–2.5 cm, bulb cylindrical to ovoid, 3.5–7.5 × 1.8–3.2 (–6) cm, covered with membranous dry leaf bases fraying into fine fibres at the tip, (4–) 6–11 cm long; **R** half-fleshy, fibrous, vertical; **L** drought-deciduous, (2–) 4–10, erect-spreading, linear to linear-lanceolate, narrowed towards the base, somewhat succulent, slightly channelled, occasionally gently undulate, tip acute to acuminate, with medium-sized point, smooth, (12–) 24–45 (–80) × (0.5–) 1–2.7 cm, dark brown to shining green, sometimes with purple dots, at times red-speckled on the lower face near the base, without prominent veins, margins narrow, hyaline, sometimes streaked with purplish-red, papillate to erose-denticulate, usually rough to the touch; **Inf** 97–200 cm, ‘spicate’, peduncle greenish with purple tinge, peduncular **Bra** 6–12, similar to the leaves, fertile part (10–) 25–33 cm; **Fl** (5–) 10–25, sessile, diffuse to ascending, tubular, congested, nearly erect, 30–40 mm, slightly curved at the junction of ovary and tepal tube; **Tep** tube cylindrical, slightly widened towards the throat, tip cucullate, with a tuft of short hairs, 9–21 × (3–) 5–6 (in the middle) mm, lobes oblong, revolute,

8–16 × 2–4 (–7) mm, green-yellowish to reddish with purple tinge; **Fil** 26–45 (–54) mm, exceeding the tube for 22–42 (–50) mm, inserted slightly unequally in the middle of the tube, greenish-yellow to greenish-red; **Anth** 11–14 mm, reddish to yellowish-green; **Ov** cylindrical, (8–) 9–11 (–12) × 3–5 mm, not constricted, apex prolonged into the tepal tube for 1 mm; **Sty** 40–60 mm, exerted for 30–48 mm; **Sti** clavate, trigonous, shallowly furrowed, yellowish-green with small purple dots; **Fr** ellipsoid to subcylindrical, 15–20 × 12–17 mm; **Se** deltoid, plane-concave, with narrow margin, 3–4 × 4–5 mm.

This species shares many floral and fruit characters with *A. guttata*, but is nevertheless easily distinguished by its longer, narrower and more pliable and herbaceous leaves and its distribution. It may represent the moist-forest counterpart of the more xeromorphic *A. guttata* (Verhoek-Williams 1975: 252–253, as *Manfreda*). *A. debilis* is morphologically also similar to the recently published *A. verhoekiae* (for differences see there).

**A. decipiens** Baker (Bull. Misc. Inform. Kew 1892: 183, 1892). **Type** [lecto]: USA, Florida (*Dodge* s.n. [K, BUS, CICY?, US]). — **Lit:** Berger (1915: 242–243, with ill.); Gentry (1982: 573–574, with ill.); Zona (2002: with ill.); Reveal & Hodgson (2002); Franck (2012: 6–7, with ill.); Rubal Lobo & al. (2013: with ill.). **Distr:** USA (S Florida); coastal sands, sandy soil in hammocks, at sea-level; flowers November/December to March. **I:** Curtis’s Bot. Mag. 122: t. 7477, 1896, as *A. laxifolia*; Heller (2006: 79, 80); Richter (2011: 128); Pilbeam (2013: 70); Hochstätter (2015: VII: 39); Moore (2016: 263).

**Incl.** *Agave laxifolia* Baker (1896); **incl.** *Agave spiralis* Brandegees ex A. Berger (1912).

[2g] Arborescent, trunk 1–3 (–4) m, very broad through bulging leaf bases, frequently suckering; **Ros** extending down for some distance from the stem tip, 1–1.5 × 1.5–2 m, not caespitose; **L** 36–72, linear-lanceolate, rigidly spreading to recurving, fleshy, narrowed at the thickened base, long-acuminate, convex below towards the base, concave above towards the apex, (24–) 70–100 (–200) × (1.3–) 7–10 cm, bright green or yellowish-green, without imprints from the central

bud, margins slightly wavy, repand; **marginal teeth** 2–3.6 mm at mid-leaf, curved upwards or downwards, dark brown, 10–20 mm apart, on low prominences, the slender tips upcurving, often with some smaller intermittent teeth, intervening margins not continuously horny; **terminal Sp** conical, without groove, 10–29 mm, brown or brownish-black, decurrent or not; **Inf** 3–5 m, paniculate, peduncle with caducous **Bra**; part-**Inf** ascending, 8–18 in the upper ½ of the inflorescence, with ±15–23 flowers, to 45 cm, often bulbiferous; **Ped** 5–11 mm; **Fl** erect, 60–80 mm, foetid-scented; **Tep** greenish-yellow, tube funnel-shaped, 6–13 × 4–6 mm, lobes incurved, tips cucullate, with a tuft of short white hairs, subequal, 17–26 mm, greenish-yellow, outer linear, drying reflexed on the tube; **St** long-exserted; **Fil** erect, terete, 27–47 mm, yellow, inserted at 2 levels at or slightly above mid-tube; **Anth** 13–25 mm, yellow; **Ov** large and thick, 22–43 mm, neckless; **Fr** ellipsoid to oblong, 35–50 mm, apex beaked, shortly stipitate; **Se** unknown. — **Cytology**: 2n = 120, 150, 160, 180, 190 (Banerjee & Sharma 1989, Reveal & Hodgson 2002, Simpson & al. 2011).

Geographically isolated from the remainder of the genus (except *A. neglecta*). The taxon is most probably of cultivated origin. It was reported to occur at old Indian village sites in 1933 and may well represent an old pre-Columbian food or fibre plant, comparable to *A. delamateri*. The different chromosome numbers suggest a prolonged human propagation and probable hybrid origin (Reveal & Hodgson 2002). *A. decipiens* is possibly derived from *A. angustifolia*, from which it mainly differs in its obvious stem 1.5 m long or more (Gentry 1982, Zona 2002), but individuals of the latter with distinct stems are found on the Yucatán peninsula (Cruz-Ramos & al. 1985, Zona 2002). Plants from the Yucatán peninsula placed here belong to *A. angustifolia* (Gentry 1982, Zona 2002: as *A. vivipara*), Further differences from *A. angustifolia* are the longer ovaries and shorter anthers of *A. decipiens* (Zona 2002). Gentry's "lectotypification" (1982: 573) represents a neotypification and is superfluous, since the type material is extant (Zona 2002). Franck (2012) designated a lectotype at K from the 3 extant specimens of the type collection. Rubal Lobo &

al. (2013) and López-Pujol & al. (2015b): report the species as naturalized in Prov. Cádiz, Spain. The report of the species as naturalized in S Africa (Smith & Steyn 1999) actually refers to *A. angustifolia* (Smith & al. 2008: as *A. vivipara*). Introduced ants exploit the nectar of plants cultivated in Florida (Koptur & Truong 1998).

**A. delamateri** W. C. Hodgson & Slauson (Hazeltonia 3: 130–140, ill., 1995). **Type**: USA, Arizona (Hodgson 5478 [DES, ASU]). — **Lit**: Hodgson (1999a: 5, 14, 19, with ill.); Reveal & Hodgson (2002); Parker & al. (2007); Parker (2018a: 22, 24, with ill.). **Distr**: USA (C Arizona); gravelly places in desert scrub, rarely in chaparral or pinyon-juniper woodlands, 725–1555 m; flowers late June through July. **I**: Pilbeam (2013: 71).

**Incl.** *Agave repanda* Trelease ex Gentry (1982) (*nom. inval.*, ICN Art. 36.1c).

[2h] Acaulescent; **Ros** 0.9–1 × 0.9–1 m, solitary to caespitose, freely suckering; **L** lanceolate or oblanceolate, rigid, erect or erect-ascending, broadest near or just below the middle, acuminate, guttered, apex conspicuously incurved, mostly 50–63 (–74) × 7.5–9 cm, bluish-grey-glaucous with purple-maroon tinge and green cross-banding, margins straight or repand; **marginal teeth** variable, usually reflexed, becoming porrect near the leaf base, 3.5–5 mm, 10–30 mm apart, intermittent teeth 1–1.5 mm, (3–) 6–12 mm apart, mostly along the distal ⅓ of the leaf; **terminal Sp** slender, 28–35 (–49) mm, brownish-grey, decurrent for ⅙–⅓ of the leaf length; **Inf** 4.5–6 m, broadly paniculate, open, peduncle with persistent triangular **Bra** 1–5.5 cm long, part-**Inf** widely spaced, horizontal, 12–17 in the upper ⅓–½ of the inflorescence, >10 cm, with 14–20 flowers each; **Fl** erect, long-lived, 47–67 (–70) mm; **Tep** pale cream tinged light green, tube campanulate, 11–16 × 11–16 mm, lobes spreading, unequal, 9–18 mm, apex tinged with maroon, persistent and often leathery during and after anthesis; **St** long-exserted; **Fil** erect, 30–53 mm, yellow, apex tinged with maroon, inserted at a single level ± at mid-tube; **Anth** 11–20 mm, yellow; **Ov** 21–29 mm, neck slightly constricted, 1–3.5 mm; **Sty** cream-coloured, maroon-flecked, becoming more

maroon towards the stigma; **Sti** capitate, 3-lobed, cream-coloured tinged with maroon; **Fr** aborting, never fully developed; **Se** inexistent.

According to the protologue already collected around 1920 by S. D. McKelvey and recognized as distinct by Trelease, who in 1929 used the unpublished name *A. repanda*. It is most closely related to the allopatric *A. fortiflora* and *A. palmeri*, but distinguished esp. by its numerous rhizomatous offsets, easily cut leaves, and 1- (instead of 2-) seriate filaments. *A. delamateri* was first known only from about 90 sites, always in association with Mogollon or Salado settlement features, and probably represents a cultivar derived from *A. palmeri* or a closely related taxon by pre-Columbian people. Later field studies yielded more than 200 sites so that *A. delamateri* is the most common one among the pre-Columbian cultivars from Arizona (Parker 2018a). It hybridizes with *A. chrysantha* (Hodgson 1999a, Reveal & Hodgson 2002). Parker & al. (2007) found a low level of genetic diversity, relating to its continued vegetative propagation from few clones only (see also under *A. murpheyi*). *A. phillipsiana*, another pre-Columbian cultivar species in Arizona, differs in having longer leaves and flowers, a longer tepal tube, and longer tepal lobes (Klopper & al. 2010: 63). For further pre-Columbian cultivar species in Arizona, see also under *A. verdensis*.

**A. deserti** Engelm (Trans. Acad. Sci. St. Louis 3: 310–311, 370, 1875). **Type**: not established. — **Lit**: Trelease (1912b: 45, 52–53, tt. 41–42); Berger (1915: 262–263); Gentry (1978: 15–25, t. 1, with ills.); Gentry (1982: 376–385, with ills.); Turner & al. (1995: 50–54, with ills.); Hodgson (1999a: 5–6); Reveal & Hodgson (2002); Starr (2012: 84–89, with ills.); Webb & Starr (2015: 81–82, with ills.). **Distr**: SW USA, NW Mexico.

The protologue cites specimens from Hitchcock and Palmer (= syntypes; specimens located at F, GH, MO [2 sheets and printed material], NY, PH); Gentry (1978: 16) adds that both were collected on Rancho San Felipe, San Diego County. No attempt for a formal lectotypification seems to have been made so far.

A large and variable complex with hard-to-define limits, difficult to separate from *A. cerulata*, and also close to *A. subsimplex* (Gentry 1982: 405) (see there for differences). Moreover, also the recognized subspecies are not always clearly separable on morphological grounds, and a molecular study of 14 samples embracing all 3 subspecies did not find a clear correlation with Gentry's infraspecific concept as used here (Navarro-Quezada & al. 2003). Gentry's (1982) ssp. *pringlei* is here recognized at species rank (as *A. pringlei*) following Webb & Starr (2015).

**A. deserti** ssp. **deserti** — **Lit**: Trelease (1912b: 45, 52–53, tt. 41–42); Berger (1915: 262–263); Gentry (1978: 15–25, t. 1, with ills.); Gentry (1982: 376–380, with ills.); Hodgson (1999a: 5–6, as *A. deserti*); Reveal & Hodgson (2002:

**Fig. 20** *Agave deserti* ssp. *deserti* (Eggl s.n.: USA; California, Anza Borrego State Park). (Copyright: U. Eggl)

**Fig. 21** *Agave deserti* ssp. *deserti* (Eggl s.n.: USA; California, Anza Borrego State Park). (Copyright: U. Eggl)

with ills., as var.); Starr (2012: 84–89, ills.); Webb & Starr (2015: 77, 81–82, with ill.). **Distr:** USA (S California), Mexico (N & C Baja California); sandy to gravelly or rocky places, in desert scrub and pinyon-juniper woodlands, 500–1500 m; flowers mainly April to July, also November to January and in September. **I:** Irish & Irish (2000: t. 14); Heller (2006: 30); Richter (2011: 80, 125); Pilbeam (2013: 72); Hochstätter (2015: V: 9). – Figs. 20 and 21.

**Incl.** *Agave deserti* Orcutt (1883) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave consociata* Trelease (1912).

[2i] **Ros** mostly 30–70 × 40–80 cm, rather open, sparingly or prolifically suckering; **L** variable, ascending, narrowly triangular-lanceolate to lanceolate to linear-lanceolate, thick, rigid, scarcely narrowed above the broad clasping convex base, acuminate to long-acuminate, deeply guttered towards the apex, mostly 25–70 × 4.5–10 cm, 4–7 × as long as broad, greyish-white, grey, blue-glaucous to (yellowish-) green, often lightly cross-zoned, margins usually straight but sometimes undulate or crenate; **marginal teeth** usually regularly spaced, loosely to firmly attached, variously curved or reflexed, smaller teeth 2–3 mm, longer teeth 5–10 mm, grey, mostly 10–30 mm apart, slender-tipped, brown to pruinose-grey, sometimes with a brown ring at the base; **terminal Sp** subulate to acicular, openly grooved, strong, generally

20–40 mm, light brown to greyish, decurrent to the 1. or 2. tooth to mid-blade; **Inf** 2–6 m, paniculate, peduncle slender to thick, green to glaucous, with scarious triangular **Bra** 8–15 cm long, fertile part usually narrowly to somewhat broadly paniculate, part-**Inf** short, small, 6–15 in the upper 1/5–1/4 of the inflorescence; **Fl** 30–60 mm; **Te** yellow, tube shallow, angular, openly funnel-shaped, 3–10 × 9–15 mm, pale green to yellow, lined with a thick nectariferous disk, lobes (broadly) linear, erect to spreading, rounded and abruptly hooked inwards at the apex, equal, 13–20 × 4–6.5 mm, (light) yellow, wilting at anthesis; **Fil** 25–42 mm, unequally inserted 2.75–3.75 mm above the tube base, or subequally at the base of the lobes, pale yellow; **Anth** 13–21 mm, yellow; **Ov** 15–30 (–38) mm, greenish, neck slightly narrowed to constricted, 4–6 mm, yellow to pale green; **Sty** 24–29 mm, pale yellow; **Fr** ovoid to oblong or obovoid, mostly 35–55 × 12–20 mm, shortly stipitate, apex beaked or shortly rounded to rostrate; **Se** 5–6 × 4–4.5 mm, black. — **Cytology:** 2n = 59, 60, 118 (Cave 1964, Simpson & al. 2011).

Field experiments (Jordan & Nobel 1979) showed that successful seedling establishment takes only place in 1 out of 17 years. The length of the first drought period is the limiting factor for establishment, with water-stress in the seedling stage as the single most important factor. For a

**Fig. 22** *Agave deserti* ssp. *simplex* (Etter & Kristen 250: USA; Arizona, Maricopa County, Saddle Mountain, 350 m). (Copyright: J. Etter & M. Kristen)

summary of many further ecological and ecophysiological studies on *A. deserti* see Nobel (1988).

**A. deserti** ssp. **simplex** Gentry (Occas. Pap. Calif. Acad. Sci. 130: 22, ill. (pp. 23–24), 1978). **Type:** USA, Arizona (Gentry 23404 [US, ARIZ, ASU, DES, MEXU]). — **Lit:** Gentry (1982: 382–385, with ill.); Hodgson (1999a: 6); Reveal & Hodgson (2002: as var.); Starr (2012: 84–89, with ill.); Webb & Starr (2015: 77, 81–82, with ill.); Parker (2017: 256, 260, with ill., as var.). **Distr:** USA (SW Arizona, SE California), Mexico (NW Sonora); sandy to gravelly or rocky places, in desert scrub and pinyon-juniper woodlands, 300–1500 m; flowers mainly May and June, also in November and February. **I:** Heller (2006: 80); Pilbeam (2013: 74); Ettelt (2014: 123); Hochstätter (2015: V: 11). — Fig. 22.

≡ *Agave deserti* var. *simplex* (Gentry) W. C. Hodgson & Reveal (2001).

[2i] Differs from ssp. *deserti*: **Ros** usually solitary, rarely with 1–3 offsets; **L** lanceolate, moderately acuminate, light green to light glaucous-grey, margins repand to crenate; **marginal teeth** friable; **Inf** 4–6 m; part-**Inf** in the upper 1/3 of the inflorescence. — **Cytology:** 2n = 60 (Reveal & Hodgson 2002).

Ssp. *simplex* refers to the N and E populations of the species from hot, dry and low elevations, characterized by a predominantly solitary habit (Gentry 1982, Parker 2017). It hybridizes with *A. schottii* ssp. *schottii*, and possibly with *A.*

*mckelveyana* (Hodgson 1999a, Reveal & Hodgson 2002). It is esp. well-suited for hot and dry gardens in the SW USA (Parker 2017).

**A. desmetiana** Jacobi (Hamburg. Gart.- & Blumenzeit. 22: 217, fig. 32, 1866). **Type** [neo]: Mexico, Sinaloa (Gentry 11569 [US, ARIZ, MEXU]). — **Lit:** Berger (1915: 234, as *A. miradorensis*); Gentry (1972: 94–99, with ill.); Gentry (1982: 622–624, with ill.); Reveal & Hodgson (2002); Franck (2012: 7–8, with ill.). **Distr:** Cultivated only; flowers September to November. **I:** Irish & Irish (2000: tt. 15–16); Pilbeam (2013: 75); Hochstätter (2015: VII: 40, as *A. demeesteriana*); Moore (2016: 267, 268).

**Incl.** *Agave demeesteriana* Jacobi (1866); **incl.** *Agave regeliana* Jacobi (1866) ≡ *Agave miradorensis* var. *regeliana* (Jacobi) A. Terracciano (1885) (*incorrect name*, ICN Art. 11.4); **incl.** *Agave ananassoides* Jacobi (1868); **incl.** *Agave miradorensis* Jacobi (1868).

[2c] Stems short, trunk <0.5 m, commonly suckering in early years; **Ros** 0.7–0.9 (–1.2) × 0.7–0.9 (–1.8) m; **L** linear-lanceolate, spreading and arching, openly ascending, brittle, firm, abruptly or gradually narrowed towards the base, guttered, 50–90 (–105) × 7–13 cm, dark to glaucous-green, not cross-zoned, margins straight, smooth, finely and sparsely fibrous, without distinct colouration; **marginal teeth** typically none, or small, regular, 1–2 mm, chestnut-brown, 10 to

>20 mm apart or few and irregularly spaced; **terminal Sp** subulate, shortly and broadly grooved above, 20–30 mm, dark brown to reddish-brown; **Inf** 2.5–3 m, paniculate, peduncle with persistent triangular **Bra** 0.5–2 cm long, fertile part long, narrow and compact, often bulbiferous, part-**Inf** ascending, congested, 20–36 in the upper  $\frac{1}{2}$ – $\frac{2}{3}$  of the inflorescence, with 15–21 flowers, >10 cm long; **Fl** erect, 40–60 mm; **Tep** green in bud, pale yellow at anthesis, drying ferruginous, tube salverform, 10–12 × 14–17 mm, distinctly flanged inside below the inner tepals, deeply grooved and ridged on the outside, lobes erect, nearly equal, 13–15 mm; **OTep** 1 mm longer; **ITep** sharply involute; **St** long-exserted; **Fil** erect, 30–40 mm, yellow, inserted near the mouth of the tube; **Anth** centric, 13–26 mm, yellow; **Ov** 15–25 mm, 6-grooved in the upper part, shortly stipitate, neck 1–3 mm, not constricted; **Fr** and **Se** unknown. — **Cytology**:  $2n = 60$  (Reveal & Hodgson 2002).

Distinguished by its smooth unarmed arching leaves and the short compact inflorescences with small flowers with a very short ovary and a broad tube (Gentry 1982: 623). According to Ullrich (1990d), it was originally introduced from Cuba as *A. anomala*, where it may have originated (see also under that species). Trelease (1920: 121) assumed an origin from El Mirador (Huatusco, Veracruz), based on the epithet of the synonymous *A. miradorensis*. Gentry (1972) and Gentry (1982) found it cultivated in Sonora and Sinaloa.

Its systematic position is unclear, since it does not fit well into any section; Gentry's placement in Sect. *Sisalanae* (as Group) is regarded as artificial by Ullrich (1990d). Here, Reveal & Hodgson (2002) and Govaerts (2014+) are followed who regard the species as a sterile, possibly ancient cultivar possibly derived from *A. sisalana*/*A. kewensis* or *A. kewensis*, respectively. It is consequently placed in Sect. *Sisalanae*. Govaerts (2014+) considers the earlier *A. demeesteriana* as correct name for the species. A conservation proposal is thus necessary to retain the established name *A. desmetiana*. The epithet honours the Belgian nurseryman De Smet but is frequently misspelled 'desmettiana'. The species is naturalized in Florida (Franck 2012). The plant depicted as naturalized in Spain (Guillot Ortiz &

Meer 2009a) has larger, cross-banded leaves and may merely represent *A. sisalana*. 'Joe Hoak' is a variegated cultivar traded in the USA (Starr 2014: 222, with ill.). Guillot Ortiz & Meer (2016d) discuss variegated and normal-leaved cultivars cultivated in Spain. Variegated plants are also shown by Moore (2016).

**A. difformis** A. Berger (Agaven, 95–96, 1915).

**Type**: Ex cult. (Berger s.n. [US, K]). — **Lit**: Gentry (1982: 135–138); Eguiarte & Scheinvar (2008: 44–47); both with ill.; Trejo-Salazar & al. (2015: pollination); López-Pujol & al. (2016). **Distr**: Mexico (W-C San Luis Potosí, N-C Querétaro, Hidalgo); coarse limestone rocky soils, in desert and submontane scrub on the arid side of the Sierra Madre Oriental, 1560–2100 m; flowers May to August; neophyte in Spain. **I**: Curtis's Bot. Mag. 139: t. 8481, 1912, as *A. haynaldii*; Heller (2006: 82); Richter (2011: 68); Pilbeam (2013: 76); Hochstätter (2015: IX: 82); Greulich (2016c: 151).

**Incl.** *Agave haynaldii* Todaro (1878).

[lg] Stems short; **Ros** open, rather vigorous, variable, 0.7–1 × 1–1.5 m, freely suckering; **L** 25–50, polymorphic, straight or falcate or sinuous, stiffly ascending, thickly convex below, concave above, 50–80 × 4–6 cm, (dark) green to yellow-green, margins straight or repand, firm or detachable, predominantly light grey; **marginal teeth** variable, generally 5–10 mm, dark brown to grey, 20–30 mm apart, rarely double, sometimes with smaller intermittent teeth, or reduced or entirely lacking; **terminal Sp** conical-subulate, stout, with a short open groove above, 15–30 mm, dark brown to grey; **Inf** 3.5–6 m, 'spicate', peduncle waxy-glaucous, with thin, narrow, chartaceous, deflected **Bra**, fertile part slender, in the upper  $\frac{1}{3}$ – $\frac{1}{2}$  of the inflorescence; fertile **Bra** mostly longer than the flowers; **Fl** 30–40 mm; **Tep** light green to yellow and pink, tube flaring, 2.5–3.5 mm, lobes mostly erect, equal, sharply hooded at the apex, 15–18 × 3–4 mm, pale yellow or tinged pink, clasping the filaments at anthesis; **Fil** 35–45 mm, pale green (Gentry: pale to pinkish), inserted on the rim of the tube; **Anth** excentric, 15–18 mm, yellow or bronze-coloured; **Ov** 15–21 mm, waxy green, neck short; **Sty** slender, pale green, somewhat darker below the

stigma; **Sti** slightly thickened; **Fr** oblong, transversely rugose, 22–26 × 12–15 mm, dark brown, shortly beaked, sessile; **Se** crescent-shaped, 5 × 3 mm, somewhat wavy on the faces, wing low, hilar notch small.

A robust species, within Sect. *Heteracanthae* (as Group *Marginatae*) characterized by its very polymorphic long-ensiform leaves. Some forms resemble *A. lechuguilla* (Gentry 1982: 137). Magallán Hernández & Hernández Sandoval (2001) provide a new record for Querétaro. — The 5 type specimens at US bear 4 different dates and thus represent different gatherings. *A. haynaldii*, if really conspecific, antedates the established name *A. difformis*, and a formal proposal to conserve the established name is necessary.

From 740 flowers produced at average, only 47% develop into fruits. These may have 117 ovules of which only 37% form viable seeds. When the fruits of an inflorescence open, they release about 23,100 viable seeds dispersed by wind. Nocturnal nectar-feeding bats are the most important flower visitors. In the morning, bees, hummingbirds, hymenopterans and bumblebees visit the flowers, and at sunset various hawk-moths. The species shows relatively high levels of genetic diversity with little differentiation among the populations which is possibly generated by high gene flow provided by the pollinators (Eguarte & Scheinvar 2008).

The pollination biology of this and further sympatric species was studied by Rocha & al. (2005) and Trejo-Salazar & al. (2015), recording bats and sphingids as primary pollinators. López-Pujol & al. (2016) report the species as neophyte from Spain.

**A. doctorensis** L. Hernández & Magallán (Brittonia 67(1): 1–3, ill., 2014). **Type:** Mexico, Querétaro (Hernández 6094 [QMEX, ENCB, IEB, MEXU, TEX, XAL]). — **Distr:** Mexico (E-C Querétaro: Sierra del Doctor); on gentle slopes and flatlands on a superficial calcareous substrate, in rosette scrub or in juniper forests, 2400–2600 m; flowers in November (?). **I:** Hochstätter (2015: IX: 28).

[1g × 2a?] **Ros** open, 1–1.2 × 0.8–1 m, surculose; **L** 15–25 (–30), erect, lanceolate to

narrowly elliptic, rigid, smooth, 50–75 (–95) × 4–9.5 cm in the middle, pale green with imprints from the next inner leaves, margins corneous, easily detached, straight, to 1 mm wide, reddish, covered with narrow lines of wax that can be lost with age; **marginal teeth** deltoid or hooked, bases wide, retrorse, brittle, flat, 1–2 (–8) × 1 mm, 15–45 mm apart, abundant close to the base, absent near the leaf tip, with small interstitial teeth, greyish, or occasionally toothless; **terminal Sp** subulate, curved to straight, grooved above, 27–43 mm, slightly decurrent; **Inf** 4.2–4.5 m, ‘racemose-paniculate’, peduncle with broadly acuminate papyraceous to chartaceous **Bra** 17–28 × 2.5–6.5 cm, beige to greenish, spine-tipped, reflexed, fertile part only 12–25% of the total inflorescence height, **part-Inf** 70–80, compact, conical, dorsiventrally flattened, with 6–7 flowers, the lower 7 cm, diminishing to 1.8 cm towards the tip; **Ped** 5–30 mm; **Fl** 42–54 mm; **Top** yellowish-green, tube funnel-shaped, 4–10 × 5–8 mm, lobes oblong to linear, channelled, unequal, 13–23 × 16–25 mm, outer 3–4 mm longer than the inner, margins involute, apex dark brown to reddish, thick, inner lobes cucullate; **Fil** dorsiventrally flattened, 35–45 mm, the outer inserted 5–7 mm from base of the tube, the inner 4–6 mm from the base of the tube; **Anth** 18–24 mm, yellow; **Ov** broadly elliptic, (20–) 24–28 (–33) mm, neck constricted; **Sty** ± as long as the filaments; **Fr** usually oblong, 27–35 × 13–15 mm, beaked, dark brown, perianth persisting almost to maturity; **Se** crescent-shaped to deltoid, 5–6 × 1–2 mm, shiny black.

Placed in Sect. *Heteracanthae* (as Group *Marginatae*) in the protologue and compared with *A. ×glomeruliflora*, which is the name used for a series of natural intersubgeneric hybrids between Subgen. *Littaea* and Subgen. *Agave* with intermediate ‘racemose-paniculate’ inflorescences (see there), as well as with *A. montium-sancticaroli* with similar intermediate inflorescences (and thus supposedly another intersubgeneric hybrid; see there). *A. doctorensis* also has these intermediate ‘racemose-paniculate’ inflorescences and possibly represents the hybrid between the sympatric *A. americana* (Subgen. *Agave*) and *A. funkiana* (Subgen. *Littaea*).

**A. dolichantha** Thiede & Eggli (Kakt. and Sukk. 50(5): 111, 1999). **Type** [syn]: Mexico, Jalisco (*Rose & Hay* 6290 [US, GH, NY, P]). — **Lit**: *Rose* (1903a: 10); *McVaugh* (1989: 253–254); *Cedano & al.* (1995); *Cházaro Basáñez & Machuca Núñez* (1995: with ill.); *García-Mendoza* (2003); *Cházaro Basáñez & al.* (2010b: with ill.); *Machuca Núñez & Cházaro Basáñez* (2015: with ill.); all as *Polianthes longiflora*. **Distr**: Mexico (Jalisco, Michoacán); wet meadows, in ill-drained clayish soils or at disturbed places, in pine/oak or tropical deciduous forests, 1400–2700 m; flowers July to August. **I**: *Feria-Arroyo & al.* (2010: 19); *Castro-Castro & al.* (2016: 721); *Castro-Castro* (2017: 137); all as *Polianthes longiflora*.

≡ *Polianthes longiflora* *Rose* (1903); **incl.** *Polianthes michoacana* *Cedano & al.* (1995) ≡ *Agave michoacana* (*Cedano & al.*) *Thiede & Eggli* (1999).

[3b1] Herbaceous; corm cylindrical, to 5.5 × 2.5 cm, with many spirally arranged, deltoid, white leaf scars; bulb ovoid to oblong, (2–) 3–5 × 1.3–1.8 (–2.5) cm, covered with fibrous dry leaf bases lacerate at the apex; **R** fibrous, white when young, turning brownish-grey with age; **L** (2–) 4–6 (–10), recurved, narrowly oblanceolate to linear, semi-amplexicaul, glabrous, apex acute, (14–) 26–37.5 × (0.2–) 0.4–1.6 cm, green, with purple dots near the base, upper ones appressed to ascending, linear, carinate, broadly acuminate, 12–18.5 × 0.6–1 cm, margins hyaline, papillose or denticulate, rarely entire; **Inf** erect, (14–) 30–70 cm, spike-like, fertile part with 2–5 (–8) floral nodes, internode length decreasing distally; **Ped** none; **Fl** geminate, fragrant, ± (75–) 85–120 mm; **Tep** white, pink, sometimes red with age, buds whitish to rose, tube erect or nearly so in the basal part, narrowly tubular, 2 mm Ø, gradually widening in the distal ½ or ⅓, there funnel-shaped, curved outwards at or above the middle, tube at the base or sometimes whole tube with purple to pink dots, (63–) 70–106 × 2–6 (–8) mm, mouth oblique, lobes (somewhat) extended or arched-reflexed; **OTep** oblong to ovate, attenuate towards the rounded apex, 15–27 × 6 mm; **ITep** lanceolate, fleshy, margins somewhat wavy, apex cucullate, with short white hairs, 12–27 × 3–8 mm; **Fil** filiform, white, 5.6–10 mm, inserted near the

mouth of the tube; **Anth** linear, (7–) 12–17 mm, apex scarcely surpassing the tube; **Ov** cylindrical, 7–10 × 2.5–5 mm; **Sty** filiform, 48–87 (–100) mm, included at anthesis, white; **Sti** 3-lobate, lobes oblong, internally ciliolate; **Fr** globose, (13–) 20–30 × 10–16 mm; **Se** semicircular, 4.4 × 3.1 mm, shiny or dull.

*Machuca Núñez & Cházaro Basáñez* (2015) report 22 populations from 16 municipios in Jalisco, and in addition known from 3 populations in Michoacán. Since its description by *Rose* (1903a: 10), the species was long known only from incomplete specimens offered for sale as cut flowers (*McVaugh* 1989: 253) until its recent discovery in the wild at several localities in Jalisco (*Cedano & al.* 1995, *Cházaro Basáñez & Machuca Núñez* 1995). *Cedano & al.* (1995) published similar plants from Michoacán as *Polianthes michoacana*, but its differences fall within the range of variability in *A. dolichantha* so that the populations from Michoacán were included in the latter (*García-Mendoza* 2003, *Cházaro Basáñez & al.* 2010b, *Feria-Arroyo & al.* 2010, *Castro-Castro & al.* 2016: 722; all as *Polianthes longiflora*). *A. dolichantha* is locally harvested for the cut-flower trade; its habitats are threatened by grazing (*Cházaro Basáñez & al.* 2010b, *Machuca Núñez & Cházaro Basáñez* 2015, both as *P. longiflora*). The geographical distribution, niche modelling and extinction risk of the species are dealt with by *Solano & Feria* (2007) and *Feria-Arroyo & al.* (2010). — The “holotype” at US consists of 2 sheets which are not cross-labelled and thus represent syntypes; US 396106 is the true species, whereas US 396105 is *Polianthes sessiliflora* (here treated as *A. apedicellata*) according to a label by E. Solano C. placed on the specimen in the year 2000 (see also *McVaugh* 1989: 254). — When placed in *Agave*, a new name was necessary to avoid homonymy with *A. longiflora* (*Rose*) G. D. Rowley (1977).

**A. durangensis** *Gentry* (*Agaves Cont. North Amer.*, 433–436, ill., 1982). **Type**: Mexico, Durango (*Gentry & Gilly* 10576 [US, ARIZ, MEXU, MICH]). — **Lit**: *Cházaro Basáñez & Vázquez-García* (2006: with ill.); *Vázquez-García & al.* (2007b: 51–52, t. H); *González-*

Elizondo & al. (2009: 65–68, with ills.); Almaraz-Abarca & al. (2013b: genetic variability). **Distr:** Mexico (S Durango, N & C Zacatecas); rocky slopes and gravelly bajadas in grama grasslands, pine-oak or sometimes tropical deciduous forests, 1700–2600 m; flowers April to July, also in November. **I:** Etter & Kristen (2007b: 177); Klopper & al. (2010: 60); Richter (2011: 52); Pilbeam (2013: 77); Hochstätter (2015: IV: 8).

[2h] Stems short; **Ros** (0.6–) 0.8–1.2 (–1.8) × (0.7–) 1.2–1.8 (–3.1) m, solitary or caespitose; **L** broadly lanceolate, narrowed above the broad base, widest in the middle, straight to outcurving, flat to concave esp. towards the apex, thick and convex towards the base, asperous, mostly 40–90 (–130) × 14–22 cm, glaucous-grey, pruinose, margins heavily armed, deeply crenate-mamillate; **marginal teeth** variously curved, prominent, broadly flattened, 10–20 mm, generally 10–20 mm apart; **terminal Sp** strong, broadly channelled above, (30–) 40–60 mm, pruinose-grey over brown; **Inf** 7–8 m, paniculate, peduncle short, with scarious remote reflexed **Bra** 15–25 cm long, fertile part long, lax, axis flexuous or zig-zag, part-**Inf** 18–30, sinuously spreading, trifurcate, small, in the upper  $\frac{3}{4}$  of the inflorescence; **Fl** 60–80 mm; **Tep** yellow, tube cylindrical, broad and fleshy, lightly grooved, 15–22 × 12–17 mm, lobes strictly appressed to the filaments, becoming leathery, unequal; **OTep** larger, 10–12 mm, thickly rounded on the back and overlapping the inner, apex conspicuously papillate, almost horny, reddish; **ITep** smaller, sharply keeled; **Fil** somewhat flattened, 48–60 mm, inserted at 2 levels 8–12 and 6–10 mm above the tube base; **Anth** 18–25 mm; **Ov** 30–45 mm (incl. the unconstricted neck); **Sty** somewhat longer than the tepals; **Sti** capitate; **Fr** oblong, 45–60 × 16–18 mm, rounded and shortly beaked, obscurely stipitate; **Se** small, crescent-shaped to obovate or tear-shaped, 4.5–6 × 3.5–5 mm, with a broad but little raised rim wing.

Distinguished by the large, rigid, broadly lanceolate leaves heavily armed with flexuous teeth on deeply crenate margins, and the large, long, lax panicle with a flexuous or zigzag axis, a short peduncle, and without close relationship to other species of Sect. *Ditepalae* (as Group) according

to Gentry (1982). Vegetatively, it may be confused with the sympatric *A. scabra* of Sect. *Agave* (Gentry 1982: 436, as Group *Americanae*). *A. temacapulinensis*, also of Sect. *Ditepalae*, is very similar (see there).

*A. durangensis* is economically important for the mescal industry in Durango (Contreras-Hernández & al. 2016). Molecular studies of 3 natural populations found evidence for genetic differences between the populations, some incongruence between molecular data and morphology, and advanced diversification in 1 of the 3 populations (Almaraz-Abarca & al. 2013b). Seed morphology, germinability and phenolic profiles varied among 3 natural populations (Barriada-Bernal & al. 2013). Pollen and foliar phenol profiles indicate the presence of several chemotypes and allow the separation of the 2 studied populations (Almaraz-Abarca & al. 2009). The edible flowers of *A. durangensis* represent an important source of antioxidant flavonols (Barriada-Bernal & al. 2014). The arthropod communities associated with the species were studied by González-Castillo & al. (2011).

**A. eggersiana** Trelease (Mem. Nation. Acad. Sci. 11: 28, tt. 31–33, 1913). **Type:** US Virgin Islands, St. Croix (*Ricksecker* 282 [MO, US]). — **Lit:** Berger (1915: 220); Britton & Wilson (1923: 156); Proctor & Acevedo-Rodríguez (2005: 118); Chamorro & al. (2016: with ills.). **Distr:** US Virgin Islands (St. Croix); coastal cliffs and dry coastal shrubland, in open-canopy and open-understorey habitats exposed to full sun. **I:** Hochstätter (2015: VII: 60).

[2s] Acaulescent, not surculose; **L** numerous, narrowly lanceolate, nearly straight and erect, gradually acute, concave, mostly 120–200 × 10–15 cm, dull green, transiently slightly glaucous; **marginal teeth** straight or upcurved, narrowly triangular, 1–1.5 mm, usually 10 mm apart, with broadly lenticular blackish-brown base, intervening margin nearly straight, at first reddish; **terminal Sp** conically subulate, usually somewhat upcurved, often laterally compressed, smooth, 15–20 mm, brown, rather glossy, with slender dull-brown involute basal thickening to 3 × 10–15 mm, decurrent for its length or more and

dorsally intruded into the green leaf tissue; **Inf** 5–7 m, ‘paniculate’, peduncle with distant, deltate, spreading or reflexed **Bra**, fertile part densely flowered, part-**Inf** (slightly) ascending,  $\pm 25$ , freely bulbiferous, in the upper  $\frac{1}{4}$  of the inflorescence; **Ped** 20–25 mm; **Fl** 50–60 mm, pumpkin-scented; **Tep** deep yellow, tube broadly open, 5–7 mm, lobes 20–25  $\times$  5–8 mm; **Fil** 45–50 mm, inserted nearly in the throat; **Anth** not described; **Ov** oblong-fusiform, 20–30 mm; **Fr** and **Se** not produced.

For the typification, see Smith & Figueiredo (2014c: 233). Endemic to St. Croix in the US Virgin Islands where it now appears to be largely extinct in the wild, but persisting as relatively few cultivated plants on St. Croix as well as on St. Thomas (Proctor & Acevedo-Rodríguez 2005: 118). The species is threatened by the Agave Snout Weevil (*Scyphophorus acupunctatus*) recently reported from St. Croix; Chamorro & al. (2016) provide management recommendations.

In the first edition of this handbook, *A. eggersiana* was placed in the synonymy of *A. missionum* (the only other native *Agave* species on the US Virgin Islands) based on Álvarez de Zayas (1995), but it is here recognized as a distinct species following Proctor & Acevedo-Rodríguez (2005). *Agave missionum* differs from *A. eggersiana* by broader leaves and longer marginal teeth (Proctor & Acevedo-Rodríguez 2005: 117).

**A. ellemeetiana** K. Koch (Wochenschr. Vereines Beförd. Gartenbaues Königl. Preuss. Staaten 8: 103 [1. April], 1865). **Type** [neo]: Ex cult. (*Anonymus* s.n. [K 524804, K [524802 + 524803]]). — **Lit**: Gentry (1982: 94–97); Thiede (2014b); both with ills. **Distr**: Mexico (C Veracruz, N & W Oaxaca).

**Incl.** *Agave ellemeetiana* Regel (1865) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave ellemeetiana* Jacobi (1865) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave ellemeetiana* [?] *obovata* Hort. Sutherland (1875) (*nom. inval.*, ICN Art. 38.1a).

*A. ellemeetiana* was previously ascribed to Jacobi (Hamburg. Gart.- & Blumenzeit. 21: 457, 1865), but was first published as cited above (Thiede 2014b). Ullrich’s (1991k) notion that the species might possibly represent hardly more than

a garden clone of *A. attenuata* ssp. *dentata* (as *A. pedunculifera*) must be dismissed. *A. ellemeetiana* differs from *A. attenuata* esp. in its nearly stemless habit with even fewer, bright green leaves, and its eastern distribution. For the history, rediscovery, distribution and habitats of the species, see Thiede (2014b).

**A. ellemeetiana** ssp. **ellemeetiana** — **Lit**: Berger (1915: 125–126); Gentry (1982: 94–97); Alsemgeest (2004); Cházaro Basáñez & al. (2012); Thiede (2014b); all with ills. **Distr**: Mexico (C Veracruz, N Oaxaca); on often near-vertical cliffs and rock-faces, in cloud or tropical subdeciduous forests, in the cloud belt, rarely epiphytic, 400–1460 m; flowers February to May. **I**: Refug. Bot. 3: t. 163, 1869; Baker (1888b); Heller (2006: 83); Richter (2011: 62); Hochstätter (2015: VIII: 36); Castillo-Hernández & Flores-Olvera (2017: 541, as *A. gomezpompae*).

[1c] Stems nearly none; **Ros** open, 0.35–0.5  $\times$  0.7–1 m, surculose; **L** rather few, ovate to oblong, somewhat recurved, reclining at maturity, thickly soft-succulent, widest in the middle, acuminate, flat beyond the thick base, concave to flat above, smooth, 50–70  $\times$  12–20 cm, light bright green, margins thin, friable, smooth, unarmed, white, sometimes reddish, sometimes finely serrulate towards the leaf tip; **terminal Sp** none, but leaf tip shortly acuminate and slightly calloused; **Inf** erect, 3–4.5 m, ‘spicate’, peduncle with ovate caudate-acuminate **Bra** 8–10 cm long, fertile part densely flowered from near the base, part-**Inf** usually with 4 flowers; **Ped** united in pairs, 15–20 mm; **Fl** campanulate, 28–40 mm; **Tep** pale greenish-yellow, tube very short, 1–2 mm, lobes lanceolate, concave, somewhat hooded at the tip, 13–15  $\times$  5 mm, inner somewhat wider; **Fil** long exerted, 50–60 mm, inserted on the rim of the tube together with the lobes; **Anth** 10–12 mm, yellow; **Ov** bottle-shaped, 13–20 mm, neck conspicuously elongate; **Sty** slender, as long as the filaments; **Sti** thickened; **Fr** trigonous, rounded at the base, 13–15  $\times$  10 mm, light brown, beaked; **Se** numerous, 3 mm, black, shiny.

Introduced into cultivation from Mexico in 1862 or before, and persisting in cultivation esp. in Europe up to the present. Its natural habitats

**Fig. 23** *Agave ellemetiana* ssp. *subdentata* (Etter & Kristen 3905: Mexico; Oaxaca, ± 10 km S of Yosonicaje, 2320 m). (Copyright: J. Etter & M. Kristen)

remained unknown until the recent past. At present, ssp. *ellemetiana* is known from 3 areas in the Sierra Madre Oriental of C Veracruz and NE Oaxaca (Thiede 2014b), namely from the Sierra de Zongolica in C Veracruz (Cházaro Basáñez & al. 2012), and in N Oaxaca from the Sierra Mazateca (= Sierra de Huautla) (Lorea Hernández & Munn-Estrada 2005) and from near San Bartolomé Ayautla where it was first observed by A. B. Lau (Ullrich 2007: fig. 6, as “*A. attenuata*?”).

**A. ellemetiana** ssp. *subdentata* (Trelease) Thiede (Bradleya 32: 157, 2014). **Type** [neo]: Mexico, Oaxaca (*Spath & Griffin* s.n. [ZSS]). — **Lit**: Köhres (2008: with ill., as *A. ellemetiana*). **Dist**: Mexico (W Oaxaca: Putla/Tlaxiaco/Santiago Nuyoó area); volcanic rocks in cloud or tropical subdeciduous forests, 2300–2600 m; flowers in January. **I**: Pilbeam (2013: 78, as *A. ellemetiana*); Hochstätter (2015: VIII. 37). — Fig. 23.

≡ *Agave ellemetiana* var. *subdentata* Trellease (1914).

[1c] Differs from ssp. *ellemetiana*: **L** margins whitish or reddish, finely but clearly denticulate throughout; **L** of adult plants have a wax bloom absent from ssp. *ellemetiana* and appear to be partly broader, but measurements are not available (Thiede 2014b).

Köhres (2008) reported plants of *A. ellemetiana* from the W slopes of the Sierra Madre del Sur in Oaxaca above Santiago Nuyoó, and

published the first habitat photographs of it. Since these plants differ from typical *A. ellemetiana* by leaf margins being finely denticulate throughout, Thiede (2014b) re-established the forgotten name var. *subdentata* Trellease (described as having the “leaves very minutely denticulate”) at subspecific rank. Localities of the subspecies in the Putla/Tlaxiaco/Santiago Nuyoó area were also visited by other collectors, and plants belonging here are commercially offered in the USA and Europe. A preliminary investigation using AFLP data placed material from Putla probably belonging to ssp. *subdentata* separate from *A. ellemetiana* (Gil-Vega & al. 2007: as *A. aff. pedunculifera*). Further studies are needed to establish the status of ssp. *subdentata* and its differences from ssp. *ellemetiana*.

**A. × engelmannii** Trellease *pro sp.* (Annual Rep. Missouri Bot. Gard. 3: 167, tt. 55–56, 1892). **Type**: Ex cult. Missouri BG (*Anonymous* s.n. [K [2 sheets, cross-labelled]]). — **Lit**: Anonymous (1892: 398); Berger (1915: 184–185); both as *A. engelmannii*. **Dist**: Cultivated only.

**Incl.** *Agave attenuata* var. *subdentata* Hort. Hoopes *ex* Trellease (1892) (*nom. inval.*, ICN Art. 38.1a).

[1b? × 2] Raised from seed by J. Hoopes and flowered and fruited at the Missouri Botanical Garden 1890–1891. Seedlings from Missouri flowered later at La Mortola and were described

by Berger (1915). Placed close to *A. horrida* ssp. *perotensis* (as “*A. polyacantha*”) by Trelease (1920: 135) and in the synonymy of that species by Gentry (1982: 228). With inflorescences intermediate between the subgenera, with distinctly stalked part-inflorescences with up to 7 flowers (protologue t. 55, sheet K 001096501!) and thus obviously of intersubgeneric hybrid origin involving a species of Subgen. *Littaea* (possibly *A. attenuata*) and one of Subgen. *Agave*.

**A. ensifera** Jacobi (Nachtr. Versuch syst. Glied. Agaveen 1: 13–14, 1868). **Type** [neo]: Ex cult. La Mortola (*Berger* s.n. [US 1023791]). — **Lit:** Baker (1877a: 369, with ill., as *A. heteracantha*); Berger (1915: 99); Gentry (1982: 139); Meer & Puche (2014: as *A. univittata* var. *ensifera*, *A. lophantha* var. *latifolia* and *A. heteracantha*). **Distr:** Known from cultivation only. **I:** Roosbroeck (2014); Hochstätter (2015: VII: 29).

≡ *Agave univittata* var. *ensifera* (Jacobi) P. Van der Meer & C. Puche (2014); **incl.** *Agave heteracantha* Baker (1877) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave lophantha* var. *latifolia* A. Berger (1915) ≡ *Agave univittata* var. *latifolia* (A. Berger) Breitung (1959).

[lg] **Ros** dense, caespitose; **L** linear-lanceolate, ensiform, leathery-fleshy, strongly convex below and above, upwards becoming concave to the apex, at the base 1.5–1.7 cm thick, smooth, 50–60 × 4–5 (3.8–4 near the base) cm, dark green with a distinct light longitudinal central stripe 5–7 mm wide up to the middle, margins with a narrow grey border 0.5–1 mm wide; **marginal teeth** mostly antrorsely curved, 4–6 mm, light grey, closely set, 10–20 mm apart, mostly with broad bases, interspersed with smaller teeth, altogether 30–40 teeth per leaf side; **terminal Sp** short, basal groove above short and opening broadly with decurrent border, 10–15 mm, brown to grey; **Inf** 2–2.5 m, ‘spicate’, peduncle with deflected subulate **Bra** 6–10 cm long, part-**Inf** mostly with geminate flowers; **Ped** 2–3 mm; **Fl** 35–42 mm; **Te** light green, tube open, short, 2–3 mm, lobes linear, involute around the filaments at anthesis, subequal, 14–17 mm, light yellowish, outer overlapping the inner at the base; **Fil** slender, 40–45 mm, inserted on the tube rim;

**Anth** 16 mm, yellow; **Ov** 20–24 mm, neck constricted, ±3 mm; **Sty** whitish, equalling the anthers; **Fr** and **Se** unknown.

Of unknown origin and commonly cultivated along the Mediterranean Riviera at Berger’s time; apparently related to the *A. lechuguilla* – *A. difformis* group and recognized specifically by its long narrow leaves with numerous teeth of 2 sizes regularly spaced along the narrow margins, and the short, mostly weak terminal spine (Gentry 1982: 139). Meer & Puche (2014) classified the plant as *A. univittata* var. *ensifera*, but the name *A. univittata* var. *latifolia* (A. Berger) Breitung would take priority. The plants depicted as *A. lophantha* var. *latifolia* by Guillot Ortiz & Meer (2012: 33) and as *A. univittata* var. *ensifera*, *A. lophantha* var. *latifolia* and *A. heteracantha* by Meer & Puche (2014: 59–62, 64) have lanceolate leaves with teeth on distinct prominences and are most probably misidentified.

Gentry (1982: 139) selected two specimens of Berger (Château Grimaldi, *Berger* s.n., 19. 6. 1909, US 1023791 & 1023763) as “lectotype”, but since Jacobi did not cite any material, this is interpreted as first-step neotypification (ICN Art. 9.17) as they are not cross-labelled. Meer & Puche (2014: 59) designated US 1023791 as “lectotypus” (but actually representing a neotype), and US 1023763 as well as a third specimen (*Berger* s.n., 19. 6. 1909, ARIZ 268297) as “isolectotype”. These specimens are both not cross-labelled and are thus interpreted to represent different gatherings and not isoneotypes.

**A. evadens** Trelease (Mem. Nation. Acad. Sci. 11: 20–21, tt. 9–10, 116, 1913). **Type:** Trinidad (*Crueger* 1333 [B †, K 000524793, MO, NY, U, UPS, US]). — **Lit:** Berger (1915: 225); Britton & Wilson (1923: 157); Hummelinck (1938: 23–24). **Distr:** Trinidad (along the coast and on Isla de Chacachacare and Isla Monos), Venezuela (Isla de Patos); littoral deciduous seasonal forests; flowers in March. **I:** Richter (2011: 97); Hochstätter (2015: VII: 41).

**Incl.** *Agave polyacantha* Baker (1888) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave vivipara* Hart (1890) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave polyantha* Dodge (1897).

[2u] **Ros** shortly caulescent, not surculose; **L** narrowly oblanceolate, gradually acute, openly concave or somewhat conduplicate, or with inrolled margins above, 70–100 cm, green, margins almost straight; **marginal teeth** small, on low broadly conical prominences, 0.5–1.5 mm, 6–15 mm apart, margins between the teeth convex; **terminal Sp** conical, straight or somewhat recurved, slightly involute at the base, 10–14 × 2–3 mm, slightly or not decurrent; **Inf** paniculate, fertile part lax, slender, part-**Inf** few, ascending, tripartite, not known to be bulbiferous; **Ped** rather slender, (6–) 8–10 (–12) mm; **Fl** 47–55 mm; **Tep** bright yellow, tube open, 2–3.5 mm, lobes 19–25 × 4 mm; **Fil** 35–42 mm, inserted 0–0.5 mm below the tube throat; **Anth** 17–25 mm; **Ov** oblong-fusiform, 22–25 × 3–4 mm; **Sty** 32–38 mm; **Fr** broadly ellipsoid, 30–34 × 20–24 mm, slightly beaked, distinctly stipitate; **Se** D-shaped, angled, 6–8 × 4–6 mm, shiny black.

According to the protologue intermediate in foliage between *A. cocui* and *A. boldinghiana* and known to Trelease from photographs and dissociated flowers only. If the name *A. polyantha* Dodge really proves to be conspecific, it would have priority.

The characters regarded in the protologue as most important were taken by Trelease from his plate 9: Shortly caulescent, leaves narrowly oblanceolate, inflorescence laxly paniced at the end with few ascending branches. Hummelinck (1938: 24) assumed that these data have no value: the short stem appears to result from the bases of the plants being washed free, the narrowly oblanceolate leaves may be due to external circumstances, and the laxly paniced inflorescence may result from the great reduction of the picture which made flowerless branches invisible.

Apart from Trinidad (main island), *A. evadens* is also reported from Isla de Chacachacare (Hummelinck 1938: 23, Adams & Baksh-Comeau 2005: 9) and Isla Monos (Chalmers 1965) and from Isla de Patos (Williams 1924: 278), which since 1942 belongs to Venezuela. Preserved flowers from Isla Margarita (Venezuela) placed here with reservation by Trelease may belong to *A. cocui* or *A. vicina* (as *A. vivipara*; Hummelinck (1938)). Material from Puerto Santo (Venezuela)

“may possibly belong to *A. evadens*” (Hummelinck 1938: 24). Several specimens from the Venezuelan mainland placed here (*Pittier* 10238, US 1187053; *Steyermark* 107981, US 2706466; *Steyermark* 108044, US 2706464) need verification. The species was (is?) cultivated on St. Thomas (US Virgin Islands; Britton & Wilson (1923: 157)). Baksh-Comeau & al. (2016: 33) assign the species to the IUCN category “Vulnerable”.

**A. felgeri** Gentry (US Dept. Agric. Handb. 399: 60–62, ills., 1972). **Type:** Mexico, Sonora (*Gentry* 11343 [US, ARIZ, MEXU, MICH]). — **Lit:** Gentry (1982: 107–110, with ills.); Ullrich (1991j; with ills.); Turner & al. (1995); Smith & Figueiredo (2014b: with ills.). **Dist:** Mexico (Sonora, esp. Bahía San Carlos); arid desert lowlands and rocky hillsides near the coast, to 200 m; flowers May to August, also October and December. **I:** Richter (2011: 63); Pilbeam (2013: 79); Hochstätter (2015: VIII: 45).

[1d] **Ros** small, rather open, 20–50 cm Ø, surculose, forming rather densely caespitose groups; **L** rather few, erect to rigidly spreading, linear to narrowly lanceolate, straight or falcate, widest at the amplexicaul base, convex below, flat above in the lower ¼, concave in the upper ¾, epidermis rugose or scabrous above, 25–35 × 0.7–1.5 cm, matt light green to yellow-green, turning light yellow during and after flowering, with faint imprints from the central bud, frequently with pale median longitudinal stripe, margins with weakly filiferous narrow brown border, smooth, threads ± absent from older leaves; **terminal Sp** weak, small, slightly grooved at the base, 6–15 mm, grey or dark brown; **Inf** 1.2–2.5 m, ‘spicate’, peduncle light green, 7–15 mm Ø near the base, with chartaceous laxly arranged **Bra**, the lower very narrow and 2–3 cm, fertile part in the upper ¼, part-**Inf** with 1–2 flowers; **Ped** strong, 2–5 mm; **Fil** 25–30 mm; **Tep** light green, lateral sections creamy-white, the very margins purple, tube 2–4 mm, lobes linear, ± equal, 10–12 × 3–4 mm, strongly recurved to rolled back during the male phase, less so and straight with the onset of the female phase; **Fil** 20–25 mm, light shiny pinkish-purple, inserted 2 mm above the tube

base; **Anth** 8–9 mm, dull yellow; **Ov** terete, 12–14 × 4–5 mm, abruptly tapering apically, neck distinctly constricted; **Sty** stout, terete, 30–35 mm, light green; **Sti** prominent, white; **Fr** oblong, cylindrical or obovoid to globose, narrowed towards the base, 15–20 × 9–14 mm, distinctly beaked, light green to yellowish-green; **Se** irregular, thick, D-shaped, angled, wrinkled, hilar notch narrow and deep, 4–5 × 3 mm. — **Cytology**:  $n = 30$  (Baker & al. 2009).

Very similar to *A. schottii* from Sect. *Parviflorae* in vegetative features, but placed in Sect. *Littaea* (as Group *Filiferae*) due to its open shallow flower tube and long lobes, in which it occupies the most arid habitats. The type locality was destroyed for recreational development (Gentry 1982). Additional data on the reproductive morphology and phenology were provided by Smith & Figueiredo (2014b). Geographically it is closest to the broad-flowered form of *A. schidigera* which forms a more robust non-suckering colony on the Cerros del Fuerte in N Sinaloa (Gentry 1982). Ullrich (1991j) emphasizes vegetative and geographical criteria and suggests a placement in Sect. *Parviflorae* (as Group), but this is not followed here.

**A. filifera** Salm-Dyck (Hort. Dyck., 309, 1834). **Type**: [neo — icono]: Ill. Hort. 7(4): t. 243, 1860. — **Lit**: Berger (1915: 73–74); Gentry (1982: 110–111); Vázquez-García & al. (2007a: 51–52, t. I); Starr (2012: 90–93, 317–319); all with ill. except Berger. **Distr**: Mexico (Aguascalientes, Jalisco, Guanajuato, Querétaro, Hidalgo, México); on rocks, in desert scrub, thorn, oak and oak-juniper forests, 2340–3100 m; flowers June to September. **I**: Heller (2006: 84); Richter (2011: 63); Pilbeam (2013: 80, as ssp. *filifera*); Hochstätter (2015: IX: 30).

**Incl.** *Agave filifera* ssp. *filifera*; **incl.** *Agave filamentosa* Salm-Dyck (1859) ≡ *Bonapartea filamentosa* (Salm-Dyck) Boucén (1868) (*incorrect name*, ICN Art. 11.4) ≡ *Agave filifera* var. *filamentosa* (Salm-Dyck) Baker (1877); **incl.** *Agave filifera* var. *superba* J. Croucher ex R. Hogg (1874); **incl.** *Agave pseudofilifera* Ross & Lanza (1892); **incl.** *Agave filifera* var. *candida superba* Hort. Besaucèle ex A. Berger (1915)

(*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave filifera* var. *elatio*r Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave filifera* var. *immaculata* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave filifera* var. *longifolia* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave filifera* var. *mediopicta* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave filifera* var. *splendens* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave filifera* var. *viridis* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a).

[1d] **Ros** small, green, dense, surculose, forming large clumps; **L** many, lanceolate, straight, thick, broadest in the middle, acuminate, thickened and convex above and below from the base to the middle, smooth, 15–30 × (1–) 2–4 cm, green, with white imprints from the central bud, margins finely filiferous; **terminal Sp** flat above, rounded below, 10–20 mm, greyish; **Inf** 2–2.5 m, ‘spicate’, peduncle densely covered with long-caudate recurving **Bra**, fertile part tall, in the upper ½ of the inflorescence, tapering, densely flowered; **Ped** short, thick; **Fl** mostly geminate, 30–35 mm, ascending-outcurving; **Tep** reddish, tube funnel-shaped, furrowed, 5–6 × 8 mm, mouth bulging at the filament insertions, lobes recurving, lanceolate, apiculate, equal, 14 × 4 mm, inner a little wider, with prominent keel; **Fil** slender, 30–35 mm, reddish, inserted on the tube rim; **Anth** centric, 7–12 mm, reddish; **Ov** fusiform, angled, 13–15 mm, neck furrowed; **Sty** strong, longer than the filaments; **Sti** 3-lobate; **Fr** oblong-ellipsoid to oblong-obovoid, acute, 15–17 × 12 mm; **Se** semicrescent-shaped. — **Cytology**:  $2n = 60$  (Cave 1964, Simpson & al. 2011).

Separable from the closely related *A. schidigera* by its caespitose habit, smaller rosettes, shorter and thicker leaves, and smaller reddish-purple flowers with a shorter tube (Gentry 1982, Starr 2012). Ullrich (1992h) reduced *A. schidigera* and *A. multifilifera* to subspecies of *A. filifera*, but was not followed by Vázquez-García & al. (2007b), Starr (2012) and Govaerts (2014+: accessed April 2014). The species was recently recorded from E Jalisco (Hernández-Vera & al. 2007a). A record

from C Zacatecas (Ramírez Prieto 2014: 54) may refer to *A. schidigera*.

**A. flexispina** Trelease (Contr. US Nation. Herb. 23: 133, 1920). **Type** [syn]: Mexico, Durango (Palmer 330 [MO, US, CM, GH, K, NY, UC]). — **Lit:** Gentry (1982: 436–438); González-Elizondo & al. (2009: 77–79); Klopper & al. (2010: 58, 60–61); Alsemgeest & Roosbroeck (2010: 68–70); all with ills. **Distr:** Mexico (S Chihuahua, N Durango, Zacatecas, N Nayarit); rocky slopes and hillsides, in grama or oak-juniper grasslands and oak woodlands, 1300–2440 m; flowers July, October and November. **I:** Breitung (1963: 121, right-hand figure); Pilbeam (2013: 84); Ettelt (2014: 124); Hochstätter (2015: IV: 9).

[2h] **Ros** open, small, 25–35 (–45) × 50–70 cm, solitary or caespitose; **L** 35–40, ovate, acuminate, nearly flat to concave above, 16–30 × 6–8 (–12.7) cm, glaucous- to yellowish-green, margins repand to crenate; **marginal teeth** mostly retrorse, larger teeth mostly 5–8 mm, brown to pruinose, 10–15 mm apart, on small prominences, sometimes with small intermittent teeth; **terminal Sp** acicular, usually flexuous, flat to openly grooved near the base, 25–35 mm, brown to pruinose-grey, decurrent to the upper teeth; **Inf** 2–3.5 m, paniculate, peduncle with small, dry, appressed, hardly persistent **Bra**, fertile part slender, rather open, frequently narrow, part-**Inf** small, 6–12 (–16), few-flowered; **Ped** nearly none; **Fl** 50–70 mm; **Tep** greenish-yellow, with red tinge on buds and lobes, tube cylindrical to urceolate, bulging in the middle, slightly or narrowly grooved, 10–18 mm, lobes lanceolate to linear, broad, broadly rounded at the apex, unequal, outer larger, strongly overlapping the inner, 10–18 mm, persisting erect and drying leathery, inner with high narrow keel; **Fil** sometimes broadly flattened, 40–50 mm, with red tinge, inserted at one level, sometimes irregularly so; **Anth** 17–23 mm, yellow or bronze-coloured; **Ov** cylindrical, slightly angled, 22–35 mm, neck short, obscure; **Sty** longer than the filaments; **Sti** capitate, 3-lobate; **Fr** oblong, strongly trigonous, round at the apex, tardily dehiscent, 35–45 × 15–17 mm, abruptly stipitate; **Se** obovate to crescent-shaped, 5.5–7 × 4–5 mm, rim wing low.

In appearance like a small *A. shrevei* or *A. palmeri*, but differing in having the filaments inserted at a single level in the tube (vs. 2 distinct levels in the species mentioned, and indeed in most members of Sect. *Ditepalae*). Rosettes and inflorescences of *A. flexispina* are consistently smaller than normally found in other species of Sect. *Ditepalae* (as Group) (Gentry 1982). The holotype is at MO according to the protologue, but the 2 sheets (MO 3346761, leaves; MO 3346762, inflorescence) are not cross-labelled and represent syntypes (Smith & Figueiredo 2014c: 234). The specimen *Flores F. & al.* 2079 (MEXU 520551!) provides a new record from Nayarit.

The left-hand figure in Breitung (1963: 121) is incorrectly labelled and represents *A. parryi* var. *truncata* (Alsemgeest & Roosbroeck 2010: 69).

**A. fortiflora** Gentry (US Dept. Agric. Handb. 399: 122–126, ills., 1972). **Type:** Mexico, Sonora (Gentry 19808 [US, ARIZ, DES, MEXU]). — **Lit:** Gentry (1982: 421, 438–440, with ills.); Klopper & al. (2010: 61). **Distr:** Mexico (NW Sonora); on isolated mountain ranges, mostly on volcanic rocks or also on limestone ridges, in desert scrub; flowers in cultivation (California) June to July. **I:** Heller (2006: 85); Pilbeam (2013: 85).

[2h] **Ros** open, to 1 × 1.8 m, mostly solitary, occasionally suckering; **L** straightly ascending or outcurving and conduplicate, long-acuminate, gradually narrowed above the dilated base, widest in the middle, finely tuberculate-rugose (incl. teeth and terminal spine), to 50–100 × 8–12 cm, light grey-glaucous, usually cross-zoned, margins straight or teeth in the middle of the lamina on small prominences; **marginal teeth** curved downwards or erect, 5–10 mm (middle of the lamina), 10–30 mm apart, smaller and variously flexed above and below the middle, with irregularly arranged smaller intermittent teeth; **terminal Sp** subulate, rounded below, narrowly grooved above, 30–50 mm, chestnut-brown to light grey, decurrent along the margin to the uppermost teeth; **Inf** 4–6 m, paniculate, peduncle with short, triangular, chartaceous **Bra** 5–6 cm long at the lower branches, fertile part open and long-ovoid, part-**Inf** nearly horizontal, 8–15, densely 12-

18-flowered; **Ped** 4–20 mm; **Fl** long-lived, 72–82 mm; **Tep** yellow, tube broadly bulging, sinuses overlapping and deeply grooved below, 11–13 × 18–20 mm, pale yellow, lobes erect, 20–23 × 7–8 mm, yellow, outer rounded, linear-lanceolate, with an involute margin, obtuse, inner with high narrow keel and involute hyaline margins, broadly hooded at the tip; **Fil** strong, elliptic in cross section, 60 mm, persisting erect after anthesis; **Anth** centrally affixed, 20–22 mm, yellow; **Ov** 45–50 mm, pale green, conspicuously angled below the outer tepals; **Sty** finally to slightly shorter than the filaments; **Sti** capitate, 3-lobed; **Fr** and **Se** unknown.

The species is highly distinct in its floral morphology: The large flowers are sturdy (hence the name), and long-lasting, persisting erect for long after anthesis, and the flattening of the filaments is extreme, making them almost strap-shaped and quite the broadest in the genus. With these features, *A. fortiflora* does not show relations to other species of Sect. *Ditepalae* (as Group), but the erect tepal lobes dry in the same way as found in other species of the section (Gentry 1982).

Plants from near Bahía San Carlos (Sonora) placed here in the protologue (Gentry 1972: 124, 125: upper photo) (Gentry & Arguelles 19881, Felger & Russell 11455) belong to *A. colorata* (Gentry 1982: 432–433, Starr 2012: 79). — The species is very rare, known only from the Sierra Jojoba and the Sierrita de López, and has apparently not been recollected since Gentry, but Kristen & Etter (photograph in Pilbeam (2013)) recently visited the habitat. Photographs from Nacapule Canyon labelled *A. aff. fortiflora* in Greulich (2017b) appear to represent *A. chrysoglossa* (on p. 40) and *A. colorata* (on p. 46).

**A. fourcroydes** Lemaire (Ill. Hort. 11(Misc.): 65, 1864). **Type:** not typified. — **Lit:** Berger (1915: 238–240, with ill.); Gentry (1972: 138–139); Gentry (1982: 573–576, with ill.); Lott & García-Mendoza (1994: online version with ill.). **Distr:** Cultivated only; mainly E Mexico; locally naturalized in the Caribbean, Costa Rica, and the Mediterranean. **I:** Curtis’s Bot. Mag. 144: t. 8746, 1918; Heller (2006: 86);

Sánchez Gullón (2013: 51); Hochstätter (2015: VII: 42).

**Incl.** *Agave rigida* var. *longifolia* Engelmann (1875); **incl.** *Agave ixtli* var. *elongata* Baker (1877) ≡ *Agave rigida* var. *elongata* (Baker) Baker (1881) ≡ *Agave elongata* (Baker) A. Berger (1912) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave longifolia* hort. ex A. Berger (1915); **incl.** *Agave ixtli* hort. ex A. Berger (1915) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave sullivanii* Trelease (1920); **incl.** *Agave fourcroydes* var. *espiculata* L. H. Dewey (1929).

[2g] Stems thick, 1–2 × ±0.25 m; **Ros** large, suckering; **L** straight, linear, rigid, sword-like, thickly rounded at the base, acuminate, guttered, 120–180 (–250) × 7–12 cm, grey-green, margins straight; **marginal teeth** slender, 3–6 mm, dark brown, regularly spaced, 20–35 mm apart; **terminal Sp** conical, stout, openly short-grooved above at the base, mostly 20–30 mm, dark brown, somewhat decurrent; **Inf** 4–7 m, paniculate, part-**Inf** 10–18 in the upper ½, freely bulbiferous; **Fl** (50–) 60–70 mm; **Tep** greenish-yellow, tube urceolate, thick-walled, grooved, 12–16 × 12–15 mm, lobes linear, at first erect then sharply reflexing, closely overlapping, subequal, 16–18 × 3–5 mm, outer with flat outer face, inner keeled; **Fil** stout, tapered towards the apex, 45–60 mm, inserted 6–8 mm above the tube bottom; **Anth** slender, excentric, 20–24 mm, pale yellow; **Ov** fusiform, roundly-trigonous, tapered towards the base, (20–) 30–40 mm, neck briefly constricted; **Sty** stout, clearly longer than the tepals; **Sti** capitate, 3-lobate; **Fr** and **Se** normally not produced, **Fr** elongate-clavate, obtusely triangular, 3-sulcate, shortly stipitate, acutely rostrate; **Se** nearly crescent-shaped, 9–10 mm. — **Cytology:** 2n = 60, 90, 138, ±140, 150 (Doughty 1936, Castorena Sanchez & al. 1991, Lv & al. 2009, Simpson & al. 2011), in cultivars 2n = 90, 150 (Robert & al. 2008).

Widely cultivated for fibre (“Henequén”) esp. in E Mexico and Yucatán (Gentry 1982), but also used to produce an alcoholic beverage similar to mescal marketed under the registered trademark “sisal” (Larqué Saavedra 2007). The origin of *A. fourcroydes* is in Yucatán according to Lott & García-Mendoza (1994). The different cultivars subsumed under *A. fourcroydes* show different

degrees of similarity with its wild progenitor *A. angustifolia*. ‘Sac Ki’ and ‘Yaax Ki’, cultivated for cordage, show four syndromes of domestication: gigantism, greater fibrosity, less pronounced thorniness, and less reproductive capacity (Colunga-García Marín & al. 1996, Colunga-García Marín & May-Pat 1997). The major differences of *A. fourcroydes* from its wild progenitor *A. angustifolia* (thicker and longer stems, longer and broader leaves, and its sterility) reflect these domestication syndromes.

Morphological data (Colunga-García Marín & al. 1999) and combined morphological/molecular isozyme data (Colunga-García Marín 2003) indicated *A. fourcroydes* to represent a polyphyletic assemblage of different cultivars independently derived from within the variable *A. angustifolia*. However, with molecular AFLP data, several cultivars as well as variants of the progenitor species *A. angustifolia* (see there) cluster independently, so that Infante (2006) suggest the need for a revised classification. *A. fourcroydes* normally does not produce seeds and is only asexually propagated via rhizomes for plantation use, according to most authors. The sole descriptions of fruit and seed are given by Berger (1915) and Berger (1918). Offsets of a given mother plant are genetically variable so that selection of special genotypes for the improvement of Henequén is possible (Infante & al. 2003).

Locally naturalized in the Caribbean (Cayman Islands, Cuba, Dominican Republic, Haiti, Leeward Islands), Costa Rica, Italy (Govaerts 2014+), Spain (Sánchez Gullón 2013), the Balearic Islands (Sáez & al. 2016) and the Canary Islands (Acebes Ginovés & al. 2010).

**A. franzosinii** (Sprenger) Sewell (Gard. Chron., ser. 3, 6: 639, 1889). **Type:** [neo — icono]: Curtis’s Bot. Mag. 136: t. 8317, 1910. — **Lit:** Baker (1892: with ills.); Berger (1915: 157–160, with ills.); Gentry (1982: 291–292, with ills.); Guillot Ortiz & al. (2008: 50–52); Thiede (2017b). **Distr:** Known from cultivation only; locally naturalized in Spain. **I:** Irish & Irish (2000: t. 17); Lyons (2002: 162); Heller (2006: 26, 87, 157, 159); Smith & Figueiredo (2008: 57); Richter (2011: 41, 70); Pilbeam (2013: 86);

Hochstätter (2015: VII: 82, as *A. beaulueriana*); Mesquida & al. (2016: 48–49); Moore (2016: 209, 233, 234).

≡ *Agave americana* var. *franzosinii* Sprenger (1885); **incl.** *Agave beaulueriana* Jacobi (1869).

[2a] **Ros** very large, 2–2.7 (–3) × to 4.5 m, freely suckering; **L** to ±40, lanceolate, widely spreading, recurved or sharply reflexed, narrowed at the base, thickened and convex below towards the base, guttered above, somewhat asperous, 180–220 × 22–35 cm, light glaucous-grey or bluish-glaucous variously marked with green below the middle of the lamina, margins straight to repand; larger **marginal teeth** (middle of the lamina) 8–10 mm, dark brown, remote, on fleshy prominences, sometimes with smaller intermittent teeth; **terminal Sp** with short open groove above, 30–60 mm, dark brown, decurrent along the inrolled leaf tip; **Inf** 8–11.4 m, paniculate, peduncle strong, fertile part broadly cylindrical, to 2.9 m broad, part-**Inf** broadly spreading, several times compound; **Fl** large, 83–100 mm; **Tep** yellow, soon withering, tube 18–22 mm, lobes 30–32 mm, outer linear, inner keeled on the back, grooved, with 2 ribs within; **Fil** stout, 65–80 mm, yellow, inserted at mid-tube; **Anth** 38–40 mm, yellow; **Ov** 35–45 × 10–13 mm, light bright green, neck slightly narrower; **Sty** stout, to 120 mm; **Sti** clavate, 3-lobed; **Fr** elongate-clavate, 55–70 mm; **Se** to 12 × 8–9 mm, black, shiny.

A very distinctive species not easily confused with, but obviously related to, *A. americana* (Gentry 1982), although it might be viewed as a larger version of the latter with greyish to glaucous leaves. The name is commonly ascribed to Baker (Bull. Misc. Inform. Kew 1892: 3, 1892), but was first mentioned by della Valle di Casanova (Garden [London, 1871–1927] 11: 63 (1877)) at the eponymous Villa Franzosini at the Lago Maggiore (Italy). The epithet was first published at varietal rank by Sprenger (in Deutsche Gärt.-Zeitung 9: 130, 1885), which has been overlooked so far. Howard (in Howard & Thompson-Mills (1979: 489)) first established that *A. franzosinii* is antedated by *A. beaulueriana*. To conserve the established *A. franzosinii* against *A. beaulueriana*, a formal proposal to conserve was published, together with notes on typification, by Thiede

(2017b). The species is naturalized in Spain (Guillot Ortiz & al. 2008, Sáez & al. 2014).

In the USA, two different “forms” are cultivated under this name: The typical form (e.g., at Lotusland), which is also propagated by tissue culture (Gomez Rhine 2009), and a clearly different, much smaller plant with stiffer leaves with more closely spaced teeth and a different colour, which is referable to *A. ×winteriana* (see there).

**A. funkiana** K. Koch & C. D. Bouché (Wochenschr. Vereines Beförd. Gartenbaues Königl. Preuss. Staaten 3: 47, 1860). **Type** [neo]: Mexico, Hidalgo (*Gentry* 12273 [[neo — syntypes]: ARIZ, MEXU, US]). — **Lit**: Berger (1915: 91); *Gentry* (1982: 139–141, with ills.); Guillot Ortiz & al. (2008: 51, 54, with ills.). **Distr**: Mexico (C Nuevo León, W & SW Tamaulipas, San Luis Potosí, N Querétaro, Hidalgo, SW México); rocky hillsides and slopes, in oak forests and mixed woodlands, 250–1800 m; flowers in August. **I**: Heller (2006: 88); Pilbeam (2013: 87); Hochstätter (2015: VII: 82).

[1g] Acaulescent; **Ros** open, 0.6–0.9 × 1.2–1.8 m, freely suckering; **L** linear, radiating, firm, straight or somewhat falcate, patulous, base broadly clasping, convexly thickened below, concave above, mostly 60–80 × 3.5–5.5 cm, yellowish-green to dark green, frequently with pale median stripe, margins horny, nearly straight, firm, thin, brown to grey; **marginal teeth** mostly directed downwards, regular, slender, 3–5 mm, 10–25 mm apart, with a few small irregularly arranged intermittent teeth; **terminal Sp** conical-subulate, with a narrow to open groove above, 10–30 mm, brown to white; **Inf** slender, 3.5–4.5 m, ‘spicate’, peduncle glaucous-grey, the small **Bra** apparently caducous, fertile part laxly flowered in the upper ½ of the inflorescence; **Ped** ±10 mm; **Fl** geminate, 40–45 mm; **Tep** pale glaucous-green, tube conspicuously grooved and knobby-angled, 3.5–4 mm, lobes linear, mucronate with a small hood, at first spreading to ascending, 18–19 mm, appressed and clasping the filaments after anthesis; **Fil** 30–35 mm, red or pink, inserted on the tube rim; **Anth** 20 mm, yellow with pink flush towards the tips; **Ov** oblong-fusiform, 20–24 mm, neck grooved,

constricted; **Sty** somewhat longer than the tepals, red; **Sti** capitate; **Fr** transversely wavy-ridged, strong-walled, 25–30 × 15 mm, light pruinose-grey, abruptly apiculate; **Se** thick, shape very variable, 5–6 × 3.5–4.5 mm, wavy-lined on the faces, hilar notch large.

The neotype cited above was designated by *Gentry* (1982: 140). Obviously related to *A. lophantha*, but differing in its larger size, regular and linear slightly concave leaves with nearly straight fine margins, and numerous regular fine teeth. The species is not well known in habitat, and the few individuals observed show little variation (*Gentry* 1982: 140). The specimens cited by *Gentry* (1982: 189) from Chiapas (*Gentry* 12195, DES, MEXU) belong to *A. ghiesbreghtii* (Lott & García-Mendoza 1994). The following selection of specimens represent new state records: *G. B. Hinton & al.* 18722 (MO) for Nuevo León, *Hernández & Martínez* 4298 (MEXU) for Querétaro, *García Mendoza* 4393 (MEXU) for México State, and *Gentry & al.* 20095 (MEXU) for San Luis Potosí (Portal Datos Abiertos UNAM 2018+). Guillot Ortiz & al. (2008) report the species as naturalized in Spain. — ‘Fatal Attraction’ and ‘Blue Haze’ are horticultural selections, and ‘Hakuro Shiro Fukurin’ is a variegated cultivar with leaves with white margins.

**A. fusca** (Ravenna) Thiede & Egli (Kakt. and. Sukk. 52(6): 166, 2001). **Type**: Guatemala (*Ravenna* 325 [Herb. Ravenna]). — **Lit**: Ravenna (1987: with ill.); Castañeda Rojas & al. (2005: 70–71); Castillejos-Cruz (2009: [133]–[138], with ills.); all as *Manfreda*. **Distr**: Guatemala (Chimaltenango, Comalapa); sandy plains and embankments, in pine-oak forests, 1920–2410 m; flowers June to July. **I**: Lott & García-Mendoza (1994: online version); Hochstätter (2016: I: 19); both as *Manfreda*.

≡ *Manfreda fusca* Ravenna (1987).

[3a3] Plants herbaceous; corm 3–9 × 2–5 cm, subcylindrical, bulb 3–4.5 × 1.5–3 cm, shortly cylindrical to ovoid, nearly completely covered with dry leaf bases 4–12 cm long, these membranous at the base and fibrous above; **R** fleshy and fibrous, contractile; **L** drought-deciduous, 5–15, 30–60 × (1–) 2.2–3.2 cm, light green, prostrate or

semi-erect, linear-lanceolate, narrowed towards the base, semisucculent, canaliculate, lower face carinate to slightly scabrous, upper face glabrous, apex acute-acuminate, margins entire, with a papillose-denticulate hyaline band; **Inf** 77–200 cm, ‘spicate’, peduncle stiff, **Bra** 8–12, rather distant, fertile part 5–25 cm, with 7–21 flowers; floral **Bra** 0.2–1.1 × 0.3–0.6 cm; **Fl** 37–47 mm, solitary, sessile, ascending, with foetid odour; **Tep** glaucous-green to reddish on the outer face, semisucculent, forming a tube 14–24 × 5–6 mm, lobes narrowly oblong to lanceolate, extended to revolute, 15–17 × 4–6 mm, tip apiculate, with a bundle of short white hairs; **Fil** sparsely glandular-pilose, 39–42 mm, erect at anthesis, exceeding the tube for 10–20 mm, inserted at mid-tube all on the same level, yellowish-green with purple dots; **Anth** 10–11 mm, yellow; **Ov** oblong, 12–18 × (5–) 6–6.6 mm, greenish, prolonging 1 mm into the tube, not constricted above; **Sty** 37–57 mm, yellowish-green with purple dots; **Sti** capitately 3-lobed; **Fr** subglobose, 15–21 × 9–15 mm, with a scar near the apex, tepals persistent; **Se** deltoid, plane-concave, with narrow margin, 4–5 × 3–4.5 mm, shiny black.

In the protologue, no differential diagnosis is given nor is the relationship indicated. García-Mendoza & al. (2000) clearly place the species in Ser. *Guttatae* (as *A. guttata* Group) of *Manfreda* Sect. *Manfreda*, based on a study of additional specimens at MEXU. This placement is confirmed by Castañeda Rojas & al. (2005) and Castillejos-Cruz (2009) (both as *Manfreda*), who provide additional morphological data. *A. fusca* (presently known from the inaccessible holotype and 2 further gatherings only) is distinct esp. in its flower colour and foetid odour. The species was erroneously omitted from the treatment of the family for the ‘Flora Mesoamericana’ (Lott & García-Mendoza 1994), but the online-version includes photographs.

**A. galvaniae** (Castañeda & al.) Etter & Kristen (Haseltonia 12: 70, 2007). **Type:** Mexico, México (Castañeda Rojas & al. 108 [MEXU, ENCB, IEB, MEXU, MO]). — **Lit:** Castañeda Rojas & al. (2005); Castillejos-Cruz (2009: [139]–[144]); both with ill. and as *Manfreda*. **Dist:** Mexico

(S México); in disturbed tropical deciduous forests and ecotone with pine forests, 1450–1900 m; flowers in July. **I:** Hochstätter (2016: I: 20, as *Manfreda*).

≡ *Manfreda galvaniae* A. Castañeda & al. (2005).

[3a3] Plants herbaceous; corm 3–5 × 2–4 cm, subglobose to subcylindrical, bulb 2.7–4 × 1.3–2.5 cm, cylindrical, nearly completely covered with dried leaf bases 4.5–7.3 cm long, these membranous at the base and fibrous above; **R** fleshy, with filiform ramifications, contractile; **L** drought-deciduous, 2–5 (–7), prostrate or semi-erect, linear-lanceolate, 22–62 × 0.6–2.6 cm, light green, narrowed towards the base to a pseudopetiole 3–4 × 1 cm, semisucculent, slightly canaliculate, glabrous on both faces, apex acuminate, margins entire, with a hyaline band not visible to the naked eye; **Inf** 77–154 cm, ‘spicate’, erect, somewhat arched, reddish to greenish with purple tinge, peduncular **Bra** 5–8, similar to the leaves but smaller, fertile part 23–67 cm, lax, with 7–21 flowers; floral **Bra** 0.8–3.1 × 0.3–1 cm; **Fl** 27–42 mm, solitary, sessile, ascending; **Tep** reddish with purple tinge, semisucculent, forming a tube 13–24 × 4–5 mm, lobes narrowly elliptic to ovate, extended, 9–14 × 3–7 mm, tip cucullate, with a bundle of short white trichomes; **Fil** 15–24 mm, erect at anthesis, exceeding the tube for 10–20 mm, inserted at the upper ¼ of the tube all on the same level, yellowish-green; **Anth** 8–12 mm, yellow; **Ov** cylindrical, (5–) 8–12 × 2–4 (–5) mm, reddish with purple tinge, prolonging 1 mm into the tube, not constricted above; **Sty** 28–37 mm, whitish with purple tinge to yellowish-green; **Sti** capitately 3-lobed; **Fr** subglobose, 13–20 × 9–15 mm, with a scar near the apex, tepals persistent; **Se** deltoid, plane-concave, with narrow margin, 3–5 × 2–4 mm, shiny black.

In the protologue placed in Ser. *Guttatae* (as *A. guttata* Group) of Sect. *Herbaceae*, and characterized by its globose corm nearly always completely covered with dry leaf bases, linear-lanceolate pseudopetiolate leaves, short and lax inflorescences with reddish to yellowish-green with purple tinge, narrowly elliptic to ovate perianth lobes, and a shortly projecting ovary. It is morphologically closest to *A. fusca* and *A. debilis*

(= *Manfreda pringlei*), but differs in its hyaline leaf margin, the lax flower arrangement, the semi-succulence and colour of its flowers, the shape and orientation of its perianth lobes, and its short filaments.

**A. garciae-mendozae** Galván & L. Hernández (Cact. Succ. J. (US) 74(4): 188, ills. (pp. 189–190), 2002). **Type:** Mexico, Hidalgo (*Galván & Galván* 4646 [ENCB, CHAPA, MEXU, MO, QMEX, UAMIZ]). — **Lit:** Eguiarte & Scheinvar (2008: 35–39, with ills.); Trejo-Salazar & al. (2015: pollination). **Distr:** Mexico (San Luis Potosí, Querétaro, Hidalgo); mountain slopes and rocky outcrops, often in canyon bottoms, in limestone soils, in sclerophyllous scrub or oak/pine-oak forests, 1800–2650 m; flowers June to August. **I:** Pilbeam (2013: 88); Hochstätter (2015: IX: 31).

[lg] Stems short; **Ros** openly spreading, 0.75–1.15 (–1.3) × 1–1.75 m, single or somewhat caespitose; **L** (30–) 50–80, lanceolate, straight or incurved, fleshy, thin, flexible mainly in the upper ½, flat or slightly convex below, flat to somewhat concave above, (33–) 48–78 × 6–13 cm, dark green to glaucous-green, margins horny, continuous, 0.5–2 mm wide, grey to dark reddish-brown, easily separated; **marginal teeth** variable, straight to curved, narrowly acuminate, deltoid, flattened, 7–14 mm, grey with reddish-brown tip, (7–) 10–40 mm apart, often with intermittent smaller teeth; **terminal Sp** conical to subulate, sometimes somewhat reflexed, widely grooved on the upper face, keeled abaxially, 27–48 mm, grey, decurrent; **Inf** 3.2–5.5 m, ‘spicate’, peduncle reddish to glaucous-green, with long-deltoid, chartaceous to papery **Bra** 7.5–23 cm long, fertile part in the upper ½–⅔ of the inflorescence; **Ped** 2–3 mm; **Fl** geminate, 28–39 mm; **Tep** light green to yellowish-green and somewhat glaucous, tube 1.5–2.5 × 5–6 (–7) mm, lobes oblong, involute, acute, slightly cucullate and hairy, 12.5–16 × 4–5 mm, sometimes reddish, inner with a wide keel; **Fil** 38–45 mm, inserted at the base of the lobes; **Anth** 10–13 mm, yellow or greenish-yellow; **Ov** cylindrical, 8–12 × 3.5 mm, neck constricted, 2–3 × 1.2–1.8 mm; **Sty** slightly longer than the filaments; **Fr** oblong or oblong-ellipsoid, (15–)

17–20 × 9–11 mm, shortly apiculate; **Se** semicircular, black, 3–4.9 × 2–2.7 mm, marginal wing 0.8–1 mm wide, hilar notch shallow.

Showing affinities with *A. horrida* and *A. kerchovei* according to the protologue, and thus placed in Sect. *Heteracanthae* (as Group *Marginatae*). It differs from the former in its open rosettes, the colour and larger size of its flexible leaves with a grooved terminal spine, its shorter ovary and more shallow tube; and from the latter in its shorter rosettes, fewer leaves with a different colour and flexibility, its shorter ovary and shallower tube.

The inflorescences of *A. garciae-mendozae* consist on average of 3623 flowers, of which 426 are producing pollen or nectar at any one day. Only 60% of the flowers have a high probability to develop into fruits. From the total seeds per infructescence (471,120 on average), only ⅓ (142,725 on average) are viable. The plants are self-compatible, but cross-pollination is most effective for fruit set, indicating a strong inbreeding depression. Most flower visitors are nectarivorous bats, honey bees and bumblebees are infrequent, and hawkmoths rare. The species appears to have a generalist pollination system with bats as main pollinators, and bees and bumblebees ensuring reproductive success when bats are missing. Relatively high levels of genetic diversity and small genetic distances between different populations have been found (González 2004, Eguiarte & Scheinvar 2008, Eguiarte & al. 2013: 491, Trejo-Salazar & al. 2015).

The unpublished *A. hidalgensis* (also as “*hidalguensis*”) (Eguiarte & Scheinvar 2008, Arzate García 2009, both with ills.), one of the largest representatives of Subgen. *Littaea* (rosettes to 2.5 m Ø, leaves 70–90 cm, inflorescences exceeding 7 m) from the N Barranca de Metztitlán, appears to belong here.

**A. garciaruii** A. Vázquez & al. (Phytotaxa [in press], ills., 2019). **Type:** Mexico, Michoacán (*Vázquez-García & al.* 10140 [IBUG, CIMI, MEXU]). — **Distr:** Mexico (SE Jalisco, N Michoacán); rocky cliffs of the Itzicuario-Apupátaro watershed, in tropical deciduous forests, 900–1000 m; flowers in March. **I:** Vázquez-

García & al. (2007b: 41–42, t. B1–B4, as *A. angustiarum*).

[1g] Subcaulescent; **Ros** open, 0.9–1.1 m, solitary; **L** 20–34, linear to lanceolate, openly spreading, straight, thick, firm, long-acuminate, flat to concave above, convex below, 50–80 × 6–10.6 cm, green to dark green, pale green median stripe above inconspicuous or lacking, margins whitish-grey, continuous; **marginal teeth** straight or inclined in the lower part of the leaf, curved upwards or bent in the upper part, flattened, the largest somewhat scattered, 4–7 mm, dark brown to grey, (3–) 10–30 mm apart, 8–14 teeth per 10 cm, teeth absent from the topmost 5–10% of the leaf, intervening margin nearly straight; **terminal Sp** acicular, narrowly grooved above, 30–40 mm; **Inf** 3–4.2 m, ‘spicate’, flexible, peduncle with toothless triangular **Bra** 10.5–13.5 cm long, fertile part in the upper 33–40%, 15–18 cm Ø (infructescence 10–14 cm Ø); **Ped** 8–10 mm (fruiting 18–20 mm); **Fl** 57–64 mm, geminate; **Tep** pale yellow to yellowish-green, tube very short, 2–3 × 6–7 mm, lobes 17–18 × 4–5 mm, pale yellow to yellow, glaucous-greenish in bud; **Fil** 38–44 mm, yellow; **Anth** 16–21 mm, yellow; **Ov** 16–17 mm, neck narrow; **Sty** slightly longer than the filaments; **Sti** capitate; **Fr** 24–26 × 10–12 mm, fruit valves curved outwards, apically acute; **Se** crescent-shaped, 2–3 × 3–5 mm.

A local endemic, according to the protologue closest to *A. angustiarum* and differing esp. in having an inconspicuous or absent median stripe on the upper face of the leaves, denser marginal teeth, longer anthers, longer fruiting pedicels, a larger infructescence diameter, and larger capsules with acute fruit valves curved outwards. *A. garciaruzii* is also close to *A. arcedianoensis* and differs esp. in having an inconspicuous or absent median stripe on the upper leaf face, denser marginal teeth, a shorter fertile inflorescence part, pale yellow to yellowish-green flowers with larger anthers and longer pedicels, and smaller fruits with apically acute, spreading fruit valves. The records and specimens for *A. angustiarum* from SE Jalisco (Hernández-Vera & al. 2007a) and from SE Jalisco and N Michoacán (Vázquez-García & al. 2007b) belong here. The fruit valves

curved outwards are reported only for *A. garciaruzii* and *A. impressa*.

**A. geminiflora** (Tagliabue) Ker Gawler (J. Sci. Arts (London) 2: 86–90, 1817). **Type:** [icono]: Bibliot. Ital. Giorn. Lett. 1: t. inter pp. 112, 1816. — **Lit:** Berger (1915: 69–70); Gentry (1968); Gentry (1982: 113–115); McVaugh (1989); Ullrich (1995a); Cházaro Basáñez & al. (2004b); Vázquez-García & al. (2007b: 52–53, t. J); Starr (2012: 94–97, 317–319); all with ills. except Berger. **Distr:** Mexico (C Nayarit, N-C Jalisco); on rocks along arroyos, in oak woodland, 1000–1400 m; flowers October to December. **I:** Bot. [1d] Stems short; **Ros** dense, 0.7–1 m, somewhat broader than tall, solitary; **L** many, linear, eventually arching, flexible, narrow, pliable, abruptly acute, roundly convex below and above, smooth, 45–60 × 0.6–0.8 cm, green,

margins finely filiferous or rarely naked; **terminal Sp** shortly subulate, 5–7 mm, greyish; **Inf** 4–7 m, ‘spicate’, peduncle long-tapering, stout at the base (9–12 cm Ø), with narrow ascending-reflexed **Bra**, fertile part in the upper  $\frac{2}{3}$ – $\frac{3}{4}$  of the inflorescence, part-**Inf** with mostly geminate flowers; **Ped** slender, 5–8 mm; **Fl** 40–52 mm; **Tep** pale yellowish-greenish below, tinged above with red or purple, tube narrowly funnel-shaped, 6-grooved, 6–11 mm, lobes linear-lanceolate, recurving, slightly unequal, 18–21 × 4–5 mm, tinged with red, inner slightly shorter, distinctly keeled; **Fil** 35–46 mm, colourless or reddish, inserted on the tube rim; **Anth** excentric, 20–22 mm; **Ov** slender, fusiform-angled, 16–20 mm, neck grooved; **Sty** thickened above, slightly shorter than the filaments; **Sti** not thickened; **Fr** oblong, trigonous, tough, persistent, 18–20 × 9–10 mm, shortly stipitate, shortly beaked, reddish when young; **Se** crescent-shaped, thick, irregularly veined on the faces, 3–4 × 2–3 mm, with conspicuous marginal wing.

Distinct within Sect. *Littaea* (as Group *Filiferae*) by its relatively large simple stem with innumerable, very narrow, pliable, smooth leaves and large ‘spikes’ with relatively remote long flowers. It is most closely related to *A. ornithobroma* which differs esp. in its asymmetrical, few-leaved, surculose rosettes (Gentry 1982: 112). The species was of unknown wild origin until Gentry (1968) reported it from a small area N of Ocotillo, Nayarit. Recently, 2 further populations in Nayarit (Sierra de Álica, La Galinda) and a first occurrence in Jalisco at Xiloasco were found (Cházaro Basáñez & al. 2004b, Hernández-Vera & al. 2007a, Vázquez-García & al. 2007a). The report of a specimen of this taxon from S Sinaloa by McVaugh (1989: 135) is erroneous, since the collection cited (Gentry 18358) is the type collection of *A. ornithobroma*.

The plant came in 1797 from the Botanical Garden Bologna to Milano (Italy), where it first flowered in the garden of Duke Litta of Lainate in 1815, after whom it was named in a new genus as *Littaea geminiflora* (Berger 1915) (see also the historical account by Richter 2011: 24–32). The epithet of *A. geminiflora* (dating from 1816) is antedated by the name *Yucca bosicii* (1813),

which would therefore be the correct epithet for the species (Govaerts 2014+). A proposal to conserve the long-established name *A. geminiflora* was consequently published by Figueiredo & Smith (2013b) and was recommended for acceptance (Applequist 2014: 1366).

**A. gentryi** B. Ullrich (Succulenta 69(10): 210–214, ill., 1990). **Type:** Mexico, Nuevo León (Gentry 20159 [ARIZ, US]). — **Lit:** Gentry (1982: 598–601, figs. 21.8, 21.9, as *A. macroculmis*); Villarreal (1996); González-Elizondo & al. (2009: 80–84, with ill.); Starr (2012: 98–105, 325–328, with ill.); Greulich (2012c: with ill.). **Distr:** Mexico (Coahuila, Nuevo León, Tamaulipas, Durango, Zacatecas, San Luis Potosí, Guanajuato (?), Querétaro, Hidalgo, Puebla); mountain regions in open pine-oak forests, 1800–3400 m; flowers in April. **I:** Heller (2006: 89); Spracklin (2007: 148); Richter (2011: 72); Pilbeam (2013: 91); Nájera Quezada & al. (2015: 5); Hochstätter (2015: III: 3); Greulich (2016b: 38).

[2m] **Ros** 0.9–1.5 (–1.8) × (0.6–) 0.9–1.8 (–2.2) m, solitary or clustering with rhizomatous offsets; **L** 30–45, either broad from the base to above the middle before quickly tapering to the sharp tip, or long triangular and widest at the base before gradually narrowing to the tip, concave, 60–120 × 15–26 cm, light yellowish-green to deep rich green, with strong imprints from the central bud created by the marginal teeth; **marginal teeth** nearly straight, small to large, 8–12 mm, 20–40 mm apart; **terminal Sp** stout, 45–75 mm; **Inf** 2.5–5.5 m, paniculate, peduncle with overlapping, thick and succulent, entire **Bra**, fertile part elliptic, covered in a bulb-like manner by fleshy bracts before anthesis, **Fl** densely clustered in 10–18 (–21) short-stalked part-**Inf**; **Fl** 70–110 mm; **Tep** yellow, reddish in bud, tube funnel-shaped, 11–16 mm, lobes 22–28 mm; **Ov** 35–50 mm; **Fr** 60–75 × 20–25 mm; **Se** 7–8 × 6 mm.

The usage of the name *A. macroculmis* by Gentry (1982: 598) must be rejected, since this name is a synonym of *A. atrovirens* (Ullrich 1990i). This left Gentry’s distinctive plant without a name, which led Ullrich (1990i) to describe it as a new species, *A. gentryi*, using Gentry’s

**Fig. 24** *Agave ghiesbreghtii*. (Copyright: J. Etter & M. Kristen)

description of *A. macroculmis*. However, this description also includes features of the subsequently separated *A. montana*. The description given above for *A. gentryi* is based on a combination of data from Villarreal (1996), Starr (2012), and Greulich (2012c). See under *A. montana* for differences and the classification of both species.

*A. gentryi* includes 3 distinct and geographically separated forms (Starr 2012). It moreover appears to form hybrids with *A. americana* ssp. *protoamericana*, *A. asperrima*, *A. salmiana* ssp. *crassispina*, *A. mapisaga*, and *A. montana* (Starr 2012, Greulich 2012c). González-Elizondo & al. (2009) report the species from Durango. The report of “*A. macroculmis*” from Guanajuato (Zamudio & Galván Villanueva 2011) may refer to *A. gentryi*. — ‘Jaws’ is a cultivar with exceptionally large teeth (Starr 2012: 105). Greulich (2012c) depicts flowering specimens of it and considers ‘Jaws’ to be a long-leaved transitional form to *A. salmiana* with longer stalked and compound part-inflorescences. ‘La Pena Colorada’ is a variegated cultivar (Starr 2014: 222, with ill.).

The flowers are visited at day by birds and insects and at night, when nectar production and sugar content increases, by bats and insects (Castillo-Hernández & Treviño-Carreón 2014). The maroon-fronted parrot (*Rhynchopsitta terrisi*) feeds on flowers and fruits of the species during the breeding season (Ortiz-Maciel & al. 2010).

**A. ghiesbreghtii** Verschaffelt (Cat., 71: 3, 1862). **Type** [neo]: Cult. BG La Mortola (Berger s.n. [US [neo/syn?]]). — **Lit**: Berger (1915: 116–117, with ill.); Standley & Steyermark (1952: as *A. huehueteca*); Gentry (1982: 141–142, with ill.); Lott & García-Mendoza (1994: online-version with ill.); García-Mendoza (2011a: 26–27, 30). **Dist**: Mexico (México, Guerrero, Puebla, Oaxaca, Veracruz, Chiapas), W Guatemala; limestone rock slopes and outcrops in desert scrub, tropical deciduous forests, and pine-oak forests, 975–2500 m; flowers mainly June to September, also October, November and January. **I**: Heller (2006: 40, 90, 91, 156); Richter (2011: 48, as *A. purpusorum*, 66, 113); Pilbeam (2013: 92). — Fig. 24.

**Incl.** *Agave rohanii* Jacobi (1864); **incl.** *Agave leguayana* Verschaffelt (1868); **incl.** *Agave gilbeyi* Hort. Haage & Schmidt (1873) ≡ *Agave horrida* var. *gilbeyi* (Hort. Haage & Schmidt) Baker (1877) ≡ *Agave roezliana* var. *gilbeyi* (Hort. Haage & Schmidt) Trelease (1914); **incl.** *Agave roezliana* Baker (1877); **incl.** *Agave roezliana* var. *inghamii* hort. ex Baker (1877); **incl.** *Agave purpusorum* A. Berger (1915); **incl.** *Agave roezlii* hort. ex A. Berger (1915) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave huehueteca* Standley & Steyermark (1943).

[1g] Acaulescent; **Ros** compact, 0.4–0.7 × 0.6–0.8 m, solitary or copiously suckering; **L** 70–90, broadly lanceolate, ovate or deltoid,

erect, straight or upcurving, thick, rigid, narrowed above the thick base, broadest at the base or in the middle, apex acuminate, convex below, flat to slightly concave or guttered above, smooth, (20–) 30–40 (–65) × (5–) 7–12 cm, or more rarely broadly linear and 35–38 × 5.5–6 cm, dark or light green to yellow-green, sometimes with a lighter mid-stripe, margins horny, relatively straight, narrow, continuous, brown or greyish; **marginal teeth** triangular, strong, frequently straight, sometimes curved upwards or downwards, 5–8 (–15) × 3–6 (–7) mm, brown to greyish, (10–) 25–40 (–60) mm apart, with some intermittent small teeth, reduced at the leaf tip for 2.5–4.5 (–12) cm; **terminal Sp** conical or subulate, shortly shallowly grooved above, rounded below, (10–) 25–35 (–40) × 4–6 (–10) mm, brown to grey, decurrent on the lower face for 2–4 mm; **Inf** (3–) 3.5–5 (–6) m, ‘spicate’, peduncle green with purple tinge, with linear papery brown **Bra** 13–17 cm long, fertile part in the upper  $\frac{1}{2}$ – $\frac{1}{3}$ , densely flowered; **Ped** geminate, 1–4 (fruiting 5–8) mm, thick; **Fl** campanulate, 30–40 (–50) mm; **Tep** purple to greenish-red, inside yellowish, tube broadly funnel-shaped, grooved, 2–5 (–10) × 5–7 (–10) mm, lobes broadly linear to oblong, apex rounded, thickly apiculate, at first outcurving, later involute and clasping the filaments, subequal, 15–21 × 3–5 (–8) mm, inner narrower and with broad low keel; **Fil** (35–) 40–45 mm, inserted on the rim of the tube at the lobe bases, reddish; **Anth** centric, 10–15 (–22) mm, brownish to brownish-red; **Ov** cylindrical, 15–20 × 3–5 (–8) mm, green, neck 2–4 mm, constricted; **Sty** 45 to >70 mm, thickened below the stigma, brown or reddish; **Sti** capitate; **Fr** oblong, globose-ovoid or ellipsoid to obovoid, 17–23 × 8–15 mm, brownish; **Se** semicircular, finely punctiform, wing inconspicuous, (3–) 4–5 × 2–3.5 mm, shiny black. — **Cytology**: 2n = 120 (Simpson & al. 2011: p.p., as *A. gilbeyi*).

The neotype cited above was designated by Gentry (1982: 142). A species of uncertain circumscription, closely related to *A. kerchovei*, but different by its shorter and broader leaves with fewer and smaller teeth on narrower and darker horny margins (Gentry 1982: 142, García-Mendoza 2011a). Characterized by its small rosettes, deltoid or broadly

lanceolate leaves, narrow margins with few short and widely spaced teeth, short tepals, long filaments, and punctiform seeds (García-Mendoza 2011a). The species was introduced by Ghiesbreght and brought into the trade by Verschaffelt in 1862 (Berger 1915). The species (vernacular names: “pichomel”, “jabalf”) is used for living fences, and strips of dried leaves are used to make ties (García-Mendoza 2011a). Rivera-Hernández & al. (2015) provide a new record from W-C Veracruz. See also notes under *A. angustiarum*, *A. funkiana*, *A. horrida* ssp. *horrida*, and *A. kerchovei*.

**A. gigantensis** Gentry (Occas. Pap. Calif. Acad. Sci. 130: 63–67, ill. (pp. 65–66 [bottom], 68, t. 2 [top]), 1978). **Type** [syn]: Mexico, Baja California Sur (Gentry & McGill 23320 [US, ARIZ, ASU, CAS, DES, MEXU, MICH, SD]). — **Lit**: Gentry (1982: 386–388, ill. pp. 387, 388 [bottom]); Webb & Starr (2014a: 94); Webb & Starr (2014b: 7–8); Webb & Starr (2015: 73); all with ill. **Distr**: Mexico (C Baja California Sur: N Sierra de la Giganta [Cerro El Potrero & Sierra de las Palmas]); mountain slopes, mesas and cliffs, 900–1520 m; flowers April to May and November.

[2j] Acaulescent; **Ros** rather open, 0.5–1 × 0.8–1.2 m, solitary; **L** few, broadly lanceolate, flat, rigid, thick, fleshy, markedly narrowed at the base, widest at or above the middle, acuminate, smooth, 40–75 × 11–16 cm, dark green to occasionally glaucous grey-green, with distinct imprints from the central bud, turning red to purplish when plants are flowering, margins repand to prominently mammillate; **marginal teeth** variously curved, basis thick, sometimes grotesquely so, frequently 2–3 teeth on the same base, confluent along the upper leaf margins, 10–20 mm and more, brown to light greyish, generally remote and to 60–80 mm apart; **terminal Sp** strongly subulate, straight or sinuous, deeply sulcate above, 30–60 mm, grey, long decurrent as pronounced horny margin, sometimes to mid-leaf; **Inf** 4–5 m, paniculate, peduncle with narrowly lanceolate, thickly chartaceous **Bra**, fertile part rather stout, compact and narrow, part-**Inf** nearly horizontal, 18–25 in the upper  $\frac{1}{3}$  of the inflorescence; **Fl**

slender, 48–60 mm; **Tep** bright pale yellow, buds whitish or pale green, tube shortly discoid, spreading, thickened at the lobe bases, 4–5 × 11–13 mm, lobes linear, spreading, rounded and shortly hooded at the apex, 18–25 × 5–6 mm, inner with prominent keel, grooved within and strongly overlapped at the base by the outer; **Fil** slender, 30–45 mm, variable in length, inserted on the rim of the tube at the lobe bases; **Anth** somewhat excentric, 18–25 mm; **Ov** slender, fusiform, neck short, slightly grooved, constricted; **Sty** slightly longer than the filaments; **Sti** capitate; **Fr** oblong, 35–40 × 12–15 mm, neither beaked nor stipitate; **Se** unknown. — **Cytology**: 2n = 60 (Simpson & al. 2011).

Gentry's holotype indicated in the protologue for US consists of 3 sheets which are not cross-labelled, thus representing syntypes. Recent field and herbarium studies (Webb & Starr 2014a, b) showed that Gentry (1978) and Gentry (1982) included material with glaucous-blue to blue-green leaves in fact belonging to *A. sobria* ssp. *sobria* in his original concept of *A. gigantensis*. Webb & Starr (2014b) restricted the concept of *A. gigantensis* to plants with dark-green leaves and occurring only at higher elevations on the Cerro El Potrero and Sierra de las Palmas. In the above description based on Gentry (1982), the leaf colour is corrected to dark green and some further data were added from Webb & Starr (2014b) and Webb & Starr (2015), but it may still include incorrect data from *A. sobria*. Some of Gentry's photographs labelled "*A. gigantensis*" (1978: p. 66 top; 1982: p. 388 top) belong to *A. sobria* (Webb & Starr 2014b), and "*A. gigantensis*" plants with bluish leaves (Richter 2011: 79, 105, Pilbeam 2013: 93, Moore 2016: 277) apparently belong to *A. sobria*. According to Gentry (1982), the closest relatives appear to be *A. avellanidens* (with leaves not or scarcely narrowed towards the base) and *A. moranii* (with much longer leaves), both disjunct to the north. These three taxa as well as *A. turneri* are now placed in a new Sect. *Conicae* (see under *A. avellanidens*).

**A. gilbertii** A. Berger (Monatsschr. Kakt.-kunde 14: 126, 1904). **Type** [lecto]: Ex cult.

(*Anonymous* s.n. [K [sub *A. bakeri*]]). — **Lit**: Watson (1902: protologue *A. bakeri*); Hooker (1903: as *A. bakeri*); Berger (1915: 41–42); Gentry (1982: 71–72); Roosbroeck (2004); all with ills. **Distr**: Known from cultivation only. **I**: Heller (2006: 93); Richter (2011: 60, as *A. bakeri*); Hochstätter (2015: VIII: 21); Meer (2016c: 144).

**Incl.** *Agave bakeri* W. Watson (1902) (*nom. illeg.*, ICN Art. 53.1).

[1b] Stems short; **Ros** solitary, not suckering; **L** many, lanceolate, recurving, coriaceous, narrowed and thickened near the base, broadest in the middle, tapering to the base to 6.25 cm, tapering to the apex to a sharp point, convex below, concave to flat above, 90–100 × 10–12 cm, glaucous-green, with paler median stripe, margins thin, with continuous narrow brown border; **marginal teeth** none; **terminal Sp** slender, 5–20 mm, brown; **Inf** to 3 m, 'spicate', peduncle short, with linear-lanceolate **Bra** longer than the lowest flowers, fertile part cylindrical, densely flowered from near the base; **Fl** 50–60 mm, geminate; **Tep** pale greenish-yellow outside, whitish within, tube 6-furrowed, 11–12 mm, lobes reflexed or revolute, obtuse, 20 mm, greenish outside, whitish within, inner broader, with dark green keel; **Fil** rigid, 40–50 mm, whitish, inserted at the orifice of the tube 1 mm above the tube base; **Anth** 14 mm, golden-yellow; **Ov** fusiform, slender, ±20 mm, neck slender, 6-sulcate; **Sty** rigid, shorter than the filaments but longer at the female phase (Watson 1902); **Sti** 3-lobed; **Fr** and **Se** unknown (although Berger (1904) reported that the plant which flowered at Kew in 1902 yielded many seeds, which were widely distributed).

The illegitimate name and replaced synonym *A. bakeri* is usually ascribed to Hooker (1903), but was published earlier by W. Watson (Watson 1902), based on a flowering plant at Kew purchased at the sale of the *Agave* collection of the late Mr. Peacock in 1889. The notion of Gentry (1982) that the species "disappeared in cultivation" is erroneous; it is cultivated in Europe (see references) and the USA, but has never been located in habitat (Gentry 1982). The recently published *A. chazaroi* is somewhat similar, but stemless and with broader leaves with a longer terminal spine.

**A. ×glomeruliflora** (Engelmann) A. Berger *pro sp.* (Hort. Mortol. 12, 1912). **Type:** [lecto — icono]: Gard. Chron. ser. nov., 1883: 19, fig. 6. — **Lit:** Berger (1915: 94–95, as *A. glomeruliflora*); Muller (1939: with ill., as *A. chisoensis*); Gentry (1982: 142–144, with ills., as *A. glomeruliflora*); Reveal & Hodgson (2002: as *A. glomeruliflora*); Greulich (2016a: with many ills.). **Distr:** USA (W Texas), Mexico (Coahuila); gravelly calcareous slopes in grasslands and oak-juniper woodlands, 600–1600 m; flowers mid-spring to early fall. **I:** Kümmel & Klügling (2006: as *A. lechuguilla*); Richter (2011: 86); Pilbeam (2013: 94–95); Hochstätter (2015: IX: 47).

≡ *Agave heteracantha* var. *glomeruliflora* Engelmann (1883) ≡ *Agave lechuguilla* fa. *glomeruliflora* (Engelmann) Trelease (1920); **incl.** *Agave chisosensis* C. H. Muller (1939).

[1g × 2l] Obviously of intersubgeneric hybrid origin with morphological gradations between *A. lechuguilla* and *A. ×gracilipes*, *A. (parryi ssp.) neomexicana* and/or *A. havardiana* (Gentry 1982: 143) and thus only representing an aggregate of different habitually similar natural hybrids. According to Reveal & Hodgson (2002), the name *A. ×glomeruliflora* “should probably be more appropriately applied only to crosses and back-crosses between *A. lechuguilla* and *A. havardiana*”. Gentry’s selection of a neotype is superseded by his simultaneous selection of a lectotype (Gentry 1982: 143). Baker & al. (2009: 283) report a chromosome count of  $n = 60$  which is congruent with a spontaneous origin between *A. lechuguilla* × *A. parryi ssp. neomexicana*, both with  $2n = 120$ ; counts for the remaining two possible parental taxa are unknown. Few if any substantial threats were identified, and substantial populations in Big Bend and Guadalupe Mountains National Parks are under protection (Reichenbacher 1985: 103–105). Magallán Hernández & Hernández Sandoval (2001: 108) report “*A. aff. glomeruliflora*” from Municipio Cadereyta in Coahuila. Plants have survived 30 years outdoors in a mild climate in Germany with rain protection in winter (Kümmel & Klügling 2006: as *A. lechuguilla*, Greulich 2016a).

**A. gomezpompae** Cházaro & Jimeno-Sevilla (Cact.-Avent. Int. 88: 2–11, ills., 2010). **Type:** Mexico, Veracruz (*Jimeno-Sevilla & al.* 247 [XAL, CHAP, CHAPA, ENCB, IBUG, IEB, MEXU]). — **Lit:** Jimeno-Sevilla (2010: 97–99, with ills.). **Distr:** Mexico (C Veracruz: near Córdoba); karstic limestone rocks and outcrops, 850 & 1400 m, in tropical “subperennial” (semi-deciduous) or cloud forests; flowers May to July; only known from 4 populations. **I:** Richter (2011: 56); Meer (2012); Pilbeam (2013: 96); Hochstätter (2015: VIII: 21).

[1f] Caulescent, stems creeping, to >150 × 8–15 cm, bifurcating 3× or more, each stem with a repeatedly flowering **Ros** that turns upright, not surculose; **L** few, lanceolate to oblanceolate, flexible, fleshy, concave above, convex below, 80–85 × 10–13 cm, dark green, margins denticulate throughout; **marginal teeth** none; **terminal Sp** 20 mm or longer, dark; **Inf** lateral according to the protologue but actually likely terminal on rudimentary lateral rosettes, erect, to 2.7 m, ‘spicate’, peduncle with triangular **Bra** 12–16 × 3–5 mm, fertile part only ±50 cm; **Ped** 3–4 mm, single or geminate; **Fl** 32–49 mm (74 mm with stamens); **Tep** spatulate, 20–28 × 2–4 (at the base) mm, green or creamish-yellow inside, tube ± ½ as long as the obtuse lobes; **Fil** to 43 mm; **Anth** 7–9 mm, yellowish; **Ov** ovoid or barrel-shaped, 15–21 × 3–5 mm, greenish, not constricted; **Sty** slender, to 43 mm; **Sti** slightly thickened; **Fr** trigonous, 20 mm with a 5 mm long stipe, blackish; **Se** 3–4 × 2 mm, black, shiny.

Placed in Sect. *Micracanthae* (as Group *Polycephalae*) according to the protologue, and closest to the allopatric *A. pendula* with which it shares long and bifurcating stems and seemingly lateral inflorescences, but differs by thicker stems, broader and pure green leaves without yellow mid-stripe and denticulate all along the margins, and longer inflorescences.

**A. ×gonzaloii** D. Guillot & P. Van der Meer *pro sp.* (Flora Montiber. 27: 55–56, 2004). **Type:** Spain, Valencia (*Guillot & Van der Meer s.n.* [VAL 151000]). — **Distr:** Cultivated only.

≡ × *Mangave gonzaloi* (D. Guillot & P. Van der Meer) hort. (s.a.) (*nom. inval.*, ICN Art. 29.1).

[1 × 3a] A commercially offered garden hybrid with spotted leaves, most probably between a species of Subg. *Manfreda* (*A. maculosa* or *A. variegata*?) and an unknown species of Subg. *Littaea* (and thus belonging to the synonymized nothogenus × *Mangave*), found at the Botanical Garden of Valencia (Spain).

**A. graciellae** Galván & Zamudio (Acta Bot. Mex. 105: 2–4, ills., (pp. 3, 6–7), 2013). **Type:** Mexico, Querétaro (*González 569* [IEB, ENCB, MEXU, XAL]). — **Dist:** Mexico (SE San Luis Potosí, NE Querétaro); on karstic limestone rocks, in pine-oak or cloud forests, 1200–2400 m; flowers April to July. **I:** Magallán Hernández & al. (2012: 26, as *Agave* sp. 1); Hochstätter (2015: VIII: 21); Perez Badillo (2016: 120); De-Nova & al. (2018: 24).

[1a] Stems short; **Ros** hemispherical, 16–60 (–70) × 35–75 cm, caespitose, forming dense groups/clusters; **L** (65–) 100–230, linear, at the base with a deltoid sheath 2.5–5 × 1.8–2.5 (–3) cm at the base, whitish, fleshy, lamina straight to slightly incurved at maturity, fleshy-coriaceous, flexible, keeled below, flat or slightly concave above, esp. towards the apex, smooth on both faces, 13.5–55 (–60) × (1–) 1.2 (–1.5) cm, light green, striated when dried, margins corneous, 3–5 mm wide, with hyaline or yellowish border, minutely serrulate, denticles sometimes bicuspid, sometimes reddish or only at the tip; **marginal teeth** none; **terminal Sp** conical-subulate, weak, keeled below, somewhat flat above, 4–6.5 mm, reddish-brown, slightly decurrent; **Inf** 1.5–2.45 m, ‘spicate’, straight, peduncle 95–185 cm, green, often tinged reddish or reddish-brown, with linear, reddish-brown, often decurrent **Bra** 2–5 cm long, fertile part ± in the upper ¼–½, 35–75 cm; **Fl** geminate, 22–27 mm, sessile; **Tep** green or yellowish-green, often tinged purple, tube slightly flaring, 8–13 × 4–5 mm, grooved, lobes slightly spreading, ovate-oblong, unequal, 7–11 × 3–4.5 mm, cucullate, apex with a tuft of hairs; **OTep** acute; **ITep** somewhat shorter, rounded, with a broad keel; **Fil** 30–40 mm, green with reddish tinge or purple, inserted at 2 levels in the

upper ⅓ of the tube; **Anth** slightly eccentric, ±10 mm, yellow or purple; **Ov** cylindrical, grooved, 6–8 × 4–5 mm, neckless, intruding the tepal tube; **Sty** 48–55 mm, shorter than the filaments, green with reddish tinge, purple at the apex; **Sti** slightly thickened; **Fr** ovoid-ellipsoid, 15–17 × 10–12 mm, shortly beaked, dark brown; **Se** semicircular, 3.8–5 × 2.2–2.5 mm, black, shiny, with marginal wing, hilar notch shallow.

According to the protologue closest to *A. dasyliroides* and *A. petrophila*, differing from both esp. in its smooth leaves without striae in fresh condition, larger marginal denticles, and flowers tubular below and campanulate above. *A. dasyliroides* differs further in its usually solitary rosettes, its arching inflorescences, and its occurrence on igneous rocks, and *A. petrophila* in its campanulate flowers with a shorter tube, globular fruits and its occurrence in tropical deciduous forests. *A. graciellae* is also similar to *A. rzedowskiana*, which differs in its smaller inflorescences and its inclined to decumbent peduncle, shorter tepal lobes and the occurrence on igneous rocks. *A. kavandivi* is a further close relative (see there for differences). The floral buds are eaten as vegetable, and the young inflorescences are cooked and eaten as sweets according to the protologue. The specimen *Rzedowski 7128a* from San Luis Potosí, placed in *A. dasyliroides* by Gentry (1982: 249) may belong here according to the protologue.

**A. gracilipes** Trelease (Annual Rep. Missouri Bot. Gard. 22: 95, 1912). **Type** [syn]: USA, Texas (*Mulford 293 + 293a* [MO, ILL, NY]). — **Lit:** Berger (1915: 180–181); Breitung (1963: 120–121, with ills.); Gentry (1982: 526–530, 536, with ills.); Reveal & Hodgson (2002); González-Elizondo & al. (2009: 85–87, with ills.). **Dist:** USA (SE New Mexico, W Texas); Mexico (Chihuahua); gravelly to rocky, often calcareous places in grasslands, desert scrub, and pinyon-juniper woodlands, 1200–1900 m; flowers summer to early fall. **I:** Pilbeam (2013: 97); Hochstätter (2015: VII: 100); Greulich (2016a: 35).

[2l × 1g?] Acaulescent; **Ros** compact, small, 0.6–0.8 m Ø, sparingly and closely suckering; **L** 60–100, lanceolate, thick at the base, rigid,

gradually acuminate, convex below, openly concave above, smooth, 18–30 × 5–7 cm, mostly glaucous-green, margins nearly straight to wavy because of the teeth bases, slightly narrowed above the base; **marginal teeth** narrowly triangular, mostly rather straight or curved, regular, abruptly lenticular and often confluent at the base, larger along mid-leaf and 2–10 mm, light grey, 15–25 mm apart, regularly spaced, 8–12 per side, intervening margin usually slightly concave; **terminal Sp** usually straight, narrowly to openly grooved above, 20–50 (–100) × 4–5 mm, dark reddish-brown to light grey, long-decurrent; **Inf** 1.8–5 m, paniculate, peduncle slender, with scarious lanceolate **Bra**, fertile part frequently narrow and deep, with 30–40 ascending part-**Inf** in the upper  $\frac{1}{2}$ – $\frac{1}{3}$  of the inflorescence, or fertile part short, with only 10–12 ascending part-**Inf** in the upper  $\frac{1}{4}$  of the inflorescence **Ped** < 5 mm, very slender; **Fl** 35–55 mm; **Top** yellow at anthesis, red in bud, tube shallow, broadly campanulate, 4–7 × 9–15 mm, knobby by the base of the filaments, grooved below the sinuses, lobes spreading to ascending at anthesis, overlapping at the base with thin margins becoming involute above, soon narrowing, withering and sinuses spreading, slightly unequal, 14–18 mm; **Fil** 30–45 mm, slender, inserted just below the rim of the tube, yellow, sometimes red; **Anth** 16–20 mm, yellow; **Ov** slender to broadly cylindrical to fusiform, 20–32 mm, neck constricted; **Sty** intermediate in length between lobes and filaments, yellow, sometimes red; **Sti** capitate; **Fr** oblong to ovoid, 35–40 × 20 mm, sessile or shortly stipitate, straw-coloured; **Se** 5–6.5 × 4 mm. — **Cytology**: 2n = 60 (Reveal & Hodgson 2002).

A very variable complex, hypothetically of ancient hybrid (allopolyploid?) origin between *A. (parryi ssp.) neomexicana* × *A. lechuguilla*, but presently back-crossing with *A. lechuguilla*, which explains the dimorphic variation (Gentry 1982). Pinkava & Baker (1985) list the taxon as putative intersubgeneric hybrid *A. neomexicana* × *A. lechuguilla*. Reveal & Hodgson (2002) are reluctant to designate the taxon as nothospecies until populations are studied cytologically in detail, and this view is followed here. The fact that *A. parryi ssp. neomexicana* is absent from

major parts of the area of *A. × gracilipes* excludes a spontaneous hybrid origin with *A. lechuguilla* and would favour the hypothesis of an allopolyploid origin. The diploid chromosome number, however, dismisses an allopolyploid origin, since both putative parental species are tetraploid. For the time being, *A. gracilipes* must be upheld as valid species, but its origin and status needs further study.

*A. gracilipes* is very similar in habit to *A. applanata* (Berger 1915) and was formerly included in the concept of the latter as “Texas form”, e.g. by Mulford (1896: 83), but differs from that species in its much smaller flowers with much shorter tubes (Berger 1915). In the protologue, Mulford, 293, 293a, 1895 are designated as “the types” (plus several paratypes), so that all four specimens of both gatherings (ILL 00009818, ILL 00009819, MO 202075, NY 00170405) represent syntypes. Similar plants from N Durango are provisionally placed here by González-Elizondo & al. (2009) as “*A. aff. gracilipes*”.

**A. gracillima** A. Berger (Agaven, 33, 288 [erratum], 1915). **Type**: Mexico, Durango (Rose 2341b [US]). — **Lit**: Rose (1903c: 21); Verhoeck-Williams (1975: 283–286); Piña Luján (1986: 13–15); McVaugh (1989: 229–230); Castillejos-Cruz (2009: [127]–[132], with ills.); all as *Manfreda elongata*. **Distr**: Mexico (S Durango, S Nayarit, S Zacatecas (?), C Jalisco); valleys and grassy plains in the mountain region, in oak and tropical deciduous forests and grasslands, 1000–1380 m; flowers mid-August to September. **I**: Hochstätter (2016: I: 18); Castro-Castro & al. (2017: 62); both as *Manfreda elongata*.

≡ *Manfreda elongata* Rose (1903) ≡ *Polianthes elongata* (Rose) Shinnars (1966) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave gracilis* A. Berger (1915) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Polianthes rosei* Shinnars (1967) (*nom. illeg.*, ICN Art. 52.1).

[3a2] Herbaceous; corm 5–10 × 2.5–4 cm, cylindrical, bulb 4–6.5 × 2.5–3 cm, ovoid to cylindrical, covered with fibrous dry leaf bases 6–12 cm long; **R** fleshy, with filiform ramifications, contractile; **L** drought-deciduous, 2–5, recurvate to arching, extended, linear-lanceolate,

slightly canaliculate, glabrous on both faces, apex acute, with a short soft tip, 40–60 (–95) × 2–4 (–5) cm, light green, shiny, margins entire, with a hyaline band, slightly revolute; **Inf** 120–140 (–160) cm, erect, glaucous-green, ‘spicate’, **Bra** 8–10, similar to the leaves but smaller, fertile **Inf** part 20–40 (–70) cm, lax, with 20–30 flowers; floral **Bra** (0.6–) 1.4–2 × 0.3–0.7 cm, narrowly deltoid; **Fl** 28–32 mm, solitary, sessile, ascending; **Tep** yellowish-green to reddish-green, forming a funnel-shaped tube (9–) 13–18 × 4–5 mm, slightly recurved, lobes oblong, extended to revolute, 11–16 × 3–6 mm, tip cucullate, with a soft tip and a bundle of short white trichomes; **Fil** 25–35 mm, erect at anthesis, exceeding the tube for 24–28 mm, inserted in the upper part of the tube on the same level, greenish-yellow with purple dots; **Anth** 10–12 mm, greenish-yellow; **Ov** cylindrical, 12–16 × 4–5 mm, greenish, not extending into the tube, not constricted above; **Sty** 30–42 mm, yellowish-green with purple dots; **Sti** capitately 3-lobed; **Fr** cylindrical, 20–26 × 12–14 mm, slightly apiculate, tepals persisting; **Se** deltoid, plane-concave, 3–4 × 3–5 mm, dull black.

Distinguished by its long, recurving, channelled leaves, the long-acuminate floral bracts, and the styles, which are usually much longer than the stamens. The flowers of *A. gracillima* are similar to those of *A. scabra* but with a proportionately longer style and a bluntly angled perianth tube (Verhoek-Williams 1975: 285, as *Manfreda elongata* and *M. scabra*).

The protologue wrongly cites the number of the type collection as “2341” (Verhoek-Williams 1975: 283). The map in Castillejos-Cruz (2009) shows a locality in S Zacatecas, but does not cite a specimen from that state.

**A. graminifolia** (Rose) Govaerts & Thiede (Willdenowia 43(2): 332, 2013). **Type:** Mexico, Jalisco (*Rose* 2571 [US, GH, K, MO, NY]). — **Lit:** *Rose* (1903a: 11–12, as *Polianthes*); *McVaugh* (1989: 251–252, as *Polianthes geminiflora* var.); *Solano Camacho & García-Mendoza* (1998: 476–477, as *Polianthes*). **Distr:** Mexico (S Zacatecas, Aguascalientes, Jalisco); grasslands, rocky slopes and grassy openings in oak forests, (1400?–) 2000–2250 m; flowers July to September. **I:**

*Castro-Castro & al.* (2015: 145); *Castro-Castro & al.* (2016: 721); *Hochstätter* (2016: II: 14); all as *Polianthes*.

≡ *Polianthes graminifolia* *Rose* (1903) ≡ *Bravoa graminifolia* (*Rose*) *Conzatti* (1903) ≡ *Polianthes geminiflora* var. *graminifolia* (*Rose*) *McVaugh* (1989) ≡ *Agave duplicata* ssp. *graminifolia* (*Rose*) *Thiede & Eggli* (1999) (*incorrect name*, ICN Art. 11.4).

[3b2] Herbaceous; corm short, ±0.8 × 0.8 cm, bulb oblong, ±3 × 1.6–1.7 cm, covered with dry leaf bases; **R** contractile, thickened; **L** ±6, linear, ascending or drooping, involute, ± densely pubescent on the lower face on the nerves and margins and on exposed portions of the leaf sheath, glabrous on the upper face, 15–20 (–30 (–60)) × 0.1–0.2 (–0.8) cm; **Inf** (20–) 50–85 cm, ‘spicate’, peduncle with narrow subulate-tipped **Bra** 2–6 cm long, pubescent in the lower part, fertile **Inf** part 15–30 cm, with 8–15 widely spaced flowering nodes, lower ones often on 1 cm long peduncles, lower internode 5–7 cm, internode length decreasing towards the distal portion; **Ped** 3 mm, elongating in fruit to 4–4.5 (–10?) mm; **Fl** geminate, ±25 mm; **Tep** rose to dark red, forming a tube curved downwards near the base, widening between the curvature and the base of the lobes, ±22–25 × 3–4 (at the tip) mm, lobes unequal, outer 2–3 × (1.5–) 3–4 mm, inner 1.5–3 × 1.5–2.5 mm, apex obtuse to rounded, rose; **St** included; **Fil** filiform, inserted low in the tube 3.5–8 mm above the tip of the ovary; **Anth** not described; **Ov** cylindrical, ±5 × 1.5 mm; **Sty** not exerted at anthesis; **Sti** 3-lobate, with 3 flat suborbicular lobes, ± reaching the anther tips; **Fr** and **Se** not described.

For some time considered to represent merely an infraspecific taxon of *A. coetocapnia* (*McVaugh* 1989: as *Polianthes geminiflora* var., *Thiede & Eggli* 1999: as *A. duplicata* ssp.), it is here accepted at species rank based on *Solano Camacho* (2002) (where it represents an independent clade in the morphological analysis), *García-Mendoza & Solano* (2007), and *Solano & García-Mendoza* (2013) (all as *Polianthes*). Its most characteristic feature is the pubescence of distinct, upright, stiff hairs to ±0.2 mm that cover the veins and margins of the leaf sheath and lamina and the lower part of

the peduncle (McVaugh 1989: as *Polianthes geminiflora* var. *graminifolia*). Albeit well collected (29 records from 12 localities; Solano & Feria 2007: 1888), no detailed morphological description is yet available.

**A. grisea** Trelease (Mem. Nation. Acad. Sci. 11: 34–35, tt. 54–56, 1913). **Type:** Cuba, Santa Clara (*Grey* 1 [MO [4 sheets, syn?]]). — **Lit:** Berger (1915: 208–209); Álvarez de Zayas (1996: 118–119, 123, with ills.); Guillot Ortiz & Meer (2011). **Distr:** S-C Cuba (Bahía de Cienfuegos); on calcareous coastal cliffs; flowers January to March. **I:** Hochstätter (2015: VII: 70).

**Incl.** *Agave grisea* var. *grisea*; **incl.** *Agave grisea* var. *cienfuegosana* Trelease (1913); **incl.** *Agave grisea* var. *obesispina* Trelease (1913).

[2p] Acaulescent, not surculose; **Ros** semi-globular, solitary; **L** lanceolate, somewhat concave, or oblanceolate, (100–) 110–130 (–160) × (10–) 12–16 (–20) cm, yellowish grey-green, passing into glaucous, or grey, rather dull, margins between the teeth from nearly straight to conspicuously concave; **marginal teeth** gently curved, broadly triangular, or acuminate tapered from the hardened tops of asymmetrical green prominences, sometimes wider or sublenticular at the leaf base, 2–5 (–10) × 1–4 mm, 10–25 mm apart; **terminal Sp** triquetrously conical or somewhat subulate, slightly curved, flattened or shallowly concave to or beyond the middle or becoming subinvolute, smooth, (10–) 12–22 (–25) × 3–6 mm, reddish chestnut-brown or brown, ± dull, decurrent for its length or more; **Inf** 4–6 (–8) m, paniculate, fertile part oblong, part-**Inf** in the upper  $\frac{2}{3}$  of the inflorescence, 45–50 cm, not bulbiferous; **Ped** 5–10 mm; **Fl** 42–47 (–50) mm; **Tep** golden-yellow, tube 4–8 × 7–9 mm, lobes 14–16 (–19) × 4–5 mm; **Fil** 30–36 (–40) mm, inserted nearly in the tube throat; **Anth** 14–18 mm; **Ov** fusiform, trigonous, 25–30 mm; **Sty** longer than the filaments; **Sti** capitate; **Fr** cylindrical, sometimes subpyriform, 35–40 × 14–17 (–20) mm, beaked, shortly stipitate; **Se** subtriangular, 6–7 × 5–7 mm.

The 4 type specimens at MO are cross-labelled, but the cross-labels do not appear to be original (Smith & Figueiredo 2014c: 235). A polymorphic

species. Since the 2 published varieties merely differ gradually and in addition appear to be connected by transitional forms (Berger 1915: 209), they were included in the synonymy by Álvarez de Zayas (1996) and in the first edition of this handbook. *A. grisea* differs from *A. brittoniana* and *A. acicularis* esp. in its longer leaves, and from *A. offoyana* (as *A. legrelliana*) in its greyish leaves and golden-yellow flowers (Álvarez de Zayas 1996). The omnivorous bat *Phyllonycteris poeyi* feeds predominantly on the nectar of the species (Mancina 2010). According to the IUCN Red List categories, the species is considered as “Endangered” (Berazaín & al. 2005, González-Torres & al. 2016). The plant depicted by Guillot Ortiz & Meer (2011: 12) has teeth on distinct prominences and is most probably misidentified.

**A. guadalajarana** Trelease (Contr. US Nation. Herb. 23: 123, 1920). **Type:** Mexico, Jalisco (*Pringle* 4473 [MO, BR, COLO, E, F, JE, K, MEXU, NY, NDG, RM, S, US, VT]). — **Lit:** Gentry (1982: 531–532, with ills.); McVaugh (1989: 135, 137); Cházaro Basáñez & Mostul (1999: with ills.); Kemble (2006: with ills.); Hernández-Vera & al. (2007b); Starr (2012: 312–313, with ill.). **Distr:** Mexico (Jalisco, known only from the region of Guadalajara; S Nayarit); grassy slopes in oak woodlands and ecotone with tropical deciduous forests, in volcanic rocky soils, 1400–2000 m; flowers April to November. **I:** Kemble (2004: 208); Heller (2006: 16, 93); Etter & Kristen (2012: 83); Pilbeam (2013: 99–101); Hochstätter (2015: IV: 22); Moore (2016: 279); Castro-Castro (2017: 136).

[21] **Ros** compact, 25–50 (–70) cm Ø, broader than tall, solitary, rarely suckering; **L** numerous, obovate to oblong, rigid, closely imbricate, obtuse, flat to incurved, 20–30 × 8–12 cm, inner leaves shiny but glaucous, outer leaves dull grey, margins nearly straight, upper part with prominences; upper **marginal teeth** (5–) 8–10 mm, remote, on strong prominences, those below mid-leaf much smaller, 3–4 mm, reddish-brown to dusty grey, 5–10 mm apart; **terminal Sp** subulate, straight to sinuous, flat to shallowly hollowed above, roundly keeled below, 25 mm, greyish; **Inf**

3–5 m, paniculate, peduncle slender, pruinose, fertile part very lax, part-**Inf** nearly horizontal, small, remote, 15–25 in the upper  $\frac{1}{2}$  of the inflorescence, pale reddish; **Fl** 60 mm; **Tep** lobes slender, much longer than the short tube,  $\pm 20$  mm, tips cucullate, greenish or yellow-green to pale yellow, tips in bud sometimes purplish, in flower tips of **OTep** rose to purple, tips of **ITep** less so; **Fil** slightly exerted, rose to purplish; **Ov** fusiform,  $\pm 25$  mm, green, neck short, slightly constricted and slightly sulcate; **Sty** longer than the tepals, rose to purplish; **Sti** capitate; **Fr** narrowly oblong, thick-walled,  $38\text{--}45 \times 15\text{--}18$  mm, shortly beaked, stipitate, dark brown; **Se** crescent-shaped,  $6 \times 4$  mm.

The protologue is rather short, and the description in Gentry (1982) is incomplete, lacking data on filaments and ovary, which were added here from Cházaro Basáñez & Mostul (1999), Kemble (2006) and Etter & Kristen (1997+: accessed Dec. 2015). The specimen Norris & Taranto 14380 (MICH) from Nayarit doubtfully assigned here by Gentry (1982: 546), is listed under *A. guadalajarana* by McVaugh (1989). Portal Datos Abiertos UNAM (2018+: accessed Jan. 2019) lists three further specimens from S Nayarit (MEXU 606850, 615834, 878517).

Resembling the other members of Sect. *Parryanae* in the compact rosettes with closely imbricate, short, broad, rigid leaves with the largest teeth confined to the upper third of the margin, and the proportions of flower tube and lobes. The short obtuse leaves resemble those of *A. parryi* var. *truncata*, but the conspicuous prominences along the leaf margins and the lax panicles distinguish *A. guadalajarana* from that species and all others of Sect. *Parryanae* (as Group) (Gentry 1982). — Hummingbirds are (occasional?) flower visitors (photo in Cházaro Basáñez & Mostul 1999: 12).

**A.  $\times$  guemensis** D. Guillot & P. Van der Meer (Stud. Bot. (Salamanca) 24: 87–89, 2006). **Type:** Spain (*Anonymous* s.n. in VAL 169523 [VAL]). — **Distr:** Cultivated only.

[1f  $\times$  1f] This is the garden hybrid *A. horrida* ssp. *perotensis* (as “*A. polyacantha*”)  $\times$  *A. warelliana*.

**A. guerrerensis** (Matuda) G. D. Rowley (Repert. Pl. Succ. 26: 4, 1977). **Type:** Mexico, Guerrero (*González Medrano & al.* s.n. [MEXU 231698, MEXU 526057]). — **Lit:** Matuda (1975: protologue, with ill.); García-Mendoza (2003); Castillejos-Cruz (2009: [145]–[149], with ills.); all as *Manfreda*. **Distr:** Mexico (Guerrero); oak forests, 1250 m; flowers in October.

$\equiv$  *Manfreda guerrerensis* Matuda (1975).

[3a3] Plants herbaceous; corm  $4\text{--}8.2 \times 2.2\text{--}3.5$  cm, succulent, cylindrical, bulb  $3\text{--}4.2 \times 1.5\text{--}3.5$  cm, conical to ovoid, covered with dried fibrous leaf bases  $1.5\text{--}6.5$  cm long; **R** fleshy, with filiform ramifications, contractile; **L** drought-deciduous, 2–3,  $40\text{--}45 \times 6\text{--}8$  cm, prostrate to semi-erect, linear-lanceolate, narrowed towards the base, semi-amplexicaul, slightly pubescent at the leaf base, apex acute to obtuse, dark green to glaucous-green, with cherry to purple dots, margins entire; **Inf** (120–)  $150\text{--}260$  cm, erect, glabrous with purple dots at the base, ‘spicate’, peduncular **Bra** 5–12, lower similar to the leaves, fertile **Inf** part 35–40 cm, lax, with 6–12 flowers; floral **Bra**  $0.7\text{--}3.5 \times 0.4\text{--}0.8$  cm; **Fl** 40–50 mm, solitary, ascending, sessile or the basal ones shortly stipitate; **Tep** reddish-green, semisucculent, forming a tube  $27\text{--}33 \times 5\text{--}7$  mm, lobes narrowly elliptic to oblong, erect to extended,  $13\text{--}17 \times 5\text{--}7$  mm, tip cucullate, with a bundle of short white trichomes; **Fil** 30–47 mm, erect at anthesis, exceeding the tube for 23–40 mm, inserted at  $\frac{3}{4}$  of the tube length on the same level, reddish-green; **Anth** 8–11 mm, yellow with reddish dots; **Ov** cylindrical, (6–)  $8\text{--}12 \times 3\text{--}5$  mm, not prolonging into the tube, not constricted above; **Sty** 30–38 mm, yellowish-green; **Sti** capitate 3-lobed; **Fr** oblong-ellipsoid,  $15\text{--}21 \times 9\text{--}18$  mm, without scar near the apex, tepals persisting; **Se** deltoid, plane-concave,  $4\text{--}5 \times 3\text{--}4$  mm, shiny black.

According to the protologue, the species keys out near *A. debilis* (as *Manfreda pringlei*) in the key to *Manfreda* of Rose (1903c). A full description complementing the partly sparse data from the protologue was provided by Castillejos-Cruz (2009). The species is remarkable for its pubescent leaves (although the pubescence is less pronounced than in *A. maculata* and *A. pubescens*),

**Fig. 25** *Agave guiengola*  
(Etter & Kristen 83:  
Mexico; Oaxaca, Presa Lic.  
Benito Juárez, 190 m).  
(Copyright: J. Etter &  
M. Kristen)

and is characterized by its broad, ovate-lanceolate leaves gradually narrowing towards the base. Morphologically it is closest to *A. scabra* and *A. pubescens*. At present known from 4 collections only (Castillejos-Cruz 2009). — For details of the typification see González Medrano (1991). — The species is erroneously omitted from the *Manfreda* accounts of Piña Luján (1985), Piña Luján (1986), and Hochstätter (2016). It has to be considered as “Rare” in the IUCN Red List Categories

**A. guiengola** Gentry (Brittonia 12: 98–100, ills., 1960). **Type:** Mexico, Oaxaca (*Gentry* 16436 [US, ARIZ, DES, MEXU, MICH]). — **Lit:** Gentry (1982: 97–99, with ills.); Ullrich (1991k: with ills.); García-Mendoza (2003: with ill.); (García-Mendoza & al. 2019: 8). **Distr:** Mexico (Oaxaca: Cerro Guiengola); limestone rocks in short-tree forests, 100–1000 m, flowers in March. **I:** MacDougall (1956: as ‘blue Agave’); MacDougall (1966: as *A. guiengolensis*); MacDougall (1970: as *A. guiengolensis*); Irish & Irish (2000: t. 19); Heller (2006: 95, 160); Richter (2011: 62); Pilbeam (2013: 102–103); Greulich (2013); Gonzales & Mera (2015: 12); Moore (2016: 226, 227). — Fig. 25.

[1c] Acaulescent; **Ros** open, mostly solitary; **L** few, at maturity 9–16 (to 25–30 in cultivation), broadly lanceolate, sometimes ovate, openly ascending, fleshy-leathery, short-acuminate, nearly

flat above but briefly and narrowly channelled apically, 30–50 × 14–25 cm (larger in cultivation), light grey or white-glaucous, with transversal bands, epidermis finely and densely papillate, margins repand, discontinuous, variously serrate; **marginal teeth** flattened, blunt, fine or coarse, unequal, 1- to 3-cuspidate, 1–10 × 2–9 mm, (5–) 15–20 mm apart, often basally confluent, dark brown, on prominences or on a lenticular base; **terminal Sp** acicular, rounded above and below, pungent, 6–8 (–15) mm, dark brown, not decurrent; **Inf** erect, (1.6–) 2–4 (–5) m, ‘spicate’, peduncle with recurved, long attenuate upper **Bra** and bracteoles, **Bra** scarious, with a dark midvein, subulate-lanceolate, 10–20 × 3 mm at the deltoid base, fertile **Inf** part from near the base, part-**Inf** with 2–3 flowers; **Ped** 5–8 mm; **Fl** inconspicuous, 30–45 mm; **Tep** greenish-yellow, pale yellow or yellowish-white, tips reddish or rose on the outer face, 17–18 × 4–5 mm, erect or slightly incurved, tube funnel-shaped, 2–4 mm (García-Mendoza 2003; “virtually tubeless” according to the protologue), lobes elliptic to lanceolate, openly ascending, straight; **Fil** 15–21 mm, yellowish, inserted at the lobe bases; **Anth** excentric, versatile, 13 mm, yellow; **Ov** cylindrical to obconical, sulcate, 10–14 mm, neck narrowly constricted, green; **Sty** longer than the filaments; **Sti** thickened; **Fr** oblong-ovate, thin-walled, 11–18 × 5–6 mm (from *García-Mendoza* 6062,

ASU0000570!; protologue: 22–24 mm), shortly beaked; **Se** “small”, without further data.

A strikingly ornamental and very distinct species esp. due to its broad, thick, white-glaucous leaves. In the protologue, where the flowers are described as “nearly tubeless”, placed in Sect. *Choritepalae* (as Group), but differing from the other species (*A. bracteosa*, *A. ellemetiana*, *A. gypsicola*) geographically as well as in the shape and colouration of the toothed leaves, its strictly monocarpic rather than polycarpic habit (protologue), and its seed morphology (Ullrich 1991k). Ullrich (1991k) therefore regards Sect. *Choritepalae* (as Group) as artificial (see also the introduction to the genus). The description by García-Mendoza (2003) differs from the protologue, esp. by giving a tube length of 2–4 mm. The fruits, as described above, are among the smallest in the genus. — For the closely related *A. gypsicola* see there.

The type locality Cerro Guiengola is a karstic limestone formation  $\pm 20$  km NW Tehuantepec, where the species grows “on sheer cliff-faces in prodigious numbers, resembling dense colonies of sea-stars” (Trager 2011) and even on the ancient Zapotec pyramids (MacDougall 1956, Ullrich 1991k). The species was also collected at the microwave tower at Santa María Jalapa del Marqués slightly further northwest (MEXU AGA807760). Well-nourished plants in cultivation may develop much larger rosettes and inflorescences (Greulich 2013). *A. guiengola* is propagated via tissue culture at the Huntington Botanical Garden (Gomez Rhine 2009). ‘Moto Sierra’ K. Griffin (= ISI 2011–14) is a cultivar with confluent teeth giving the leaf-margin a chain-saw-like appearance (Trager 2011), and ‘Creme Brulee’ is a variegated cultivar with cream-coloured margins (Starr 2014: 222, for illustrations see Moore 2016: 227).

**A. ×guignardii** Trelease (in L. H. Bailey, Stand. Cycl. Hort. 1: 233, 235, 1914). **Nom. inval.**, ICN Art. 38.1a. **Type:** not typified. — **Distr:** Cultivated only.

[1b × 2o] This is the artificial intersubgeneric hybrid *A. attenuata* × *A. potatorum* (as *A. verschaffeltii*). Apparently lost from cultivation.

**A. guttata** Jacobi & C. D. Bouché (Hamburg. Gart.- & Blumenzeit. 21: 561, 1865). **Type:** not typified. — **Lit:** Rose (1903c: 21–22); Verhoek-Williams (1975: 233–244); Piña Luján (1985: 35, 85–86, with ill.); McVaugh (1989: 230–231); Castillejos-Cruz (2009: [150]–[156], with ills.); all as *Manfreda*. **Distr:** Mexico (Chihuahua, Durango, Zacatecas, San Luis Potosí, Aguascalientes, Nayarit, Jalisco, Guanajuato, Querétaro, Hidalgo, Michoacán); open grassy roadsides, rocky fields, summit of hills, roadcuts, in oak, pine-oak and tropical deciduous forests, desert scrub and grasslands, 1220–2440 m; flowers mid-July to September. **I:** Curtis’s Bot. Mag. 86: t. 8429, 1912, as *A. protuberans*; Anonymous (1940); Rodríguez & Castro-Castro (2006: 624); Rodríguez & Castro-Castro (2007: 9); Richter (2007: 42); Hochstätter (2016: I: 21); Castro-Castro & al. (2017: 62); all as *Manfreda*.

≡ *Manfreda guttata* (Jacobi & C. D. Bouché) Rose (1903) ≡ *Polianthes guttata* (Jacobi & C. D. Bouché) Shinnars (1966); **incl.** *Agave protuberans* Engelm. ex Baker (1888) ≡ *Leichtlinia protuberans* (Engelm. ex Baker) H. Ross (1894); **incl.** *Leichtlinia commutata* H. Ross (1896).

[3a3] Plants herbaceous; corm 2–5 × 2–4.5 cm, oblong to subcylindrical, succulent, stoloniferous; bulb 1.8–3 × 1.8–3.5 cm, cylindrical, nearly completely covered with dried leaf bases 4.5–6 cm long, these slightly membranous at the base and fibrous above; **R** fleshy, with filiform ramifications, contractile; **L** drought-deciduous, 2–7 (–13), extended, lanceolate to lanceolate-elliptic, narrowed towards the base, semisucculent, canaliculate, slightly wavy, lower face slightly papillose above the veins, upper face glabrous, apex obtuse, apiculate, (8–) 17–34 × (0.9–) 1.2–3.5 cm, light green to glaucous, sometimes with small to large confluent dark-green to purple dots, margins entire, with a cartilaginous, finely denticulate to erose hyaline band; **Inf** 60–160 cm, erect, light green to yellowish, ‘spicate’; **Bra** 8–12, lower ones similar to the leaves; fertile **Inf** part (2.3–) 4–14 cm, dense, with (2–) 4–25 (–33) flowers; floral **Bra** 0.8–3.1 × 0.3–1 cm; **Fl** 27–42 mm, solitary, sessile, ascending; **Tep** yellowish-green to reddish with purple tinge, semisucculent, forming a tube 7–11 × 4–5 mm, lobes oblong to

narrowly elliptic, recurved to revolute, 10–15 (–17) × 4–5 mm, tip cucullate, with a bundle of short white trichomes; **Fil** 26–38 (–46) mm, arching upwards at anthesis, exceeding the perianth tube for 19–32 (–42) mm, inserted at the upper end of the tube on the same level, reddish-green with small purple dots; **Anth** (9–) 12–15 mm, yellow; **Ov** cylindrical to slightly ellipsoid, 7–13 × 4–7 mm, greenish, prolonging 1–5 mm into the perianth tube, slightly constricted above; **Sty** 36–52 mm, yellowish-green; **Sti** capitate 3-lobed; **Fr** ellipsoid, 13–22 (–25) × 10–18 mm, with a scar near the apex, base of tepals and style persisting; **Se** deltoid, plane-concave, with narrow margin, 3–4 × 2–3 mm, shiny black.

The cylindrical storage rhizome and the presence of spreading rhizomes, the denticulate-erose leaf margin, dense inflorescence, and the stubby flowers with revolute lobes and exerted stamens and styles are diagnostic for this widespread species (Verhoek-Williams 1975: 238, Castillejos-Cruz (2009). Morphologically closest to *A. planifolia* (as *Manfreda*) esp. in its flowers, and to an as yet undescribed species “*Manfreda valsequillana*” (Castillejos-Cruz 2009); the latter appears to be the same as the undescribed *M. riosramirii* from Mpio. Valsequillo in Puebla, dealt with in the same publication.

**A. gypsicola** García-Mendoza & D. Sandoval (Acta Bot. Mex. 126: e1461: 6, ills. (pp. 7, 15), 2019). **Type:** Mexico, Oaxaca (*García-Mendoza & Franco Martínez* 11218 [MEXU [2 parts], IEB, MEXU, MO]). — **Distr:** Mexico (W-C Oaxaca: Tlaxiaco Distr., upper Río Verde basin); on gypsisols in xerophytic scrub, 1350–1600 m; flowers January to March.

[1c] Acaulescent; **Ros** open, solitary, 0.7–1 × 1–1.4 m; **L** 20–40, broadly ovate to semi-orbicular, erect, soft, thickened at the base, with acute apex or caudate, flattened, 45–60 × 20–26 cm, 1.8–2.5 × longer than broad, glaucous or glaucous-yellowish, epidermis densely papillate, margins straight, horny, continuous, reddish-brown or whitish-yellow when young, dentate; **marginal teeth** deltoid, straight or antrorse, 1–3 (–4) × 2–4 mm, brownish-red, <5 mm apart;

**terminal Sp** 25–55 × 3–7 mm, brownish-reddish, decurrent for (15–) 40–70 mm; **Inf** inclined above, 4.5–5 (–6) m, ‘spicate’, peduncle green-yellowish, ± erect, with chartaceous long triangular **Bra** (12–) 15–19 × 3–5 cm, fertile part ± inclined to overhanging, dense, in the upper ½ of the inflorescence; floral **Bra** 0.8–1.5 × 0.2–0.3 cm, filiform; **Ped** short; **Fl** 30–35 (–37) mm; **Te** greenish-yellowish, tube none, replaced by a discoid receptacle, lobes oblong, slightly recurved at anthesis, 17–18 × 2–4 mm; **Fil** 40–45 mm, pale yellow, inserted at the lobe bases; **Anth** 10–15 mm, yellow; **Ov** cylindrical, 15–17 × 3–4 mm, neck 3–4 mm; **Sty** 40–45 mm, whitish-yellowish; **Sti** filiform to clavate; **Fr** clavate or ellipsoid, (20–) 30–32 × 12–14 mm; **Se** semicircular, unwinged, 3–4 × 2–3 mm, black.

In the protologue placed in Sect. *Choritepalae* (as Group), and compared with *A. guiengola* from which it differs in having more and broadly ovate to semi-orbicular, glaucous or glaucous-yellowish leaves with smaller and narrower marginal teeth and a longer, decurrent terminal spine, its inclined inflorescences with greenish-yellowish flowers with lobes recurved at anthesis, larger fruits, and its occurrence at higher altitudes on soils rich in gypsum.

Vernacular name: “maguey blanco” (Zapotec: “xavi kuiji”). Fresh leaves are cooked and flowers and buds are eaten as stew or dried; the dried inflorescences are used for fences. The species is assigned to the “Endangered” IUCN Red List Category.

**A. gypsophila** Gentry (Agaves Cont. North Amer., 510–512, ills., 1982). **Type:** Mexico, Guerrero (*Floyd & Ryan* 103 [MICH, ARIZ, UC]). — **Lit:** McVaugh (1989: 137); Vázquez-García & al. (2013). **Distr:** Mexico (S Guerrero); limestone outcrops, in thorn and tropical dry forests, occasionally near the ecotone with pine-oak forests, 600–900 m; flowers February to June. **I:** Etter & Kristen (1997+: accessed 2016). – Fig. 26.

[2n] Acaulescent; **Ros** 0.8–1 × 0.9 m tall, solitary, not surculose; **L** 8–11, narrowly lanceolate to obtusulate, firm but brittle, smooth, 70–100 (–125) × 8–19 cm, light to dark green, not

**Fig. 26** *Agave gypsophila*

(Etter & Kristen 1671:  
Mexico; Guerrero, S of  
Acahuizotla, 860 m).  
(Copyright: J. Etter &  
M. Kristen)

evidently cross-zoned, margins repand; **marginal teeth** 1–2 mm, on low prominences 2–4 × 4–6 mm, 5–16 (–25) mm apart at mid-leaf, intervening margin concave; **terminal Sp** 5–11 mm; **Inf** 5–6 m, paniculate, not bulbiferous, peduncle slender, ±7–10 mm Ø; **Fl** 31–34 mm; **Tep** orange-yellow, tube 4–5 × 9 mm, lobes ± equal, triangular, 10–11 × 3–4 mm; **Fil** 20–23 mm, inserted 1–2 mm above the tube base, orange-yellow; **Anth** 11–12 mm, orange-yellow; **Ov** ±15 × 3.5–4 mm, greenish, neck slightly constricted; **Fr** 28–30 × 17–20 mm; **Se** 3–3.7 × 1.7–2.4 mm.

The recent study of the *A. gypsophila* complex by Vázquez-García & al. (2013) has led to a re-circumscription of *A. gypsophila* and the publication of 4 new species (*A. abisaii*, *A. andreae*, *A. kristenii*, *A. pablocarrilloi*). Gentry's protologue of *A. gypsophila* cites 3 specimens from Guerrero that correspond to the narrowed circumscription of the species, 1 specimen from Jalisco (Gentry 23532) now placed in *A. abisaii*, and 3 specimens from Colima (Gentry 19563, 22193, 23533) now placed in *A. pablocarrilloi* (Vázquez-García & al. 2013).

At present, no full description of *A. gypsophila* s.s. is available, and the data above are taken from the comparative table in Vázquez-García & al. (2013), augmented from Etter & Kristen (1997+: accessed 2016), and the holotype. The diagnostic characters for *A. gypsophila* s.s. include narrowly lanceolate to obovate, smooth, flexible, green, and not evidently cross-zoned leaves.

Nearly all illustrations available published or in the web under the name of *A. gypsophila* are misidentified. The illustrations in Vázquez-García & al. (2007b: M5–M8) are *A. abisaii*, the illustrations in Cházaro Basáñez & al. (2006a) and Vázquez-García & al. (2007b: M1, M3) are *A. andreae*, the illustrations in Vázquez-García & al. (2007b: M2, M9, M10) are *A. kristenii*, and the illustrations in Gentry (1982: 511: figs. 18.4 & 18.5), Newton (1999), García-Mendoza (2003), Newton (2004), Richter (2011: 82), Pilbeam (2013: 104), Guillot Ortiz & Meer (2016c: 28: fig. 2, 29: figs. 3–5), and Moore (2016: 268, 269) represent *A. pablocarrilloi*. The new record from coastal Michoacán (Ullrich 1991b) is *A. kristenii*, but the plant depicted appears to be *A. pablocarrilloi*. The only correctly labelled illustrations of *A. gypsophila* at present appear to be those on the web page of Etter & Kristen (1997+: accessed Dec. 2016).

**A. harrisii** Trelease (Mem. Nation. Acad. Sci. 11: 34, tt. 50–51, 1913). **Type** [syn]: Jamaica (*Harris* s.n. [MO [4 sheets from 1907, 1909 and 1911]]). — **Lit**: Berger (1915: 208); Adams (1972: 81). **Dist**: Jamaica; arid coastal to densely wooded interior limestone, 10–50 (–700) m; flowers March to April. **I**: Richter (2011: 137); Hochstätter (2015: VII: 71).

[2p] Acaulescent; **Ros** solitary; **L** narrowly lanceolate, ± sigmoidally curved, upper ¼ recurved, gradually acute, slightly guttered, 100–200 ×

15–35 cm, rather glossy dark green, margins between the teeth straight or concave; **marginal teeth** straight or curved, narrowly triangular, scarcely 2 mm, 10–20 mm apart, often from the tops of green prominences; **terminal Sp** conical, somewhat flexuous or recurved, narrowly channelled towards the base, smooth, 10–15 × 2 mm, reddish-brown, glossy, not decurrent; **Inf** 8–10 m, paniculate, not known to be bulbiferous, part-**Inf** ±60 cm; **Ped** 5–10 mm; **Fl** 45–50 mm; **Tep** ±20 mm, yellow, tube open, 7–8 mm, lobes erect, 12–15 × 4 mm; **Fil** 30–35 mm, inserted near the bottom of the tube; **Ov** fusiform, 25–30 mm; **Sty** ± as long as the filaments; **Fr** narrowly oblong, 45–50 × 15–20 mm, shortly beaked, turbinate narrowed rather than stipitate; **Se** crescent-shaped, 7 × 4–5 mm.

The protologue cites types with three different collection dates thus representing syntypes (Smith & Figueiredo 2014e: 236). *A. harrisii* is one of only three native Jamaican agaves. It differs from *A. sobolifera* in its longer ovary (25–30 vs. 15–20 (–25) mm) and from *A. longipes* in its shorter pedicels (5–10 vs. 20 mm) and shorter flowers (45–50 vs. 60–70 mm) (Adams 1972).

**A. hauniensis** J. B. Petersen (Bot. Tidsskr. 48: 158–159, ill., 1948). **Type:** Cult. BG Kobenhaven (*Anonymous* P1875/459 [C]). — **Lit:** Verhoek-Williams (1975: 227–232); Piña Luján (1985: 84–85, 87); Castillejos-Cruz (2009: [157]–[163], with ill.); all as *Manfreda*. **Distr:** Mexico (Michoacán, México, Morelos, Guerrero, Oaxaca); lava fields, rocky slopes in juniper, oak and pine-oak and tropical deciduous forests or in full sun in glades, 700–2150 m; flowers October to January. **I:** Rodríguez & Castro-Castro (2006: 623, 625); Hochstätter (2016: I: 22); both as *Manfreda*.

≡ *Manfreda hauniensis* (J. B. Petersen) Verhoek-Williams (1978); **incl.** *Manfreda tlatlayensis* Matuda (1965) (*nom. inval.*, ICN Art. 29.1); **incl.** *Manfreda insignis* Matuda (1966).

[3a1?] Plants herbaceous, very large (for Subgen. *Manfreda*); rhizome cylindrical, branched, 7 cm Ø, reproducing vegetatively by lateral shoots from the storage rhizome, covered with dried leaf bases, these cartilaginous at the base and fibrous above; **R** abundant, fibrous; **L** 6–10, semi-erect to slightly arcuate, linear-lanceolate,

46–95 × 4–12 cm, green, canaliculate, somewhat coriaceous, slightly glaucous on the lower face, dark on the upper face, apex acute, with a long pungent point, margins hyaline, cartilaginous, irregularly dentate, teeth small to large, simple, bifid or trifid; **Inf** 2–3.5 (–3.8) m, erect, glaucous-green, ‘spicate’; **Bra** 7–10, diminishing in size upwards; fertile **Inf** part (20–) 45–60 cm, dense, with 20–40 flowers; floral **Bra** (2–) 2.7–3 × (0.4–) 0.7–1 cm; **Fl** 40–48 mm, solitary, sessile, ascending; **Tep** green in bud, mature brownish-green, forming a funnel-shaped perianth, straight, tube 12–22 × 4–8 mm, lobes oblong, extended to revolute, 25–32 (–37) × 5–7 mm, tip semi-succulent, cucullate, with a bundle of short white trichomes; **Fil** ±125 mm, erect to extended at anthesis, exceeding the tube for (69–) 73–85 (–89) mm, inserted at mid-tube on the same level, reddish with brown dots; **Anth** 22–29 mm, yellow to reddish; **Ov** ellipsoid to ovoid, 12–22 × 5–8 mm, reddish-green, not constricted above; **Sty** (72–) 77–108 (–112) mm, reddish-brown; **Sti** clavate, 3-lobed, reddish-brown; **Fr** ovoid to oblong, 22–35 × 12–20 mm, tepals persisting (?); **Se** plane-concave, 5–6.3 × 5 mm, rough, dull black.

*A. hauniensis* was published based on a cultivated specimen of unknown wild origin which flowered at BG Copenhagen in 1945. It is well characterized within Sect. *Herbaceae* by its considerable size, leaves with a hardened pungent tip (not found in other species) and denticulate margins, and in possessing a branched rhizome without bulb (all other species are bulbous). All these characters point towards Subgen. *Littaea*, and the species might have arisen as an allopolyploid between a species of Sect. *Herbaceae* and a species of Subgen. *Littaea*, but evidence from karyology or other sources is wanting as yet. The leaf longevity (evergreen?) is unknown. The rhizome is used for laundry (Castillejos-Cruz 2009).

**A. havardiana** Trelease (Annual Rep. Missouri Bot. Gard. 22: 91, tt. 84–86, 1912). **Type** [syn]: USA, Texas (*Havard* s.n. [MO]). — **Lit:** Berger (1915: 178); Gentry (1982: 531–535, with ill.); Reveal & Hodgson (2002); Starr (2012: 106–109, 322–323, ill.). **Distr:** USA (SW

**Fig. 27** *Agave havardiana* (Eggl s.n.: USA; Texas, Big Bend National Park, Chisos Mts., 1450 m). (Copyright: U. Eggl)

Texas: Big Bend region), Mexico (N Chihuahua, N Coahuila); rocky slopes in mountain grassland with scattered oak and juniper, frequently on limestone, 1200–2000 m; flowers June to September. **I**: Kuppen (2000: 87); Irish & Irish (2000: t. 20); Heller (2006: 96); Bulot (2010: 40); Richter (2011: 128); Pilbeam (2013: 105); Hochstätter (2015: III: 14). – Fig. 27.

[21] Acaulescent; **Ros** rather open, (0.4–) 0.5–0.8 × (0.5–) 1–1.5 m, mostly solitary, suckering sparingly; **L** lanceolate to broadly lanceolate, ascending, thick, rigid, broadest at the clasping base, slightly narrowed above the base, widest below the middle, convex below, concave above, 30–60 (–70) × 15–27 cm, rarely larger, glaucous-grey to light or grey-green, occasionally yellowish, not cross-zoned, margins straight; uppermost **marginal teeth** ± straight, other teeth reflexed, single, well defined, numerous, larger teeth towards the leaf tip, mostly (3–) 7–10 mm, gradually diminishing downwards, 15–25 (–30) mm apart; **terminal Sp** stout, straight to sinuous, subulate, roundly keeled below, broadly grooved above, mostly 30–50 (–100) × 5–7 mm, dark brown to greyish, long decurrent, sometimes as a complete horny margin; **Inf** 2–7 m, paniculate, peduncle with persistent lanceolate **Bra** (3–) 5–10 cm long, fertile part broad, dense, part-**Inf** slightly ascending, large, 12–20, with 21–48 flowers, comprising the upper  $\frac{1}{2}$ – $\frac{2}{3}$  of the inflorescence, >10 cm, not bulbiferous; **Fl** erect, 68–90 mm;

**Tep** yellow to yellow-green, tube deeply funnel-shaped, 14–22 × 15–22 mm, lobes erect, slightly unequal, 18–24 × 4–5 mm, inner shorter, narrower, involute-conduplicate, wilting early and inwards; **St** long-exserted; **Fil** erect, long-tapered to the apex, 50–65 mm, yellow, inserted rather irregularly above mid-tube; **Anth** excentric, 25–30 mm, yellow; **Ov** fusiform, 30–40 mm, green, neck short, thick, constricted; **Sty** stout, longer than the tepals; **Sti** capitate, 3-lobate; **Fr** oblong to obovoid, 40–55 × 14–20 mm, apex beaked, broadly short-stipitate, on strong pedicels; **Se** 6–7 × 4–5 mm, smoothly black, marginal wing low, hilar notch small.

Distinguished within Sect. *Parryanae* (as Group) by the very broad-based acuminate leaves with reflexed teeth, and tepals forming a deep tube and with relatively short lobes (Gentry 1982: 535). *A. havardiana* hybridizes with *A. lechuguilla* (= *A. ×glomeruliflora*), and backcrosses with that hybrid (see there). The 4 type sheets at MO are not cross-labelled and represent syntypes.

The species has a multiple pollinator syndrome and is pollinated by birds during the day and by bats during the night; nectar production and stigma receptivity is both nocturnal and diurnal (Slauson 2002a). The feeding ecology of flower-visiting hummingbirds was studied by Kuban & Neill (1980) and Kuban & al. (1983), and the nectar sugar variability by Reid & al. (1985).

**A. hiemiflora** Gentry (Agaves Cont. North Amer., 480–482, ills., 1982). **Type:** Guatemala (Gentry 23640 [US, ARIZ, DES, MEXU, MICH]). — **Lit:** Lott & García-Mendoza (1994: online version with ills.); Véliz Pérez (2013: 237–239, 479, 489, with ill.). **Distr:** Mexico (Chiapas: E mountains), Guatemala (Huehuetenango); montane slopes, often on limestone, in pine-oak or also in montane rain forests, rarely epiphytic, 800–2290 m; flowers October to December. **I:** Richter (2011: 114, 123); Pilbeam (2013: 106); Hochstätter (2015: VI: 7).

[2o] Acaulescent; **Ros** compact, 1–1.5 m Ø, solitary, not surculose; **L** 50–90, lanceolate to ovate, openly spreading, rather softly fleshy, gradually narrowed and thickened towards the base, acuminate, flat to slightly concave above, mostly 30–60 × 8–15 cm, light grey-glaucous to pale green, margins repand to deeply crenate; larger **marginal teeth** curved or retrorse, rarely straight, (1–) 5–8 mm at mid-leaf, (10–) 20–40 mm apart, light to dark brown or greyish, or teeth smaller and more distal on the repand margins, all on distinct prominences, the slender tips variously curved up or down; **terminal Sp** slender or thick, sinuous or contorted to straight, openly grooved to flat above, generally 20–40 mm, brown, decurrent; **Inf** 2–5 m, paniculate, peduncle with remote, triangular, quickly drying **Bra**, fertile part slender, narrow, part-**Inf** small, dense, densely tufted with scarious, frequently dark-coloured bractlets, 20–30 in the upper ½–¾ of the inflorescence, on very short (4–5 cm) or longer (10–20 cm) stalks; **Ped** slender, to 5 mm; **Fil** slender, 45–55 (–70) mm; **Tep** yellow, sometimes red in bud, tube broadly tubular to funnel-shaped, angled to rather knobby, lightly grooved, 5–13 mm, lobes oblong, unequal, 15–23 mm, involute; **OTep** linear-lanceolate, erect-ascending, obtuse, frequently reddish towards the tip, overlapping the inner tepals at the base; **ITep** smaller, narrower but widened at the base, keel narrow; **Fil** slender, flattened adaxially, (30–) 45–60 mm, inserted in the middle or near the mouth of the tube, reddish; **Anth** straight, regular, centric, 15–27 mm, yellow; **Ov** angled-cylindrical, 20–30 (–40) mm, neck short, smooth, little-constricted; **Sty** finally longer than the stamens; **Sti** capitate, triquetrous;

**Fr** ovoid to oblong, 30–40 × 14–20 mm, scarcely beaked; **Se** 5–6 × 3.5–4 mm.

A highland relative of *A. seemanniana* and *A. congesta*, sharing with both moderate leaf variability, and an openly grooved to flat terminal spine. It differs from *A. seemanniana* in a more regular leaf form and size with a less narrowed base, and the densely tufted bracteolate apex of the part-inflorescences, and from *A. congesta* in its small rosette, less robust and more richly branched open inflorescence with fewer part-inflorescences, and filaments more evenly inserted at a lower level in the tube (Gentry 1982: 480). The species is used for fibre. The IUCN Red List Category is “Vulnerable” according to Véliz Pérez (2013).

**A. hookeri** Jacobi (Hamburg. Gart.- & Blumenzeit. 22(4): 168, 1866). **Type** [neo]: Ex cult. Kew (*Brown* s.n. [K]). — **Lit:** Berger (1915: 162–163); Gentry (1982: 338–340, with ills.); McVaugh (1989: 137–138); Hernández-Vera & al. (2007b). **Distr:** Mexico (Jalisco, Michoacán); apparently cultivated only or as spontaneous escape (?), in mountain regions in pine-oak forests, 1920–2285 m; flowers October to January. **I:** Richter (2011: 111); Pilbeam (2013: 107); Greulich (2014a: 57–59, 61);

[2d] Stems short, thick; **Ros** to 2 m, solitary; **L** lanceolate, arching in age, thickly fleshy, gradually narrowed towards base and tip, generally concave above, 120–175 × 20–25 cm, glaucous to green or yellow-green, margins repand to crenate, esp. in the middle of the lamina, nearly straight below; **marginal teeth** straight or curved, 8–12 mm (middle of the lamina), dark brown to greyish-brown, 20–50 mm apart, with few smaller intermittent teeth, much reduced and closely spaced towards the base, broadly based on fleshy prominences; **terminal Sp** subulate, shortly openly grooved above, roundly keeled below, and with linguiform protrusion into the leaf, 35–60 mm, edges decurrent as toothless smooth horny border for 15–20 cm; **Inf** 7–8 m, paniculate, peduncle with narrow, triangular, reflexed **Bra**, part-**Inf** compact, 20–40 in the upper ½ of the inflorescence; floral **Bra** caducous; **Ped** long; **Fil** slender, 63–80 mm; **Tep** yellow, red to pink in

bud, tube grooved, 5–8 × 13–14 mm, lobes red to pink, linear, erect, elongate, conduplicate, unequal, outer 28–32 mm, rounded on the back, cucullate, inner 2–3 mm shorter, with prominent keel; **Fl** slender, flattened, 50–60 mm, inserted above mid-tube; **Anth** excentric, 26–34 mm, yellow; **Ov** cylindrical, angled, smooth, 34–41 mm, neck long, grooved, constricted; **Sty** almost as long as the filaments; **Sti** capitate; **Fr** oblong, rounded at the tip, thick-walled, 50–55 × 25 mm, stipitate; **Se** broadly crescent-shaped, rugose, 8–9 × 6–7 mm, lucid black, hilar notch broad, marginal wing broad but little raised.

Recognizable among the species of Sect. *Crenatae* (as Group) by its large size, the glaucous leaves with long-decurrent spine-bases, the short flower tube and the very long tepal lobes (Gentry 1982: 340). Gentry's "type" represents in fact a neotype (McVaugh 1989: 138). The collection *Diguét* s.n. (P) cited by McVaugh for Jalisco is likely a misidentification with *A. inaequidens*, and the collection Gentry s.n. (DES, now at ARIZ 266166) from Jalisco cited by Gentry (1982: 352) appears to represent a cultivar introduced from Michoacán according to Hernández-Vera & al. (2007a); a further collection from Jalisco (García-Mendoza & al. 6409, ASU 0000674!, MEXU AG817141) is designated as "semi-cultivada". Widely cultivated for pulque in Michoacán. Morphometric studies showed that *A. hookeri* is most similar to cultivated *A. inaequidens*, supporting the hypothesis that it could merely represent the extreme of a domestication gradient *A. inaequidens* wild → *A. inaequidens* cultivated → *A. hookeri* cultivated (Figueredo-Urbina & Casas 2012, Figueredo & al. 2014). A cluster analysis of morphological data showed *A. hookeri* to be nested within *A. inaequidens* (Figueredo-Urbina & al. 2017). For differences from *A. inaequidens* see there.

The name *A. hookeri* was independently published three times for different taxa: The oldest, *A. hookeri* K. Koch (1865), is a synonym of *A. spicata* Cavanilles (1802), the younger *A. hookeri* Jacobi (1866) was based on cultivated plants and applied by Gentry to plants he collected in Michoacán, and are described above, and the illegitimate *A. hookeri* Baker (1881) is a synonym

of *A. inaequidens* K. Koch (1860). A proposal to conserve the established name *A. hookeri* Jacobi against *A. hookeri* K. Koch was published by Figueiredo & Smith (2014) and was recommended by the relevant committee (Applequist 2014: 1368).

**A. horrida** Lemaire *ex* Jacobi (Hamburg. Gart.- & Blumenzeit. 20: 546–547, 1864). **Type** [neo]: Mexico, Morelos (*Pringle* 8206 [US, CM, E, G, MEXU, MO, NDG, NY, P, S, VT]). — **Distr**: S Mexico.

The neotype cited above was designated by Gentry (1982: 146).

**A. horrida** ssp. **horrida** — **Lit**: Berger (1915: 100–101); Gentry (1982: 144–146, with ill.); Ullrich (1993b: with ill.); Starr (2012: 110–114, with ill.). **Distr**: Mexico (México, Morelos, C Puebla, C Guerrero, NW Oaxaca); volcanic rocks and rocky slopes in mountain regions, pine-oak forests and rosette scrub, 1600–2440 m; flowers January to March and July. **I**: Curtis's Bot. Mag. 106: t. 6511, 1880; García-Mendoza (2002: 186); Heller (2006: 97, 156); Richter (2011: 68, 122); Pilbeam (2013: 108); Hochstätter (2015: IX: 33); Moore (2016: 254–255).

**Fig. 28** *Agave horrida* ssp. *perotensis* (Etter & Kristen 994: Mexico; San Luis Potosí, Sierra Alvarez, 2350 m). (Copyright: J. Etter & M. Kristen)

ICN Art. 36.1c); **incl.** *Agave regelii* Hort. Besauccèle *ex* A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a).

[lg] Acaulescent; **Ros** compact, formidably armed, 0.3–0.6 × 0.45–0.9 m, solitary; **L** 80–100 in mature rosettes, ovate to elliptic-lanceolate, patulous, rigidly thick-fleshy, slightly narrowed above the base, short-acuminate, convex below, flat to guttered above, generally 18–35 × 4–7.5 cm, yellowish-green, green or dark olive-green, margins thickly horny, straight to sinuous between the teeth; **marginal teeth** straight to variously curved, sometimes hooked, broadly flattened at the base, massive, generally 10–15 mm, rarely much smaller, light grey, 5–10 mm apart, continuing to near the base of the terminal spine; **terminal Sp** semicircular to subdeltoid in cross-section, very pungent, flattened rather than grooved above, 25–40 mm; **Inf** 2–2.5 m, ‘spicate’, slender, peduncle 1–1.5 m, with deltoid-attenuate, narrow, appressed **Bra**, fertile part slender, part-**Inf** with 1–2 flowers; **Ped** slender, 4–8 mm; **Fl** 35–40 mm; **Tep** dark purple, red or yellow, tube shortly funnel-shaped, 3–5 × 8–9 mm, lobes linear, obtuse with small hood, equal, 15–16 × 4–6 mm, the inner broader, with a prominent keel; **Fil** slender, regular, flattened, 36–42 mm, mostly reddish, inserted near the rim of the tube; **Anth** centric, regular, 14–16 mm, bronze to red or purple; **Ov** fusiform, 17–20 mm, neck constricted, smooth or slightly grooved; **Fr** ovoid, 20–25 × 12–14 mm, beaked, on strongly

jointed pedicels 10–12 mm long; **Se** crescent-shaped, 3–4 × 2–3 mm.

Exhibited for the first time by Verschaffelt in 1862, and introduced by the collector C. Besserer as *A. artichaut* (Berger 1915). Hardly separable from some small-leaved forms of *A. ghiesbreghtii*, from which it otherwise differs by larger, more numerous leaf margin teeth continuing nearly to the base of the terminal spine (Gentry 1982). Plants with yellow or reddish flowers may occur in the same population (e.g. Gentry 23368 (DES 00009541!, ASU 131463!); García Mendoza 6143 (ASU 0000670!)). The collection Steinmann & Ramírez-Amezcuca 5771 (MEXU; det. A. García-Mendoza) is a new record for Guerrero (Portal Datos Abiertos UNAM 2018+: accessed Dec. 2018).

The species is self-compatible and mainly pollinated by a nocturnal bat, but two species of diurnal hummingbirds are also regular visitors and successful, though less efficient pollinators (Flores-Torres & Galindo-Escamilla 2017).

**A. horrida** ssp. *perotensis* B. Ullrich (Cact. Suc. Mex. 35(4): 80, ill. (p. 96), 1990). **Type:** Mexico, Veracruz (Gentry & al. 20417 [US, ARIZ, MEXU]). — **Lit:** Gentry (1982: 161–164, as *A. obscura*); Ullrich (1992f); Jimeno-Sevilla (2010: 377–378); Starr (2012: 111, 113–114); all with ills. **Distr:** Mexico (N Puebla, C Veracruz). **I:** Aalsemgeest & al. (2006b: 214); Heller (2006: 97); Richter (2011: 115); Pilbeam (2013: 109); Hochstätter (2015: IX: 34). — Fig. 28.

[1g] Differs from ssp. *horrida*: **Ros** with somewhat more leaves, small to medium-sized; **L** narrowly linear to ovate, 25–40 × 5–8 cm, pale green to green; **marginal teeth** variable, small (3–5 mm) or large (10–15 mm), straight to curved or flexuous, frequently slanted downwards and curved, <10 mm or 20–30 mm apart; **terminal Sp** conical to subulate, 30–50 mm, broadly decurrent; **Inf** long, tapering, 3–5 m, more densely flowered in the upper  $\frac{2}{3}$  in spiralling sequence, **part-Inf** with geminate flowers with shorter pedicels.

Plants belonging to this taxon were previously misinterpreted as *A. obscura* (see there) by Trelease (1920: 137), Breitung (1959: 146) and Gentry (1982).

**A. howardii** (Verhoek-Williams) Thiede & Eggl (Kakt. and. Sukk. 50(5): 112, 1999). **Type**: Mexico, Colima (*Howard & al.* 72–70 [RSA 240114]). — **Lit**: Verhoek-Williams (1976: with ill.); McVaugh (1989: 252–253); Solano Camacho & García-Mendoza (1998: 55); Guillot Ortiz & al. (2006: 64, with ill.); Feria-Arroyo & al. (2010: with ill.); all as *Polianthes*. **Distr**: Mexico (S Jalisco, Colima); well-drained soils in partial shade in oak or tropical deciduous forests, 1000–1100 m; flowers July to August. **I**: Hannon (2002: 250); Barba-Gonzalez & al. (2012: 124); Castro-Castro & al. (2015: 145); Hochstätter (2016: II: 15); Castro-Castro & al. (2016: 239); all as *Polianthes*.

≡ *Polianthes howardii* Verhoek-Williams (1976).

[3b2] Plants herbaceous, glabrous, corm and bulb fleshy, erect, 3 × 0.9 cm, with dry leaf bases 3.5–4 cm long; **R** fleshy near the corm, becoming wiry distally; **L** 5–6, in a basal rosette from a fibrous-coated bulb, erect-spreading, broadly channelled, narrowly oblanceolate to linear, tip acute or mucronate, glabrous, 22–27 (–36) × (1–) 1.5–2.5 cm, glossy green, lower face sometimes flecked with magenta, margins entire; **Inf** 0.6–1.1 m, ‘spicate’, peduncle with ±7 **Bra**, these gradually smaller than the leaves, sometimes flecked with magenta at the base, fertile **Inf** part elongate, open, 20–70 cm, with 13–30 widely spaced solitary flowers, lowest ±3–5 (–10) cm apart; **Ped** erect, 17–29 (–50) mm,

slender, becoming thicker at fruiting time; **Fl** tubular, semipendent, deflected ±30° from the horizontal; **Tep** glaucous, outer face coral-red at the base, grading to green in the distal  $\frac{1}{3}$ , irregularly streaked with yellow, inner face greenish-yellow, often with maroon stripes in the tube, tube nearly straight, at a slight angle with the ovary and constricted just above the ovary, 18–21 × 3–5 mm, throat slightly oblique, 3–5 mm Ø, lobes rounded, slightly flaring, apical hair tuft inconspicuous, 1.5–3 × 2 mm; **St** included or anthers exerted for 2 mm, **Anth** ±5 mm, yellow; **Fil** inserted near the tube base, the upper slightly longer than the lower; **Ov** 3–4 × 2.5–3 mm; **Sty** longer than the stamens, white; **Sti** white, papillate, 3-lobed, lobes reflexed at maturity; **Fr** globose, 8–10 mm Ø; **Se** unknown. — **Cytology**: 2n = 60 (Tapia-Campos & al. 2013).

Distinctive in Sect. *Polianthes* because only it and *A. confertiflora* have solitary flowers and only in *A. confertiflora* and *A. neonelsonii* is the throat of the tube as asymmetrical. Despite these similarities, *A. howardii* has closer affinities with Ser. *Bravoa* on account of its coral-red flowers and the insertion of the stamens at the base of the tube (Verhoek-Williams 1976: as *Polianthes*).

**A. hurteri** Trelease (Trans. Acad. Sci. St. Louis 23(3): 136, tt. 8–10, 1915). **Type** [syn]: Guatemala (*Trelease* 3 [ILL]). — **Lit**: Standley & Steyermark (1952: 112–113); Gentry (1982: 482–485, with ill.); Lott & García-Mendoza (1994: online version with ill.); Smith & Steyn (2004: with ill.); Véliz Pérez (2013: 238–239, 478, 485, with ill.). **Distr**: NW Guatemala (Sierra de los Cuchumatanes, Quetzaltenango); mountains in the pine-oak forest zone, 1800–3300 m; flowers December to January and March to April. **I**: Schindhelm (2006); Richter (2011: 123); Pilbeam (2013: 110).

**Incl.** *Agave samalana* Trelease (1915).

[2o] Stems none or short and thick; **Ros** rather open with outcurving leaves to compact with ascending leaves, 1–1.8 × (1.2–) 2–3 m, solitary; **L** numerous, (broadly) lanceolate, ascending to spreading, rarely reflexed, broadest at or above

the middle, acuminate, thick-fleshy, thickly rounded below, flat to slightly guttered above, slightly rough above, more asperous below, mostly 70–130 × 13–22 cm, rarely narrower, light glaucous to pale green and yellow-green, margins ± straight or repand; **marginal teeth** straight to curved, larger teeth (2–) 6–12 mm (middle of the lamina), dark brown, 10–25 (–55) mm apart, on broad bases, rarely smaller and closer or margins quite toothless, with small intermittent teeth, brown or grey; **terminal Sp** subulate or conical, broad at the base, openly grooved above, scabrous, 30–60 (–75) mm, dark brown to greyish-brown, decurrent for more than 2× its length; **Inf** (2–) 5–8 m, paniculate, peduncle short, with deltoid to lanceolate **Bra** 15–18 cm long, fertile part stout, narrow, part-**Inf** rounded, 20–45 in the upper 2/3 of the inflorescence, 15–30 cm, freely bulbiferous; **Ped** 12–30 mm; **Fl** 55–70 (–85) mm, distinctly and strongly fruit-scented; **Tep** greenish-yellow to yellow with purple tinge, tube funnel-shaped to angulate-cylindrical, thick-walled, grooved, 7–15 × 15–20 mm, lobes linear-lanceolate or spatulate, unequal, outer 16–28 × 7 (at the base) mm, erect-ascending, rounded to obtuse, inner conduplicate-involute, with thin margins, distinctly grooved dorsally; **St** bronze, purplish or yellow; **Fil** stout to slender, flattened adaxially, 45–70 mm, inserted somewhat irregularly in the middle of the tube or below the mouth, maroon-dotted; **Anth** centric, regular, straight, 17–20 (–30) mm; **Ov** cylindrical, usually rather thick, 20–45 mm, neck short; **Sty** finally slightly longer than the filaments, maroon-dotted; **Sti** capitate; **Fr** oblong, 20–50 × 15–20 mm, not or slightly beaked, stipitate or not; **Se** D-shaped, 7–8 × 5 mm.

A variable complex, usually distinguishable from other members of Sect. *Guatemalenses* (as Group *Hiemiflorae*) with rounded part-inflorescences by its larger many-leaved rosettes and consistently longer stalked part-inflorescences in the short-peduncled panicles (Gentry 1982). Standley & Steyermark (1952) placed *A. pachycentra* in the synonymy, but this was not followed by other authors. Smith & Steyn (2004) provide an amplified description and illustrations. The “type” at ILL consists of 5 sheets which are not cross-labelled thus representing syntypes (Smith & Figueiredo

2014e: 236). The species is used for fences, esp. on rock walls (Steinberg & Taylor 2008: 256, 261). To be considered as “Endangered” in the IUCN Red List categories (Véliz Pérez 2013).

**A. ×hybrida** J. Verschaffelt *pro sp.* (Nursery Cat. (Jean Verschaffelt) 12: 2, 1868). **Type:** not typified. — **Lit:** Baker (1877a: 527–528, with ills., as *A. perbella*, *A. hybrida*, *A. xylacantha vittata*); André (1903: 227, as *A. armata*); Berger (1915: 98, as *A. armata*; 114, as *A. simonii*); Trelease (1920: 237, as *A. ×hybrida*, *A. ×perbella*); Thiede & al. (2019b). **Distr:** Cultivated only.

**Incl.** *Agave xylonacantha* [?] *vittata* Hort. Belg. ex Ellemeet (1871) (*nom. inval.*, ICN Art. 38.1a); **incl.** *Agave perbella* Baker (1877); **incl.** *Agave ×armata* hort. ex Thuysbaert *pro sp.* (1903) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave simonii* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a).

[1g × 1g] This is apparently the first-ever artificial *Agave* hybrid, *A. lophantha* (as *A. univittata*) × *A. xylonacantha*, cross-pollinated in summer 1865 by Gustave-Philippe de Kerchove d’Ousselghem near Ghent, Belgium. Kerchove apparently gave seeds to J. Verschaffelt who offered material, as far as known without description, in his catalogue of 1865 (not seen) (Thiede & al. 2019b). Berger (1915: 114) later described a leaf of the hybrid. Apparently lost from cultivation.

**A. impressa** Gentry (Agaves Cont. North Amer., 146–149, ills., 1982). **Type:** Mexico, Sinaloa (*Gentry* 23366 [US, ARIZ, ASU, CAS, DES, MEXU, MICH]). — **Lit:** McVaugh (1989); García-Mendoza (2003: with ill.); Vázquez-García & al. (2007b: 41–42, t. N); González-Elizondo & al. (2009: 88–89, with ills.); Etter & Kristen (2011: with ills.). **Distr:** Mexico (S Sinaloa, Nayarit); in tropical semideciduous forests on volcanic rocks in the hot lowlands, 150–700 m; flowers January to March. **I:** Etter & Kristen (2002: fig. 3 + front cover); Heller (2006: 98); Richter (2011: 108); Pilbeam (2013: 111); Hochstätter (2015: IX: 35); Moore (2016: 259). – Fig. 29.

[1g] Subcaulescent; **Ros** openly spreading, 0.5–0.85 × to 1.6 m, solitary; **L** linear to lanceolate, rigidly spreading, thickly fleshy with

**Fig. 29** *Agave impressa*

(Etter & Kristen 3070:  
Mexico; Sinaloa, ± 30 km  
E of El Rosario, 240 m).  
(Copyright: J. Etter &  
M. Kristen)

viscid adhesive sap and few fibres, convex below, flat to guttered above, 40–60 × 5–9 cm, pale yellowish-green, with conspicuous white imprints from the central bud on the upper face, margins horny, continuous, straight to sinuous between the teeth, 2–3 mm wide, light to dark grey; **marginal teeth** straight or slightly curved, flattened, regular, blunt, mostly 3–5 mm, grey like the leaf margin, 10–15 mm apart; **terminal Sp** subulate, stout, rounded below and sometimes protruding from the base into the leaf tissue, flat and broad at the base above, rarely channelled, sharp to blunt at the tip, 30–50 mm; **Inf** erect, 2–3 m, ‘spicate’, flowering from near the closely bracteate base, part-**Inf** with 2–3 flowers; **Ped** slender, 20–25 mm; **Fl** 35–40 mm; **Tep** yellow, green in bud, tube short, spreading, 1.5–2 × 7 (at the mouth) mm, lobes linear-elliptic, thin, ascending, partially recurved, apex rounded, apiculate, equal, 17–18 × 4–5 mm, outer flat, inner wider, involute, with broad low keel; **Fil** very slender, flattened, 35–40 mm, white, inserted 1–2 mm above the tube base; **Anth** regular, centric, 15–16 mm, yellow; **Ov** slender, fusiform, slightly angled, 17–20 × 4 mm, neck smooth, not constricted; **Fr** 15–18 × 8–10 mm, sharply beaked, fruit valves curved outwards; **Se** 2–3 × 2–3 mm, shiny.

A distinctive species without close relatives. The symmetrical rosettes with spreading, white-marked, light green leaves with blunt teeth and spines are quite unlike any other *Agave* species.

Its placement in Sect. *Heteracanthae* (as Group *Marginatae*) is for convenience only, and it might also be close to *A. attenuata* ssp. *dentata* (as *A. pedunculifera*) of Sect. *Inermes* (as Group *Amolae*) (Gentry 1982). Molecular data (Gil-Vega & al. 2007) place it among Sect. *Heteracanthae* and apart from Sect. *Inermes*.

Known to Gentry (1982) only from its type locality SE of Escuinapa (Sinaloa; Etter & Kristen (2002)) where the vernacular name “masparillo” is used. Etter & Kristen (2011) report further localities near Escuinapa. In Sinaloa, *A. impressa* also occurs near La Guásima NNE of Concordia (González-Elizondo & al. 2009; Van Devender & al. 2007-126 [ARIZ, DES]). Gentry (1982) was informed that an *Agave* named “masparillo” would occur towards Bolaños in the “Sierra de los Huicholes” in Jalisco, but *A. impressa* was not found there (Hernández-Vera & al. 2007a: 500). Probably, vernacular names were confused, since “masparillo” is also used for *A. maximiliana* which is abundant in the Sierra de los Huicholes (Hernández-Vera & al. 2007a). Etter & Kristen (2011) finally found *A. impressa* on the W side of the Sierra de los Huicholes in Nayarit 50 km SW of Mesa del Nayar, and also at Presa Aguamilpa near Tepic (Nayarit), where the species was collected earlier by Charles Glass. Based on sterile specimens, Cházaro Basáñez & Valencia (2003) reported the species from the Barranca de Colimilla in Jalisco, but flowering plants proved to be different and were later described as a

new species *A. arcedianoensis* (Vázquez-García & al. 2007b; see also there). — ‘Green Giant’ is a cultivar with longer leaves and larger rosettes.

**A. inaequidens** K. Koch (Wochenschr. Vereines Beförd. Gartenbaues Königl. Preuss. Staaten 3: 28, 1860). **Type** [neo]: Mexico, México (Gentry & al. 19612 [US, ARIZ [2 sheets], MEXU [2 sheets]]). — **Lit**: Gentry (1982: 340–344, with ills.). **Dist**: C Mexico.

The neotype at US designated by Gentry (1982: 341) consists of two specimens (US 2601951 & 2601952) which were apparently cross-labelled afterwards.

**A. inaequidens** ssp. **barrancensis** Gentry (Agaves Cont. North Amer., 342–344, ills., 1982). **Type**: Mexico, Durango (Gentry & Arguelles 22282 [US †, syn: ARIZ [2 sheets], DES, MEXU [3 sheets], MICH [2 sheets]]). — **Lit**: González-Elizondo & al. (2009: 90–93, with ills.). **Dist**: Mexico (E-C Sinaloa, Durango); mountainous slopes of deep barrancas in the pine-oak forest and woodland region, 1800–2400 m; flowers September and December. **I**: Pilbeam (2013: 112).

[2d] Differs from ssp. *inaequidens*: **Ros** 1.5–2 × 3–3.5 m; **L** mostly longer and narrower, 100–170 (–200) × 10–17 (–24) cm, margins nearly straight to undulate; terminal **Sp** subulate-acicular and longer, 40–60 mm; **Inf** broader and shorter, part-**Inf** 20–30, broadly spreading.

Looking like a larger *A. jaiboli*, but its relations are with *A. inaequidens* (Gentry 1982). Known to Gentry (1982) only from along the Durango—Mazatlán road, but González-Elizondo & al. (2009) provide new records from NW and W-C Durango. The gathering *A. C. Sanders & al.* 4430 (ARIZ 249820, UCR 33674, UTEP 24614, WIS 0352581!) is a new state record just across the border in E-C Sinaloa.

The holotype, cited for US in the protologue, appears to be missing, leaving 8 syntypes as cited above. Most probably, Gentry intended the most complete specimens (ARIZ 266209 & 266210) both bearing his stamp “Gentry Herbarium” and his handwriting “Type Collection” to be sent to US as “holotype”. The 2 sheets at MICH were apparently cross-labelled later.

**A. inaequidens** ssp. **inaequidens** — **Lit**: Berger (1915: 165); Gentry (1982: 340–342); McVaugh (1989: 138); Vázquez-García & al. (2007b: 57–58, t. N); Greulich (2014a: with ills.); Greulich (2015: with ills.). **Dist**: Mexico (Nayarit, Jalisco, Michoacán, México, D.F., Morelos, Guerrero); rocky slopes in pine-oak forests, mostly 1850–3100 m; flowers October to April, and August. **I**: Etter & Kristen (2012: 81–82); Pilbeam (2013: 112).

**Incl.** *Agave amoena* Lemaire ex Jacobi (1865); **incl.** *Agave mescal* K. Koch (1865); **incl.** *Agave crenata* Jacobi (1866); **incl.** *Agave fenziiana* Jacobi (1866); **incl.** *Agave megalacantha* Hemsley (1880); **incl.** *Agave hookeri* Baker (1881) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave reginae* hort. ex A. Berger (1912); **incl.** *Agave heterodon* hort. ex A. Berger (1915); **incl.** *Agave bourgaei* Trelease (1920).

[2d] Stems short; **Ros** openly spreading, 1.5–3.5 m Ø, solitary; **L** variable, broadly or narrowly lanceolate or oblanceolate, ascending to outcurving, thickly fleshy (esp. towards the rounded base), concave above, esp. towards the rounded base, mostly 75–150 × 11–21 cm, light green to yellow-green, rarely faintly glaucous, margins undulate to repand and crenate; **marginal teeth** dimorphic, straight or variously curved, the flattened bases longer than the height of the teeth, commonly 8–10 mm long, chestnut-brown to dark brown, 25–40 mm apart, with few smaller intermittent teeth, larger teeth on broad prominences; **terminal Sp** stout, broadly deeply channelled above, 25–55 mm, dark brown, protruding into the leaf tissue below, sharply decurrent to the uppermost teeth; **Inf** 5–8 m, paniculate, peduncle short, fertile part narrow in outline, part-**Inf** compact, 30–50 in the upper ½ of the inflorescence; **Fl** 60–90 mm; **Tep** yellow, buds reddish-purple, tube deeply grooved, 5–12 (–15) mm, thick-walled, bulging at the filament insertions, lobes linear, erect, narrow, conduplicate, involute, strongly cucullate and papillate within at the tip, unequal, 25–30 (–34) mm, reddish; **Fil** stout, ovate in cross section, 50–60 mm, inserted above mid-tube; **Anth** centric to excentric, 26–34 mm; **Ov** cylindrical, trigonous, 30–40 mm, neck short, furrowed; **Sty** slightly longer than the tepals; **Sti**

capitate; **Fr** oblong, 40–45 × 20 mm, rounded to apiculate at the apex, without beak, stipitate, brown; **Se** semicircular, 6–7.5 × 4.5–5.5 mm, shiny black, finely punctate, the marginal wing half-curved or straight, hilar notch broad.

*A. inaequidens* is the predominant *Agave* in the Trans-Mexican mountains from Morelos through Michoacán to Jalisco. Fernández Nava & al. (1998) and the collections Soto N. & Martínez S. 5004 (MEXU 384410!) and Martínez S. & Soto N. 3677 (MEXU 843995!) provide a new record for Guerrero (Balsas Basin). Gutiérrez G. & al. 77 (MEXU 1213265! & 1213428!), a new record for Guanajuato, is filed as ssp. *barrancensis*, but may belong here according to its leaf size. Vázquez-García & al. (2007b: 57) list the species for Hidalgo and Nayarit, but no specimens could be located. Madrigal-Sanchez & Diaz-Barriga (1991) describe a fasciated inflorescence.

Best distinguished from the closely related *A. hookeri* from the same region by its bright yellowish-green leaves with teeth all along the margin (vs. glaucous light grey with teeth lacking 15–20 cm below the terminal spine; Gentry (1982)). Morphometric studies showed that *A. hookeri* is similar to cultivated *A. inaequidens*, supporting the hypothesis that it could represent the extreme of a domestication gradient *A. inaequidens* wild → *A. inaequidens* cultivated → *A. hookeri* cultivated only (Figueredo & al. 2014). Figueredo & al. (2015) found little genetic structuring of wild, silviculturally managed and cultivated populations and conclude that domestication (for mescal production) is still in its early stages.

**A. inaguensis** Trelease (Mem. Nation. Acad. Sci. 11: 47, tt. 103–105, 1913). **Type** [syn]: Bahamas, Little Inagua (Nash & Taylor 342 etc. [MO]). — **Lit**: Berger (1915: 269); Britton & Millspaugh (1920: 76); Correll & Correll (1982: 312); Jestrow & al. (2014: 234, 238, with ill.). **Distr**: Bahamas (Great Inagua, Little Inagua), Turks & Caicos Islands (South Caicos); open sandy flats and rocky dwarf coastal coppices; flowers mostly June to August. **I**: Hochstätter (2015: VII: 97).

[2t] Acaulescent; **Ros** caespitose, freely suckering; **L** oblong or lanceolate, stiffly erect, hard,

straight, narrow, rather abruptly acute and flat, sometimes conduplicate, tip sometimes sigmoidally upcurved, 40–100 × 6–9 cm, typically white-glaucous; **marginal teeth** more recurved and less uniform than in *A. nashii*, slender, very narrowly triangular, 1–2 mm, almost continuously joined by a narrow blackish border, 2–9 mm apart; **terminal Sp** 20–30 mm, dark brown; **Inf** 4–5 m, paniculate, part-**Inf** few, on slender outcurved **Br** in the upper ¼ of the inflorescence; **Ped** 5–10 mm; **Fl** ±50 mm; **Tep** yellow, tube open, ±5 mm, lobes 15–17 × 5 mm; **Fil** 35 mm, inserted almost in the tube throat; **Ov** subfusiform, 25–30 mm; **Sty** longer than the filaments; **Sti** capitate; **Fr** oblong-ellipsoid, 30–40 mm, beaked, broadly and shortly stipitate; **Se** ±6 mm.

From the 6 collections cited as “type” in the protologue (“Nash and Taylor, 342, 1215, 21832; 329, 1202, 21833, Nov. 1904”; = syntypes), none is available electronically; however, 3 specimens of the collection Nash & Taylor 1389, 1. Nov. 1904, not cited in the protologue, are at NY. According to the protologue with the habit of *A. nashii*, the second species of Sect. *Inaguenses*. *A. nashii* differs by having gradually tapering, deeply guttered leaves with a rather slender terminal spine and deltoid to broad-based marginal teeth. Originally published from Little Inagua and South Caicos, but later also collected on Great Inagua where *A. nashii* also occurs (Howard & Dunbar 1964: 12).

**A. indagatorum** Trelease (Mem. Nation. Acad. Sci. 11: 42, t. 92, 1913). **Type**: Bahamas, Watling Island (Britton & Millspaugh 6155 [MO 2056579 & 2056580 [photo & letter], F [2 sheets], NY [2 sheets]]). — **Lit**: Berger (1915: 205); Britton & Millspaugh (1920: 76); Correll & Correll (1982). **Distr**: Bahamas (Long Island, San Salvador [Watling] Island); rocky soil in coastal coppices, to 450 m; flowers mostly March to June. **I**: Hochstätter (2015: VII: 84).

[2r] Acaulescent; **Ros** solitary; **L** very narrowly lanceolate or almost oblong, fleshy, outcurved-ascending to upcurved towards the tip, gradually acute, lower face flattened or convex, upper face concave, 150–250 × 20–25 mm, dark green, somewhat greyish and at first very

glaucous beneath, almost silvery towards the base, glossy on the upper face, margins between the teeth straight, somewhat membranous, at first slightly pink; **marginal teeth** straight or slightly recurved, narrowly triangular, not lenticular at the base,  $\pm 1$  mm, 3–12 mm apart, at first slightly pink, somewhat membranous; **terminal Sp** conical, nearly straight, slender, involutely grooved to the middle, smooth,  $\pm 12$  mm, chestnut-brown or red-brown, rather glossy, decurrent for about its own length; **Inf** to  $\pm 9$  m, paniculate, reportedly bulbiferous; **Ped** 15–20 mm; **Fl**  $\pm 55$  mm; **Tep** yellow, tube rather open,  $\pm 6$  mm, lobes  $\pm 20 \times 2$  mm; **Fil**  $\pm 35$  mm, inserted in the tube throat; **Ov** ellipsoid, 20–25 mm, extended as a neck into the flower tube; **Fr** narrowly oblong, thickly stipitate, 35–60  $\times$  17–20 mm, acuminate pointed; **Se** 7–8  $\times$  5 mm.

In the key of Trelease (1913: 39) closest to *A. acklinicola*, which differs in its teeth often with lenticular bases and a stout terminal spine. See also the note under *A. bahamana*. — The species is “named in commemoration of the explorers who are reputed to have sighted this island [Guanahani, Watling or San Salvador Island] first in the New World” (Trelease 1913: 42).

**A. intermixta** Trelease (Mem. Nation. Acad. Sci. 11: 32, t. 64, 1913). **Type:** Hispaniola, Haiti (Parry 1871 [MO 2056581, US 125674]). — **Lit:** Berger (1915: 206–207); Howard (1961: 133). **Distr:** Haiti (near Santiago de los Caballeros); stream bank, on steep hills; flowers in February. **I:** Hochstätter (2015: VII: 71, identity uncertain).

[2p] **L** 100  $\times$  12 cm or more; **marginal teeth** rather broadly triangular, nearly straight, on somewhat rounded or lenticular bases, 4–5 mm, 15–25 mm apart, intervening margin nearly straight; **Inf** not known to be bulbiferous; **Ped** slender, 15–25 mm; **Fl**  $\pm 65$  mm, congested at the ends of the part-**Inf**; **Tep**  $\pm 35$  mm, yellow (?), tube narrowly conical, 8–10 mm, lobes 20  $\times$  3–4 mm; **Fil** 30 mm, inserted almost at the throat of the tube; **Ov** elongated-fusiform, 35  $\times$  5 mm; **Fr** rather broadly pear-shaped and oblong, 40  $\times$  20 mm, stipitate and beaked, somewhat rugose, light brown; **Se** somewhat glossy, narrowly winged, 7–8  $\times$  5 mm.

The herbarium specimens of *A. intermixta* are “hopelessly” intermixed with material of *A. antillarum* (Trelease, unpubl. manuscript). The protologue is a much abbreviated description as a footnote only, based on fruiting part-inflorescences with disassociated flowers, but without data on rosette, leaves, and inflorescence. Trelease had prepared a complete description of *A. intermixta* and a discussion of its affinities, but this was never published and is kept at MO (Howard 1961: 133); detail data from it are added here. The type at MO (Parry 1871) is stated to be from “Santo Domingo”, but was actually collected on the bank of a stream near Santiago de los Caballeros, according to the original field notes (Howard 1961: 133). The leaf margin in t. 43.1 of Trelease (1913) may be that of *A. intermixta* (Howard 1961: 133). According to the unpublished manuscript of Trelease at MO, *A. intermixta* differs from *A. antillarum* in its long-pedicelled elongated flowers with deep tube and filaments scarcely  $\frac{1}{2}$  longer than the perianth segments and, apparently, in leaf and fruit characters. According to Álvarez de Zayas (1995: 41) it is possibly conspecific with *A. antillarum* (see there). — Aqueous extracts are used in traditional medicine and have anti-inflammatory, cytotoxic and antibacterial effects (e.g. Quílez & al. (2004); identity doubtful).

**A. involuta** (McVaugh) Thiede & Egli (Kakt. and. Sukk. 50(5): 110, 1999). **Type:** Mexico, Jalisco (Bauml & Voss 1466 [RSA, MICH]). — **Lit:** McVaugh (1989: 231–232); Rodríguez & al. (2008: with ill.); Castillejos-Cruz (2009: [169]–[174], with ill.); all as *Manfreda*. **Distr:** Mexico (S Zacatecas, S Nayarit, N, W & C Jalisco); grassy openings and hillsides in dry oak or pine-oak forests and grasslands, 740–2000 m; flowers March to July. **I:** Rodríguez & Castro-Castro (2006: 625); Rodríguez & Castro-Castro (2007: 9); Hochstätter (2016: I: 23); Castro-Castro (2017: 136); Castro-Castro & al. (2017: 62); Castro-Castro & al. (2018: 499); all as *Manfreda*.  $\equiv$  *Manfreda involuta* McVaugh (1989).

[3a3] Plants herbaceous; corm 2.5  $\times$  1–2 cm, erect, cylindrical, bulb 3.5–5.5  $\times$  1–2.3 cm, cylindrical, completely covered with dry leaf bases 5–8 cm long, these membranous at the base and

fibrous above for 2–3 cm; **R** fleshy, with filiform ramifications, contractile; **L** drought-deciduous, often absent during flowering, 6–11, linear, canaliculate or in the middle involute, then nearly tubular and only 2–3 mm  $\varnothing$ , lower face papillate on the veins, upper face glabrous, 18–80  $\times$  0.2–0.9 cm, light green, margins entire to papillose, with a hyaline band; **Inf** 60–180 cm, ‘spicate’, erect to slightly arching, green-reddish and somewhat glaucous; **Bra** 6–9, rather distant; fertile **Inf** part 10–20 (–35) cm, lax, with 3–18 flowers; floral **Bra** 0.4–1  $\times$  0.2–0.4 cm; **Fl** 20–28 mm, solitary, sessile, ascending, funnel-shaped; **Tep** green with purplish tinge mainly on the inner face, tube 12–15  $\times$  5–7 mm, constricted at the mouth, lobes oblong, erect, 7–8  $\times$  3–5 mm, tip cucullate, with a bundle of short white trichomes; **Fil** 12–18 mm, erect at anthesis, exceeding the tube for 3–9 mm, inserted at mid-tube all on the same level, reddish to purplish; **Anth** 7–8.5 mm, yellow with purple tinge; **Ov** ellipsoid, 10  $\times$  2.5 mm, greenish with purple tinge, constricted above; **Sty** 28–33 mm, dark purplish; **Sti** 3-lobed; **Fr** globose to subglobose, 13–15  $\times$  11–13 mm, glaucous, sometimes with short apex, tepals persisting; **Se** deltoid, 4.8–6  $\times$  4.5 mm, shiny black.

According to the protologue (McVaugh 1989: 231–232) known from 2 collections in Jalisco only and of uncertain affinities due to its apparently unique combination of a very early flowering

season, very narrow involute leaves, and slender tepal tubes longer than the lobes. With its papillate leaf margins, the ovary protruding into the tube and the cylindrical tube not narrowed above the ovary, the taxon fits well into Ser. *Guttatae* of Sect. *Herbaceae*, however. Rodríguez & al. (2008) and Castillejos-Cruz (2009) cite additional collections from Zacatecas and Nayarit, and provide additional morphological data.

**A. isthmensis** García-Mendoza & F. Palma (Sida 15(4): 565–568, ills., 1993). **Type:** Mexico, Chiapas (*García-Mendoza & al.* 4177 [BRIT/SMU  $\dagger$ ?, DES  $\dagger$ ?, ENCB, MEXU]). — **Lit:** Starr (2012: 115–119, 312–313). **Distr:** Mexico (E Oaxaca, W Chiapas: near the Isthmus of Tehuantepec); sandstone or soils of calcareous origin, in tropical deciduous and oak forests, 50–980 m; flowers January. **I:** Smith (2002: 221); Forster (2006: 179–181); Heller (2006: 99); Richter (2011: 84, 113); Pilbeam (2013: 113–115). — Fig. 30.

[2o] **Ros** compact, 17–32  $\times$  25–36 cm, young plants with numerous rhizomatous offsets, adult plants with axillary offsets, forming dense clonal colonies; **L** 84–132, ovate, narrowed towards the base, apex truncate, concave, scabrous below, 8–10  $\times$  5–8 cm, mostly grey-glaucous to white-glaucous, sometimes green, margins deeply crenate; **marginal teeth** deltoid, (2–) 3–4 mm, brown-reddish,

**Fig. 30** *Agave isthmensis* (Beisel s.n.: Mexico; Oaxaca, near Salinas Cruz). (Copyright: U. Eggli)

on distinct prominences, <10 mm apart; **terminal Sp** sinuous, slightly applanate, 12–15 mm, brown-reddish, decurrent for 6–10 mm; **Inf** 1.7–2.2 m, paniculate, peduncle with deltoid papyraceous **Bra** 3.4–3.8 cm long, fertile part oblong, with (6–) 20–25 part-**Inf**, these 9–16 cm, in the upper  $\frac{3}{4}$  of the inflorescence; **Ped** 3–4 mm, elongating to 10 mm at fruiting time; **Fl** succulent, 38–46 mm; **Tep** yellow, tube funnel-shaped, trisulcate, 4–5 mm, lobes oblong, subequal, 19–21 × 4 mm; **Fil** 27–33 mm, yellowish, inserted at the tepal base; **Anth** 14–17 mm, yellowish; **Ov** 16–21 mm; **Sty** as long as the filaments; **Sti** capitate, 3-lobate; **Fr** ovoid, 16–22 × 10–18 mm, rostrate; **Se** applanate, 2–4 × 1–2 mm, black.

According to the protologue closest to *A. potatorum* and *A. seemanniana* (as *A. pygmaea*) and distinct by its compact, small, many-leaved rosettes with small, glaucous leaves with scabrous lower face and the rhizomatous as well as axillary offsetting. Variegated cultivars are ‘Ohi Raijin Fukurin Nishiki’ with cream-coloured leaf margins, ‘Rum Runner’ (ISI 2014-11) with broad golden-yellow midstripe (Trager 2014), and ‘Ohi Raijin Shiro Nakafu’ with broad white central stripe (Starr 2014: 222–223).

**A. jaiboli** Gentry (US Dept. Agric. Handb. 399: 89–94, ills., 1972). **Type**: Mexico, Sonora (Gentry 21177 [US, ARIZ, ASU, MEXU, MICH, US]). — **Lit**: Gentry (1982: 344–346, with ills.); Martin & al. (1998: 469). **Distr**: Mexico (S Sonora); open grassy slopes and volcanic cliffs in short-tree forest and oak woodlands, 300–1400 m; flowers in May. **I**: Pilbeam (2013: 116); Greulich (2014a: 55); Hochstätter (2015: IV: 26).

[2d] **Ros** usually open, 0.6–1 × 1.4–2 m, solitary; **L** linear to lanceolate, usually straightly ascending to spreading, sometimes incurved, widest at or above the middle, gradually narrowed below, long-acuminate, flat to guttered, 60–100 × 8–12 cm, green to yellowish-green, margins not corneous; **marginal teeth** curved down- or upwards, 5–8 mm, reddish-brown, larger teeth ±20–30 mm apart, on small regular prominences, smaller intermittent teeth 1 to several, 1–4 mm; **terminal Sp** subulate, terete, openly or narrowly

grooved in the lower  $\frac{1}{2}$  to  $\frac{2}{3}$ , smooth, 30–40 mm, reddish-brown, shiny, narrowly horny decurrent for less than its length; **Inf** 6–8 m, paniculate, peduncle with narrow scarious **Bra**, fertile part with 12–15 ascending, rather sigmoid, small, diffuse, 4-flowered part-**Inf** in the upper  $\frac{1}{2}$ – $\frac{1}{3}$  of the inflorescence; **Ped** short; **Fl** ±60 mm; **Tep** yellow tinged ferruginous, tube funnel-shaped, deeply grooved, 9–11 × 15 mm, bulging at the filament insertions, lobes unequal, rather thin, conduplicate and involute; **OTep** 22–23 × 4–5 mm, ascending, incurved, linear-lanceolate, acute, slightly guttered; **ITep** with broad keel; **Fil** somewhat flattened, 45 mm, pink, inserted above mid-tube; **Anth** nearly centric, 23–24 mm; **Ov** angular-fusiform, shortly tapered at the base, 25–30 mm incl. the 3–4 mm long neck, green; **Sty** stout, longer than the anthers at the end of anthesis; **Sti** capitate, 3-lobate; **Fr** 40–50 × 18–20 mm, shortly beaked, long-stipitate, brown; **Se** rugose, very finely punctate, 7 × 5 mm, prominently winged, shiny black.

The flower structure and the dimorphic teeth on the soft, fleshy, crenate leaves place the species in Sect. *Crenatae*. Here it is distinguished by its narrow, almost ensiform leaves. Its Sonoran relative *A. bovicornuta* is further distinguished by its broader leaves much narrowed towards the base (Gentry 1982). The Wariho ethnic group esteem the species for its sweet edible qualities (young flowering shoots and the stems are cooked and eaten), in contrast to the unpalatable *A. bovicornuta* (Gentry 1982). The holotype at US consists of 2 sheets (US 2549714 & 2549715) which were apparently cross-labelled later.

**A. jaliscana** (Rose) A. Berger (Agaven, 38, 1915). **Type** [lecto]: Mexico, Jalisco (*Pringle* 1850 [US, BM, BR, F, G, GH, LE, M, NDG, NY, P, S, VT]). — **Lit**: Rose (1903c: 22); Gentry (1972: 152–153); Verhoek-Williams (1975: 291–294); Piña Luján (1986: 15–16); McVaugh (1989: 232); Castillejos-Cruz (2009: [175]–[180], with ills.); all as *Manfreda*. **Distr**: Mexico (Sonora, Sinaloa, Durango, Nayarit, Jalisco, Michoacán); loose black loam or rocks, in oak, pine-oak or tropical deciduous forests and on

grassy slopes, (100–) 500–2500 m; flowers October to April. **I:** Hochstätter (2016: I: 24); Castro-Castro (2017: 136); Castro-Castro & al. (2017: 62); all as *Manfreda*.

≡ *Manfreda jaliscana* Rose (1903) ≡ *Polianthes jaliscana* (Rose) Shinnars (1966).

[3a2] Plants herbaceous; corm 6–10 × 3–4 cm, cylindrical, bulb 2–3.5 × 2–3 cm, ovoid to sub-cylindrical, completely covered with dried leaf bases 4–7.5 cm long, these membranous at the base and fibrous above; **R** fleshy, with filiform ramifications, contractile; **L** drought-deciduous, 5–10, prostrate or semi-erect, linear-lanceolate, slightly canaliculate, papillose on the veins on both faces, apex acute, 38–78 (–90) × 0.6–1.4 (–2.6) cm, light green, margins entire, with a hyaline band, and with scattered papillae throughout its length; **Inf** 90–180 cm, ‘spicate’, erect, light green to yellowish-green, with purplish tinge, **Bra** 6–9, fertile part 10–40 cm, lax, with 25–40 flowers; floral **Bra** 0.8–1.1 × 0.3–0.5 cm; **Fl** 19–26 mm, solitary, sessile, appressed to ascending; **Tep** greenish-yellow, semisucculent, campanulate, tube 7–9 × 4–5 mm, lobes narrowly elliptic to oblong, extended, 7–12 × 4–6 mm, tip cucullate, with a bundle of short white trichomes; **Fil** sparsely glandular-pilose, 40–75 (–85) mm, erect at anthesis, exceeding the tube for 4–5 mm, inserted at mid-tube at the same level, green-yellowish with reddish dots; **Anth** 7–10 mm, yellow; **Ov** cylindrical, (4–) 8–11 × 3–4 (–5) mm, greenish, not prolonging into the tube, slightly constricted above; **Sty** 60–90 mm; **Sti** 3-lobed, yellowish-green; **Fr** cylindrical to ellipsoid, 13–27 × 12–17 mm, apex apiculate, with persisting tepals; **Se** deltoid, plane-concave, with narrow black shiny margin, 5–6 × 4–5 mm.

Easy to recognize in flower by its long-exserted stamens, the short tepal tube and long lobes. The very long narrow leaves with papillose margins are also characteristic (McVaugh 1989). Similar to *A. chamelensis*, *A. fusca* and *A. debilis*, which together form a group characterized by tepal tubes <25 mm long, and filaments inserted at mid-tube (Castillejos-Cruz 2009).

**A. jarucoensis** A. Álvarez (Revista Jard. Bot. Nac. Univ. Habana 1(1): 5–11, ills., 1981). **Type:**

Cuba (Álvarez 41680 [HAJB]). — **Lit:** Álvarez de Zayas (1985: 12–15, with ills.). **Distr:** W Cuba; limestone rocks and cliffs, 200–290 m; flowers in November. **I:** Hochstätter (2015: VII: 91).

[2q] Stems short; **Ros** semiglobular, solitary, not rhizomatous; **L** many, lanceolate, weak, slightly curved to flexuous, fleshy, coriaceous, narrowed below the middle, slightly concave in the lower  $\frac{2}{3}$ , 90–120 × 12–16 cm, green to greyish, slightly dull, margins straight or lobed; **marginal teeth** triangular, straight or weakly retrorse, slightly lenticular at the base, 1–5 × 0.1–0.4 mm, larger at mid-leaf, castaneous-red-dish, base reddish, 4–15 mm apart; **terminal Sp** acicular, straight, pungent, flattened at the base, narrowly canaliculate up to the middle, 15–22 × 3–4 mm, slightly lustrous, chestnut-brown to grey, not decurrent; **Inf** 2–4 m, paniculate, fertile part in the upper  $\frac{2}{3}$  to  $\frac{3}{4}$ , part-**Inf** ±14–23, tripartite, ascending, 35–45 cm; **Ped** 5–15 mm; **Fl** 35–60 mm; **Tep** yellowish-green, tube open, narrow, 5–7 mm, lobes narrowly ovate to lanceolate, 13–16 mm, apex cucullate, yellow, inner with broad margin, outer dorsally keeled, all constricted and furrowed at the base; **Fil** 26–32 mm, yellow, inserted near the tube throat; **Anth** 17–20 mm, golden-yellow; **Ov** subcylindrical or fusiform, narrowly angulate, constricted at the base, apically furrowed, 18–24 mm, greenish; **Sty** slightly shorter than the filaments; **Sti** capitate; **Fr** oblong to nearly rounded, shortly apiculate, 22–40 × 15–20 mm, walls thick; **Se** subtriangular, 5–6 mm, shiny.

According to the protologue and Álvarez de Zayas (1985) similar to *A. papyrocarpa*, but differing in its more robust habit, ascending part-inflorescences, larger flowers, and thick fruit walls, and from *A. tubulata* in its larger, relatively shorter tepal lobes. It occurs at least sometimes in regions with a predominance of ophiolitic soils (López Almira 2013). Hochstätter (2015) published the first photograph of the species.

**A. jimeno**i Cházaro & A. Vázquez (Phytotaxa 134(1): 55–57, ills., 2013). **Type:** Mexico, Veracruz (*Jimeno & al.* 702 [XAL, IBUG, MEXU]). — **Lit:** Cházaro Basáñez & Narave-Flores (2015: with ills.). **Distr:** Mexico (C Veracruz: Tlapacoyan

region); cliff dweller in lowland tropical sub-perennial forests,  $\pm 150$  m; flowers April to June; only known from 2 localities. **I:** Hochstätter (2015: IX: 12).

[1f] Caulescent, to 60 cm, not surculose, according to the protologue polycarpic; stems 34–90  $\times$  5.1–6 (at the base) cm, pendent, bifurcate, each branch with a terminal **Ros** that turns upright; **L** 16–20, oblanceolate, flexible, concave above when young, 39–42  $\times$  8.4–8.5 cm, green-glaucous, marginal denticles concolourous with the lamina, absent from the uppermost 6 cm; **terminal Sp** flexible, 5–13 mm, dark brown; **Inf** erect, lateral according to the protologue, but actually likely terminal on rudimentary lateral rosettes, 1.32–1.4 m, ‘spicate’, peduncle with lanceolate narrow **Bra** (0.22–) 1–16  $\times$  0.22–1.2 cm, acuminate, fertile part in the upper  $\frac{1}{2}$  of the inflorescence; **Ped** 3–5.8 mm; **Fl** geminate, 28–30 mm (excl. stamens);  **Tep** yellowish, tube 7  $\times$  5 mm, lobes lanceolate, 10.5–13  $\times$  5–6.5 mm; **St** 41–44 mm; **Anth**  $\pm 15$  mm, reddish to yellow; **Ov** 13  $\times$  4–4.5 mm, without neck; **Sty**  $\pm 47$  mm,  $\pm$  as long as the filaments; **Sti** slightly thickened; **Fr** ellipsoid, 15.8–18.8  $\times$  12–13 mm; **Se** 2–3.3  $\times$  3.4–4.8 mm, black.

Compared with *A. gomezpompae* in the protologue, which is also from lowland habitats in C Veracruz in tropical semideciduous forests. Both have a long bifurcate stem, oblanceolate, flexible leaves, and erect inflorescences with flowers in their upper  $\frac{1}{2}$ . *A. jimenoii* differs in having shorter and pendent stems, smaller glaucous-green leaves with the marginal denticles lacking below the terminal spine, and shorter inflorescences. *A. jimenoii* is distantly related to *A. pendula*.

**A. justosierrana** (García-Mendoza) Thiede (Haseltonia 17: 94, 2012). **Type:** Mexico, Guerrero (*García-Mendoza & al.* 6739 [MEXU [2 sheets]]). — **Lit:** García-Mendoza (2011b: with ills., as *Manfreda*). **Distr:** Mexico (Guerrero); open, sunny spots in brownish sandy soil, in pine-oak or montane cloud forests, 1930–2400 m; flowers November to December. **I:** Hochstätter (2016: I: 25, as *Manfreda*).

$\equiv$  *Manfreda justosierrana* García-Mendoza (2011).

[3a2] Plants herbaceous; corm 3–5  $\times$  3–4.5 cm, cylindrical, bulb 4–8  $\times$  3–4.5 cm, covered with fibrous dried leaf bases; **R** filiform, contractile roots fleshy; **L** drought-deciduous, 3–11, coriaceous, recurved, broadly oblong to elliptic, narrowed at the base to 0.8–1.3 cm, apex hardened, not pungent, (25–) 40–50  $\times$  (4–) 6–9 cm, light green with large reddish dots which may fuse to irregular blotches, asperous, surface papillose, esp. on the veins, margins papillose on a hyaline band, often undulate; **Inf** erect, ‘spicate’, 1.6–2.4 m, peduncle 1.6–1.9 m, reddish, with 8–10 **Bra**; fertile part 25–50 cm, with 25–35 laxly arranged flowers; floral **Bra** 1–1.7  $\times$  0.1–0.2 cm; **Fl** (38–) 45–52 mm, solitary, sessile, ascending to diffuse; **Tep** forming a tube 22–25 (–30)  $\times$  5–10 mm, greenish-yellow, lobes oblong, revolute, 10–15  $\times$  2–4 mm, yellowish; **Fil** 30–45 mm, light green to whitish, inserted at  $\frac{3}{4}$  of the tube length; **Anth** 15–20 mm, yellow, with discontinuous reddish lines; **Ov** cylindrical, 10–15  $\times$  2–3 mm, green; **Sty** 45–65 mm, light green to whitish; **Sti** 3-lobate, papillose; **Fr** ovoid to ellipsoid, 15–25  $\times$  10–20 mm, with persistent tepals; **Se** crescent-shaped, with inconspicuous margin, 6–7  $\times$  4–5 mm, black, shiny.

Morphologically most similar to *A. scabra* according to the protologue (as *Manfreda*), and characterized by oblong to elliptic coriaceous leaves with papillose surface, esp. on the veins, large reddish dots on the upper leaf face, an inflorescence with reddish peduncle with short bracts, and laxly arranged flowers with a long tube.

**A. karatto** Miller (Gard. Dict., Ed. 8, no. 6, 1768). **Type** [neo]: St. Kitts (*Rose* 3231 [NY, US]). — **Lit:** Trelease (1913: 23–24, tt. 14–15); Berger (1915: 214–215); Hummelinck (1936: 241–243, 249, as *A. trankeera*); Hummelinck (1938: 24–27, tt. Ia, IVb); Howard & Thompson-Mills (1979: 488–492, with ills., as several synonyms); Hummelinck (1986: as several synonyms, with ills.); Hummelinck (1987: as several synonyms, with ills.); Hummelinck (1993: with ills.); Rogers (1999: with ills., as *A. barbadensis*); Rogers (2000). **Distr:** Lesser Antilles: Leeward Islands (Anguilla, St. Martin, Saba, St. Eustatius, St. Kitts, Nevis, Barbuda, Antigua, Redonda, Montserrat, Guadeloupe, La Désirade), Windward

Islands (Dominica, Martinique, St. Lucia, Barbados, St. Vincent, Grenada and the Grenadines); rocky places and grasslands in open exposed habitats, in well drained shallow soils; flowers from March to mid-summer. **I:** Etter & Kristen (1997: front cover, as *A. obducta*, 98, as *A. unguiculata*, 99); Richter (2011: 23, 94, 95); Pilbeam (2013: 41, as *A. barbadensis*, 50, as *A. caribaeicola*, 117); Hochstätter (2015: VII: 55, as *A. caribaeicola*, 58, 60, as *A. dussiana*).

**Incl.** *Agave americana* Dillenius (1774) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave keratto* Haworth (1819) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave keratto* Steudel (1840) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave kerrato* Salm-Dyck (1859) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave kerrato* Salm-Dyck (1859) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave martiana* K. Koch (1860); **incl.** *Agave salm-dyckii* Baker (1877); **incl.** *Agave caribaea* Baker (1888) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Furcraea tuberosa* Drummond (1907) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Furcraea gigantea* Boldingh (1909) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave barbadensis* Trelease (1913); **incl.** *Agave caribaeicola* Trelease (1913); **incl.** *Agave dussiana* Trelease (1913); **incl.** *Agave grenadina* Trelease (1913); **incl.** *Agave medioxima* Trelease (1913); **incl.** *Agave montserratensis* Trelease (1913); **incl.** *Agave nevidis* Trelease (1913); **incl.** *Agave obducta* Trelease (1913); **incl.** *Agave scheurmaniana* Trelease (1913); **incl.** *Agave trankeera* Trelease (1913); **incl.** *Agave unguiculata* Trelease (1913); **incl.** *Agave vangrolae* Trelease (1913); **incl.** *Agave ventum-versa* Trelease (1913).

[2s] **Ros** mostly solitary, sometimes with basal suckers; **L** lanceolate, straight or curved outwards, occasionally slightly twisted, 100–220 (–244) × (8–) 12–23 (–40) cm, green with light glaucescence; **marginal teeth** highly variable, deltoid to acicular, usually with ± lenticular base, antrorse to retrorse, (0.1–) 0.5–3 (–5) mm, usually dark-coloured (or reddish when fresh); **terminal Sp** comprised of hardened inrolled **L** margins, stout and sharp, recurved, or straight, or incurved, long-tapered to short and stubby, (5–) 10–30 (–45) mm, 5–10 mm Ø, blackish; **Inf** 3–8 (–10) m, paniculate, with up to 4 (–5) orders of branching, part-**Inf** spreading, in the upper 1/3 of the inflorescence,

freely bulbiferous; **Ped** 7–25 mm; **Fl** 55–105 mm, often aborting; **Tep** golden-yellow, tube conical, (2–) 4–12 (–15) mm deep, lobes (14–) 20–25 (–37) × 3–8 (–12) mm; **Ov** fusiform, (18–) 20–42 (–48) mm, constricted at the apex; **Sty** (24–) 38–65 mm; **Sti** 3-lobed; **Fr** broadly oblong, 30–60 × 20 mm, often beaked, basal stalk 2–10 mm; **Se** D-shaped or irregularly polygonal, 6.5–9 mm, black.

Trelease (1913) published 12 new *Agave* species from the Lesser Antilles in Sect. *Caribaeae* (as Group), but only some of them were accepted by later authors such as Howard & Thompson-Mills (1979), or in the first edition of this handbook. A taxonomic revision of the genus in the Lesser Antilles (Leeward and Windward Islands) by Rogers (2000), including the designation of the above-cited neotype, placed all 12 species of Trelease (1913) in the synonymy of *A. karatto*, and interpreted all of them to merely represent insular variants of a now broadly circumscribed *A. karatto*. Rogers (2000) considers *A. karatto* most similar to the mainland Mexican *A. nayaritensis* of Sect. *Marmoratae* (as Group), thus confirming Gentry (1982: 507) who stated that the Caribbean *Agaves* resemble his mainland Group *Marmoratae*. *A. karatto* is partially sterile and mainly propagates vegetatively by bulbils, which, together with minimal morphological differences, is attributed to prehistoric human selection, dispersal and cultivation activities (Rogers 2000). On the Leeward Antilles (Aruba, Curaçao, Bonaire), *A. karatto* is cultivated only as hedge-row plant (Hummelinck 1938: 24).

**A. karwinskii** Zuccarini (Flora 15: 2(Beiblatt 2): 98, 1832). **Type** [neo]: Mexico, Oaxaca (*Gentry* 12049 [US [2 sheets], ARIZ, DES †, MEXU, MICH]). — **Lit:** Berger (1915: 255); Gentry (1982: 577–579, with ills.); Palma Cruz (1991: 107–111); Arias Toledo & al. (2000: 14, with ill.); Guillot Ortiz & al. (2008: 57, 61, with ill.); García-Mendoza (2011a: 27–30); León Vázquez & al. (2013). **Distr:** Mexico (S Puebla, N & C Oaxaca); limestone hills or sandy sediments in arid regions, in thorn forests, desert scrub and tropical deciduous forests, 700–2000 m; flowers September to October. **I:** Heller (2006: 153);

Richter (2011: 34); Pilbeam (2013: 118 [ill. on p. 119 is *Yucca* sp.]); Phillips (2013: 141); Mahr (2015: 8).

**Incl.** *Agave laxa* Salm-Dyck (1834); **incl.** *Agave karwinskiana* Herbert (1837); **incl.** *Agave corderoyi* Baker (1877); **incl.** *Agave bakeri* Ross (1894).

[2g] Arborescent, stems 0.3–0.7 m (to 3 m in cultivation), forming clonal colonies with spreading rhizomes; **Ros** dense, 0.6–1 × 1–1.5 m, extending down the stem from the stem tip with leaves reflexing along the stems with age; **L** 80–100, linear to linear-lanceolate, rigid, fibrous, ascending to radiately spreading or erect, narrowed and thickened towards the base, acuminate, involute at the tip towards the base of the terminal spine, convex below, guttered or concave above, (33–) 40–65 (–80) × 2–7 (–8) cm, dark to yellowish-green, margins straight; **marginal teeth** delicate, nearly straight or antrorse to cuspidate and flexuous, pyramidal with broad base, 2–4 (–6) mm (at mid-leaf), blackish, dark brown or reddish, (10–) 20–40 (–70) mm apart; **terminal Sp** variable, subulate or conical with thickened base, narrowly to broadly grooved above, 15–30 (–45) mm, blackish or dark brown to greyish and corroding at the base, decurrent or not; **Inf** 3–4 (–6) m, paniculate, peduncle green, with chartaceous triangular **Bra** 4–11 cm long, fertile part openly diffuse, oval to oblong, part-**Inf** lax, 10–15 in the upper 1/2–1/4, 15–30 cm; **Ped** 2 mm, **Fl** 40–50 (–57) mm; **Tep** greenish to pale yellow, tube bulging

between the grooves, rather thin-walled, 10–11 × 8–11 mm, lobes linear-spatulate to oblong, erect, involute, incurving before anther dehiscence, quickly wilting, unequal, 11–19 × 2–3 mm, with ferruginous tinge; **Fil** 35–40 mm, inserted irregularly at mid-tube or slightly above, greenish, dotted reddish; **Anth** regular, centric, 15–22 mm, yellow(ish); **Ov** angularly cylindrical, 20–30 × 7–9 mm, neck 1–2 mm, slightly 6-grooved; **Sty** 45 mm, dotted reddish; **Fr** oblong or obpyriform to subglobose, 35–50 × 25–30 mm; **Se** 7–10 × 6–10 mm, winged for <1 mm. — **Cytology:** 2n = 60 (Flores-Maya & al. 2010).

Easily recognized not only within Sect. *Rigidiae* (as Group) by the stem-forming tall habit with relatively small leaves and small flowers (Gentry 1982). León Vázquez & al. (2013) describe morphological and habitat characteristics. Cultivated forms have stems up to 3 m tall and have more leaves which remain persistently green all along the stem also when dry, and have a longer flowering period from August to February (García-Mendoza 2011a). Naturalized in Spain (Guillot Ortiz & al. 2008). Gentry's "neotype" at US consists of 2 sheets which appear to have been cross-labelled later. See also under *A. schneideriana*.

**A. kavandivi** García-Mendoza & Chávez-Rendón (Revista Mex. Biodivers. 84: 1071–1072, ills., 2013). **Type:** Mexico, Oaxaca (*García-Mendoza & al.* 10184 [MEXU, ENCB, IEB, MO, OAX]). — **Lit:** Ullrich (1990f); Polka (2006),

**Fig. 31** *Agave kavandivi*

both with ills., as *A. dasyliroides*; Thiede (2014b). **Distr:** Mexico (Oaxaca: Mixteca Alta); steep limestone slopes in rosette scrub and ecotones to pine-oak forests, 1300–2300 m; flowers October to November. **I:** Brand (2012: as *A. dasyliroides*); Hochstätter (2015: VIII: 13). – Fig. 31.

[1a] Stems decumbent, to 50 cm; **Ros** compact, hemispherical, 30–50 (–60) × 40–60 (–70) cm, surculose; **L** 60–80 (–100), narrowly elliptic, erect or somewhat incurved, flat, rigid, leathery, base 2–2.5 × 2–3 cm, whitish, deltoid, fleshy, with scattered papillae on some veins, lamina 25–35 (–42) × (1.2–) 1.5–2 (in the middle) cm, 1.2–1.8 cm wide at the base, glaucous or glaucous-yellow, striate, margins straight, finely denticulate, scabrous, yellowish; **terminal Sp** conical-subulate, upper face flat near the base, 6–8 (–15) × 1–2 mm, reddish-brown; **Inf** 0.6–1.5 (–2.5) m, ‘spicate’, inclined or arching, peduncle reddish, with **Bra** (6–) 11–15 × 0.2–0.5 (–1.2) (at the base) cm, linear above the deltoid base, red to purple, decreasing in size upwards, densely flowered in the upper 1/3–1/2; floral **Bra** (2.5–) 3–6.5 × (0.1–) 0.3–0.5 mm, linear above a deltoid base, the upper shorter; **Ped** ±1 mm; **Fl** (22–) 25–33 mm, campanulate, geminate; **Tep** purple, tube (5–) 8–15 × 9–12 (at the mouth) mm, somewhat sulcate, lobes 10–14 × 4–7 mm, outer slightly broader than the inner, inner ovate, erect, slightly incurved at the apex, with a triangular rib 4–4.5 mm wide; **Fil** (25–) 30–47 mm, purple, inserted in the middle of the tube; **Anth** (7–) 10–15 × 1–2 mm, purple; **Ov** (6–) 10–14 × 3–5 mm, straight, without neck, apex projecting slightly into the tepal tube, green or reddish-green; **Sty** 30–45 mm; **Sti** hardly thickened; **Fr** ellipsoid to 3-lobed, 10–18 × 7–12 mm, transversally striated, with a ring at the apex, beaked, reddish-green, with persisting tepal remains; **Se** 2–3 (–3.8) × 2–2.4 mm, black, thickened and ornamented with transversal ribs on the convex distal face.

First collected by A. B. Lau in 1988, and illustrated by Ullrich (1990f) (sterile) and Polka (2006) and Brand (2012) (flowering) under the name *A. dasyliroides*. The new species is compared with *A. stricta*, *A. rzedowskiana* and esp. *A. dasyliroides* in the protologue. It shares the

arching inflorescences with the latter, but differs in its branched habit (vs. solitary), and the characteristic reddish peduncles, and purple bracts and flowers. Commercially offered clump-forming, green-leaved plants from N of Santiago Lachiguiri (Oaxaca) might represent a related, undescribed species.

**A. kerchovei** Lemaire (Ill. Hort. 11: 64, 1864).

[1g] Acaulescent; **Ros** lax, 0.9–1.5 × 1–1.5 m, solitary; **L** 15–40 (–50), long triangular, erect, rigid, coriaceous, fibrous, base broadened, tip long acuminate, convex below, guttered above, smooth, (70–) 100–150 × 5–10 cm (at the base), green to dark green, margins horny, straight, whitish; **marginal teeth** triangular, straight to variously curved, 8–15 (–20) × 6–13 mm, remote,

(40–) 60–85 (–100) mm apart at mid-leaf, with small intermittent teeth, white-greyish, generally toothless 15–22 (–50) cm below the terminal spine; **terminal Sp** conical, deeply channelled above, (25–) 35–60 × 3–6 (–8) mm, brown to white-greyish, decurrent on the lower leaf face for (3–) 8–10 cm; **Inf** 3–5 m, ‘spicate’, erect, peduncle greenish, with linear chartaceous deciduous brown entire **Bra** 19–20 cm long, fertile part in the upper  $\frac{1}{2}$ – $\frac{2}{3}$  of the inflorescence; **Ped** 3–5 mm (fruiting 7–8 mm); **Fl** campanulate, (30–) 34–40 mm; **Tep** greenish outside, dark reddish inside, tube (2–) 4–5 × (7–) 9–10 (above) mm, lobes elliptic, subequal, 15–17 × 3–5 (–8) mm, **OTep** succulent, **ITep** keeled; **Fil** 30–35 (–40) mm, inserted at the mouth of the tube, yellowish with reddish dots; **Anth** 10–15 mm, reddish; **Ov** cylindrical, (15–) 18–21 × 4–7 mm, green, neck 20–40 mm, constricted; **Sty** 30–35 mm, yellowish; **Fr** ellipsoid, 22–30 (–35) × 8–10 (–12) mm; **Se** 3–4 (–4.5) × 2–3 mm, wing <1 mm. — **Cytology**: 2n = 120 (Palomino & al. 2007, Simpson & al. 2011).

One of the more robust species of Sect. *Heteracanthae* (as Group *Marginatae*), typically easily distinguishable by the long triangular leaves prominently armed with large, variable, remotely spaced teeth which generally lack for a long distance below the apex (Gentry 1982, García-Mendoza 2011a). Gentry’s concept included *A. convallis*, which is here recognized as a species of its own. *A. kerchovei* is closely related to *A. ghiesbreghtii*, which is sympatric over much of S Puebla and Oaxaca and differs esp. by its smaller rosettes with more and smaller deltoid leaves with less remote teeth, its longer filaments, and its much smaller, obovoid fruits (Gentry 1982, García-Mendoza 2011a). The record from Hidalgo (Barranca de Metztlán; Gentry & Sánchez-Mejorada 23383, DES; Gentry (1982: 190)) is not confirmed by later authors (García-Mendoza 2011a) and might represent a misidentification with *A. xylonacantha*, which is common there (Eguiarte & Scheinvar 2008). — The drawing selected as “lectotype” by Gentry (1982: 151, ill. on p. 150) is in fact a neotype. The species is most certainly named after Gustave-Philippe de Kerchove d’Ousselghem (1802–1881) who had one of the

most important *Agave* collections in Europe in the mid-1800s near Ghent, Belgium (Thiede & al. 2019b).

The species (vernacular name: “Maguey de ixtle”) is baked for the extraction of fibres; flower buds (vernacular names: “cacayas” (buds) and “rabo de león” (plants)) are used locally in Puebla and Oaxaca as food for humans and livestock (García-Mendoza 2011a, Brena-Bustamante & al. 2013). Aqueous suspensions of the dry powder have molluscicidal properties (Shoeb & al. 1990). In the Zapotitlán Valley, the species often hosts coccids whose honey-dew is foraged by ants and further insects (Diptera, Hymenoptera); the surplus is used as substrate by sooty moulds. Most insect visitors are predators or parasites which are attracted by a large quantity of possible prey or hosts (Cautle & al. 1998, Cautle & al. 1999). *A. kerchovei* forms part of the diet of the white-tailed deer (*Odocoileus virginianus*) in Oaxaca (Villarreal-Espino & al. 2011). The flowers are bat-pollinated (Arias Toledo & al. 2000).

**A. kewensis** Jacobi (Hamburg. Gart.- & Blumenzeit. 22: 218–219, 1866). **Type**: K 000524824 [neo, ex cult. RBG Kew]. — **Lit**: Gentry (1982: 624–626, with ills.); Ullrich (1990d: with ills., as *A. grijalvensis*); Lott & García-Mendoza (1994: online version with ills.); García-Mendoza (2003). **Distr**: Mexico (W-C Chiapas); cliff edges in calcareous soil, in tropical deciduous forests, 400–1100 m; flowers January to February. **I**: Curtis’s Bot. Mag. 123: t. 7532, 1897; García-Mendoza (2002: 181, as *A. grijalvensis*); Pilbeam (2013: 98, as *A. grijalvensis*); Hochstätter (2015: VI: 29, as *A. grijalvensis*); Berthold (2017: 52, as *A. grijalvensis*).

**Incl.** *Agave grijalvensis* B. Ullrich (1990).

[2c] Acaulescent (or with stem to 15 cm in cult.); **Ros** open, large, solitary; **L** 30–60, (narrowly) lanceolate, arching or sprawling, thickly succulent, arcuate, pliable, guttered, narrowed gradually towards the broadened base, scabrous above, 120–200 × 12–16 cm, yellowish-green, margins straight or nearly so; **marginal teeth** straight, small, deltoid, larger teeth 1–3 (–4) mm (in the upper  $\frac{1}{3}$  of the lamina), 10–40 mm apart, much reduced below or lacking on the lower  $\frac{1}{3}$  of

**Fig. 32** *Agave kristenii*

(Etter & Kristen 1293:  
Mexico; Michoacán, ±  
70 km SE of San Juan de  
Alima, 110 m). (Copyright:  
J. Etter & M. Kristen)

the lamina, brown; **terminal Sp** acicular, weak, scarcely pungent, narrowly grooved above, 30–50 mm, not decurrent; **Inf** 3–6 m, paniculate, peduncle usually short, fertile part lax, part-**Inf** 3-branched, 12–20 in the upper ½ of the inflorescence, bulbiferous; **Ped** 5–8 mm, sparsely bracteolate; **Fl** slender, 40–50 (–60 (–74)) mm; **Te**p brilliant yellow, tube funnel-shaped, 12–15 mm, grooved from the open lobe sinuses, lobes lanceolate, ascending, falcate, unequal, 18–20 × 5–6 mm, outer longer and with dark glandular apex; **Fil** 46–52 mm, inserted above mid-tube; **Anth** excentric, 26–27 mm; **Ov** slender, cylindrical, (20–) 30–40 mm, neck slightly constricted; **Sty** longer than the anthers; **Sti** capitate; **Fr** obovate or oblong, 30–35 mm, stipitate, shortly beaked; **Se** 4 × 3 mm, not further described.

Described by Jacobi 1866 from a sterile living plant cultivated at Kew (and named accordingly), which flowered not until 1895 and was then figured in Curtis’s Bot. Mag. (1897). A specimen prepared in 1895 from the flowering plant was designated as neotype (as “type”) by Gentry (1982) who identified plants from C Chiapas as *A. kewensis*. Ullrich (1990d) questioned this identification, considered *A. kewensis* as of Caribbean origin, and published the plant from Chiapas as a new species *A. grijalvensis*. The *A. kewensis* plant figured in Curtis’s Bot. Mag. was obviously cultivated under lush conditions, and deviating measurements between *A. kewensis* from Jacobi and

later sources and Gentry’s plant from Chiapas disappear with the character expressions presently known (e.g.; ovary 25 mm (Curtis’s Bot. Mag.) vs. 30–40 mm (Gentry 1982), but (20–) 30–40 mm according to Lott & García-Mendoza (1994)) Field-collected specimens (*Breedlove* 23290, MO 2602957 barcode MO-206100!) are a good match for the neotype. Gentry (1982: 630) assumed that *A. kewensis* may be one of the parents of *A. sisalana*.

Ullrich (1990d: as *A. grijalvensis*) provisionally placed the species in Sect. *Marmoratae* (as Group), based on vegetative features (rather than in Sect. *Sisalanae* (as Group) as suggested by Gentry (1982)) The molecular AFLP data of Gil-Vega & al. (2007: as *A. grijalvensis*) place *A. kewensis* widely separate from *A. marmorata* and closest to *A. sisalana* and thus confirm its placement in Sect. *Sisalanae*. — For the in vitro propagation and seed germination, see Sanchez-Urbina & al. (2008) and Santíz & al. (2012). Previously known only from rock cliffs along the Río Grijalva ravine (Gentry 1982, Ullrich 1990d: as *A. grijalvensis*, García-Mendoza 2003, Sarmiento & Ramos 2013: with ill., as *A. grijalvensis*), the species has recently also been found in the understorey of tropical deciduous forests near Tuxtla Gutiérrez (Espinosa-Jiménez & al. 2014), on rock cliffs W of Ocozocoautla at El Aguacero (Martínez-Meléndez & al. 2008, Berthold 2017), and at Villa Allende (Pérez-Farrera & al. 2016: 67–68).

**A. kristenii** A. Vázquez & M. Cházaro (Syst. Bot. 38(2): 326–328, ills., 2013). **Type:** Mexico, Michoacán (*Vázquez-García* 9076 [IBUG, MEXU, MICH, MO, WIS]). — **Distr:** Mexico (W Michoacán); seaward facing slopes of limestone outcrops, thorn forests, 50–130 m; flowers February to March. **I:** Vázquez-García & al. (2007b: Fig. M2, M9, M10, as *A. gypsophila*). — Fig. 32.

[2n] Acaulescent; **Ros** 0.4–0.5 × 1.4 m, surculose; **L** 7–10, linear to narrowly triangular or narrowly lanceolate, generally arched and wavy, firm, rigid, thick throughout, rough, convex below, guttered, 30–79 × 5–6.2 cm, to 5.5 cm wide and to 5.1 cm thick at the base, green to grey, or reddish-brown, glaucously cross-zoned on both faces, margins straight to slightly repand, involute, with prominences 4–5 × 4–5 mm; **marginal teeth** closely set basally and apically, firm, flattened, mostly curved toward the base, mostly 1–2.9 mm, basally 1–2 mm wide, 15–30 mm apart, dark brown intermittent denticles few or none; **terminal Sp** usually short and conical, firm, 5–6 mm, dark brown, not decurrent; **Inf** 3–3.6 m, paniculate, peduncle with triangular **Bra** to 14 cm long at the base, fertile part open, oblong, part-**Inf** 15–18, in the upper  $\frac{2}{3}$  of the inflorescence, with 80–87 flowers; **Fl** 32–36 mm; **Tep** orange, tube somewhat funnellform, 3–4 × 7–10 mm, lobes triangular, erect, fleshy, 10–14 × 4–5 mm, orange and galeate at the apex; **Fil** firm, 21–29 mm, inserted 1–1.5 mm above the tube base, orange; **Ov** 14–20 × 4–5 mm, neck constricted, 2.5–5 mm, green; **Sty** ± as long as the filaments; **Fr** oblongoid, slender, 30–32 × 14–15 mm, stipitate, apiculate; **Se** semicircular, flat, membranous, 4–4.5 × 3–4.5 mm, black.

The recent study of the *A. gypsophila*-complex by Vázquez-García & al. (2013) resulted in a narrower re-circumscription of *A. gypsophila* (see there for further comments). No material of *A. kristenii* was known to Gentry, and the species is narrowly endemic in coastal W Michoacán. It differs from most other members of Sect. *Marmoratae* in its surculose habit and orange rather than bright yellow flowers, and is related to *A. gypsophila* s.s., with which it shares brittle leaves with few fibres, restriction to limestone

outcrops, and similar purported medicinal properties. The plant depicted as *A. kristenii* by Guillot Ortiz & Meer (2016c: 28, fig. 1) has no cross-zoned leaves; it might belong to *A. pablocarrilloi*.

**A. lagunae** Trelease (Trans. Acad. Sci. St. Louis 23(3): 143, t. 21, 1915). **Type** [syn]: Guatemala (*Trelease* 10 [ILL 00009776 & 00009777]). — **Lit:** Standley & Steyermark (1952: 113–114); Gentry (1982: 485); Lott & García-Mendoza (1994); Véliz Pérez (2013: 241, 242, 244, 489, with ill.). **Distr:** Guatemala (regions of Escuintla/Amatitán); on gravel, talus and shady cliffs in mesophytic lowland mountains with pine-oak forests or cloud forests, 700–1600 m; flowers November; only known from the region of the type locality. **I:** Etter & Kristen (1997+).

[2o] Acaulescent; **Ros** openly spreading, to 1.4 m Ø, sparingly suckering; **L** few, linear to lanceolate, acuminate, spreading, flat to concave, finely asperous on the lower face, (30–) 60–75 × 8–15 cm, glaucous-green, margins nearly straight; **marginal teeth** straight or curved, slender, bases slightly elevated, larger teeth 4–10 mm (at mid-leaf), dark brown, 10–30 mm apart; **terminal Sp** subulate, groove above openly channelled to narrow, 30–40 mm, dark brown; **Inf** 3–4 m, paniculate, fertile part rather open, part-**Inf** rather small, 15–20 in the upper  $\frac{1}{2}$ ; **Fl** slender, 60–70 mm; **Tep** yellow, tube funnel-shaped, 5–10 mm, lobes thin, lanceolate, faintly striate, 15–21 × 5 mm, **OTep** involute towards the apex, apiculate, **ITep** with flattened keel; **Fil** somewhat flattened, 45–50 mm, inserted ± at mid-tube; **Anth** regular, centric, 10–15 (–21) mm, yellow; **Ov** slender, cylindrical, 39–45 mm, neck grooved, long, slender, constricted; **Sty** exerted after anthesis, longer than the filaments; **Sti** clavate, 3-lobate; **Fr** and **Se** unknown.

A poorly known species, classified as “Vulnerable” according to IUCN Red List categories (Véliz Pérez 2013: 489). The filaments are inserted unusually low for Sect. *Guatemalenses* (as Group *Hiemiflorae*) (Gentry 1982). The plant depicted as “*Agave lagunae*” by Hochstätter (2015: VI: 9) has much broader leaves and appears to be misidentified. Trelease’s “holotype” consists of 2 specimens which are not cross-

labelled and thus represent syntypes (Smith & Figueiredo 2014e: 237).

**A. lechuguilla** Torrey (in Emory, Rep. US Mex. Bound. 213, 1858). **Type** [lecto]: USA, Texas (*Wright* 682 [US 125459, GH, K, NY]). — **Lit:** Gentry (1982: 154–157, with ills.); Reveal & Hodgson (2002); González-Elizondo & al. (2009: 94–96, with ills.); Greulich (2016a: with ills.); Scheinvar & al. (2016: diversification). **Distr:** USA (S New Mexico, W & SW Texas), Mexico (Chihuahua, Coahuila, Nuevo León, Tamaulipas, Durango, Zacatecas, San Luis Potosí, Guanajuato, Querétaro, Hidalgo, México, D.F.); gravelly to rocky calcareous places in desert scrub, Chihuahuan Desert, 500–2500 m; flowers May to August; locally naturalized in Spain. **I:** Irish & Irish (2000: t. 21); Heller (2006: 101); Richter (2011: 115, 117); Pilbeam (2013: 121); Meer & al. (2014); Hochstätter (2015: IX: 37). — **Fig.** 33.

**Incl.** *Agave poselgeri* Salm-Dyck (1859) ≡ *Agave lophantha* var. *poselgeri* (Salm-Dyck) A. Jacobsen (1973); **incl.** *Agave univittata* var. *foliis striatis* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave univittata* var. *recurvispinis* Hort. Besaucèle ex A. Berger

(1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave univittata* var. *viridis* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave univittata* var. *zonata* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a).

[1g] Acaulescent; **Ros** rather open, mostly 30–50 × 40–60 cm, openly caespitose, freely suckering; **L** few, linear-lanceolate, mostly ascending to erect, sometimes falcately spreading, thick, stiff, deeply convex below, deeply guttered above, (25–) 30–50 × 2–4 (–5.2) cm, light green to yellowish-green, sometimes marked with darker green, margins straight and continuous, light brown to grey, easily separable from dry leaves; **marginal teeth** typically deflected, weak and friable, regular in size, 2–6 mm, brown or mostly light grey, mostly (10–) 15–40 mm apart, 8–20 on each leaf margin, rarely absent; **terminal Sp** conical to subulate, strong, the short groove above open or closed at the base, 15–45 mm, greyish; **Inf** (2–) 2.5–3.5 m, ‘spicate’, peduncle generally glaucous, with caducous linear **Bra** 1–3 cm long, fertile part in the upper ½, part-**Inf** mainly with 2–3 flowers (Gentry: rarely ascending with longer stalks (2–15 cm) and several- to many-flowered; = hybrids with Subgen. *Agave*?); **Fl** (24–) 30–45 mm; **Tep** yellow or frequently tinged with red or purple, tube open, campanulate, shallow, 1.5–4 × 6–12 mm, lobes linear, ascending, subequal, 11–20 mm, outer widely overlapping the inner at the base, thickly

**Fig. 33** *Agave lechuguilla*. (USA; Texas, Big Bend National Park, Lajitas). (Copyright: U. Eggli)

hooded, involute around the filaments; **Fil** spreading, 25–42 mm, yellow to reddish, inserted on the tube rim; **Anth** (11–) 15–20 mm, pale yellow; **Ov** fusiform, roundly angled, (8–) 15–22 mm, neck constricted, (2–) 4–8.5 mm; **Sty** somewhat longer than the tepals; **Sti** slightly thickened; **Fr** oblong to pyriform, rounded, apex short-beaked, 18–25 (–30) × 11–18 mm, glaucous, abruptly very shortly pedicellate or sessile; **Se** with small hilar notch and low fluted wing around the curved side, 4.5–6 × 3.5–4.5 mm. — **Cytology**:  $2n = 120$  (Granick 1944, Cave 1964, Bennett & Leitch 1995, Zonneveld 2003, Simpson & al. 2011).

Usually easily recognizable by its widely suckering habit and narrow leaves with down-slanted teeth on straight margins. This is the dominant *Agave* species in the Chihuahuan Desert, and a characteristic component of several desert communities. It has one of the most extensive ranges of all agaves, and the number of individuals probably exceeds those of all other native agaves (Gentry 1982). It hybridizes with *A. havardiana*, *A. lophantha*, *A. (parryi* ssp.) *neomexicana*, *A. nickelsiae*, *A. victoriae-reginae*, *A. ×glomeruliflora*, and *A. ×gracilipes* (Gentry 1982, Reveal & Hodgson 2002, Richter 2011: 86 Greulich 2016a) and *A. scabra* (Pinkava P-13603 [ASU0000634!]). Zamudio & Galván Villanueva (2011) provide a new record for Guanajuato.

The protologue designated *Wright* 682 and *Wright* 1907 as syntypes. The designation of *Wright* 682 (US 125459) as “type” by Gentry (1982: 154) represents a lectotypification.

*A. lechuguilla* is poisonous to cattle, goats, and sheep (Gentry 1982). In former times, it was an important source of hard fibres known as “istle”, “ixtle” or “Tampico fibre” (García-Moya & Ayala-Sosa 2007), and there is a recent revived interest in this natural resource (Castillo Quiroz & al. 2011). The ethnobotany in the fibre-harvesting “zona ixtlera” is reviewed by Sheldon (1980). It appears that the extraction of fibres from natural populations does not affect the population density, but increases the growth of the central bud on short terms (Pando-Moreno & al. 2008). Leaf growth depends mainly on water status, with nearly all leaf-unfolding occurring during the wet period (Nobel & Quero 1986). Molecular data (Scheinvar & al. 2016) reveal pleistocene area contractions and expansions concomitant with glacial-interglacial events which are consistent with biogeographical regions in the Chihuahuan Desert.

The peduncles may grow as rapidly as 20 cm/day and reach full height in 3–4 weeks. The energy for flowering is stored almost entirely in the leaves (Freeman & Reid 1985). A study along the whole range of the species in the Chihuahuan Desert found a latitudinal pattern in flower shape and colour and flower visitors: Flowers tended to be shorter, more open, and

**Fig. 34** *Agave* × *leopoldii*. (Copyright: U. Eggli)

colourful in the N part of the range, and the number of flower visits by all potential pollinators decreased significantly with increasing latitude, as did fruit set. Main pollinators are nocturnal hawk moths and esp. 2 species of diurnal large bees; bats were not observed (Silva-Montellano & Eguiarte 2003a). The overall genetic variation as revealed by allozymes is high, but without geographic pattern. The differentiation among populations is low, with S populations having the lowest levels suggesting high levels of gene flow, and N populations with greater levels, suggesting low gene flow, in consistence with floral traits and pollinator visitation rates across the species' range (Silva-Montellano & Eguiarte 2003b).

Aymerich & Gustamante (2016) and Aymerich (2016) report the taxon as locally naturalized in Spain.

**A. ×leopoldii** W. Watson (Gard. & Forest 6: 394, 1893). **Nom. illeg.**, ICN Art. 53.1. **Type:** [neo — icono]: Curtis's Bot. Mag. t. 8451, 1912, as *A. disceptata*. — **Lit:** Drummond (1912: with ill., as *A. disceptata*); Watson (1912: 414, as *A. leopoldii*); Anonymous (1913: 10–11, with ill., as *A. leopoldii*); Berger (1915: 76, as *A. leopoldii*); Smith & Figueiredo (2014d: with ills.); Walker (2018: with ill.). **Distr:** Cultivated only. **I:** Gard. Chron. ser. 3, 53: 10–11, 1913; Richter (2011: 87); Pilbeam (2013: 123). — Fig. 34.

**Incl.** *Agave ×disceptata* J. R. Drummond (1912).

[1d × 1d] According to the protologue, this is the garden hybrid *A. filifera* × *A. schidigera* (see also Berger (1915: 76)) raised around 1870 by W. B. Kellock, UK, characterised by narrow leaves with filiferous margins. The earlier name *A. leopoldii* Rafarin 1874 refers to a completely different plant with large marginal teeth and was described to be “of the Verschaffelti type” (Anonymous 1874). *A. ×leopoldii* W. Watson is therefore an illegitimate homonym, and a conservation proposal to avoid a name change was published by Figueiredo & Smith (2013a), which was recommended by the relevant committee (Applequist 2014: 1366). — The plant is not uncommon in cultivation.

**A. littoralis** (García-Mendoza & al.) Thiede & Egli (Kakt. and. Sukk. 52(6): 166, 2001). **Type:** Mexico, Guerrero (*García-Mendoza & al.* 6900 [MEXU, MO]). — **Lit:** García-Mendoza & al. (2000); Castillejos-Cruz (2009: [181]–[186]); both with ills. and as *Manfreda*. **Distr:** Mexico (Guerrero, Oaxaca); tropical (sub-) deciduous forests, rocky sites, in small soil pockets, 20–260 m; flowers August to December. **I:** Hochstätter (2016: I: 26, as *Manfreda*).

≡ *Manfreda littoralis* García-Mendoza & al. (2000).

[3a3] Plants herbaceous; corm 3–5 × 2.5–3 (at the base) cm, conical-truncate, stoloniferous, bulb 1.8–2.5 × 1.5–2.2 cm, subcylindrical, covered with dried membranous leaf bases 1.5–2.5 (–3.5) cm long; **R** fleshy, with filiform ramifications; **L** drought-deciduous, 4–6, flat, prostrate or semi-erect, semisucculent, elliptical to elliptical-lanceolate, narrowing to a canaliculate pseudo-petiole 0.5–1 cm wide, apex apiculate or acuminate, glabrous on both faces, 9–20 (–27) × 2–5 (–6) cm, greenish-yellow with purplish or dark-green dots, margins entire to the touch, microscopically finely papillose in some sections, on a narrow hyaline band; **Inf** 60–70 (–80) cm, erect to slightly arched, ‘spicate’, reddish at the base and glaucous-green above, **Bra** 9–12 (–15), fertile part 3.5–4.5 (–6.5) cm, dense, with 11–14 (–24) flowers; floral **Bra** 0.3–0.5 × 0.3–0.4 cm; **Fl** 15–20 (–25) mm, solitary, sessile, sometimes the lower with <1 mm long pedicels, erect; **Tep** greenish-yellow, campanulate, tube 1–2 (–2.8) × 2–3 mm, lobes oblong, erect or reflexed, 9–10 (–11) × 1.5–2 (–3.5) mm, tip cucullate; **Fil** (13–) 17–21 mm, erect at anthesis, exceeding the tube for (10–) 14–18 mm, inserted at the end of the tube on the same level, whitish; **Anth** 7–8 (–9) mm, whitish; **Ov** cylindrical, 3–5 (–6) × 1.5–2.5 (–4) mm, greenish, extending for <1 mm into the tube, not constricted above; **Sty** 18–22 mm; **Sti** 3-lobed, whitish; **Fr** subglobose, triquetrous, 9–10 × 8–10 mm, with inconspicuous scar at the apex, tepals persisting; **Se** plane-concave, blackish, opaque, 3–4 × 3 mm.

Placed in Ser. *Guttatae* (as *Manfreda guttata*-group) and closest to *A. guttata* and *A. planifolia* according to the protologue, but also similar to *A. bulbifera* and *A. pratensis* (Castillejos-Cruz

& Solano 2008) (as *Manfreda* & *M. rubescens*). The tropical lowland habitat is atypical and apparently not known for Subgen. *Manfreda* except *A. chamelensis*, *A. petskinil* and *A. paniculata*.

**A. longibracteata** (Verhoek-Williams) Thiede & Eggl (Kakt. and. Sukk. 50(5): 110, 1999). **Type:** Mexico, Michoacán (*Verhoek-Williams & al.* 613 [US, BH, MEXU]). — **Lit:** Verhoek-Williams (1978a: with ills.); Piña Luján (1986: 13–14); Castillejos-Cruz (2009: [187]–[192], with ills.); all as *Manfreda*. **Distr:** Mexico (W Jalisco, Colima, N Michoacán); open spots among rocks, in oak forests, grasslands, and scrub, 1120–2070 m; flowers July to September. **I:** Rodríguez & Castro-Castro (2006: 624); Rodríguez & Castro-Castro (2007: 9); Hochstätter (2016: I: 27); Castro-Castro & al. (2017: 62); all as *Manfreda*.

≡ *Manfreda longibracteata* Verhoek-Williams (1978).

[3a2] Plants herbaceous; corm 5–7 cm Ø, globose to subglobose, with stoloniferous vegetative shoots, bulb 1.5–2 × 1.2–1.8 cm, cylindrical, only at the apex covered with dried fibrous leaf bases 6–8 cm long; **R** fibrous; **L** drought-deciduous, 8–14, erect and extended, linear-lanceolate to lanceolate, narrowed towards the base, apex obtuse, apiculate, broadly canaliculate, sometimes wavy, glabrous on both faces, 21–39 × 1.5–3.5 (–4.3) cm, shiny green, sometimes with purple dots near the base, margins entire, with a hyaline band, slightly revolute; **Inf** 120–140 (–160) cm, erect, ‘spicate’, green-glaucous, **Bra** 8–10, rather distant, fertile part 10–15 (–25) cm, lax, with 15–20 flowers; floral **Bra** 1.7–4 × 1.5–2.3 cm; **Fl** 30–35 mm, solitary, sessile, ascending; **Tep** glaucous-green with reddish dots at the base, inner face greenish-yellow, forming a funnel-shaped tube 15–20 × 4–5 mm, slightly recurved, lobes oblong, extended to recurved, 12–15 × 6–7 mm, tip cucullate, with soft tip and a bundle of short white trichomes; **Fil** 34–39 mm, erect at anthesis, somewhat flattened, abruptly narrowing below the anthers, exceeding the tube for 22–24 mm, inserted at ¼ above the base of the tube and all on the same level, yellowish-green with purple dots; **Anth** (10–) 13–14 mm,

greenish-yellow; **Ov** oblong, 12–15 × 4–5 mm, greenish, prolonging slightly into the tube, not constricted above; **Sty** 44–47 (–54) mm; **Sti** 3-lobed, greenish-yellow; **Fr** ellipsoid, 20–26 × 10–14 mm, apiculate, tepals persisting; **Se** deltoid, plane-concave, 3–4 × 3–4.5 mm, opaque.

According to the protologue vegetatively most noticeable for the crisp bright green leaves with a broad round channel, and in bud or flower recognizable by the long floral bracts (see above-cited ills. by Rodríguez & Castro-Castro and Castro-Castro & al.). It appears to be closest to *A. scabra* (Verhoek-Williams 1978a: as *Manfreda*), but differs in its globose rhizome, delicate leaves, larger floral bracts, smaller filaments and styles, and its strong citronella-scent (Castillejos-Cruz 2009).

**A. longiflora** (Rose) G. D. Rowley (Repert. Pl. Succ. 26: 4, 1977). **Type:** USA, Texas (*Runyon* 10 [US, ILL, K, NY]). — **Lit:** Rose (1922: with ills., as *Runyonia*); Verhoek-Williams (1975: 222–226); Piña Luján (1985: 63–64); Reveal & Hodgson (2002); García-Mendoza (2003); Castillejos-Cruz (2009: [193]–[197], with ills.); all as *Manfreda* except Rose. **Distr:** USA (Texas), Mexico (N Tamaulipas); clay slopes, dry gravelly hills and prairies in sandy loam overlying caliche, in desert scrub, thorn forests or grasslands, always in the shade of other plants, 0–100 m; flowers end of August to September. **I:** Hannon (2002: 248, 249); Richardson & King (2011: 18); both as *Manfreda*.

≡ *Runyonia longiflora* Rose (1922) ≡ *Manfreda longiflora* (Rose) Verhoek-Williams (1975); **incl.** *Runyonia tenuiflora* Rose in sched. (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Runyonia tubiflora* Rose in sched. (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Polianthes runyonii* Shinnery (1966).

[3a1] Herbaceous, medium-sized (for Subgen. *Manfreda*), corm cylindrical, succulent, 2.5–6.5 × 0.8–2 cm, bulb 2.5–4 × 1–2 cm, covered with dry membranous leaf bases (2–) 5–9 cm long; **R** fleshy-fusiform, contractile, with filiform ramifications; **L** evergreen, succulent, 3–7 (–15), forming a rosette, linear-lanceolate to narrowly lanceolate, erect to semi-erect, recurved to undulate, channelled, fleshy, tip acute, with a soft

medium-sized point, 10–27 × 1.2–1.8 (–2 in cultivation) cm, light green to glaucous, with purple, brown or darker green spots over the whole surface above, margins with coarse, distantly-spaced, cartilaginous, deltoid to truncate, occasionally retrorse teeth 3–10 mm apart, intervening margin hyaline; **Inf** 20–50 (–62) (–96 in cultivation) cm, ‘spicate’, reddish to green with purple tinge, peduncle with 3–4 truncate **Bra**, fertile part 8–20 (–35 in cultivation) cm, with (7–) 10–21 densely or laxly arranged flowers; **Fl** 45–55 mm, sessile, erect, fragrant; **Tep** semisucculent, tube straight, narrowly funnel-shaped, 23–36 × 3–4 mm, lobes oblong, revolute, tip obtuse, with a small tuft of hairs, 8–15 (–19) × 3–4 mm, whitish-pink to reddish-pink with age; **St** very short; **Fil** 5–6 mm, exceeding the tube for 5–6 mm, inserted at the throat of the tube, whitish; **Ov** ellipsoid, 4–6 × 3–4 mm, not prolonging into the tube; **Sty** 35–40 mm, included or slightly exerted; **Sti** 3-lobed, papillate, greenish-yellow; **Fr** globose to ovoid, triquetrous, 9–12 × 10–13 mm, apiculate; **Se** deltoid, plane-concave, with narrow margin, 3–4 × 3–4 mm, shiny. — **Cytology**: 2n = 60 (Granick 1944).

Reddish flowers with a long tube and sessile anthers were not known from *Manfreda* when Rose (1922) described the taxon, which prompted him to erect the separate genus *Runyonia*. The species is characterized by flowers with a long, narrow tube, stamens inserted at the mouth of the tube, stamens and style included or only shortly

exserted, and a small, globose fruit (Castillejos-Cruz 2009). It is closely related to *A. maculosa* with which it shares the consistency, colour and type of the leaf margin and flower colour (Castillejos-Cruz 2009: as *Manfreda*) and is distinguished by the longer narrow tepal tube, almost sessile anthers, and included styles, and smaller and more flattened fruits (Verhoek-Williams 1975: 224, as *Manfreda*). The plant depicted by Hochstätter (2016: I: 28) is misidentified.

**A. longipes** Trelease (Mem. Nation. Acad. Sci. 11: 36, t. 63, 1913). **Type** [syn]: Jamaica (*Maxon* 1624 [US 247915 & 247916]). — **Lit**: Berger (1915: 211); Hummelinck (1927: with ill.); Adams (1972: 81). **Dist**: Jamaica (St. Andrews); local on well-drained conglomerate or igneous rocky slopes, 840–1200 m; flowers March to April. **I**: Hochstätter (2015: VII: 73).

[2p] **L** as in the broader-leaved forms of *A. sobolifera*, curved, tip outcurved, margins straight; **marginal teeth** narrowly triangular, often appressed-recurved, 2–4 mm, on broad lenticular bases, 15–30 mm apart, intervening margin straight; **terminal Sp** sometimes much compressed and conical, more strongly and persistently flattened on the upper face and less involute, 25–50 mm, often grey; **Inf** ‘paniculate’, fertile part oblong, part-**Inf** slightly ascending, ±40–45, rather flat and broad, in the upper ⅓ of the inflorescence, not known to be bulbiferous; **Ped** 20 mm; **Fl** larger, 60–70 mm; **Tep** yellow, tube openly conical,

**Fig. 35** *Agave lophantha*. (cult.: USA; Arizona, Desert Botanical Garden Phoenix). (Copyright: J. Thiede)

6–8 mm, lobes 20–25 × 5–6 mm; **Fil** 50–60 mm; **Ov** oblong-fusiform, 28–40 × 6–8 mm; **Fr** ±40 × 15 mm, slightly beaked; **Se** unknown.

Similar to *A. sobolifera*, but with larger flowers and longer filaments (Adams 1972). For differences from *A. harrisii*, see there.

**A. lophantha** Schiede (Linnaea 4: 581–582, 1829). **Type:** not typified. — **Lit:** Berger (1915: 91–94); Gentry (1982: 157–161, with ill.); Reveal & Hodgson (2002: as *A. univittata*). **Distr:** USA (Texas), Mexico (Coahuila, Nuevo León, Tamaulipas, San Luis Potosí, Veracruz, Puebla, Chiapas); cliffs and rocky outcrops, frequent on limestone, 30–1500 m; flowers irregularly, in February, April, June, August, and October; locally naturalized in Spain. **I:** Refug. Bot. 3: t. 215, 1870, as *A. univittata*; Curtis's Bot. Mag. 108: t. 6655, 1882, as *A. univittata*; Irish & Irish (2000: t. 22); Heller (2006: 102, 103); Richter (2011: 34); Pilbeam (2013: 124); Beutelspacher & García-Martínez (2017). — Fig. 35.

Jacobsen (1973); **incl.** *Agave lophantha* var. *subcanescens* Jacobi (1866)

≡ *Agave univittata* var. *subcanescens* (Jacobi) H. Jacobsen (1973); **incl.** *Agave lophantha* var. *angustifolia* A. Berger (1915) ≡ *Agave univittata* var. *angustifolia* (A. Berger) H. Jacobsen (1973); **incl.** *Agave lophantha* var. *pallida* A. Berger (1915).

[1g] Stems sometimes visible on old rosettes; **Ros** 0.3–0.6 × 0.5–1 m, solitary or surculose; **L** numerous, linear to lanceolate, radiating, patulous, rather thin, pliable, somewhat thickened towards the base and rounded below, flat to concave above, generally 30–70 × 3–5 cm, light green to yellow-green, with or without pale mid-stripe, margins horny, repand to crenate; **marginal teeth** straight or mildly curved, slender, single or occasionally double, mostly 4–8 mm, 10–20 mm apart, on broad low prominences; **terminal Sp** subulate, flattened above at the base, small, 10–20 mm, ferruginous to grey; **Inf** 3–4.5 m, slender, ‘spicate’, **Fl** in the upper ½, part-**Inf** with 1–2 or also with 3–7 flowers, on short stalks; **Ped** 5–10 mm; **Fl** 35–47 mm; **Tep** light grey-glaucous-green to yellow, tube campanulate, short, open, 2–4 × 8–10 mm, lobes erect to slightly spreading, subequal, 14–20 mm, persisting erect around the filaments; **St** long-exserted; **Fil** spreading, 30–45 mm, greenish or lavender, inserted on the tube rim; **Anth** 15–20 mm, pale yellow; **Ov** fusiform, 18–22 mm, neck short or long (5–7 mm) and constricted; **Sty** thick, longer than the tepals; **Sti** slightly thickened; **Fr** oblong and 18–24 × 10–12 mm or globose and 15–20 × 12–18 mm, sessile or with short (2–3 mm) pedicel; **Se** crescent-shaped, faces with wavy ridges, edges with raised margins, 5–6 × 3–4 mm. — **Cytology:** 2n = 60 (Simpson & al. 2011: as *A. univittata*).

Often confused with the closely related *A. lechuguilla*, and distinguished by flatter leaves with sinuous to repand firm borders, prominences usually with at least one double set of teeth (frequently more), and by teeth that are more slender and closely set. Some *A. lophantha* forms with broad leaves and crenate margins with large prominences look very much like *A. xylonacantha*, and may be inseparable (Gentry 1982). *A. heteracantha* Zucc. is commonly placed in the synonymy here, but Alsemgeest & al. (2007b) suggest

that it is probably the hybrid *A. lophantha* × *A. xylonacantha*. Beutelspacher & García-Martínez (2017) provide a new record for Chiapas.

The name *A. lophantha* was first mentioned by Schiede as cited above with a short description considered as inadequate by some authors, so that the valid publication of the name is commonly ascribed to Kunth (in Enum. Pl. 5: 838, 1850) (Reveal & Hodgson 2002). The latter is antedated by *A. univittata* Haworth (Philos. Mag. Ann. Chem. 10: 415, 1831). Both names are not typified nor is any authentic material known. Gentry (1982) treated *A. lophantha* as validly published by Schiede, and this was widely followed. Breitung (1959) was the first to adopt the name *A. univittata*, and he was recently followed by Reveal & Hodgson (2002) and Govaerts (2014+). In order to clarify the matter, a formal request for a binding decision whether the descriptive statement of Schiede (1829) is adequate for valid publication was submitted by Smith & al. (2018a) and the widely established name *A. lophantha* is retained here.

Reported as local neophyte from Spain (Aymerich 2015: 100, as *A. univittata*, Gómez-Bellver & al. 2019: 24–25). Cultivars cultivated in Spain are presented by Guillot Ortiz & Meer (2012). ‘Quadricolor’ (Guillot Ortiz & Meer 2012, Puche 2014, Starr 2014: 223) is a variegated cultivar widely offered commercially.

**A. lurida** Aiton (Hort. Kew. 1: 472, 1789). **Type** [neo]: Ex cult. (*Masters* s.n. [K]). — **Lit**: Drummond (1910); Berger (1915: 244–245); Gentry (1982: 292–294, with ills.); García-Mendoza (2003); Guillot Ortiz & Meer (2008b: 25–26, with ill.); Guillot Ortiz & al. (2008: 64–65, with ill.); García-Mendoza (2011a: 32, 36); López-Pujol & al. (2015a: 55–57, with ills.). **Dist**: Mexico (NW Oaxaca); volcanic slopes in semi-arid tropical forests, ±1830 m; flowers July to August. **I**: Curtis’s Bot. Mag. 37–38: t. 1522, 1813; Refug. Bot. 5: t. 307, 1871; Heller (2006: 103); Richter (2011: 21).

Desfontaines (1815) (*nom. inval.*, ICN Art. 61.1?); **incl.** *Agave lepida* D. Dietrich (1840); **incl.** *Agave haworthiana* M. Roemer (1847); **incl.** *Agave polyphylla* K. Koch (1860); **incl.** *Agave cyanophylla* Jacobi (1866); **incl.** *Agave verna* A. Berger (1915); **incl.** *Agave breviscapa* A. Berger ex Roster (1916).

[2a] Stems short; **Ros** lax, 1.2–1.8 × 2–3.4 m, solitary or only rarely surculose; **L** 60–80, linear-lanceolate, stiffly ascending to outcurving, concave to guttered and narrowed towards the base, 110–150 × 12–18 cm, dull green to glaucous-grey, margins nearly straight; **marginal teeth** straight, very regular, larger teeth (at mid-leaf) 4–6 mm, (7–) 10–15 (–20) mm apart, smaller and closer together towards the leaf base, with low black lenticular bases, on low prominences, tips usually deltoid-flattened, straight or curved, dark blackish to brown or greyish; **terminal Sp** conically subulate, shallowly grooved above, 30–45 × 6–8 (at the base) mm, greyish-brown, decurrent for several to 30 cm; **Inf** 6–8 m, paniculate, peduncle glaucous-green, with deltoid chartaceous **Bra** 30 cm long, fertile part rhomboidal, lax, with 18–25 ascending part-**Inf** 1–1.5 m long, these diffusely spreading, several times compound, open, in the upper 1/3–1/2 of the inflorescence; **Ped** slender, 5–9 mm, minutely bracteolate; **Fl** campanulate, 50–55 (–65) mm; **Te** greenish-yellow, tube funnel-shaped, grooved, 8–10 (–13) × 7–9 (–15) mm, lobes oblong, erect, incurved at the tip and hooded, slightly unequal, 18–24 × 2–3 (–6) mm (**ITe** slightly shorter), wilting after anthesis, inner with narrow thin margins; **Fil** 40–45 (–60) mm, inserted above mid-tube or towards the top; **Anth** 15–22 mm, (bright) yellow; **Ov** cylindrical to fusiform, 25–30 (–34) × 5–8 mm, neck 4–6 mm, constricted, grooved; **Fr** oblong, 55–80 × 25–40 mm, stipitate; **Se** 8–11 × 6–8 mm, winged for ±2 mm, shiny black. — **Cytology**: 2n = 90, 100, 108, 114, 120 (Simpson & al. 2011).

Characterized by glaucous linear-lanceolate leaves with closely set small teeth with broad base, large rhomboidal inflorescences with diffuse part-inflorescences, and small, soon withered flowers with short tube. It is rare in nature and threatened by extinction (García-Mendoza 2011a).

Frequently mentioned in the older literature, and for long only known from cultivation in Europe, until Gentry rediscovered material assignable to this taxon after  $\pm 200$  years in one spot in Oaxaca (Gentry 1982). The taxon is without close relatives. Ullrich (1991f) regards the neotypification of Gentry and the correlation of the re-collected material with the name *A. lurida* as doubtful. Gentry cited the prioritable name *A. vera-cruz* Miller (Gard. Dict. ed. 8: *Agave* n. 7, 1768) as a synonym, although with a question mark. Here the established name is retained pending a formal proposal to conserve it against the older competitor.

Locally naturalized in Spain (Guillot Ortiz & Meer 2008b, Guillot Ortiz & al. 2008, López-Pujol & al. 2015a, Verloove & al. 2018: 34, all with ills.).

**A. iyobaa** García-Mendoza & S. Franco (Acta Bot. Mex. 126: e1461: 2–3, ills. (pp. 4, 15), 2019). **Type:** Mexico, Oaxaca (*García-Mendoza & Martínez Aguirre* 11091 [MEXU, ENCB, MEXU, MO, OAX]). — **Distr:** Mexico (S Puebla, C Oaxaca); flat or slightly inclined sites, on limestone rocks, xerophytic scrub and ecotone with oak forests, also grown as ornamental or for mescal production, 1550–1900 m; flowers August to October.

[2h] Acaulescent; rarely stems to 80 cm; **Ros** lax to subcompact, 0.5–0.8  $\times$  0.8–1.3 m, solitary; **L** 20–50 (–100), lanceolate, erect, thickened at the base, flattened, concave towards the apex, apex

acuminate or acute, 30–50  $\times$  6–9.5 cm, 4–6  $\times$  longer than broad, greenish-yellow or dark-green, margins straight or occasionally wavy; **marginal teeth** antrorse or straight, 4–6  $\times$  4–6 mm at mid-leaf, 15–30 mm apart at mid-leaf, greyish or dark-brown, sometimes on small mamilliform bases; **terminal Sp** straight, broadly grooved to flat, 30–55  $\times$  5–7 mm, greyish or dark-brown, decurrent for 10–20 mm; **Inf** (3–) 5–7 m, paniculate, peduncle green, waxy, with triangular chartaceous **Bra** 10–15 cm long, fertile part 1.5–3 m, lax, ellipsoid, **part-Inf** (slightly) ascending, 15–25 in the upper  $\frac{1}{2}$  of the inflorescence, 20–50 cm, 2.-order branches 4–9 cm, 3.-order branches 2–4.5 cm; **Fl** (40–) 45–55 mm; **Tep** green or yellowish-green, tube tubular or urceolate, 8–15  $\times$  8–12 (at the mouth) mm, lobes erect, oblong, 10–15  $\times$  3–4 mm, dimorphic, **OTep** 1–2 mm longer than the keeled **ITep**, margins all involute, apex callose, cucullate, inner face with a tiny orange-coloured dot in bud; **Fil** erect, inserted at 2 levels at mid-tube, (30–) 35–45 mm, yellowish to purple; **Anth** 15 mm, yellowish; **Ov** cylindrical, 25–30  $\times$  3–5 mm, neck 3–5 mm; **Sty** 50–55 mm, yellowish to purple; **Sti** clavate, 3-lobate; **Fr** ellipsoid, 40–60  $\times$  25–35 mm; **Se** semicircular, unwinged, 6–9  $\times$  6–8 mm, black.

In the protologue placed in Sect. *Ditepalae* (as Group) where it is the S-most species. It is compared with *A. palmeri*, from which it differs in its smaller leaves with more remote marginal

**Fig. 36** *Agave macroacantha* (Lau s.n.: Mexico; Oaxaca, Cañón de Tomellín). (Copyright: U. Eggli)

teeth and an acuminate or acute apex, inflorescences with the fertile part in its upper  $\frac{1}{2}$ , flowers with a tube shorter than or equal to the tepals, tepals with a reddish-brown to violet tinge in bud and with an orange dot, filaments inserted at mid-tube, and ellipsoid fruits. — Vernacular names: “shtob bnijh” (Zapotec), “magüey del duende”, “magüey coyote”. The epithet is derived from the Zapotec “Lyobaa”, the name for the pre-Hispanic city of Mitla, which translates to “place of tombs” or “place of rest”; plants cultivated at the Mitla archaeological site are assumed to have originated from the surrounding mountains. The species is classified in the IUCN Red List Category “Endangered”.

**A. macroacantha** Zuccarini (Flora 15: 2 (Beiblatt 2): 97, 1832). **Type** [neo]: Mexico, Puebla (*Gentry & al.* 20242 [US, ARIZ, MEXU [2 sheets]]). — **Lit**: Trelease (1907: 247–252, tt. 18–28); Gentry (1982: 578–580, with ills.); Arias Toledo & al. [2g] Stems none or short, to 30 cm, creeping or erect; **Ros** 20–40 × 30–50 cm, commonly caespitose and forming colonies with up to 10 rosettes; **L** (35–) 50–70, linear or oblong, rigid, erect or radiately spreading, patulous, acuminate, convex below, flat above, 15–25 (–35) × 1.5–2.5 (–3.5) cm, bluish-grey-glaucous or yellowish-glaucous, slightly canaliculate, margins straight or slightly repand; larger **marginal teeth** antrorse, larger ones (at mid-leaf) 3–5 (–7) × (at the base) 4–6 mm, blackish to dark brown, irregularly spaced (10–) 20–35 mm apart, with slender tips mostly curved from small low bases; **terminal Sp** conical, straight to sinuous, rounded below, flat above and flatly grooved, (20–) 25–35 (–45) × (at the base) 3–6 (–7) mm, blackish or dark brown to grey, decurrent, penetrating into the leaf tissue for 2–3 mm; **Inf** 2–3 (–3.5) m, paniculate, peduncle glaucous-reddish, with chartaceous triangular **Bra** 5–8 (–13) cm long, fertile part lax, slender, oblong, part **Inf** shortly spreading, 8–14 in the upper  $\frac{1}{2}$  of the inflorescence, 20–30 cm, sometimes bulbiferous, bulbils leafy; **Ped** 2–5 mm; **Fl** slightly urceolate, (45–) 50–55 (–60) mm; **Tep** glaucous-green with purple tinge, tube broadest in the middle or urceolate, grooved, 10–15 × 7–10 mm, lobes oblong, erect, ± equal, 13–20 × 2–3.5 mm, reddish or with purple tinge; **ITep** with narrow keel but soon receding, quickly wilting at anthesis; **Fil** (30–) 35–45 mm, reddish or purple, inserted at mid-tube or slightly above; **Anth** slightly excentric, spotted, 20–21 mm, yellowish; **Ov** cylindrical to angular-fusiform, 25–30 × 4–6 mm, neck 2–4 mm,

constricted, deeply grooved; **Sty** 45–50 mm; **Sti** 3-lobed; **Fr** oblong to ovoid, 40–60 × 20–30 mm, dark brown, beak prominent, constricted, stipitate; **Se** triangular, winged for ±2 mm, 6–8 × 4–7 mm, dull black. — **Cytology**: 2n = 60 (Flores-Maya & al. 2010).

Characterized by small, dense rosettes with short, glaucous leaves with few teeth (5–11), a large, black terminal spine, and a short and oblong inflorescence (García-Mendoza 2011a). Trelease (1907) gives a detailed review of the complicated taxonomic history throughout European literature and lists many synonyms and misapplications of Zuccarini's name. His treatment is followed here.

*A. macroacantha* 'Verde' is an invalidly published cultivar name for a form with light green leaves (Heller 2006: 104–105, with ill.). The cultivars 'Royal Spine' (Starr 2012: 227–229, with ill.) and 'Little Shark' (Starr 2014: 219) are hybrids with *A. victoriae-reginae*. 'Bloodspot' is a hybrid with *A. [Manfreda] maculata* (×*Mangave*; Klein (2010: as *Manfreda maculosa*)), and 'Lavender Lady' and 'Inkblot' are further ×*Mangave* hybrids with 'Bloodspot' as one parent (Trager 2018: 99). Meer & Guillot Ortiz (2015) show cultivars cultivated in Spain. Moore (2016: 285) depicts variegated specimens.

The flowers of *A. macroacantha* are visited by Hymenoptera, butterflies, and hummingbirds during the day, and by bats and moths during the night. Nectar is principally produced during the night, and only nocturnal visitors are successful pollinators (Arizaga & al. 2000a). *A. macroacantha* is extremely dependent on nocturnal pollinators, and bats are esp. important, with the seed set being different between different bat species (Arizaga & al. 2000b). Most rosettes are derived from rhizomatous offsets, and propagation by seed and bulbils is rare and possibly only occurs in rainy years and under protective nurse plants (Arizaga & Ezcurra 2002). Bulbil production is highest when flowers are abortive or pollination fails, thus acting as an insurance increasing the probability of successful reproduction (Arizaga & Ezcurra 1995).

**A. maculosa** Hooker (Curtis's Bot. Mag. 85: t. 5122 + text, 1859). **Type**: [suggested lecto —

icono]: l.c. t. 5122. — **Lit**: Mulford (1896: 70–72, t. 28); Rose (1903c: 17); Berger (1915: 30–31, with ill.); Small & Runyon (1934); Verhoek-Williams (1975: 209–221); Piña Luján (1985: 62–63); Verhoek-Williams & Hess (2002: 464); Diggs & al. (2006: 410–411, with ill.); Castillejos-Cruz (2009: [210]–[215], with ill.); the last 5 as *Manfreda maculosa*. **Distr**: USA (S Texas), Mexico (Coahuila, Nuevo León, N Tamaulipas); dry chaparral, on slopes or between rocks, and in pine or oak or tropical deciduous forests or desert scrub, 10–2000 m; flowers May to July. **I**: Howard (2001: 10); Richardson & King (2011: 18); Hochstätter (2016: II: 5); all as *Manfreda*.

≡ *Manfreda maculosa* (Hooker) Rose (1903) ≡ *Polianthes maculosa* (Hooker) Shinnars (1966); **incl.** *Agave maculata* Engelm. ex Torrey (1858) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave maculosa* var. *minor* Jacobi (1869); **incl.** *Agave maculosa* var. *brevituba* Engelm. (1875) ≡ *Agave maculata* var. *brevituba* (Engelm.) Mulford (1896).

[3a1] Plants herbaceous, medium-sized, reproducing vegetatively by buds in the axils of the leaves or from the corm; corm 3.5–5 (–6) × (0.8–) 1.5–2 cm, bulb short, 1.8–5.5 (–6.5) × 1–2 cm, covered with dried membranous leaf bases (1.8–) 3.5–7 cm long; **R** fleshy, with filiform ramifications, contractile; **L** evergreen, 4–6 (–11), erect-arching, lanceolate to narrowly elliptic, fleshy, very brittle, slightly channelled, 10–26 (–36) × 1–2.5 (–3.9 in cultivation) cm, dark green to glaucous, spotted with lighter green and brown or green, spots round to elliptic, sometimes glaucous, margins hyaline, apex acute, weak; **marginal teeth** usually present, large, cartilaginous, deltoid to truncate, bipartite, 3–7 mm apart; **Inf** (0.3–) 0.6–1.4 (–1.8 in cultivation) m, erect, 'spicate', reddish to greenish with purple tinge, fertile part (7.5–) 14–22 (–29; to 48 in cultivation) cm, lax, with 7–33 (–41) diffuse to ascending flowers; **Fl** 25–36 mm, sessile; **Te**p tube funnel-shaped, (6–) 12–21 × 4–5 mm, lobes oblong, involute, extended, tips obtuse, with a bunch of white hairs, (6–) 11–13 (–16) × 3–4 mm, greenish-white or whitish-pink to yellowish, aging to deep rose, purple or nearly brown; **Fil** erect at anthesis, 10–18 (–24) mm, exceeding the tube for 8–16 (–22) mm, inserted at the same level almost at

the mouth of the tube, yellowish-white; **Anth** 6–10 mm, yellow; **Ov** ellipsoid, 6–14 (–19) × 3–4 mm, not constricted, not extending into the tube; **Sty** 36–40 mm, to 10 mm shorter or to 4 mm longer than the lobes; **Sti** 3-lobate, yellowish-green; **Fr** globose or ellipsoid to oblong or subcylindrical, 11–20 (–25) × 10–16 mm; **Se** deltoid, plane-concave, with narrow margin, 4–5 × 3–4 mm, shiny.

Baker (1888a: 196), Mulford (1896: 70), and recently Govaerts (2014+: accessed Sept. 2018) interpreted *A. maculata* Regel 1856 as earliest name for this taxon, but Engelmann (1878: 301), Rose (1903c: 17) and Small & Runyon (1934: 49) argue that Regel described a clearly different species, esp. on account of its long-exserted stamens.

*A. maculosa* is characterized by involute perianth lobes, the funnel-shaped tube, and filaments 10–24 mm long inserted near the mouth of the tube not or hardly exceeding the lobes (Castillejos-Cruz 2009). It is closest to *A. longiflora*, with which it shares the consistency, colour and margins of the leaves, short stamens, lobed stigma, and the white to yellowish perianth ageing to rose, therewith closely approaching Sect. *Polianthes*. Both species occur in similar arid habitats and share succulent leaves with CAM photosynthesis (Verhoek-Williams 1975: 217; Castillejos-Cruz 2009; both as *Manfreda*). The lectotype suggested by Verhoek-Williams (1975: 209) was not effectively published.

The plant is sometimes used as ornamental, the corm as soap and shampoo and the chewed leaves against snakebites (Verhoek-Williams 1975: 213, Piña Luján 1985: 63, both as *Manfreda*). The species is the specific host plant for the caterpillars of the butterfly *Manfreda* Giant-Skipper (*Stallingsia maculosa*) (Quinn 2014). The cultivar ‘Silver Leopard’ has leaves with a silvery-grey hue and large, dark maroon dots, and ‘Bloodspot’ hort. Klein (2010) is a hybrid with *A. macroacantha* of Subgen. *Agave* (= ×*Mangave*).

**A. ×madrensis** Villarreal & al. (J. Bot. Res. Inst. Texas 8(2): 443–445, ills., 2014). **Type:** Mexico, Nuevo León (*Ramírez* 106 [MEXU, ANSM, CFNL, ENCB, TEX]). — **Distr:** Mexico (Nuevo León); in limestone soils on steep slopes, in oak scrubland to forests, 2500–2700 m; flowers during summer.

[1g × 2m] This is the putative natural hybrid *A. lechuguilla* (Subgen. *Littaea*) × *A. gentryi* (Subgen. *Agave*), with a ‘racemose-paniculate’ inflorescence intermediate between both subgenera. According to the protologue, it is intermediate in habit between its putative parents and morphologically similar to *A. montium-sancticaroli*, with a similar intermediate inflorescence and thus likewise strongly suggested to represent a similar intersubgeneric hybrid (see there). Only known from 4 plants and additional immature specimens believed to belong here.

**Fig. 37** *Agave manantlanicola* (Etter & Kristen 3728: Mexico; Jalisco, Sierra de Manantlán, 2800 m). (Copyright: J. Etter & M. Kristen)

**A. manantlanicola** Cuevas & Santana-Michel (Brittonia 64(3): 330–335, ills., 2012). **Type:** Mexico, Jalisco (Cuevas & al. 10065 [ZEA, IBUG, IEB, MEXU]). — **Lit:** Kristen & Etter (2014: with ills.). **Distr:** Mexico (Jalisco: Sierra de Manantlán); near-vertical rocky volcanic cliffs or occasionally peak cliffs with fog during the rainy season, in pine forests, 2640–2865 m; flowers June to August. **I:** Pilbeam (2013: 126–127); Hochstätter (2015: VII: 22). — Fig. 37.

[1b] Stems mostly prostrate with age, 50–90 × 20–25 cm, covered throughout with often dry leaves, with up to 10 suckers; **Ros** polycarpic, open, to 1 × 1.8 m; **L** 50–60, plus 30–70 recurved dry leaves, oblong, linear, often falcate, apex ascending, channelled, 45–76 × 6–13 cm, 5 cm thick at the base, glaucous or yellowish-green at the base, turning reddish at anthesis, margins horny, continuous and razor-sharp; **marginal teeth** none; **terminal Sp** canaliculate, 30–45 mm, reddish-brown, decurrent; **Inf** 3–5 m, ‘spicate’, peduncle red to reddish-brown, basal **Bra** ovate-linear, 7.8–10.7 × 1.6–3 cm, all bracts reflexed with age, fertile part confined to the upper 1/3 of the inflorescence; **Ped** 1–2 mm; **Fl** 39–48 mm, geminate; **Te** reddish outside, yellowish-green inside, tube 2–6.5 mm, lobes oblong, reflexed at anthesis, apex cucullate, galeate, blunt or sharp, 15–22 × 2.5–6.5 mm, yellow-green inside, apex reddish, inner lobes with white margins, usually 2–3 mm wider than the outer lobes; **St** 6 or sometimes 7; **Fil** inserted at the base of the lobes on the mouth of the tube, 27–45 mm, tip reddish; **Ov** cylindrical, striate, 18–22 × 5–8 mm, yellow-green, neck 2–3 mm; **Sty** cylindrical, hollow, 30–42 mm, tip reddish; **Sti** 3-lobate, barbate; **Fr** oblong, trigonous, (20–) 24–34 × (13–) 16–18 mm, shortly apiculate, stipe 3–7 mm; **Se** semicircular, sometimes ellipsoid, 5–6 × 3.3–4 mm, bright black, margin slightly winged.

Similar to other W Mexican species of Sect. *Inermes* (as Group *Amolae*) according to the protologue, including *A. attenuata*, *A. gilbertii* (as *A. bakeri*), and *A. vazquezgarciae*, as well as *A. chazaroi* which is here placed in Sect. *Inermes* (as Group *Marginatae*). It stands out for its bluish leaf colour, its thick stems, and its high-elevation habitats. *A. manantlanicola* appears most similar

to the likewise stem-forming *A. attenuata* ssp. *attenuata*, which differs in more slender stems, smooth or serrulate leaf margins, absence of a terminal spine, and yellowish-green tepals. Both are termed “polycarpic” and flower repeatedly from “lateral” inflorescences, which are actually likely terminal on rudimentary lateral rosettes. It hybridizes with *A. inaequidens* in 1 of the 3 populations (Kristen & Etter 2014).

**A. mapisaga** Trelease (Contr. US Nation. Herb. 23: 130, 1920). **Type:** Mexico, D.F. (Trelease 147 [MO 188125]). — **Lit:** Gentry (1982: 602–603, with ill.); Vázquez-García & al. (2007b: 59, t. P); García-Mendoza (2011a: 35–37). **Distr:** Mexico (Tamaulipas, Zacatecas, Jalisco, Querétaro, Hidalgo, México, Guerrero, Tlaxcala, Puebla, Oaxaca); cultivated only, 1900–2700 m; flowers April to August. **I:** Smith (2002: 226, as var. *mapisaga*); Lyons (2002: 163, as var. *lisa*); Gomez Rhine (2009: 22, as var. *lisa*); Pilbeam (2013: 128); Hochstätter (2015: II: 7; 8, as ssp. *lisa*).

**Incl.** *Agave salmiana* var. *recurvata* Jacobi (1866); **incl.** *Agave salmiana* var. *angustifolia* A. Berger (1915); **incl.** *Agave mapisaga* var. *lisa* Gentry (1982) ≡ *Agave mapisaga* ssp. *lisa* (Gentry) Hochstätter (2015).

[2b] Stems short, massive; **Ros** openly spreading, 2–2.5 × 2.5–4.8 m, surculose; **L** 30–50, linear, spreading to ascending, rigid to flexible, sometimes re- or inflexed when mature, base very thickly fleshy, long-acuminate, upwards guttered, convex below, flat above, 150–250 × 19–30 cm, green, pale glaucous, or zonate, margins mostly straight to repand; **marginal teeth** straight, small, sometimes keeled below, dark brown, 2–5 mm from low broad bases forming a continuous horny margin, 15–50 (–60) mm apart, uppermost 25–40 cm without teeth; **terminal Sp** conical-subulate, robust, narrowly grooved above, 25–50 mm, dark to greyish-brown, long decurrent; **Inf** massive, 5–9 m and more, paniculate, peduncle greenish, with closely-set large succulent deltoid reddish-brown **Bra** 15–40 cm long, fertile part lax, pyramidal, in the upper 1/3–1/2 of the inflorescence, to 1 m, with 20–25 widely spreading, massive and dense part-**Inf** several times compound; **Ped** 10–18 mm; **Fl** funnel-shaped,

80–90 (–100) mm, succulent; **Tep** yellow to yellowish-green, sometimes with reddish tinge, buds frequently reddish, tube funnel-shaped, fleshy thick-walled, deeply grooved, 14–21 × 10–15 mm, lobes linear, erect to incurving, margin involute, unequal, 20–30 × 6–8 mm; **OTep** conduplicate and narrowing to 5 mm, apex bluntly galeate; **ITep** 2–3 mm shorter, with thick fleshy keel, involute and 2-costate within; **Fil** thick but flattened, 55–80 mm, inserted at 2 levels 11–15 mm above the tube base and at mid-tube, yellow; **Anth** excentric, 25–35 mm, yellow; **Ov** cylindrical, thick, roundly 3- to 6-angled, 40–52 × 5–8 mm, green, neck 4–5 mm, not constricted; **Sty** stout, 80–95 mm and eventually longer than the stamens; **Fr** oblong, woody, 60–70 × 20–25 mm, brown, short-beaked, stipitate; **Se** drop-shaped, 7–8 × 5–6 mm, wavy-sculptured, hilar notch near apex, marginal wing very narrow, upcurving, black. — **Cytology**: 2n = 150 (= 5×) (Gómez-Pompa & al. 1971, Simpson & al. 2011).

A pentaploid cultivar cultivated for pulque for thousands of years, distinguished from the related *A. salmiana* by its longer, linear, long-acuminate leaves with straight margins, smaller and more narrowly spaced teeth and shorter terminal spine, without the sigmoid apical bend characteristic for the latter, but less often cultivated than *A. salmiana* (Gentry 1982, García-Mendoza 2011a; see also under *A. salmiana*). A detailed ordination and classification of 48 morphological characteristics from 62 populations of the *A. salmiana* group (Mora-López & al. 2011) showed a gradient of domestication in the sequence *A. salmiana* ssp. *crassispina* (wild) → *A. salmiana* ssp. *salmiana* (cultivated only) → *A. mapisaga* (cultivated only), concomitant with the increase in rosette and leaf size and the reduction of the marginal teeth and terminal spines. The highly domesticated *A. mapisaga* is derived from within *A. salmiana* and “only cultivated in highly humanized environments” such as plantations (Mora-López & al. 2011).

*A. mapisaga* var. *lisa*, apparently a clonal variety with unknown provenance, was obtained at Huntington BG from F. Schmoll of Querétaro, Mexico, as “maguey lisa” (Gentry 1982; a specimen from 1933 is filed as *A. mapisaga* ‘Lisa’

(HNT 417)). It is propagated at the Huntington by in vitro-techniques (Gomez Rhine 2009). According to Gentry (1982), it is the largest-growing *Agave*; only *A. franzosinii* and *A. atrovirens* may reach similar or even larger sizes. García-Mendoza (2011a) referred it to the synonymy of the species, which is followed here; it can be retained as cultivar ‘Lisa’.

*A. salmiana* var. *recurvata* Jacobi and *A. salmiana* var. *angustifolia* A. Berger are placed in the synonymy here following García-Mendoza (2011a) and Govaerts (2014+: accessed April 2014). Due to the long, linear leaves, both taxa fit better here than in *A. salmiana* as proposed for the latter by Gentry (1982: 609).

**A. margaritae** Brandege (Proc. Calif. Acad. Sci., ser. 2, 2: 206, t. x, 1889). **Type**: Mexico, Baja California (*Brandege* s.n. [UC 149990]). — **Lit**: Trelease (1912b: 57–58, tt. 55–56); Breitung (1963: 173–174, ills.); Gentry (1978: 48, 108, t. 1); Gentry (1982: 389); Ullrich (1989a: with ills.); Webb & Starr (2015: 82, ill.). **Dist**: Mexico (Baja California Sur: Santa Margarita and Magdalena Islands). **I**: Richter (2011: 105); Pilbeam (2013: 129); Hochstätter (2015: V: 21).

**Incl.** *Agave connochaetodon* Trelease (1912).

[2i] Acaulescent; **Ros** compact, to 0.25–0.3 × 0.5–0.75 m, prolifically caespitose; **L** 40–50, ovate to broadly lanceolate, rather openly spreading, thick, fleshy and rigid, narrowed above the base, shortly acuminate, concave above, smooth, 12–25 × 6–10 cm, yellowish-green to glaucous-blue, transversely banded, margins crenate; **marginal teeth** variously curved or flexed, weakly attached, 4–5 mm or to 8–15 mm (middle of the lamina), reddish-brown to greyish, 10–15 mm apart, sometimes on moderate to prominent prominences; **terminal Sp** subulate, shortly and shallowly grooved above, 20–30 mm, chestnut-brown becoming dull grey, shortly decurrent; **Inf** 2–4 m, paniculate, peduncle with small bracts, fertile part slender, part-**Inf** 6–12 in the upper 1/3 or less of the inflorescence; **Ped** 2–3 mm; **Fl** 45–50 mm; **Tep** light yellow, tube ±10 mm, lobes attenuate, 15 × 10 mm; **Fil** 25 mm, adnate to the base of the lobes; **Ov** fusiform, 25–30 mm; **Fr** oblong or pear-shaped, 30–50 × 15–20 mm, not stipitate but

**Fig. 38** *Agave marmorata* (Etter & Kristen 126: Mexico; Puebla, near Zapotitlán Salinas, 1520 m). (Copyright: J. Etter & M. Kristen)

somewhat beaked; **Se** 3–5 × 4 mm, smooth. — **Cytology**:  $n = 30$  (Baker & al. 2009).

An island endemic known only from Isla Magdalena and Isla Margarita, with considerable variation in the size, curvature and colour of the teeth and its prominences (Gentry 1978, Gentry 1982). It is distinguished from all other taxa from Baja California esp. by its short, broad leaves and the deep flower tube; the latter is also found in *A. vizcainoensis*, which differs, however, in its leaf characters (Gentry 1978, Gentry 1982, Webb & Starr 2015).

**A. maria-patriciae** Cházaro & Arzaba (Phytotaxa 360(3): 263–268, ills., 2018). **Type**: Mexico, Veracruz (Arzaba & al. 451 [XAL, CHAPA, MEXU]). — **Distr**: Mexico (C Veracruz); volcanic substrate in oak forests, ±650 m; flowers December to January; only known from the type locality.

[1f] Stems 0.1–0.2 m, suberect, bifurcately branching, with persistent leaf sheaths; **Ros** usually 2–3 per plant; **L** 13–18, lanceolate to oblong, fleshy, frequently inflexible, 25–29 × 3.5–6.8 cm, light green with pale and blurred yellow mid-stripe, margins straight, with continuous red colouration, **marginal teeth** mere denticles, 2–3 mm, dark brown or reddish-brown, absent 4–5 cm below the terminal spine; **terminal Sp** 5–9 mm, dark brown; **Inf** 1.05 m, from the main rosette, ‘spicate’, peduncle with narrowly triangular **Bra** 3–9.6 × 2–3 cm, fertile part in the upper ½ of the

inflorescence, apex recurved; **Ped** ±1 mm; **Fl** geminate, 24–26 mm; **Tep** pale green, tube funnel-shaped, 7–8 × 8 mm, lobes lanceolate, fleshy, reflexed, apex obtuse, scarcely cucullate, dimorphic; **OTep** 12 × 4 mm, green-brownish inside, pale green outside; **ITep** 11 × 5 mm, membranous, with a conspicuous brownish keel on the back; **St** exserted; **Fil** flattened, tapered, 18 mm, pale greenish-yellow with reddish dots at the apex, inserted shortly below the rim of the tube; **Anth** centric, 10–13 × 2 mm, brown; **Ov** fusiform, 13 × 6 mm, smooth, green, neck slightly constricted, 2–3 × 3–4 mm; **Sty** 27–30 mm, pale greenish-yellow with reddish dots at the apex; **Sti** capitate; **Fr** trigonous, 15–18 × 5 mm, shortly beaked, brown (unripe yellow-green); **Se** crescent-shaped to auriculate, 3–4 × 2–3 mm, shiny.

According to the protologue most similar to *A. pendula*, with which it shares lanceolate to oblong leaves with a yellow mid-stripe, but differing in its shorter leaves, shorter stems and shorter inflorescences, leaves with reddish margins, longer denticles and a thicker terminal spine, its smaller and succulent flowers with reflexed and not broadly cucullate tepals, and subsessile capsules.

**A. marmorata** Roez (Gartenflora 23: 76, 1874). **Type**: [neo — icon]: Curtis’s Bot. Mag., 138: t. 8442, 1912. — **Lit**: Berger (1915: 270–271, with ills.); Gentry (1982: 512–514, with ills.); Ullrich (1992a: with ills.); Arias Toledo & al. (2000: 17, with ill.); García-Mendoza (2011a:

37–39); Hernández López & al. (2017: with ills.). **Distr:** Mexico (S Puebla [esp. around Tehuacán], Oaxaca); gravelly hillsides, volcanics and sedimentaries, in arid scrub and tropical deciduous forests and ecotones of both with oak forests, 680–1830 m; flowers March to April, also in August. **I:** García-Mendoza (2002: 180, 185); Heller (2006: 105); Forster (2006: 176); Etter & Kristen (2007b: 178); Richter (2011: 45, 82); Pilbeam (2013: 130); Mahr (2015: 8); Hochstätter (2015: VI: 21); Moore (2016: 239). – Fig. 38.

**Incl.** *Agave todaroi* Baker (1888).

[2n] Acaulescent; **Ros** openly spreading, 1–2 × 1.5–2.5 m, solitary, rarely surculose; **L** 16–20 (–50), broadly lanceolate, frequently repand, thick at the base, infolding along the middle of the lamina, involute at the tip at the spine base, convex below, flat above, generally roughly scabrous-papillose, (60–) 100–135 (–170) × 20–30 (–40) cm, yellowish- or light green to glaucous-grey, sometimes glaucously zonate, margins crenate, with fleshy prominences 1–2.5 cm tall; **marginal teeth** straight, flattened, with very broad bases, 6–10 (–15) × 7–10 (–15) (at the base) mm, light to dark brown or blackish, 15–30 (–60) mm apart, often with intermittent teeth; **terminal Sp** shortly conical, sinuous, strong, papillose, laterally flattened, grooved, 15–20 (–40) mm, brown or greyish, rarely shortly decurrent; **Inf** 5–7 (–10) m, paniculate, peduncle green, stout, with chartaceous triangular **Bra** 15–20 (–27) cm long, fertile part lax, oblong, with 20–40 (–50) part-**Inf** several times diffusively compound, in the upper ½–⅓ of the inflorescence, 30–50 cm; **Ped** 5–8 mm; **Fl** campanulate, small, 30–40 (–50) mm; **Tep** brilliant yellow, tube shallowly funnel-shaped, grooved, the sinuses soon spreading, (3–) 4–6 × (7–) 10–12 mm, lobes linear to oblong, fleshy, erect, involute, apex galeate, equal, 12–17 (–20) × 2–3 (–5) mm, dark-coloured; **Fil** slender, 30–37 mm, yellow, inserted at mid-tube or at the base of the lobes; **Anth** centric, 10–13 (–18) mm, yellow; **Ov** cylindrical, (17–) 20–25 × 3–5 mm, light green, neck 1–3 mm, not constricted, scarcely grooved; **Sty** ±30 mm; **Sti** capitate; **Fr** oblong, 25–35 (–40) × 15–20 (–25) mm, short-beaked, slenderly stipitate, brown; **Se** winged for ±1 mm, 5–7 × 3–5 mm. — **Cytology:** 2n = 60 (Flores-Maya & al. 2015).

Introduced 1872–1873 by Benedict Roezl and published the following year. Distinguished by its lax rosettes of coarsely rough leaves with strong prominences and a strong, shortly conical terminal spine, and small golden-yellow flowers in large, lax panicles (Gentry 1982, García-Mendoza 2011a). The above-cited neotype was designated by Gentry (1982: 512).

It is used for the production of pulque and aguamiel, the stems and young inflorescences are eaten, and the flowers are used as Easter decoration (García-Mendoza 2011a). The flowers are visited nocturnally by bats, which are not pollinating, and during the day by 6 species of hummingbirds acting as nectar robbers and 9 species of perching birds, of which Orioles are the most possible pollinators (Ornelas & al. 2002). The harvesting practices in sylviculturally managed populations in Puebla have negative effects on the population dynamics because harvesting for mescal decreased individual survival and growth (Jiménez-Valdés & al. 2010). The germination in habitat may be enhanced on biological soil crusts (Godínez-Alvarez & al. 2012).

**A. ×massiliensis** A. Berger *pro sp.* (Agaven, 167, 1915). **Type:** not typified. — **Lit:** Berger (1912: 361); Trelease (1914: 235, 236); both as *A. massiliensis*. **Distr:** Cultivated only.

[1f × 2a] This is the garden hybrid *A. americana* × *A. mitis* [var. *mitis*] (as *A. densiflora*). It was distributed by the nursery Haage & Schmidt (Erfurt, Germany) in 1901 (Berger 1912). The name was first mentioned by Berger (1912), and is attributed to “Trelease in L. H. Bailey 1914” by Govaerts (2014+) but the first description was given by Berger (1915). — Apparently lost from cultivation.

**A. maximiliana** Baker (Gard. Chron., ser. nov. 8: 201, 1877). **Nom. illeg.**, ICN Art. 52.1. **Type** [neo]: Cult. Kew (*Brown* s.n. [K 000543880]). — **Lit:** Gentry (1982: 325, 348–351, with ills.). **Distr:** Mexico (Sinaloa, Durango, Zacatecas, Nayarit, Jalisco, Colima).

See Smith (2017a) for the typification.

**A. maximiliana** var. **katherineae** (A. Berger) Gentry (Agaves Cont. North Amer., 350, ill. (p.

351), 1982). **Nom. inval.**, ICN Art. 35.1. **Type** [lecto]: Ex cult. BG La Mórtoia (*Berger* s.n. [US 1023783]). — **Lit:** *Berger* (1915: 197–198, as *A. katherinae*); *Gentry* (1982: 350–351, with ill.); *McVaugh* (1989: 139); *Vázquez-García & al.* (2007b: 60); *González-Elizondo & al.* (2009: 98, 101, with ill.). **Distr:** Mexico (E-C Sinaloa, W-C Duango, Nayarit, W & C Jalisco, Colima); rocky slopes in pine-oak or oak forests and ecotones with oak woodlands and tropical deciduous forests, 900–2350 m; flowers December to July.

≡ *Agave katherineae* A. *Berger* (1915).

[2d] Differs from var. *maximiliana*: **Ros** larger; **L** larger, 60–90 cm, greener, margins more crenate-repand, with numerous interstitial teeth; **Tep** tube longer, 12 × 12 mm, lobes longer, 22–23 mm; **Fil** inserted 9–10 mm above the tube bottom near its throat.

This is a variant esp. with larger rosettes and greener leaves (*Gentry* 1982). It was included in the synonymy of the species by *McVaugh* (1989), but upheld by *Vázquez-García & al.* (2007b), *González-Elizondo & al.* (2009) and *Govaerts* (2014+), which is followed here. — *Berger* (1915) named the taxon after Lady Katherine Hanbury but incorrectly gave the epithet as ‘katharinae’, which is here corrected. The incorrect spelling ‘katherinae’ is also sometimes encountered.

The type at US consists of 2 sheets prepared by *Berger* (s.n.) in 1914 (US 1023758 & 1023783) which are not cross-labelled and thus represent syntypes. The designation by *Gentry* (1982: 350) that the “Type” “consists of leaf margin, a peduncular bract, and leaf cross section” refers to US 1023783 and represents a cryptic lectotypification.

**A. maximiliana** var. **maximiliana** — **Lit:** *Berger* (1915: 195); *Gentry* (1982: 346–350, with ills.); *McVaugh* (1989: 139); *Vázquez-García & al.* (2007b: 59–60, t. Q); *González-Elizondo & al.* (2009: 97–101, with ills.). **Distr:** Mexico (C Sinaloa, C-W Durango, S Zacatecas, Nayarit, W Jalisco, Colima); dry rocky mountain slopes in the oak- and pine-forest zone, in rather dry calcareous or igneous rocky soils, 930–2000 (–2700) m; flowers December to August. **I:** *Richter* (2011: 73, 108, 110); *Etter & Kristen* (2012: 86);

*Pilbeam* (2013: 131, as *A. maximiliana*); *Greulich* (2014a: 56, 61); *Hochstätter* (2015: IV: 27).

**Incl.** *Agave gustaviana* J. N. *Haage & E. Schmidt* (1874); **incl.** *Agave gustaviana* *Baker* (1877) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Agave crenata* A. *Berger* (1911) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave conjuncta* A. *Berger* (1915).

[2d] Acaulescent to short-stemmed; **Ros** to 1.6 m Ø, solitary; **L** usually broadly (ob-) lanceolate, curved, straight or slightly recurved, softly fleshy, generally 40–80 × 10–20 cm, mostly pale glaucous-pruinose over yellow-green to green, or bluish-glaucous, margins variously repand to crenate, with strong prominences; **marginal teeth** dimorphic, the larger teeth variously curved, compressed, 6–10 mm (at mid-leaf), 15–30 mm apart, tips slender from elongate low (sometimes confluent) bases, on strong prominences, intermittent teeth much smaller, numerous, variable; **terminal Sp** slenderly conical, straight, openly grooved above, rounded below and shortly protruding at the base, smooth, 25–40 mm, brown or chestnut-brown to grey, shortly decurrent; **Inf** 5–8 m, paniculate, fertile part narrow, **part-Inf** small, rather rounded, 15–25 (–30) in the upper 1/3–1/2 of the inflorescence; **Fil** slender, 52–65 mm; **Tep** greenish-yellow, frequently tinged with brown-red, tube openly funnel-shaped, grooved, 5–9 (–12) × 12–14 mm, lobes linear, narrow, ascending to incurved, conduplicate, roundly cucullate, subequal, 15–22 × 4–6 (–7) mm, inner with high or low keel, involute; **Fil** 28–35 mm, sometimes pink, inserted above mid-tube; **Anth** mostly centric, regular, 18–24 mm, yellow; **Ov** angular-cylindrical to fusiform, 28–35 (–38) mm, neck short or long, furrowed; **Sty** slightly longer than the filaments; **Sti** capitate; **Fr** shortly oblong, tip rounded, 35–50 × 17–20 mm, stipitate; **Se** with wavy testa, 5.5–6 × 4.5–5 mm, finely punctate, marginal wing abruptly raised.

The most common wild upland *Agave* in W-C Mexico (Nueva Galicia), replaced more E-wards by the similar but larger *A. inaequidens* (*McVaugh* 1989). *González-Elizondo & al.* (2009) describe and depict a “possibly undescribed variant” with narrow, shorter leaves (27.5–36 × 10.5–14.3 cm)

**Fig. 39** *Agave mckelveyana*. (cult.: USA; Arizona, Arizona-Sonora Desert Museum Tucson). (Copyright: J. Thiede)

from the Sierra de los Huicholes (Nayarit, Zacatecas, Durango and Jalisco).

The prioritable name *A. gustaviana* J. N. Haage & E. Schmidt (Pflanzen-Verzeichnis 1874: 1, 1874) was validated by a diagnosis in the nursery catalogue (Reveal 2012, Smith & Figueiredo 2014d: 68). Smith (2015) regarded the descriptive statement as inadequate for valid publication, but it was subsequently “recommended to treat as validly published” (Applequist 2016). To avoid a name change, Smith (2017b) proposed to conserve *A. maximiliana* against *A. gustaviana*. — Vernacular names: “maguey de la sierra”, “lechuguilla”, “masparillo”, “a’hl mai” (= maguey chico) (Vázquez-García & al. 2007b). The flowers are used in a stew with eggs and butter called “Bayusa” (Etter & Kristen 2003b, ill. in Etter & Kristen 2012: 86).

**A. mckelveyana** Gentry (Cact. Succ. J. (US) 42: 225–228, ills., 1970). **Type:** USA, Arizona (Gentry 21979 [US, ARIZ, DES, MEXU]). — **Lit:** Gentry (1982: 390–392, with ills.); Turner & al. (1995: 55–56); Hodgson (1999a: 6–7); Reveal & Hodgson (2002); Hawker (2016: 60–64, ills.); Parker (2017: 256, 261, with ills.). **Distr:** USA (W-C Arizona); open sandy, gravelly or rocky places in upper desert scrub, chaparral and pinyon-juniper woodlands, 800–2200 m; flowers May to July. **I:** Heller (2006: 106, 107); Richter (2011: 81); Pilbeam (2013: 132); Hochstätter (2015: V: 12). — Fig. 39.

**Incl.** *Agave aquariensis* Trelease ex Gentry (1970) (*nom. inval.*, ICN Art. 39.1, 40.1).

[2i] Acaulescent; **Ros** 20–45 cm, solitary or suckering; **L** rather few, linear or lanceolate, rigid, firm, spreading, tip ascending, broadest in the middle, acuminate, thickish and deeply concave towards the base, guttered towards the apex, 17.5–40 × 2.8–5 cm, light glaucous-green or yellowish- to dark green, usually lightly cross-zoned, margins nearly straight or repand; **marginal teeth** upcurved or recurved, rather friable, small to medium-sized, larger teeth in the middle of the lamina, 4–8 mm, greyish with reddish tips, sometimes with a brown ring at the base, mostly 10–30 mm apart, on low tubercle-like prominences; **terminal Sp** subulate, rounded except for a shallow groove above at the base, 15–40 mm, chestnut-brown to grey, decurrent to the 1. or 2. tooth; **Inf** 2–5 m, paniculate, peduncle slender, green, with persistent triangular **Bra** 0.5–2 cm long, fertile part narrow, part-**Inf** small, compact, ascending, 10–19 in the upper 1/3–1/2 of the inflorescence, with 6–12 flowers, > 10 cm; **Ped** shortly bracteolate; **Fl** 30–40 mm; **Tep** openly spreading, light yellow, tube shallow, broadly campanulate, 2–4.5 × 8–10.5 (–18) mm, light green to light yellow, lobes linear-conduplicate, spreading, thin, with open sinuses, equal or subequal, 11–13 × 2.5–4 mm, outer longer and narrower than the round-keeled inner, both abruptly hooded at the tip, wilting soon after anthesis; **St** long-exserted; **Fil** flattened towards the base, 25–33 mm, inserted

near or at the top of the tube, light yellow; **Anth** (7–) 9–16 mm, yellow; **Ov** fusiform or cylindrical, faintly grooved below the tepal sinuses, 16–22 mm incl. the slightly constricted neck 1–2.5 mm, light green to grey; **Sty** 25–38 mm; **Sti** capitate, 3-lobate; **Fr** linear to (narrowly) oblong, obtuse to apiculate, striate, 30–45 × 10–14 mm, beaked, shortly stipitate; **Se** obovate or crescent-shaped, 5–6.5 × 4–4.5 mm, rugose, margin with a complete low wing. — **Cytology**:  $n = 30$  (Baker & al. 2009).

Ecologically separated by its more humid and cooler mountain habitat from its close relative *A. deserti* ssp. *simplex*, which is confined to lower elevations in the Sonoran Desert (Gentry 1982). It hybridizes with *A. deserti* ssp. *simplex*, *A. utahensis* ssp. *utahensis* and *A. chrysantha* (Hodgson 1999a, Reveal & Hodgson 2002: as var., Parker 2017). *A. mckelveyana* occurs outside the range of nectar-feeding bats and is pollinated by hummingbirds, carpenter bees, and wasps. Fruit set is low and appears to be resource- (nutrient) limited rather than pollinator- or pollen-limited (Turner & al. 1995).

**A. megalodonta** García-Mendoza & D. Sandoval (Acta Bot. Mex. 126: e1461: 11–12, ills. (pp. 13, 15), 2019). **Type**: Mexico, Oaxaca (García-Mendoza & al. 11145 [MEXU, IEB, MEXU, MO, OAX]). — **Distr**: Mexico (S Puebla, E Guerrero, W Oaxaca: upper Balsas River basin); in soils derived from limestone and gypsum, in tropical deciduous forests and xerophytic scrub, 1000–1600 m; flowers December to January.

[lg] Acaulescent; **Ros** lax, solitary, (0.8–) 1–1.4 × (1–) 1.3–1.7 m; **L** 15–40, ensiform to oblong-lanceolate, erect to recurved, fibrous, thin at the base, broadly canaliculate, smooth to the touch, apex long acuminate, (50–) 60–100 × 7–12 (–14) cm, 6–10× longer than broad, green-yellowish or dark green, with purplish dots on both faces, upper face with yellowish longitudinal mid-stripe, often with impressions of the teeth on both faces, margins straight, corneous, continuous, white or greyish, dentate; **marginal teeth** antrorse or straight, very variable in shape, hooked, (10–) 15–35 × 10–15 (–25) mm at mid-leaf, white or greyish, 20–50 (–70) mm apart at mid-leaf, sometimes with 1–2

small teeth at the base; **terminal Sp** acicular, (30–) 45–70 (–90) × (5–) 10–25 mm, greyish; **Inf** erect, (3–) 5–6.5 m, ‘spicate’, peduncle glaucous or purplish, waxy, with long triangular chartaceous **Bra** 25–30 × 1.5–3.5 cm, fertile part dense, in the upper  $\frac{1}{3}$ – $\frac{1}{2}$  of the inflorescence; floral **Bra** 3–6 × 0.3 cm, filiform; **Ped** short; **Fl** (32–) 35–45 mm; **Tep** pale yellow or greenish-yellowish, tube campanulate, 3–6 × 4–7 mm (at the mouth), lobes elliptic or oblong, straight to diffuse, with purple dots on the margins and the adaxial face, 15–20 × 3–5 mm, **ITep** narrower, clasping the filaments after anthesis; **Fil** 35–40 (–47) mm, purple to brownish, inserted in the distal part of the tube; **Anth** 10–15 mm; **Ov** cylindrical, 14–18 (–25) × 3–4 mm, neck 3–5 mm; **Sty** 35–40 mm, with purplish dots; **Sti** 3-lobate, with purplish dots; **Fr** ovoid-ellipsoid, 15–20 × 10 mm; **Se** semicircular, unwinged, 3 × 2–2.5 mm, black.

In the protologue placed in Sect. *Heteracanthae* (as Group *Marginatae*). It is closely related to *A. xylonacantha*, which occurs ±250 km further N and differs in its longer and relatively narrower, smooth leaves with straight margins with larger teeth variable in shape, a longer terminal spine, and flowers with a longer tube and broader lobes, and smaller capsules. However, the protologue does not account for the full range of character expressions for *A. xylonacantha* given by Gentry (1982) and here; with these data, the differences in leaf size and tube length largely disappear. — Vernacular name: “maguey espumoso”. Occasionally used for mescal production. Classified in the IUCN Red List Category “Near Threatened”.

**A. microceps** (Kimmach) A. Vázquez & Cházaro (in Vázquez-García & al. (eds.), *Agaves Occid. Méx.*, 61, ills. (t. O, pp. xlii–xliii), 2007). **Type**: Mexico, Sinaloa (Kimmach 1923 [HNT, MEXU, US]). — **Lit**: Kimmach (1995: as *A. filifera* ssp., with ills.). **Distr**: Mexico (C Sinaloa, S Nayarit); rocky mountain ridge with tropical deciduous forests at 460 m (Sinaloa), and rocky cliff with mixed pine-oak-*Arbutus* forests at 2100 m (Nayarit); only known from 2 localities. **I**: Pilbeam (2013: 81, as *A. filifera* ssp.); Hochstätter (2015: VIII: 50).

≡ *Agave filifera* ssp. *microceps* Kimmach (1995); **incl.** *Agave filifera* var. *compacta* Trelease (1914).

[1d] Densely caespitose, forming cushions to  $\geq 1 \times 0.3$  m; **Ros** 20–35  $\times$  20–30 cm; **L** linear to linear-oblongate, acuminate, acute, 12–20  $\times$  1–2 (in the middle) cm, abruptly widening to 2.5–3.5 cm within 2 cm of the base, 4–10 mm thick near the base, 2–4 mm thick above, youngest leaves sometimes with 1–3 white streaks on the upper face, margins with a brownish or purplish grey band  $\pm 2$  mm wide, and every 1–3 cm with a separating, sinuous, white thread 10–40  $\times$  1–2 mm, otherwise entire; **terminal Sp** acicular, short; **Inf** 1–1.35 m, ‘spicate’, peduncle in the basal 30 cm with prominent, linear, acuminate, acute **Bra** 8–10 cm long, basal 1 cm of the bracts at right angles to the axis, remaining part parallel to the axis, upper **Bra** smaller, yellowish-pink, fertile part of the inflorescence 80 cm; **Fl** geminate, 5–10 mm apart on a peduncle  $\pm 2$ –4 mm long; **Ped**  $\pm 2$  mm; **Fl** 50–55 mm, at right angles to the axis; **Tep** greenish-yellow, tube longitudinally grooved, 8–10  $\times$   $\pm 4$  (at the base) mm, gradually widening to 6 mm at the mouth, greenish-yellow, lobes subequal, 9–10  $\times$   $\pm 5$  (in the middle) mm, obtuse, cucullate; **OTep** ovate,  $\pm 10$  mm, tips suberect; **ITep** slightly obovate,  $\pm 9$  mm, tips abruptly recurving; **Fil** narrowing just below the anther, 22–25  $\times$   $\pm 1$  mm, pinkish-yellow; **Anth** 10–11 mm, yellow; **Ov** oblong, truncate at the base, narrowing more gradually at the top, slightly ridged, 7–8  $\times$   $\pm 5$  mm, greenish-yellow; **Sty** 39–44 mm, greenish-yellow; **Sti** truncate, 3-lobed, lobes  $< 1$  mm, papillose; **Fr** oblong-ellipsoid, 10–12  $\times$  6–8 mm, slightly apiculate, light brown; **Se** flattened, semicircular, 4–4.5  $\times$   $\pm 2.5$  mm,  $\pm 1.5$  mm thick, black.

According to the protologue (as ssp. of *A. filifera*), the rosettes are similar to those of *A. schidigera*, but are much smaller and proliferous, and the inflorescences are smaller with larger flowers. The taxon is possibly a redescription of *A. filifera* var. *compacta*, but the name has priority at species and subspecies rank. Plants were first distributed 1980 as ISI 1184. The fruits were not described in the protologue, and data is here added

from the specimen Kimmach & Sánchez-Mejorada 2260 (MEXU; digital image!). See also under *A. filifera*.

**A. millsaughii** Trelease (Mem. Nation. Acad. Sci. 11: 41, tt. 87–88, 1913). **Type:** Bahamas, Great Exuma (Britton & Millspaugh 3091 [MO 2056612, F, NY]). — **Lit:** Berger (1915: 204); Britton & Millspaugh (1920: 75); Correll & Correll (1982: 313); Álvarez de Zayas (1995: 40); Acevedo-Rodríguez & Strong (2012: 86); Freid & al. (2014: 210, 211, 218). **Distr:** Bahamas (Great Exuma); dry slopes, low coppices and scrublands; flowers mostly December to February. **I:** Hochstätter (2015: VII: 85).

[2r] Acaulescent; **Ros** solitary; **L** narrowly oblanceolate, concave, to 125  $\times$  15 cm or more, green, somewhat glossy; **marginal teeth** straight and spreading or occasionally reflexed, sometimes with upcurved tips, narrowly triangular, 3–5 mm, brown to nearly black, mostly 15–25 mm apart, scarcely lenticular at the base, intervening margins nearly straight; **terminal Sp** triquetrous, conical, straight, round-grooved to about the middle or occasionally involute, smooth, rather dull, 15–20  $\times$  3–4 mm, red-brown, decurrent for its length or more; **Inf** to  $\pm 10$  m, paniculate, oblong, peduncle with broadly triangular **Bra**, fertile part with subascending part; **Inf** in the upper  $\frac{2}{3}$  of the inflorescence; **Ped**  $\pm 10$  mm; **Fl** 45–50 mm; **Tep** yellow, tube conical,  $\pm 7$  mm, lobes 15–20  $\times$  4 mm; **Fil** scarcely 30 mm, inserted nearly in the tube throat; **Ov** fusiform, 19–25  $\times$  4–5 mm; **Fr** shortly oblong, 33–35  $\times$  18–20 mm, beaked, shortly stipitate; **Se** crescent-shaped, 7  $\times$  5 mm.

In the key provided in the protologue closest to *A. bahamana*, which differs in its dull grey leaves with rather short terminal spine. See also the note under *A. bahamana*.

**A. minor** Proctor (Contr. US Nation. Herb. 52: 118, 2005). **Type:** Puerto Rico (Proctor & al. 46978 [SJ, NY [photo], UPRRP [photo], US [photo]]). — **Lit:** Acevedo-Rodríguez & Strong (2012: 86). **Distr:** Puerto Rico (Cabo Rojo); dry scrubland, 100–200 m; known only from a single population of several individuals.

[2q] Acaulescent; **Ros** tight, clustering by means of short stolons; **L** lanceolate or narrowly elliptic, ascending to erect, 40–60 × 4.5–6 cm; **marginal teeth** ±1 mm, mostly 6–10 mm apart; **terminal Sp** needle-like, to 30 mm; **Inf** (only 1 seen) 1.2 m, ‘paniculate’, peduncle ±90 cm, **Bra** widely separated, deltate-acuminate with spinose apex, 3–4.5 cm, part-**Inf** few, short, ascending, 1.5–4 cm stalked; **Fl** densely clustered on very short branches; **Tep** (only dried withered ones seen) ±15 mm, yellow; **St** not known; **Ov** not described; **Fr** rounded-oblong, deeply grooved between the locules, ±20 × 14–16 mm; **Se** angular, rugose, ±5 mm wide.

Differing from the other two *Agave* species native in Puerto Rico (*A. missionum* of Sect. *Antillanae*; *A. eggersiana* of Sect. *Caribaeae*) in its smaller size. It is compared with *A. missionum* in the protologue, from which it differs in smaller leaves, inflorescences and fruits, but remains insufficiently known. With its small teeth, small flowers, and small seeds, the species can clearly be placed in Sect. *Antillares*, which otherwise includes 6 species from Cuba, indicating that *A. minor* is not close to the two other species from Puerto Rico.

**A. missionum** Trelease (Mem. Nation. Acad. Sci. 11: 37–38, tt. 72–75, 1913). **Type:** Virgin Islands, St. Thomas (Trelease 15 [MO]). — **Lit:** Berger (1915: 212–213); Britton & Wilson (1923: 156); Hummelinck (1986: 162–163, with ill.); Álvarez de Zayas (1995: 41); Francis (2004: 34–35, with ill.); Proctor & Acevedo-Rodríguez (2005: 118–120, figs. 27a–e, 388: fig. 61e); Acevedo-Rodríguez & Strong (2012: 86). **Distr:** Puerto Rico (incl. Culebra and Vieques), US Virgin Islands (St. Croix, St. John, St. Thomas); British Virgin Islands (Anegada, Guana, Tortola, Virgin Gorda); dry rocky mostly non-calcareous habitats over sedimentary or igneous rocks, sandy dunes, often at disturbed sites, near sea level to ±800 m; flowers around Easter. **I:** Hochstätter (2015: VII: 74).

**Incl.** *Agave vivipara* Oldendorp (1777) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave morrisii* Eggers

(1889) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave portoricensis* Trelease (1913).

[2p] Acaulescent; **Ros** solitary, large, not surculose; **L** lanceolate to broadly lanceolate, gradually acuminate to a spinose apex, fleshy, mostly 90–275 × 13–23 (–25) cm, dark glossy green or very slightly greyish, sometimes slightly glaucous when young, margins nearly straight; **marginal teeth** straight or variously recurved, conspicuously triangular, 2–5 (–8) mm, brown or blackish, mostly 7–15 (–30) mm apart, smaller teeth from often confluent lenticular bases; **terminal Sp** subulate, straight or a little upcurved, round-grooved to about the middle or occasionally involute, smooth, (10–) 15–25 mm, brown, or grey in age, somewhat glossy, decurrent at the base and dorsally intruding into the green leaf tissue; **Inf** 5–7 m, ‘paniculate’, narrowly oblong, often bulbiferous, part-**Inf** ±30–35, nearly horizontal or sometimes slightly ascending, in the upper ½–⅔ of the inflorescence, with dense cymose flower clusters; **Ped** 10–20 mm; **Fl** erect, 45–55 mm; **Tep** yellow or greenish-yellow, tube conical, 6.5–8.5 mm, lobes 15–23 × 5 mm; **St** long-exserted; **Fil** 28–40 mm; **Anth** falcate, 14–21 mm; **Ov** oblong-fusiform, 20–35 × 6–10 mm; **Sty** 40–50 mm; **Sti** 3-lobed; **Fr** broadly oblong-ellipsoid, somewhat turbinate, or subglobose, stipitate and beaked, 25–48 × 17–25 mm; **Se** only rarely produced, irregularly and obtusely triangular, flat, 5–9 × 5–6 mm.

In the first edition of this handbook, *A. eggersiana* was placed in the synonymy here, and *A. portoricensis* was recognized as a distinct species, but following Proctor & Acevedo-Rodríguez (2005), *A. eggersiana* is now recognized as distinct species, and *A. portoricensis* is treated as synonym of *A. missionum*. *A. missionum* is somewhat variable in several characters, including the size of the marginal teeth, the shape of the panicle, the texture of the capsules, and the presence or absence of bulbils (Francis 2004, Proctor & Acevedo-Rodríguez 2005). Recently, a third species from Puerto Rico was published, *A. minor* (see there). — The dried inflorescences are used by some residents as christmas tree (Colli

**Fig. 40** *Agave mitis* (Etter & Kristen 993: Mexico; San Luis Potosí, Sierra Alvarez, 2350 m). (Copyright: J. Etter & M. Kristen)

1983: 20). Vernacular names: “karata”, “corita”, “cocuiza”.

**A. mitis** Martius (Del. Sem. Hort. Bot. Monac. 1848: 4, 1848). **Type** [neo]: Mexico, Tamaulipas (Gentry 20077 [MEXU, DES, US]). — **Lit:** Berger (1915: 62–66, as *A. mitis*, *A. celsii* & *A. albicans*); Gentry (1982: 220–224, as *A. celsii* & var. *albicans*, with ills.); Smith & Steyn (2002b: as *A. celsii* var. *albicans*); Eguiarte & Scheinvar (2008: 48–50, as *A. celsii* var. *albicans*); Starr (2012: 136–139); Thiede (2016); all with ills. **Distr:** Mexico (SE Coahuila, S Nuevo León, W & SW Tamaulipas, SW & S San Luis Potosí, NE Guanajuato, N & NE Querétaro, N & C Hidalgo, N Puebla); mostly on limestone outcrops, also in stream-side thickets, in cloud forests, rarely epiphytic, 460–2440 m; flowers March to July. **I:** Curtis’s Bot. Mag. 82: t. 4934, 1856, as *A. celsii*; Curtis’s Bot. Mag. 102: t. 6248, 1876, as *A. botteri*; Curtis’s Bot. Mag. 123: t. 7527, 1897, as *A. haseloffii*; Curtis’s Bot. [1f] **Ros** branching axillary, forming large, long-lived, dense clumps; **L** ovate, oblong, or spatulate, ascending to outcurving, thickly soft-fleshy, short-acuminate, sometimes undulate, convex below, guttered or concave above, 30–60 (–70) × 7–13 cm, green to light grey-glaucous, margins straight to sometimes ± wavy; **marginal teeth** small, frequently 2-tipped, sometimes with ciliate crests, 1–3 mm, whitish to reddish-brown, closely spaced; **terminal Sp** acicular, weak, 10–20 mm, brownish, decurrent along the leaf tip for 1–6 cm and more; **Inf** 1.5–2.5 m, ‘spicate’, (always?) “lateral” but likely terminal on rudimentary lateral rosettes, peduncle with dense, chartaceous, deltoid, long-caudate, persistent **Bra** 1.5–7 cm long, fertile part dense, becoming lax at fruiting time, part-**Inf** with geminate flowers; **Fl** fleshy, 40–60 mm; **Tep** green outside, yellow to reddish or lavender to purplish within, tube funnel-shaped, thick-walled, 3-angled, 6-furrowed, 10–17 × 10–12 (at the apex) mm, lobes linear-lanceolate, thick-fleshy, ascending to recurving, shortly acuminate, cucullate, glandular-floccose at the tip, unequal, 12–18 × 5–8 mm, inner with a broad fleshy keel; **Fil** 40–60 mm, whitish with fine pale purple stripes, yellowish, brownish, or brownish-purple, inserted at the tube apex; **Anth** mostly excentric, 17–22 mm, yellow, green(ish), red or brown, before dehiscence yellowish, brown, purplish-brown or dark purple; **Ov** 3-angled, cylindrical, 6-grooved, truncate at base and apex,

13–20 mm, without neck; **Sty** stout, shorter, as long as or longer than the filaments, whitish-green, light greenish-cream, rose, (pale) purple or brown, sometimes dotted with purple or reddening towards the tip; **Sti** weakly 3-lobate; **Fr** angularly ovoid, thick-walled, 18–25 × 9–12 mm, rough, dark brown, beaked; **Se** semicircular, 3–4 × 2–3 mm, with well-developed complete marginal wing. — **Cytology**: 2n = 60 (Cave 1964, Simpson & al. 2011).

Distinguished by its small compact rosettes, broad, delicately denticulate leaves with mostly 2-tipped teeth, and dense, clavate inflorescences (Gentry 1982: 222). Gentry wrongly used the name *A. celsii* for this taxon, and the nomenclature, including the designation of a neotype as cited above, was finally clarified by Ullrich (1993a) and reviewed by Thiede (2016). *A. ehrenbergii* Jacobi (1865) should be placed in the synonymy here (Thiede 2016; see note under *A. legrelliana*).

The plates in Curtis’s Botanical Magazine cited above finely illustrate the considerable variability of the species. This variability in the colouring of tepals, filaments, anthers and styles is remarkable and may occur within the same population from plant to plant (Gentry 1982: 223). Plants with pale glaucous to nearly whitish leaves (var. *albidior*/var. *albicans*) were introduced into cultivation before 1859 (Thiede 2016). A small colony along the eastern rim of the N and C Barranca de Metztlán was assigned to this variety by Gentry (1982) (map in Eguiarte & Scheinvar (2008)). The deviating leaf colouration is bridged by intermediates to typical green-leaved plants, and the differences in the length of the lobes given by Gentry are not supported by early authors, so that this variety can not be upheld (Thiede 2016). — ‘Multicolor’ is a variegated cultivar (Starr 2012: 140).

The probability that a flower develops into a fruit is 43.9%, and that at least one ovule of a flower develops into a seed is 35%. On average, each inflorescence develops only 51 fruits with 49 viable seeds each. Main floral visitors are bats and also bees, bumblebees, sphingids, and hummingbirds (Eguiarte & Scheinvar 2008). The genetic variation is high and mostly found within populations. The populations are moderately differentiated from each other, suggesting a

relatively low gene flow among them, with more distant populations being genetically more different (Eguiarte & Scheinvar 2008).

**A. montana** Villarreal (Sida 17(1): 191–195, ills., 1996). **Type:** Mexico, Nuevo León (*Villarreal & al.* 8120 [MEXU, ANSM, ASU, DES, ENCB, IBUG, XAL]). — **Lit:** Greulich (2012c); Starr (2012: 141–147, 325–327); Alsemgeest & Roosbroeck (2012?); all with ills. **Distr:** Mexico (S Nuevo León, W Tamaulipas, NE Querétaro); rocky limestone slopes in mountain regions, in open pine-oak forests or above the timberline, 2300–3400 m; flowers May to July. **I:** Spracklin (2007: 146); Pilbeam (2013: 135); Grieco (2013); Hochstätter (2015: III: 4); Greulich (2016b).

[2m] Acaulescent; **Ros** semiglobose, compact, 0.75–1.25 × 1.25–1.65 m, solitary; **L** 84–112, regular in 12–16 rows, shortly elliptic, base broadened, apex acuminate, slightly guttered to nearly flat, 30–50 × 15–18 cm, yellowish-green, margins straight, near the tip bordered brown-purple; **marginal teeth** antrorse, retrorse or nearly straight, broadly triangular from a lenticular base, 3–10 × 5–15 mm, longest in the upper 1/2, much shorter below, greyish, 6–20 (–35) mm apart, 16–18 per leaf margin; **terminal Sp** acicular, narrowly triangular, 30–50 mm, greyish, decurrent for 4–12 cm as broad margin confluent with the upper marginal teeth; **Inf** 3.5–4.5 m, paniculate, peduncle thick, with elliptical succulent **Bra** 18–25 × 8–12 cm, reddish-brown, completely covering the peduncle, fertile part ovoid, part-**Inf** 20–30 in the upper 2/3 of the inflorescence, 25–30 cm; **Ped** 10–15 mm; **Fl** 60–70 mm; **Tep** yellow, reddish in bud, tube 20 × 12–14 mm, lobes lanceolate, 20 × 3–4 mm; **Fil** flattened, 50–60 × 3 mm, inserted at the base of the lobes; **Anth** 19–20 mm, yellow; **Ov** 30 mm, neck slightly constricted; **Sty** shorter than the filaments; **Fr** oblong, 50–60 × 15–20 mm, coffee-brown; **Se** drop-shaped, 5–6 × 3–4 mm, shiny black.

According to the protologue related to *A. parrasana* of Sect. *Parryanae* (as Group) and esp. to *A. gentryi* (= *A. macroculmis sensu* Gentry p.p.) in which it was formerly erroneously included despite being clearly distinct in many features. The descriptions of both Gentry (1982) and Ullrich

(1990i) for *A. gentryi* combine characters of both species (see there).

According to the protologue, *A. montana* differs from the partially sympatric *A. gentryi* by larger, non-offsetting rosettes with more and smaller leaves with curved marginal teeth, and inflorescences with dentate bracts, the fertile part ovate in outline with 20–30 part-inflorescences and smaller flowers. First only known from the type locality, further localities have been discovered subsequently. It shows possible intergrades (hybrids?) with *A. gentryi* where they are sympatric (Starr 2012: 99, Greulich 2012c: 49–52); the cultivar ‘Baccarat’ is such an intermediate of wild origin (Starr 2014: 219, with ill.). Alsemgeest & Roosbroeck (2012?) even suggest a separate Group *Parrasanae* (*nom. inval.*) for the three species *A. gentryi*, *A. montana* and *A. parrasana*. Hochstätter (2015: I: 31) published his Sect. *Hibernicae* for *A. montana* and *A. gentryi* which is accepted here, also including *A. parrasana*. The species is somewhat frost-hardy under garden conditions, see Grieco (2013).

**A. montium-sancticaroli** García-Mendoza & al. (J. Bot. Res. Inst. Texas 1(1): 79–81, ills., 2007). **Type:** Mexico, Tamaulipas (*García-Mendoza & al.* 7605 [MEXU, ENCB, TEX, UAT]). — **Distr:** Mexico (Tamaulipas); on plains and plateaus over calcareous rocks and sandy soils, in submontane scrub or its transitions to oak forests, 150–800 m. **I:** Hochstätter (2015: IX: 40).

[1g × 2g?] **Ros** compact, 1.5–2 × 2–2.5 m, surculose; **L** 50–80 (–100), erect, lanceolate, rigid, 100–120 × 9–12 cm, yellowish-green, glaucescent towards the base, sometimes with transversal glaucous bands, margins with thin horny band; **marginal teeth** straight to retrorse, 4–6 × 1.5–3 (at the base) mm, 10–30 (–45) mm apart, more narrowly set near the leaf base, with 1 or several small denticles between the teeth, greyish; **terminal Sp** dorsally channelled, 25–35 mm, decurrent for 12–16 cm; **Inf** 5.5–7 m, ‘racemose-paniculate’, ± fusiform, peduncle 3–4 m, with deltoid chartaceous **Bra** 11–16 × 2.5–5.5 cm, part-**Inf** (60–) 80–140, the lower 8–13 cm, diminishing to 2–4 cm towards the tip; **Ped** (0.5–) 1–1.5 mm, elongating to 20 mm in ripe fruits; **Fl** 45–50 (–55)

mm, in groups of 10–20 per ‘umbel’; **Tep** yellowish-green, tube 5–6 (–8) × 7–10 (–12) (at the apex) mm, lobes 15–22 × 3–4 (–7) mm, apex cucullate; **Fil** 35–40 (–55) mm, green with purple tinge, inserted at the tube apex; **Anth** 13–15 (–20) mm, yellow; **Ov** cylindrical, 20–25 (–30) × 4–6 mm, neck constricted; **Sty** 50–55 mm; **Sti** 3-lobed; **Fr** oblong, 35–45 × 17–20 mm; **Se** 4–6 × 3–4 mm, winged for 0.5 mm, black.

In the protologue placed in Sect. *Heteracanthae* (as Group *Marginatae*) and compared with *A. × glomeruliflora*, which is the name used for a series of natural hybrids between *A. lechuguilla* (Subgen. *Littaea*) and *A. gracilipes*, *A. havardiana* and *A. (parryi) ssp. neomexicana* (Subgen. *Agave*) with an intermediate ‘race-mose-paniculate’ inflorescence. The inflorescence of *A. montium-sancticaroli* is similarly intermediate between the subgenera, and thus likewise strongly suggests that the species is an inter-subgeneric hybrid, possibly between *A. angustifolia* (which it resembles in habit) and the sympatric *A. funkiana* or *A. lophantha*. Indeed Etter & Kristen (1997+: accessed Oct. 2018) list it as hybrid. According to the protologue, it is used for mescal production. *A. doctorensis*, likewise with an intermediate inflorescence and of putative hybrid origin, is compared with *A. montium-sancticaroli* in the protologue (see there).

**A. moranii** Gentry (Occas. Pap. Calif. Acad. Sci. 130: 58, ill. (pp. 59–61), 1978). **Type:** Mexico, Baja California (Gentry & McGill 23287 [US [syn], ARIZ, ASU, CAS, DES, MEXU, MICH, SD]). — **Lit:** Gentry (1982: 392–395, with ill.); Turner & al. (1995: 56–57); Thorne & al. (2010: 32–33); Webb & Starr (2015: 74–75, with ill.). **Distr:** Mexico (Baja California: S San Pedro Martír); rocky slopes and plains in a small desertic area, in desert scrub and ecotone with chaparral, 450–2065 m; flowers April to July. **I:** Pilbeam (2013: 136); Hochstätter (2015: V: 23).

[2j] Stems short; **Ros** symmetrically sword-leaved, 1–1.5 × 2 m, solitary; **L** triangularly long-lanceolate, straightly ascending to spreading, rigid, rounded beneath, deeply guttered, 70–120 × 8–12 cm, light to yellowish-green, sometimes glaucous, margins towards the tip white-horny;

**marginal teeth** sinuously curved, flattened, 6–12 mm (at mid-leaf and below), light grey, 20–40 mm apart, base broad or continuous with the leaf margin, teeth reduced and more remote towards the leaf tip; **terminal Sp** stout, broadly grooved above, 40–60 mm, nearly white, tip chestnut-brown, decurrent to the middle of the lamina; **Inf** 4–5 m, paniculate, peduncle frequently swollen and closely bracteate below the fertile part, part-**Inf** closely spaced, compact, large, subtended by prominent, lanceolate, reflexing, strong **Bra**, 20–30 per **Inf**; **Ped** slender, 10–30 mm, bracteolate; **Fl** 50–70 mm; **Tep** bright yellow, tube broadly funnel-shaped, 4–6 × 12–13 mm, **Nec** ridged by the decurrent filaments, lobes broadly linear, erect to ascending, acute, with papillate tufted beak, 18–24 × 6–7 mm, inner with a prominent bulbous keel and 2 costae within, slightly lobed at the base; **Fil** very slender, 35–46 mm, inserted on the nectary rim and partly on the lobe bases; **Anth** centric; **Ov** fusiform, tapered at the base, 25–40 mm, neck short, grooved, thick; **Sty** slightly longer than the filaments; **Sti** capitate; **Fr** long-oblong, 50–70 × 16–20 mm, short-beaked, stipitate, yellowish to brown; **Se** drop-shaped, 7–8 × 5–6 mm, marginal wing smooth, variable in width, shiny.

Characterized and distinguished by its large solitary rosettes with large, long, rigid, sword-like leaves with an apical white-horny margin, stout peduncles and relatively congested panicles. Gentry (1982) placed it in his Group (now Sect.) *Deserticolae* and allied it with *A. avellanidens* and *A. gigantensis*. Webb & Starr (2015) placed all three species as well as *A. turneri* in a separate Sect. *Conicae* (see also under *A. avellanidens*). The species appears to hybridize with *A. pringlei* according to Gentry (1978) and Gentry (1982: as *A. deserti* ssp.), but Webb & Starr (2015) found no evidence in the field. Gentry’s “holotype” at US consists of three sheets which thus represent syntypes; two of them were apparently cross-labelled later.

**A. × mortolensis** A. Berger *pro sp.* (Hort. Mortol. 13, 361, 1912). **Type:** not typified. — **Lit:** Berger (1915: 156); Ullrich (1993b: 25, 30); both as *A. mortolensis*. **Distr:** Cultivated only.

[2a × 2b] A garden hybrid that originated at La Mótola, possibly *A. americana* ssp. *americana* (as *A. ingens* in the protologue) × *A. salmiana* ssp. *salmiana*. Apparently lost from cultivation.

**A. multicolor** (E. Solano & Dávila) Thiede (Haseltonia 17: 95, 2012). **Type:** Mexico, Guanajuato (Solano C. & Correa D. 871 [MEXU, CHAPA, ENCB, FEZA, IEB, MO, NY, RSA, UAMIZ, US]). — **Lit:** Solano Camacho & Dávila Aranda (2003: with ills., as *Polianthes*). **Distr:** Mexico (Guanajuato); dark to brown soils with sandy texture, in pine, pine-oak and oak forests and grasslands, 2200–2490 m; flowering August. **I:** Castro-Castro & al. (2015: 145); Hochstätter (2016: II: 18); Castro-Castro & al. (2016: 721); Castro-Castro (2017: 137); all as *Polianthes*.

≡ *Polianthes multicolor* E. Solano & Dávila (2003).

[3b2] Herbaceous; corm cylindrical, ±0.8–1 × 2 cm; bulb long ovoid, (1.5–) 2.7–4 (–4.5) × 1–1.5 (–2) cm, covered with dried leaf bases; **R** contractile, thickend; **L** 2–4 (–6), linear, grass-like, (7–) 11–30 (–37) × 0.1–0.45 (–0.9) cm, papillose (“buliforme”), margins papillose; **Inf** (28–) 33–64 cm, ‘spicate’, fertile part with 3–9 (–16) floral nodes with geminate flowers, **Bra** at the base of the peduncle 4–18 (–21) × 0.14–0.43 (–0.7) cm, linear; **Ped** (3.5–) 4.4–16 mm; **Fl** geminate, fragrant, 18–28 mm, at the base with 2 bracteoles; **Tep** tube inside completely yellow,

sometimes white, nearly funnel-shaped, abruptly curved just above the ovary, 1.4–3.6 (–4.2) mm Ø at the mouth, lobes broadly ovate to broadly elliptic, perpendicularly spreading, 2–4 × 1.1–3.3 (–3.6) mm, tips obtuse to rounded, colour variable, from cream to nearly white, white-pinkish, pink, pink with white stripes, yellowish-pink, nearly red to orange-yellowish; **Fil** 10–17 mm, white to yellow, inserted 3–6 mm above the tip of the ovary; **Anth** oblong, 3.9–5.4 (–6) mm, yellow, included; **Ov** ±4 × 1–2 mm; **Sty** (11–) 12–17 mm, white or yellow; **Sti** 3-lobed; **Fr** semiglobose, 10–13 (–24) × 8–10 mm; **Se** semicircular, (2.1–) 3–3.9 × 2.2–2.9 mm, black.

According to the protologue characterized by its nearly funnel-shaped flowers with a great colour variability. It is similar to *A. coetocapnia* (as *Polianthes geminiflora*), which differs in having broader bulbs, broader leaves and bracts, and tubular, pendent and orange or coral-pink to red flowers with erect lobes. *A. multicolor* has the greatest flower colour variability of all taxa of Sect. *Polianthes*.

**A. multifilifera** Gentry (US Dept. Agric. Handb. 399: 46–50, ills., 1972). **Type:** Mexico, Chihuahua (Gentry 8167 [US 2558493 + 2558494 [syn], ARIZ, DES, MEXU, US]). — **Lit:** Bye & al. (1975: 97, 111, with ill.); Gentry (1982: 112–117, with ills.); González-Elizondo & al. (2009: 75–76, with ills., as *A. filifera* ssp.); Starr (2012: 148–153, 317–319, ills.). **Distr:** Mexico

**Fig. 41** Agave *multifilifera*. (Mexico; Chihuahua, El Divisadero) (Copyright: J. Thiede)

(SE Sonora, SW Chihuahua, N Sinaloa, N Durango); cliffs and rocky sites in pine-oak or oak forests, 1400–2200 m. **I:** Irish & Irish (2000: t. 24); Heller (2006: 109); Richter (2011: 130); Pilbeam (2013: 82, as *A. filifera* ssp.); Hochstätter (2015: VII: 41, 47, as *A. filifera* ssp.). – Fig. 41.

≡ *Agave filifera* ssp. *multifilifera* (Gentry) B. Ullrich (1992).

[1d] **Ros** ±1 × 1.5 m, solitary, not surculose, with a short trunk at maturity; **L** 200 or more, linear-lanceolate, erectly ascending to declined, broadest at the base, firm but pliable, slightly convex below, flat above, smooth, 50–80 × 1.2–3.5 cm, light green, margins with numerous long detaching fibres; **terminal Sp** long, subulate, flattened above, 10–15 mm, castaneous to aging grey; **Inf** to 5 m, ‘spicate’, fertile from just above the longest leaves, part-**Inf** with 2 (–3) flowers; floral **Bra** ±8 cm in the lowest flowers, greyish, subulate, higher up shorter; **Ped** short, thick; **Fl** 40–43 mm; **Tep** pale waxy green with pink tinge on the lobes, buds green with lavender luster, tube shortly funnel-shaped, 5 × 10 (at the apex) mm, the nectariferous tissue ± filling the tube, lobes narrowly elliptic, some erect, some recurving at anthesis, apiculate, subequal, 16–17 mm, the papillate area broad and decurrent on the inner lobes, outer lobes narrower, 5–5.5 mm wide, and also with a low keel; **Fil** long, slender, elliptic in cross section, 35–40 mm, red; **Anth** 16–17 mm, yellow; **Ov** fusiform, 20–21 mm, neck 5 mm, constricted, faintly grooved; **Sty** slender, whitish; **Sti** slightly thickened; **Fr** slenderly ovoid, 20–25 × 10–12 mm, apiculate; **Se** 3.5–4.5 × 2.5–3 mm, hilar notch abrupt, the curved margin with a wrinkled or erose winglike edge.

One of the most robust taxa in Sect. *Littaea* (as Group *Filiferae*), differing from the other species related to *A. filifera* mainly by its larger dimensions, its higher leaf number and its short and broad floral tube. See also the note for *A. schidigera*. Ullrich (1992h) reduced *A. multifilifera* and also *A. schidigera* to subspecies of *A. filifera*, but his reclassification was not followed by Vázquez-García & al. (2007b: 71), Starr (2012) and Govaerts (2014+). Gentry’s two “holotype” sheets at US are not cross-labelled thus representing syntypes.

The leaves are an important source of fibre, and the hearts and leaf bases are pit-baked and eaten or made into “mesagoli” (mescal bread) or “sugui” (alcoholic beverage) (Bye & al. 1975: 97).

**A. murpheyi** F. Gibson (Contr. Boyce Thompson Inst. Pl. Res. 7: 83, fig. 1, 1935). **Type:** USA, Arizona (Gibson s.n. [Herb. Boyce Thompson Arboretum]). — **Lit:** Gentry (1972: 99–101, with ills.); Gentry (1982: 440–443, with ills.); Nabhan (1995: with ills.); Adams & Adams (1998: with ills.); Hodgson (1999b); Reveal & Hodgson (2002); Parker & al. (2007); Klopper & al. (2010: 61–62); Parker (2018a: 22–23). **Distr:** USA (C & S Arizona), Mexico (NW Sonora); near drainage systems in desert scrub, around pre-Columbian living sites, 400–1000 m; flowers March to July. **I:** Irish & Irish (2000: tt. 25–26); Pilbeam (2013: 137); Hochstätter (2015: III: 11).

[2h] Acaulescent; **Ros** compact, 0.6–1.2 × 0.8–1.4 m, caespitose, freely suckering; **L** numerous, linear-spatulate, ascending, firm, thin, straight, thickish and convex towards the base, broadest just in the middle, short-acuminate, convex towards the base below, concave towards the apex above, 50–80 × 6–10 cm, light glaucous-green to yellowish-green, frequently lightly cross-zoned, with clearly visible impressions left by the central bud, margins repand; **marginal teeth** regular, single, mostly curved to the margin, or upcurved, small, mostly 3–4 mm, dark brown to black or grey, ±10–20 mm apart; **terminal Sp** conical, thick, very shortly grooved or flattened above, short, 12–20 mm, dark brown to pruinose-grey, decurrent for 3.5–5 cm to the uppermost teeth; **Inf** 3–4 m, paniculate, peduncle thickish, green, with persistent triangular **Bra** 10–15 cm long, fertile part narrow, part-**Inf** (slightly) ascending, compact, short, 10–16 in the upper ¼ or ⅓ of the inflorescence, with 12–21 flowers, > 10 cm, freely bulbiferous, rarely producing fruits; **Fl** thick, stout, (51–) 60–75 mm; **Tep** cream, tips purplish to brownish, tube deep, urceolate, 14–20 × (11–) 14–19 mm, lobes erect, leathery, unequal, (14–) 15–20 × 4–7 mm, outer somewhat larger, with roughened thick brownish hooded tip, all tepals slightly clasping the filaments; **St** long-exserted; **Fil** erect, (33–) 45–50 mm, yellow, inserted

unequally at or slightly above mid-tube, cream to pale yellow; **Anth** (16–) 22–26 mm, yellow; **Ov** (18–) 22–40 mm, neck slightly constricted, 0.5–3 (–6) mm; **Fr** rarely produced, obovoid to oblong or ovoid, 50–70 mm, apex short-beaked, shortly pedicellate; **Se** (7–) 9–11 × 6 mm. — **Cytology**:  $2n = 60$  (Pinkava & Baker 1985).

A cultigen derived via domestication, cultivated from ±600 to 1350 CE and used as food by the ethnic group of the Hohokam. The plants persisted as relict clones up to the present, always associated with pre-Columbian living sites of native Americans (Nabhan 1995; Parker & al. 2007). Genetic studies by Parker & al. (2007) showed that the genetic variability is lower than in purely wild species and comparable to modern agricultural crops, but the species is not derived from a single clone, and its genetic variation does not follow a geographic pattern, possibly resulting from genetic exchange by bulbils and seeds. It is of conservation concern.

Hybridization with *A. chrysantha* is known from Arizona (Gentry 1982, Reveal & Hodgson 2002). *A. murpheyi*, *A. verdensis* and *A. yavapaiensis* are the sole species among the pre-Columbian cultivar species in Arizona which (rarely) develop ripe fruits and seeds (fruits of *A. delamateri*, *A. phillipsiana* and *A. sanpedroensis* are unknown). For notes on further pre-Columbian cultivar species in Arizona, see *A. verdensis*. — ‘Rodney’ is a variegated cultivar with yellow leaf-margins (Moore 2016: 242).

**A. nanchitlensis** (Matuda) Thiede & Govaerts (Phytotaxa 306(3): 238, 2017). **Type**: Mexico, México (Matuda 37640 [MEXU, CODAGEM, UAMIZ]). — **Lit**: Matuda (1974); Piña Luján (1986: 14); Ullrich (1989b); García-Mendoza (2003); Castillejos-Cruz (2009: [216]–[220]); all with ill. and as *Manfreda*. **Distr**: Mexico (México); rocky sloping oak or pine-oak forests, 1600–2100 m; flowers October to January. **I**: Hochstätter (2016: I: 31).

≡ *Manfreda nanchitlensis* Matuda (1974).

[3a2] Plants herbaceous, small (for Subgen. *Manfreda*), daughter **Ros** arising in the axils of the current year’s rosette; corm 2.5–4.5 × 1.5–3 cm, cylindrical, bulb 1.2–6.8 × 2.5–3.2 cm,

cylindrical, completely covered with dried fibrous leaf bases 6–9 cm long; **R** fleshy and fibrous, with filiform ramifications, contractile; **L** drought-deciduous, 4–10, spreading, recurved, linear, thick, canaliculate, papillose on both faces, apex obtuse, 20–30 × 0.4–0.8 cm, shiny green, with abundant purple dots near the base, margins entire, with a hyaline band; **Inf** 40–95 (–150) cm, erect, green-glaucous, ‘spicate’, peduncle with 7–10 **Bra**, base truncate, increasingly smaller upwards, fertile part 10–20 (–25) cm, lax, with 7–10 flowers; floral **Bra** 5–8 × 1 mm; **Fl** 28–31 mm, solitary, sessile, diffuse to divaricate; **Tep** yellowish-green to reddish-green on the outer face, forming a tube (16–) 22–30 × 4–5 mm, sparsely recurved, lobes oblong, revolute, 9–14 × 3–4 mm, tip cucullate, with a bundle of short white trichomes; **Fil** 27–37 mm, somewhat flattened, erect at anthesis, exceeding the tube for 22–32 mm, inserted near the mouth of the tube all on the same level, yellowish-green with purple dots; **Anth** 10 mm, greenish-yellow; **Ov** oblong, 11–16 × 3–5 mm, green-glaucous, not extending into tube, slightly constricted above; **Sty** 54–62 mm, yellowish-green; **Sti** 3-lobed; **Fr** cylindrical to ellipsoid, 22–27 × 10–20 mm, apiculate, with persistent perianth; **Se** deltoid, plane-concave, 3–4 × 3 mm, shiny.

According to Verhoek-Williams (1975: 289), this is the most slender species in Sect. *Herbaceae* (as *Manfreda*) and thus easily recognized by its nearly grass-like leaves, its lax inflorescence, and its long narrow floral tube. Only *A. graminifolia* (not covered by Verhoek-Williams) has even narrower leaves. — The combination under *Agave* was first published invalidly by Thiede & Egli (1999) and was later validated as given above.

**A. nashii** Trelease (Mem. Nation. Acad. Sci. 11: 45–46, tt. 101–103, 1913). **Type** [syn]: Bahamas, Inagua (Nash & Taylor 517 [B, MO, NY]). — **Lit**: Berger (1915: 269); Britton & Millspaugh (1920: 76); Correll & Correll (1982: 313–314); Álvarez de Zayas (1995: 40); Acevedo-Rodríguez & Strong (2012: 86); Freid & al. (2014: 218). **Distr**: Bahamas (Great Inagua); in sandy-rocky soils on dry S exposures, in dwarf shrubs and

scrubland; flowers throughout the year. **I:** Hochstätter (2015: VII: 98).

[2t] Acaulescent; **Ros** caespitose, freely suckering; **L** attenuate-oblong, erect, hard, straight, narrow, gradually tapering, guttered, 30–50 × 4–5 cm, grey-green, sometimes purple-tinged, somewhat glaucous and transversely banded; **marginal teeth** straight or somewhat curved, acuminately triangular, sometimes nearly or quite confluent, scarcely 2 mm, usually 3–5 mm apart, intervening margin nearly straight; **terminal Sp** conical, tapered, recurved or upcurved at the tip, smooth, somewhat polished, narrowly slit-grooved to beyond the middle, 15 × 3 mm, purplish-brown, decurrent; **Inf** 3.5–4 m, ‘paniculate’, very lax, part-**Inf** ±6–8, on slender outcurved **Bra** in the upper 1/3 or more of the inflorescence; **Ped** 5–10 mm; **Fl** 35–50 mm; **Tep** yellow to light yellow, tube openly conical, 3 mm, lobes 10 × 3 mm; **Fil** 25 mm, inserted almost in the tube throat; **Ov** subfusiform, or obovoid in development, 16–20 × 5–7 mm; **Fr** oblong or oblong-pear-shaped, 20–35 × 13–20 mm, shortly stipitate, beaked; **Se** 4–5 × 4 mm.

Insufficiently known. The name is based on 3 syntypes, those not shown above are *Nash & Taylor* 1389 and *Nash & Taylor* 21855. — For differences from *A. inaguensis*, the second species of Sect. *Inaguenses*, see there.

**A. nayaritensis** Gentry (Agaves Cont. North Amer., 515–516, ills., 1982). **Type:** Mexico, Nayarit (*Gentry* 21167 [US, ARIZ, DES, MEXU, MICH]). — **Lit:** McVaugh (1989: 139–140); Etter & Kristen (2002: with ills.); Cházaro Basáñez & al. (2005a: with ills.); Etter & Kristen (2007c); Vázquez-García & al. (2007b: 61–62, tt. R2, R3, S); González-Elizondo & al. (2009: 102–103, with ill.). **Distr:** Mexico (S Sinaloa, SW Durango?, Nayarit); volcanic cliff edges in tropical deciduous forests, 350–700 m; flowers March to May. **I:** Cházaro Basáñez & al. (2005a); Richter (2011: 82); Pilbeam (2013: 138); Hochstätter (2015: VI: 22).

[2n] Acaulescent or stems rarely to 10 cm; **Ros** open, 0.7–1.1 × 1.3–1.8 (–2.2) m, solitary, rarely surculose; **L** 9–30 (–40), lanceolate, rather floppy, etiolated when growing in the shade, narrowed

towards the base to 8–10 cm, widest above the middle or at 2/3 of their length, long-acuminate, somewhat asperulous, 85–115 × 12–15 (–18) cm, light green to light yellowish-green, partly with glaucous tinge at the base, margins repand to straight; **marginal teeth** small, 1–4 mm, chestnut-brown or darker, regularly spaced, 3–20 mm apart, sometimes with scattered minute intermittent teeth; **terminal Sp** conical, with a short narrow groove above, sometimes up to the middle, 9–20 mm, dark brown, sometimes black, not decurrent; **Inf** (1.2–) 2–4 m, paniculate, peduncle short, reddish, with large, triangular-lanceolate, chartaceous **Bra**, fertile part diffuse, (long) ovate, part-**Inf** widely spreading, several times compound, 10–15 in the upper 1/2 of the inflorescence, 25–55 cm long; **Ped** short, bracteolate; **Fl** 40–45 mm; **Tep** bright yellow, tube broadly funnel-shaped, shortly grooved, 4 mm, lobes linear from spreading sinuses, erect to slightly incurved, involute, galeate at the tip, rather thin, subequal, 15–17 × 3–4 mm, inner with a small keel; **Fil** 35–37 mm, inserted near the mouth of the tube; **Anth** centric, 15–16 mm, yellow; **Ov** rounded-trigonous, 20–25 mm, neck short, slightly constricted, furrowed; **Fr** opening for the upper 2/3 only, 16–28 × 10–14 mm, dark brown; **Se** with surface pattern, 5 × 3.5 mm, dull black.

Distinguished by its slender green leaves with small marginal teeth and terminal spine, and its broad, diffuse panicle with small, bright yellow flowers with shallow, open tubes, but without close relationship to other members of Sect. *Marmoratae* (as Group) (Gentry 1982). Long known from the type locality in C Nayarit only, the species was recently found at further localities in Nayarit and S Sinaloa (Etter & Kristen 2002, Etter & Kristen 2007c), and these authors also provide additional morphological data. González-Elizondo & al. (2009) tentatively place sterile plants from SW Durango here. Gentry’s “holotype” at US consists of two sheets which were apparently cross-labelled later. — See also the note under *A. karatto*.

**A. neocernua** Thiede (Bradleya 33: 83, 2015). **Type:** Mexico, Jalisco (*Castro-Castro & al.* 2495

[IBUG, IEB, MEXU]). — **Lit:** Castro-Castro & al. (2015: as *Polianthes cernua*, with ills.). **Distr:** Mexico (W Jalisco); in deep and acid soils in open pine-, oak- and juniper-forests, 1700–2120 m; flowers in early August. **I:** Hochstätter (2016: II: 7); Castro-Castro & al. (2016: 721); Castro-Castro (2017: 145); all as *Polianthes cernua*.

≡ *Polianthes cernua* Art. Castro & al. (2015).

[3b2] Herbaceous; corm 0.6–1.9 × 1.1–1.5 cm, oblong, bulb 2–2.6 × 1.5–1.9 cm, ovoid, completely covered with dried fibrous leaf bases; **R** fleshy, thickened, contractile; **L** drought-deciduous, (2–) 3 (–4), sometimes an additional one attached a few cm above the peduncle base, prostrate or slightly elevated from the ground, oblong-obovate, widest at the middle, tapering somewhat abruptly at base and apex, glabrous, apex acute, (6–) 8–12 × 0.6–2.2 (–4.5) cm, shiny green, margins entire, with a hyaline band; **Inf** 45–80 cm, erect, ‘spicate’, greenish, peduncle with 2–3 **Bra**, linear-lanceolate, base truncate, internodes decreasing in size distally, fertile part ±35–38 cm, very lax, with (3–) 4–6 (–10) remote floral nodes; floral **Bra** 6–15 × 2–3 mm; **Ped** 11–17 mm during anthesis, 15–20 mm in fruit, strongly recurved; **Fl** geminate, unscented, 20–25 × 3–6 mm, pendent; **Tep** orange in the lower 2/3, upper 1/3 and lobes yellowish-green, forming a straight tube 16–19 × 4–6 mm at the base of the lobes, lobes broadly ovate, almost equal, erect, imbricate, 2–4 × 2.5–3 mm, margin hyaline, apex of **OTep** obtuse, apex of **ITep** truncate, apices with a bundle of short white trichomes; **Fil** filiform, 14–16 mm, included, inserted 1–1.5 mm above the ovary apex, yellow; **Anth** linear, 4–5 mm, green, at anthesis placed at the upper portion of the mouth of the tube; **Ov** fusiform, 4.5–5 × 2.5–3 mm; **Sty** filiform, 16–20 mm, greenish-orange, exerted from the tube 2–3 mm at anthesis; **Sti** 3-lobed, papillose; **Fr** globose to oblong, 8–20 × 7–11 mm, with persisting tepals; **Se** ovate-depressed, flat, 4–6 × 3–5 mm, black to dark brown, dull.

According to the protologue characterized by its oblong-ovate, prostrate leaves, recurved pedicels, tubular, not curved, bicolorous perianth with imbricate and erect lobes, and morphologically closest to *A. bicolor*, which shares bicoloured flowers, and to *A. coetocapnia* ssp. *clivicola*,

which shares pendent flowers. Hummingbirds were observed as flower visitors; this might also be the case for other red-flowering species of Sect. *Polianthes*. — Upon transfer to *Agave*, a replacement name was necessary due to the earlier name *A. cernua* A. Berger.

**A. ×neokewensis** Thiede (Haseltonia 17: 95, 2012). — **Lit:** Watson (1899a); Anonymous (1910); both as *Bravoa kewensis*. **Distr:** Cultivated only.

**Incl.** *Bravoa ×kewensis* W. Watson (1899).

[3b2] This is the garden hybrid *A. coetocapnia* (as *Bravoa geminiflora*) × *A. bulliana* (as *Bravoa (Prochnyanthes) bulliana*). It was raised at Kew in 1894 and was described as *Bravoa ×kewensis* when it flowered in 1899 (Watson 1899a, Anonymous 1910). Upon transfer to *Agave*, a replacement name was necessary due to *A. kewensis* Jacobi 1866. It is the only hybrid known that involves *A. bulliana* (the only species of the former genus *Prochnyanthes*) as parent. Apparently lost from cultivation.

**A. neonelsonii** Thiede & Egli (Kakt. and Sukk. 50(5): 112, 1999). **Type:** Mexico, Durango (Nelson 4630 [US, GH]). — **Lit:** Rose (1903a: 10); Solano & Ríos-Gómez (2014: 100–101, ill.); both as *Polianthes nelsonii*. **Distr:** Mexico (S Chihuahua, Durango, Aguascalientes); on grassy meadows, slopes or ridges in pine-oak or pine forests, 1900–2500 m; flowers June to August. **I:** Barba-Gonzalez & al. (2012: 124); Hochstätter (2016: II: 19); Castro-Castro & al. (2016: 721); all as *Polianthes nelsonii*.

≡ *Polianthes nelsonii* Rose (1903).

[3b1] Herbaceous; corm 1.2–2 × 1–1.2 cm; bulb 1–3 (–5) × 0.6–1.8 cm, oblong, completely covered with dried fibrous leaf bases; **R** fleshy, thickened, contractile; **L** drought-deciduous, (2–) 4–5 (–7), erect to semi-erect, linear, narrow and grass-like, glabrous, 12–26 (–29) × 0.1–0.7 cm, green, margins serrulate; **Inf** (20–) 25–54 (–61) cm, erect, green, ‘spicate’, peduncle with 2–4 **Bra** much reduced upwards, lowest one (3.5–) 7–20 × 0.1–0.5 cm, fertile part ± (5–) 8–9.5 cm, very lax, with (1–) 2–6 remote floral nodes; floral **Bra** ±4–7 × 2 mm; **Ped** none; **Fl** geminate,

55–63 mm, upright at the base; **Tep** white, then pink, senescent red, forming a tube 30–66 × 2–5 mm, very slender below, greenish at the base grading to whitish or pink near the middle, curved downwards near the middle, mouth strongly oblique, lobes ovate, erect, 2–5 × 1.5–4 mm, apex rounded; **Fil** filiform, 3–9 (–16) mm, included, inserted 25–50 (–60) mm from the apex of the ovary, near the mouth of the tube; **Anth** linear, 4.5–8 (–9) mm; **Ov** fusiform, ±6–8 × 3–4 mm; **Sty** filiform, 35–60 (–73) mm, exerted at anthesis; **Sti** 3-lobed, exerted; **Fr** and **Se** unknown.

For long recorded from the type and paratype collection from Durango only, but Solano & Feria (2007), who studied the geographical distribution and niche modelling of the species, list 74 records from 25 localities in Aguascalientes and esp. in Chihuahua and Durango. A similarly strongly asymmetrical mouth of the tube is found only in *A. confertiflora*. Morphologically also similar to *A. alboaustralis* (see there). The record for Guerrero by Martínez Gordillo & al. (1997: 131) is probably a misidentification for *A. coetocapnia* (= *Polianthes geminiflora*) or *A. producta* (= *P. elongata*), the sole species of Sect. *Polianthes* in that state. *A. neonelsonii* is locally used as ornamental (Barba-Gonzalez & al. 2012: 125). — Upon transfer to *Agave*, *Polianthes nelsonii* needed a new name to avoid homonymy with the earlier *A. nelsonii* Trelease 1912.

**A. nickelsiae** Roland-Gosselin (Rev. Hort. (Paris) 67: 579–580, 1895). **Type**: [neo — icono]: Cact. Succ. J. (US) 32: 36, fig. 22 left, 1960. — **Lit**: Berger (1915: 90, as *A. ferdinandi-regis*); Alsemgeest & al. (2007a: figs. 4 & 6, as *A. victoriae-reginae* fa. *ferdinandi-regis*); González-Elizondo & al. (2011: 78–81); Martínez-Palacios & Eguiarte (2011); Thiede (2011: 151–152); Starr (2012: 154–156); all with ill. except Berger. **Distr**: Mexico (SE Coahuila: only near Saltillo), conglomerate ridges with sparse soil and frequent calcareous rock fragments at the surface, in desert scrub, 1500–1690 m. **I**: Brown (1945: 108, 109, as *A. ferdinandi-regis*); Heller (2006: 14, as *A. victoriae-reginae*; 145, as *A. ferdinandi-regis*); Richter (2011: 131); Roosbroeck (2012: 162);

Pilbeam (2013: 231–232, as *A. victoriae-reginae* fa.); Hochstätter (2015: IX: 55); Walker (2017: 165).

≡ *Agave victoriae-reginae* fa. *nickelsiae* (Roland-Gosselin) Trelease (1920); **incl.** *Agave victoriae-reginae* var. *laxior* A. Berger (1912); **incl.** *Agave ferdinandi-regis* A. Berger (1915) ≡ *Agave victoriae-reginae* fa. *ferdinandi-regis* (A. Berger) Alsemgeest & al. (2007) (*nom. inval.*, ICN Art. 41.5).

[lg] Acaulescent or with short invisible stem; **Ros** to 75 × 65 cm, subcompact or open, caespitose, rarely solitary, not surculose; **L** 170–280, oblong, narrowing gradually towards the apex, not incurved, 13–23 × 5.5–8.5 cm, white bands inconspicuous at the rounded tip, turning black towards the terminal spine, dorsally keeled in the upper part, ventrally concave except towards the base, there thickened and strongly convex to keeled, greyish-green to dull green, with white bands 1 (–2) mm broad on both faces and the margins, puberulent, margins horny, white, entire, continuous over the whole length, sometimes separating in the upper part, 3–5 mm wide; **marginal teeth** none; **terminal Sp** pyramidal to lanceolate, thick, 20–28 mm, broadly channelled above and roundly keeled below, nearly black, base broad, strongly decurrent along the leaf margins, usually with 3 adjacent teeth; **Inf** erect, 4.5–6.5 m, ‘spicate’, peduncle robust, with several chartaceous deltoid **Bra**, part-**Inf** usually with 3 flowers; **Ped** short, thick; **Fl** 58–65 mm; **Tep** cream-white or greenish-white, tinged purple at the apex, tube funnel-shaped, 3–5 × 8–9 mm, lobes extended, subequal, broadly linear, 18–22 × 4–6 mm, flat towards the apex, inner somewhat keeled; **Fil** 60–66 mm, inserted above the throat of the tube, with purple tinge; **Ov** thickly fusiform, 18–21 mm, neck short; **Fr** and **Se** unknown. — **Cytology**: 2n = 60, 120, 180 (Zonneveld 2003).

A recent study of the *A. victoriae-reginae* complex by González-Elizondo & al. (2011) re-established *A. nickelsiae*, better known as *A. ferdinandi-regis*, as a separate species and published the similar, completely new *A. pintilla*. Both have open to subcompact rosettes with greyish-green to pale green or bluish-green leaves. *A. nickelsiae* differs by having 170–280

**Fig. 42** *Agave nizardensis* (Etter & Kristen 3892: Mexico; Oaxaca, near Nizanda, 190 m). (Copyright: J. Etter & M. Kristen)

grey-green to dull green, puberulent, oblong leaves with a strong, decurrent terminal spine (vs. 60–180 green to bluish-grey-green, narrowly triangular, not puberulent leaves with a not or hardly decurrent terminal spine in *A. pintilla*). Almaraz-Abarca & al. (2013c) investigated the phenol composition of these taxa and found *A. pintilla* to be well-characterized chemically, while *A. nickelsiae* is very similar to *A. victoriae-reginae*.

For the history and introduction, see Thiede (2011). The species forms natural hybrids esp. with *A. asperrima* (see *A. × saltilloensis*) and also with *A. lechuguilla*. In contrast to *A. victoriae-reginae* which mainly propagates by seeds, *A. nickelsiae* propagates mainly clonally with rhizomes, and flowers only rarely (González-Elizondo & al. 2011). The reason may be that cross-pollination between individuals in the diploid *A. victoriae-reginae* is unimpeded, but limited between di-

tetra- and hexaploid individuals of *A. nickelsiae* (Thiede 2011).

The neotypification by Gentry (1982: 185, as *A. victoriae-reginae* fa. *nickelsii*) wrongly cites the figure and page number from the collective reprint of Breitung's series of papers (Breitung 1968) (p. 26, fig. 53 [correct is 55]), rather than from Breitung (1960: 36, fig. 22 left).

**A. nizardensis** Cutak (Cact. Succ. J. (US) 23(5): 143–145, ill., 1951). **Type:** Mexico, Oaxaca (Cutak 19 [MO]). — **Lit:** Breitung (1960: 182–183, with ill.); Gentry (1982: 75); Palma Cruz (1991: 123–125); Ullrich (1991i: with ill.); García-Mendoza (2003: with ill.). **Distr:** Mexico (Oaxaca: Nizanda); steep slope in crevices and pockets of limestone rocks in tropical deciduous forests, 120–350 m. **I:** MacDougall (1960); Heller (2006: 14, 111); Richter (2011: 61); Pilbeam (2013: 140). – Fig. 42.

[1b] Acaulescent; **Ros** open, small, unarmed, surculose; **L** 8–15, linear-lanceolate, ± patent and nearly horizontally spreading, sparsely fibrous, rather brittle or pliable, ± straight, convex below, flat above, tapering gradually from the broad base to the rounded tip, 20–35 × 1–1.5 (–2.5) cm, green with distinct pale midstripe, margins finely serrulate with irregular deltoid whitish denticles; **marginal teeth** none; **terminal Sp** conical, not pungent, small, 3–8 mm, reddish; **Inf** 1–2 m, 'spicate', peduncle slender, glaucous, with numerous ascending oblong-lanceolate **Bra** 4–10 cm long, fertile part to 25 cm, in the upper ¼, sparsely flowered, part **Inf** 5–10, more remote below and few densely arranged at the tip, with 2–4 flowers; **Ped** geminate, 6–10 mm, bracteolate; **Fl** 23–33 (–40) mm; **Tep** greenish-yellow to pale yellow, tube shortly funnel-shaped, 3–4 mm, lobes narrowly elliptic to lanceolate, ascending, involute, subequal, 15–16 mm, outer more apiculate and narrower (4 mm wide) than inner; **Fil** 35–40 mm, inserted at the mouth of the tube; **Anth** centrally affixed, 13–14 mm, grass-green to yellow; **Ov** cylindrical, 7–12 (–15) mm, neck short, not constricted; **Sty** longer than the filaments; **Sti** capitate, 3-lobate; **Fr** globose, 10–19 × 12–16 mm, dark brown, thin-walled, unripe green with glaucous hue; **Se**

5–6 × 2–4 mm, crescent-shaped. — **Cytology:**  $n = 60$  (Gómez-Pompa & al. 1971; Simpson & al. 2011).

According to Gentry (1982) a very distinct species without close relatives, only known from around the type locality Nizanda and few collections ±5 km N- to E-wards. It does not fit well into any section or group but was nonetheless placed in Sect. *Inermes* (as Group *Amolae*) (Gentry 1982). This prompted Ullrich (1991i) to erect the monotypic Sect. *Nizandensae* for the species, but this is not followed here.

The taxon was discovered by MacDougal in February 1939 (MacDougal 1971: 3) and later reintroduced by him (MacDougal 1960). Molecular data (Gil-Vega & al. 2007) place the species closest to *A. spicata* (as *A. yuccaefolia*) and close to other members of Sect. *Inermes* (as Group *Amolae*). Glass (1983) depicts a hybrid of cultivated origin with *A. striata* ssp. *falcata* (as *A. falcata*).

**A. nuusaviorum** García-Mendoza (Acta Bot. Mex. 91: 78–80, ills., 2010). **Type:** Mexico, Oaxaca (García-Mendoza & al. 9204 [MEXU, ENCB, IEB, MO, OAX, US]). — **Lit:** García-Mendoza (2011a: 39–43, with ills.). **Distr:** Mexico (NW Oaxaca).

**Incl.** *Agave nussaviorum* García-Mendoza (2010) (*nom. inval.*, ICN Art. 61.1).

García-Mendoza (2011a) corrected the original spelling of the epithet ‘nussaviorum’ as shown above, since it derives from “ñuu savi” (= land of clouds), the local name for the Mixteca Alta region and its inhabitants, according to the protologue.

**A. nuusaviorum** ssp. **deltoidea** García-Mendoza (Acta Bot. Mex. 91: 83–85, ills., 2010). **Type:** Mexico, Oaxaca (García-Mendoza & Martínez 6051 [MEXU, OAX]). — **Lit:** García-Mendoza (2011a: with ills.). **Distr:** Mexico (Oaxaca); igneous rocky sites, 2400–2600 m; flowers September to October. **I:** Pilbeam (2013: 142).

[2o × 1g?] Differs from ssp. *nuusaviorum*: **L** deltoid to broadly lanceolate, 20–40 × (8–) 14–20 (at the base) cm, margins entire, straight, horny or rarely dentate; **marginal teeth** (1–) 4–5 mm, from

bases (6–) 10–13 mm broad, retrorse, appressed to the margin or rarely free and recurved, greyish, 10–20 mm apart; **terminal Sp** (40–) 60–100 × 5–8 mm, greyish, dorsally channelled, decurrent for 10–14 cm or continuous with the leaf margins.

Occurring in the same region as ssp. *nuusaviorum*, but in a different habitat with different soil and at higher altitude. The intermediate, ‘racemose’ inflorescence of ssp. *deltoidea* suggests that it might have arisen as hybrid or allopolyploid between taxa of Subgen. *Agave* and Subgen. *Littaea*. If *A. nuusaviorum* should indeed be of allopolyploid intersubgeneric hybrid origin (see under ssp. *nuusaviorum*), ssp. *deltoidea* might have arisen independently and should then be recognized at species rank.

**A. nuusaviorum** ssp. **nuusaviorum** — **Lit:** García-Mendoza (2011a). **Distr:** Mexico (Oaxaca); flats or hill slopes on soils derived from calcareous rock or sandstone, in pine or pine-oak forests or dry scrub, 1700–2500 m; flowers late August to December. **I:** Pilbeam (2013: 141); Meer (2016b: 154).

[2o × 1g?] Acaulescent; **Ros** solitary, open to compact; **L** 25–40, lanceolate, oblong to ovate, erect to recurved, flexible, somewhat concave towards the middle and apex, (12–) 20–40 × (5–) 7–11 cm, greenish-yellow, glaucous towards the base, margins crenate, prominences conspicuous towards mid-leaf, 5–10 mm, variably curved; **marginal teeth** retrorse, antrorse or straight, (5–) 8–12 × (5–) 8–10 mm, chestnut-brown to greyish, 20–35 mm apart, narrower and smaller towards the base, with broad base covering the tip of the prominences, sometimes with intermittent denticles; **terminal Sp** sinuous to straight, channelled above, 20–30 (–40) × 3–5 (–8) mm, chestnut-brown to greyish, decurrent for 1–2 cm; **Inf** (1.5–) 3–5 (–6) m, ‘racemose’, peduncle greenish to purple, with triangular, reddish-brown **Bra** 12–17 cm long, fertile part  $\frac{1}{3}$ – $\frac{1}{6}$  of the inflorescence, congested, part-**Inf** 20–40 (–60), ‘umbellate’, with 6–12 flowers, 3–5 cm apart, stalk <3 cm; **Ped** 2–5 (–10) mm; **Fl** slightly campanulate, 45–55 (–70) mm; **Tep** yellowish with purple tinge, tube slightly sulcate, 7–10 (–13) × 7–10 (at the tip) mm, lobes triangular or oblong,

thickish, 15–25 × 2–5 mm, subequal, outer slightly larger, margins involute, apex cucullate, hard, inner keeled; **Fil** (25–) 35–45 (–55) mm, inserted 2–3 mm below the lobe bases, yellowish with purple tinge; **Anth** 20–25 × 2 mm, yellowish; **Ov** cylindrical, 23–30 (–35) × 4–6 mm, green, neck 2–3 (–5) mm; **Sty** 40–60 mm; **Sti** clavate, 3-lobate; **Fr** oblong to ovoid, 40–60 × 20–25 mm, rostrate, stipitate; **Se** crescent-shaped, flat, 5–6 × 4–5 mm, with narrow wings, black.

In the protologue the species is placed in Gentry's Group *Hiemiflorae* (now Sect. *Guatemalenses*) and compared with *A. potatorum* and *A. seemanniana*. It is most similar to the former from which it differs in its much more open rosettes with fewer, greenish-yellow leaves, and esp. in its 'racemose' inflorescences. The intermediate, 'racemose' inflorescence suggests that *A. nuusaviorum* might have arisen as hybrid between species of Subgen. *Agave* and Subgen. *Littaea*, and the protologue gives *A. potatorum* (Subgen. *Agave*) and *A. convallis* or *A. angustiarum* (Subgen. *Littaea*) as possible parents. The hybrid hypothesis is unlikely, however, as the taxon has a relatively broad distribution, and the putative parents are absent at many localities. *A. nuusaviorum* could be of allopolyploid origin and would then be tetraploid, which is consistent with the observation that it propagates by seed. The hybrid hypothesis was accepted by Etter & Kristen (1997+; accessed Oct. 2018), who list the taxon as *A. ×nuusaviorum*.

**A. oaxacana** (García-Mendoza & E. Solano) Thiede (Haseltonia 17: 95, 2012). **Type:** Mexico, Oaxaca (García-Mendoza & Solano 6970 [MEXU]). — **Lit:** García-Mendoza & Solano (2007: as *Polianthes*). **Distr:** Mexico (Oaxaca); mountain slopes, in pine-oak forests, 2390–2600 m; flowering September to October. **I:** Hochstätter (2015: II: 20, as *Polianthes*).

≡ *Polianthes oaxacana* García-Mendoza & E. Solano (2007).

[3b2] Herbaceous; corm cylindrical, (1.5–) 4–5 × 1–2 cm, with leaf scars, bulb ovoid, 5–8 × 2–3 cm, covered with dried fibrous leaf bases; **R** thickened, 8–12 cm, contractile; **L** 3–4, linear, semisucculent, curved, attenuate, tip acute,

slightly thickened, (40–) 60–70 × 1–1.5 (–2) cm, green, base whitish, margins hyaline, microscopically papillose, sometimes reddish; **Inf** erect, 'spicate', 1.4–1.8 m, peduncle 1.2–1.5 m, with 6–7 **Bra** similar to the leaves, fertile part 10–30 cm, with 3–7 laxly arranged flowering nodes; **Fl** sessile, geminate, 45–52 mm, zygomorphic, unscented; **Tep** tube ascending at the base, curved in the middle, broadly dilatated distally, throat campanulate, (30–) 38–42 × 10–14 mm, lobes ovate to orbicular, subequal, 5–7 × 4–6 mm, distally rose outside, yellowish inside, with violet tinge when dry, apex cucullate, acute to apiculate, slightly thickened, papillose; **St** included; **Fil** 10–12 mm, inserted at different heights near the throat, lower (15–) 20–21 mm above the ovary, upper (20–) 25–27 mm, rose; **Anth** linear, (7–) 9–10 mm, greenish-yellow, at anthesis appressed to the upper part of the throat; **Ov** (6–) 9–13 × 4–6 mm, slightly prolongating into the tepal tube; **Sty** filiform, 35–42 mm, whitish-yellow, included; **Sti** 3-lobed; **Fr** oblong to globose, 15–20 × 13–16 mm; **Se** deltoid to semicircular, flat, 4–6 × 3.5–4 mm.

Belonging to Ser. *Bravo* of Sect. *Polianthes* according to the protologue, and characterized by sessile flowers with a tube ascending at the base, curved in the middle, and campanulate above that is rose outside and yellowish inside. This makes *A. oaxacana* intermediate between the Ser. *Polianthes* and Ser. *Bravo*, but its stamen insertion and the colour of the unscented flowers argue for a placement in the latter.

**A. obscura** Schiede (Linnaea 5: 464, 1830). **Type** [neo]: Mexico, Veracruz (Gentry & al. 20417 [US, ASU, DES, MEXU]). — **Lit:** Berger (1915: 49–50, 51–53, as *A. obscura* & *A. densiflora*); Cházaro Basáñez (1981); Gentry (1982: 230, as *A. polyacantha* & var. *xalapensis*); Ullrich (1990j); Ullrich (1992f); Alsemgeest & al. (2006b); Jimeno-Sevilla (2010: 379–380); all with ill. except Berger. **Distr:** Mexico (W-C Tamaulipas, C San Luis Potosí, N & W-C Veracruz, N & C Oaxaca); in pine and oak forests or on volcanic lava flows ('malpais') with pines, rarely epiphytic, 1000–2440 m; flowers May to July. **I:** Curtis's Bot. Mag. 83: t. 5006, 1857, as

*A. densiflora*; Heller (2006: 112); Pilbeam (2013: 143); Hochstätter (2015: IX: 8).

**Incl.** *Agave densiflora* Hooker (1857)  $\equiv$  *Agave polyacantha* var. *densiflora* (Hooker) A. Terracciano (1885); **incl.** *Agave chloracantha* Salm-Dyck (1859); **incl.** *Agave uncinata* Jacobi (1865); **incl.** *Agave xalapensis* Roezler ex Jacobi (1865)  $\equiv$  *Agave polyacantha* var. *xalapensis* (Roezler ex Jacobi) Gentry (1982); **incl.** *Agave brauniana* Jacobi (1866)  $\equiv$  *Agave chloracantha* var. *brauniana* (Jacobi) A. Terracciano (1885); **incl.** *Agave muilmannii* Jacobi (1870); **incl.** *Agave micracantha* Baker (1872) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave flaccifolia* A. Berger (1915); **incl.** *Agave densiflora* var. *angustifolia* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave densiflora* var. *foliis striatis aureis* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave hookeri* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave myriacantha* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a).

[1f] **Ros** openly spreading, medium-sized, single or caespitose; **L** lanceolate-acuminate to oblong short-acuminate or more ovate, straightly ascending to upcurving, tissue firm, finely fibrous, lamina narrowed above the base, broadest in the middle, usually flat, 35–65  $\times$  7–12 cm, green or yellow-green, passing into glaucous, margins generally straight, not horny except for the thinly decurrent terminal spine; **marginal teeth** deltoid, sometimes curved up or down, 2–6 mm, reddish to coffee-brown or dark brown, 5–12 mm apart, occasionally with small intermittent teeth; **terminal Sp** acicular, straight, small, rounded below and above, sometimes flatly grooved above, 5–35 mm, dark or reddish brown; **Inf** 2–3 m, ‘spicate’, stout, peduncle with long-caudate deltoid **Bra**, fertile part laxly or densely flowered, in the upper  $\frac{1}{3}$ – $\frac{1}{2}$ , rarely bulbiferous; **Ped** stout, 2–3 mm; **Fl** 46–51 mm, mostly geminate; **Tep** reddish, tube funnel-shaped, scarcely grooved, smooth, glandular-thickened at the filament strands and between, 7–9  $\times$  9 mm, lobes unequal, lanceolate, ascending to outcurved, 19–23  $\times$  5 mm, **OTep** rounded on the back, **ITep** usually narrower, with large keel, keel broad at the base,

long tapering to the tip; **Fil** 50–70 mm, reddish, inserted on the rim of the tube; **Anth** nearly centric, 19–21 mm; **Ov** cylindrical, 17–20  $\times$  7 mm, green, neck short, not constricted; **Fr** obovoid, 18–24  $\times$  10 mm, constricted at the base, obtuse at the tip, dark brown; **Se** crescent-shaped, 3.5–4  $\times$  2–3 mm, dull black, hilar notch on the rounded end, marginal wing low. — **Cytology**: 2n = 60 (Gómez-Pompa & al. 1971, Simpson & al. 2011, both as *A. xalapensis*).

Schiede (1830) collected his reddish-flowered *A. obscura* on the malpais (lava flow) W of Xalapa between La Joya and Las Vigas in W-C Veracruz, which information is repeated by Cházaro Basáñez (1981), Ullrich (1990j), and Ullrich (1992f). Trelease (1920: 137), Breitung (1959: 146) and Gentry (1982: 161) misapplied the name to a plant occurring  $\pm$ 30 km SW from that region between El Limón (in W-C Veracruz) and Zacatepec (in E-C Puebla). Gentry (1982: 230) used the name *A. polyacantha* var. *xalapensis* for Schiede’s plant from between La Joya and Las Vigas, but *A. xalapensis* actually represents a later synonym of Schiede’s *A. obscura*. The plants from between El Limón and Zacatepec are closest to *A. horrida* (Cházaro Basáñez 1981) and, since they were as yet without name, were published as *A. horrida* ssp. *perotensis* by Ullrich (see under that name).

In the concept applied here (following Ullrich (1990j) and Ullrich (1992f)), *A. obscura* encompasses *A. polyacantha* and its var. *xalapensis sensu* Gentry (1982). Ullrich (1990j: 81) designated the Gentry collection from Las Vigas cited above as neotype for *A. obscura*. The neotype designated by Gentry (1982: 161) for his “*A. obscura*” is in conflict with the protologue of the species, as shown above, and was chosen by Ullrich (1990j) as holotype for his *A. horrida* ssp. *perotensis*. *A. obscura* differs from other species in Sect. *Micracanthae* (as Group *Polycephalae*) in that its leaves are firmly fleshy and not soft, and that its tepal tube and ovary are not markedly furrowed, and its ovary is not 3-angled (see key in Cházaro Basáñez & Vázquez-García (2013)).

*A. polyacantha* Haworth 1821, published with black spines and unknown inflorescence, was compared with the Caribbean *A. vivipara* of Subgen. *Agave*, cannot be applied with certainty and

**Fig. 43** *Agave ocahui* var. *ocahui* (Etter & Kristen 660: Mexico; Sonora, near Matape, 800 m). (Copyright: J. Etter & M. Kristen)

the name should be abandoned (Ullrich 1990j). For *A. engelmannii*, placed in the synonymy of *A. polyacantha* by Gentry (1982: 228), see under *A. ×engelmannii*.

**A. ocahui** Gentry (US Dept. Agric. Handb. 399: 72–76, ills., 1972). **Type:** Mexico, Sonora (Gentry & Arguelles 16637 [US [syn], ARIZ, DES, MEXU, MICH]). — **Lit:** Gentry (1982: 75–79, with ills.). **Distr:** Mexico (Sonora).

Related to other Sonoran species of Sect. *Inermes* (as Group *Amolae*) (*A. vilmoriniana*, *A. chrysoglossa*), based on the smooth narrow leaves with unarmed margins, the prolifically flowering inflorescences and the small, slender, yellow flowers with shallow tubes and tepals clasping the filaments (Gentry 1982: 78). — The “holotype” at US consists of 2 sheets, which are not cross-labelled, and thus represent syntypes.

**A. ocahui** var. **longifolia** Gentry (Agaves Cont. North Amer., 78, ills. (p. 79–80), 1982). **Type:** Mexico, Sonora (Gentry 11610 [US, ARIZ, DES, MEXU]). — **Lit:** Etter & Kristen (2001: with ills.); Starr (2012: 158). **Distr:** Mexico (E-C Sonora); scattered in the mountain region in woodland or on volcanic or limestone rocks, 460–1370 m; flowering February. **I:** Pilbeam (2013: 145); Hochstätter (2015: VII: 24, as ssp.).

≡ *Agave ocahui* ssp. *longifolia* (Gentry) Hochstätter (2015).

[1b] Differs from var. *ocahui*: Stem thick and round; **L** linear-lanceolate, straightly ascending or recurving, sometimes falcate, mature **L** 60–80 (–90) × 2–3 (near the base) cm.

These larger, more robust and longer-leaved plants maintain these features even when cultivated together with the shorter-leaved var. *ocahui*. Varietal status is appropriate since they appear not to be geographically isolated from var. *ocahui* (Gentry 1982: 78–79).

**A. ocahui** var. **ocahui** — **Lit:** Gentry (1982: 75–78); Etter & Kristen (2001); Starr (2012: 157–161); all with ills. **Distr:** Mexico (NE Sonora); cliffs and outcrops of volcanic rocks, 460–1370 m; flowering April to June. **I:** Irish & Irish (2000: t. 28); Heller (2006: 17, 113); Pilbeam (2013: 144); Hochstätter (2015: VIII: 24); Moore (2016: 71). – Fig. 43.

[1b] Stems short; **Ros** dense, green, *Yucca*-like, 0.3–0.6 (–0.9 in cultivation) × 0.3–0.6 (–0.9 in cultivation) m, solitary; **L** numerous, linear-lanceolate, erect to ascending, some older leaves declined or falcate, mostly stiff, widest at the base, flat above, surface smooth, minutely and densely punctate in fine lines, 25–50 × 1.5–2.5 cm, green, margins straight, lined with a narrow reddish-brown firm border detachable in dry leaves; **marginal teeth** none; **terminal Sp** weak, rather brittle, 10–20 mm, pruinose-grey over brown; **Inf** slender, 3–4.5 m, ‘spicate’, peduncle with numerous narrow chartaceous **Bra**, densely flowered from 1–1.5 m

above the base, part-**Inf** with geminate flowers; **Fl** 30–38 mm; **Ped** short; **Tep** yellow, tube broadly funnel-shaped, 2–4 mm, lobes oblong, subequal, tips abruptly acute, outcurving, clasping the filaments after anthesis, 14–16 × 4.5 mm; **Fil** inserted at the tepal base, 35–40 mm, pale yellow; **Anth** centric, 10–15 mm, yellow; **Ov** 15–20 mm, neck constricted; **Sty** thick, clearly longer than the tepals; **Sti** capitate; **Fr** small, ovoid, 12–15 × 7–8 mm, apiculate, tardily dehiscent, yellowish-tan to reddish; **Se** small, crescent-shaped, rather thick, 2.5 × 1.5–1.7 mm.

Young plants can be confused with *A. × arizonica* (with shorter leaves), *A. pelona* (with leaves 2× broader and turning purplish in sun, and with white margins and a much longer terminal spine), young *A. chrysoglossa* (with fewer, thicker and longer leaves), and also with young plants traded as “*A. × romani*” (see there) (with broader, more guttered and glaucous green leaves). ‘Blue Glow’ is a hybrid with *A. attenuata* (Starr 2012: 56–58, ills.).

**A. occidentalis** (Art. Castro & Aarón Rodríguez) Thiede & Gideon F. Smith (Bradleya 37: 262, 2019). **Type:** Mexico, Jalisco (*Rodríguez & al.* 5924 [IBUG, CIIDIR, IEB, MEXU, SLPM]). — **Lit:** Castro-Castro & al. (2017: with ills., as *Manfreda*). **Distr:** Mexico (S Nayarit, W Jalisco); ecotone between oak and pine forests, subdeciduous tropical forests, and savannoid vegetation, 700–1000 m; flowers in August.

≡ *Manfreda occidentalis* Art. Castro & Aarón Rodríguez (2017).

[3a3] Plants herbaceous; corm (2.9–) 4.5–5.6 (–13.5) × 1.4–2.4 (–5) cm, oblong-ovoid, bulb 2–2.6 × 1.5–1.9 cm, oblong-ovoid, completely covered with dried leaf bases ±3–6 cm long; **R** fleshy, cuneiform, 7–17 cm long, with filiform ramifications, contractile; **L** drought-deciduous (?), 4–7 (–10), erect, lanceolate to oblong-elliptic, widest in the middle and tapering at both ends, thin to leathery, canaliculate, papillate on the veins on both faces, apex acute, not pungent, formed by the involute lamina, 48–83 × 1.8–4.5 cm, dull green, margins with a hyaline band, finely denticulate-erose under magnification; **Inf** (60–) 90–190 (–220) cm, erect, greenish, ‘spicate’, peduncle with 6–10 **Bra**, 2 lower ones larger,

similar to vegetative leaves, fertile **Inf** part 7–28 cm, dense, with 15–30 flowers; floral **Bra** triangular to subulate, 7–18 × 2–6 mm, truncate, soon drying, frequently deciduous; **Fl** 18–25 mm, solitary, sessile (rarely to 0.2–0.5 mm pedicellate), ascending to diffuse; **Tep** yellowish with light purple stripes, perianth as a whole funnel-shaped, tube 3–5 × 2–4 mm, straight, lobes lanceolate, reflexed, 10–15 × 2–4 mm (measurements corrected, given too small in the protologue), tip papillate; **Fil** 14–25 mm, subulate, inserted 3–7 mm above the ovary apex, yellow; **Anth** 9–11 mm, green and red striate, helicoidal after dehiscence; **Ov** oblong-ovoid, 5–7 × 3–4 mm, greenish, protruding 1–2 mm into the tube, slightly constricted above; **Sty** filiform, 21–35 mm, yellowish, exerted 18–30 mm from the tube; **Sti** 3-lobed, papillose, clavate; **Fr** globose to ovoid, trigonous, 15–20 × 7–13 mm, apiculate, with persisting tepals; **Se** crescent-shaped to ovate, 4–6 × 3–4 mm, shiny.

According to the protologue (as *Manfreda*), the species belongs to Ser. *Guttatae* (as *Manfreda guttata*-group) and is morphologically most similar to *A. planifolia*, but differing in its oblong-ovoid corm (vs. globose to ovate), canaliculate leaves papillate on the veins on both faces (vs. flat and not papillate), shorter, funnel-shaped, yellowish flowers with light purple stripes, a shorter tube and a shorter style (vs. salver-shaped and yellow flowers).

**A. offoyana** De Smet *ex* Jacobi (Hamburg. Gart.- & Blumenzeit. 21: 214–215, 1865). **Type:** not typified. — **Lit:** Trelease (1913: 35–36, tt. 58–62); Berger (1915: 209–211, with ill.); León (1946: 316–317, with ill.); Álvarez de Zayas (1985: 3, 9); all as *A. legrelliana*; Álvarez de Zayas (1995: 41); Acevedo-Rodríguez & Strong (2012: 86, as *A. ehrenbergii*). **Distr:** W & C Cuba (Havana, Mayabeque, Matanzas, Camaguey); rocky slopes, xerophytic scrub and coastal thickets, on limestone and serpentine; flowers February to March. **I:** Richter (2010: 40); Guillot Ortiz & Meer (2011: 11); Kattermann (2012: 7); all as *A. legrelliana*; Pilbeam (2013: 122, as *A. legrelliana*; 146); Hochstätter (2015: VII: 95, as *A. ehrenbergii*); Biletzke (2016: 26, 27, as *A. legrelliana*).

**Incl.** *Agave americana* A. Richard in Sagra (1850) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave melanacantha* Lemaire ex Jacobi (1865); **incl.** *Agave laurentiana* Jacobi (1866); **incl.** *Agave legrelliana* Jacobi (1866); **incl.** *Agave coccinea* Lachaume (1876) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave legrelliana* var. *breviflora* Trelease (1913).

[2p] Acaulescent; **Ros** solitary; **L** variably lanceolate, ascending, upper part often recurved in older leaves, thin, rather weak, subacuminate, concave, sometimes conduplicate, 100–160 × 20–30 cm, dark green; **marginal teeth** usually down-curved below, narrowly triangular, acuminate tapered, 2–6 mm, variously brown, 10–15 (–20) mm apart, or from abrupt green prominences whose tops harden in a crescent-shaped manner, intervening margin often concave; **terminal Sp** conically subulate, a little curved, openly or flatly grooved below the middle or involute, smooth, 15–20 × 4–5 mm, brown, dull, scarcely decurrent; **Inf** 6–8 m, paniculate, amply ovoid throughout, part-**Inf** on ascending-recurved branches, not known to be bulbiferous; **Ped** 20–30 mm; **Fl** (55–) 70–80 mm; **Tep** deep orange, tube ±15 mm, lobes 30 × 7 mm; **Fil** 35–60 mm, inserted nearly in the throat of the tube; **Ov** oblong, somewhat contracted at the base and at the top, to 40–45 mm; **Fr** rather narrowly oblong, 40–50 × 15–20 mm, slightly beaked, stipitate; **Se** 7 × 4 mm.

This species and subsequently *A. legrelliana* were both published on the base of exhibited plants seen by Jacobi, having been imported by Mme. Legrelle d'Hanis, Antwerp (Belgium), from “Havana” and “Matanzas” on Cuba, respectively. Material of *A. offoyana* (Cuba, La Habana, Hanis s.n., MO 2056689, not digitized) is apparently preserved. Later authors applied either the former or the latter name to the variable orange-flowered species common on the N coast of Cuba from E of Havana to around Matanzas (Trelease 1913, Berger 1915, Álvarez de Zayas 1985). Trelease (1913) hesitatingly treated both names as conspecific, and Álvarez de Zayas (1995) finally placed *A. legrelliana* in the synonymy of the older *A. offoyana*.

Govaerts (2014+: accessed April 2014) applied the name *A. ehrenbergii* Jacobi (1865) to

this species, and he is followed by some authors (e.g. Acevedo-Rodríguez & Strong (2012)), but this name is a synonym of *A. mitis* (see there and Thiede (2016: 214)). *A. melanacantha* was based on a plant of unknown origin exhibited by de Smet together with *A. offoyana*. It was described as very similar to the latter, and is placed in its synonymy here. The same applies to *A. laurentiana*, which was placed in the synonymy of *A. legrelliana* by Berger (1915: 211). — The taxon was first classified as “Endangered” in the IUCN categories (Berzaín & al. 2005: 17, as *A. legrelliana*), but later classified as of “Least Concern” (González-Torres & al. 2016: 47). Phytotoxic steroidal saponins from leaves and flowers of *A. offoyana* were studied by Pérez & al. (2013) and Pérez & al. (2014).

**A. ornithobroma** Gentry (Agaves Cont. North Amer., 117–119, ills., 1982). **Type:** Mexico, Sinaloa (*Gentry* 18358 [US †; syn: ARIZ, CAS, DES, MEXU, MICH]). — **Lit:** McVaugh (1989: 147); García-Mendoza (2003); Vázquez-García & al. (2007b: 63, t. T); González-Elizondo & al. (2009: 107–108, with ills.). **Distr:** Mexico (S Sinaloa, Nayarit, N Jalisco); volcanic rocks in tropical deciduous forests and ecotones with oak forests, 60–1920 m; flowers November to December. **I:** Etter & Kristen (2011: 57); Richter (2011: 28); Etter & Kristen (2012: 93); Pilbeam (2013: 147); Hochstätter (2015: VIII: 51).

[1d] Stems short; **Ros** asymmetrical, to 1 × 1.5 m, solitary to caespitose, suckering sparingly at maturity; **L** few, narrowly linear, straight-ascending to frequently curving to one side, or falcate, shortly acuminate, convex below from the base to the tip, convex above from the base to the middle of the lamina, smooth, 60–75 × 0.5–0.8 cm, light green to reddish, margins filiferous, reddish to white; **terminal Sp** subulate, weak, fraying, 6–10 mm; **Inf** 2.5–4 m, ‘spicate’, slender, peduncle narrowly bracteate, green to red, fertile part laxly flowered, in the upper ½ of the inflorescence, part-**Inf** with geminate flowers; **Ped** 5–8 mm, thickened at fruiting time; **Fl** slender, 30–48 mm, oriented (nearly) horizontally to slightly ascending; **Tep** green with reddish or purplish flush, tube narrowly funnel-shaped,

triquetrous, finely grooved, 9–13 × 5–6 mm, lobes ± equal, linear-lanceolate, obtuse, recurving, rather thin, 10–17 × 4–5 mm, inner with low rounded keel; **Fil** inserted with the tepal lobes on the rim of the tube, 20–25 mm, red to purplish; **Anth** slender, somewhat excentric, 12–20 mm, green to yellow; **Ov** small, fusiform-angulate, 12–17 mm, neck slightly constricted; **Sty** reddish, longer than the filaments; **Fr** obovoid, small, 7–8 × 6–7 mm, with short and broad beak, dark brown, slightly ascending; **Se** unknown. — **Cytology**: 2n = 90 (Pinkava & Baker 1985).

Closely related to *A. geminiflora*, but separable by its caespitose habit, small, few-leaved rosettes and slender inflorescences with small flowers. The epithet (Greek, = bird's food) alludes to the observation that small parrots eat many of the flowers and buds (Gentry 1982; see also the note under *A. geminiflora*). The triploid *A. ornithobroma* is a putative natural hybrid involving *A. geminiflora* (Pinkava & Baker 1985). According to Jankalski (2008 in Agavaceae@yahoo.com), the second putative parent is *A. rzedowskiana*, which contributes the surculose habit, smaller rosettes, more slender inflorescences and smaller flowers to the hybrid. If this parentage is correct, *A. rzedowskiana*, at present only known from Sinaloa and Jalisco, should also occur in Nayarit (Jankalski l.c.). Vázquez-García & al. (2007b: t. T3) show an infructescence with ripe fruits, albeit fruit formation in sterile triploids should not be possible. Possibly, the species also includes fertile allopolyploids; this is also suggested by its occurrence at localities from where the putative parental species were not reported. Vázquez-García & al. (2007b: 63) and Hernández-Vera & al. (2007a: 505) provide a new record for Jalisco.

The holotype, cited for US in the protologue, appears to be missing, leaving 5 syntypes as cited above. Most probably, Gentry intended the most complete specimen (ARIZ 265553) bearing his stamp "Gentry Herbarium" and his handwriting to be sent to US as holotype.

**A. oroensis** Gentry (Agaves Cont. North Amer., 294–296, ill., 1982). **Type**: Mexico, Zacatecas (Gentry & Engard 23592 [US [3 syn], ARIZ,

ASU, DES, MEXU]). — **Distr**: Mexico (N Zacatecas); cultivated only, silty soil derived from limestone, 1830 m; flowers in August. **I**: Pilbeam (2013: 148); Hochstätter (2015: VII: 19).

[2a] Acaulescent; **Ros** low, openly spreading, to 1 × 2 m, solitary or suckering; **L** linear-lanceolate, straight to recurving, narrow and thickly convex below towards the base, long-acuminate, guttering upwards, slightly asperous, 80–100 × 8–10 cm, green, margins straight to repand; **marginal teeth** mostly straight, 3–6 mm (middle of the lamina), greyish, mostly 20–30 mm apart, smaller and more closely spaced towards the leaf base; **terminal Sp** acicular, narrowly grooved above for ½ of the length, 25–30 mm, greyish, finely decurrent to the uppermost teeth; **Inf** 5–6 m, paniculate, peduncle slender, with small **Bra**, fertile part in the upper ½, part-**Inf** 12–16, laxly flowered, spreading, extending 50 cm or more; **Ped** slender, to 10 mm, with tongue-shaped **Bra**; **Fl** very slender, 70–75 mm; **Tep** yellow, pink in bud, tube urceolate (but funnel-shaped in the drawing), grooved, walls thickened at the filament insertions, thin above, 16–18 mm, lobes linear, scarcely involute, connivent or adherent to one another, rather thin, unequal, 20–21 × 4.5–5 mm, outer bluntly apiculate with reddish rugose cap, inner with a low keel, without ribs within; **Fil** slender, flattened, long-tapering, inserted at slightly different levels 10 and 11 mm above the tube base, yellow; **Anth** slender, excentric, curved or sinuous, 29–30 mm, yellow; **Ov** fusiform, 34–37 mm, greenish, neck grooved; **Sty** much thicker than the filaments, soon exerted beyond the anthers; **Sti** capitate, 3-lobed; **Fr** and **Se** unknown.

A local cultivar in the mining region around Concepción del Oro, unique in Sect. *Agave* (as Group), and well-characterized by its thick, narrow, green leaves and esp. the broad, open, pink-budded panicles with flowers with a tube constricted at the mouth (Gentry 1982: 294). — Gentry's "holotype" at US consists of 3 sheets which are not cross-labelled and thus represent syntypes.

**A. ovatifolia** G. Starr & Villarreal (Sida 20(2): 495–496, ill., 2002). **Type**: Mexico, Nuevo León

(Villarreal & al. 9180 [MEXU, ANSM, ENCB, IBUG, IEB, NY, TEX]). — **Lit:** Starr (2004); Etter & Kristen (2009b); Starr (2012: 162–169, 322–323); all with ills. **Distr:** Mexico (N Nuevo León: Sierra de Lampazos); rocky slopes and mesetas, in calcareous soil, in oak forests, grasslands with *A. lechuguilla* or thorn scrub, 900–1500 m. **I:** Etter & Kristen (2008: 80–81 & title page); Alsemgeest & Roosbroeck (2010: 276); Richter (2011: 57); Pilbeam (2013: 149–152); Greulich (2014b: 62–64); Hochstätter (2015: II: 16); Moore (2016: 221, 230–231).

**Incl.** *Agave noah* Nickels (1894) (*nomen rejiciendum*, Art. 56.1).

[21] **Ros** semiglobular, somewhat compact, 0.6–0.9 (–1.2) × 0.8–1.2 (–1.8) m, solitary (in cultivation rarely sparingly offsetting); **L** 40–50, in 8–10 spiral rows, broadly ovate to elliptic, slightly concave to nearly flat, sometimes with 1–2 dorsal ribs, broadened at the base, apex acute, with brown border, 35–60 × 20–27 (in the middle) cm, silver-blue to greyish sky-blue, margins straight; **marginal teeth** 15–19 per side, slightly down-curved, 4–12 mm or more, evenly spaced and 20–25 mm apart, more closely spaced at the base; **terminal Sp** ±20 mm, decurrent; **Inf** 3.5–4 m, paniculate, peduncle slightly sigmoid, with elliptic-triangular **Bra** 20–25 cm long at the base, most bracts upright, fertile part in the upper ½, elliptic to broadly ovoid, part-**Inf** 13–16, nearly straight to slightly ascending, 30–50 cm, each with 5–6 dense ‘umbels’; **Ped** 4–8 mm; **Fl** 67–74 mm; **Tep** greenish-yellow, tube 15–20 × 15 (in the middle) mm, lobes broadly triangular, 15–17 × 5–7 (at the base) mm, outer with glandular apex; **Fil** 50–60 mm, inserted at the lobe bases, greenish-yellow; **Ov** cylindrical, 30–35 mm, constricted; **Sty** 80–90 mm; **Fr** cylindrical, not beaked, 50–60 × 15–20 mm, coffee-brown; **Se** drop-shaped, 5–6 × 3–4 mm, black, shiny.

Within Sect. *Parryanae* (as Group) closest to *A. havardiana* and *A. parrasana* according to the protologue. It differs from the former in its relatively shorter and broader, elliptic to ovate-elliptic, more bluish leaves with obtuse tip and shorter terminal spine, and its shorter flowers with shorter tepal lobes, and from the latter in its larger and much broader leaves with obtuse tip and

shorter terminal spine, and its larger flowers. Starr (2012: 163, fig. p. 167) mentions 2 further populations from near Monterrey possibly belonging here. Plants introduced as *A. noah* by Anna B. Nickels about 1894 were considered conspecific in the protologue. The name was proposed for rejection by Villarreal & al. (2003), but the nomenclatural committee argued that the name is invalid (Brummitt 2005: 533); in a later vote, the description is regarded as adequate (Wilson 2017a: 189), and the original proposal to reject the name must now be reconsidered (Wilson 2017b: 478).

‘Flipper’ (Starr 2012: 165, 169) and ‘Orca’ (Starr 2014: 224) are variegated cultivars, and ‘Frosty Blue’ (produced by San Marcos Growers) has densely wax-powdery leaves with an almost turquoise hue.

**A. pablocarrilloi** A. Vázquez & al. (Syst. Bot. 38(2): 328–329, ills., 2013). **Type:** Mexico, Colima (*Vázquez-García & al.* 9090 [IBUG, MEXU, MO]). — **Distr:** Mexico (C Colima); limestone outcrops, in succulent woodland, thorn and tropical dry forests, 300–610 m; flowers February to April. **I:** Gentry (1982: 511, figs. 18.4, 18.5); Ullrich (1991b: identification uncertain); Newton (1999); García-Mendoza (2003); Newton (2004); Richter (2011: 82); Pilbeam (2013: 104); Guillot Ortiz & Meer (2016c: 28; fig. 2, 29: figs. 3–5); Moore (2016: 268, 269); all as *A. gypsophila*; Hochstätter (2015: I: 22).

[2n] **Ros** 0.8 × 1.8 m, sparsely to densely surculose; **L** 10–15, narrowly lanceolate, undulate, firm, rigid, wider at the base and above mid-leaf, concave at the lower third, occasionally flat at the distal half, with a semi-amplexicaul sheath, rough, 50–70 (–100) × 7–8.5 cm, bluish-glaucous-grey on both faces, not evidently cross-zoned, margin distinctly crenate in the middle; **marginal teeth** firm, flattened, frequently curved, 2–3.5 mm, dark brown, from broad deltoid bases 2–3 mm wide, usually ascending, intervening margin curved with denticles more frequent at mid-leaf, teeth 9–25 mm apart at mid-leaf, 5–10 mm towards the base, on distinct prominences 4–5 × 5–6 mm; **terminal Sp** short and conical, firm, 4–5 mm, dark brown, not decurrent; **Inf** small, 2.3–4 m, paniculate, peduncle with triangular **Bra** to 12 ×

5 cm at the base, fertile part open, oblong, part-**Inf** few, 8–15 (–19), in the upper ½, with ±50 flowers; **Fl** 28–36 mm; **Tep** orange-yellow, tube somewhat funnel-shaped, 4–5 × 6–8 mm, lobes triangular, fleshy, 10–13 × 3 mm, galeate; **Fil** firm, 7–24 mm, inserted 1 mm above the tube base, orange; **Ov** 14–18 × 3.5–4 mm, neck constricted; **Sty** shorter than the tepals; **Sti** capitate; **Fr** oblongoid, 21–28 × 13–16 mm, stipitate, apiculate; **Se** subtriangular or semicircular, thin, 4–6 × 3–4 mm, black.

The recent study of the *A. gypsophila* complex by Vázquez-García & al. (2013) led to a narrower circumscription of *A. gypsophila* and the description of this and 3 more new species (*A. abisaii*, *A. andreae*, *A. kristenii*). The 3 specimens cited by Gentry (1982: 519) as well as his figs. 18.4 and 18.5 on p. 511, as well as 4 specimens cited from Colima by Vázquez-García & al. (2007b: 55) belong here. *A. pablocarrilloi* differs from *A. gypsophila* in its suckering habit, rough, bluish-glaucous-greyish leaves that are flat in the lower half, closely set firm teeth, smaller panicles with only 8–15 (–19) branches, and occurs at lower elevations. — ‘Ivory Curls’ (ills.: Moore (2016: 14, 268, as *A. gypsophila*)) is a variegated cultivar with yellowish leaf margins.

**A. pachycentra** Trelease (Trans. Acad. Sci. St. Louis 23(3): 135, 1915). **Type:** Guatemala, Dept. Progreso (*Trelease* 2 [ILL]). — **Lit:** Trelease (1915: 140–141, ills., as *A. opacidens* & *A. tenuispina*); Berger (1915: 200–201, as *A. eichlamii* & *A. weingartii*); Standley & Steyermark (1952: 112–115, as *A. hurteri*, *A. opacidens* & *A. tenuispina*); Gentry (1982: 486–488, with ills.); Lott & García-Mendoza (1994: online version with ills.); Véliz Pérez (2013: 240, 242, with ill.). **Distr:** S Mexico (Chiapas), Guatemala, El Salvador, Honduras; volcanic rocky outcrops in tropical deciduous or thorn forests, thorn scrub or grasslands, 220–975 (–1675) m; flowers November to January and March. **I:** Richter (2011: 50, 84); Pilbeam (2013: 153); Hochstätter (2015: VI: 11).

**Incl.** *Agave eichlamii* A. Berger (1915); **incl.** *Agave eichlamii* var. *interjecta* A. Berger (1915); **incl.** *Agave opacidens* Trelease (1915); **incl.** *Agave tenuispina* Trelease (1915); **incl.** *Agave weingartii* A. Berger (1915).

[2o] Acaulescent; **Ros** rather open, to 1 × 1.5–2 m, solitary, rarely surculose; **L** variable, broadly lanceolate, rarely linear-lanceolate, thickly fleshy and gradually narrowed towards the base, acuminate, flat to guttered, rougher or scabrous below, asperous above, (40–) 70–100 × (8–) 12–17 (–20) cm, glaucous-white to yellowish or pale green, margins repand to straight, concave between the teeth; **marginal teeth** variable, 3–6 (–10) mm (middle of the lamina), brown, (10–) 15–40 mm apart, tips straight or variously curved above low broad bases, brown, with intermittent teeth; **terminal Sp** finely subulate to nearly conical from a broad base, broadly to narrowly grooved above, keeled to rounded below, scabrous, 35–50 (–70) mm, long-decurrent to the upper teeth; **Inf** 2–6 m, paniculate, peduncle usually crooked, young white-pruinose, fertile part open, rather irregular, part-**Inf** (6–) 20–30, small, laxly arranged, on stalks 20–30 cm long; **Ped** slender, 5–12 mm; **Fl** (35–) 40–55 (–62) mm; **Tep** yellow, tube funnel-shaped to urceolate, knobby, grooved, 5–11 mm, lobes linear-lanceolate, erect to ascending, incurved, involute, subequal, 13–20 × 4–5 mm, outer closely overlapping the inner at the base, frequently reddish at the apex, inner with narrow thick keel; **Fil** slender, (30–) 40–50 mm, inserted at mid-tube or just above, sometimes on 2 levels; **Anth** centric, regular, straight, 17–22 mm; **Ov** thick-fusiform to slender-cylindrical, (12–) 25–35 mm, green, neck constricted, grooved, short; **Fr** oblong to ovoid, apex rounded, 35–40 × 15–17 mm, nearly beakless, stipitate; **Se** crescent- to drop-shaped, 5–6 × 3–4.5 mm, very finely punctate, marginal wing raised to ± the thickness of the seed.

Highly variable in leaf characters, but generally recognizable by its rather open, medium-sized to rather large rosettes with pale green to nearly white, broadly lanceolate leaves and crooked, laxly flowered, open panicles with small ‘umbels’ (Gentry 1982: 487). *A. hurteri* has similar lax inflorescences, but with compact ‘umbels’, and larger flowers, longer marginal teeth, and larger rosettes (Lott & García-Mendoza 1994). Standley & Steyermark (1952) treated *A. pachycentra* as synonym of *A. hurteri*. — The chromosome count (2n = 210) in Granick (1944: 286) based on a

**Fig. 44** *Agave palmeri*  
(Etter & Kristen 4061:  
Mexico; Sonora, near La  
Huachinera, 1220 m).  
(Copyright: J. Etter &  
M. Kristen)

plant from Texas of uncertain identity is highly doubtful and disregarded here.

‘Chunky Monkey’ and ‘Flying Saucer’ are two nearly identical-looking cultivars (Starr 2014: 220, with ills.).

**A. palmeri** Engelm (Trans. Acad. Sci. St. Louis 3: 319–320, 1875). **Type** [syn]: USA, Arizona (*Rothrock* 496 [F 304130, US 125477]). — **Lit**: Gentry (1972: 101–105, with ills.); Gentry (1982: 443–447, with ills.); Turner & al. (1995: 57–59); Hodgson (1999a: 7–8); Reveal & Hodgson (2002); Klopper & al. (2010: 62–65, with ills.); Starr (2012: 170–172, 324, with ills.); Parker (2017: 256, 258–259, with ills.). **Dist**: USA (SE Arizona, SW New Mexico), Mexico (N Sonora, NW Chihuahua); sandy to gravelly places on limestone in oak woodlands and grama grasslands, 900–2000 m; flowers June to September. **I**: Irish & Irish (2000: t. 29); Heller (2006: 114); Richter (2011: 79, 101, 106); Pilbeam (2013: 154); Hochstätter (2015: IV: 4, 11). – Fig. 44.

[2h] Acaulescent; **Ros** rather open, 0.4–1.3 × 0.6–1.3 m, solitary, rarely suckering with age; **L** numerous, linear-lanceolate to lanceolate, ascending to spreading, rather rigid, thick at the base, widest near the middle, acuminate to long-acuminate, concave towards the apex above, convex towards the base below, somewhat guttered, 35–92 × 3.5–19 cm, pale to glaucous-green or

pale to deep green, sometimes tinged reddish, not cross-zoned, margins almost straight or somewhat crenate, with or without small tubercle-like bases to the teeth; **marginal teeth** variously curved, rather regular, slender, firmly attached, 3–6 mm, (5–) 10–20 mm apart, dark or reddish-brown to pruinose-grey, sometimes with 4–6 smaller intermittent teeth, mostly along the distal  $\frac{2}{3}$  of the leaves; **terminal Sp** acicular, strong, shortly and openly grooved above the base, 30–60 mm, chestnut-brown, reddish-brown or brown to aging grey, decurrent to the 1. or 2. teeth; **Inf** (1.7–) 4–6.5 (–7.2) m, paniculate, peduncle glaucous-green or purple-maroon, with persistent triangular **Bra** 1–5 cm long, fertile part broad, open, part-**Inf** slightly ascending, (8–) 11–26 (–32) in the upper  $\frac{1}{3}$  of the inflorescence, 6–38 cm, with 8–16 congested flowers; **Fl** narrow, erect, cylindrical-urceolate, 45–64 (–75) mm, with strong musky-sour fragrance; **Tep** cream to pale yellow or light green below, conspicuously red to brownish on the calloused tips, reddish in bud, tube urceolate, 10–18 × 10–16 mm, slightly bulging at the base of the lobes, lobes erect, dimorphic, **OTep** 12–18 × 6–11 mm, **ITep** (6.5–) 9–14 × 9–14 mm, persistent and often leathery during and after anthesis, clasping the filaments; **St** long-exserted; **Fil** erect, inserted at 2 levels above mid-tube and near the rim, 40–58 mm, cream, pale yellow or pinkish, apex often tinged with maroon, inserted at 2 levels; **Anth**

11–25 mm, yellow; **Ov** stout, thickish, 18–36 mm, neck slightly constricted, (0.5–) 4–6 mm, angled to roundish; **Sty** 39–62 mm, cream or light yellow, usually tinged with maroon; **Sti** capitate, 3-lobed; **Fr** narrowly oblong to oblong or pyriform, 35–60 × 18–20 mm, dry walls thick and strong, apex short- to long-beaked, shortly and broadly stipitate; **Se** thin, flat, 5–7 × 4–5 mm, sooty black. — **Cytology**: 2n = 60 (Pinkava & Baker 1985, Simpson & al. 2011).

A “stupendously diverse” taxon (Parker 2017: 259), characterized by long lanceolate leaves, typically narrow in the northern part of its range, close-set slender teeth, sometimes with smaller ones between, and reddish tepals about equalling the tube. A smaller form occurs in N Sonora at somewhat lower elevations. The broad, glaucous-green leaves in populations in the Río Bavispe drainage (Sonora, Mexico) resemble those of *A. shrevei*, but its smaller flowers with shallower tubes place the plants in *A. palmeri*. *A. palmeri* shows introgression with *A. chrysantha* in Arizona (see there) and with *A. shrevei* in Sonora (Gentry 1982). For the closely related *A. lyobaa*, see there. The typification is unresolved: 2 of 3 syntypes are available (Rothrock 496, F 304130! [leaves & flowers], US 125477; Palmer s.n. [as *Anonymous*] MO 3949111 [seeds only]); Schott s.n. (“Dr. Schott collected the flowers in 1855”) could not be located.

*A. palmeri* shows some floral shifts from nocturnal bat to diurnal pollination, allowing for multiple pollinators at the N edge of its range where bats become infrequent (Slauson 2000). Scott (2004) observed (almost) no bats during the first 60% of the flowering period, while the migratory nectar-feeding bats were common visitors during the last part of the flowering period. Flowering, nectar and pollen production, sugar concentration, and fruit and seed set in burn-damaged plants are as high as in unburned rosettes (Slauson 2002b).

The seemingly bat-adapted flowers of *A. palmeri* are also visited by the hawkmoth *Manduca sexta*. The hawkmoths feed primarily on *Agave* as a result of learning and behavioural flexibility, and only shift to the moth-adapted flowers of their larval host plant *Datura wrightii* when these become abundant (Riffell & al. 2008). Laboratory

experiments by Alarcón & al. (2010) showed that female hawkmoths feed longer on *A. palmeri* than on *Datura*, whereas male moths feed longer on *Datura*. — For microsatellite primers suitable for population genetic studies in *A. palmeri*, see Lindsay & al. (2012).

**A. palustris** (Rose) Thiede & Eggl (Kakt. and Sukk. 50(5): 112, 1999). **Type**: Mexico, Nayarit (Rose 1943 [US, GH, K, MEXU]). — **Lit**: Rose (1903a: 9, with ill.); McVaugh (1989: 254); García-Mendoza (2003); Feria-Arroyo & al. (2010: with ill.); Solano & Ríos-Gómez (2014: 100, 101, with ill.); all as *Polianthes*. **Dist**: Mexico (Nayarit); on moist pastures and secondary habitats in oak forests, 2100 m; flowers in August. **I**: Barba-Gonzalez & al. (2012: 124); Hochstätter (2016: II: 21); both as *Polianthes*.

≡ *Polianthes palustris* Rose (1903).

[3b1] Herbaceous; corm 0.5–1 × 1.2–1.6 cm, bulb 2–3 × 1.4–2.2 cm, ovoid, completely covered with dried fibrous leaf bases; **R** fleshy, thickened, contractile; **L** drought-deciduous, 2–6, erect, linear, glabrous, attenuate at the base, apex acute, 18–30 × (0.8–) 1.2–1.5 cm, green, margins entire; **Inf** 37–58 cm, erect, ‘spicate’, peduncle with 3–4 **Bra**, linear, lowest 12–18 cm, internodes decreasing in size distally, fertile part 3–13 cm, lax, with 3–8 floral nodes; floral **Bra** ±0.7 cm; **Ped** 0–5 mm, ascending; **Fl** geminate, fragrant, 50–60 mm, divergent; **Tep** white, white-pink at senescence, the basal portion forming a tube 30–60 × 4 mm, curved out near ½ or just below, distally dilated, mouth very slightly oblique, lobes ovate, erect or sometimes spreading, obtuse, equal, 5–6 × 3–4 mm, apex cucullate, with a bundle of white trichomes; **Fil** filiform, 1–2 mm, included, inserted near the distal end of the tube 40 mm above the ovary apex; **Anth** linear, 6–7 mm; **Ov** ellipsoid, ±6 × 3 mm; **Sty** filiform, 35 mm, included; **Sti** 3-lobed; **Fr** and **Se** unknown.

Long known from the type collection only and thought to be possibly extinct (Feria-Arroyo & al. 2010: 20), but recently rediscovered and known from 3 collections in Nayarit (Pérez & al. 2010). Morphologically similar to *A. alboaustralis* (for differences see there), *A. apedicellata* and *A. dolichantha*, which both have longer and

oblong-elliptic lobes, flowers sessile throughout, longer anthers, and leaves usually less than 1 cm broad (see Castro-Castro & al. 2016: 726), and to *A. neonelsonii*, which has narrower leaves and flowers curved downwards with a strongly oblique tube mouth, much longer filaments, and a longer style.

**A. paniculata** (L. Hernández & al.) Thiede (Haseltonia 17: 94, 2012). **Type:** Mexico, Yucatán (Hernández-Sandoval & al. 5815 [CICY, MO, QMEX]). — **Lit:** Hernández-Sandoval & al. (2008); Orellana (2012); Carnevali (2013); all with ills. and as *Manfreda*. **Distr:** Mexico (Campeche, Yucatán, Quintana Roo); open habitats with limestone rocks in secondary tropical sub-deciduous forests, often associated with sinkholes (“cenotes”) or lakes, 5–130 m; flowers November to March. **I:** Hochstätter (2016: I: 32); Pérez-Sarabia & al. (2017: 45); both as *Manfreda*.

≡ *Manfreda paniculata* L. Hernández & al. (2008).

[3a5] Herbaceous; **Ros** caulescent, 0.2–0.4 m, freely suckering through axillary offsets and stolons; rhizomes cylindrical to oblong, 5–30 cm, erect at maturity; **R** thick, succulent; **L** mostly lost during the dry season, some persisting, 20–70, lanceolate to lanceolate-triangular, succulent ( $\pm 2.1$  mm thick at the widest place), lasting for >1 year, channelled, surface almost smooth, 20–55  $\times$  2.5–10 cm, dark green, variegated with darker green to reddish-brown spots, these more vivid on some individuals and when exposed to bright light, margins sinuate, denticulate to spinulose, with chartaceous teeth 0.5–1 mm in mature leaves, apex long-attenuate with a flexible apical tip 10–20 mm long; **Inf** (1–) 1.75–2.5 (–3.8) m, paniculate, peduncle 0.5–1.8 m, with 6–20 internodes, reddish-brown, glaucous, with 13–15 **Bra**, these  $\pm 2$  cm in the upper part, fertile part ovoid to pyramidal, 1- to 3-branched, rhachis 0.2–2 m, mature inflorescences often producing bulbils on some of the distal nodes; **Ped** 3.5–4.5 mm; **Fl** solitary but sometimes appearing almost geminate on young branches, 30–35 mm; **Tep** pale dull greenish-yellow, glaucous outside, shiny pale green inside, tube 6–8 mm, narrowly funnel-

shaped, lobes ovate-lanceolate, 15–20  $\times$  1.5–3.5 (–4.5) mm, reflexed during the male phase of anthesis, later erect, with incurved margins at maturity, apex obtuse, cucullate, with a tuft of glandular white hairs; **Fil** filiform, 40–55 mm, dark shiny reddish-brown; **Ov** cylindrical to fusiform, 15–18 mm, angulate to ribbed, concolourous with the tepals; **Sty** filiform, 50–55 mm, dark shiny reddish-brown; **Sti** clavate to capitate, 3-lobed; **Fr** oblong to pear-shaped, 25–40 mm, dark brown to almost black at maturity; **Se** crescent-shaped, 6–9  $\times$  4–6 mm, black, shiny, marginate.

Most unusual in Subgen. *Manfreda* due to its huge, broadly paniculate inflorescence, solitary pedicellate flowers subtended by a single bracteole, and the production of bulbils, while leaves and flowers are typical. Within the subgenus, *A. paniculata* is closest to *A. petskinil*, likewise from the Yucatán Peninsula, but also similar to *A. sileri* and *A. hauniensis* (Hernández-Sandoval & al. 2008). The species is often cultivated in villages far from the natural populations, and is used medicinally and as ornamental (Hernández-Sandoval & al. 2008). The tropical lowland habitat is untypical and apparently not known for other species of Subgen. *Manfreda* except *A. petskinil*, *A. chamelensis* and *A. littoralis*. *A. paniculata* and the similar *A. petskinil* are both unusual in having paniculate inflorescences and a tendency to become caulescent, as well as having denticulate to spinulose leaf margins and a longer apical tip, suggesting natural hybridization between a species of Subgen. *Manfreda* and a paniculate *Agave* (likely *A. fourcroydes* or *A. angustifolia* as well as the cultivated *A. variegata* (?)) (Jankalski, message in Agavaceae@yahogroups.com, 24. 6. 2008). Material of this species was earlier identified as *Manfreda maculata* (e.g. in the palynological study by Ludlow-Wiechers & Ojeda (1983)).

**A. papyrocarpa** Trelease (Mem. Nation. Acad. Sci. 11: 44, tt. 95–97, 1913). **Type:** Cuba, Isla de la Juventud (*Curtiss* 335 [MO [2 syn], CM, HAC, NY, P, US]). — **Lit:** Berger (1915: 273); Jennings (1917: 32, 95–96); León (1946: 319); Álvarez de Zayas (1985: 11, 13–15, with ills.); Álvarez de Zayas (1995: 41); Acevedo-Rodríguez & Strong

(2012: 86); Greuter & Rankin Rodríguez (2017: 36). **Distr:** Cuba (Isla de la Juventud [Isla de Pinos]); ecology unknown.

For differences from *A. jarucoensis*, see there. The species is considered as “Endangered” by Berazaín & al. (2005). The “holotype” consists of 2 sheets (MO 2056690 & 2056685), which were only cross-labelled at a later stage, and thus represent syntypes. The illustration by Hochstätter (2015: VII: 92) from the W end of Cuba, labelled “*A. papyrocarpa*”, is misidentified and may be *A. tubulata*.

**A. papyrocarpa** ssp. **macrocarpa** A. Álvarez (Revista Jard. Bot. Nac. Univ. Habana 5(3): 7, ills., 1985). **Type:** Cuba, Isla de Pinos (Álvarez 43981A [HAJB [several syn]]). — **Lit:** Álvarez de Zayas (1995: 41); Acevedo-Rodríguez & Strong (2012: 86); Greuter & Rankin Rodríguez (2017: 36). **Distr:** Cuba (W Isla de la Juventud [Isla de Pinos]); ecology unknown.

[2q] Differs from ssp. *papyrocarpa*: **terminal Sp** shorter, 5–8 mm; **Inf** with less compact part-**Inf** at the tip; **Fr** larger, oblong, (22–) 25–45 × 12–20 mm.

Based on a single allopatric population. The type includes 7 sheets, 2 are labelled as “Holotipo”, 5 as “Isotipo”, but the sheets are not cross-labelled and thus represent syntypes. HAJB 00079! contains fruits only about 22 mm long, so that the distinction of this taxon needs restudy.

**A. papyrocarpa** ssp. **papyrocarpa** — **Lit:** Berger (1915: 273, as *A. papyrocarpa*); Jennings (1917: 95–96, as *A. papyrocarpa*); León (1946: 319, as *A. papyrocarpa*); Álvarez de Zayas (1985: 11, 13–15, with ills.); Álvarez de Zayas (1995: 41); Acevedo-Rodríguez & Strong (2012: 86); Greuter & Rankin Rodríguez (2017: 36). **Distr:** Cuba (N & NE Isla de la Juventud [Isla de Pinos]); on open exposed limestone knobs and hills with *Bombax* and *Plumeria*, and on often near-vertical cliffs; flowers in February. **I:** Pilbeam (2013: 155–156, as *A. papyrocarpa*).

[2q] Acaulescent; **Ros** solitary; **L** oblong to elongate-oblong, gradually acute, somewhat concave, sometimes a little conduplicate above, 75–125 × 10–15 cm, green, at first slightly

glaucous and rather dull; **marginal teeth** straight or variously and unequally curved mostly downwards, triangular from scarcely or slightly dilated bases, (1–) 3–4 mm, 10–25 mm apart, occasionally with 1 or several minute intermittent teeth, intervening margin nearly straight or concave on young plants; **terminal Sp** usually a little curved and somewhat conically subulate, narrowly grooved below the middle, smooth or slightly granular below, somewhat polished towards the end, 8–15 × 3 mm, brown, not decurrent; **Inf** 3–4 mm, paniculate, part-**Inf** few, very laxly arranged on slender outcurved nearly horizontal branches 30–40 cm long, in the upper ½ or more of the inflorescence; **Ped** slender, 10–12 mm; **Fl** 36–43 mm; **Tep** light yellow, tube conical, narrow, 4–5 mm, lobes 15 × 4 mm; **Fil** 25 mm, inserted nearly in the throat; **Anth** 12–15 mm; **Ov** fusiform, 20 × 4–6 mm; **Sty** much longer than the filaments; **Sti** capitate; **Fr** globose-oblong, thin-walled, 20–30 × 15–20 mm, little beaked, stipitate or not; **Se** 5–6 × 4–5 mm.

**A. parrasana** A. Berger (Notizbl. Königl. Bot. Gart. Berlin 4: 250, 1906). **Type:** Mexico, Coahuila (*Purpus* s.n. [MO 3346980, US [type collection]]). — **Lit:** Trelease (1912b: 90, tt. 80–81); Berger (1915: 176–177); Breitung (1963: 75); Gentry (1982: 537–538); Ullrich (1992j: 250–252); Ullrich (1992c); García-Mendoza (2003); Starr (2012: 173–178, 322–323); all with ills. **Distr:** Mexico (C, S & SE Coahuila); limestone mountains, chaparral shrub and pine and oak forests above the desert proper, 1200–2480 m; flowers May to June. **I:** Ullrich (1994c); García-Mendoza (2002: 178); Kemble (2004); Heller (2006: 115); Spracklin (2007); Richter (2011: 81); Alsemgeest & Roosbroeck (2012?); Pilbeam (2013: 157); Hochstätter (2015: III: 17); Moore (2016: 257).

**Incl.** *Agave wislizeni* ssp. *parrasana* (A. Berger) Gentry (1975).

[2m] Acaulescent; **Ros** compact, small, 30–50 cm Ø, solitary, with few or no suckers; **L** 40–60, ovate, closely imbricate, thick, rigid, short-acuminate to merely acute, flat to concave above, generally 20–30 × 10–12 cm, glaucous grey-green to green, frequently light grey to bluish-glaucous; **marginal teeth** straight to curved,

slender from small low bases, 5–10 (–15) mm, largest near the leaf tip, rapidly becoming smaller further down, greyish-brown, 10–25 mm apart; **terminal Sp** slender from a broad base, flat to openly grooved above, 20–30 (–40) mm, dark brown to greyish, sharply decurrent to the uppermost teeth; **Inf** 3–4 m, paniculate, peduncle with and part-**Inf** subtended by large reddish to purplish (rarely greenish) **Bra**, fertile part ellipsoid, part-**Inf** compact, 12–15; **Fl** 50–60 mm; **Tep** pale yellow, buds tinged red or purple, tube cylindrical, lightly grooved, 13–14 × 13–14 mm, lobes lanceolate, rather thick, subequal, 13–15 × 5–6 mm, pale yellow, outer more acute, 2 mm longer than the inner, tinged with red at the tip; **Fil** slender, 45–50 mm, inserted near mid-tube; **Anth** centric, 18–19 mm, yellow; **Ov** 25–30 mm, neck short, not constricted; **Sty** slightly longer than the tepals; **Sti** capitate; **Fr** stoutly oblong, shortly stipitate, shortly beaked, 50–53 × 17–20 mm; **Se** 5–6 × 4–5 mm, black.

Only known from a few limestone mountains in Coahuila, and easily distinguished by its short, broad, abruptly short-acuminate leaves. Gentry (1982) placed *A. parrasana* in his Group (now Sect.) *Parryanae*, in which it differs from all other taxa known by its large succulent purplish-coloured bracts on the peduncle that cover the budding part-inflorescences, but these may also be green (habitat photograph in Alsemgeest & Roosbroeck 2012?). Here, it is placed together with *A. gentryi* and *A. montana*, which both have similar large bracts, in Sect. *Hibernicae*. González-Elizondo & al. (2009: 110) mention specimens labelled *A. parrasana* from N Durango which need verification. For the in vitro propagation, see Santacruz-Ruvalcaba & al. (1999). Hardy to –8 °C or more (Spracklin 2007). — ‘Fireball’ is a variegated cultivar, and ‘Meat Claw’ a cultivar with large teeth (Starr 2012: 177).

The typification of *A. parrasana* needs clarification. US 1023807, labelled as “holotype”, was apparently preserved in 1912 (“L[a]. M[ortola]. VIII, 1912”), i.e., after the publication of the name, and includes flowers preserved at a different date than the leaves (“Blüten nachträglich aus La Mortola erhalten”). The leaf from Berger

(MO 3346980) labelled as “isotype” was given as and depicted as “type” by Trelease (1912b: t. 80, 1), this is viewed as (unintended) lectotypification.

**A. parryi** Engelm (Trans. Acad. Sci. St. Louis 3(20): 311–313, 1875). **Type** [lecto]: USA, Arizona (*Rothrock* 274 [MO [3 sheets]]). — **Lit**: Berger (1915: 179–180); Breitung (1963: 74–77, with ills.); Gentry (1982: 538–545, with ills.); Ullrich (1992j); Hodgson (1999a: 8–9); Reveal & Hodgson (2002); González-Elizondo & al. (2009: 111–114, with ills.); Alsemgeest & Roosbroeck (2010: with ills.); Starr (2012: 178–199, 322–323, with ills.); Parker (2018a: 27–28, with ills.). **Distr**: SW USA, NW, N & W-C Mexico.

≡ *Agave applanata* var. *parryi* (Engelmann) Mulford (1896); **incl.** *Agave leopoldii* Rafarin (1874).

*A. parryi* has the most extensive range of any species in Sect. *Parryanae* (as Group) and is distinguished by its compact, multi-leaved, freely suckering, light green to greyish rosettes (Gentry 1982). According to Ullrich (1992j) the earlier but illegitimate name *A. scabra* Salm-Dyck (1858) was based on a collection attributable to *A. parryi*, and so represents a synonym of it. Here, the view of Villarreal & al. (2005) is followed who consider *A. scabra* as illegitimate name for *A. asperriima* (see there). The earlier but rejected name *A. leopoldii* Rafarin is treated as synonym of *A. parryi* on the base of Govaerts (2014+: accessed Oct. 2018).

The protologue cites material from Emory, Bischoff and Rothrock (= syntypes) kept at MO. The designation by Trelease (1912b: 94) as “*Rothrock*, 274, 1874,—to be accepted as the type”) and by Gentry (1982: 539) as “Type: *Rothrock* 274, in 1874” represent first-step lectotypifications since 3 sheets, not cross-labelled, are present at MO.

**A. parryi** ssp. **neomexicana** (Wooton & Standley) B. Ullrich (Sida 15(2): 259, 1992). **Type**: USA, New Mexico (*Standley* 541 [US 498333, ARIZ]). — **Lit**: Wooton & Standley (1913: 115–116, t. 48, as *A. neomexicana*); Gentry (1982: 535–537, with ills., as *A. neomexicana*); Reveal & Hodgson (2002); González-Elizondo &

al. (2009: 104–106, with ills., as *A. neomexicana*); Starr (2012: 188–191, with ills.). **Distr:** USA (S New Mexico, SW Texas), Mexico (Durango, Coahuila?); gravelly to rocky places in grasslands and desert scrub, 1600–2100 m; flowers mid-spring to early summer. **I:** Irish & Irish (2000: t. 27); Heller (2006: 110); Richter (2011: 128); Pilbeam (2013: 139); Hochstätter (2015: III: 15); all as *A. neomexicana*. — Fig. 45.

≡ *Agave neomexicana* Wooton & Standley (1913) ≡ *Agave parryi* var. *neomexicana* (Wooton & Standley) McKechnie (1949).

[21] Differs from ssp. *parryi*: **Ros** flat-topped, smaller, 35–45 × 40–60 cm, generally in smaller groups; **L** lanceolate, more slender, 4–12 cm wide; **Inf** smaller, (2–) 3–4.5 m, part-**Inf** fewer, (7–) 10–17; **Fl** smaller, 55–67 mm; **Tep** yellow to yellowish-green, red to orange in bud, tube longer, 12–18 mm, lobes smaller, 15–20 × 3–4 mm; **Fil** shorter, 35–45 mm, inserted (sometimes irregularly) above mid-tube; **Ov** with shorter neck, 4–7 mm; **Fr** smaller, 25–35 mm. — **Cytology:** 2n = 120 (Granick 1944: as ‘4n’ for *A. neomexicana*).

Ullrich (1992j) reduced *A. neomexicana* to subspecific rank under *A. parryi*, which is followed by Reveal & Hodgson (2002) and Govaerts (2014+: accessed April 2014). The occurrence in Coahuila is based on a single doubtful specimen only and needs verification (Gentry 1982: 547). González-Elizondo & al. (2009) place plants from Durango here, which is a new record for the state. Ssp.

*neomexicana* is difficult to distinguish from *A. ×gracilipes* (see also there). The Mescalero Apaches were so named due to their use of the plant for food (as ‘mescal’). Historical overuse may partly account for its present limited distribution and infrequent occurrence (Reveal & Hodgson 2002). The variability in the nectar sugar composition is studied by Reid & al. (1985: as *A. neomexicana*). — ‘Sunspot’ is a variegated cultivar with creamy-yellow leaf margins (Starr 2012: 191).

**A. parryi** ssp. **parryi** — **Lit:** Gentry (1982: 538–542, with ills.); Ullrich (1992j: with ill.); Hodgson (1999a: 8–9); Reveal & Hodgson (2002); González-Elizondo & al. (2009: 111–114, with ills.); Alsemgeest & Roosbroeck (2010: 33–40, with ills.); Starr (2012: 178–180, 192–195, 322–323, with ills.). **Distr:** S USA (C & SE Arizona, SW New Mexico), NW & W-C Mexico (E Sonora, NW, C & S Chihuahua, W-C Durango, NW Zacatecas, NE Jalisco, Guanajuato, Querétaro?); gravelly to rocky places and open slopes in grama grasslands, oak woodlands, chaparral, desert scrub, pinyon-juniper, and pine-oak-forests, 1200–2800 m; flowers May to July. **I:** Ullrich (1991h); Irish & Irish (2000: t. 30); Heller (2006: 31, 116); Richter (2011: 51, 57, 107, 119, 140); Pilbeam (2013: 158).

**Incl.** *Agave americana* var. *latifolia* Torrey (1859); **incl.** *Agave marcusii* De Smet (1876); **incl.** *Agave patonii* Trelease (1911); **incl.** *Agave chihuahuana* Trelease (1912); **incl.** *Agave*

**Fig. 45** *Agave parryi* ssp. *neomexicana* (Etter & Kristen 178: USA; New Mexico, Culberson County, Guadalupe Mountains National Park). (Copyright: J. Etter & M. Kristen)

*marensii* hort. ex Trelease (1912); **incl.** *Agave marcusea* hort. ex Trelease (1912) (*nom. inval.*, ICN Art. 61.1?); **incl.** *Agave parryi* hort. ex Trelease (1912) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave parreyi* hort. ex Trelease (1912) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave paryi* hort. ex Trelease (1912) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave payrii* hort. ex Trelease (1912) (*nom. inval.*, ICN Art. 61.1).

[21] **Ros** compact, flat-topped or globose, 15–75 × 25–85 cm, freely suckering; **L** 90–160, lanceolate to broadly ovate, closely imbricate, rigid, thick, little constricted above the base, widest just below the middle, short-acuminate to truncate, rounded below, nearly flat to concave towards the apex, 10–65 × 4.5–20 cm, glaucous-grey to light green, margins nearly straight to repand or undulate; **marginal teeth** mostly straight to recurved, small, largest above the middle of the lamina, 3–8 mm, dark brown to greyish, mostly 10–20 (–30) mm apart; **terminal Sp** openly grooved, 15–30 mm, dark brown to grey with age, decurrent to the 1. or 2. teeth; **Inf** 4–6 m, paniculate, peduncle thick, glaucous-green to grey, with large reflexing **Bra**, fertile part with 20–36 slightly ascending congested part-**Inf** in the upper ½ of the inflorescence; **Fl** 43–81 mm; **Tep** greenish to deep yellow, pink to red in bud, tube fleshy, thickly angled, deeply grooved, 6–12 × 11–21 mm, lobes subequal, ascending to erect, thick, soon involute and wilting, linear above the rather open sinuses, papillate within well below the hooded tip, 13–27 × 2–7 mm, **ITep** thickly keeled, 2-costate within; **Fil** broad, (35–) 40–58 (–65) mm, yellow, inserted 4–11 mm above the base of the tube; **Anth** excentric to centric, 12–34 mm, yellow; **Ov** 20–48 mm, usually with a neck (2–) 6–9 mm, slightly angled or rounded, green; **Sty** 52–70 mm, eventually longer than the stamens; **Sti** capitate, 3-lobed; **Fr** oblong to obovate, 35–50 × 15–20 mm, shortly and stoutly stipitate, beaked, strong-walled; **Se** semi-circular, 7–8 × 5–6 mm, with low thick rim and shallow hilar notch.

Alsemgeest & Roosbroeck (2010) provide a richly illustrated account of the typical subspecies and its varieties and forms. Ullrich (1992j) reduced all to the synonymy of ssp. *parryi*, but,

albeit being weakly differentiated, they appear to have some geographical separation and are upheld by Hodgson (1999a) and Reveal & Hodgson (2002). Ssp. *parryi* was recently recorded from NE Jalisco (Hernández-Vera & al. 2007a). Alsemgeest & Roosbroeck (2010: 74) place plants from near Los Trigos in Querétaro here. For plants from Guanajuato named “*A. spatularia*”, see under *A. applanata*. Putative wild populations show higher genetic variability than populations domesticated over 600 years ago. Anthropogenic populations are not simply derived from the closest wild population, but came from more distant wild populations (Parker & al. 2010).

**A. parryi** var. **couesii** (Engelmann ex Trelease) Kearney & Peebles (J. Washington Acad. Sci. 29(11): 474, 1939). **Type:** USA, Arizona (*Coues & Palmer* 253 [MO]). — **Lit:** Trelease (1912b: 94–95, tt. 94–97, as *A. couesii*); Berger (1915: 180, as *A. couesii*); Gentry (1982: 542–543, with ill.); Hodgson (1999a: 8); Reveal & Hodgson (2002); Alsemgeest & Roosbroeck (2010: 38–40, 178–182, with ill.); Starr (2012: 181–184, with ill.). **Distr:** USA (C Arizona); open slopes and gravelly places in grasslands, chaparral, pinyon-juniper, and oak woodlands, 1100–2100 m; flowers June to July. **I:** Heller (2006: 158); Richter (2011: 126); Starr (2012: 16); Pilbeam (2013: 159); Hochstätter (2015: III: 20, as ssp. *couesii*);  
≡ *Agave couesii* Engelmann ex Trelease (1911)  
≡ *Agave parryi* ssp. *couesii* (Engelmann ex Trelease) Hochstätter (2015); **incl.** *Agave parryi* fa. *integrifolia* Breitung (1963).

[21] Differs from var. *parryi*: **Ros** smaller, 35–55 × 40–65 cm; **L** ovate, smaller, 25–42 (–47) × 6.5–11 cm; **Fl** smaller, 43–58 (–60) mm; **Tep** tip more densely papillate, tube 6–9 mm, lobes 13–21 mm; **Fil** shorter, 33–44 mm, inserted 4–8 mm above the tube base; **Ov** shorter, 20–34 mm; **Sty** shorter, 52–62 mm. — **Cytology:** 2n = 120 (Pinkava & Baker 1985).

According to Wolf (1988: 1609) Engelmann annotated the type with the name “couessi”, but this spelling would be erroneous as the name honours Elliot Coues. This taxon represents a variant of smaller growth from the NW border of the species’ range. However, small-leaved forms

occur at random elsewhere (Gentry 1982). *A. parryi* fa. *integrifolia* represents a toothless variant found in populations of this variety; such aberrations are widespread in the genus and do not merit formal taxonomic recognition. In Arizona, the taxon hybridizes with *A. chrysantha* (Hodgson 1999a, Reveal & Hodgson 2002).

This variety as well as var. *huachucensis* and var. *truncata* were reduced to synonyms of *A. parryi* ssp. *parryi* by Ullrich (1992j) who regarded them as mere ecotypes with size modified by more humid or arid conditions, and merging into typical plants in cultivation. All three varieties are weakly differentiated, but appear to have some geographic distinction and are upheld here following Hodgson (1999a) and Reveal & Hodgson (2002).

**A. parryi** var. **huachucensis** (Baker) Little ex L. D. Benson (Amer. J. Bot. 30(3): 235, 1943). **Type:** USA, Arizona (*Pringle* s.n. [K, BR, CM, G, GH, LE, NY, US, VT]). — **Lit:** Trelease (1912b: 91–92, tt. 87–89, as *A. huachucensis*); Berger (1915: 178–179, as *A. huachucensis*); Breitung (1963: 76–77, with ill.); Gentry (1982: 542); Hodgson (1999a: 8); Reveal & Hodgson (2002); Alsemgeest & Roosbroeck (2010: 36–39, 68–74, with ills.); Starr (2012: 185–187, with ills.). **Distr:** USA (SE Arizona), Mexico (NE Sonora, NW Chihuahua?); open slopes in oak woodland and pine forests, 1550–2200 m; flowers (March to) June to July (to August). **I:** Watson (1895); Skinner (1961); Irish & Irish (2000: t. 31); Lyons (2002: 161); Richter (2011: 127); Pilbeam (2013: 160); Hochstätter (2015: III: 21, as ssp.);

≡ *Agave huachucensis* Baker (1888) ≡ *Agave applanata* var. *huachucensis* (Baker) Mulford (1896) ≡ *Agave parryi* ssp. *huachucensis* (Baker) Hochstätter (2015).

[21] Differs from var. *parryi*: **Ros** more robust, 45–75 × 75–85 cm; **L** ovate, larger, 32–65 or more × 10–20 cm; **Inf** broader; **Fl** larger, 62–81 mm; **Tep** tube 8–9 mm, lobes 20–27 mm; **Fil** 46–58 mm, inserted 6–8 mm above the tube base; **Ov** 34–47 mm.

A widely cultivated upland variant with larger growth. The populations studied by Parker & al. (2014) differed significantly morphologically and

genetically from *A. parryi* (ssp./var. *parryi*), with wild populations showing greater genetical diversity than ancient anthropogenic populations planted by native Americans at lower elevations than at which the taxon naturally occurs (ill.: Parker 2018a: 28). — Variegated cultivars are ‘Medio-Picta Pallida’ with leaves with a broad pale yellow mid-stripe, ‘Excelsior’ (also named ‘Medio-Picta’ or ‘Kitsuyoteh Hakafu’) with a clear yellow midstripe (ill.: Greulich 2017c: 159), and ‘Medio-Picta Alba’ with a white midstripe. Further variegated cultivars are ‘Jaggedmeister’, ‘Point of Interest’, and ‘Spring Sun’ of Plant Delights Nursery (USA).

**A. parryi** var. **parryi** — **Lit:** Trelease (1912b: 93–94, tt. 91–93, as *A. parryi*); Gentry (1982: 538–542, with ills.); Ullrich (1992j: with ill.); Hodgson (1999a: 8–9); Reveal & Hodgson (2002); González-Elizondo & al. (2009: 111–114); Alsemgeest & Roosbroeck (2010: 33–37, with ills.); Starr (2012: 192–195, with ills.). **Distr:** S USA (C & SE Arizona, SW New Mexico), NW Mexico (E Sonora, NW, W & SW Chihuahua, W Durango, NE Jalisco, Guanajuato); gravelly to rocky places and open slopes in grama grasslands, oak woodlands, chaparral, desert scrub, pinyon-juniper, and pine-oak forests, 1200–2800 m; flowers June to July. **I:** Irish & Irish (2000: t. 30); Ullrich (1991h); Heller (2006: 31, 116); Richter (2011: 51, 57, 107, 119, 140); Pilbeam (2013: 158); Hochstätter (2015: III: 18, 19). — Fig. 46.

[21] **Ros** (35–) 40–60 × 60–75 cm; **L** linear-ovate, (18–) 25–50 × (4.5–) 8–12 cm; **Fl** 60–77 mm; **Tep** tube 9–12 × 14–18 mm, lobes (17–) 19–24 mm; **Fil** 40–54 mm, inserted 6–11 mm above the base of the tube; **Ov** (27–) 30–47 mm; **Sty** 60–70 mm. — **Cytology:** 2n = 60, 120 (Simpson & al. 2011: as *A. parryi*).

In Arizona, var. *parryi* hybridizes with *A. chrysantha* and *A. schottii* ssp. *schottii* (Hodgson 1999a, Reveal & Hodgson 2002). ‘J. C. Raulston’ and ‘Sierra Estrella’ are normal-leaved cultivars (Starr 2012: 194).

**A. parryi** var. **truncata** Gentry (Agaves Cont. North Amer., 543–545, ills., 1982). **Type:** Mexico, Zacatecas-Durango (*Gentry & Gilly* 10566

**Fig. 46** *Agave parryi* var. *parryi*. (Mexico; Chihuahua, Rosales Mpio., SE Chihuahua towards Delicias). (Copyright: J. Thiede)

[US 2540275, DES 0004758, MEXU 00231534, MICH]). — **Lit:** Alsemgeest & Roosbroeck (2010: 68, 70, 73–74, with ills.); Starr (2012: 196–199, with ills.). **Distr:** Mexico (Durango/Zacatecas border); open rocky limestone slopes in oak-juniper grasslands,  $\pm 2280$  m; flowering in cultivation in July; only known from the region of the type locality. **I:** Irish & Irish (2000: t. 32); Heller (2006: 116); Richter (2011: 100); Pilbeam (2013: 161–162); Hochstätter (2015: III: 21, as ssp.).

≡ *Agave parryi* ssp. *truncata* (Gentry) Hochstätter (2015).

[21] Differs from var. *parryi*: **Ros** copiously surculose with long rhizomes; **L** very short and broad, oblong, 10–30 (sometimes only 7–15)  $\times$  7–12 cm, light grey, tip shortly acuminate to truncate, margins repand to wavy; **marginal teeth** variable, usually flexed downwards, the larger ones 4–8 mm, dark brown; **Inf** infrequently produced.

A diminutive variant at the SE border of the species' range. Its small size appears to result from the arid habitat conditions and the taxon may thus represent a mere modification only; in cultivation, well-watered plants may attain a size comparable to other *A. parryi* variants (Gentry 1982: 544, Etter & Kristen 1997+: accessed 2014). Plants in habitat are somewhat different from those commonly seen in cultivation, which seem to have been derived mostly from plants grown at Huntington Botanical Gardens

(California) (Pilbeam 2013: 161–162); this clone is named as cultivar 'Huntington' (Starr 2012: 198–199, with ill.).

The protologue cites "*Gentry & Gilly* 10566", "June 8, 1951" at US as "holotype", which corresponds to the field-collected US 2540275! (also databased as holotype, and labelled "Holotipo" by A. García-Mendoza 2002); ARIZ-0004758! and MEXU 00231534! are isotypes. Sheets prepared from a plant of the type collection cultivated at Huntington BG (US 2826228! & 2826228!, ARIZ-0004759! & 0004760!, DES 00019018!) were preserved in June or July 1977 and thus represent a different gathering and are not type material.

**A. parva** (Aarón Rodríguez) Thiede (Haseltonia 17: 94, 2012). **Type:** Mexico, Guerrero (*Rodríguez & Pérez-Álvarez* 5518 [IBUG, ENCB, IEB, MEXU, WIS, XAL]). — **Lit:** Rodríguez (2009); Castillejos-Cruz (2009); both with ills. and as *Manfreda*. **Distr:** Mexico (Guerrero: Sierra de Taxco near Taxco); slightly inclined rocky slopes in disturbed pine-oak forests, 1845 m; flowers in July. **I:** Hochstätter (2016: I: 33, as *Manfreda*).

≡ *Manfreda parva* Aarón Rodríguez (2009).

[3a3] Herbaceous; corm 1–4  $\times$  1–2 cm, bulb oblong, 2–2.5  $\times$  1–1.5 cm, covered with dry leaf bases 6–6.5 cm long, these membranous at the base and fibrous above; **R** fleshy, thickened, contractile; **L** (5–) 11–24, semisucculent, extended, linear, falcate, glabrous, tip acute, 10–20 (–25)  $\times$

0.4–0.7 (–0.9) cm, green, margins entire, with a very narrow hyaline band not visible to the naked eye; **Inf** erect, 0.35–0.6 m, peduncle 0.2–0.3 m, with 4–7 **Bra**, fertile part 15–30 cm, with (4–) 9–15 solitary, ascending, sessile and laxly arranged flowers; **Fl** 35 mm, green throughout; **Tep** green with small reddish dots, tube straight or slightly curved towards the rhachis, 15–18 × 4–5 mm, not constricted, lobes oblong, revolute, 7–8 × 4–5 mm, apex thickened, cucullate, with a bundle of white hairs; **St** erect at anthesis, green with red dots, inserted at the mouth of the tube all on the same level, exceeding the tube for 25 mm; **Ov** obclavate, 7 × 4 mm, green with reddish dots; **Sty** ±43 mm, at first ± ½ as long as the stamens, then elongating and finally of the same length; **Sti** 3-lobed, green-yellowish; **Fr** subglobose, triquetrous, 12–17.5 × 8–13 mm, apex with a round scar 4–6 mm Ø; **Se** 4.5–5 × 3.5 mm, shiny.

Unique in Sect. *Herbaceae* due to the small, linear and falcate leaves, and according to the protologue placed in Ser. *Guttatae* (as *Manfreda guttata*-Group). *A. parva* is most similar to *A. bulbulifera*, but has more leaves, shorter filaments, a longer tepal tube and smaller tepal lobes. Both species differ from others in the group by their laxly arranged flowers and inflorescences with a short peduncle measuring about ½ of the inflorescence.

**A. parvidentata** Trelease (J. Washington Acad. Sci. 15(17): 395, 1925). **Type** [lecto]: El Salvador (*Calderón* 2085 [US 92237, ARIZ, ILL, US 92238]). — **Lit**: Gentry (1982: 488–489, with ill.); Ullrich (1992b); Lott & García-Mendoza (1994). **Distr**: El Salvador, Honduras; volcanic rocky slopes in open scrub vegetation, 1000–2500 m; flowers December and March. **I**: Richter (2011: 124).

**Incl.** *Agave compacta* Trelease (1927).

[2o] Stems short; **Ros** dense, to 1 × 1.7 m, solitary; **L** numerous, ascending to out- or incurving, ovate-lanceolate, contracted into the thick base, thickly fleshy, concave above the middle, sometimes plicate, flat, long acuminate, smooth, 80–100 × 15–25 cm, pale green to light glaucous-grey, margins straight or somewhat concave between the teeth; **marginal teeth** deltoid from lenticular bases, nearly straight, 3 (–5) mm (middle of the

lamina), 10–20 mm apart, reduced up- and downwards; **terminal Sp** acicular, involutely grooved to above the middle, smooth, 40–55 mm, dull light brown, somewhat intruded into the leaf tissue and decurrent for more than its length; **Inf** 1.5–3 m, paniculate, peduncle shorter than the leaves to 1.5 (–2) × longer, fertile part oblong, dense, part-**Inf** globose, 30–50, bulbiferous, the lateral branches ± horizontal to ascending, closely ramified, tertiary branchlets with many small bracts; **Ped** 5–15 mm; **Fl** slender, 40–50 mm; **Tep** yellow, tube openly conical, 3–5 mm, lobes linear, spreading, involute, tip acute with small hood, subequal, 10–20 mm; **Fil** slender, ascending-spreading, 35–50 mm, inserted in the orifice of the tube; **Anth** centric, 15–20 mm, yellow; **Ov** fusiform, 20–25 × 3–5 mm; **Fr** oblong, distinctly notched at the base, 36–40 × 18–21 mm, dark brown; **Se** unknown.

Closest to *A. pachycentra* and *A. wercklei*. The very short-peduncled inflorescences branching from the level of the upper leaf tips mentioned as characteristic by Gentry (1982: 488) are not supported by photographs from Volcán Santa Ana from the internet, showing mostly longer peduncles. Similar plants with inflorescences branching from the level of the upper leaf tips also occur in Chiapas (S Mexico) (Ullrich 1992b). The fruit description was added from *Linares* 4930 (US 3459009!). The leaves of *Kimmach* 419 from Honduras (DES 26840 & 26844!) fit very well here; the more robust flowers may result from its cultivation at the Huntington Botanical Garden. For the typification, see Smith & Figueiredo (2014e: 240–241).

Ullrich (1992b) proposes *A. calderonii* Trelease (1923) as oldest name for *A. parvidentata*. Lott & García-Mendoza (1994), however, treat *A. calderonii*, which is known from the type collection only, as a name of doubtful identity (which is accepted here) tentatively assignable to Sect. *Rigidae* (as Group).

**A. parviflora** Torrey (in Emory, Rep. US Mex. Bound. 214, 1859). **Type** [lecto]: Mexico, Sonora (*Schott* s.n. [US, NY]). — **Lit**: Gentry (1982: 200–203, with ills.); Starr (2012: 200–203, 310–311, with ills.). **Distr**: USA (Arizona), Mexico (Sonora).

US 125479, designated as “type” (= lectotype) by Gentry (1982: 201, 213), includes a leaf of a “*Manfreda*”; and the single flower that is much too large for *A. parviflora* might likewise belong to the latter.

**A. parviflora** ssp. **densiflora** G. D. Starr & Devender (Cact. Succ. J. (US) 83(5): 225, ills. (p. 228), 2011). **Type:** Mexico, Sonora (*Reina G. & Devender* 98-1892 [ARIZ, DES, MEXU, MO, USON]). — **Lit:** Starr (2012: 201, 203, 309); Greulich (2018a); both with ills. **Distr:** Mexico (Sonora: near Yécora); rocky hill slopes and rock outcrops, at canyons, in pine-oak forests, oak woodland and rocky grasslands, 1300–1600 m; flowers May and July. **I:** Hochstätter (2015: VIII: 59).

[1e] Differs from ssp. *parviflora*: **Ros** compact, 35–40 × 30 cm; **L** 15 × 1.8–1.9 cm; **terminal Sp** 5–8 mm; **Inf** 2–2.1 m, part-**Inf** with up to 6–8 flowers; **Fl** 16–18 mm, more densely arranged; **Tep** tube 5–7 mm, 2 × as long as the lobes, lobes 2–3 mm; **Fil** erect, 12–13 mm; **Ov** 5–8 mm.

Differs from the other subspecies primarily in its longer and broader leaves and inflorescences with more densely arranged flowers and in groups of 6–8.

**A. parviflora** ssp. **flexiflora** Gentry (US Dept. Agric. Handb. 399: 56–57, ills., 1972). **Type:** Mexico, Sonora (*Gentry* 16638 [US, ARIZ, DES †, MEXU, MICH]). — **Lit:** Gentry (1982: 201–203, with ills.); García-Mendoza (2003); Starr & Devender (2011: 227, 229); Starr (2012: 201). **Distr:** Mexico (NE Sonora); grama grasslands and oak woodlands, 600–1500 m. **I:** Etter & Kristen (2007b: 179); Pilbeam (2013: 164); Ettelt (2014: 115); Hochstätter (2015: VIII: 60).

[1e] Differs from ssp. *parviflora*: **L** dimorphic, linear to lanceolate, 6–10 × 1 cm or 15–18 × 1.2 cm; **terminal Sp** whitish; **Inf** 1.5–2.5 m, part-**Inf** with 1–3 (mostly 2) flowers; **Fl** saccate; **Tep** with anthers and style bent downwards at anthesis, tube 3–4 mm, lobes 3.5–5 mm; **Ov** 6–8 mm. — **Cytology:** 2n = 60 (Palomino & al. 2015, with 3 structurally different cytotypes).

Best differentiated from the other subspecies by its tube and tepal lobes about equal in length and its reflexed flowers (Starr & Devender 2011).

**A. parviflora** ssp. **parviflora** — **Lit:** Trelease (1894: t. 32); Berger (1915: 77–79); Breitung (1960: 79, with ill.); Gentry (1972: 53–56, with ills.); Gentry (1982: 200–203, with ills.); Ullrich (1990e: with ill.); Hodgson (1999a: 9); Reveal & Hodgson (2002); García-Mendoza (2003); Starr & Devender (2011: 227–229, with ills.); Starr (2012: 200–203, 310–311, with ills.); Parker (2017: 262, 264, with ill.). **Distr:** USA (S Arizona), Mexico (NE Sonora); open rocky slopes, mostly in desert grasslands and oak woodlands, 600–1500 m; flowers May to August. **I:** Irish & Irish (2000: t. 33); Heller (2006: 117); Pilbeam (2013: 163); Ettelt (2014: 116); Hochstätter (2015: VIII: 58).

**Incl.** *Agave hartmanii* S. Watson (1891).

[1e] Acaulescent; **Ros** 10–15 × 15–40 cm, solitary or rarely caespitose; **L** ascending to erect, oblong-linear, firm, adaxially flat towards the apex, abaxially convex towards the base, widest at or above the middle, apex abruptly acuminate, 6–10 × 0.8–1 cm, dark green, both faces with white imprints from the central bud, margins straight, conspicuously filiferous, fibres white, tightly and uniformly curled; **marginal teeth** minute, near the leaf base only; **terminal Sp** weakly subulate, 5–8 mm, brown to greyish-white; **Inf** 1–2.1 m, ‘spicate’, peduncle with caducous, narrowly triangular **Bra**, the lowest 1–3 cm long, **Inf** laxly to densely flowered in the upper ½, this part frequently reddish, part-**Inf** with 2–4 flowers; **Ped** < 2 mm; **Fl** strongly recurved, 13–18 mm; **Tep** pale yellow to light greenish-yellow, tube urceolate, 5–7 × 4.5–5.5 mm, lobes erect to incurved, subequal, inner ones nearly orbicular, constricted near the tube, outer slightly longer than the inner, 2–3.5 × 1.5–4 mm; **St** slightly exerted; **Fil** erect, 9–14 mm, pinkish-red, inserted at the base of the tube; **Anth** 5–6 mm, yellow; **Ov** 4–8 × 3–5 mm, neck slightly constricted, 1–2 mm; **Sty** shorter than the filaments; **Fr** globose, 6–8 × 6–10 mm, apex short-beaked, stipe none to short; **Se** semicircular, 3–3.5 × 2–2.5 mm, thinner on the inner edge, thicker on the outer and curved edge. — **Cytology:** 2n = 60 (Bhattacharyya 1968, Zonneveld 2003).

This taxon has the smallest flowers in the genus. It is closely related to *A. polianthiflora*

from which it is only separable with certainty by the distinctive flowers (Gentry 1982: 201).

The name *A. hartmanii* S. Watson caused some confusion. It was based on a sterile cultivated plant whose features correspond to both *A. parviflora* and *A. polianthiflora*, but no original material was preserved (Gentry 1982: 205). Ullrich (1990e) provided an authentic illustration and showed that *A. hartmanii* was collected near Nacori (Sonora), within the area of *A. parviflora* ssp. *flexiflora*, which suggests its identity with the latter. Laferrière (1995a) selected the holotype of *A. parviflora* as neotype for *A. hartmanii*, making the name a homotypic synonym of *A. parviflora*. — The species is listed in CITES Appendix I.

The taxon occurs in Arizona at about a dozen localities, none with more than 200–300 individuals, and is at present the only *Agave* included in the US Endangered Species List, classified as “Endangered” (Parker 2017).

With largely diurnal anther dehiscence and nectar production with a high nectar sugar concentration, *A. parviflora* appears to be predominantly adapted to diurnal insect pollination. Indeed, the flowers are primarily visited by bumblebees; nocturnal bat visitation appears unlikely due to the lack of floral rewards (Slauson 2002a).

**A. pax** Giraldo-Cañas (Caldasia 39(1): 35–38, ills. (pp. 41–46), 2017). **Type:** Colombia, Antioquia (*Giraldo-Cañas & Giraldo-Osorio* 6139 [COL, COL]). — **Distr:** Colombia (Antioquia: Rio Cauca canyon); in tropical deciduous forests, common, 500–800 m; flowers in January.

[2g] Stems to 50 × 18 cm, simple; **Ros** dense, suckering; **L** 32–43, straight, lanceolate, rigid, coriaceous, broadened at the base, guttered, papillose on both faces, veins distinct only when dried, 142–154 × 6.5–12 cm, opaque green, darker on the upper face, pruinose, margins straight; **marginal teeth** absent or as few irregular denticles, 2–3 mm, light to dark brown, shiny, on small prominences; **terminal Sp** conical, rigid, slightly rough, not grooved at the base, 18–22 mm, brown, basally cream, shiny, not decurrent; **Inf** 8–10 m, paniculate, peduncle dark green, with lanceolate **Bra** 35–76 cm long at the base, fertile part

ellipsoid, lax, with 21–24 4-branched part-**Inf** in the upper ½, the basal ones 45–59 cm long, bulbiferous, bulbils scarce, degenerate; **Ped** 2–8 (–10) mm; **Fl** 52–58 (–61) mm; **Tep** light green or yellowish-green, tube urceolate, grooved, (5–) 8–16 × (5–) 7–10 (–12) mm, lobes triangular, longitudinally brownish striate, erect to slightly reflexed, equal, ±18–21 × 2–3 mm; **Fil** filiform, 45–55 mm, light brown, inserted 3–3.2 mm below the tube throat, long-exserted; **Anth** slender, 20–22 mm, yellow; **Ov** fusiform, rounded, 23–30 (–32) × (4–) 5–8 mm, light green, neck 3–4 mm, mostly constricted; **Sty** filiform, longitudinally striate, 50–55 mm, cream, long-exserted; **Sti** capitate, 3-lobed, papillose, cream to dark brown; **Fr** and **Se** never produced.

According to the protologue the sole South American native *Agave* with light green to yellowish-green flowers, and most similar to *A. sisalana*, but differing esp. in its papillose leaves, slightly rough terminal spine, larger inflorescences mostly with more part-inflorescences, ovaries mostly with distinct neck, a shorter style, light brown filaments inserted below the tube throat, smaller anthers, and the scarce degenerate bulbils. — Thought to be endangered (IUCN category EN).

**A. ×peacockii** Croucher *pro sp.* (Gard. Chron. 1873: 1400, fig. 283, 1873). **Type:** [lecto — icono]: Gard. Chron. 1873: 1400, fig. 283, 1873. — **Lit:** Berger (1915: 120–121); Gentry (1982: 165–169, with ills.); Valverde & al. (1996: with ills.); Ullrich (1996a: with ills.); García-Mendoza (2003: with ill.); García-Mendoza (2011a: 42, 44–45, 50); Smith & Figueiredo (2014c: with ills.); all as *A. peacockii*. **Distr:** Mexico (S Puebla, N Oaxaca); thorn forests on arid calcareous hills, 1000–2200 m; flowers December to April. **I:** Curtis’s Bot. Mag. ser. 3, 57: t. 7757, 1901, as *A. peacockii*; Heller (2006: 118, as *A. peacockii*); Richter (2011: 85); Pilbeam (2013: 165); Hochstätter (2015: IX: 46).

≡ *Agave ghiesbreghtii* var. *peacockii* (Croucher) A. Terracciano (1885) ≡ *Agave roezliana* var. *peacockii* (Croucher) Trelease (1914).

[1g × 2n] *A. ×peacockii* is only known from a small area around Tehuacán in S Puebla and, as recently reported by García-Mendoza (2011a), N

**Fig. 47** *Agave pelona*

(Etter & Kristen 3182:  
Mexico; Sonora, ±  
30 km S of Caborca,  
500 m). (Copyright: J. Etter  
& M. Kristen)

Oaxaca. Berger (1915) was the first to suggest a hybrid origin, and Gentry (1982) assumed that the taxon represents the putative natural hybrid between the sympatric *A. kerchovii* and *A. marmorata*. This is above all suggested by the inflorescences that are intermediate between those of species of Subgen. *Littaea* and Subgen. *Agave* (Gentry 1982). A detailed morphometric analysis of the hybrid and comparisons with its putative parents were provided by Valverde & al. (1996). The illustration cited as ‘type’ by Gentry (1982: 165) is to be treated as neotype, but is superseded by designation of the plate accompanying the protologue as lectotype (Smith & Figueiredo 2014c). The taxon is in danger of extinction (Smith & Figueiredo 2014c).

**A. pelona** Gentry (US Dept. Agric. Handb. 399: 76–80, ills., 1972). **Type:** Mexico, Sonora (Gentry & Arguelles 1989 [US [2 syn], ARIZ, DES, MEXU]). — **Lit:** Gentry (1982: 169–172); Turner & al. (1995: 59–61); Starr & al. (2008); Starr (2012: 204–208); Greulich (2017a); all with ills. **Distr:** Mexico (NW & W Sonora: Sierra del Viejo, Cerro Aquituni, Sierrita de Lopez); limestone rocks and cliffs in arid desert mountains, 500–1220 m; flowers February to May. **I:** Etter & Kristen (2001: 166–167, 169–171, 174); Heller (2006: 120); Richter (2011: 52); Pilbeam (2013: 168); Hochstätter (2015: IX: 41); Moore (2016: 291). – Fig. 47.

[lg] Stems short; **Ros** compact, 40–60 × 60–80 cm, solitary; **L** many, linear-lanceolate,

erect to ascending, thick, stiff, sometimes slightly narrowed towards the base, long-acuminate, rounded below, flat above, epidermis smooth, minutely punctate, waxy, 35–50 × 3–5 cm, shiny dark green, turning reddish to purplish during drought or with age, margins with smooth white firm border becoming brittle and detachable on dried specimens; **marginal teeth** none; **terminal Sp** strong, sharp, sharply angled below, grooved or flat above, 40–70 mm, white to reddish, decurrent as a white border down the leaf margins; **Inf** 2–3 m, ‘spicate’, **part-Inf** in the upper ½, with geminate flowers; **Ped** 30–50 mm, bifurcate; **Fl** campanulate, 45–50 mm; **Tep** dark red, tube openly funnel-shaped, lined with a nectariferous tissue, 8–9 × 15–17 mm, lobes linear-ovate, flat and unkeeled, 18 × 8–10 mm, inner wider, 8- to 9-veined, recurved at the tip, tip apiculate, white-papillate; **Fil** 35–40 mm, inserted on the tube rim, red; **Anth** centric, 15–17 mm, red; **Ov** cylindrical, slender, faintly striate, 20 mm incl. neck, light green; **Sty** slightly longer than the tepals, slightly thickened; **Fr** oblong, thin-walled, rounded, 25–30 × 12–15 mm, shortly apiculate, light pruinose; **Se** thick, rugose, irregular in size and shape, mostly 4–5 × 4–5 mm, sooty black.

Without close relatives in Sect. *Heteracanthae* (as Group *Marginatae*) and geographically isolated from its remaining species, but possibly closest to *A. potrerana*, which likewise has a red corolla and a strong tendency towards the reduction of the marginal teeth (Gentry 1982: 169).

*A. pelona* might be misplaced in this group and perhaps belongs to Sect. *Littaea* (as Group *Filiferae*), as indicated by its funnel-shaped flower tube with nectariferous inner lining and red tepals with recurved lobes. Molecular AFLP data (Gil-Vega & al. 2007) place the species among Sect. *Heteracanthae* (as Group *Marginatae*), however. Specimens from the Sierra Seri with smaller, greener leaves and caespitose rosettes were included in the strictly solitary *A. pelona* by Gentry (1972), Gentry (1982) and Turner & al. (1995), but specimens from that area were found to be misidentified by Starr and have been identified as *A. chrysoglossa* by R. Felger (Starr 2012: 205). Gentry's type at US consists of two sheets which are not cross-labelled and thus represent syntypes.

*A. pelona* is an important part of the diet and water source for Bighorn Sheep (*Ovis canadensis mexicana*), which feed on whole plants throughout the year and during the flowering period on inflorescences to meet its food and water demands. In the first half of the twentieth century, the species was harvested at small scale for the production of an alcoholic beverage (Velazco Macías & Alanís Flores 2002), and Seri Indians used to eat the hearts (Turner & al. 1995). Nevertheless, the populations are healthy, with plants of all sizes and ages being found (Velazco Macías & Alanís Flores 2002).

**A. pendula** Schnittspahn (Z. Gartenbau-Vereins Darmstadt 6: 7, 1857). **Type** [neo]: Ex cult. (*Anonymous* s.n. [K]). — **Lit:** Todaro (1876–92: 32–35, t. VIII, 1876, as *A. caespitosa*); Berger (1915: 60–61, as *A. sartorii*); Gentry (1982: 217, 226–228, with ills.); Lott & García-Mendoza (1994); Cházaro Basáñez (2001: with ills.); Cházaro Basáñez & al. (2010a: 3, 10, with ills.); Cházaro Basáñez & Vázquez-García (2013: 59, map). **Distr:** Mexico (C Veracruz, W Chiapas), W Guatemala (Huehuetenango); cliffs and steep canyon walls in tropical deciduous forests, 50–1000 m; flowers January to February. **I:** Curtis's Bot. Mag. 103: t. 6292, 1877, as *A. sartorii*; Cházaro Basáñez (2001); Pilbeam (2013: 169).

**Incl.** *Agave aloina* K. Koch (1860); **incl.** *Agave sartorii* K. Koch (1860); **incl.** *Agave noacksii* Hort. Tonel ex K. Koch (1862); **incl.** *Agave noackii*

Jacobi (1865)  $\equiv$  *Furcraea noackii* (Jacobi) hort. ex Baker (1877); **incl.** *Agave pulcherrima* hort. ex K. Koch (1865) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave rufocincta* Jacobi (1868); **incl.** *Agave rubrocincta* Jacobi (1869); **incl.** *Agave caespitosa* Todaro (1876)  $\equiv$  *Agave sartorii* var. *caespitosa* (Todaro) A. Terracciano (1885).

[1f] Stems long, to 200  $\times$  5–11 cm, bifurcate, sometimes creeping but mostly pendent; **Ros** open, spreading, branching axillary; **L** 20–30, oblong to slenderly lanceolate, softly fleshy, ascending to somewhat outcurving, rounded below, flat to concave above, 40–93  $\times$  4.8–11 cm, light green to yellow-green, with pale yellow mid-stripe, margins not horny, denticulate, denticles  $\pm$  1 mm, absent for 12–16 cm below the tip, brown; **terminal Sp** small, 5–8 mm, brown, not decurrent; **Inf** “lateral” according to Cházaro Basáñez & al. (2010a: 8), but actually likely terminal on rudimentary lateral rosettes, 1.3–1.8 m, ‘spicate’, fertile part slender, drooping, laxly flowered in the upper  $\frac{1}{3}$ – $\frac{1}{2}$  of the inflorescence, part-**Inf** with solitary or geminate **Fl** 30–45 mm long; **Te** greenish or tinged with lavender, whitish inside, tube funnel-shaped, 6–13 mm, lobes linear,  $\pm$  equal, 12–16  $\times$  5–7 mm, with broad adaxial nerve, slightly recurved at the tips; **Fil** 30–50 mm, yellowish-green to brownish; **Anth** 10–18 mm, yellowish to brownish; **Ov** bluntly trigonous, 10–15  $\times$  6–7 mm, neck long, constricted for 4–5 mm; **Sty** thick, strong, longer than the filaments, brownish; **Sti** 3-lobed; **Fr** globose to oblong, thin-walled, rounded at the base, obtuse at the apex, 20–22  $\times$  10–12 mm; **Se** hemispherical, sharply angled, with pronounced marginal wing, 4  $\times$  2.5–3 mm, shiny black. — **Cytology:** 2n = 60 (Vignoli 1936: as *A. sartorii*, Simpson & al. 2011).

Very distinctive with long stems and rosettes with overhanging inflorescence. Additional morphological and distributional data with a first record for Guatemala were published by Cházaro Basáñez & al. (2010a). *A. pendula* is closely related to the recently published *A. gomezpompa* and *A. wendtii* from Veracruz (see there for differences), and more distantly to *A. jimenoii*. Mature clumps flower frequently with several inflorescences (Gentry 1982). Material was distributed

by ISI as ISI 2003-11. Gentry (1982: 226, 234) designated 2 sheets at K as neotype, but this is only a first-step neotypification as the sheets are not cross-labelled.

**A. petiolata** Trelease (Mem. Nation. Acad. Sci. 11: 20, t. 8, 1913). **Type:** Curaçao (*Boldingh* A8 [MO [4 sheets]]). — **Lit:** *Boldingh* (1913: 150); *Boldingh* (1914: 18); *Berger* (1915: 225); *Hummelinck* (1936: 243–244); *Hummelinck* (1993: 104, 106–107, 222, with ill.). **Distr:** Leeward Antilles (Curaçao); cultivated on former plantations, on calcareous flats in xeric shrubland. **I:** Online Flora of Curaçao (2018).

**Incl.** *Agave lurida* Hamelberg (1898) (*nom. illeg.*, ICN Art. 53.1).

[2u] Stems to 1 m, grey; **Ros**  $\pm 2$ –2.5 m  $\varnothing$ , solitary and not suckering; **L**  $\pm 15$ , lanceolate, rather abruptly contracted into a long neck at the base, widest below the middle, gradually acute, 80–130  $\times$  10–20 cm, blue-glaucous, with imprints from the central bud, margins nearly straight between the teeth or prominences; **marginal teeth** rather slenderly subulate, straight or variously curved, downcurved somewhat below the middle, narrowly triangular from half-round bases 5–10 mm wide, purplish chestnut-brown, raised on well to rather strongly developed hardening or green prominences, teeth 5–7 (–11 below and above the middle) mm, granular-roughened, purplish chestnut-brown, 15–30 (–60) mm apart, occasionally with much smaller intermittent teeth; **terminal Sp** acicular, straight or somewhat curved,  $\pm$  flexuous, broadly round-grooved to or beyond the middle, granular-roughened below, covered with very many minute tubercles, smooth towards the tip, 18–35 (–60)  $\times$  3–4.5 mm, chestnut-brown, shortly decurrent, dorsally not intruding into the leaf tissue; **Inf** 3–9 m, paniculate, not further described; **Ped** scarcely 5 mm; **Fl** 35–40 mm; **Tep** tube open, 5 mm, lobes 15  $\times$  3 mm; **Fil** 30 mm, inserted nearly in the throat; **Ov** fusiform, 15 mm; **Fr** and **Se** unknown.

A curious plant, in leaf armature suggesting some of the Mexican species grown for pulque (Trelease 1913). One sheet of the holotype (MO 138457) is annotated as “cultivated; only on two plantations and in small numbers”, which was

repeated by *Boldingh* (1913) (“gekweekt”) and *Boldingh* (1914) (“cultivated”). The species gives *Hummelinck* (1936) “the strong impression of not belonging to the native flora”. It is regarded as introduced by *Hummelinck* (1938: 15) and is today only found in an area where fibre Agaves were formerly cultivated (*Hummelinck* 1993: 107), but on naturally appearing habitats (*Hummelinck* 1993: 106, Fig. 18; Online Flora Curacao 2018). *Hummelinck* (1938: 15) excludes the species from Sect. *Viviparae* (as Group), but does not provide an alternative placement. — The photograph in *Pilbeam* (2013: 170) labelled *A. petiolata* appears to represent *A. vicina* (cf. *Pilbeam* (2013: 230)).

**A. petrophila** García-Mendoza & E. Martínez (*Sida* 18(2): 627, 1998). **Type:** Mexico, Guerrero (*Martínez & al.* 2639 [MEXU, BRIT, ENCB, K, MO]). — **Lit:** García-Mendoza & Martínez (1998); García-Mendoza (2011a: 45–50); Starr (2012: 209–212, 314–316); all with ill. **Distr:** Mexico (E Guerrero, S Puebla, W & N Oaxaca); steep to vertical rocky slopes, in calcareous soil, desert scrubs, tropical deciduous forests and ecotones to pine-oak forests, 850–2100 m; flowers October to December. **I:** *Pilbeam* (2013: 171); *Hochstätter* (2015: VIII: 7).

$\equiv$  *Agave gracilis* García-Mendoza & E. Martínez (1998) (*nom. illeg.*, ICN Art. 53.1).

[1a] Stems procumbent, to 1 m; **Ros** semi-globose, compact, 50–80  $\times$  60–80 cm, caespitose; **L**  $> 100$ , linear, straight or somewhat recurved, flat, flexible, subcoriaceous, with longitudinal striae, 40–70  $\times$  0.4–0.9 (at mid-leaf) cm, broadened to 1–1.5 cm at the base, light glaucous to glaucous-green, margins yellowish, finely denticulate; **terminal Sp** weak, subulate, 3–6 (–8) mm, brownish-reddish; **Inf** 1.8–2 m, ‘spicate’, erect or slightly inclined, peduncle with filiform delicate brown **Bra** 5–15 cm long, fertile part in the upper  $\frac{1}{4}$ – $\frac{1}{2}$  of the inflorescence; floral **Bra** linear, 2–3.5  $\times$  0.1–0.2 cm, much longer than the flowers, persisting; **Ped** 1 mm, at fruiting time 2 mm; **Fl** campanulate, 20–22 (–25) mm; **Tep** oblong, green to greenish-yellow, tips dark reddish, tube sulcate, 3–5 (–8)  $\times$  5–8 mm, lobes deltoid or oblong, divaricate, recurved or straight, 5–9 (–11)  $\times$  2.5–3.5

(–4.5) mm, **ITep** keeled; **Fil** 27–30 mm, inserted at the mouth of the tube, yellow to reddish above; **Anth** centric, 7–9 mm, reddish; **Ov** cylindrical, 7–10 × 2–4 mm, without neck, slightly penetrating into the tepal tube; **Sty** 30–35 mm; **Sti** slightly thickened; **Fr** subglobose, trigonous, ringed at the apex, 9–10 × 8–9 mm, sessile, rostrate, green-brown, with stamens and style persisting; **Se** thickened on the curved side, 3–3.5 × 2–2.5 mm, black.

Sharing morphological characteristics with *A. dasyliroides*, but differing in its small caespitose rosettes, smaller and narrower leaves, erect or slightly inclined inflorescences, much smaller flowers and smaller and globose fruits (García-Mendoza & Martínez 1998). The species was first named *A. gracilis*, but this is an illegitimate later homonym of *A. gracilis* Jacobi (1871). García-Mendoza (2011a) provides a new record from Puebla.

García-Mendoza & Martínez (1998) provisionally placed the plant from Yosondua, Oaxaca referred to *A. dasyliroides* by Ullrich (1990f) here, but that plant is the recently published close relative *A. kavandivi* (see there for differences). *A. graciellae* is a further recently published close relative (see there for differences); and *A. rzedowskiana* has similar flowers but different leaves (see there). Molecular AFLP data (Gil-Vega & al. 2007) place the species closest to *A. stricta* and less close to *A. tenuifolia*, *A. striata* and *A. dasyliroides*, but no further species of Sect. *Juncineae* (as Group *Striatae*) were sampled.

**A. petskinil** (R. A. Orellana & al.) Thiede (Haseltonia 17: 94, 2012). **Type:** Mexico, Yucatán (*Carnevali & Ramírez* 7206 [CICY, MO, QMEX]). — **Lit:** Hernández-Sandoval & al. (2008); Orellana (2012); Carnevali (2013); all with ill. and as *Manfreda*. **Distr:** Mexico (Yucatán); open or shaded areas over limestone, rocky shallow soils in tropical (sub-)deciduous forests, often associated with sinkholes (“cenotes”), 5–30 m; flowers January to April. **I:** Hochstätter (2016: I: 34, as *Manfreda*).

≡ *Manfreda petskinil* R. A. Orellana & al. (2008).

[3a5] Herbaceous, acaulescent; **Ros** 0.3–0.5 m; rhizomes globose, 5–7 cm, producing new

rosettes from lateral meristems at the base of the inflorescence; **R** succulent; **L** mostly lost during the dry season, some persisting, 7–30, linear-lanceolate, recurved, somewhat flaccid, succulent (±1.4 mm thick at the widest section), slightly channelled, surface almost smooth, 18–38 × 1–2 cm, pale to dark green, with darker green to reddish spots, these more vivid on some individuals and when exposed to bright light, margins hyaline, denticulate with small, irregular teeth 0.25–5 mm long, apex long-attenuate with a short soft tip; **Inf** 1.3–1.6 m, a raceme or more often a panicle with 2–5 branches in well-developed plants, peduncle 1.1–1.35 m, with 3–6 internodes, green or reddish, often with darker blotches as in the leaves, with several **Bra** 1–3 cm long, fertile part 20–35 cm, branches suberect, 15–23 cm, densely flowered; **Ped** 1–1.5 (–2) mm; **Fl** solitary, 30–35 mm; **Tep** light green outside, glaucous, dull yellowish-green inside or with reddish tinge, tube 5–7 mm, broadly funnel-shaped, lobes 12–15 × 2–4 mm, reflexed during the staminate phase of the anthesis, then erect, apex cucullate, with a small tuft of glandular white hairs; **Fil** filiform, 40–70 mm, dark shiny reddish-brown; **Ov** cylindrical, 12–18 mm, coloured as the tepal outside; **Sty** linear, 60–68 mm, dark shiny reddish-brown; **Sti** capitate to clavate, 3-lobed; **Fr** trapezoid or asymmetrically oblong to ovoid when unripe, 10–15 × 7–8 mm, ripe **Fr** not seen; **Se** unknown.

Closest to *A. paniculata* according to the protologue, likewise from the Yucatán Peninsula, which is a much larger plant with a larger, more complex inflorescence. *A. petskinil* was included in *A. variegata* by earlier authors, from which it differs in its puberulent and denticulate leaves, ascending flowers, and filament insertion at the throat of the tube. The stamens of *A. petskinil* are widely divergent as opposed to the commonly subparallel stamens in most species of Sect. *Herbaceae*. The tropical lowland habitat is atypical and apparently not known for other species of Subgen. *Manfreda* except *A. paniculata*, *A. chamelensis*, and *A. littoralis*.

*A. petskinil* and the similar *A. paniculata* share the unusual paniculate inflorescences and a tendency towards becoming caulescent, suggesting natural hybrids between Subgen. *Manfreda* and a paniculate

Agave, namely *A. fourcroydes* or *A. angustifolia* (Jankalski, message in Agavaceae@yahoo.com, 2008). Both species have been found primarily near sinkholes and might have been perpetuated as superior medicinal, soap and fibre producing or ornamental plants (Jankalski l.c.); the leaves of *A. petskinil* are used against headache according to the protologue.

**A. ×pfersdorffii** Hort. Besaucèle *ex* André (Rev. Hort. (Paris) 76: 326, 1904). **Type:** not typified. — **Lit:** Berger (1915: 50). **Distr:** Cultivated only.

[1f × 1g] According to Berger (1915: 50), this name was first published by Besaucèle in his elusive (no copies have been traced so far) “Catalogue Raisonné” from 1894 with the statement “Hybride très remarquable, de grandes dimensions. Les feuilles sont larges bleutées” for a hybrid between *A. obscura* (as *A. xalapensis*) × *A. lechuguilla* (as *A. univittata*), raised by Pfersdorff at Paris. André (1904) provides a short description of a plant flowering in the collection of Ch. Simon and states that the second parent is *A. xylonacantha*, a view also expressed by Trelease (1914: 236).

**A. phillipsiana** W. C. Hodgson (Novon 11(4): 410–411, ills., 2001). **Type:** USA, Arizona (Hodgson 11861 [DES, ASU, GCNP, MO [photo], SD]). — **Lit:** Hodgson (1999b: 11–12, with ills., as *A. sp.*); Brian (2000: with ills., as *A. sp. nova*); Reveal & Hodgson (2002); Klopper & al. (2010: 62); Parker (2018a: 22, 25, with ills.). **Distr:** USA (Arizona: Grand Canyon National Park); sandy to gravelly places with desert scrub along permanent waterways, 700–1140 m; flowers September.

[2h] Acaulescent; **Ros** open, 0.75–1 × 0.75–1 m, solitary to caespitose, freely suckering; **L** numerous, ascending to spreading, lanceolate, acuminate, firm, broadest just below the middle, thickish and convex towards the base, concave towards the apex, 76–78 × 10–11 cm, slightly glaucous-green to dark green, very lightly cross-zoned, margins straight or repand; **marginal teeth** variable, upcurved or reflexed, weakly attached, 4–7 mm, red-brown aging to grey, 10–25 mm apart, intermittent teeth (2–) 3–7 along the upper 2/3 of the leaf; **terminal Sp** slender, openly grooved,

25–40 mm, dark brown to grey, decurrent for up to 7.2 cm to the upper teeth; **Inf** 2.5–5.5 m, narrowly paniculate, fertile part open, maroon-glaucous-pruinose, with 9–16 short slightly ascending to horizontal part-**Inf** in the upper 1/3–1/2, with 32–45 densely clustered flowers; **Ped** 5–10 mm; **Fl** 68–86 mm, thick; **Tep** tube very thick, bulging at the lobe bases, 5.5–20 × 15–23 mm, pale creamy yellowish-green, lobes broadly lanceolate, erect, leathery, persistent, clasping the filaments, unequal; **OTep** 20–21.5 × (5–) 8–12 mm, whitish-cream with a light green tinge, becoming dark maroon at anthesis, tips brown-maroon, felt-like, rugose and hooded; **ITep** 15–19 × (4–) 5–8 mm, strongly keeled, similarly coloured; **Fil** 48–64 mm, subequally inserted 7.5–11 and 9–12 mm above the tube base; **Anth** 17–25 mm, yellow; **Ov** thick, 29–46 mm, neck 4–8 mm, slightly constricted, pale creamy yellowish-green; **Sty** 60–78 mm, slightly longer than the filaments, pale creamy yellowish-green flecked with maroon; **Sti** capitate, 3-lobed; **Fr** and **Se** not produced. — **Cytology:** 2n = ±120 (protologue).

The species reproduces exclusively by vegetative means. According to the protologue known from only four places within the Grand Canyon National Park, three of which are near pre-Columbian agricultural features or habitation sites, but Parker (2018a: with map) reports the species from numerous localities across N & C Arizona, allied with the ancient Sinagua culture. It possibly represents an ancient cultivar selected by pre-Columbian people from populations related to *A. palmeri*, *A. colorata*, or other closely related taxa. For further pre-Columbian cultivar species in Arizona, see also under *A. verdensis*.

**A. pintilla** S. González & al. (Acta Bot. Mex. 95: 81–83, ills., 2011). **Type:** Mexico, Durango (Reséndiz & al. 131 [CIIDIR, ENCB, MEXU]). — **Lit:** González-Elizondo & al. (2009: 132–136, as *A. victoriae-reginae* El Mezquital); Thiede (2011: 153–155); both with ills. **Distr:** Mexico (SE Durango); conglomerate slopes in a volcanic area with igneous rock fragments, in calcareous soils in desert scrub, 1440–1580 m. **I:** Roosbroeck (2012: 164); Pilbeam (2013: 172); Ettelt (2014: 122); Hochstätter (2015: IX: 54).

[lg] Acaulescent; **Ros** 30–60 × 20–35 cm, lax, open, caespitose or solitary, surculose; **L** 60–180, narrowly triangular, narrowing gradually towards the apex, very broad at the base, tip acute, with a prominent white apical band 5–10 mm wide around the base of the terminal spine, dorsally rounded or keeled in the upper part, ventrally concave or flat towards the base, 13–22 × 5.8–8 cm, pale green to bluish-green, with white bands on both faces and the margins, margins horny, white, entire, continuous to the leaf base and apex or terminating 2–3 cm below the apex, 3–5 mm wide; **marginal teeth** none; **terminal Sp** narrowly pyramidal to lanceolate, 20–29 mm, broadly channelled above and roundish keeled below, nearly black, not or only very slightly decurrent along the leaf margins, usually with 3 adjacent teeth or at least with 1 very short dorsal spine; **Inf** erect, 1.6–4.3 m, ‘spicate’, peduncle robust, with several chartaceous deltoid **Bra**; **Fl** laxly arranged, usually geminate, 58–65 mm; **Tep** 40–44 mm, whitish to greenish-white, tube funnel-shaped, 3–5 × 8–10 mm, lobes ascending to patent, subequal, broadly linear, 18–22 × 5–7 mm, somewhat conduplicate at the base, flat towards the apex; **Fil** 58–66 mm, inserted above the throat of the tube, greenish-white or with purple tinge; **Ov** thickly fusiform, 18–21 mm, neck short, greenish; **Fr** woody, broadly oblong, rounded at the base, 22–24 × 16–18 mm, shortly apiculate; **Se** suborbicular, semicircular or drop-shaped, 4–5 × 2.5–4 mm, black, shiny or dull black.

First depicted by González-Elizondo & al. (2009: 135, 136) as “*A. victoriae-reginae* El Mezquital, Dgo.”. Two years later, this species was described in the context of the study of the *A. victoriae-reginae* complex by González-Elizondo & al. (2011), in which *A. nickelsiae* was also re-established as species. *A. pintilla* is characterized by 60–180 (vs. 170–280 in *A. nickelsiae*) green to bluish-grey-green, narrowly triangular, not puberulent leaves (vs. grey-green to dull green, puberulent, oblong) with a not or hardly decurrent terminal spine (vs. decurrent). The species propagates by seeds and vegetatively by rhizomes; the latter is commoner (González-Elizondo & al. 2011). In its foliar phenole profile,

the species differs clearly from all other members of the *A. victoriae-reginae* complex (Almaraz-Abarca & al. 2013c).

According to the protologue, *A. pintilla* is restricted to near El Mezquital, SE Durango, ±170 km apart from the closest localities of *A. victoriae-reginae* ssp. *swoboda* in NE Durango. However, the species also occurs ±150 km N of Ciudad Durango and possibly also near Nombre de Dios (Thiede 2011). *A. pintilla* rarely forms natural hybrids with *A. salmiana* ssp. *crassisipina* (González-Elizondo & al. 2011).

**A. planifolia** S. Watson (Proc. Amer. Acad. Arts 22: 479, 1887). **Type:** Mexico, Chihuahua (Pringle 1141 [GH, VT]). — **Lit:** Rose (1903c: 22); Berger (1915: 37); Gentry (1972: 153); Verhoek-Williams (1975: 255–258); Piña Luján (1985: 88–89); García-Mendoza (2003); Castillejos-Cruz (2009: [226]–[231], with ills.); Castro-Castro (2017: 61–63, 68, with ills.); all as *Manfreda*. **Distr:** Mexico (SE Sonora, C & S Chihuahua, C Nayarit); sandy banks near streams and in grasslands, pine or pine-oak forests, 1400–2300 m; flowers September to December. **I:** Hochstätter (2016: I: 35, as *Manfreda*).

≡ *Manfreda planifolia* (S. Watson) Rose (1903) ≡ *Polianthes planifolia* (S. Watson) Shinnors (1966).

[3a3] Herbaceous, medium-sized (for Subgen. *Manfreda*); corm globose to subglobose, 3–4 × 3–3.8 cm, bulb globose, 3.5–4 × 3–3.5 cm, covered almost entirely with dry leaf bases 3.8–7 cm long; **R** fleshy, with filiform ramifications, contractile; **L** drought-deciduous, 4–5, spreading-arching, oblong to narrowly elliptic, narrowed towards the clasping, petiole-like, 1.5–2 cm long base, tip acuminate, with a short point, channelled in the petiolar portion and at the tip, nearly flat in the middle, semisucculent, drying leathery, smooth, with raised ribs below, 20–32 × (2.5–) 3–7.5 cm, green, unspotted, margins with a narrow hyaline band, minutely and irregularly to regularly denticulate; **Inf** 1.2–1.6 m, erect, ‘spicate’, light green to yellow, peduncle with 5–8 truncate, narrowly elliptic, slightly amplexicaul **Bra**, upper ones lanceolate, fertile part short,

dense, (6–) 10–12 cm, with 6–14 sessile flowers; floral **Bra** 8–12 × 3–5 mm; **Fl** 18–28 mm, ascending; **Tep** yellowish-green, tube cylindrical, at a slight angle to the ovary, 5–7 × 4–5 mm, slightly constricted at the apex of the ovary, lobes oblong to narrowly elliptic, recurved to reflexed, apex cucullate, with a tuft of short white hairs, 12–19 × 4–5 mm, yellow-green; **Fil** erect at anthesis, 26–40 (–56) mm, inserted at the same level at mid-tube, reddish-green with small purple dots; **Anth** 12–15 mm, yellow; **Ov** cylindrical to slightly ellipsoid, 9–15 × 5–7 mm, extending 1–4 mm into the tepal tube; **Sty** 36–55 mm, exceeding the tube by 35–42 mm at anthesis, yellowish-green; **Sti** clavate, 3-lobed; **Fr** ovoid to subglobose, 15–20 × 15–18 mm, with a scar near the apex, base of style and dry perianth persistent; **Se** deltoid, plane-concave, 4–5 × 3–4 mm, with a narrow margin, black, shiny.

Characterized by broad leaves flattened in the middle and channelled at the base and tip, and the narrowed leaf base forming a pseudopetiole (Castillejos-Cruz 2009). Closely related to *A. guttata*, but distinctive because of its elliptic leaves with the appreciably narrowed and clasping base and acuminate tip, as well as the more N range (Verhoek-Williams 1975: 257, Castillejos-Cruz 2009). The species shares the flower shape, the size of the tepal tube as well as the size and shape of the lobes with *A. guttata* and the undescribed *Manfreda riosramirii* (from Puebla) but both these species do not have the fragile and brittle leaves of *A. planifolia* and its unpleasant floral odour (Castillejos-Cruz 2009) (as *Manfreda*). — The species is known from few collections only and is listed as threatened with extinction (Rodríguez & Castro-Castro 2006, Rodríguez & Castro-Castro 2007) (both as *Manfreda*).

**A. platyphylla** (Rose) Thiede & Eggli (Kakt. and. Sukk. 50(5): 112, 1999). **Type:** Mexico, Jalisco (Rose 2598 [US, GH, MEXU, MO, NY]). — **Lit:** Rose (1903a: 11); McVaugh (1989: 255–256, with ills.); García-Mendoza (2003); Feria-Arroyo & al. (2010: with ill.); all as *Polianthes*. **Distr:** Mexico (S Durango, S Zacatecas, Nayarit, Jalisco); grasslands, rocky mesas among grasses, hillsides in pine, pine-oak or oak

and tropical deciduous forests, 1400–2520 m; flowers June to November. **I:** Hochstätter (2016: II: 22); Castro-Castro & al. (2016: 721); Castro-Castro (2017: 137); Solano & al. (2019: 5, 8, 9, with ills.); all as *Polianthes*.

≡ *Polianthes platyphylla* Rose (1903) ≡ *Bravoa platyphylla* (Rose) Conzatti (1947).

[3b1] Herbaceous; corm ±0.5–0.8 × 1–1.2 cm, bulb 1.8–3.5 × 1.2–2.3 cm, ovoid, nearly completely covered with dried leaf bases, these membranous at the base and fibrous above; **R** fleshy, thickened, tapering, to 3–7 cm, contractile, in a dense cluster; **L** drought-deciduous, (1–) 2–6 (–10), lying flat on the ground, elliptic-lanceolate to narrowly ovate, narrowed at the base to a short subpetiolar part to 5 mm wide, apex long-acute, apiculate, 7–16 × 1–4 cm, green, with purple dots near the base, margins entire, with a narrow hyaline band; **Inf** 27–60 cm, erect, ‘spicate’, peduncle with 2–3 **Bra**, bracts lanceolate-attenuate, 2–10 cm, internodes decreasing distally, fertile part (4–) 6–13 cm, lax, with 3–25 remote floral nodes; floral **Bra** deltoid-ovate, 0.8–1.2 cm; **Ped** none; **Fl** geminate, fragrant with *Gardenia*-like scent, 15–22 mm; **Tep** white, cream or rose to red at senescence, tube cylindrical, ±10–16 (–21) × 2.5–3.5 mm (near the filament insertion), curved outwards just above the ovary, diffuse to divaricate, mouth oblique, lobes equal, ovate to orbicular, 2–2.5 (–3) × 2–2.5 (–3) mm, **OTep** nearly erect, **ITep** reflexed, apex cucullate, rounded, with a bundle of white trichomes; **Fil** filiform, 1–5 mm, included, inserted 3–6 mm below the mouth of the tube; **Anth** linear, 3–4 mm; **Ov** ellipsoid, ±3.5–4 × 2.5–3 mm, erect at anthesis or nearly so; **Sty** filiform, 10–18 mm, white, tips exerted; **Sti** 3-lobed, white; **Fr** narrowly ellipsoid to subglobose, stoutly stipitate, 7–13 × 7–10 mm, with persisting tepals; **Se** crescent-shaped, flat, 2.5–4 × 2–3.4 mm, shiny or opaque.

*A. platyphylla* is distinct in Ser. *Polianthes* of Sect. *Polianthes* esp. in its mostly broader, lanceolate leaves and its sessile flowers with short tube. *A. rosei* has a similarly short tube, but differs in its ensiform, narrower leaves and pedicellate flowers. Feria-Arroyo & al. (2010) assess the extinction risk and classify the species as “Endangered”.

**A. polianthiflora** Gentry (US Dept. Agric. Handb. 399: 51–54, ills., 1972). **Type:** Mexico, Chihuahua (*Gentry* 8013 [US, ARIZ, MEXU]). — **Lit:** Gentry (1982: 202–205); Ullrich (1989c); García-Mendoza (2003); Starr & Devender (2011:

220–230); Starr (2012: 213–216, 310–311); all with ills. except García-Mendoza. **Distr:** Mexico (E & SE Sonora, W, SW & C Chihuahua); infrequently in small clones on rock outcrops, slopes and grazed pastures, in pine-oak or oak forests, 1220–2000 m; flowers June to July. **I:** Thiede & Eggli (1999: 109); Etter & Kristen (2003a: 10); Heller (2006: 121, 122); Richter (2011: 64, 107); Pilbeam (2013: 173); Ettelt (2014: 116); Hochstätter (2015: VIII: 61); Greulich (2018a: 31–33). — Figs. 48 and 49.

[1e] Acaulescent; **Ros** 8–20 × 12–30 cm, solitary or caespitose; **L** linear-lanceolate, widest in the middle, convex below, flat above, 10–20 × 1–1.3 cm, green, both faces with white impressions from the central bud, margins conspicuously white-filiferous; **marginal teeth** minute, near the leaf base only; **terminal Sp** weak, 7–10 mm, greyish; **Inf** 1.2–2 m, ‘spicate’, axis red, with deltoid-lanceolate subulate chartaceous **Bra** 1–2 cm long, part-**Inf** in the upper ½ of the inflorescence, usually with 2 (or 1 or 3) laxly arranged flowers; floral **Bra** triangular, 3–6 mm; **Ped** short; **Fl** 37–42 mm; **Tep** pruinose-pink, tube long, very narrow and curved below, 22–32 × 6–8 (at the mouth) mm, lobes ovate to deltoid, subequal, 4–7 mm; **Fil** 27–37 mm, inserted 4–6 mm above the tube base; **St** shortly exerted, reddish before anthesis, yellow afterwards; **Ov** ovoid, 9–12 × 3.5–5 mm, red; **Sty** slender, exerted before anthesis; **Sti** thickened; **Fr** globose to ovoid, rugose,

**Fig. 48** *Agave polianthiflora* (Cultivated material without known wild origin). (Copyright: U. Eggli)

**Fig. 49** *Agave polianthiflora* (Eggli & al. 2038: Mexico; Sonora, Yecora, 1600 m). (Copyright: U. Eggli)

10–15 mm, apiculate, pruinose; **Se** thick, 3.5–4 × 2.5–3 mm, black.

Differs from all other members of Subgen. *Littaea* by its long tubular flowers with very short lobes, similar to those of Sect. *Polianthes*. Moreover, as the style is exerted before anther dehiscence, its flowers are not proterandrous, as in other agaves (Gentry 1982). *A. polianthiflora* is difficult to distinguish from *A. parviflora* vegetatively, but its leaf tip is at a less obtuse angle than in *A. parviflora*, its leaves tend to be widest below the middle (vs. broadest at or above the middle), and the leaf marginal fibres tend to be either straight or slightly curved back (vs. fibres shaped like an inverted U; Starr 2012: 311). The species was first collected by Pringle back in 1888 (Pringle 1995; MO, US) and first depicted by Jacobsen (1954: 149, as *A. parviflora*).

In moist or more fertile situations and if watered frequently in cultivation, the leaves become much larger than in its natural habitat (Gentry 1982). The Wariho Indians manufactured a sweet food from pit-baked plants, and used the inflorescence stalks as arrow shafts (Gentry 1982).

**A. potatorum** Zuccarini (Flora 15:2(Beiblatt 2): 96–97, 1832). **Type** [neo]: Mexico, Puebla (Gentry & al. 20427 [MEXU 116053, ARIZ, US]). — **Lit:** Berger (1915: 185–187); Gentry (1982: 468, 490–493); Arias Toledo & al. (2000: 18); Forster (2006); García-Mendoza (2010: 73–78, 90–92); García-Mendoza (2011a); Starr (2012: 217–222, 312–323); all with ills. **Distr:** Mexico (Puebla, Oaxaca, W-C Veracruz); plains or slightly inclined sites in soils derived from calcareous rocks, in tropical deciduous forests and xerophytic scrub with cacti or oaks, and ecotones of both with oak forests, 1240–2400 m; flowers end of August to November. **I:** Curtis's Bot. Mag. 91: t. 5493, 1865, as *A. saundersii*; Refug. Bot. 5: t. 306, 1872, as *A. verschaffeltii*; Refug. Bot. 5: t. 328, 1872, as *A. scolymus*; Ettelt & Riedel (1998); Heller (2006: 123, 162); Richter (2011: 84, 112); Pilbeam (2013: 174–176).

**Incl.** *Agave potatorum* var. *minor* hort. (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Agave scolymus* Karwinsky ex Salm-Dyck (1834); **incl.** *Agave elegans* hort. ex Salm-Dyck (1859); **incl.** *Agave*

*latifolia* Karwinsky ex Salm-Dyck (1859); **incl.** *Agave pulchra* hort. ex Salm-Dyck (1859); **incl.** *Agave quadrata* Lemaire (1864); **incl.** *Agave saundersii* Hooker fil. (1865); **incl.** *Agave schnittspahnii* Jacobi (1865); **incl.** *Agave verschaffeltii* Lemaire ex Jacobi (1865) ≡ *Agave potatorum* var. *verschaffeltii* (Lemaire ex Jacobi) A. Berger (1915); **incl.** *Agave scolymus* var. *polymorpha* A. Terracciano (1885); **incl.** *Agave auricantha* Baker (1888).

[2o] Acaulescent; **Ros** compact to openly spreading, 30–50 × 40–60 cm, solitary, rarely with 1–3 offsets on stolons; **L** 30–60 (–100), erect, ovate, oblong or (shortly) lanceolate, softly fleshy but rather rigid, thickened and narrowed towards the base, flat to somewhat concave above towards the apex, 15–35 × (5–) 8–10 cm, glaucous to glaucous-green, margins repand to deeply crenate, with tubercle-like prominences 4–7 (–10) mm long, esp. above mid-leaf; **marginal teeth** on low broad bases, straight, recurved or antrorse, at mid-leaf 4–6 (–12) × 4–6 (–8) mm, chestnut-brown to greyish-brown, mainly 10–30 mm apart; **terminal Sp** broad at the base, sharply pointed, straight or sinuous, broadly grooved to flat above, 30–40 × 4–7 mm, chestnut- to greyish-brown, sharply decurrent as a ridge to the uppermost teeth; **Inf** 3–5 (–6) m, paniculate, peduncle green to reddish-brown, with triangular chartaceous reddish-brown **Bra** 12–20 cm long, fertile part open, with (7–) 11–25 small compact part-**Inf** in the upper 1/3 or 1/2 of the inflorescence, these 10–30 cm and separated for 15–30 cm, with (15–) 20–40 flowers; **Ped** 10–15 mm; **Fl** campanulate to somewhat urceolate, (50–) 55–70 mm; **Tep** light green to yellowish-green, frequently tinged red or purplish in bud, tube cylindrical to funnel-shaped, sulcate, (10–) 13–16 × (8–) 13–18 mm, lobes erect, triangular to oblong, thick, outer 1–2 mm longer than the inner, margins involute, tip cucullate, hard, keeled on the inner face; **Fil** 30–40 (–45) mm, inserted at mid-tube or above, yellowish, sometimes with purple tinge; **Anth** 15–25 mm, yellow; **Ov** cylindrical to slightly triquetrous, 25–30 × 4–6 mm, green, neck 2–3 (–5) mm; **Sty** 55–60 mm; **Sti** clavate, 3-lobate; **Fr** oblong, (35–) 40–60 × 15–20 mm, stipitate, rostrate; **Se** crescent-shaped, flat, faintly winged, 5–6 × 4–5 mm,

black. — **Cytology:**  $2n = 45-60, 60 (= 2 \times)$  (Gómez-Pompa & al. 1971: as *A. verschaffeltii*, Lv & al. 2009, Simpson & al. 2011).

This very polymorphic species is widely distributed in horticulture and vegetatively characterized by its compact rosettes with a large number of flat leaves with small prominences and teeth. In the central valleys of Oaxaca, it shows a great variation in vegetative and reproductive features which is probably due to genetic exchange with the sympatric and synchronously flowering, closely similar *A. seemanniana*. The latter differs in its recurved to erect leaves which are longer and broader, spatulate to ovate, and have larger and more widely spaced teeth on larger prominences (Gentry 1982, García-Mendoza 2010, García-Mendoza 2011a). In C Oaxaca, it forms apparent intermediate hybrids with *A. seemanniana* (García-Mendoza 2010: 77). Forster (2006) illustrates the variability of the species. Rivera-Hernández & al. (2015: 52) provide a new record from W-C Veracruz.

Eguiarte & al. (2013), based on population genetic studies, conclude that *A. potatorum* and *A. cupreata* represent one species only in the evolutionary sense, which is adapted to different climates either in upland forests and open areas (*A. potatorum*) or in the lower areas in the Balsas basin slopes (*A. cupreata*). *A. schnittspahnii* is here included as synonym on the base of Govaerts (2014+), while Berger (1915: 174) placed it in the synonymy of *A. applanata*. — Gentry (1982: 490) designated 2 specimens at M as neotypes, which constitutes a first-step neotypification; García-Mendoza (2010: 75) subsequently designated on of the specimens as the neotype cited above.

Its traditional management and use (for mescal, medicine and fodder), and strategies for its sustainable use are described by Delgado-Lemus & al. (2014). Aguirre-Dugua & Eguiarte (2013) report on the conservation and sustainable use of wild populations for mescal production. Félix-Valdez & al. (2016) show that the extraction of plants for mescal production from wild populations does not significantly decrease the genetic diversity. Torres & al. (2015) calculate a 30–90% population decline in the next 30 years due to continued extraction of adult plants

for mescal production, and show that the population regeneration would be most effective when 1- or 2-year old seedlings are transplanted, and this size class also predominates in nature. Seeds from different localities show significant differences in size, weight, and germinability; germinability decreases with age (Ortiz-Hernández & al. 2018).

A small form with green leaves has been named ‘Minor’ (Heller 2006: 123, with ills.). ‘Kichijokan’ and the variegated ‘Kissho Kan’ (with several different spellings) are cultivars assigned to this species (Starr 2012: 120–126, with ills.), and ‘Cubic’ is selected from seedlings of ‘Kichijokan’ (Starr 2014: 218). ‘Snowfall’ is a variegated cultivar (Starr 2012: 222, with ill.); Moore (2016: 283) illustrates further variegated forms.

**A. potosina** B. L. Robinson & Greenman (Proc. Amer. Acad. Arts 29: 393–394, 1894). **Type** [syn]: Mexico, San Luis Potosí (*Pringle* 3745 [ARIZ, B, BM, BR, COLO, E, F, G, GH, GOET, K, LE, MA, MEXU, MO, MSC, MU, NY, P, PH, PUL, S, US, VT]). — **Lit:** Rose (1903c: 18); Verhoek-Williams (1975: 182–186); Piña Luján (1985: 29, 58–60, with ills.); García-Mendoza (2003: with ill.); Castillejos-Cruz (2009: [232]–[237], with ills.); all as *Manfreda*. **Distr:** Mexico (S Coahuila, SW Nuevo León, E Durango, C Zacatecas, W-C San Luis Potosí); dry desert and limestone mesas, in desert scrub, 1300–2400 m; flowers June to July. **I:** Hochstätter (2016: I: 36, as *Manfreda*). — Fig. 50.

≡ *Manfreda potosina* (B. L. Robinson & Greenman) Rose (1903) ≡ *Polianthes potosina* (B. L. Robinson & Greenman) Shinnery (1966); **incl.** *Delpinoa gracillima* Ross (1898).

[3a1] Herbaceous, small (for Subgen. *Manfreda*), corm shortly cylindrical, (1–) 2–3 × 1.1–2 cm, bulb 3–5 × 1.8–2.5 cm, covered almost entirely with dry leaf bases 2.8–9.5 cm long, these almost entirely membranous, with fibrous top; **R** fleshy, fusiform, with filiform ramifications, contractile; **L** evergreen, 2–7, succulent, semi-erect, recurved, lanceolate to linear-lanceolate, channelled, verrucose on both faces, 8–16 × 1.2–2 cm, light green to glaucous, margins with irregular cartilaginous

**Fig. 50** *Agave potosina*

(Etter & Kristen 4228:  
Mexico; San Luis Potosí, ±  
20 km NE of Huizache,  
1420 m). (Copyright:  
J. Etter & M. Kristen)

teeth, these coarse, broad and usually truncate, blunt, usually incised at the acute to slightly caudate tip, occasionally retrorse, 2–5 (–14) mm apart; **Inf** (15.5–) 24–54 (–75) cm, ‘spicate’, erect, green-grey to red, peduncle with 2–4 **Bra** with truncate base, the lower linear-lanceolate, similar to the leaves, the upper caudate-lanceolate to deltoid, fertile part 9–29.5 cm, semidense to open above, with 6–15 (–31) nodes; floral **Bra** 4–7 × 2–3 mm; **Ped** none to short; **Fl** erect, sessile, 10–18 mm, ascending to appressed to the axis, mostly solitary, rarely geminate; **Tep** yellowish-green to green-glaucous, tube straight, tubular, constricted above the ovary, 6–14 mm, lobes erect, elongate to narrowly lanceolate, extended to appressed to the axis, apex apiculate, with a tuft of short white hairs, 2–5 × 1–2 mm; **Fil** erect at anthesis, 18–22 mm, of 2 lengths, inserted at the base and the middle of the tube, yellowish-green; **Anth** 5–8 mm, yellow; **Ov** ellipsoid to slightly ovoid, 6–14 × 2–3 mm, not constricted, not extending into the tube; **Sty** 12–18 mm; **Sti** 3-lobate, yellowish-green; **Fr** ± globose to subglobose, (9–) 10–13 (–15) × 8–14 mm, without a scar near the apex, dried perianth persisting; **Se** deltoid, plane-concave, granular, 3–4 × 2–3 mm, dull.

The small, narrow flowers, short style and two lengths of the filaments are characteristic features of this species (Verhoek-Williams 1975: 184, Castillejos-Cruz 2009). Fleshy, succulent leaves with irregularly dentate margins are also found in

*A. brunnea*, *A. longiflora*, *A. maculosa*, *A. variegata*, *A. sileri* and *A. virginica*; *A. potosina* is distinguished from these by its smaller stature and flowers (Castillejos-Cruz 2009) (as *Manfreda*).

The lectotypification attempt by Verhoek-Williams (1975: 182) is ineffective because the work was not effectively published. The specimen *G. B. Hinton* 27200 (GBH, MO, TEX) is a new record for Nuevo León. The species is listed as threatened with extinction.

**A. potrerana** Trelease (Contr. US Nation. Herb. 23: 138, 1920). **Type:** Mexico, Chihuahua (*Pringle* 802 [MO, B, BR, COLO, JE, LL, KFTA, MEXU, MICH, MIN, NDG, NY, P, S, UC, US, VT]). — **Lit:** Gentry (1977b: 76–79 & front cover, with ills.); Gentry (1982: 172–174, with ills.); McVaugh (1989: 148); Vázquez-García & al. (2007b: 66–67, t. O4-O5); González-Elizondo & al. (2009: 115); Starr (2012: 223–226, with ills.); Greulich (2016a: 35, 38, with ills.). **Distr:** Mexico (C, S & SW Chihuahua, N Coahuila, W Zacatecas?); oak-pine grasslands in volcanic ranges, 425–2500 m. **I:** Richter (2011: 117); Pilbeam (2013: 177); Hochstätter (2015: IX: 42).

[1g] **Ros** thick-stemmed, regularly spreading, 0.7–1 × 1.5–2 m, solitary; **L** numerous, lanceolate, straight, rigid, widest below the middle, convex below, roundly guttered above, mostly 40–80 × 6–7 cm, glaucous to light or dark green, margins horny, continuous, straight, firm, brown

towards the base, grey above; **marginal teeth** mostly straight, generally small, 2–4 mm, commonly 20–30 mm apart, lacking or reduced to serrations below mid-leaf; **terminal Sp** acicular, sharply angled below, flat to broadly canaliculate above, 25–40 mm, light brown to grey; **Inf** 4–8 m, ‘spicate’, peduncle with narrow scarious **Bra**, fertile part stout, straight or arching, densely flowered through the upper  $\frac{2}{3}$ , part-**Inf** with 2–4 flowers; floral **Bra** long attenuate, shorter than the flowers; **Ped** geminate, 4–15 mm; **Fl** 46–58 mm; **Tep** pink to red or yellow, tube thick-walled, 3–6 mm, lobes linear to ovate, erect, obtuse, clasping the filaments after anthesis, nearly equal, 17–24 × 5–7 mm, outer  $\pm$ 1 mm longer and closely overlapping the inner, inner broader, with a wide keel; **Fil**  $\pm$ 50 mm, inserted at the lobe base, yellow or red; **Anth** centric or excentric, 14–21 mm, yellow; **Ov** cylindrical, slender, 25–32 mm, neck smooth, constricted; **Sty** up to as long as the filaments; **Fr** oblong, rarely pear-shaped, strong-walled, rounded at the base, 25–40 × 10–15 mm, glaucous, shortly beaked; **Se** crescent-shaped, with low broad circumferential margin, hilar notch shallow, 4–5 × 3–3.4 mm.

Distinct and without close relatives in Sect. *Heteracanthae* (as Group *Marginatae*). It differs by its solitary habit, tall inflorescences with large usually red flowers, and the long-acuminate leaves with reduced or lacking teeth on the lower  $\frac{1}{2}$  of the margin (Gentry 1982: 174). The epithet is sometimes erroneously spelled ‘potreriana’, rather than ‘potrerana’ as in the protologue, where the collection number of the type is erroneously cited as ‘302’ instead of ‘802’. The disjunct record from W Zacatecas of Gentry (1982: 193) is based on *Rose* 2404 (US 301314!), which consists of two leaves only and needs confirmation (McVaugh 1989). González-Elizondo & al. (2009) mention the possible, but not yet documented occurrence in Durango.

**A. pratensis** A. Berger (Agaven, 37, 1915). **Type:** Mexico, Nayarit (*Rose* 1994 [US 300886 [lecto], K, MEXU, US 300887]). — **Lit:** *Rose* (1903c: 22); Verhoek-Williams (1975: 245–247); Piña Luján (1985: 86–87); McVaugh (1989:

233–234); Castillejos-Cruz (2009: [265]–[269], with ills.); all as *Manfreda rubescens*. **Distr:** Mexico (N Nayarit, S Jalisco); small grassy openings along road cuts and little streams, in oak and tropical deciduous forests, 700–1500 m; flowers August to September. **I:** Hochstätter (2016: I: 40); Castro-Castro & al. (2017: 62); both as *Manfreda*.

$\equiv$  *Manfreda rubescens* *Rose* (1903)  $\equiv$  *Polianthes rubescens* (*Rose*) *Shinners* (1966).

[3a3] Herbaceous, small (for Subgen. *Manfreda*); corm 1.5–4 × 1–2 cm, cylindrical, bulb 2–6.8 × 2.5–3 cm, cylindrical, completely covered with dried fibrous leaf bases 6–8 cm long; **R** fleshy, with filiform ramifications, contractile; **L** drought-deciduous, 3–6 (–10), recurved to erect, linear to linear-lanceolate, thin, slightly canaliculate, lower face papillose on the veins, upper face glabrous, apex acute, 17–30 (–60) × 0.6–1.4 cm, shiny green, margins entire, with a hyaline band; **Inf** 60–85 (–135) cm, erect, ‘spicate’, glaucous green, peduncle with 6–8 **Bra**, base truncate, lowest similar to the foliage leaves, fertile **Inf** part 6–10 (–18) cm, dense, with 5–9 (–16) flowers; floral **Bra** 8–10 × 6 mm; **Fl** 23–27 mm, solitary, sessile, ascending to diffuse; **Tep** greenish-red to purple-brownish dorsally, tube broadly funnel-shaped to campanulate, (3–) 5–6 × 4 mm, lobes oblong, extended to irregularly reflexed, 12–14 × 2–3 mm, tip cucullate with a soft tip, with a bundle of short white trichomes; **Fil** 20–27 mm, erect at anthesis, exceeding the tube for 18–23 mm, inserted at  $\frac{3}{4}$  of the tube length on the same level, reddish-green with purple dots; **Anth** 8–10 mm, yellowish-green; **Ov** ellipsoid, 7–10 × 3–5 mm, greenish, prolonging 1–2 mm into the tube, not constricted above; **Sty** 28–30 mm; **Sti** 3-lobed, greenish-red; **Fr** cylindrical to ellipsoid, 20–22 × 13–16 mm, with a scar near the apex and persisting tepals; **Se** deltoid, plane-concave, 3–4 × 4 mm, dull.

Perhaps nearest to *A. guttata* and sharing the short tepal tube, the compact inflorescence and the flower shape, but differing by purple (vs. greenish-yellow) flowers and thin and glabrous leaves (Verhoek-Williams 1975: 246, Castillejos-Cruz 2009; both as *Manfreda*). *A. pratensis* is morphologically also similar to *A. bulbulifera* and *A. littoralis* (Castillejos-Cruz & Solano 2008: as

*Manfreda*). McVaugh (1989: 234) and Castro-Castro & al. (2017: 61, 63) provide records for Jalisco. Rose's type at US consists of 2 sheets (US 300866! & 300887!). The attempted lectotypification by Verhoek-Williams (1975: 245) fails as the work was not effectively published, but the designation by McVaugh (1989: 234) "US300886!, the lectotype" represents a lectotypification.

**A. pringlei** Engelm. *ex* Baker (Handb. Amaryll., 182, 1888). **Type:** Mexico, Baja California Sur (*Orcutt* s.n. [K, CAS, MEXU, MPU, NY, US]). — **Lit:** Trelease (1912b: 54, t. 44); Berger (1915: 263–264); Gentry (1978: 20–22, with ill.); Gentry (1982: 380–382, with ill.); Turner & al. (1995: 51, 53, with ill.); Starr (2012: 85–86, 89); the last 4 references as *A. deserti* ssp.; Webb & Starr (2015: 83–84, with ill.); **Distr:** Mexico (N Baja California); desert plains and slopes, 595–1830 (–2300) m; flowers mainly April to August, also August and October. **I:** Heller (2006: 81); Richter (2011: 37, 103); Pilbeam (2013: 73); Hochstätter (2015: V: 10); all as *A. deserti* ssp.

≡ *Agave deserti* ssp. *pringlei* (Engelm. *ex* Baker) Gentry (1978) ≡ *Agave deserti* var. *pringlei* (Engelm. *ex* Baker) W. C. Hodgson & Reveal (2001); **incl.** *Agave scaberrima* Hort. Peacock *ex* Baker (1888).

[2i] Acaulescent; **Ros** 40–70 × 50–80 cm, rather strict, caespitose, offsetting closely from the root crown; **L** ascending, narrowly triangular-lanceolate, deeply canaliculate, thick and widest at the base, very long-acuminate, guttered and thinner above, smooth, mostly 40–70 × 5–7 cm, green to yellowish-green or light glaucous-grey, margins nearly straight; **marginal teeth** slender and little curved, more rarely smaller or more broadly flattened and irregularly flexed, triangular, lenticular at the base, mostly 5–10 mm, grey, rather regularly spaced 10–20 mm apart; **terminal Sp** acicular, usually narrowly grooved for a short distance at the base, 30–40 mm, reddish-brown to light grey, decurrent as a corneous margin to the upper teeth or to mid-leaf; **Inf** 3–6 m, paniculate, fertile part very narrow or more ample with longer part-**Inf** with larger 'umbels', part-**Inf** 10–15; **Fl** 40–60 mm; **Tep** yellow, tube ample, 3–8 ×

12–15 mm, bulging, strongly furrowed from the tepal sinuses, lobes linear, spreading, rounded over a finely cucullate apex, nearly equal, 14–20 × 5–7 mm, **ITep** broader and with broad low keel; **Fil** 30–35 mm, inserted on the rim of the nectary in the orifice of the tube; **Anth** 14–15 mm; **Ov** fusiform, roundly angular, 20–35 mm, neck furrowed; **Fr** mostly oblong, 30–55 × 12–15 mm, short-stipitate, beaked, greyish straw-coloured; **Se** crescent-shaped, 5–7 × 3–4.5 mm, black.

This taxon, apparently restricted to the Sierra San Pedro Mártir and Sierra Juárez, was reduced to a subspecies of *A. deserti* by Gentry (1978) and Gentry (1982), based on "apparent introgression" and a "hybrid swarm" between both at San Matias Pass. Hodgson (2001a) went even further and reduced it to a variety of *A. deserti*, whose range it borders and partly overlaps to the S and W. Webb & Starr (2015: 82) found both species in that area clearly separated and with little evidence of a hybrid swarm (only isolated hybrids were found), thus justifying species status as *A. pringlei*, based on clear differences from *A. deserti*: Green, long triangular-lanceolate leaves often with a conspicuous brown ring around the marginal teeth, and shorter inflorescences. The brown ring on the teeth is otherwise typical of *A. cerulata* and suggests a closer link with it rather than with *A. deserti* (Webb & Starr 2015). This view is, however, contradicted by molecular data (Navarro-Quezada & al. 2003), which associate *A. pringlei* with *A. deserti*, and apart from *A. cerulata*, but the analysis may be influenced by inclusion of hybrids.

**A. producta** Thiede & Egli (Kakt. und Sukk. 50(5): 112, 1999). **Type:** Mexico, Guerrero (*Chisholm* s.n. in *Section Plant Introduction USDA* 11260 [US, NY]). — **Lit:** Rose (1905: 437, as *Polianthes elongata*). **Distr:** Mexico (Guerrero); flowers in October. **I:** Hochstätter (2016: II: 10, as *Polianthes elongata*).

≡ *Polianthes elongata* Rose (1905).

[3b2] Herbaceous; corm ±1.2 × 2 cm, bulb ovoid, 3.5 × 1.2 cm, completely covered with dried light brown membranous leaf bases to 5.5 cm long; **L** drought-deciduous, erect, elongate, oblanceolate, trough-shaped below, flat above,

30 × 1–1.2 (near the tip) cm, green, hardly if at all glaucous, margins entire; **Inf** 80–90 cm, erect, ‘racemose’, reddish at the base, glaucous above, glabrous, peduncle with 6–7 **Bra**, these much reduced upwards, fertile part 22–24 cm, lax, with 12–18 flowering nodes; floral **Bra** ovate-linear, acuminate, 1–1.5 cm, reddish; **Ped** 10–15 mm; **Fl** ±24 mm, geminate; **Tep** reddish, forming a tube, bent just above the base almost at right angles with the ovary axis, tube ±20 mm, lobes short, somewhat spreading, ±1 mm, tip rounded; **Fil** included, inserted near the base of the tube; **Anth** 6 mm, tips just projecting from the mouth of the perianth; **Ov** ellipsoid, ±4 × 2 mm; **Sty** finally projecting a short distance beyond the mouth of the perianth; **Sti**, **Fr** and **Se** unknown.

Known from the type collection only (depicted by Hochstätter (2016)); the description was added from both cited specimens. The holotype (US 399706!) was annotated as *Polianthes geminiflora* var. *geminiflora* (= *A. coetocapnia* ssp. *coetocapnia*) by E. Solano in 2000, the sole other species of Sect. *Polianthes* in Guerrero. Castro-Castro & al. (2015: 141), in contrast, recognize *Polianthes elongata* as distinct, which is followed here. *A. producta* differs from *A. coetocapnia* mainly in its narrower, unspotted, not glaucous leaves, inflorescences with a shorter fertile part, and flowers with filaments inserted near the base of the tube and somewhat spreading and much shorter perianth lobes. Castro-Castro (pers. comm. to author, Nov. 2018) found a population close to the type locality which may belong here. — When transferring *Polianthes elongata* to *Agave*, a new name was necessary to avoid homonymy with *A. elongata* Jacobi (1865).

**A. pubescens** Regel & Ortgies (Gartenflora 23: 227–228, t. 804, 1874). **Type**: Ex cult. BG St. Petersburg (*Anonymous* s.n. [LE 00011016]). — **Lit**: Berger (1915: 31); Verhoek-Williams (1975: 298–300); Piña Luján (1986: 15–17, 35, with ill.); Castillejos-Cruz (2009: [248]–[254], with ill.); the last 3 as *Manfreda*. **Distr**: Mexico (Michoacán, Mexico, Morelos, Guerrero, Oaxaca, Chiapas, Veracruz); rocky slopes in mountain regions, in tropical deciduous forests, thorn forests, pine-oak forests, (semi-) evergreen rain forests, and

montane cloud forests, 300–2500 m; flowers July to August. **I**: Hochstätter (2016: I: 38, as *Manfreda*).

≡ *Agave brachystachys* var. *pubescens* (Regel & Ortgies) A. Terracciano (1885) ≡ *Manfreda pubescens* (Regel & Ortgies) Espejo & López-Ferrari (1993).

[3a2] Herbaceous; corm cylindrical, 2–6 (–12) × 2–3 cm, bulb ovoid, 3.5–6 × 1.5–2.5 cm, covered with fibrous dry leaf bases 4–7 (–9.5) cm long; **R** fleshy, contractile; **L** drought-deciduous, 3–4 (–9), linear-lanceolate to lanceolate, ribbed, prostrate, narrowing towards the base, tip acute, densely pubescent on both faces, 18–28 (–70) × 2.2–4.2 (–6) cm, dark green with abundant purple spots, margins entire, slightly wavy, with a hyaline band; **Inf** erect, 60–160 (–185) cm, ‘spicate’, peduncle reddish to greenish, pubescent at the base, with 5–8 **Bra**, these truncate at the base, lower ones linear-lanceolate and similar to the leaves, fertile part 15–40 (–55) cm, with 10–22 solitary, laxly arranged flowers; floral **Bra** 4–11 × 3–4 mm; **Fl** sessile, ascending, 32–40 mm, tubular to infundibuliform; **Tep** yellowish-green, tube 18–26 × 4–5 mm, constricted at the tip of the ovary, lobes narrowly elliptic to oblong, revolute, 11–18 × 4–5 mm, apex cucullate, with a bundle of white hairs; **Fil** erect, 26–45 mm, exceeding the tube for 22–38 mm, inserted all on the same level at mid-tube, greenish-yellow with reddish dots; **Anth** 8–12 mm, yellow; **Ov** ellipsoid, 10–16 × 2–4 mm, not extending into the tube; **Sty** first bent downwards, straight at maturity, 36–53 (–60) mm; **Sti** clavate, 3-lobed, green-yellowish; **Fr** cylindrical to subellipsoid, 16–25 × 12–15 mm, apiculate, without an apical scar, remains of perianth persisting; **Se** deltoid, plane-concave, with narrow margin, 3–4 × 3 mm, black, shiny.

Characterized by its large corm and large and pubescent leaves narrowed at the base. Apart from *A. maculata*, this is the only species in Sect. *Manfreda* with pubescent leaves, but distinguished by its generally larger size with larger inflorescences, lobes and filaments and much more exerted stamens and styles (Verhoek-Williams 1975: 299, Castillejos-Cruz 2009) (as *Manfreda*).

**A. × pumila** De Smet ex Baker pro sp. (Handb. Amaryll., 172, 1888). **Type** [neo]: Cult. (*Anonymous* s.n. in *Huntington* BG 16230 [ARIZ,

HNT]). — **Lit:** Trelease (1911: 13–15, with ills.); Berger (1915: 90–91); Breitung (1960: 91, 121, with ills.); Gentry (1982: 174–176, with ills.); Ullrich (1991c: with ills.); Thiede (2011: 152–153); Roosbroeck (2012: 165–166, with ill.); all as *A. pumila*. **Distr:** Known from cultivation only. **I:** Kuppen (2000: 185); Heller (2006: 124); Richter (2011: 69); Pilbeam (2013: 179–180); Hochstätter (2015: IX: 42); all as *A. pumila*; Walker (2017: 166, as *A.* ‘Pumila’).

**Incl.** *Agave simonis* hort. ex Hirscht (1898) (*nom. inval.*, ICN Art. 38.1a).

[1g × 1g] Plants dimorphic, **juvenile form** persisting for 8–12 years; **Ros** small, 5–8 cm Ø, surculose; **L** ovate-orbicular, thickly succulent, broader than long, base broadly clasping, rounded below, deeply concave above, 2–4 × 3–4 cm, glaucous, lower face striped, margins thin, friable, white; **marginal teeth** several, weak and small; **terminal Sp** conical, flexuous, small; **adult form** thick-stemmed; **Ros** open, short, 40–50 × 60–70 cm, not suckering; **L** deltoid-lanceolate, rigid, patulous, thickened at the base, upper face concave, lower face convex, 30–38 × 4–4.5 cm, glaucous, without stripes below, margins narrowly horny, detaching, white; **marginal teeth** small, weak, 1–2 mm, 10–15 mm apart; **terminal Sp** conical, slender, 15 mm, decurrent along the leaf margins and along the keel in the middle of the lower face; **Inf**, **Fl** and **Fr** unknown. — **Cytology:** 2n = 120 (4×) (Zonneveld 2003).

Long known only from the stunted juvenile form, but developing into large ‘normal’ rosettes when given enough space (Gentry 1982); such a dimorphism is unknown in other Agaves. First brought into the trade in 1877 by De Smet (Berger 1915). Trelease (1911) placed the species close to *A. lechuguilla* due to the shared presence of longitudinal stripes on the lower leaf face. Gentry (1982) assumes an origin as (natural) hybrid, probably *A. nickelsiae* (as *A. victoriae-reginae*) × *A. lechuguilla*, adding the narrow detachable leaf margins as further character shared with the latter. The stunted juvenile growth form might result from incongruence of chromosome numbers of its putative parental species: *A. nickelsiae* is di-, tetra- and hexaploid, and *A. lechuguilla* as well as *A. ×pumila* are tetraploid (Thiede 2011).

González-Elizondo & al. (2011) equated *A. pumila* with the natural hybrid *A. nickelsiae* × *A. asperrima* (see under *A. ×santilloensis*), arguing that the leaf shape of adult plants points towards *A. asperrima* as one parent. However, the presence of longitudinal stripes on the lower face of the leaves of *A. ×pumila*, which are a typical feature of *A. lechuguilla* but are absent in *A. asperrima*, strongly favours *A. lechuguilla* as putative parent.

Gentry (1982: 174, 193) selected a neotype at US, but the specimen does not appear to be extant; however, the specimen ARIZ 0004769 with Gentry’s handwriting “Neotype” and his stamp “Gentry herbarium” was apparently intended as neotype, but was not sent to US. ‘Green of Jealousy’ (Roosbroeck 2012: 166, with ill.) is a cultivar with green leaves.

**A. quilae** (Art. Castro & Aarón Rodríguez) Thiede & Govaerts (Phytotaxa 306(3): 238, 2017). **Type:** Mexico, Jalisco (*Rodríguez & Castro-Castro* 7149 [IBUG, CIIDIR, ENCB, IEB, MEXU, XAL]). — **Lit:** Castro-Castro & al. (2016: protologue, with ills.). **Distr:** Mexico (C Jalisco); with grasses in deep and acid soils or on rocks in pine-oak forests, 1500–2350 m; flowers late July to early August.

≡ *Polianthes quilae* Art. Castro & Aarón Rodríguez (2016).

[3b2] Herbaceous; corm 0.8–1.5 × 0.9–1.2 cm, oblong, bulb (2.5–) 3.3–4.5 × (1.3–) 1.6–2.5 cm, ellipsoid or ovoid in saxicolous individuals, completely covered with dried fibrous leaf bases; **R** fleshy, thickened, contractile; **L** drought-deciduous, 3–6, mostly erect, sometimes prostrate or slightly elevated from the surface, ensiform, chartaceous and soft, hyaline, glabrous, apex acute, (10–) 15–24 (–36) × (0.5–) 0.8–1.4 cm, shiny green, margins entire; **Inf** 55–94 cm, erect, ‘spicate’, glaucous, peduncle with 2–4 **Bra**, these ensiform, 4–21 cm, base truncate, internodes decreasing in size distally, fertile **Inf** part ±32 cm, lax, with 4–12 remote floral nodes; floral **Bra** 8–33 × 2–4 mm; **Ped** 9–21 mm at anthesis, 12–24 mm in fruit, ascending; **Fl** geminate, unscented, 14–25 mm, divergent to inclinate; **Tep** bicoloured, the bottom ⅓ orange-reddish,

the upper  $\frac{1}{3}$  and the lobes purple-glaucous, forming a ventricose tube, middle portion inflated, and the distal portion tapered, not curved,  $\pm 18 \times 5$  mm at the base of the lobes, lobes unequal, ascending, imbricate,  $2-3 \times 2-3$  mm, **OTep** ovate, acute, **ITep** circular, hyaline, obtuse, apex with a bundle of white trichomes; **Fil** filiform, 12–16 mm, included, inserted 3–5 mm above the ovary apex, orange-yellowish; **Anth** linear, 4–5 mm, yellow, at anthesis below the upper portion of the mouth of the tube; **Ov** ellipsoid,  $3.6-4 \times 2.5-3$  mm; **Sty** filiform, 18–20 mm, orange, distally yellowish, included; **Sti** 3-lobed, papillose; **Fr** globose to ellipsoid,  $8-10 \times 7-9$  mm, with persisting tepals; **Se** deltoid, flat,  $3-3.5 \times 2.2-2.5$  mm, shiny.

According to the protologue morphologically closest to *A. cernua* (as *Polianthes*) and *A. coetocapnia* ssp. *clivicola* (as *P. geminiflora* var.), which share esp. oblong corms, ellipsoid or ovoid bulbs, entire hyaline and glabrous leaves, ensiform sterile bracts, and globose to ellipsoid fruits. It differs, however, in its ensiform erect leaves, glaucous inflorescences with 4–12 floral nodes, pedicels 9–21 mm long at anthesis, and esp. in the orientation, length, shape, and colour of the perianth. The species is considered to be endangered (IUCN category EN).

**A. quotepecensis** García-Mendoza & S. Franco (Acta Bot. Mex. 126: e1461: 9, ills. (pp. 10, 15), 2019). **Type:** Mexico, Oaxaca (*García-Mendoza & al.* 10349 [MEXU, ENCB, MEXU, MO, OAX]). — **Distr:** Mexico (N Oaxaca: middle and upper río Papaloapan basin); on sandy reddish soils in low tropical deciduous forests, 525–845 m; flowers December to March.

[lg] Acaulescent; **Ros** lax, solitary,  $1.4-1.5 \times 2-2.5$  m; **L** 40–70, lanceolate, ovate in young plants, erect, rigid, thickened at the base, flattened or slightly canaliculate, slightly keeled on the lower face, apex long acuminate, involute and grooved,  $70-90 \times 10-13$  (–20) cm,  $5-7$  (–10)  $\times$  longer than broad, yellowish-green, sometimes with a lighter longitudinal midstripe, margins straight, corneous, continuous, greyish or brown, dentate; **marginal teeth** deltoid to irregular,

straight, antrorse or rarely retrorse, (10–)  $15-28 \times 8-20$  mm at mid-leaf, greyish to occasionally brown, (25–)  $50-90$  mm apart at mid-leaf, sometimes with smaller interstitial teeth; **terminal Sp** keeled on the lower face, (30–)  $40-55 \times 6-10$  mm, greyish, decurrent for 14–20 (–35) cm, corneous base penetrating 2–7 (–15) mm into the lower leaf face; **Inf** erect, 4–5 m, ‘spicate’, peduncle green, with deltoid coriaceous **Bra** 12–20 (–28)  $\times 1.5-4$  cm, fertile part dense, in the upper  $\frac{1}{2}$  or  $\frac{3}{4}$  of the inflorescence; lowest floral **Bra** 10–20  $\times 2-5$  cm; **Ped** short; **Fl** 45–50 mm; **Tep** greenish-yellowish, tube campanulate,  $1-4 \times 7-10$  mm (at the mouth), lobes oblong, straight to slightly recurved at anthesis,  $19-23 \times 3-6$  mm; **Fil** 50–67 mm, yellowish, inserted in the distal part of the tube; **Anth** 12–16 mm, yellowish; **Ov** cylindrical,  $25-28 \times 3-4$  mm, neck 6–8 mm; **Sty** 40–50 mm, yellow with purplish tinge; **Sti** 3-lobed, yellow with purplish tinge; **Fr** ellipsoid,  $20-21 \times 10$  mm; **Se** semicircular, unwinged,  $3-4 \times 2-3$  mm, black.

In the protologue placed in Sect. *Heteracanthae* (as Group *Marginatae*). It is closely related to *A. titanota*, which occurs to the NW and differs in its longer leaves with long acuminate apex, straight margins with more distant teeth, a shorter terminal spine decurrent for a longer distance, a spine base intruding for a shorter distance into the lower leaf face, and larger flowers with longer filaments and longer ovaries. However, the protologue applies a restricted range of character expressions; with the data given in this handbook for *A. titanota*, the differences in the distance of the teeth, the length of the terminal spine, the flower size, and the length of the filaments disappear or show broad overlap. One of the paratypes (*García-Mendoza & Palma* 5712) was formerly included in *A. titanota* by García-Mendoza (2011a: 64) (see also under the latter). — Vernacular name: “rabo de león”. The leaves are used for making ropes, complete inflorescence are used as fodder, and boiled flower buds (“cacayas”) are eaten as vegetables. Classified in the IUCN Red List Category “Near Threatened”.

**A. revoluta** Klotzsch (Allg. Gartenzeitung 8: 274, 1840). **Type:** Ex cult. BG Berlin

(*Anonymous* s.n. [B]). — **Lit:** Rose (1903c: 21); Berger (1915: 34); Verhoek-Williams (1975: 295–297); Piña Luján (1986: 16); Castillejos-Cruz (2009: [255]–[259], with ills.); all as *Manfreda* except Berger. **Distr:** Mexico (México); clay bluffs, in pine or oak forests, 1300–2200 m; flowers July to August. **I:** Hochstätter (2016: I: 39, as *Manfreda*).

≡ *Manfreda revoluta* (Klotzsch) Rose (1903)  
 ≡ *Polianthes revoluta* (Klotzsch) Shinnery (1966).

[3a2] Herbaceous; corm cylindrical, 5–9 × 1.8 cm, bulb conical, 3–6 × 1.8–2.5 cm, covered with dry leaf bases 4.5–6 cm long and fibrous above; **R** fleshy, contractile; **L** drought-deciduous, 5–6, linear-lanceolate, prostrate to semi-erect, channelled, narrowed towards the base, apex attenuate, acute, with small and recurved tip, glabrous, 12–20 × 1.5–2 cm, greenish-yellow to dark green, margins hyaline, narrow, entire or finely papillose to erose-papillose, revolute; **Inf** 0.8–1 (–2) m, erect, ‘spicate’, with 6–12 somewhat inclined **Bra** with truncate bases, the lower leaf-like, the upper reduced, fertile part (15–) 20–30 (–40) cm, with 20–30 solitary, laxly or sometimes densely arranged flowers; **Fl** sessile, erect, 22–26 mm, tubular to funnel-shaped; **Tep** greenish-red to greenish-yellow, semisucculent, tube 12–15 × 5–7 mm, not constricted, lobes oblong, reflexed to revolute, 8–12 × 5–8 mm, tips thickish, cucullate, with a bunch of white hairs; **Fil** erect, exceeding the tube for 19–34 mm, greenish-yellow, adnate to the tube, all inserted at the same level; **Anth** 10–12 mm, greenish-yellow to greenish-red; **Ov** ellipsoid, 7–12 × 5 mm, greenish-yellow; **Sty** 30–47 mm; **Sti** 3-lobed, greenish-yellow; **Fr** ellipsoid, triquetrous, 15–22 × 15–18 mm; **Se** plane-concave, 3–4 × 4 mm, black, dull.

This species belongs to Ser. *Scabraea* within Sect. *Herbaceae*. It differs from other members by its short revolute leaves. The specimen at B (cult. Horto Bot. Berol., Jun [18]40; not digitized] appears to represent the type material of Klotzsch (Verhoek-Williams 1975: 296). It is morphologically similar to *A. galvaniae*, but distinguished by larger, ellipsoid fruits and smaller floral bracts (Castillejos-Cruz 2009).

**A. rhodacantha** Trelease (Contr. US Nation. Herb. 23: 117, 1920). **Type** [neo]: Mexico, Nayarit (*Gentry & Gilly* 10704 [ARIZ 266622, ARIZ, MEXU [2 sheets], US [3 sheets]]). — **Lit:** Gentry (1972: 141–143, with ills.); Gentry (1982: 580–582, with ill.); McVaugh (1989: 140–141); Vázquez-García & al. (2007b: 67–68, t. X); González-Elizondo & al. (2009: 116–118, with ills.); García-Mendoza (2011a: 51–52); **Distr:** Mexico (Sonora, Sinaloa, Durango, Zacatecas, Nayarit, Jalisco, México, Puebla, Oaxaca); in arid scrub and tropical (sub-) deciduous pine-oak, oak, thorn or short-tree forests, 50–2080 m; flowers May to July. **I:** García-Mendoza (2002: 179); Pilbeam (2013: 181); Hochstätter (2015: VII: 45).

[2g] Stems none or 50–90 cm or more; **Ros** truncate, large, 1.7–3 × 2.5–5 m, solitary or caespitose; **L** 100–200, ascending, lanceolate to linear-lanceolate, hard-fibrous, rigid, straight, much thickened and scarcely narrowed at the base, smooth, (80–) 100–250 (–300) × (5–) 6–18 cm, green to faintly glaucous-green, margins straight to repand; **marginal teeth** upcurved, firm, slender, very sharp, regular, 4–10 × (4–) 6–12 mm, dark brown to blackish, mostly 10–30 mm apart, not decurrent; **terminal Sp** conical but frequently with subulate tip, with short open groove above, 10–30 × 5–6 mm, dark brown; **Inf** 6–9 m, paniculate, peduncle green, with triangular chartaceous **Bra** 30–38 cm, fertile part lax, rhomboidal to oblong, part-**Inf** 25–45, large, remote, in the upper ½ of the inflorescence, 40–55 cm long; **Ped** 5 mm; **Fl** 55–65 mm; **Tep** green, yellowing at anthesis, tube urceolate, 8–10 × 9–10 mm, lobes linear to oblong, erect, strongly involute, rounded and strongly hooded at the apex, subequal, 16–23 × 4 mm, wilting at anthesis and soon reflexing; **Fil** 40–45 mm, inserted in the upper ¼ of the tube; **Anth** 14–28 mm; **Ov** cylindrical to fusiform, 25–35 mm incl. the short neck; **Fr** oblong, 70–80 × 25–30 mm, shortly beaked, long-stipitate (but not always), stipe 10–15 mm; **Se** 10–11 × 7–8 mm, oblique, curved margin not wing-like, hilum notch shallow. — **Cytology:** 2n = 60 (Moreno Salazar & al. 2007, Simpson & al. 2011).

The taxon is difficult to characterize and is distinguished from its close relative *A. angustifolia* by its many, very long, rigid leaves with large,

robust and narrow teeth, and large inflorescences with long part-inflorescences and large fruits (Gentry 1982: 582, García-Mendoza 2011a). According to Gentry (1982), the fruits are long-stipitate, but this character has not been seen in the material studied by García-Mendoza (2011a). Some forms may be indistinguishable from *A. angustifolia* (Gentry 1972, McVaugh 1989). New records are provided by Gentry 18298 (MEXU 109971) for Zacatecas, *Matuda* 32069 (MEXU 160226) for México, Hernández-Vera & al. (2007a: 501) for Jalisco, and González-Elizondo & al. (2009) for Durango.

The protologue indicates “Lundstrom, in 1909” “from Mocerito” at MO as “type” which was thought to be lost so that Laferrière (1995b) designated a neotype. However, MO houses 2 specimens collected by A. A. Lundström 1909 at Mocerito, which appear to represent syntypes: MO 1800295, filed as *A. fourcroydes* (det. H. S. Gentry), and MO 1800296, filed as *A. tequilana* (both without digital image).

Zizumbo-Villarreal & al. (2013) report a landrace of the taxon as being used locally in S Jalisco for sustainable mescal and tequila production. According to ethnobotanical and morphological studies (Vargas-Ponce & al. 2007), wild populations of *A. rhodacantha* and *A. angustifolia* as well as unclassified putative hybrids between both are the primary gene pools from which traditional landraces have been selected in S Jalisco. Genetically, *A. rhodacantha* and *A. tequilana* ‘Sigüin’ and ‘Chato’ form a group separate from *A. angustifolia* and *A. tequilana* ‘Azul’ (Trejo & al. 2018). Five landraces from Jalisco showed a clearly higher genetic diversity than the commercial *A. tequilana* ‘Azul’ (Vargas-Ponce & al. 2009).

**A. ×romanii** Hort. De Smet *ex* Anonymous [J. C.] (Gard. Chron., ser. 3, 33: 325, 1903). — **Lit:** Baker (1888a: 166); Trelease (1914: 236–238); Berger (1915: 74); all as *A. romanii*. **Distr:** Cultivated only. **I:** Richter (2011: 86).

[1d × 1f] According to Baker (1888a) and Trelease (1914) a garden hybrid *A. filifera* × *A. obscura* (as *A. xalapensis*), raised by the Belgian nursery of L. de Smet. A specimen prepared by

Berger (a single leaf with fraying margins) which fits Berger’s description taken from Besaucèle is kept at US (US 1023732!). Plants designated as *A. romanii* presently offered or cultivated in the USA and in Europe include plants with dark fraying margins corresponding to the description, but also plants apparently not belonging here, either with small marginal teeth, or with entire margins and partly broader leaves. For the latter the parentage is given as *A. filifera* × *A. mitis* (as var. *albidior*). Here included is the cultivar ‘Shadow Dancer’ with light leaf colouration esp. during summer (photograph in Greulich 2017c: 159).

**A. rosei** Thiede & Egli (Kakt. and. Sukk. 50 (5): 112, 1999). **Type:** Mexico, Nayarit (*Rose* 2178 [US, GH, MEXU]). — **Lit:** Rose (1903a: 11); McVaugh (1989: 259–260); Solano & al. (2019: 5, 8, 9, with ills.); all as *Polianthes montana*. **Distr:** Mexico (Nayarit, Jalisco); ecology unknown, 1500–2040 m; flowers July to August. **I:** Barba-Gonzalez & al. (2012: 124); Hochstätter (2016: II: 17); both as *Polianthes montana*.

≡ *Polianthes montana* Rose (1903).

[3b1] Herbaceous; corm unknown, bulb ±4 × 1–1.5 cm, oblong, completely covered with dried fibrous leaf bases; **R** unknown; **L** drought-deciduous, 2–3, erect, linear-ensiform, nearly smooth, not narrowed at the base, apex attenuate, acute, ±20–30 × 0.27–0.8 cm, margins obscurely papillose; **Inf** 110–120 cm, erect, ‘spicate’, ± glaucous, peduncle with 6 distant **Bra**, these ensiform, lowest 19.5–25 cm, upper ones much smaller, internodes decreasing in size distally, fertile part 6.5–18 cm, lax, with 4–12 remote floral nodes; floral **Bra** ±0.4 cm; **Ped** 2.5–4 (–6) mm, ± ascending; **Fl** geminate, strongly fragrant, ±20–24 mm, ± divergent; **Tep** white, pink when senescent, forming a cylindrical tube (slightly) curved near the base, ±14–15 mm, lobes erect, 4–9 × 2.9–4.3 mm, ovate, rounded; **Fil** filiform, 7–25 mm, longer than the anthers, inserted much below the middle of the tube; **Anth** 4.3–4.7 mm, included; **Ov** ellipsoid, ±1.25 × 2.5 mm; **Sty** 10–14 mm, included; **Sti** unknown; **Fr** 6 × 7 mm; **Se** unknown.

An incompletely known species, long known only from the type specimen, but recently

collected in Jalisco (Solano Camacho 2002) and now known from 12 records from 6 localities (Solano & Feria 2007: 1988). Solano & al. (2019) provide additional morphological data. Within Ser. *Polianthes* of Sect. *Polianthes* easily distinguishable by its short tube, linear-ensiform leaves, and pedicellate flowers (see also under *A. platyphylla*). McVaugh (1989) suggests the possibility that the specimen regarded as type, which much resembles *A. duplicata* (*Polianthes geminiflora*), has erroneously been substituted for the original white-flowering type specimen of *A. rosei* ( $\equiv$  *Polianthes montana*). Locally used as ornamental (Barba-Gonzalez & al. 2012: 125). — The new name was necessary to avoid homonymy with *A. montana* Villarreal 1996.

**A.  $\times$  rosselloana** D. Guillot & P. Van der Meer (Flora Montiber. 27: 55, 2004). **Type:** Ex cult.: Spain, Valencia (Guillot & Van der Meer s.n. [VAL 151001]). — **Distr:** Cultivated only.

[1f  $\times$  1f] This is the garden hybrid *A. obscura* (as *A. polyacantha* var. *xalapensis*)  $\times$  *A. warelliana* found in the Botanical Garden of Valencia (Spain). The original spelling ‘rossellonensis’ is to be corrected as shown above, as the epithet honours Sr. Rosselló.

**A.  $\times$  rovelliana** Todaro *pro sp.* (Index Seminum Panormitani 1888: 36, 1889). **Type:** not typified. — **Lit:** Pax (1893: with ills.); Berger (1915: 58–59); Ullrich (1992: 87, 89, 92, with ill.); Richter (2011: 45–47: with ill.); all as *A. terraccianoii*. **Distr:** Cultivated only. **I:** Greulich (2018b: 78, as *A. rovelliana*).

**Incl.** *Agave terraccianoii* Pax (1893).

[1f?  $\times$  3a] This most probably represents an artificial hybrid between a species of Subgen. *Littaea* (possibly *A. mitis*) and a species of Sect. *Herbaceae* of Subgen. *Manfreda*, as strongly indicated by the spotted leaves not present in Subgen. *Littaea* and flowering nodes with 1–2 flowers intermediate between both groups (Ullrich 1992, Richter 2011). Ullrich (1992: 89) depicts a plant with spotted leaves labelled “*A. terraccianoii*” in his collection purportedly going back to Pax’s original plants at BG Berlin. A plant labelled “*A. terraccianoii*” cultivated at BG Berlin

and possibly going back to Pax flowered there in 2002 (Richter 2011). The plant depicted by Richter has unspotted leaves possibly due to shady cultivation; plants kept more sunny seen in the botanical collection at Berlin in 2002 by the writer were intensely spotted. Vignoli (1936: 193–194) reported an aberrant aneuploid chromosome number of  $2n = 50$  for *A. rovelliana*, which, if not a miscount, might be related to its hybrid origin.

**A. rutteniae** Hummelinck (Recueil Trav. Bot. Néerl. 33: 238, 1936). **Type** [syn]: Aruba (Hummelinck 19a + b [U]). — **Lit:** Hummelinck (1938: 19–20); Hummelinck (1993: 10–11, with ills.); Thomson (2014: with ills.). **Distr:** Leeward Antilles (Aruba: slopes of the Hooiberg); debris of igneous rocks, 60–90 m; flowers May to June; only known from the type locality. **I:** Pilbeam (2013: 182); Hochstätter (2015: VII: 46).

[2u] Acaulescent; **Ros** 1  $\times$  0.9–1.5 m  $\varnothing$ , suckering; **L**  $\pm$  15–25, narrowly elliptic or lanceolate, straight or very slightly S-curved, acute, narrowed towards the 4–5 cm broad base, widest at or somewhat above the middle, tip usually slightly curved upwards, guttered, 40–70  $\times$  7.5–9 cm; **marginal teeth** slender-acicular, usually somewhat recurved below the middle of the leaf, 4–5 mm (5–7 mm below the middle), 9–17 per 10 cm, on small or rather well-developed, hardening or partly green prominences; **terminal Sp** acicular, straight, often somewhat flexuous, narrowly and usually shallowly grooved below or beyond the middle, involute or slightly involute towards the base, smooth or with some very small denticles at the margin, 22–30  $\times$  2–3 mm, decurrent, dorsally not intruding into the leaf tissue; **Inf** 1.4–3.6 m, paniculate, peduncle with rather few, toothed **Bra**, the lowest one 5–17.7 cm, fertile part oblong or obovate, 16–145 cm, with (3–) 10–15 part-**Inf**, on slightly S-curved,  $\pm$  ascending branches 6–21 cm long, in the upper  $\frac{1}{4}$ – $\frac{1}{3}$  of the inflorescence, axis distinctly swollen below the insertion of the branches, forming fruits and at the same time freely bulbiferous; **Ped** (4–) 5–6 (–8) mm; **Fl** 40–45 mm; **Tep** yellow, tube conical, 4.5–8 mm, lobes 14–21 mm; **Fil** 25–30 mm, inserted 0–2 mm below the tube throat, long-exserted; **Anth** 14–17 mm; **Ov** not described;

**Sty**  $\pm 40$  mm, long exserted, slightly exceeding or equalling the filaments; **Fr** shortly oblong, 24–30  $\times$  15–18 mm, not or nearly not beaked, stipitate, only rarely formed; **Se** 5.5–6.5  $\times$  4–5 mm.

Hummelinck differentiates *A. rutteniae* in the protologue from *A. vicina* (as *A. vivipara*) on account of its generative features only: The inflorescence axis is distinctly swollen below the insertion of the branches, the flower tube is longer, and the fruits are only 1.5–1.75 $\times$  as long as broad (Hummelinck 1938: 16), and from *A. arubensis* esp. in its shorter leaves, shorter inflorescences, shorter perianth lobes, and smaller fruits (Hummelinck 1993: 223). The species was thought to have possibly disappeared, but was recollected by Howard (Howard 20311, US 3567226! & NY 0140250!, Jan. 1986) and Thomson (2014).

**A. rzedowskiana** P. Carrillo & al. (Brittonia 55 (3): 240–242, ill., 2003). **Type:** Mexico, Jalisco (Carrillo-Reyes & Cabrera 1503 [IBUG, GUADA, MEXU, NY]). — **Lit:** Cházaro Basáñez & al. (2004a: with ill.); Vázquez-García & al. (2007b: 68–69, 73, t. Y). **Distr:** Mexico (S Sinaloa, Nayarit, Zacatecas, C Jalisco); igneous rocky slopes and cliffs, in oak or oak-pine forests, 1600–2500 m; flowers February to April. **I:** Etter & Kristen (2007a: 58); Richter (2011: 56); Etter & Kristen (2012: 84); Pilbeam (2013: 183–184); Ettelt (2014: 125); Hochstätter (2015: VIII: 8).

[1a] Stems repent, to 50 cm; **Ros** hemispherical, compact, 25–45 (–65)  $\times$  20–40 cm, caespitose, given as “polycarpic” and flowering repeatedly from “lateral” inflorescences, which are actually likely terminal on rudimentary lateral rosettes; **L** 100–260, linear-triangular, straight or falcate, rigid, acuminate, striate on both surfaces, (11–) 20–35 (–50)  $\times$  (0.7–) 0.8–1.2 (–1.4) cm (in the middle, at the base to 2.1 cm), glaucous or green, margins hyaline, minutely serrulate with 17–30 teeth per cm; **terminal Sp** rigid, (8–) 10–19 (–23) mm, reddish-brown; **Inf** inclined to decumbent, occasionally sinuous, (42–) 70–170 cm, ‘spicate’, fertile part 10–32 (–53) cm, dense, in the upper  $\frac{1}{8}$ – $\frac{1}{3}$ , with 50–200 flowers; peduncular **Bra** 2.5–9  $\times$  0.5–0.7 cm; floral **Bra** longer than the flowers; **Ped** < 1 mm; **Fl** funnel-shaped, (20–)

22–23 (–24) mm; **Tep** greenish-purple, tube 7–7.5 (–10)  $\times$  9–10 mm, lobes ovate-elliptic, incurved, subequal, the inner slightly narrower than the outer, 4–6 (–8)  $\times$  2–4 (–6) mm, with a tuft of microscopic hairs at the apex; **Fil** (22–) 28–38 (–45) mm, inserted at mid-tube; **Ov** cylindrical to fusiform, glabrous, 7–9  $\times$  3–3.5 (–4) mm, slightly protruding from the tube; **Sty** filiform, sinuate when young, straight at anthesis 40–48 (–51) mm; **Sti** capitate; **Fr** subglobose, erect or appressed to the axis, 7–13  $\times$  6–9 mm, smooth or verrucose; **Se** hemispherical, triangular in cross section, 2.4–3.1  $\times$  1.2–2.1 mm, black.

According to the protologue, the species clearly belongs to Sect. *Juncineae* (as Group *Striatae*) due to its narrow, striate, hard and thick leaves with scabrous serrulate margins and flowers without neck and the ovary slightly protruding from the tube. Its leaves resemble those of *A. striata* ssp. *falcata*, but its floral morphology is more similar to *A. petrophila* and *A. dasyliroides*, with which it shares a short floral tube about as long as the tepals. According to the protologue distinguished from *A. petrophila* by its wider leaves, longer floral tube and shorter tepal lobes, and from *A. dasyliroides* by its caespitose habit, narrower leaves and shorter flowers. In the protologue, the inflorescences are given as inclined to decumbent; a habitat photograph by Etter & Kristen (2007a) shows that the inflorescences may indeed bend down to the ground. Etter & Kristen (2007a: 58) list the plant for Nayarit and Zacatecas. According to Vázquez-García & al. (2007b: 69, 73), *A. rzedowskiana* belongs to the *A. striata* complex and should be compared with its infraspecific taxa, and the population at Cerro El Gallo, Bolaños (Jalisco) assigned to the former may in fact represent *A. striata* ssp. *falcata*.

**A. salmiana** Otto ex Salm-Dyck (Bonplandia 7: 88, 1859). **Type:** not typified. — **Distr:** Mexico.

$\equiv$  *Agave atrovirens* var. *salmiana* (Otto ex Salm-Dyck) Trelease (1920).

**A. salmiana** ssp. **crassispina** (Trelease) Gentry (Agaves Cont. North Amer., 609, ill. (pp. 597, 609), 1982). **Type:** not typified. — **Lit:** González-

Elizondo & al. (2009: 122). **Distr:** Mexico (Coahuila, Zacatecas, San Luis Potosí, NE Jalisco, Guanajuato, Hidalgo, Puebla, C Veracruz); in desert scrub, 1450–2700 m. **I:** Martínez-Morales & Meyer (1985: 63); Irish & Irish (2000: t. 35); Heller (2006: 125); Richter (2011: 9); Pilbeam (2013: 186).

≡ *Agave crassispina* Trelease (1914); **incl.** *Agave crassispina* var. *culta* Trelease (1920).

[2b] Differs from ssp. *salmiana*: **Ros** smaller, 0.8–1.2 m; **L** fewer and smaller, 60–90 × 16–25 cm (rarely larger), margins repand to crenate; **marginal teeth** firm, with a broad base, mostly 7–12 mm, dark brown becoming grey with age, 10–30 mm apart.

This subspecies represents the extensive wild populations of *A. salmiana* differing from the cultivated ssp. *salmiana* mainly in its smaller size and stronger marginal teeth (Gentry 1982: 610). It rarely forms natural hybrids with *A. pintilla* (González-Elizondo & al. 2011). Hernández-Vera & al. (2007a) provide a new record from NE Jalisco. In W San Luis Potosí, wild plant are intensively collected for mescal production leaving soil and offsets exposed, and overgrazing is a major problem for the establishment of offsets (Martínez-Morales & Meyer 1985). In Zacatecas, human population increase with increased *Agave* exploitation has led to ecological deterioration of the local plant stands, without contributing to socio-economic improvements (Martínez-Salvador & al. 2007).

**A. salmiana** ssp. *salmiana* — **Lit:** Berger (1915: 134–137); Breitung (1964: 13–14, as *A. atrovirens* var.); Gentry (1982: 605–608); González-Elizondo & al. (2009: 119–122); García-Mendoza (2011a: 53–54); Starr (2012: 230–233, 325–327); all with ills. **Distr:** Mexico (Coahuila, Durango, Zacatecas, San Luis Potosí, Colima, Jalisco, Guanajuato, Querétaro, Hidalgo, Michoacán, México, Distrito Federal, Puebla, Oaxaca); cultivated only; flowers March to July; neophyte in Spain, Portugal, and RSA. **I:** Heller (2006: 126, 154); Richter (2011: 11); Pilbeam (2013: 185); Smith & Figueiredo (2014a: 15, as var.);

**incl.** *Agave latissima* auct. (s.a.) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave jacobiana* Salm-Dyck

(1859); **incl.** *Agave ferdinand-cortez* Hort. Tonel ex K. Koch (1862); **incl.** *Agave montezumae* Hort. Tonel ex K. Koch (1862); **incl.** *Agave maximiliana* P. Blázquez & I. Blázquez (1865); **incl.** *Agave atrovirens* Heldreich (1867) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave lehmannii* Jacobi (1869); **incl.** *Agave cochlearis* Jacobi (1870) ≡ *Agave salmiana* var. *cochlearis* (Jacobi) A. Terracciano (1885); **incl.** *Agave chinensis* F. P. Smith (1871) (*nom. inval.*, ICN Art. 38.1a); **incl.** *Agave ragusae* A. Terracciano (1897) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave salmiana* var. *glauca* Becker (1898); **incl.** *Agave quioitifera* Trelease ex Ochoterena (1913); **incl.** *Agave compluviata* Trelease (1914); **incl.** *Agave whitackeri* hort. ex Trelease (1914) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Agave caratas* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave dyckii* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave potatorum* hort. ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Agave salmiana* var. *contorta* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a).

[2b] Stems short, thick; **Ros** massive, 1.5–2 × ±3–4 m, closely surculose; **L** broadly linear-lanceolate, thickly fleshy, acuminate, tip sigmoidally curved, deeply convex below at the base, concave to guttered upwards, 100–200 × 20–35 cm, green to glaucous-greyish, margins of the upper ½ often ± repand, sometimes with small prominences; **marginal teeth** mostly 5–10 mm (largest at mid-leaf), brown to greyish-brown, 30–50 mm apart, tips straight to curved from low broad bases; **terminal Sp** subulate, stout, long, 50–100 mm, dark brown, grooved above for >½ of the length, long decurrent (sometimes to the middle of the lamina) as heavy horny margin; **Inf** 7–8 m, paniculate, peduncle with closely imbricate large fleshy **Bra**, fertile part broad, stout, part-**Inf** large, several times compound, 15–20 in the upper ½ of the inflorescence; **Fl** 80–110 mm, thickly fleshy; **Tep** yellow, tube funnel-shaped, thick-walled between the lobe sinuses, 21–24 × 20 mm, lobes lanceolate, curling inwards with progressing anthesis, unequal, outer 21–25 × 6 mm, bulging at the base, narrowed above, with thin involute margins, bluntly galeate,

inner 2–3 mm shorter, with a broad keel; **Fil** 55–70 mm, inserted just above mid-tube, those in front of the outer tepals frequently 1–3 mm taller than the others; **Anth** excentric, 30–35 mm, yellow; **Ov** cylindrical, thick, 50–60 mm, green, neck not constricted; **Sty** exceeding the stamens after anthesis; **Fr** 55–70 × 20–22 mm, stipitate, beaked, brown; **Se** drop-shaped, 8–9 × 6–7 mm, black, hilar notch shallow, apical. — **Cytology**:  $2n = 120$  (Simpson & al. 2011).

Consisting of many forms cultivated in the pulque industry. It is generally recognizable by its broad, heavy, well-armed green leaves with long-acuminate sigmoid tips and large peduncular bracts subtending broad large pyramidal ‘panicles’ (Gentry 1982: 605). *A. salmiana* as well as *A. mapisaga* both include several cultivars which are morphologically and genetically different but show low genetic diversity within each cultivar due to low levels of gene flow (Alfaro Rojas & al. 2007). A detailed study of 48 morphological characteristics from 62 populations of the *A. salmiana* group (Mora-López & al. 2011) showed a gradient of domestication in the sequence *A. salmiana* ssp. *crassispina* (wild) → *A. salmiana* ssp. *salmiana* (cultivated only), concomitant with the increase in rosette and leaf size and the reduction of the marginal teeth and terminal spines (see also under *A. mapisaga*).

Brunel & Rull (2010) report this species and *A. atrovirens* as hosts of the Ulidid fly *Pseudodyscrasis scutellaris*, whose larvae develop in the leaf tissue and cause necrotic spots and discolourations. Previous herbivore damage by beetles and lepidopterans seems to promote *Pseudodyscrasis* attacks, as its adults feed on herbivory-associated rotting *Agave* tissues, etc. Caterpillars of the moth *Comadia redtenbacheri* feed on the plants and may eventually kill them. The boiled and fried caterpillars are eaten as “gusano rojo” or “red agave worms” (Acuña & al. 2011: 159). Plant communities change after long-time use towards *Opuntia* spp. (nopaleras) as replacement of the original communities, and *A. salmiana* density decreases concomitantly (Martínez Salvador & al. 2012). Gómez-Aíza & Zuria (2010) report that flowers of plants in an urban area are visited by 39 species of birds.

The taxon is mentioned as neophyte in Spain (Guillot Ortiz & Meer 2008a, Peña Ramos & Sánchez Gullón 2016), Portugal (Silva & al. 2015) and RSA (Eastern Cape) (Smith & Figueiredo 2012).

**A. salmiana** var. **mitriformis** (Jacobi) A. Berger (Gard. Chron., ser. 3, 33: 294, 1903). **Type**: not typified. — **Lit**: Berger (1915: 132–134, with ill., as *A. ferox*); Breitung (1964: 11–13, with ills., as *A. ferox* and *A. mitriformis*); Gentry (1982: 611–612, with ills., as *A. salmiana* var. *ferox*); García-Mendoza (2011a: 55–57, as *A. salmiana* ssp. *tehuacanensis*); Starr (2012: 231, 233, as *A. salmiana* var. *ferox*). **Distr**: Mexico (México, Puebla, Oaxaca); mainly cultivated but apparently also spontaneous; neophyte in Spain and New Zealand. **I**: Heller (2006: 5, 14, 40, 125); Pilbeam (2013: 187); Smith & Figueiredo (2014a: 15); Zimer (2014: 100); all as *A. salmiana* var. *ferox*.

≡ *Agave mitriformis* Jacobi (1869); **incl.** *Agave tehuacanensis* Karwinsky ex Salm-Dyck (1859) ≡ *Agave salmiana* ssp. *tehuacanensis* (Karwinsky ex Salm-Dyck) García-Mendoza (2011); **incl.** *Agave ferox* K. Koch (1860) ≡ *Agave salmiana* var. *ferox* (K. Koch) Gentry (1982) ≡ *Agave salmiana* ssp. *ferox* (K. Koch) Hochstätter (2015); **incl.** *Agave coarctata* Jacobi (1869); **incl.** *Agave bonnetiana* Peacock ex Baker (1877); **incl.** *Agave coelum* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a).

[2b] Differs from ssp. *salmiana*: **Ros** 1–1.5 × ±2–3 m; **L** broadly oblanceolate, outcurving, thick, tip shortly acuminate, 50–90 × 15–30 cm, light shiny green, margins crenate with strong prominences; **marginal teeth** (5–) 10–15 × 10–20 mm, on prominent broad-based tubercles; **Inf** 3.5–5 (–6) m, peduncle with coriaceous **Bra**, fertile part with (6–) 10–15 part-**Inf**; **Fl** more slender, 70–85 mm. — **Cytology**:  $2n = 120$  (Simpson & al. 2011: as *A. ferox*).

An easily recognizable variant of uncertain systematic status (Gentry 1982: 611). In a classification of 13 morphological characters, it is multiply nested within (and possibly derived from) *A. salmiana* ssp. *crassispina* (Mora-López & al. 2011). García-Mendoza (2011a) elevated this

taxon to subspecific rank as *A. salmiana* ssp. *tehuacanensis*, but the retention of varietal rank is deemed more appropriate due to geographical overlap with ssp. *salmiana*. This taxon was previously treated as *A. salmiana* var. *ferox*, but the name used here has nomenclatural priority.

Reported as neophyte from Spain (Guillot Ortiz & al. 2008: 72–73, Mesquida & al. 2016: 50–53), and New Zealand (Zimer 2014: 100). — ‘Butterfingers’ is a normal-leaved cultivar of smaller size (Starr 2012: 233, sub *A. salmiana* var. *ferox*).

**A. ×santilloensis** Hort. B. Ullrich (ined., 1991). **Nom. inval.**, ICN Art. 29.1. — **Lit:** Gentry (1967: as *A. asperrima* × *A. victoriae-reginae*); Shields (1972: 96, as *A. nigra* etc.); Gentry (1982: 185, as *A. scabra* × *A. victoriae-reginae*); Ullrich (1993c: as *A. asperrima* × *A. victoriae-reginae*); Thiede (2011: 151, 152, as *A. nickelsiae* × *A. scabra*); González-Elizondo & al. (2011: 87, 88, as *A. nickelsiae* × *A. asperrima*); Starr (2012: 240–243, as *A.* ‘Sharkskin’); all with ills. **Distr:** Mexico (Coahuila: NE Saltillo); on limestone ridges in desert scrub, 1220–1525 m; flowers June to July. **I:** Kuppen (2000: 186, as *A. victoriae-reginae* × *A. asperrima*); Heller (2006: 146, as *A. nigra*); Richter (2011: 87, as *A. nigra*); Roosbroeck (2012: 164, as *A. nickelsiae* × *A. asperrima*).

**Incl.** *Agave victoriae-reginae* fa. *viridis* Breitung (1960); **incl.** *Agave ferdinandi-regis* var. *nigra* Shields (1972) (*nom. inval.*, ICN Art. 36.3, 39.1); **incl.** *Agave nigra* Shields (1972) (*nom. inval.*, ICN Art. 36.3, 39.1); **incl.** *Agave victoriae-reginae* var. *nigra* Shields (1972) (*nom. inval.*, ICN Art. 36.3, 39.1).

[1g × 2a] This is the natural hybrid *A. asperrima* × *A. nickelsiae*, known from extensive, very variable introgressive hybrid swarms in the vicinity of Saltillo with all intergrades between its putative parents. The hybrids were dealt with in detail by Gentry (1967) and Gentry (1982: 185), and represent the best-known natural hybrid in *Agave*.

It is widely cultivated esp. under the name *A. nigra*, which was invalidly published by Shields (1972). In an unpublished manuscript in 1991,

B. Ullrich coined the name *A. santilloensis* for these hybrids, which is adopted here. See also the note under *A. ×pumila*. ‘Sharkskin’ is a cultivar selected from the hybrid swarm (Starr 2012). In habitat, most plants of the hybrid swarm, esp. the horticulturally more attractive plants, were missing in 2012 and had apparently been illegally collected (P. Spracklin, pers. comm. Nov. 2012).

**A. sanpedroensis** W. C. Hodgson & Salywon (Syst. Bot. 43(3): 735–738, ills., 2018). **Type:** USA, Arizona (*Hodgson & Salywon* 29603 [DES [3 sheets], NY, US]). — **Distr:** USA (S Arizona: Tucson region); on pre-Columbian agricultural fields in the Arizona Upland subdivision of the Sonoran Desert, 915 m; flowers late July to August.

[2h] Acaulescent; **Ros** open, 0.5–0.75 × 0.5–0.75 m, caespitose, freely suckering; **L** numerous, erect-spreading, linear-lanceolate to linear-oblongate, acuminate, firm, broadest at, just below, or just above the middle, canaliculate, thick at the base, 44–49 × 5–7.3 cm, glaucous-grey, cross-zoned with alternating bands of grey and grey-green, with conspicuous white imprints from the central bud, margins repand; **marginal teeth** strongly recurved, occasionally porrect or upturned in the basal and distal 1/6–1/4, weakly attached, ±1.5–3.5 mm, glaucous-grey (-brown), with brown ring at the base, 12–25 mm apart, intermittent teeth (0–) 4–6 along the lower 2/3 of the leaf; **terminal Sp** slender, openly grooved, 24–35 mm, grey with dark grey-mahogany-brown at the tip, decurrent for ±40 mm to the upper teeth; **Inf** 4.75–6 m, narrowly paniculate, maroon-green glaucous, fertile part open, with 9–13 short, perpendicular to sigmoid/sinuuous-ascending part-**Inf** in the upper 1/3–2/5, to 22 cm long, with 21–31 flowers; **Bra** broadly lanceolate, acuminate to long acuminate; **Ped** very short; **Fl** 55–65 mm, with sweet-musky fragrance at anthesis; **Tep** tube thick, bulging at the lobe bases, 11.5–14 × (11–) 13.5–17 mm, light green, lobes broadly lanceolate, persistently erect, becoming leathery with age, margins sometimes strongly involute, clasping the filaments, (slightly) unequal to equal; **OTep** 15.2–19.25 mm, creamy light yellow (to very light chartreuse-green), sometimes lightly flushed with maroon, tips brown,

papillose, cucullate; **ITep** 13.5–16.25 mm, creamy light yellow (to very light chartreuse-green), strongly keeled, tips less cucullate and lighter; **Fil** 51–60 mm, unequally to subequally or equally inserted 5–6.9 mm above the tube base, light chartreuse-cream, sometimes becoming lightly flushed with maroon distally; **Anth** 15–19 mm, yellowish; **Ov** 24–30 × 8–9 mm, neck 1.5–4.7 mm, slightly constricted, light chartreuse-green-cream or chartreuse-green; **Sty** 32–59 mm, ± as long as the filaments, cream or light chartreuse-green-cream with or without slight maroon flush; **Sti** capitate, 3-lobed; **Fr** and **Se** not observed.

According to the protologue similar to *A. phillipsiana* and *A. palmeri* in its flower colour, but these two species differ in having darker green leaves without conspicuously thickened bases and without imprint of the central bud.

*A. sanpedroensis* is known from less than a dozen sites with roughly 200 individuals, all occurring within pre-Columbian agricultural fields with numerous rock piles and terraces; no occurrences at non-anthropogenic sites are known. It appears to be sterile; only two flowering specimens were observed which did not produce any fruit. The species reproduces vegetatively via rhizomatous offsets and thus has persisted for centuries in these fields since they were abandoned. For further pre-Columbian cultivar species in Arizona, see also under *A. verdensis*.

**A. santanamichelii** (Art. Castro & Aarón Rodríguez) Thiede & Gideon F. Smith (Bradleya 37: 262, 2019). **Type:** Mexico, Jalisco (*Carrillo-Reyes & Tinoco-Villa* 8160 [IBUG, CIIDIR, MEXU]). — **Dist:** Mexico (W Jalisco); ecotone between open pine-oak forests and savannoid vegetation, in deep acidic soils, 920–1060 m; flowers in November.

≡ *Manfreda santanamichelii* Art. Castro & Aarón Rodríguez (2018).

[3a3 × 3b2?] Plants herbaceous; corm 2–2.8 × 1–1.3 cm, cylindrical, with conspicuous buds, bulb 3.5–4.8 × 2–2.5 cm, oblong-ovoid, nearly completely covered with tunicate reddish-brown dried leaf bases; **R** fleshy and thickened, 2–7.5 cm, contractile; **L** drought-deciduous, 7–10, erect, linear, falcate, involute, thin to

leathery, lower and upper face papillate, apex acute and soft, 30–45 × 0.2–0.5 cm, greyish-green, uniformly coloured, margins hyaline, retrorsely and antrorsely denticulate; **Inf** 90–135 cm, erect, green, ‘spicate’, peduncle with 6–9 **Bra**, the lowermost similar to vegetative leaves, **Int** decreasing in length upwards, fertile part 26–36 cm, lax, with 12–17 floral nodes; floral **Bra** 3–45 × 0.2–2 mm; bracteoles 2 per node; **Ped** 4–25 mm, glaucous; **Fl** ±25–30 mm, geminate, ascending, actinomorphic, funnel-shaped; **Tep** yellowish-green or pale red-yellowish on the outer face and pale yellow inside, forming a tube 9–15 × 3–4 mm at the base of the lobes, slightly tapering towards both ends, not curved, lobes ovate to lanceolate, extended, 7–9 × 3–4 mm, tip with a bundle of short white trichomes; **Fil** subulate, 3.7–5.6 mm, erect at anthesis, exceeding the tube for its length, inserted at the base of the lobes on the same level, yellow; **Anth** 4.5–5.5 mm, yellow; **Ov** ovate, 5–7 × 3–5 mm, greenish, slightly constricted above; **Sty** filiform, 17–21 mm, whitish, exerted for 3–5 mm at anthesis; **Sti** capitate, 3-lobed; **Fr** globose, 12–16 × 10–15 mm, with persisting tepals; **Se** deltoid, plane-concave, 3–3.5 × 2.2–2.5 mm, shiny black.

According to the protologue resembling *A. involuta* and *A. singuliflora* (both as *Manfreda*). In its geminate flowers, *A. santanamichelii* differs from all other species of Sect. *Herbaceae* (with single flowers), but resembles Sect. *Polianthes* (with geminate flowers). It might have originated as a spontaneous natural hybrid or allopolyploid between the sympatric *A. involuta* (Sect. *Herbaceae*) with similarly coloured flowers and *A. bulliana* (Sect. *Polianthes*, = *Prochnyanthes mexicana*; A. Castro, pers. comm. Nov. 2018). Artificial hybrids between species of Sect. *Polianthes* and Sect. *Herbaceae* were raised by Lindstrom (2006); some of these have flowers very similar to *A. santanamichelii* (webpage J. T. Lindstrom on <https://www.flickr.com/photos/jonsplants/3642338622>, accessed 6. 11. 2018).

**A. scabra** Ortega (Nov. Pl. Descr. Dec. 2: 13, 1797). **Type:** not typified. — **Lit:** Rose (1903c: 20); Berger (1915: 32); Standley & Steyermark

(1952: 108–110, with ills.); Verhoek-Williams (1975: 265–282); all as *Manfreda brachystachys* except Berger; Piña Luján (1986: 12–13, 35, with ill., as *M. brachystachya*); McVaugh (1989: 234–235, fig. 37, as *M. scabra*); Ullrich (1992k: with ill., as *M. brachystachya*); Robbins (2001: online version with ills., as *M. scabra*); Castillejos-Cruz (2009: [270]–[281], with ills., as *M. scabra*). **Distr:** Mexico (Durango, Zacatecas, San Luis Potosí, Nayarit, Aguascalientes, Jalisco, Guanajuato, Querétaro, Hidalgo, Michoacán, México, D. F., Morelos, Puebla, Veracruz, Guerrero, Oaxaca, Chiapas), Guatemala, Honduras, El Salvador, N Nicaragua; rocky slopes in oak or pine-oak forests, tropical deciduous forests, thorn forests, (semi-) evergreen forests, cloud forests, and grasslands, 100–3100 m; flowers July to September, in Chiapas and C America October to November. **I:** Edwards's Bot. Reg. 25: t. 55, 1839, as *A. saponaria*; Verhoek-Williams (1978b: 126, as *Manfreda brachystachya*); Rodríguez & Castro-Castro (2006: 621); Rodríguez & Castro-Castro (2007: 4); Richter (2007: 41); Hochstätter (2016: I: 41); Castro-Castro & al. (2017: 62); as *M. scabra* when not mentioned otherwise.

≡ *Manfreda scabra* (Ortega) McVaugh (1989); **incl.** *Agave brachystachys* Cavanilles (1802) ≡ *Manfreda brachystachys* (Cavanilles) Rose (1903) ≡ *Polianthes brachystachys* (Cavanilles) Shinnars (1966); **incl.** *Agave spicata* De Candolle (1813) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave polyanthoides* Schlechtendal & Chamisso (1831); **incl.** *Agave saponaria* Lindley (1838); **incl.** *Agave humilis* M. Roemer (1847); **incl.** *Agave polianthoides* M. Roemer (1847) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave brachystachys* var. *strictior* Jacobi & C. D. Bouché (1865); **incl.** *Agave sessiliflora* Hemsley (1880) ≡ *Manfreda sessiliflora* (Hemsley) Matuda (1961); **incl.** *Agave langlassei* André (1901); **incl.** *Manfreda oliveriana* Rose (1903) ≡ *Agave oliveriana* (Rose) A. Berger (1915) ≡ *Polianthes oliveriana* (Rose) Shinnars (1966); **incl.** *Manfreda malinaltenangensis* Matuda (1976).

[3a2] Plants herbaceous, large (for Subgen. *Manfreda*); corm (2.5–) 4–7.2 × (1.7–) 2.5–4.5 cm, cylindrical, reproducing vegetatively by buds, bulb 4–7 × (1.5–) 2.5–4 cm, covered with fibrous

dry leaf bases separating into coarse fibres 7.5–12 cm long; **R** fleshy and thickened, with filiform ramifications, contractile; **L** drought-deciduous, 2–5, recurved to arched, broadly or narrowly linear-lanceolate, spreading, glabrous on both faces, coriaceous to herbaceous, slightly canaliculate, often gently undulate, 40–60 (–95) × 2–4 (–5) cm, light green, often glaucous, glossy, tip acute, with a short and soft tip, veins prominent on the lower face, each vein usually with a single row of papillae, margins with a narrow hyaline band, entire or slightly scabrous and papillate, slightly revolute; **Inf** 1.2–1.4 (–1.6) m, erect, ‘spicate’, green-glaucous, peduncle with 8–10 **Bra**, base truncate, similar to the leaves, decreasing in size upwards, fertile part elongate, lax, 20–40 (–70) cm, with 20–30 flowering nodes; floral **Bra** (0.6–) 1.4–3.8 (–4.4) cm, narrowly deltoid; **Fl** sessile, 28–32 mm, ascending, tubular; **Te**p greenish-yellow to reddish-green, tube narrowly funnel-shaped, slightly recurved, 13–28 × 4–7 mm, lobes oblong, reflexed to revolute, (10–) 12–18 (–23) × 4–6 mm, cucullate, with a soft tip and a tuft of short white trichomes; **Fil** erect, 36–55 mm, exceeding the tube for 26–36 (–45) mm, inserted at  $\frac{3}{4}$  from the base of the tube all on the same level, yellowish-green with purple dots; **Anth** 11–16 mm, greenish-yellow; **Ov** cylindrical, 12–16 (–20) × 4–5 mm, not extending into the tube, not constricted; **Sty** 30–42 mm, yellowish-green with purple dots; **Sti** capitate, 3-lobed; **Fr** cylindrical, slightly apiculate, (15–) 20–26 (–30) × 12–16 mm, with persisting tepals; **Se** deltoid, plane-concave, 4.5–6 × 4–6 mm, dull.

McVaugh (1989: 234) has replaced the well-established name *Manfreda brachystachys* (based on *Agave brachystachys*, as ‘*brachystachya*’) by the new combination *Manfreda scabra*, based on the earlier name *Agave scabra*. *A. scabra* is the most widely distributed species of Subgen. *Manfreda* and with the exception of the Guatemalan *A. fusca* the only one reaching Central America. It is less variable in the N and rather variable in the C and S part of its area (Castillejos-Cruz 2009) and is characterized by leaves with prominent veins with a row of papillae and margins which are entire or equally papillate, as well as the elongate open inflorescence, a semihorizontal

flower position during anthesis and ascending at maturity, and the tepal tube, which is longer than the ovary and the lobes (McVaugh 1989, Castillejos-Cruz 2009).

*A. scabra* is morphologically similar to the recently published *A. justosierrana* (see there). *Manfreda malinaltenangensis* was placed in the synonymy of *A. hauniensis* in the first edition of this handbook, but represents a synonym of *A. scabra* (Castañeda Rojas & al. 2005). The main pollinator is a long-nosed bat species, minor pollinators are other bats, hawkmoths, and hummingbirds, and perching birds and bees rob nectar (Eguiarte & Búrquez 1987).

**A. scaposa** Gentry (Agaves Cont. North Amer., 303–304, ills., 1982). **Type:** Mexico, Oaxaca (Gentry 22472 [US [syn], ARIZ, DES, MEXU, MICH]). — **Lit:** García-Mendoza (2011a: 58–59). **Distr:** Mexico (S Puebla, NW Oaxaca); on igneous or limestone rocks, in dry scrub, oak-palm grasslands or oak forests, 1980–2550 m; flowers June to August. **I:** Pilbeam (2013: 188); Hochstätter (2015: VII: 20).

[2a] Stems short; **Ros** dense, 1.5–2.2 × 2.5–3 m, solitary; **L** 60–100, broadly lanceolate, ascending, outcurving to spreading, coriaceous, somewhat flexible, heavily succulent, slightly narrowed above the thick base, upper face almost flat to concave, smooth, 90–120 × 20–28 cm, light to dark green or yellowish-green, with glaucous transverse bands, margins straight or repand to crenate; **marginal teeth** numerous, usually straight, closely set, on broad flattened reddish bases, sometimes on small prominences, 3–6 (–8) × 7–10 mm, confluent or 10–20 (–25) mm apart, dark brown or brownish to greyish, sometimes with few smaller intermittent teeth placed at random; **terminal Sp** subulate, base conical, with deep narrow groove above, 25–60 × 3–5 mm, dark brown or greyish, decurrent to ¼–½ of the lamina; **Inf** 6–10 (–13) m, paniculate, peduncle green to greyish-green, 5–7 m, with narrow chartaceous triangular reflexed **Bra** 30–40 cm, fertile part lax, broadly oblong to ovate, part-**Inf** 25–40 in the upper ½–¼ of the inflorescence, 25–40 cm long; floral **Bra** small, scarcely persistent; **Ped** 5–15 mm, slender; **Fl** (45–) 50–60 (–65)

mm; **Tep** intense greenish-yellow, tube 4–10 × (8–) 10–18 mm, lobes oblong, erect, thick, subequal, 14–20 (–25) × 3–5 mm, the outer slightly larger, the inner ribbed; **Fil** (30–) 35–45 mm, inserted at the mouth of the tube, yellowish; **Anth** 20–22 mm, yellow; **Ov** cylindrical to somewhat triquetrous, 30–38 × 5–10 mm, green, neck 3–5 mm; **Sty** 50 mm; **Fr** oblong, strong-walled, 50–60 × 20–30 mm, stipitate, shortly beaked; **Se** drop-shaped, 7–9 × 5–6 mm, dull black.

Characterized by its large rosettes with dark to yellowish-green leaves with repand to crenate margins with small, narrow teeth, and small, intense greenish-yellow flowers on large inflorescences overtopping the tree stratum (García-Mendoza 2011a). Rarely observed in habitat. Its tall narrow panicles with dry small scapose peduncular bracts relate it with Sect. *Agave* (Gentry 1982, as Group *Americanae*). The flowers were unknown to Gentry (1982) and the description is added from García-Mendoza (2011a).

The caterpillars of the butterfly *Aegiale hesperiaris* feed within the leaves esp. of *A. scaposa* and represent a most valued delicacy in the traditional food system (“conduchos” or “white agave worms”; Acuña & al. 2011). This species, *A. aff. atrovirens*, and *A. salmiana* occurring in areas cleared for agriculture are protected by transplanting young individuals to areas or terraces surrounding the plots in order to favour retention of soil and water and to make use of them as fodder, fuel, food, and wood (Blancas & al. 2010). — The holotype at US consists of 3 sheets thus representing syntypes; 2 of the sheets were apparently cross-labelled later.

**A. schidigera** Lemaire (Ill. Hort. 8(6): in adnot. ad t. 289, 1861). **Type:** [neo — icono]: Ill. Hort. 9(7): t. 330, 1862. — **Lit:** Berger (1915: 74–76 [but ill. placed in *A. colimana* by Gentry (1982: 120)]); Breitung (1963: 118); Gentry (1982: 119–121); McVaugh (1989: 142–143); Ullrich (1992h); Vázquez-García & al. (2007b: 70–71, t. BB); Hernández-Vera & al. (2007a); González-Elizondo & al. (2009: 69–74, as *A. filifera* ssp.); Starr (2012: 234–239, 317–318); all with ills. except McVaugh. **Distr:** Mexico (Sonora, Chihuahua, Sinaloa, Durango, Zacatecas, San Luis

Potosí, Nayarit, Jalisco, Guanajuato, Aguascalientes, Michoacán, Guerrero?); tropical deciduous forests, pine-oak-forests and ecotones, 875–3000 m; flowers mainly June to November, also records for February, March, May, and December. **I:** Curtis's Bot. Mag. 93: t. 5641, 1867; Curtis's Bot. Mag. 135: t. 8271, 1909, as *A. wrightii*; Heller (2006: 127); Richter (2011: 44, 109, 110, 118); Pilbeam (2013: 83, as *A. filifera* ssp.).

≡ *Agave filifera* var. *schidigera* (Lemaire) A. Terracciano (1885) ≡ *Agave filifera* ssp. *schidigera* (Lemaire) B. Ullrich (1992); **incl.** *Agave filifera* var. *ignescens* hort. (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Agave filifera* var. *adornata* Scheidweiler (1861); **incl.** *Agave filifera* var. *pannosa* Scheidweiler (1861); **incl.** *Littaea roezlii* Roezl (1861) (*nom. inval.*, ICN Art. 36.1b); **incl.** *Agave filifera* var. *angustifolia* Lemaire (1865); **incl.** *Agave schidigera* var. *angustifolia* Lemaire (1865); **incl.** *Agave schidigera* var. *ignescens* Lemaire (1865); **incl.** *Agave schidigera* var. *plumosa* Lemaire (1865); **incl.** *Agave vestita* S. Watson (1890); **incl.** *Agave taylorii* Hort. Besaucèle ex A. Berger (1894) (*nom. illeg.*, ICN Art. 53.1) ≡ *Agave schidigera* var. *taylorii* (Hort. Besaucèle) H. Jacobsen (1955); **incl.** *Agave wrightii* J. R. Drummond (1909) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave perplexans* Trelease (1914); **incl.** *Agave schidigera* ssp. *huicholensis* Ullrich ex I. Richter (2011) (*nom. inval.*, ICN Art. 38.1a, 40.1).

[Id] Stems short or none; **Ros** symmetrical, solitary, 0.4–1.14 × 0.9–2 m, not surculose; **L** > 100, linear, straight, sometimes falcate, relatively thin, pliable, widest at or below the middle, acuminate, convex below towards the base, flat above, smooth, 30–40 (–50) × (1.3–) 1.5–3 (–4) cm, green to greyish-green or yellowish-green, rarely reddish, with white imprints from the central bud, margins brown to white, coarsely white-filiferous; **terminal Sp** flat above, round below, 5–16 (–20) mm, brown to grey with age, shortly decurrent; **Inf** 2–3.5 m, 'spicate', peduncle with narrow **Bra**, fertile part slender, laxly flowered in the upper ½, part-**Inf** with 1–2 flowers; **Ped** short; **Fl** 30–45 mm; **Te** green to yellow or purplish, tube narrowly funnel-shaped, grooved, 7–10 mm,

lobes linear, acute, recurving, thin, overlapping at the base, equal, 13–20 mm, greenish to yellow or tinged purple; **Fil** slender, 35–50 mm, pale-coloured to purple, inserted on the tube rim; **Anth** very slender, frequently excentric, 13–21 mm, yellow to purplish; **Ov** fusiform, angled, 12–20 mm, neck furrowed; **Sty** longer than the filaments; **Sti** capitate; **Fr** variable in size and shape, ovoid and 12 × 6–7 mm, or oblong and 18–20 × 6–9 mm, usually beaked, shortly stipitate; **Se** thick, deltoid and 2 × 1.5 mm, or crescent-shaped and 3.5 × 2 mm, sharply cornered rather than winged, rugose or irregularly veined on the faces. — **Cytology:** 2n = 52, 180 (Simpson & al. 2011: as *A. wrightii*).

Closely related to *A. filifera*, but separable by its non-surculose habit, its mostly larger rosettes with longer, thinner, more pliable leaves and coarse rather than finely filiferous margins, and its longer floral tube (Gentry 1982: 120, McVaugh 1989, Starr 2012: 317). Narrow-leaved forms may vegetatively be indistinguishable from *A. colimana*, but the latter usually has a shorter terminal spine (5–8 mm; McVaugh 1989). González-Elizondo & al. (2009: 72) show a caespitose form from Durango as well as natural hybrids with *A. asperrima* and a further unknown species. For a form from the Sierra Huichol (Saucito, Nayarit) with esp. long and narrow leaves collected by A. B. Lau, the unpublished name *A. schidigera* ssp. *huicholensis* is used (Richter 2011: 109, with ill.). González-Elizondo & al. (2009) mention the species for Sonora (possibly based on *Reina-G. & Van Devender*, ARIZ 348293, from S Sonora). The records for Hidalgo (González-Elizondo & al. 2009) and México (McVaugh 1989) need specimen citations. The record cited by Gentry (1982: 122) for Guerrero is uncertain.

Ullrich (1992h) reduced this taxon as well as *A. multifilifera* to subspecific rank under *A. filifera*, based on mere literature interpretations, which was followed in the first edition of this handbook for practical reasons. Vázquez-García & al. (2007b) and Govaerts (2014+) reinstated Gentry's (1982) concept of separate species, and this is followed here.

Horticultural selections are distributed as 'Black Widow' and 'Durango Delight', and 'Shira Ito No Ohī' is a variegated cultivar (Starr 2012).

**A. schneideriana** A. Berger (Agaven, 256, 1915). **Type:** not typified. — **Distr:** Mexico (Puebla: Tehuacán?); ecology unknown.

[2g] Stems short, laxly leafy along the whole length, covered with leaf sheaths; **L** ±17–20, linear-lanceolate, upright-projecting, somewhat irregularly curved inwards or outwards, leathery, little fleshy, at mid-leaf ±4 cm broad, from there long attenuate towards the tip and narrowed to 2.5 cm at the base, there 9–10 mm thick, convex below, dull dark green, smooth but rough towards the tip, above flatly concave, somewhat canaliculate towards the tip, smooth, dull dark green, margins fine, pale, hyaline and cartilaginous; **marginal teeth** remote, somewhat irregular and relatively large, the larger ±30–40 mm apart, on flat, fleshy prominences with crescent-shaped to lenticular base ±6 mm long, tip of the teeth narrowly deltoid, curved hook-like, 2–3 mm, mostly up-flexed, sometimes with small intermittent teeth, upper teeth more remote and becoming smaller, basal teeth somewhat narrower, young chestnut-brown, later black-brown; **terminal Sp** slender, nearly straight, subulate, narrowly and shortly grooved above, 17–30 mm, 52 (sic!, 5.2?) mm thick, black-brown, shiny, not decurrent, sharply offset from the green tissue; **Inf, Fl, Fr** and **Se** unknown.

This “forgotten” name was not mentioned by Gentry (1982), and was listed as unplaced in the first edition of this handbook. Recently, it was recognized as a distinct species by Espejo Serna & López Ferrari (1993) and Govaerts (2014+), which is followed here. The plant was sent in 1906 from Mexico by C. A. Purpus to his brother A. Purpus at BG Darmstadt (Germany), from where Berger received material. According to the protologue, it is a very distinct species closest to *A. karwinskii*, but with a much laxer rosette, a different stem, and the leaves reminiscent of *A. cantala*. Ullrich (1993b: 56) placed *A. schneideriana* for the time being in the synonymy of *A. karwinskii*. Purpus may have collected the material from the *A. karwinskii* localities around Tehuacán (Puebla) from where he sent many plants, esp. in 1906, and it may have represented a natural hybrid with a narrow-leaved species such as *A. angustifolia*.

**A. schottii** Engelm (Trans. Acad. Sci. St. Louis 3: 305–306, 1875). **Type:** USA, Arizona (*Schott* s.n. [MO 3347375, NY 320043]). — **Lit:** Gentry (1982: 205–207, with ills.); Turner & al. (1995); Parker (2017: 262). **Distr:** USA (Arizona, New Mexico), Mexico (Sonora).

The types are the two specimens cited above from the “Serra del Pajarito” in S Arizona, collected in July 1855.

**A. schottii** var. **atricha** Trelease (Contr. US Nation. Herb. 23: 140, 1920). **Type:** not typified. — **Lit:** Toumey (1901: with ills., as *A. treleasei*); Berger (1915: 76–77, as *A. treleasei*); Gentry (1982: 207, with ill.); Hodgson (1999a: 10); Reveal & Hodgson (2002); Parker (2018a: 21, with ill.); the last 4 as *A. schottii* var. *treleasei*. **Distr:** USA (S Arizona); gravelly to rocky places, mostly in desert scrub, grasslands, juniper and oak woodlands, 1100–2000 m; flowers May to July.

**Incl.** *Agave treleasei* Toumey (1901) ≡ *Agave schottii* var. *treleasei* (Toumey) Kearney & Peebles (1939).

[1e] Differs from var. *schottii*: **L** larger, thicker and wider (1.2–2.5 cm), deep green, without imprints from the central bud, margins not filiferous; **terminal Sp** longer, 12–19 mm; **Inf** subspicate to narrowly racemose-paniculate; **Fl** larger, 35–50 mm.

For this taxon, the name *A. schottii* var. *treleasei* (published 1939) is commonly applied, but that name is antedated by *A. schottii* var. *atricha* (1920) which, according to the protologue, is “without marginal threads” and thus belongs here and not to the synonymy of var. *schottii* as previously thought.

According to Gentry (1982: 207) a doubtful variant in need of better study, occurring sympatrically with var. *schottii* (Gentry 1972: 77). It appears to be based on scattered aberrant specimens. At the type locality, only few plants were found in 1940 (Little 1981: 68) and none later in the 80ies (Reichenbacher 1985: 103). The taxon may be of hybrid origin involving *A. schottii* var. *schottii* and *A. chrysantha* or *A. palmeri* (Reveal & Hodgson 2002). According to Parker (2018a), it is the hybrid *A. schottii* var. *schottii* × *A. chrysantha*, occurring in few small clumps in the

**Fig. 51** *Agave schottii* var. *schottii* (Eggl s.n.: USA; Arizona, Organ Pipe National Monument). (Copyright: U. Eggl)

Santa Catalina Mts. near Tucson, Arizona. Hybridisation with a member of Subgen. *Agave* is also indicated by its inflorescences, partly with branchlets to 4 cm long with up to 6 flowers (Hodgson 1999a). If the hybrid origin can reliably be documented, the taxon should be treated as *A. ×treleasei*. — Plants are consumed by wildlife, perhaps rodents (attributed to “Hodgson & al. 1994” by Turner & al. (1995).

**A. schottii** var. **schottii** — **Lit:** Berger (1915: 71–72, with ill.); Gentry (1972: 67–60, with ill.); Gentry (1982: 205–207, with ill.); Ullrich (1992e); Turner & al. (1995); Hodgson (1999a: 9–10); Reveal & Hodgson (2002); Starr & Devender (2011: 230, with ill.). **Distr:** USA (S & SE Arizona, SW New Mexico), Mexico (N Sonora); gravelly to rocky places, mostly in desert scrub, grasslands, juniper and oak woodlands, 900–2000 m; flowers April to August. **I:** Curtis’s Bot. Mag. 123: t. 7567, 1897; Irish & Irish (2000: t. 38); Heller (2006: 129); Richter (2011: 128); Pilbeam (2013: 189); Hochstätter (2015: VIII: 62, 64). — Fig. 51.

**Incl.** *Agave geminiflora* var. *sonorae* Torrey (1859) ≡ *Agave sonorae* (Torrey) Mearns (1907); **incl.** *Agave schottii* var. *serrulata* Mulford (1896); **incl.** *Agave mulfordiana* Trelease (1920).

[1e] **Ros** small, densely caespitose; **L** narrowly linear, straight, incurved, or falcate, pliable, widest at the base, deeply convex below, flat or somewhat convex above, smooth on both faces, 25–40

(–50) × 0.7–1.2 cm, yellowish-green to green, with conspicuous imprints from the central bud on both faces, margins with a narrow border and sparse brittle threads; **terminal Sp** delicate, rather weak and brittle, 8–12 mm, greyish; **Inf** 1.6–2.5 m, ‘spicate’, peduncle with straw-coloured filiform acicular **Bra** 2–4 cm long, fertile part slender, frequently crooked, in the upper ¼–½, part-**Inf** with 1 or 2–3 flowers; floral **Bra** thread-like, 10–15 mm at the lower nodes but shorter further up; **Ped** stout, <2 mm; **Fl** 29–42 mm; **Tep** yellow, tube deeply funnel-shaped, very narrow below, 8–11 (–14) × 5–8 mm, lobes unequally spreading at anthesis, unequal, 8–11 (–14) × 5–8 mm, outer without keel, light yellow; **Fil** 15–22 mm, inserted 6–13 mm above the tube base; **Anth** 10–15 mm, light yellow; **Ov** 8–15 mm incl. the 4–6 mm long neck, greenish-yellow; **Sty** shorter than the filaments; **Sti** slightly thickened; **Fr** rounded to apiculate, 10–20 mm; **Se** with hilar notch at one corner, variably thickened, 3–3.5 mm along the straighter thinner edge. — **Cytology:** 2n = 60, 120 (Granick 1944, Zonneveld 2003, Simpson & al. 2011).

The flowers of *A. schottii* have a long tubular appearance due to the slender tube and the long narrow neck of the ovary. The taxon is easily confused with narrow-leaved forms of *A. felgeri*, but the latter has a short flower tube (Gentry 1982: 207). In *A. schottii*, the leaves are longer and taper more towards the tip than those of the

habitually similar *A. parviflora*, and have thinner, more irregular marginal fibres, while the rosette has a more open appearance (Starr & Devender 2011). *A. schottii* var. *schottii* hybridizes with *A. deserti* ssp. *simplex*, *A. chrysantha*, and possibly *A. palmeri* or *A. parryi* var. *parryi* (Reveal & Hodgson 2002).

*A. geminiflora* var. *sonorae* Torrey (1858) is treated as homotypic synonym by Govaerts (2014+: accessed Dec. 2018), but is according to the protologue based on “Sierra del Pajarito, Sonora, August, Schott” and thus from the Sonoran (Mexican) side of the Pajarito Mts.; the type appears to be *Schott* s.n., 1855, from “Sonora” (US 125669!).

The flowers are visited by hummingbirds, bees, wasps, ants, and bats. Nectar production is mainly nocturnal suggesting bat pollination, but the sweet fragrance, low protein content of the pollen, and the yellow flowers might favour bee pollination. Possibly, the species undergoes a shift from bat to bee pollination (Turner & al. 1995). Pollination experiments and genetic analyses showed that the taxon experiences inbreeding depression and a trend towards outbreeding depression; individuals 1 m apart had a higher genetic similarity than plants further apart (Trame & al. 1995). — The taxon has been used for washing clothes and hair and is unpalatable to livestock (Turner & al. 1995).

**A. sebastiana** Greene (Bull. Calif. Acad. Sci. 1: 214, 1885). **Type:** Mexico, Baja California (*Greene* s.n. [CAS 0000141, CAS, UC]). — **Lit:** Trelease (1912a: 47–48, tt. 23–26); Berger (1915: 172); Breitung (1963: 49–50, with ills.); Gentry (1978: 96–97, t. 6); Gentry (1982: 645–646, with ills.); Turner & al. (1995: 63); Webb & Starr (2014a: 93, 95–96, with ill.); Heim (2014: 7, 19–23, with ills.); Webb & Starr (2015: 91–92, with ill.). **Distr:** Mexico (Isla San Benito, Isla Cedros and Isla Natividad off the coast of Baja California); low desert scrub, 0–600 m; flowers March to May. **I:** Greulich (2005a: 28); Heller (2006: 129); Richter (2011: 75); Klaassen (2011: 28–30); Pilbeam (2013: 190–191); Hochstätter (2015: IV: 31); Moore (2016: 218, 220, 221, 275); Vanderplank & al. (2017: 25, 26); Greulich (2018b: 95).

≡ *Agave shawii* var. *sebastiana* (Trelease) Gentry (1949); **incl.** *Agave disjuncta* Trelease (1912).

[2f] **Ros** elongate, 0.6–0.9 × 0.75–1 m, single or mostly prolifically caespitose; **L** closely imbricate, broadly linear, broadly linear-lanceolate, broadly linear-ovate, or ovate, shortly acuminate, thick and rigid, sometimes slightly narrowed towards the base, rounded below, flat to slightly hollowed above, generally 25–45 × 8–24 cm, silvery-blue, blue-grey or glaucous blue-green, with imprints left by the central bud, margins rather straight, usually thick-horny, dark brown; **marginal teeth** frequently down-flexed, slender, larger teeth (at mid-leaf) 5–10 mm, reddish-brown, 10–20 mm apart, or smaller and more numerous; **terminal Sp** stout, variously grooved above, 20–30 mm (rarely shorter), black to somewhat grey, decurrent to the 5. or 6. tooth; **Inf** 2–3 m, paniculate, peduncle stout, with small deltoid scarious appressed pink to yellow **Bra**, fertile part short, widely spreading, rounded to nearly flat at the top, congested with 8–12 large part-**Inf** in the upper ¼ of the inflorescence; **Fl** thickly fleshy, 70–90 mm; **Tep** green in bud, opening yellow, tube broadly funnel-shaped, 14–20 × 18–22 mm, lobes lanceolate, markedly cucullate and glandular-floccose at the tip, 16–25 × 5–7 mm, inner shorter, strongly keeled; **Fil** stout, 50–60 mm, inserted at mid-tube 8–14 mm above its bottom; **Anth** 20–21 mm, yellow; **Ov** cylindrical, 35–55 mm; **Fr** large, ±60–80 × 30 mm, beaked but scarcely stipitate; **Se** 7 × 11 mm, glossy black.

Closely related to *A. shawii*, but differing significantly in the pale green somewhat glaucous leaves with more slender teeth, the smaller more remote and scarious peduncular bracts and the broader flatter inflorescences (Gentry 1978, Gentry 1982). Plants from the Bahia Tortugas area assigned here by Gentry (1982) belong to *A. vizcainoensis*, and *A. sebastiana* is thus absent from mainland Baja California (Webb & Starr 2014a). No other Agaves are known from Isla San Benito and Isla Natividad (Webb & Starr 2015), but from Isla Cedros, *A. cerulata* has recently been reported (see there). Greulich (2005a) describes a flowering hybrid of cultivated origin with a species of Subgen. *Littaea*.

**A. seemanniana** Jacobi (Abh. Schles. Ges. Vaterl. Cult., Abth. Naturwiss. 1868: 154, 1869). **Type** [neo]: Honduras (*Gentry* 20684 [US, DES, MEXU]). — **Lit**: Trelease (1915: 137–138); Standley & Steyermark (1952: 116); *Gentry* (1982: 494–499, with ill.); Ullrich (1992g: with ill.); Lott & García-Mendoza (1994); Cseh (2008: with ill., p.p. as *A. pygmaea*); García-Mendoza (2010: 86–92, with ill.); García-Mendoza (2011a: 59–60). **Distr**: Mexico (Oaxaca, Chiapas), Guatemala, Honduras, El Salvador, N & NW Nicaragua, Costa Rica; dry rocky slopes, in soils derived from calcareous or granitic rocks, in dry scrub, savannas, tropical deciduous or subtropical oak or pine-oak forests, 100–2600 m; flowers September to January. **I**: Irish & Irish (2000: t. 34, as *A. pygmaea*); Richter (2011: 55, 84, 124); Pilbeam (2013: 192–193, as ssp. *seemanniana* and ssp. *pygmaea*); Smith (2014).

[2o] Acaulescent; **Ros** compact, open, ((±0.3–) 0.8–) 1–1.5 × ((±0.4–) 1.3–) 1.5–2 mm, solitary; **L** (16–) 30–40, spatulate, broadly lanceolate or ovate, recurved or erect, thickly succulent, thickened and strongly narrowed at the base, flat

to slightly guttered, ((12–) 22–) 30–55 (–65) × (6–) 10–16 (–22) cm, glaucous, greenish-glaucous to yellowish-green, zonate, margins repand to sharply crenate; **marginal teeth** mostly straight or curved, deltoid, (2–) 6–10 (–15) × (±5–) 10–14 mm, dark to greyish-brown or greyish, ((10–) 30–) 40–55 mm apart, with broad bases covering the top of the marginal prominences, these (7–) 10–15 (–20) mm; **terminal Sp** subulate, very broad at the base, sinuous, broadly grooved above, (15–) 20–45 (–50) × 5–10 mm, dark brown to greyish, conspicuously decurrent as a sharp ridge to the upper teeth for 2–6 cm; **Inf** (2–) 4–6 (–7) m, paniculate, peduncle short, with triangular chartaceous **Bra** 15–22 cm long, fertile part open, ovate to oblong in outline, with (8–) 12–30 (–50) spreading part-**Inf** in the upper 1/3–1/2 of the inflorescence, with ((±20–) 40–) 60–80 flowers, primary branches (10–) 15–30 (–50) cm, 15–30 cm apart; **Ped** (3–) 8–17 mm; **Fl** slender, (31–) 40–70 mm, salver-shaped to broadly campanulate; **Tep** yellow, tube broadly funnel-shaped, (4–) 7–10 (–13) × 7–10 (–12) (at the apex) mm, lobes linear, erect, thick, slightly unequal, (11–) 13–20 (–24) × 3–5 mm, outer slightly larger, involute, sometimes purple-tinged, inner linear, erect, thickish, keeled, cucullate at the tip; **Fil** (20–) 30–45 mm, yellow, inserted at ± different levels 1–2 (–3) mm below the base of the lobes; **Anth** versatile, 12–20 mm, yellow; **Ov** slender, triquetrous, fusiform to cylindrical, (15–) 25–38 × 5–7 mm, green, neck 3–5 mm, slightly furrowed; **Sty** (±30–) 45–60 mm; **Sti** 3-lobed; **Fr** oblong, (30–) 45–50 (–65) × (14–) 20–25 mm, shortly rostrate, shortly stipitate; **Se** crescent-shaped, applanate, unwinged, 5–7 × 3.5–6 mm, black. — **Cytology**: 2n = 60 (M. Baker 1997, label on DES00040525, as *A. pygmaea*).

Characterized by open compact rosettes with few recurved, spatulate to broadly lanceolate leaves with margins with distinct prominences and marginal teeth with broad, decurrent bases (García-Mendoza 2011a: 59–60). The species exhibits considerable variation in leaf characters and is within its geographical range recognizable by its open compact rosettes with broad flat leaves markedly narrowed at the base (*Gentry* 1982). It is

close to *A. potatorum*, but the latter differs in its shorter and narrower, erect leaves with smaller and less distant teeth on smaller prominences (García-Mendoza 2010). Grayum (2003) provides a new record for Costa Rica.

The species is commonly assumed to have been discovered by the eponymous B. Seemann in Nicaragua in 1866 (see Ullrich 1992g). However, the species was first collected by A. S. Ørsted who sent plants from Nicaragua to Copenhagen in 1848 where they flowered after 70 years in 1918 and were identified as *A. guatemalensis* (Ostenfeld 1924: 47).

The caespitose *A. pygmaea* (distributed as ISI 2009-11) was described by Gentry (1982: 494–495) as “a depauperate form generated by the arid limestone on which it was found” in E Chiapas (Mexico). Lott & García-Mendoza (1994) and García-Mendoza (2010) place *A. pygmaea* in the synonymy of *A. seemanniana*. Similar small caespitose forms are reported locally from arid limestone rocks in S Nicaragua where they are threatened by extending human settlements (Cseh 2008).

**A. shaferi** Trelease (Mem. Nation. Acad. Sci. 11: 35, t. 57, 1913). **Type:** Cuba (*Shafer* 3800 [MO, NY]). — **Lit:** Berger (1915: 209); León (1946: 318); Acevedo-Rodríguez & Strong (2012: 86); Greuter & Rankin Rodríguez (2017: 36). **Distr:** E Cuba (Sierra de Nipe); rocky peaks and steep slopes of karstic serpentine dome hills (mogotes), in pine-*Agave*-woodland, 400–1000 m; flowers January to February. **I:** Hochstätter (2015: VII: 74); Fernández Velázquez & al. (2018: 37).

[2p] Acaulescent; **Ros** hemispherical, to >2 m Ø, solitary; **L** elongate-lanceolate, erect, recurved in the upper part, rather gradually pointed, guttered, ±75 – ±150 × 10 – ±20 cm, light green to green, not glaucous; **marginal teeth** straight or slightly curved upwards or downwards, triangular from lenticular bases, 1–2 mm, brown, 10–25 mm apart, intervening margin slightly concave; **terminal Sp** conically subulate, unguiculate recurved, openly V-grooved to the middle, smooth, 10–20 × 3 mm, brown, dull, not decurrent; **Inf** 6–7 m, paniculate; **Ped** ±15–23 mm; **Fl** 40–50 mm; **Tep** bright yellow, tube conical, 5–6 mm, lobes 14 × 4 mm; **Fil**

scarcely 25 mm, inserted nearly in the tube throat; **Ov** fusiform, 25–30 × 4–5 mm; **Fr** oblong-fusiform, ±35–42 × 8–16 mm, shortly stipitate; **Se** unknown.

An insufficiently known local endemic. In the key of Trelease (1913: 31) it is keyed out with oblong capsules and short pedicels (5–10 mm), albeit that pedicels and fruits were unknown to him; these data were added from *Carabia* 3582 (NY!). It is treated as “Vulnerable” according to IUCN Red List categories (Berazaín & al. 2005: 17).

**A. shawii** Engelmann (Trans. Acad. Sci. St. Louis 3: 314–316, 370, 1875). **Type** [lecto]: USA, California (*Hitchcock* s.n. [MO 3347373]). — **Lit:** Gentry (1982: 639–645, with ill.); Turner & al. (1995: with ill.). **Distr:** USA (S California), Mexico (Baja California).

The protologue cited material of Parry, Parker and Hitchcock, and Palmer. The designation by Trelease (1912a: 47) “Hitchcock, 1875, -the type” represents a lectotypification.

**A. shawii** ssp. **goldmaniana** (Trelease) Gentry (Occas. Pap. Calif. Acad. Sci. 130: 93, 1978). **Type:** Mexico, Baja California (*Nelson & Goldman* 7151 [US, MO]). — **Lit:** Trelease (1912b: 44, 49, tt. 29–31, as *A. goldmaniana*); Berger (1915: 173, as *A. goldmaniana*); Breitung (1963: 49–50, with ill., as *A. goldmaniana*); Gentry (1978: 92–96, with ill. & t. 6); Gentry (1982: 642–644, with ill.); Turner & al. (1995: 63–65); Starr (2012: 245); Webb & Starr (2015: 91–92, 94–95, with ill.); **Distr:** Mexico (C & S Baja California); coastal desert scrub with nocturnal fogs from fall to spring, 5–700 m; flowers December to May. **I:** Ullrich (1990g); Heller (2006: 22, 131); Richter (2011: 75, 98); Pilbeam (2013: 195); Heim (2014: 6, 11–13, as var.); Hochstätter (2015: IV: 30).

≡ *Agave goldmaniana* Trelease (1912) ≡ *Agave shawii* var. *goldmaniana* (Trelease) A. Heim (2014).

[2f] Differs from ssp. *shawii*: **Ros** often larger; **L** lanceolate rather than linear-ovate, more acuminate, longer, 40–70 × 10–18 cm; **Inf** with peduncular **Bra** below lowest part-**Inf** smaller and not closely clustered, fertile part longer than

broad, part-**Inf** mostly 20–30. — **Cytology**:  $2n = 60$  (Pinkava & Baker 1985, Simpson & al. 2011: as *A. goldmaniana*).

Representing the ecotype of the more arid interior habitats (Gentry 1978, Gentry 1982). The coastal ssp. *shawii* differs from the inland ssp. *goldmaniana* in having shorter bright green leaves and inflorescences about as long as broad and large, succulent, red to purple subtending bracts (Gentry 1978, Gentry 1982, Webb & Starr 2015).

**A. shawii** ssp. **shawii** — **Lit**: Engelmann (1878: with ills.); Trelease (1912b: 44, 46–47, tt. 19–21); Berger (1915: 170–171); Breitung (1963: 16–17, with ills.); all as *A. shawii*; Gentry (1978: 86–93, with ills. & t. 5); Gentry (1982: 639–643, with ills.); Turner & al. (1995: 63–65, with ill.); Reveal & Hodgson (2002); Starr (2012: 12, 244–249, with ills.); Vanderplank (2014: conservation California); Webb & Starr (2015: 91–93, with ill.). **Dist**: USA (S-most California), Mexico (N & C Baja California); coastal bluffs with coastal sage scrub and chaparral with frequent fogs and dew, 0–100 m; flowers January to May. **I**: Irish & Irish (2000: t. 39); Heller (2006: 130); Richter (2011: 38, 103); Pilbeam (2013: 194); Heim (2014: 7, 16–18, as var.); Starr & Webb (2015: 93); Hochstätter (2015: IV: 29); Moore (2016: 272, 273); mostly as *A. shawii*.

**Incl.** *Agave orcuttiana* Trelease (1912); **incl.** *Agave pachyacantha* Trelease (1912).

[2f] Stems short to long (2 m), erect to decumbent, frequently branching from leaf axils, forming fragmented clones, or sometimes remaining single; **Ros** compact, 0.8–2 × 1–2.5 m; **L** ovate to linear-ovate, ascending, thick, fleshy, rigid, ± as wide at mid-leaf as at the base, shortly acuminate, flat to slightly hollowed above, slightly asperous, mostly 20–50 × 8–20 cm, glossy light to dark green; **marginal teeth** very variable in size and shape, straight or variously curved, 5–20 mm (at mid-leaf), decreasing in size below, reddish to dark brown or dark grey, usually 10–20 mm apart or rarely confluent; **terminal Sp** acicular, straight or sinuous, broad at the base, openly grooved above, 20–40 mm, dark reddish-brown to grey, decurrent as horny margin for 8–10 cm or along the entire leaf; **Inf** 2–4 m, paniculate, fertile

part ± as long as broad, with closely imbricate, lanceolate to triangular, succulent, persistent, large (10–25 cm), purple **Bra** closely investing the part-**Inf**, part-**Inf** dense, broad, stout, elliptic to oval in cross section, horizontal to ascending, commonly 8–14 per **Inf** in the upper  $\frac{1}{4}$ – $\frac{1}{2}$ , >10 cm, with 35–75 flowers; **Ped** none or short; **Fl** 60–100 mm, densely clustered; **Tep** yellow or reddish, esp. upon withering, frequently purplish or red in bud, tube broadly funnel-shaped, thickly fleshy, knobby at the filament insertions with furrows between, smooth, shiny, sinuses sometimes at unequal levels, 12–19 × 15–22 mm, light yellow, lobes erect, broad and thick at the base, becoming linear-lanceolate, thinner, soon involute and wilting while the stamens extend, unequal, 25–38 mm, the outer longer than the inner, rounded to flat on the outer face, inner with fleshy keel and thin involuting margins, yellow or reddish; **St** long-exserted; **Fil** thick, tapered towards the apex, 43–70 mm, inserted near mid-tube 8–12 mm above its base; **Anth** usually centric, 20–35 mm; **Ov** cylindrical, thick-fleshy, shortly tapered at the base, 30–50 mm, with grooved scarcely constricted neck 6–15 mm long, greenish; **Sty** thick, finally much longer than the filaments; **Sti** capitate; **Fr** variable in shape and size, obovoid or pear-shaped to oblong, slightly attenuate to rounded at the base, thickly succulent when green and drying as a scurfy exocarp, 55–70 × 15–23 mm, with short to long (15 mm) beak; **Se** crescent-shaped to cuneate, 4–7 × 5–6 mm, dull to lustrous black. — **Cytology**:  $2n = 60$  (Pinkava & Baker 1985, Simpson & al. 2011).

*A. shawii* and *A. sebastiana*, making up Sect. *Umbelliflorae*, are unique in the genus by being confined to a Mediterranean-type climate with winter-spring rainfall, supplemented by frequent fogs. Ssp. *shawii* was frequent in S California at the beginning of the twentieth century, but plant collectors and habitat destruction significantly reduced the populations. In the USA, natural populations are at present known only from Border Fields State Park N of Tijuana, although plants have been introduced at other places (Reveal & Hodgson 2002). — Plants may flower at an age of 20–40 years. The flowers are visited by hummingbirds, bats and bees (Turner & al. 1995). The

anthetic flower morphology is described in detail by Engelmann (1878).

**A. shrevei** Gentry (Publ. Carnegie Inst. Washington 527: 95, 1942). **Type:** Mexico, Chihuahua (*Gentry* 2028 [CAS 0000143 [lecto], ARIZ, US]). — **Lit:** Gentry (1972: 111–117); Gentry (1982: 447–455); Klopper & al. (2010: 59–60, 62–63); Starr (2012: 250–253); all with ills. **Distr:** NW Mexico.

Gentry's protologue indicates his collection "2028" as "type and isotypes" (= syntypes). His later designation (Gentry 1972: 112) of "*Gentry* 2028" "deposited in the Dudley herbarium" refers to the specimen CAS 0000143 and represents a lectotypification.

**A. shrevei** ssp. **magna** Gentry (Agaves Cont. North Amer., 451–453, ills., 1982). **Type:** Mexico, Chihuahua (*Gentry & Bye* 23360 [US [4 sheets, status uncertain], ARIZ, ASU, DES, MEXU]). — **Lit:** González-Elizondo & al. (2009: 125–127, with ills.); Klopper & al. (2010: 62–63); Starr (2012: 250–251, 253, with ill.). **Distr:** Mexico (SE Sonora, SW Chihuahua, N Sinaloa, S Durango); rocky slopes in oak woodlands, oak grasslands or oak forests, 1040–1980 m; flowers June to July, October and January. **I:** Richter (2011: 79); Pilbeam (2013: 197); Hochstätter (2015: IV: 13).

[2h] Differs from ssp. *shrevei*: **Ros** larger, 1.4–1.7 × up to 2.5 m, mostly solitary; **L** outcurving, guttered, thickened and broadened towards the base, finely asperous, mature **L** larger, mostly 120–150 × 15–25 cm, margins remotely crenate; **marginal teeth** along most of the lamina, 6–10 (–15) mm, mostly 30–50 mm apart, on pronounced prominences, frequently with small intermittent teeth; **terminal Sp** longer, 35–60 mm; **Inf** larger, 6–7 m, part-**Inf** more numerous, 20–30 per inflorescence; **Fil** longer, 48–70 mm.

The main difference from ssp. *shrevei* is the larger overall size (Gentry 1982: 451). González-Elizondo & al. (2009) provide a new record for Durango.

**A. shrevei** ssp. **matapensis** Gentry (US Dept. Agric. Handb. 399: 115–117, ills., 1972). **Type:**

Mexico, Sonora (*Gentry* 11607 [US 2540344, ARIZ, MEXU, MICH]). — **Lit:** Gentry (1982: 454–455, with ills.); Klopper & al. (2010: 62–63); Starr (2012: 251, 253). **Distr:** Mexico (C Sonora), limestone or granitic slopes in woodlands, 610–1800 m; flowers April to May. **I:** Richter (2011: 78); Pilbeam (2013: 198); Hochstätter (2015: IV: 14).

[2h] Differs from ssp. *shrevei*: **Ros** suckering late and sparingly; larger **marginal teeth** at mid-leaf recurved; **Fil** smaller, ±50 mm; **Tep** tube shorter, 15–20 mm, outer lobes longer and broader, 11–16 × 7 mm; **Fil** longer, 45–55 mm; **Ov** (partly) shorter, 22–41 mm incl. the short unconstricted neck; **Fr** shorter, 35–40 × 20 mm.

Resembling some forms of ssp. *shrevei* (Gentry 1972: 117), but distinguished as detailed above.

**A. shrevei** ssp. **shrevei** — **Lit:** Breitung (1963: 15–17, as *A. shrevei*); Gentry (1972: 111–115); Gentry (1982: 447–450); González-Elizondo & al. (2009: 123–127); Klopper & al. (2010: 60, 62–63); Starr (2012: 250–253); all with ills. **Distr:** Mexico (E & SE Sonora, SW Chihuahua, S Durango); open rocky volcanic or also limestone slopes in oak woodlands and pine-oak forests, 930–1980 m; flowers August, October and February. **I:** Heller (2006: 131); Richter (2011: 78); Pilbeam (2013: 196); Hochstätter (2015: IV: 12). — Fig. 52.

[2h] **Ros** small to medium-sized, closely suckering at maturity; **L** ovate, shortly acuminate, 20–35 × 8–10 cm, or lanceolate, acuminate and 50–60 × 12–18 cm, generally narrowed above the base, firm, thick, flat to conduplicate, straight or outcurving near the tip, light grey, glaucous; **marginal teeth** variable, straight or flexed up- or downwards, larger teeth 5–10 mm (mid-leaf), dark brown to grey, on small to pronounced prominences; **terminal Sp** acicular, stout, with a narrow or open groove from the base to above the middle, mostly 25–50 mm, brown; **Inf** 2.5–5 m, paniculate, with deltoid, long-acuminate **Bra** drying early, fertile part with 8–16 small ascending part-**Inf** in the upper 1/3; **Fil** erect, slender, 60–70 mm, persisting; **Tep** light green to pale yellow, buds at the tips red to purplish, tube cylindrical or urceolate, 18–23 × 10–12 mm, lobes

**Fig. 52** *Agave shrevei* ssp. *shrevei*. (cult.: USA; Arizona, Arizona-Sonora Desert Museum Tucson) (Copyright: J. Thiede)

strictly erect, leathery, unequal, outer 10–12 × 5–7 mm, with red to purplish calloused tips, flat, widely overlapping the shorter keeled inner lobes, pea-green to light yellow; **Fil** flattened, 40–50 mm, inserted unequally at mid-tube, yellow or red; **Anth** large, 22–26 mm, yellow; **Ov** 25–35 mm incl. the constricted neck; **Sty** clearly longer than the tepals; **Sti** capitate; **Fr** oblong, 45–70 × 15–25 mm, shortly stipitate, shortly beaked; **Se** 6–7 × 4.5–5 mm, hilar notch small, marginal wing prominent.

Well distinguished by its broad, light glaucous-grey leaves with margins bearing prominences with well-developed brown teeth, and the leathery perianth with a deep tube, and short, persistently erect tepal lobes, much shorter than the tube (Gentry 1982). Typical and smaller-leaved plants resemble *A. flexispina* in leaf characters, but the latter's flowers appear closer to *A. palmeri* (with a tube and tepals ± equal). A population at Guajaráy (Sonora) with larger leaves in variable shapes shows some characters of *A. palmeri* (Gentry 1972: 115, Gentry 1982: 448). González-Elizondo & al. (2009) provide a new record for Durango. The plants are used as food, for mescal production, and in curing and death ceremonies (Bye & al. 1975: 96, 109, ill.).

**A. sileri** (Verhoek-Williams) Thiede & Eggl (Kakt. and. Sukk. 50(5): 111, 1999). **Type:** USA, Texas (*Siler* s.n. [BH 69–518B]). — **Lit:** Verhoek-Williams (1975: 205–208, as *Manfreda variegata*

var.); Verhoek-Williams (1978a: 168–170, with ills.); Piña Luján (1985: 62); Reveal & Hodgson (2002); Diggs & al. (2006: 410–412, with ills.); Castillejos-Cruz (2009: [282]–[287], with ills.); all as *Manfreda*. **Distr:** USA (S Texas), Mexico (Tamaulipas); open sunny areas on clay soil, in desert scrub and tropical deciduous forests, to 100 m; flowers April to July. **I:** Richardson & King (2011: 19); Hochstätter (2016: I: 42); both as *Manfreda*.

≡ *Manfreda sileri* Verhoek-Williams (1978); **incl.** *Manfreda variegata* var. *sileri* Verhoek-Williams (1975) (*nom. inval.*, ICN Art. 29.1).

[3a1] Plants herbaceous, large (for Subgen. *Manfreda*); corm 5–6 × 4–5 cm, subglobose to subcylindrical, bulb 4–5 × 3.8–4.5 cm, ovoid to subglobose, covered with dry leaf bases 3.8–4.8 cm long, these membranous, not separating into fibres, reproducing vegetatively by buds from the leaf axils of the parent rosette or from the corm; **R** fleshy, thick, with filiform ramifications, contractile; **L** evergreen, 6–8, spreading to slightly ascending, broadly lanceolate to ovate-lanceolate, channelled and undulate or somewhat flattened, long-attenuate towards the tip, tip acute with a soft medium-sized point, succulent, brittle, glabrous on both faces, 15–40 × 2.2–4.8 cm, light green to glaucous, with round to oval, dark green, brown or purple, often confluent spots 1 × 0.5 cm, margins with a conspicuous cartilaginous band, minutely denticulate, teeth in various sizes, irregularly spaced, often some retrorse; **Inf** erect,

2.4–2.6 m, erect, ‘spicate’, green-glaucous, peduncle with 10–15 somewhat inclined **Bra** with truncate base, lower similar to lower leaves, upper smaller and deltoid-acuminate, fertile part dense, 25–42 cm, with 27–46 (–81) flowers; floral **Bra** 0.5–1 × 0.4–0.7 cm; **Fl** 20–36 mm, sessile, erect to ascending, funnel-shaped to broadly campanulate; **Tep** glaucous-green on the outer face, greenish-yellow to golden-yellow on the inner face, tube broadly funnel-shaped to campanulate, (7–) 9–15 (–22) × 6–9 mm, constricted near the tip of the ovary, lobes oblong, reflexed to revolute, keeled on the outer face, tip slightly broadened to acute, with a tuft of short white hairs, (7–) 10–21 mm; **Fil** 43–69 (–100) mm, inserted near the tube base, yellowish-green, with multiple purple dots over the whole surface; **Anth** 9–13 mm, reddish to brownish; **Ov** ellipsoid to slightly obclavate, (10–) 12–20 × 6–7 mm; **Sty** erect, 44–66 (–95) mm, almost reaching the level of the anthers; **Sti** clavate-capitate, 3-lobed, tip papillate; **Fr** cylindrical to subellipsoid, 23–31 × 16–19 mm, apiculate for ±2 mm; **Se** deltoid, flat-concave, 5–6 × 5 mm, black, dull.

Closely related to *A. variegata*, of which it was first classified as a variety (Verhoek-Williams 1975). Both have a similar robust habit and occur in similar habitats (Verhoek-Williams 1978a, Castillejos-Cruz 2009). *A. sileri* differs in its larger size, spreading and only shallowly channelled glaucous leaves spotted with large brown dots, leaf margins with irregularly spaced teeth of different sizes and shapes, and densely many-flowered inflorescences with flowers with yellow-green to golden filaments (Verhoek-Williams 1978a, Castillejos-Cruz 2009). *Manfreda longistaminata* is a related, unpublished new species from Tamaulipas (Castillejos-Cruz 2009).

**A. ×simoni** André (Rev. Hort. (Paris) 76: 297–299, figs. 128–130, 1904). **Type:** not typified. — **Lit:** Berger (1915: 187, as *A. simoni*). **Distr:** Cultivated only.

[2o × 2] This is the garden hybrid “*A. vandervinneni*” (an unplaced name) × *A. potatorum* (as *A. verschaffeltii*). The cross was made in 1877 at the “Jardin Botanique au Parc de la Tête d’Or” in Lyon (France) by its “chef de

culture” M. Gaulain, and a plant raised from the cross flowered in 1903 at Charles Simon at Saint-Ouen (France), and resembled *A. potatorum* (as *A. verschaffeltii*) in habit (Berger 1915: 187). — For *A. simonii* see under *A. ×hybrida*, and for *A. simonis* under *A. pumila*.

**A. singuliflora** (S. Watson) A. Berger (Agaven, 31, 1915). **Type** [syn]: Mexico, Chihuahua (Pringle 1142 [GH, US]). — **Lit:** Rose (1903c: 16–17); Gentry (1972: 151–152); Verhoek-Williams (1975: 259–264); Piña Luján (1985: 87–89); Castillejos-Cruz (2009: [288]–[293], with ill.); all as *Manfreda* except Berger. **Distr:** Mexico (E Sonora, W, SW & S Chihuahua, W Sinaloa, N, W & S Durango, W Zacatecas, N Jalisco); cool slopes in grasslands and in fir, pine, oak, and pine-oak and tropical deciduous forests, 1500–2800 m; flowers late June to early October. **I:** Hochstätter (2016: I: 43); Castro-Castro & al. (2017: 62); Castro-Castro & al. (2018: 499); all as *Manfreda*.

≡ *Bravoa singuliflora* S. Watson (1887) ≡ *Manfreda singuliflora* (S. Watson) Rose (1903) ≡ *Polianthes singuliflora* (S. Watson) Shinnars (1966).

[3a1] Plants herbaceous?, medium-sized (for Subgen. *Manfreda*); corm 1.7–2.4 × 1.2–1.5 cm, cylindrical, bulb 1.8–5 × 1.5–2 cm, cylindrical, completely covered with dry membranous leaf bases 4–8 cm long; **R** fleshy, with filiform ramifications, contractile; **L** evergreen, 3–8, recurved to erect, spreading, linear to linear-lanceolate, channelled, succulent, tip acute, with a medium-sized point, glabrous, 17–30 (–60) × 0.5–1.5 cm, light green to glaucous, occasionally red-speckled at the base, margins bordered by a narrow hyaline band; **Inf** 50–90 (–115) cm, erect, ‘spicate’, glaucous green, peduncle with 5–6 truncate **Bra**, the lower linear-lanceolate, similar to the leaves, the upper lanceolate, decreasing in size upwards, fertile part open, 15–23 (–30) cm, with 5–18 (–26) flowers; floral **Bra** lanceolate, 1.1–1.7 × 0.2–0.4 cm; **Fl** 32–36 mm, usually sessile, reclined to descending; **Tep** green, green with a brown-maroon streak on the lower parts, or yellowish-green, to reddish-green on the outer face, tube narrowly funnel-shaped, arched so that the throat

faces downwards, tapering towards the base near the ovary, 15–25 × 5 mm, lobes oblong, reflexed to revolute, 10–12 × 2–4 mm, apex cucullate, tip soft, with a tuft of short white hairs; **Fil** erect, 17–20 mm, exceeding the tube by 4–6 mm, inserted at mid-tube all at the same level, reddish-green; **Anth** 8–10 mm, yellowish-green to reddish; **Ov** nearly erect, at a narrow angle to the inflorescence axis, cylindrical to ellipsoid, 4–9 × 3–5 mm, apiculate, without a scar near the apex; **Sty** 30–35 mm, exceeding the tube for 5–12 (–15) mm, ± at the anther level, white; **Sti** clavate-capitate, deeply 3-lobed, papillate at the apex; **Fr** globose or cylindrical to subellipsoid, 13–16 × 11–13 mm, apiculate for ±2 mm; **Se** deltoid, flat-concave, 4–5 × 4 mm, black, dull.

Differing from all other members of Sect. *Herbaceae* by the extreme curvature of the downwards-facing perianth (Verhoek-Williams 1975: 263, Castillejos-Cruz 2009). Due to its semisucculent to succulent leaves and its filaments inserted at mid-tube morphologically related to *A. brunnea* and *A. variegata*, but different from both in the strongly recurved perianth tube and the much shorter filaments (Castillejos-Cruz 2009: as *Manfreda*). Martin & al. (1998: 471) provide a new record for Sonora. The lectotypification attempt by Verhoek-Williams (1975: 259) is ineffective because the work was not effectively published.

**A. sisalana** Perrine (Trop. Pl. [U.S. House Representatives Rep. no. 564], 87–88 (8–9, 16, 47, 60, 86), 1838). **Type** [neo]: Mexico, Chiapas (*Gentry* 16434 [US, DES?]). — **Lit**: Berger (1915: 230–232, with ills.); Standley (1930: 233); Standley & Steyermark (1952: 117–118); Breitung (1961: 179, with ills.); Gentry (1982: 628–630, with ills.); Lott & García-Mendoza (1994: online version with ills.); Smith & Mössmer (1996: with ills.); Reveal & Hodgson (2002). **Dist**: Cultivated only; nearly worldwide in tropical and subtropical regions; flowering winter to early spring; naturalized in many places, e.g. RSA. **I**: Irish & Irish (2000: t. 40); Heller (2006: 28, 133); Richter (2011: 13, 139); Pilbeam (2013: 199); Hochstätter (2015: VII: 47).

≡ *Agave rigida* var. *sisalana* (Perrine) Engelm (1875) ≡ *Furcraea sisalana* (Perrine)

Posada-Arango (1909); **incl.** *Agave franceschiana* Trelease ex A. Berger (1912); **incl.** *Agave sisalana* var. *armata* Trelease (1913) ≡ *Agave sisalana* fa. *armata* (Trelease) Trelease (1920); **incl.** *Agave amaniensis* Trelease & Nowell (1933); **incl.** *Agave sisalana* fa. *marginata* Medina (1955); **incl.** *Agave sisalana* fa. *medio-picta* Medina (1955); **incl.** *Agave segurae* D. Guillot & P. Van der Meer (2005).

[2c] Stems 0.4–1 m; **Ros** 1.5–2 × 1.5–2.5 m, commonly suckering with elongate rhizomes; **L** lanceolate, ensiform, spreading, fleshy, firm, slightly convex below, flat above, 60–150 (–180) × (2.5–) 5–12 cm, shiny green, somewhat slightly cross-zoned and glaucous when young, margins straight, finely fibrous, not corneous; **marginal teeth** of young leaves few, minute, 1–2 mm, 20 to >50 mm apart, usually absent on mature leaves; **terminal Sp** conical, subulate, shortly shallowly grooved above, 20–25 mm, dark brown, somewhat lustrous, not decurrent; **Inf** 5–6 m, paniculate, peduncle short, with persistent triangular **Bra** 0.5–2 cm long, fertile part ellipsoid, with 10–15 (–25) ascending part-**Inf** > 10 cm long in the upper ½ of the inflorescence, bulbiferous after flowering; **Fl** erect, 40–65 mm, unpleasantly scented; **Te** greenish-yellow, tube broadly urceolate, 15–18 × 10–12 mm, lobes linear-lanceolate, erect, equal, 17–18 × 5–6 mm, **St** long-exserted; **Fil** erect, 50–60 mm, inserted ± at mid-tube, yellow; **Anth** 20–25 mm, yellow; **Ov** shortly fusiform, 15–25 × 8–9 mm, neck slightly constricted, 2–4 mm; **Fr** and **Se** unknown. — **Cytology**: 2n = 138, 140–149, 147, 149, 150 (5×), 180 (Satô 1935, Doughty 1936, Granick 1944, Castorena Sanchez & al. 1991, Robert & al. 2008); in cultivars 54–65 (2×), 77–99 (3×), 118–128 (4×), 137–151 (5×) (Lv & al. 2009).

Easily recognizable by its green, unarmed mature leaves with a short, dark brown, conical to subulate, non-decurrent terminal spine. The taxon appears to represent a sexually sterile clone that is widely cultivated in fibre plantations and could be of hybrid origin, possibly between *A. angustifolia* of Sect. *Rigidae* (as Group) and *A. kewensis* of Sect. *Sisalanae* (as Group) (Gentry 1982: 630). Ullrich (1990d) consequently removed it from Gentry's Group *Sisalanae* and placed it in

Sect. *Rigidae* (as Group), but this is not followed here. Molecular AFLP data (Gil-Vega & al. 2007) place *A. sisalana* closest to *A. kewensis* and both close to, but separate from species of Sect. *Rigidae* (as Group). The species is not known from the wild, and was probably widely distributed by pre-Columbian people (Reveal & Hodgson 2002). It is naturalized in (sub-)tropical regions, e.g., in the Mediterranean (e.g., Spain: Guillot Ortiz & Meer (2006c) and Guillot Ortiz & Meer (2008b: as *A. amaniensis*), both with ills.) and in RSA (Smith & Mössmer 1996, the plants described appear to be esp. well-nourished individuals and reach much larger size than otherwise reported). Cultivars cultivated in Spain are presented by Guillot Ortiz & Meer (2009a: with ills.). For the synonymous *A. franceschiana*, see also under *A. weberi*.

**A. sobolifera** Houttuyn (Nat. Hist. 2(8): 374, 1777). **Type:** not typified. — **Lit:** Baker (1887: 543, 549, Fig. 165, as *A. morrisii*); Trelease (1913: 32–33, tt. 44–48); Berger (1915: 207); Hummelinck (1927: with ills.); Adams (1972: 81); Hummelinck (1984: 208–212, 226–228, with ills.); Acevedo-Rodríguez & Strong (2012: 85). **Distr:** Jamaica; dry rocky well-drained calcareous hillsides, 30–850 m; flowers February to April. **I:** Richter (2010: 41); Richter (2011: 90, 91, 138); Pilbeam (2013: 200); Hochstätter (2015: VII: 75).

**Incl.** *Agave americana* Lamarck (1783) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave laetevirens* K. Koch (1865); **incl.** *Agave morrisii* Baker (1887); **incl.** *Agave sobolifera* [?] *marginata* hort. ex Trelease (1908); **incl.** *Agave morrisii* Kent (1908) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave sobolifera* fa. *spinidentata* Hummelinck (1984) (*nom. inval.*, ICN Art. 38.1a).

[2p] Acaulescent; **Ros** to 2 × 2.5 m, solitary; **L** 20 or more, variably lanceolate, massive, curved, gradually acute or somewhat subacuminate, often deeply and conduplicately or undulately concave, ±125–200 × 15–24 cm, 9 cm thick near the base, rather light green, somewhat glossy; **marginal teeth** curved or reflexed-triangular (rarely straight), 1–4 mm, glossy dark brown, 5–15 mm apart, often hardened on the tops of green prominences

of the margin, intervening margin ± concave; **terminal Sp** conical, nearly straight, slightly flattened, grooved or slightly involutely channelled below the middle when mature, smooth, somewhat glossy, 15–25 × 3–4 mm, reddish-brown, not decurrent; **Inf** 5–9 m, paniculate, oblong, part **Inf** on rather short spreading branches, above the middle of the inflorescence, freely bulbiferous; **Ped** stout, 8–10 mm; **Fl** ±50 mm; **Tep** golden-yellow to light orange, tube open, 5–7 mm, lobes bluntly triangular-oblong, ±20 × 7 mm; **Fil** ±45 mm, inserted towards mid-tube; **Ov** narrowly fusiform, 15–20 (–25) mm, from slightly shorter to longer than the perianth; **Fr** narrowly oblong, turbinate narrowed at the base, 45–50 × 13–25 mm, shortly beaked at the tip, stipitate; **Se** 7 × 4–5 mm.

Previously ascribed to Salm-Dyck (Hort. Dyck., 307, 1834), but published earlier, as given above (Govaerts 2014+: accessed Oct. 2018). See Trelease (1913: 33) on the difficult interpretation of this name. Plants from the Cayman Islands previously included in *A. sobolifera* were published as a separate species, *A. caymanensis* (see there for differences).

**A. sobria** Brandegee (Proc. Calif. Acad. Sci., ser. 2, 2: 207, 1889). **Type** [syn]: Mexico, Baja California Sur (*Brandegee* 2 [UC, CAS 0000145]). — **Lit:** Gentry (1982: 394–404, with ills.); Turner & al. (1995: 65–67, with ill.). **Distr:** Mexico (Baja California Sur).

The protologue gives “Comondu on the mesas” as type indication, which refers to *Brandegee* 2 (Trelease 1912a: 56); the 2 available sheets represent syntypes.

**A. sobria** ssp. **frailensis** Gentry (Occas. Pap. Calif. Acad. Sci. 130: 54–56, ills., 1978). **Type:** Mexico, Baja California Sur (*Gentry & Cech* 11264 [US 2562946, ARIZ, MEXU, US]). — **Lit:** Gentry (1978: 54–58); Gentry (1982: 401–404); Turner & al. (1995: 66); Webb & Starr (2015); all with ills. **Distr:** Mexico (Baja California Sur: Cape region); on granite hillslopes; flowers May and October. **I:** Richter (2011: 80, 105); Pilbeam (2013: 202); Hochstätter (2015: V: 19).

[2i] Differs from ssp. *sobria*: **Ros** compact, smaller, sparingly caespitose; **L** more numerous, broadly lanceolate, mostly 20–35 × 6–8 cm, glaucous-green to bluish-glaucous, margins with pronounced prominences; **marginal teeth** numerous, smaller, mostly 6–10 mm, chestnut-brown to greying, closely spaced; **terminal Sp** frequently sinuous or contorted, 30–40 mm; **Inf** with 10–15 part-**Inf**; **Fl** slender, 45–63 mm; **Ov** cylindrical, 25–40 mm, lobes 4–6 mm wide.

Ssp. *frailensis* occupies the S part of the total range of *A. sobria*, and is the S-most taxon of Sect. *Deserticolae*. The protologue indicates “Gentry & Cech 11264” at US as “Type”. From the 2 sheets at US, US 2562946 is annotated as “Type” by Gentry (= holotype); US 2540165, annotated as “Type coll.”, is an isotype.

**A. sobria** ssp. **roseana** (Trelease) Gentry (Occas. Pap. Calif. Acad. Sci. 130: 54, 1978). **Type**: Mexico, Baja California Sur (*Rose* 16854 [US, MO, NY]). — **Lit**: Trelease (1912b: 59, tt. 58–60, as *A. roseana*); Berger (1915: 267, as *A. roseana*); Breitung (1963: 173, with ills., as var.); Gentry (1978: 54–56, with ills.); Gentry (1982: 400–403, with ills.); Ullrich (1994b: with ills.); Turner & al. (1995: 66); Webb & Starr (2015: 77, 83, 87, with ill.). **Dist**: Mexico (Baja California Sur: Espíritu Santo Island and adjacent mainland); flowers February to March, May, June and October. **I**: Pilbeam (2013: 203); Hochstätter (2015: V: 20).

≡ *Agave roseana* Trelease (1912) ≡ *Agave sobria* var. *roseana* (Trelease) I. M. Johnston (1924).

[2i] Differs from ssp. *sobria*: **Ros** lax, openly spreading, sparsely surculose; **L** fewer, broadly lanceolate, frequently twisted, acuminate, smaller, 35–50 × 7–10 cm, yellow-green, margins with prominent prominences, tubercles 1–1.5 mm; **marginal teeth** flexuous, few, larger, larger teeth 10–25 mm, remote; **terminal Sp** sinuous to contorted, 50–70 mm; **Inf** with 8–12 part-**Inf**; **Fl** 45–65 mm, lobes 4–5 mm wide.

Ssp. *roseana* occupies the C part of the total range of *A. sobria*.

**A. sobria** ssp. **sobria** — **Lit**: Trelease (1912b: 56, tt. 50–51, as *A. sobria*); Berger (1915: 265, as

*A. sobria*); Breitung (1963: 149, 151, with ills.); Gentry (1978: 48–54, with ills.); Gentry (1982: 396–399, with ills.); Turner & al. (1995: 65–67); Webb & Starr (2014b: 8–11, with ills.). **Dist**: Mexico (Baja California Sur); widely scattered but common on mountain slopes on both sides of the Sierra de la Giganta, 0–1070 m; flowers February to April, and September. **I**: Heller (2006: 134); Richter (2011: 80); Pilbeam (2013: 201); Hochstätter (2015: V: 18).

**Incl.** *Agave affinis* Trelease (1912); **incl.** *Agave carminis* Trelease (1912); **incl.** *Agave slevinii* I. M. Johnston (1924).

[2i] Stems short, or appearing stemless; **Ros** open, 0.5–1.5 × 0.5–1.5 m, usually caespitose; **L** few, linear to lanceolate, straight to curved, sometimes twisted, long-acuminate, thick and convex below towards the base, flat to somewhat concave above, variable, mostly 45–80 × 5–10 cm, bright glaucous-grey, frequently cross-zoned, margins repand to tuberculate; **marginal teeth** variously curved or straight, flattened, base broad, mostly 5–10 mm, grey, reddish towards the tips, mostly 30–40 mm apart; **terminal Sp** acicular, narrowly grooved above, mostly 30–60 mm; **Inf** 2.5–4 m, paniculate, peduncle with small triangular chartaceous **Bra**, fertile part slender, sometimes arching, part-**Inf** compact, nearly globose, 12–20 per inflorescence, on short lateral branches; **Ped** 2–7 mm; **Fl** slender, 45–55 mm; **Tep** pale yellow, tube broadly funnel-shaped, 3–4 × 9–11 mm, lobes very narrow, linear, rather thin, involute at anthesis, rounded at the tip, cucullate, ± equal, 17–22 × 3–4 mm, inner keeled; **Fil** slender, 35–47 mm, inserted at the lobe base on a nectary disc; **Anth** centric, 18–23 mm; **Ov** tapering at the base, 25–35 mm, neck short, scarcely constricted; **Sty** slightly longer than the tepals; **Sti** capitate; **Fr** oblong, thick-walled, 50–65 × 15–18 mm, shortly stipitate, apiculate; **Se** crescent-shaped, 7–8 × 5–6 mm, narrowly winged. — **Cytology**: 2n = 60 (Pinkava & Baker 1985).

*A. sobria* is the S-most species of Sect. *Deserticolae*, occupying the E parts of Baja California Sur, and possibly the most variable species in Baja California (Webb & Starr 2015). Ssp. *sobria* differs from ssp. *roseana* and ssp. *frailensis* by its longer, narrower, very light-glaucous and

long-lanceolate leaves with a straight to repand margin and with remote marginal teeth, and its slender flowers with long, narrower lobes (Gentry 1978, Gentry 1982). Some forms of ssp. *sobria* were misidentified by Gentry (1982) as *A. giganteensis* (Webb & Starr 2014b, Webb & Starr 2015; see under that species).

**A. spicata** Cavanilles (Anales Ci. Nat. 5(15): 261, 1802). **Type:** Ex cult. Madrid (*Cavanilles* s.n. [MA 215275]). — **Lit:** Berger (1915: 43–44, as *A. yuccaefolia*), Breitung (1960: 181–182, with ill., as *A. yuccaefolia*); Gentry (1982: 85–86, with ill., as *A. yuccaefolia*); Ullrich (1995b: with ills.); Ullrich (1996b: with ills.); Guillot Ortiz & Meer (2002b); Alsemgeest & al. (2006a: with ills.). **Distr:** Not known from the wild; flowers September to March (in cultivation). **I:** Redouté (1802–1816: tt. 328–329, as *A. yuccaefolia*, 1811); Curtis’s Bot. Mag. 86: t. 5213, 1860, as *A. yuccaefolia*; Heller (2006: 135); Richter (2011: 61); Hochstätter (2015: VIII: 28).

≡ *Agave yuccifolia* var. *spicata* (Cavanilles) A. Terracciano (1885) (*incorrect name*, ICN Art. 11.4, 25.1); **incl.** *Agave yuccifolia* F. Delaroche (1811); **incl.** *Agave spicata* Gussone (1825) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave guccifolia* Mannetti in F. A. Gera (1834) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave hookeri* K. Koch (1865) (*nomen rejiciendum*, ICN Art. 56.1); **incl.** *Agave cohniiana* Jacobi (1866); **incl.** *Agave yuccifolia* var. *caespitosa* A. Terracciano (1885); **incl.** *Agave yuccifolia* var. *viridis* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a).

[1b] Stems short or none; **Ros** open, small to medium-sized, suckering, forming dense groups with age; **L** 12–40, linear, recurving at maturity, soft, pliable, scarcely succulent, weakly and finely fibrous, not or hardly narrowed at the base, long and finely acuminate, convex below, concave above, 50–65 × 3–3.5 cm, mostly green with pale midstripe, sometimes reddish- or purple-spotted, margins with red cartilaginous band, finely serrulate with unequal denticles, between the larger mostly a minute one; **terminal Sp** conical to subulate, fine, pungent, 3–8 mm, brown; **Inf** 2–3 m, ‘spicate’, peduncle with triangular-lanceolate long-acuminate erect

**Bra**, fertile part slender, arching, 27–30 cm, part-**Inf** mostly with geminate flowers; **Ped** short; **Fl** 40 mm, unpleasantly scented; **TeP** greenish-yellow, tube narrowly cylindrical, ±8 mm, lobes linear, obtuse, tip revolute, inner ones somewhat narrower, spreading to reflexed, 15–16 mm, inner narrower; **Fil** 40–45 mm, inserted at the orifice of the tube, reddish to reddish-brown; **Anth** 15 mm, yellow; **Ov** roundly 3-angled, 16–18 mm, neck short; **Sty** filiform, finally exceeding the filaments; **Sti** 3-lobed; **Fr** obovate, broadly 3-angled, thinly woody, 20 × 17 mm, shortly beaked, light grey-glaucous; **Se** nearly semicircular, 5 mm, shiny black.

The name *A. yuccifolia* (usually as *A. yuccaefolia*), ascribed to Redouté (1811) and published with two colour plates (reproduced by Ullrich (1995b: 115) and by Smith & Figueiredo (2016: 11)), was widely applied to this species. The herbarium specimen B-W 06789-01 0 labelled “Malmaison Febr. 1811” is probably taken from Redouté’s plant. Hooker (1860) published a colour plate of an “*A. yuccaefolia*” plant flowering at Kew that purportedly was received from Real del Monte (Hidalgo, Mexico). Koch (1865: 104) considered Hooker’s plant to be different from Redouté’s plant and published the new name *A. hookeri* K. Koch 1865 for the former, which antedates the widely applied name *A. hookeri* Jacobi (1866), thus rendering the latter illegitimate. *A. hookeri* K. Koch differs from Redouté’s plant mainly in its distinct stem and much longer inflorescence which may be due to its long cultivation under lush conditions, and the name can be referred to the synonymy of *A. yuccaefolia* (see also under *A. hookeri*). Smith & Figueiredo (2016) established the correct spelling “*yuccifolia*” and author (F. Delaroche).

Ullrich (1995b) and Ullrich (1996b) replaced *A. yuccifolia* by the older name *A. spicata*, which was based on a plant cultivated at Madrid purportedly received from the BG La Habana, Cuba, and established the specimen cited above with the original handwriting of Cavanilles, preserved in 1802, as holotype (Ullrich 1996b: 25). A detailed historical account of both species is provided by Guillot Ortiz & Meer (2002b).

*A. spicata* is a very distinct species without close relatives within Sect. *Inermes* (as Group *Amolae*) (Gentry 1982). This led Ullrich (1996b: 29) to place it in a section of its own (Sect. *Yuccifoliae* (A. Terracciano) Ullrich). Molecular AFLP data place *A. spicata* closest to *A. nizardensis* and close to other members of Sect. *Inermes* (as Group *Amolae*). The spotted leaves, a feature otherwise only known from Sect. *Herbaceae*, might indicate that the species is of hybrid origin involving a species of Sect. *Herbaceae* and one of Subgen. *Littaea* (Ullrich 1996b: 28: the former as *Manfreda*).

**A. stictata** Thiede & Egli (Kakt. and. Sukk. 50(5): 111, 1999). **Type**: not typified. — **Lit**: Rose (1903c: 18–19); Verhoek-Williams (1975: 301–306); Piña Luján (1986: 17, with ill.); Castillejos-Cruz (2009: [204]–[209]); all as *Manfreda maculata*. **Distr**: Mexico (SW México, N Guerrero, C Oaxaca); disturbed places (rocky slopes and moist shady areas) derived from oak and pine-oak forests, 1180–2000 m; flowers mid-July to mid-September. **I**: Rodríguez & Castro-Castro (2007); Hochstätter (2016: I: 29); both as *Manfreda maculata*.

**Incl.** *Polianthes maculata* Martius (1831) ≡ *Manfreda maculata* (Martius) Rose (1903).

[3a2] Plants herbaceous; corm 2–3.5 (–5) × (0.7–) 1.5–2.5 cm, subcylindrical, bulb 2.5–4 (–5.5) cm, ovoid, covered with dried fibrous leaf bases 2–4 cm long; **R** fleshy and thickened, with filiform ramifications, contractile; **L** drought-deciduous, 2–6 (–8), prostrate, lanceolate to narrowly elliptic, narrowed towards the base, canaliculate, densely pubescent on both faces with straight simple hairs 0.6–0.8 mm long, apex acute, 7–22 (–32) × 0.6–2.6 (–4.5) cm, dark green with purple dots, margins entire, slightly wavy and with a hyaline band; **Inf** 30–95 (–120) cm, erect, ‘spicate’, reddish to greenish, pubescent at its base, peduncular **Bra** 3–5, base truncate, lower similar to the leaves, decreasing in size upwards, fertile part (7–) 12–28 cm, lax, with 6–22 flowers; floral **Bra** 3–5 × 3–5 mm; **Fl** 25–32 mm, solitary, sessile, ascending; **Tep** greenish-yellowish to reddish with purplish tinge, semisucculent, forming a tube 12–20 × 4–5 mm, not constricted at the apex

of the ovary, lobes narrowly elliptic to oblong, revolute, 8–12 × 3–4 mm, tip cucullate, with a bundle of short white trichomes; **Fil** 17–22 mm, erect at anthesis, exceeding the tube for 7–14 mm, inserted at mid-tube all on the same level, yellowish-green with cherry-red dots; **Anth** 6–10 mm, yellow; **Ov** cylindrical, (6–) 8–12 × 2–4 mm, greenish, not protruding into the tube, not constricted above; **Sty** 21–37 mm, yellowish-green; **Sti** capitate, 3-lobed, yellowish-green; **Fr** cylindrical to subellipsoid, 11–17 × 9–15 mm, without scar near the apex, tepals persisting; **Se** deltoid, plane-concave, with narrow margin, 3–4 × 2–3 mm, shiny.

Differentiated from most other species of Sect. *Herbaceae* by its ovoid bulbs, and by the pubescent leaves narrowed at the base into a petiolar portion; pubescent leaves are otherwise only found in *A. pubescens* (Verhoek-Williams 1975: 303–304, Castillejos-Cruz 2009: [205]), while *A. guerrerensis* has leaves that are slightly pubescent at the base. When transferring *Manfreda maculata* to the genus *Agave*, a new epithet was necessary because of the earlier name *A. maculata* Regel 1856. The lectotypification attempt (as “Type”) by Verhoek-Williams (1975: 301) is ineffective because the work was not effectively published.

**A. striata** Zuccarini (Flora 15: 2(Beiblatt 2): 98, 1832). **Type** [neo]: Cult. RBG Kew (*Anonymous* s.n. [K]). — **Lit**: Gentry (1982: 242–247, with ills.). **Distr**: Mexico (Coahuila, Nuevo León, Tamaulipas, Durango, Zacatecas, San Luis Potosí, Querétaro, Hidalgo); limited to drier valleys and plains with annual rainfall <500 mm.

According to the genetic analysis and bioclimatic modelling of Trejo & al. (2016), both subspecies are genetically separated, coincident with climatic differences along their actual and potential (modelled) distributions, showing overlap in the genetic make-up as well as the potential distribution areas.

**A. striata** ssp. **falcata** (Engelmann) Gentry (Agaves Cont. North Amer., 245, ills. (pp. 236, 245–247), 1982). **Type** [lecto]: Mexico, Coahuila (*Wislizenus* 312 [MO [2 sheets]]). — **Lit**: Engelmann (1875: 304–305, as *A. falcata*); Todaro (1876–92: 77–78, t. 19, as *A. paucifolia*); Berger (1915:

78–80, with ills., as *A. falcata* & *A. californica*); Vázquez-García & al. (2007b: 72–73); González-Elizondo & al. (2009: 130–131, with ill.). **Distr:** Mexico (Coahuila, S Nuevo León, W Durango, NE Zacatecas); sandy coarse rocky soils on bajadas, slopes and plains in desert shrub and succulent deserts, on limestone, 1000–2000 m; flowers May to August. **I:** Irish & Irish (2000: t. 41); Richter (2011: 58, 59); Pilbeam (2013: 205); Hochstätter (2015: VIII: 10).

≡ *Agave falcata* Engelm (1875); **incl.** *Agave californica* Jacobi (1868) ≡ *Agave striata* var. *californica* (Jacobi) A. Terracciano (1885); **incl.** *Agave paucifolia* Todaro (1877); **incl.** *Agave falcata* var. *espadina* A. Berger (1915); **incl.** *Agave falcata* var. *microcarpa* A. Berger (1915).

[1a] Differs from ssp. *striata*: **L** fewer, straight to falcate, rigid, thickly keeled, more xeromorphic, broader, 30–60 × 0.8–1.8 (–2) cm, margins serrulate; **Fr** broader, 12–13 mm wide; **Se** larger, 4–5 × 2.5–3 mm.

Merges gradually into ssp. *striata* (Gentry 1982: 245). In addition to leaf characters given by Gentry (1982: 245), the taxon also differs in fruit and seed characters (González-Elizondo & al. 2009). The occurrence in San Luis Potosí (Gentry 1982: 247) is not supported by specimens and is apparently erroneous. As first noted by Baker (1877a), *A. californica* Jacobi (1868) is closest to *A. striata*, and conspecific with the younger *A. falcata* Engelm (1875), but Gentry's combination

based on the Engelm name has priority at subspecies rank. Engelm (1875), followed by Gentry (1982: 245), assumed that *A. californica* might be identical with *Hesperoyucca whipplei* (as *Yucca*), but that species does not have the curved leaves and finely serrulate leaf margins described in the protologue. Guillot Ortiz & Meer (2002a) interpret a drawing from Sessé & Mociño (1787–1803) labelled *A. angustifolia* as belonging to this taxon. *A. rzedowskiana* resembles this taxon in its leaves, but has a different floral morphology (see there).

**A. striata** ssp. **striata** — **Lit:** Zuccarini (1833: 678); Salm-Dyck (1859: 95); Jacobi (1869: 395–399, incl. *A. recurva*); Baker (1877b: 556–557, fig. 109 & 110, the latter as *A. striata* var. *recurva*); Baker (1888a: 184); Berger (1915: 78–83, incl. synonyms); Gentry (1982: 242–245, with ills.); Vázquez-García & al. (2007b: 72, with ills.); Eguiarte & Scheinvar (2008: 29–34, with ills.); González-Elizondo & al. (2009: 128–130, with ills.); Starr (2012: 254–258, 314–316, with ills., as *A. striata*); **Distr:** Mexico (Coahuila, S Nuevo León, Tamaulipas, SE Zacatecas, San Luis Potosí, Querétaro, Hidalgo); drier limestone valleys, slopes and plains with desert and succulent scrub, 200–2200 m; flowers June to July to September and January. **I:** Curtis's Bot. Mag. 82: t. 4950, 1856; Heller (2006: 38, 136); Richter (2011: 59, 116, 121); Pilbeam (2013: 204). – Fig. 53.

**Fig. 53** *Agave striata* ssp. **striata** (Martinez & Egli 228: Mexico; Hidalgo, Patria Nueva, 1900 m). (Copyright: U. Egli)

**Incl.** *Agave striata* var. *nana* hort. (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Agave recurva* Zuccarini (1845)  $\equiv$  *Agave striata* var. *recurva* (Zuccarini) Baker (1877)  $\equiv$  *Agave striata* fa. *recurva* (Zuccarini) Voss (1895); **incl.** *Bonaparteia hystrix* Pasquale (1867) (*incorrect name*, ICN Art. 11.4)  $\equiv$  *Agave hystrix* (Pasquale) Baker (1877) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave ensiformis* hort. ex Baker (1877); **incl.** *Agave richardsii* hort. ex G. Nicholson (1884); **incl.** *Agave striata* [?] *glauca* Franceschi (1900) (*nom. inval.*, ICN Art. 38.1a); **incl.** *Agave striata* var. *mesae* A. Berger (1915).

[1a] Stems short; **Ros** compact, 0.5–1  $\times$  0.5–1.2 m, often forming large dense clusters 2–3 m broad by axillary branching; **L** many, linear, straight to arching, thick, rather turgid, smooth or scabrous along the keels and below, convex above, mostly 25–60  $\times$  0.5–1 (at mid-leaf) cm, pale green to red or purplish, brownish at the tip below the terminal spine, striate, margins cartilaginous,  $\leq$  1 mm wide, pale yellow, scabrous or minutely serrulate; **terminal Sp** subulate, rounded below and above, very pungent, 10–50 mm, reddish-brown to dark grey; **Inf** erect, 1.5–2.5 m, ‘spicate’, peduncle long, **Bra** 5–10 cm, fertile part rather laxly flowered, part-**Inf** with mostly geminate flowers; floral **Bra** shorter than the flowers, deciduous; **Fl** tubular, 30–40 mm; **Tep** greenish-yellow or red to purple, tube shallowly grooved from the tepal sinuses, 14–20  $\times$  8–11 mm, lobes ovate-oblong, spreading with inflexed tips,  $\pm$  equal, 5–7  $\times$  3–5 mm, inner a little wider and with acuminate keel; **Fil** with a high knee, oval in cross section, 30–50 mm, inserted at mid-tube, usually at 2 levels; **Anth** centric, 12–16 mm, bronze or brownish, yellow when dehisced; **Ov** rounded-triangular, grooved, 12–15 mm, neckless, intruding the tepal tube; **Sty** as long as the filaments, below greenish-white, upwards somewhat purplish; **Sti** small, weakly 3-lobed; **Fr** trigonous, 13–16  $\times$  8–10 mm, truncate at the base, apiculate, dark brown; **Se** crescent-shaped, thick, esp. on the curved side, 3.5  $\times$  3 mm. — **Cytology**: 2n = 60 (Granick 1944).

The taxon is represented by extensive populations varying in growth habit, leaf forms, and to a lesser extent in flower structure. Plants with reddish to

reddish-purple leaves may co-occur with typical green-leaved plants and propagate true from seed (Richter 2011: 121, Pilbeam 2013). A small-growing form is sold as “var. *nana*”. *A. echinoides* Jacobi (inflorescence unknown) is a doubtful synonym either of this species or of *A. stricta* (Gentry 1982: 245). *A. tenuifolia* is close to *A. striata* ssp. *striata* (see there for differences). — Used locally for inferior fibres, and as hedge or fence plant (Gentry 1982: 245).

The biology is summarized by Eguiarte & Scheinvar (2008): The flowers are proterandrous, as is common in *Agave*, and last for 5 days. During the male phase on the first day, the anthers open; during the female phase in the last 4 days, the style elongates, the stigma open, and copious nectar is produced during the night. The probability that a flower develops into a fruit is 5–95% (average 50%), and the probability that an ovule develops into a seed is 32%. A plant produces on average  $\pm$ 200 fruits with  $\pm$ 40 seeds each, so an inflorescence produces on average almost 4000 seeds. However, fecundity is highly variable amongst individuals, sites and years. In controlled pollination experiments, much fewer fruits were produced when pollen from the same plant was used, indicating a very strong inbreeding depression (Rocha & al. 2005). Two studies (Rocha & al. 2005, Trejo 2007 [cited in Eguiarte & Scheinvar (2008: 31–32)]) revealed bees, bumblebees, hawkmoths and bats as pollinators, but showed differences in the relative importance of either diurnal bees and bumblebees (Rocha & al. 2005) or nocturnal bats (Trejo 2007 [cited in Eguiarte & Scheinvar (2008: 31–32)]) being most important. The genetic variation is high within populations, which exhibit a relatively high differentiation with geographically distant ones being most distinct, suggesting that gene flow is limited.

**A. stricta** Salm-Dyck (Bonplandia 7(7): 94–95, 1859). **Type** [neo]: Mexico, Puebla (Gentry & al. 20226 [US, MEXU [2 sheets]]). — **Lit**: Berger (1915: 81–82, with ill.); Gentry (1982: 248–249, with ill.); Ullrich (1990c: with ill.); Ullrich (1991d: with ills., as *A. striata* ssp.); García-Mendoza (2011a: 259–263); Starr (2012: 259–263, 314–316, with ills.). **Distr**: Mexico

(Puebla [esp. Tehuacán valley], N Oaxaca); semi-arid open calcareous slopes with sparse desert or succulent scrub, 1500–2060 m; flowers August to October. **I:** Irish & Irish (2000: t. 42); Heller (2006: 137); Richter (2011: 35); Pilbeam (2013: 206); Hochstätter (2015: VIII: 11). – Fig. 54.

≡ *Bonapartea stricta* (Salm-Dyck) Vukotinovic (1871) (*incorrect name*, ICN Art. 11.4) ≡ *Agave striata* var. *stricta* (Salm-Dyck) Baker (1877) ≡ *Agave striata* fa. *stricta* (Salm-Dyck) Voss (1895) ≡ *Agave striata* ssp. *stricta* (Salm-Dyck) B. Ullrich (1990); **incl.** *Agave echinoides* Jacobi (1868) ≡ *Agave striata* var. *echinoides* (Jacobi) Baker (1877); **incl.** *Agave hystrix* Hort. Belg. ex Jacobi (1870).

[1a] Stems elongate and branching, decumbent with age, 1–2 m; **Ros** 0.4–0.7 × 0.6–0.8 m, often densely caespitose; **L** > 100, long-lanceolate, linear, upcurved to straight, rigid, widest near the base, somewhat keeled above and below, rhombic in cross-section, 25–35 (–50) × 0.5–1 cm, glaucous-green, greenish-yellow or purple to

reddish-purple in the upper part, striate, margins thin, whitish or pale yellow to reddish, cartilaginous, scabrous-serrulate; **terminal Sp** acicular, 15–20 (–25) mm, angularly keeled below, flat above, grey, decurrent along the margin for 0.5–1.5 cm, at the base with a grey to blackish projection penetrating into the leaf tissue; **Inf** (1.5–) 2–3 m, ‘spicate’, erect or ascending, sometimes twisted, peduncle with linear or filiform deciduous whitish **Bra** 3–6.5 cm long, fertile part in the upper ½ or a little less, part-**Inf** with geminate flowers; **Ped** 2–3 mm; **Fl** ascending to outcurved, campanulate, 25–30 mm; **Tep** reddish to purplish, tube funnel-shaped, angled, grooved, 6–11 × 7–10 (at the mouth) mm, lobes erect to spreading with incurved tips, deltoid or elliptic, apiculate, equal, 7–10 × 3–6 mm, inner ones broadly keeled; **Fil** 30–37 mm, inserted at 2 levels at mid-tube, reddish; **Anth** centric, 10–13 mm, bronze to brownish-red or purple, opening yellow; **Ov** cylindrical, sharply 6-angled, 8–14 × 2–4 mm, slightly intruding the base of the tepal tube, neckless, wine-red; **Sty** 35 mm, reddish; **Fr** subglobose to pear-shaped, trigonous, 10–14 × 8–10 mm, truncate at the base, apiculate, reddish or purplish; **Se** semicircular, thickly discoid, wing inconspicuous, 3–4 × 2–3 mm, black. — **Cytology:** 2n = 50, 60 (Brandham 1969, Simpson & al. 2011).

Distinguished from the vegetatively very similar *A. striata* by the short flower tube, equalled or exceeded in length by the tepals, and from *A. dasylirioides* by the short, stiff, narrow leaves on elongate stems (Gentry 1982; see also Starr 2012: 314). From *A. petrophila*, *A. stricta* differs esp. in its much smaller rosettes, shorter and narrower leaves, larger and reddish or purple flowers, and its subglobose to pear-shaped, slightly larger fruits (García-Mendoza 2011a).

Plants with reddish-purple leaves co-occur with typical green-leaved plants without intermediates (Pilbeam 2013: 206). Ullrich (1990c) emphasizes vegetative similarities and suggests subspecific rank under *A. striata*, but he was not followed by later authors. Gentry (1982: 248) designated the neotype cited above.

Ullrich (1991d) provided a first record for N Oaxaca based on *Leuenberger* 2747 (B, MEXU), but further collections from Oaxaca are

**Fig. 54** *Agave stricta*. (Copyright: U. Eggli)

meanwhile known (García-Mendoza 2011a). The species is endemic to the Tehuacán-Cuicatlán valley (García-Mendoza 2011a). Photographs from San Luis Potosí labelled *A. stricta* (Pilbeam 2013: 206) most probably belong to *A. striata* ssp. *striata*.

**A. stringens** Trelease (Contr. US Nation. Herb. 23: 114, 1920). **Type:** Mexico, Jalisco (Trelease s. n. (1904) [MO]). — **Lit:** Gentry (1982: 582); McVaugh (1989: 143); Hernández-Vera & al. (2007a: 500); Vázquez-García & al. (2007b: 73, t. GG1, GG2). **Distr:** Mexico (Jalisco: Río Blanco barranca near Guadalajara); on rocks and cliffs. **I:** Pilbeam (2013: 207).

[2g] **Ros** to 1.5–2 m Ø, apparently solitary; **L** ±18–25, narrowly linear, lowermost nearly on the ground, uppermost upright-recurved, those in between ± recurved, concave, thin,  $\geq 60 \times 1\text{--}2$  cm, very glaucous, with bud imprints created by the marginal teeth, margins cartilaginous, narrow, yellowish-white, nearly straight; **marginal teeth** numerous, slightly upcurved, very sharp and slender, 1–2 mm, red or brown,  $\pm 10$  mm apart (Trelease: scarcely 5 mm apart), with small intermittent denticles; **terminal Sp** conical,  $\pm 8 \times 2$  mm, dark; **Inf** 2.5–3.5 m, paniculate, peduncle very long, making up  $\pm 5\%$  of the inflorescence, **part-Inf**  $\pm 10$ , ascending-spreading, lowermost long-stalked; **Tep** yellow but flowers not further described; **Fr** and **Se** not described.

A hardly known and apparently rare but distinctive species, known for long only from the sterile type specimen collected near Guadalajara (Jalisco) and a specimen from a sterile plant grown at Missouri BG, both appearing immature (Gentry 1982). McVaugh (1989) did not know the plant and repeats data from Trelease and Gentry. Hernández-Vera & al. (2007a) could not find the plant at its type locality and assume that it could be a form of *A. angustifolia*. The species was not known from habitat until its rediscovery by Kristen & Etter (Pilbeam 2013: 207; first published photograph). Etter & Kristen (1997+: accessed 2015) provide photographs of a plant with an infructescence and few additional data confirming the placement in Sect. *Rigidae*, following McVaugh (1989). The photograph in Hochstätter (2015: VII: 48) labelled “*Agave*

*stringens*” apparently shows a different plant. Further studies are needed.

**A. subsimplex** Trelease (Annual Rep. Missouri Bot. Gard. 22: 60, tt. 63–64, 1912). **Type:** Mexico, Sonora (Rose 16811 [US, MO, NY]). — **Lit:** Berger (1915: 268); Breitung (1963: 149, 151, with ill., as *A. sobria*); Gentry (1972: 131–134, with ills.); Gentry (1978: 27, 31, 34–35, with ills.); Gentry (1982: 404–407, with ills.); Turner & al. (1995: 67–68); Wilder & al. (2008: 136–137, 140, with ills.). **Distr:** Mexico (Sonora); thinly scattered in small colonies on outwash slopes of granitic and volcanic mountains and the adjacent islands (Tiburón, Dátil, Cholludo), in desert scrub, strictly coastal at low elevations; flowers April to July and October. **I:** Richter (2011: 81); Pilbeam (2013: 208); Hochstätter (2015: V: 13).

[2i] **Ros** low-spreading, 20–35  $\times$  50–70 cm, solitary or caespitose; **L** variable, lanceolate to ovate, thick, rigid, long- to short-acuminate, only a little narrowed towards the base, rounded below, hollowed above, 12–35  $\times$  3–5 cm, grey-glaucous or light yellow-green, or sometimes purple-tinged, margins nearly straight or with strong prominences; **marginal teeth** variable, friable, straight or variously curved, rarely 2-tipped, larger teeth 3–15 mm, brown or more often yellowish-grey; **terminal Sp** subulate, frequently sinuous, shallowly grooved above, 20–40 mm, glaucous-grey, not or only a little decurrent; **Inf** 2–3.5 m, paniculate, slender, narrow, **part-Inf** short and small, 5–8 per inflorescence; **Fl** 40–45 mm; **Tep** yellow to pink, tube shallow, spreading, 3–4  $\times$  10 mm, lobes elliptic, ascending, flat, widest at the middle, apiculate and scarcely hooded, equal, 12–15  $\times$  6–7 mm; **Fil** 25–28 mm, round in cross-section, inserted below the base of the lobes 3 mm above the tube bottom; **Anth** centric, 13–15 mm, yellow; **Ov**  $\pm 25$  mm, with unconstricted neck 5 mm long; **Sty** slightly longer than the tepals; **Sti** capitate; **Fr** variable, (narrowly) oblong, 35–40  $\times$  10–15 mm, bluntly apiculate, narrowly or broadly stipitate, light glaucous; **Se** roughly crescent-shaped, mostly 4.5–5  $\times$  3–4 mm, sooty black, hilum notch narrow, the opposite corner frequently apiculate, margin with a sharp winglike flange.

Closely related to *A. deserti* and *A. cerulata* with which it shares small variable leaves, nearly tubeless flowers, and narrow small panicles, all characteristic for Sect. *Deserticolae* (as Group) (Gentry 1982). *A. subsimplex* may be closest to the polymorphic *A. cerulata* of Baja California, as indicated by the small, variable leaves and the narrow, oblong, waxy capsules, but *A. subsimplex* differs in its more spreading rosettes, wider, less acuminate grey or yellow-green leaves, and filaments inserted below the base of the tepal lobes. The pink to red colour frequently occurring in the style, filaments, and corolla is distinctive for *A. subsimplex*, but not known in *A. deserti* and *A. cerulata* (Gentry 1982). In the population genetic studies of Navarro-Quezada & al. (2003), the three samples of the species form a clade nested within the *A. deserti/A. cerulata*-complex, but none of the latter two species is monophyletic. Diurnal (insects, birds) and nocturnal (insects, bats) pollinators are equally effective (Molina-Freaner & Eguiarte 2003). See also notes under *A. deserti*.

**A. ×taylorii** Hort. B. S. Williams (Gard. Chron., ser. nov. 1: 363, 1874). **Type:** not typified. — **Lit:** Baker (1877a: 620, 621: fig. 125); Baker (1888a: 186); Coulson (1897: with ill.); Trelease (1914: 236, 238); Berger (1915: 71, as *A. taylorii*). **Distr:** Cultivated only.

**Incl.** *Agave ×taylorea* Hort. B. S. Williams ex Rafarin (1877) (*nom. inval.*, ICN Art. 61.1).

[1d × 1d] This is the garden hybrid *A. geminiflora* × *A. filifera* (as *A. filamentosa*), commercially offered by the nursery of B. S. Williams. Baker (1877a) provides a plate of the plant. The second parent was given as *A. densiflora* (= *A. mitis*) in the protologue, but corrected to *A. filamentosa* (= *A. filifera*) by Baker (1888a) in agreement with the very narrow leaves. Coulson (1897) provides a detailed description and photograph of a plant in bloom. J. N. Rose prepared 3 specimens labelled *A. taylorii* from a plant at US: Rose 1132, 1897 (US 302815; leaves), and Rose 4128, 1898 (US 399839 & 399840; leaves, flowers, photographs of a flowering plant; later identified as *A. colimana* by H. S. Gentry in 1977). Trelease (1914) erroneously lists both parentages.

According to Berger (1915), the plant could be identical with *A. wrightii* (= *A. schidigera*) and would antedate that name. Apparently no longer extant in cultivation.

**A. tecta** Trelease (Trans. Acad. Sci. St. Louis 23: 145–146, tt. 26–27, 1915). **Type:** Guatemala (Trelease 17 [ILL [2 sheets, syn]]). — **Lit:** Standley & Steyermark (1952: 118–119); Breitung (1964: 36, with ill.); Gentry (1982: 612–614, with ill.); Lott & García-Mendoza (1994: & online version); Véliz Pérez (2013: 240–242, with ill.). **Distr:** NW Guatemala (region of Quetzaltenango); cultivated only, 1500–2600 m; flowers in April. **I:** Lyons (2002: 162); Hochstätter (2015: II: 9).

[2b] Stems very thick and broad; **Ros** semiglobose, open, 2 × 3–4 m, broad, freely suckering; **L** lanceolate or broadly lanceolate, straightly ascending and often outcurved, very thick, base deeply convex and thick, becoming thinner upwards, acuminate, sigmoidally upcurved at the tip, concave to guttered, smooth, 100–200 × 30–50 cm, greyish or rather dark green, margins almost straight; **marginal teeth** recurved, often lustrous, on triangular often curved prominences often dilated at the base to 15 mm or more, 8–10 (–15) mm (at mid-leaf), dull brown or chestnut-brown becoming grey, 20–70 mm apart, tips flattened, triangular, straight or curved from low bases, dull brown, teeth sometimes on a discontinuous horny band formed by their bases; **terminal Sp** conical or subacicular, subulate, often slightly flexuous, narrowly shortly grooved above to the middle, 40–70 × 5–7 mm, dull brown or chestnut-brown, becoming grey, long decurrent for 10–15 cm, somewhat intruding dorsally into the green leaf tissue; **Inf** 5–7 m, paniculate, thick, with fleshy broadly triangular amplexicaul **Bra**, basal **Bra** sometimes densely imbricate below, sometimes completely covering the peduncle, fertile part ellipsoid, lax, with ±25 slightly ascending part-**Inf**, apparently not bulbiferous; **Ped** thick, to 10 mm; **Fl** 70–95 mm; **Tep** yellow to greenish-yellow, buds tinged red, tube funnel-shaped, deeply grooved, thick-walled, 10–18 × 20 mm, lobes linear-lanceolate, unequal, outer 20–33 × 8–9 mm, thickly apiculate, deeply

cucullate, inner shorter, narrower, thickly keeled; **Fil** broadly flattened, 40–65 mm, inserted at 2 levels 10–13 mm above the tube base; **Ov** 30–43 mm, neck grooved, not constricted; immature **Fr** oblong,  $\pm 60 \times 30$  mm; mature **Fr** and **Se** unknown.

Geographically isolated from other members of Sect. *Salmianae* (as Group); possibly a remnant of former use and now cultivated as a fence plant (Gentry 1982: 614). Cultivated in many miles of hedges around Quetzaltenango (Guatemala), and easily distinguished from other Guatemalan Agaves by its massive leaves of trough-like shape (Standley & Steyermark 1952). The report from oak forests at Tixtla de Guerrero (Guerrero, Mexico; Velázquez & al. 2003: 9) appears doubtful, or might represent the native habitat? The two type specimens at ILL are not cross-labelled and thus represent syntypes (Smith & Figueiredo 2014e: 244).

**A. telegraphica** H. Jekyll (Garden (London, 1871–1927) 1: 51, ill., 1871). **Incorrect name**, ICN Art. Preamble 8. **Type**: not typified. — **Lit**: Anonymous (1872: 172); Cutak (1943: 151); Mitich (1975: 106–107); Nelson (2001: 9–10); all with ill. **Distr**: Printed matter only, and on the verge of extinction.

≡ *Polea telegraphica* (H. Jekyll) E. C. Nelson (2001) (*incorrect name*, ICN Art. Preamble 8).

[2b?] **Ros** open, solitary; **L** 7, broadly lanceolate, older arching over, to  $\pm 200 \times 40$  cm, margins with 4–5 teeth, concave between the teeth; **Inf** paniculate, with 12 regularly horizontal part-**Inf** in the upper  $\frac{2}{3}$  of the inflorescence, part-**Inf** always 2 at the same level, and all in the same plane.

The species, a “rather entertaining bit of English humor” (Cutak 1943), is based on a drawing of a huge *Agave* with an inflorescence representing a telegraph pole and its 12 “part-inflorescences” being the carrying structure for the telegraph wires. In habit, it resembles species of Sect. *Salmianae*.

**A. temacapulinensis** A. Vázquez & Cházaro (Novon 22(2): 236–237, ills., 2012). **Type**: Mexico, Jalisco (*Vázquez-García & Cházaro* 9092

[IBUG, MEXU, MICH, MO]). — **Lit**: Etter & Kristen (2012: 94–95, with ills.); Cházaro Basáñez & al. (2013: with ills.); Vázquez-García & al. (2016: with ill.). **Distr**: Mexico (Jalisco: Río Verde drainage); calcareous outcrops, 1600–1700 m, ecotones between juniper, thorn, and *Taxodium* gallery forests, 1600–1700 m; flowers May to June. **I**: Pilbeam (2013: 209–210); Hochstätter (2015: IV: 15).

[2h] **Ros** open, closed or compact, 0.8–1.15  $\times$  1.72 m, solitary or occasionally surculose; **L** 20–25, ovate to lanceolate, firm and smooth, 55–90  $\times$  (13–) 15–20 (–24) cm, glaucous to light grey, margins crenate; **marginal teeth** variously curved, usually upwards, with broad base, 8–10  $\times$  7 mm, 15–21 mm apart at mid-leaf, 12–29 mm apart towards the tip, 6–10 mm apart towards the base; **terminal Sp** flexuous, channelled, 35–45  $\times$  9 mm, black to bluish-grey, long-decurrent; **Inf** 5–6.5 m, ‘paniculate’, peduncle with reflexed triangular **Bra**, these 20  $\times$  3 cm, fertile part open, part-**Inf** 16–18 in the upper  $\frac{2}{3}$ , 20–22 cm, with 50–70 flowers; **Fl** 60–71 mm; **Tep** yellow, outer face greenish, tube 9–15  $\times$  8–9 mm, equal to or longer than the lobes, lobes dimorphic, outer 10–15  $\times$  5–6 mm, apex red, horny, inner 12–13 mm, white-puberulent, apex galeate, all dorsally with a prominent longitudinal central keel except at the apex, drying leathery, persisting erect; **Fil** inserted unequally at mid-tube, outer inserted 1 mm higher, yellow; **Ov** 17  $\times$  5 mm, neck 7  $\times$  3 mm; **Sty** slender, nearly as long as the filaments, yellow; **Sti** 3-lobed, clavate, glandular; **Fr** oblong to obovoid, 40–51  $\times$  14–18 mm, stipe 2–8 mm; **Se** subcircular to semicircular or triangular, 5–6  $\times$  3–4 mm, black, shiny, wingless.

The light glaucous rosettes, dimorphic tepal lobes, and deep floral tube clearly place the species in Sect. *Ditepalae* where it is most similar morphologically to *A. wocomahi* (with dark green to glaucous leaves with straight to repand margins, longer teeth, shorter inflorescences with a lower number of branches, and larger seeds), and also to *A. durangensis* (with rough-textured leaves, longer teeth, and taller inflorescences with more numerous branches). *A. temacapulinensis* is a locally abundant local endemic, and is threatened

by land degradation and the El Zapotillo dam project, which may flood nearly its entire habitat (Vázquez-García & al. 2016). — According to the protologue, the flowers are visited by hummingbirds during the day and by bats in the evening.

**A. tenuifolia** Zamudio & E. Sánchez (Acta Bot. Mex. 37: 47–52, ills., 1995). **Type:** Mexico, Querétaro (*Carranza* 1905 [IEB, MEXU, TEX]). — **Distr:** Mexico (C Tamaulipas, S Guanajuato, NE Querétaro, Hidalgo, Michoacán); limestone slopes with thin soil, in pine-oak or tropical (sub-)deciduous forests, 450–1500 m; flowers mid-April to July. **I:** Magallán Hernández & al. (2012: 30, as *Agave* sp. 2). Pilbeam (2013: 211); Hochstätter (2015: VIII: 12); Greulich (2018b: 90).

[1a] **Ros** lax, caespitose, forming dense groups by axillary or rhizomatous branching; **L** 30–50 (–90), linear, subcoriaceous, very thin and flexible, young straight, mature recurved, keeled on both faces, (29–) 50–100 (–130) × 0.25–0.5 (middle, to 1.3 at the base) cm, green, striate, margins horny, <1 mm wide, light green or hyaline, shortly serrulate; **terminal Sp** conical-subulate, angulate below, flattened above, 4–10 mm, reddish-coffee-brown; **Inf** (0.9–) 1.5–1.75 (–2.3) m, ‘spicate’, peduncle with triangular long-cuspidate **Bra** (3–) 7–10 (–25) cm long, decreasing in size upwards, fertile part straight, thin, lax, part-**Inf** (19–) 23–25 (–44) per inflorescence, with geminate flowers, in the upper 1/3 of the inflorescence; floral **Bra** triangular, broadly cuspidate, 8–18 mm, generally much shorter than the flowers, caducous; **Fl** tubular, 23–30 mm; **Tep** yellow-greenish, tube sulcate from the sinuses of the lobes, 12–15 × 5–9 mm, lobes ovate-oblong, equal, apex obtuse, slightly cucullate, 4–7 × 3–4 mm; **Fil** 20–35 mm, inserted at 2 levels at mid-tube; **Anth** centric or slightly excentric, 7–13 mm; **Ov** cylindrical, sulcate, (6–) 9–12 mm, neckless, protruding slightly into the tepal tube; **Sty** slightly surpassing the filaments; **Fr** trigonous, 11–18 × 9–13 mm, truncate at the base, shortly apiculate, coffee-brown; **Se** semicircular, flat, 4–5 × 3 mm, thickened in the curved part, with distinct margin, hilum lateral, black, shiny.

According to the protologue close to *A. striata* ssp. *striata* but differing in its lax rosettes, fewer, larger and pliable, recurved leaves and its lax

‘spikes’ with geminate flowers. Molecular AFLP data (Gil-Vega & al. 2006) place *A. tenuifolia* closest to that taxon. For differences from *A. stricta*, see there. *A. tenuifolia* differs from all other members of Sect. *Juncineae* (as Group *Striatae*) in having fewer and longer leaves, lax inflorescences, and short stamens which are only shortly exerted. Pilbeam (2013) provides a new record from near Xichú in Guanajuato (as “Aguascalientes”), Hochstätter (2015) from Metztlán (Hidalgo), and Etter & Kristen (1997+: accessed 2015) from Michoacán.

**A. tequilana** F. A. C. Weber (Bull. Mus. Hist. Nat. (Paris) 8: 220, ills., 1902). **Type:** [lecto — icono]: l.c. fig. 1. — **Lit:** Berger (1915: 251–252); Gentry (1982: 582–585, with ills.); McVaugh (1989: 143–145); Etter & Kristen (2007b: with ills.). **Distr:** Mexico (Sonora, Sinaloa, Jalisco, Michoacán, Oaxaca); cultivated only; flowers July to November. **I:** Irish & Irish (2000: t. 43, variegated form); Heller (2006: 29, 32); Richter (2011: 13); Etter & Kristen (2012: 79–81); Pilbeam (2013: 212–213).

≡ *Agave angustifolia* ssp. *tequilana* (F. A. C. Weber) A. Valenzuela & Nabhan (2004); **incl.** *Agave palmaris* Trelease (1920); **incl.** *Agave pedrosana* Trelease (1920); **incl.** *Agave pes-mulae* Trelease (1920) ≡ *Agave angustifolia* ssp. *rubescens* ‘Pes-mulae’ (Trelease) A. Valenzuela & Nabhan (2003) (*nom. inval.*, ICN Art. 35.1) ≡ *Agave angustifolia* var. *pes-mulae* (Trelease) A. Valenzuela & Nabhan (2003) (*nom. inval.*, ICN Art. 41.4); **incl.** *Agave pseudotequilana* Trelease (1920).

[2g] Stems short, thick, mature 30–50 cm; **Ros** radiately spreading, 1.2–1.8 m, surculose; **L** lanceolate, ascending to horizontal, firmly fibrous, mostly rigidly spreading, narrow and thickened towards the base, widest in the middle, acuminate, concave, 90–120 × 8–12 cm, generally glaucous bluish- to grey-green, sometimes cross-zoned, margins straight to repand; **marginal teeth** generally regular in size and spacing or rarely irregular, mostly 3–6 mm (at mid-leaf), light to dark brown, 10–20 mm apart, with slender tips curved from low pyramidal bases, rarely teeth remote and longer; **terminal Sp** flattened or openly grooved

above, generally 10–20 mm, rarely longer, base broad, dark brown, decurrent or not; **Inf** 5–6 m, paniculate, densely branched, part-**Inf** large, dense, diffusely several times compound, 20–25 per inflorescence; floral bracts small; **Ped** 3–8 mm; **Fl** 68–75 mm; **Tep** green, tube grooved, funnel-shaped, 10 × 12 mm, lobes linear, erect, withering quickly at anthesis, subequal, 25–28 × 4 mm, turning brownish and dry; **Fil** bent inwards against the style, 45–50 mm, inserted at 7 and 5 mm above the tube base; **Anth** 25 mm; **Ov** cylindrical, 6-ridged, slightly tapered at the base, 32–38 mm, neck short, not constricted; **Fr** ovoid, shortly cuspidate, 35–60 × 25–35 mm, sessile or shortly stipitate; **Se** semicircular, hilum subventral. — **Cytology**: 2n = 60; cultivars: 2n = 60 ('Azul'), 90, 120, 150 (Castorena Sanchez & al. 1991, Palomino & al. 2003, Guadalupe & al. 2008, Robert & al. 2008, Simpson & al. 2011).

Distinguished from its close relative *A. angustifolia* by larger leaves, thicker stems, and larger, more diffuse inflorescences with relatively large flowers with rather short tubes, albeit these differences are of degree rather than clear-cut (Gentry 1982: 583). Molecular studies showed that *A. tequilana* is derived from *A. angustifolia*, and that its different cultivars are genetically distinct (Cuevas Figueroa & Flores Berrios 2006). The taxon thus represents a polyphyletic assemblage of cultivars independently derived from within its progenitor species *A. angustifolia* and could consequently be classified at subspecific rank under it. It is here upheld at species rank due to its importance as crop plant. — Gentry (1982: 585) designated the figure cited above as "Type", which represents a lectotypification.

*A. tequilana* is of considerable economical importance as source of the distilled liquor tequila. Under Mexican laws, tequila can only be produced from the cultivar 'Azul' (Gil-Vega & al. 2001), which is cultivated in large plantations, esp. around the town of Tequila (Jalisco) after which it is named. In 2006, this landscape was declared as UNESCO World Heritage "Agave Landscape and Ancient Industrial Facilities of Tequila". The tequila landscape, industry, harvesting and manufacturing is shown and described by

Valenzuela-Zapata (1985) and Etter & Kristen (2012), and in detail by Valenzuela-Zapata & Nabhan (2003).

Molecular studies of *A. tequilana* 'Azul' revealed an extremely low level of genetic diversity, assumed to result from vegetative propagation of a single conserved genotype over many years (Gil-Vega & al. 2001). *A. tequilana* 'Azul' bulbils show genetic differences from the mother plant, while lateral shoots do not show such differences (Cuevas Figueroa & Flores Berrios 2006). In Jalisco, different genotypes exist which were conserved in different regions by asexual propagation (Torres-Morán & al. 2013). Landraces, which are ignored by the tequila industry, show domestication syndromes for fructan content or in the fibres and may be valuable for both ethanol production and genetic resource conservation (Valenzuela 2011). Trejo-Salazar & al. (2016) argue that intensified agriculture to meet the increased demand for *Agave*-derived alcoholic beverages threatens the bat-*Agave* relationship. Bat-friendly procedures should be investigated, and allowing 5% of the plants to flower would be a possible approach. — The embryo sac is of the monosporic *Polygonum*-type and the endosperm formation is helobial (González-Gutiérrez & al. 2014).

**A. thomasiae** Trelease (Trans. Acad. Sci. St. Louis 23: 138, t. 12, 1915). **Type**: Guatemala (*Trelease* 19 [ILL]). — **Lit**: Standley & Steyermark (1952: 119–120); Gentry (1982: 500–501, with ill.); Lott & Garcia-Mendoza (1994: & online version); Véliz Pérez (2013: 241–242, with ill.); Meer & Guillot Ortiz (2016: 188–189, with ill.). **Distr**: W & SW Guatemala; rocky hills in juniper, pine and oak forests, 2000–3080 m; flowers December and April. **I**: Richter (2011: 130); Pilbeam (2013: 214); Hochstätter (2015: VI: 15).

[2o] Acaulescent; **Ros** openly spreading, medium-sized, solitary or sometimes moderately to freely suckering; **L** lanceolate to broadly lanceolate, softly succulent, pliable, narrowed and thickened towards the base, acuminate, flat to mildly guttered, smooth to slightly asperous below, 60–120 × (12–) 15–19 cm, pruinose or light glaucous to pale green; **marginal teeth**

minute, 1–3 mm, 10–20 mm apart or less, reduced to denticles below, with small intermittent teeth; **terminal Sp** subulate to acicular, shallowly grooved above, 30–45 mm, dark brown; **Inf** 4–8 m, paniculate, peduncle short, fertile part narrow, part-**Inf** congested, roundish, 30–60 in the upper  $\frac{1}{2}$ – $\frac{5}{6}$  of the inflorescence; **Fl** 60–70 mm; **Tep** purple to yellow, tube funnel-shaped, knobby, trigonous, rather thin-walled, sulcate, 6–11 mm, lobes erect to incurved, long-linear, bluntly acute, cucullate, unequal, 19–29 mm, inner smaller with a prominent keel; **Fil** 45–60 mm, purple or yellow, inserted near the mouth of the tube; **Anth** regular, excentric, 15–25 mm, yellow; **Ov** strongly trigonous, 30–38 mm, tapering from the tube or with a short grooved neck; **Sty**  $\pm$  as long as the filaments; **Sti** capitate; **Fr** linear-oblong, 43–50  $\times$  20–24 mm, without beak, stipitate for 20 mm; **Se** unknown.

One of the few suckering Agaves in Guatemala. Distinguished by its soft, grey-pruinose leaves with minute teeth and variously coloured flowers with strongly trigonous ovaries (Gentry 1982: 500). The fruit description was added from *Mathiasen* 9921B (DES 00043364!).

Three further Guatemalan *Agave* species with relatively narrow leaves are insufficiently known and here listed as unresolved names on the base of Lott & García-Mendoza (1994): *A. deamiana* (Trelease 1915: 139) with small teeth and few spreading leaves from Fiscal is only known from the sterile type material and is thus of difficult

application; *A. minarum* (Trelease 1915: 139) with moderate, easily detachable teeth from the Sierra de la Minas is of uncertain affinities and could not be located in the field; and *A. kellermaniana* (Trelease 1915: 142) with close, slender-tipped, chestnut-brown teeth from blue bases, likewise from Fiscal. The latter is based on mixed sterile material: Its type (*Deam* 6239) is of uncertain identity, while *Norton* 112 belongs to *A. seemanniana* (Lott & García-Mendoza 1994).

**A. titanota** Gentry (Agaves Cont. North Amer., 176–180, ills., 1982). **Type:** Mexico, Oaxaca (*Gentry & Tejada* 22474 [US  $\dagger$ , syn?: ARIZ [3 sheets], ASU, DES, MEXU [2 sheets], MICH [3 cross-labelled sheets]]). — **Lit:** García-Mendoza (2003: with ill.); Greulich (2005b: with ills.); García-Mendoza (2011a: 63–64); Starr (2012: 264–267, with ills.); Guillot Ortiz & Meer (2014: with ills.). **Distr:** Mexico (S Puebla, NE Oaxaca); limestone canyons and slopes, in desert scrub on brown soils of limestone origin, 500–1420 m; flowers late November to January. **I:** Irish & Irish (2000: t. 44); Heller (2006: 138, 139, 160); Richter (2011: 54, 69, 113); Pilbeam (2013: 215–217); Smith & Figueiredo (2014a: 18); Hochstätter (2015: IX: 43); Moore (2016: 264, 265). — Fig. 55.

**Incl.** *Agave titanota* [?] *minor* hort. ex Heller (2006) (*nom. inval.*, ICN Art. 38.1a).

**Fig. 55** *Agave titanota* (Etter & Kristen 1805: Mexico; Oaxaca, between Tehuacán and Oaxaca, 1800 m). (Copyright: J. Etter & M. Kristen)

[1g] Stems short; **Ros** openly spreading, 0.5–0.8 × 0.8–1.5 m, solitary or rarely sparingly surculose; **L** 20–30, ovate, spatulate, or broadly lanceolate, broad, rigid, thick towards the base, short-acuminate, keeled and convex below, flat or concave above, the apex involute above, finely granular, 30–60 × 12–15 cm, typically alabaster- or glaucous-white, very rarely blue-green, sometimes with lighter mid-stripe, margins horny, wavy to crenate, widest (3–5 mm) towards the leaf tip, continuous to the base or nearly so, brownish or greyish-white; **marginal teeth** deltoid or irregular, variously curved, rough-granular, sometimes with denticles at the base, (10–) 20–40 × (6–) 10–17 mm, white-grey or dark brown, (10–) 30–50 (–85) mm apart at mid-leaf, leaf tip area sometimes toothless for the uppermost 7–12 cm; **terminal Sp** broadly conical, with deep involute groove above, keeled and protruding below for up to 20 mm, 30–65 × 10–20 mm, dark brown to grey or greyish-white, spine and decurrent part forming a horny plate 3–10 × 2–5.5 cm (on the lower face); **Inf** erect, 2.5–3 m, ‘spicate’, peduncle with deltoid, long attenuate, ascending **Bra** 9–20 cm long, fertile part in the upper  $\frac{1}{2}$ – $\frac{1}{3}$ , part-**Inf** with geminate flowers; **Ped** 10–20 mm; **Fl** (30–) 40–47 mm, campanulate; **Tep** yellow, yellowish-green or with lavender flushes, tube broadly funnel-shaped, (1–) 2–4 × 4–6 (at the mouth) mm, lobes ascending, linear, acute, thickly succulent, not clasping the filaments at anthesis, 20–30 × 2–5 mm, outer 1 mm longer, inner with a prominent keel protruding into the apex; **Fil** flattened, finely tapered towards the apex, 45–60 mm, inserted near the tube rim; **Anth** centric, 10–15 mm, yellow or with lavender flushes; **Ov** slenderly cylindrical, (12–) 17–20 (–25) × 3–4 mm, pale greenish, neck slightly constricted for 2–5 mm; **Sty** thick, 55 mm, clearly longer than the tepals; **Fr** ellipsoid or obovoid, acute at the apex, (15–) 25–28 × 10–12 mm, brown; **Se** 3.5–4 × 2–3 mm, wing <1 mm broad, black.

Characterized by ovate, spatulate to broadly lanceolate, glaucous or yellowish-green leaves with large, irregular, whitish-grey teeth, the terminal spine forming a broad robust plate on the lower face, and flowers with a short tube and long and narrow lobes. Known to Gentry (1982) only from its type locality Rancho Tambor where

only plants with alabaster- or glaucous-white leaves occur. Meanwhile, the species is known to be more widespread in NE Oaxaca (Pilbeam 2013), and was also collected in S-most Puebla (García-Mendoza 2011a) and is thus endemic to the Tehuacán-Cuicatlán valley. Illustrations in Greulich (2005b) show the variability in leaf colour and shape. Guillot Ortiz & Meer (2014) give an overview of *A. titanota* cultivars. Var. *minor* is a horticultural name for a small form with short leaves (Heller 2006: 138).

Green-leaved plants collected by F. Otero (Otero 076) in the Sierra Mixteca caused considerable discussions as to their identity. Pilbeam (2013) considers them as a mere form only with deviating leaf colour. Guillot Ortiz & Meer (2014) describe the plant as *Agave* ‘Felipe Otero’. Their speculations that this plant might represent a hybrid of *A. titanota* or *A. horrida* are unfounded, since the green plants appear to occur in pure stands, and the latter is absent from its area. Starr (2019) published the Otero plant as a new species *A. oteroi* which could no more be included in this handbook. For the closely related *A. quiotepecensis*, see there.

The holotype, cited for US in the protologue, is not accessible electronically and was probably never sent: Most probably, Gentry intended the most complete, not cross-labelled specimens (ARIZ 265732–265734) bearing his stamp “Gentry Herbarium” and his hand-writing to be sent to US as “holotype”. The specimens as cited above thus represent 8 syntypes.

**A. toumeyana** Trelease (Contr. US Nation. Herb. 23: 140, 1920). **Type:** USA, Arizona (*Toumey* 442 [MO?, ARIZ, MIN, US]). — **Lit:** Gentry (1982: 208–213, with ill.). **Distr:** USA (C Arizona).

The holotype, cited for MO in the protologue, is not accessible electronically.

**A. toumeyana** ssp. **bella** (Breitung) Gentry (Agaves Cont. North Amer., 211, ill. (pp. 212–213), 1982). **Type:** USA, Arizona (*Breitung & Gibbon* 18153 [CAS 415996]). — **Lit:** Breitung (1960: 80–81, with ill.); Weber (1965:

**Fig. 56** *Agave toumeyana* ssp. *bella* (Etter & Kristen 289: USA; Arizona, Gila County, Indian Coral Mesa, 1400 m). (Copyright: J. Etter & M. Kristen)

with ill.); Hodgson (1999a: 10); Reveal & Hodgson (2002); Starr & Devender (2011: 227, 230–231); Starr (2012: 269–274, 310–311, with ill.); Parker (2017: 262–263, with ill., as var.). **Distr:** USA (C Arizona); open gravelly to rocky limestone or basalt slopes, mostly with desert scrub, chaparral, and pinyon-juniper woodlands, 800–1700 m; flowers May to June. **I:** Heller (2006: 157); Pilbeam (2013: 219); Ettelt (2014: 118); Hochstätter (2015: VIII: 57). – Fig. 56.

≡ *Agave toumeyana* var. *bella* Breitung (1960).

[1e] Differs from ssp. *toumeyana*: **Ros** flat-topped; **L** 100–200, smaller, (3–) 9–20 (–27) × 0.5–1.2 cm, pale green, margins denticulate in the lower ½ of the leaf; **Fl** 16–21 mm; **Fil** 11–13 mm; **Ov** 8–12 mm. — **Cytology:** 2n = 60 (Pinkava & Baker 1985, Baker & al. 2009).

Quite distinct from ssp. *toumeyana* and with a nearly separate, very limited distribution area in C Arizona (Gentry 1982). It hybridizes with *A. chrysantha* (Hodgson 1999a, Reveal & Hodgson 2002).

**A. toumeyana** ssp. *toumeyana* — **Lit:** Breitung (1960: 79–80, with ill.); Weber (1965: with ill.); Gentry (1982: 208–211, with ill.); Hodgson (1999a: 10); Reveal & Hodgson (2002); Starr & Devender (2011: 227, 230–231, with ill.); Starr (2012: 270, 272, 310–311); Parker (2017: 262–263, with ill., as var.). **Distr:** USA (C

Arizona); open gravelly to rocky limestone or basalt slopes, mostly with desert scrub, chaparral, and pinyon-juniper woodlands, 600–1500 m; flowers March to June. **I:** Irish & Irish (2000: t. 45); Heller (2006: 34, 140); Richter (2011: 64); Pilbeam (2013: 218); Ettelt (2014: 117); Hochstätter (2015: VIII: 56). – Fig. 57.

≡ *Agave toumeyana* var. *toumeyana*.

[1e] **Ros** (3–) 10–50 × 15–60 cm, round-topped, freely suckering, densely caespitose; **L** 40–70, linear to linear-lanceolate, ascending to erect, straight or falcate or upcurving, rather rigid, of unequal length, thickly convex towards the base, flat above towards the acute to long-acuminate apex, smooth, 19–46 × 1.2–2 cm, pale green to yellowish, both faces with impressions from the central bud, margins straight, fine, brown with conspicuous curled white fibres, fibres infrequently sparse or absent; **marginal teeth** none, or as minute denticles at the base and apex; **terminal Sp** subulate to filiform, with a short narrow groove above, 6–20 mm, brown to greyish; **Inf** 1.5–3 m, ‘spicate’, peduncle with caducous linear-triangular **Bra** 1–3.5 cm long, fertile part densely or laxly flowered in the upper ½ of the inflorescence, part-**Inf** mostly with geminate flowers, sometimes single; **Ped** to 5 mm, basally pairwise united; **Fl** 21–28 mm, slightly recurved; **Tep** saccate, erect to incurved, green to greenish white, tube campanulate, angled, 3–4.5 × 8–10 mm, lobes lanceolate, thin, erect to

**Fig. 57** *Agave toumeyana* ssp. *toumeyana* (Etter & Kristen 532: USA; Arizona, Gila County, N of Christmas, 1080 m). (Copyright: J. Etter & M. Kristen)

incurved, appressed to the filaments, subequal, 6.5–10 mm, outer closely overlapping the inner, whitish; **Fil** shortly exerted, erect to incurved, 12–17 mm, inserted 1–3.5 mm above the tube base, whitish; **Anth** 7–16 mm, pale yellow; **Ov** 8–16 mm, neck slender, curved, 3–7 mm, slightly constricted; **Sty** thick, slightly longer than the tepals; **Fr** shortly oblong, persistent, 9–15 × 8–10 mm, sessile, short-beaked, walls thin; **Se** thick, 2 × 3 mm. — **Cytology**: 2n = 60, 120 (Zonneveld 2003, Simpson & al. 2011).

The species suggests a large version of *A. parviflora*, but the rosettes are mostly higher, and the leaves are mostly longer and always more long-acuminate, the flowers larger, the filaments are inserted higher up in the tube, and the lobes are more elongate (Gentry 1982: 210, Reveal & Hodgson 2002). Both subspecies hybridize with *A. chrysantha* in Arizona (Hodgson 1999a, Reveal & Hodgson 2002). The rosettes of *A. toumeyana* are denser with more leaves than those of *A. parviflora* and *A. polianthiflora*, and the marginal fibres are thinner and less uniform (Starr & Devender 2011).

**A. triangularis** Jacobi (Wochenschr. Vereines Beförd. Gartenbaues Königl. Preuss. Staaten 12: 178, 1869). **Type** [neo]: Mexico, Puebla (Gentry 23399 [US, ARIZ, ASU, DES, MEXU]). — **Lit**: Jacobi (1869: 149–150, incl. *A. rigidissima*); Berger (1915: 101–102; 109–110, with ill., as *A. hanburyi*); Trelease (1920: 137–138); Breitung

(1959: 176–177, with ills.); Gentry (1982: 180–182, with ills.); García-Mendoza (2011a: 64–67). **Distr**: Mexico (S Puebla, N Oaxaca); common in desert scrub on arid limestone soils, 1700–1930 m; flowers June to August. **I**: Heller (2006: 141); Richter (2011: 41, as *A. hanburyi*); Pilbeam (2013: 220); Hochstätter (2015: IX: 44); Moore (2016: 263). – Fig. 58.

≡ *Agave horrida* var. *triangularis* (Jacobi) Baker (1877); **incl.** *Agave rigidissima* Jacobi (1869) ≡ *Agave triangularis* var. *rigidissima* Trelease (1920); **incl.** *Agave kerchovei* var. *inermis* Ortgies ex Baker (1877); **incl.** *Agave hanburyi* Baker (1892); **incl.** *Agave triangularis* var. *subintegra* Trelease (1914).

[lg] Acaulescent; **Ros** slow-growing, lax, 0.6–0.7 × 0.8–1 m, widely surculose, forming open clusters; **L** 30–50, deltoid to deltoid-lanceolate, straight, ascending, rigid, thick at the base, long-acuminate, flat or upper face concave, smooth, 30–55 × 5–8 cm, olive-green to brownish-green or yellowish-brown, finely flecked with brownish-red, margins horny, continuous, straight, 1–2 mm wide, greyish; **marginal teeth** present or mostly absent, straight or variously curved, few, small teeth 1–2 mm and 30–50 mm apart, larger teeth 5–10 mm and 10–20 mm apart, grey; **terminal Sp** conical to subulate, usually straight, somewhat keeled below, grooved above, (20–) 45–60 × 4–5 mm, greyish, sometimes decurrent for ± 1 cm; **Inf** 2.5–3.5 m, ‘spicate’, peduncle green, pruinose, with long triangular or linear chartaceous

**Fig. 58** *Agave triangularis* (Etter & Kristen 1738: Mexico; Puebla, between Tehuacán and Huajuapán de León, 1720 m). (Copyright: J. Etter & M. Kristen)

**Bra** 12–14 cm long, fertile part in the upper  $\frac{1}{3}$ , lax; **Ped** 1–2 mm; **Fl** campanulate, 35–38 mm;  **Tep** yellowish-green with purple or reddish-green tinge, tube 5 × 5–8 mm, lobes oblong, divaricate to slightly recurved, 13–15 × 2–4 mm, pruinose; **Fil** 30–40 (–50) mm, yellow, inserted in the mouth of the tube; **Anth** ±13 mm, yellow; **Ov** cylindrical, 12–15 × 4–5 mm, pruinose, neck 1–3 mm, constricted; **Sty** 40 mm; **Fr** ovate, 20–25 × 15 mm, dark green, pruinose when young; **Se** 4–5 × 3–4 mm, black.

Introduced by K. Besserer from near Tehuacán (Puebla) in 1868 (Jacobi 1869, Berger 1915: 102). *A. triangularis* remained unknown to Berger (1915: 102) who knew only the synonymous *A. hanburyi* published by Baker (1892) from a plant at Hanbury (Berger 1915: 109–110). Known to all authors including Gentry (1982) only in the vegetative state. The generative parts were first described by García-Mendoza (2011a) who also provides a new record from N Oaxaca. The species is recognizable by its open rosettes with thick, rigid, deltoid to deltoid-lanceolate, olive-green to brownish-green or yellowish-brown leaves. Toothless forms are most common (Gentry 1982, García-Mendoza 2011a). The species is partly similar in habit to *A. kerchovei* (Etter & Kristen 1997+: accessed 2015). It is endemic to the Tehuacán-Cuicatlán valley (Gentry 1982, García-Mendoza 2011a). A specimen from Tlaxcala labelled “*Agave cf. triangularis*” (Patrick s.n., ARIZ, DES)

needs verification. — Giant mesquite bugs (“cocopaches”; *Thasus gigas*) feeding on the inflorescences are collected by hand for family consumption as food (Acuña & al. 2011).

**A. tubulata** Trelease (Mem. Nation. Acad. Sci. 11: 45, tt. 99–100, 1913). **Type:** Cuba (Britton & al. 9746 [MO 2148465 & 2148473, NY]). — **Lit:** Berger (1915: 274); León (1946: 317); Álvarez de Zayas (1985: 7–8, 10, 13–15, with ills.); Álvarez de Zayas (1995: 41); Acevedo-Rodríguez & Strong (2012: 87). **Distr:** W Cuba (Pinar del Río, Artemisa, La Habana); calcareous cliffs and karstic dome hills (mogotes), 750–800 m; flowers in March. **I:** Richter (2010: 41); Richter (2011: 93); Pilbeam (2013: 222, as ssp. *brevituba*); Hochstätter (2015: VII: 93); Acuña (2018: 31, 33, as ssp. *brevituba*). — Fig. 59.

**Incl.** *Agave ekmanii* var. *microdonta* Trelease *in sched.* (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Agave ekmanii* Trelease (1926); **incl.** *Agave tubulata* ssp. *brevituba* A. Álvarez (1985).

[2q] Acaulescent; **Ros** open, ±1 × 1.5 m, single, not surculose; **L** few, broadly lanceolate, gradually acute or subacuminate, sometimes conduplicate, 60–75 (–90) × 15–20 cm, rather glossy green to greyish-green, margins with green prominences or repand between the teeth; **marginal teeth** prevailingly upcurved towards the leaf tip and recurved towards the base, crescent-shaped rather than lenticular at the base, 1–3 mm, 7–20 mm apart, slender-tipped, intervening

**Fig. 59** *Agave tubulata*  
(Etter & Kristen 4127:  
Cuba; Pinar del Río, ±  
10 km N of Viñales, 130 m).  
(Copyright: J. Etter &  
M. Kristen)

margin nearly straight; **terminal Sp** acicularly conical, somewhat upcurved or flexuous, round-grooved or involute below the middle, smooth, 10–20 × 2 mm, brown, dull, decurrent; **Inf** paniculate, narrow, 2–5 m, part-**Inf** ascending, tripartite, 15–30 cm; **Ped** 4–15 mm, slender; **Fl** 25–35 mm; **Tep** yellow, tube narrowly to openly funnel-shaped, 3–8 mm, lobes 10–12 mm; **Fil** 15–25 mm, inserted nearly in the tube throat; **Anth** 10–13 mm; **Ov** oblong, 15 mm; **Sty** much longer than the filaments; **Sti** capitate; **Fr** broadly oblong, 12–40 × 8–18 mm, beaked, shortly but distinctly stipitate; **Se** 5–6 × 3–5 mm.

The “holotype” at MO consists of 2 sheets with a cross-labelling which does not appear to be original; they are therefore considered to be syntypes (Smith & Figueiredo 2014e: 245). Ssp. *brevituba* differs but very slightly, and since material cited for the new taxon was also mentioned in the protologue by Trelease, it was included in the synonymy in the first edition of this handbook and by Acevedo-Rodríguez & Strong (2012: 87) and Govaerts (2014+: accessed April 2014). For differences from *A. jarucoensis*, see there. *A. tubulata* occurs at least sometimes in regions with a predominance of ophiolitic soils (López Almira 2013) and is classified as “Least Concern” in the Cuban Red List (Berzaín & al. 2005: 49).

**A. turneri** R. H. Webb & J. M. Salazar-Ceseña (Brittonia 63(2): 204–206, ills., 2011). **Type:**

Mexico, Baja California (*Salazar-Ceseña* 3740 [MEXU]). — **Lit:** Webb & Starr (2015: 75–76, with ills.). **Distr:** Mexico (Baja California: Sierra Cucupá & Sierra Mayor); on steep slopes or cliffs or steep colluvial slopes in Sonoran desert scrub, only on granodiorite and tonalite soils, 180–400 m; flowering February to April and August. **I:** Hochstätter (2015: V: 26).

[2j] Acaulescent; **Ros** 0.4–1.2 × 0.8–1.9 m, solitary; **L** 10–40, lanceolate, generally not guttered, smooth to scaberrulose on the upper face, and scabridulous to rough on the lower face, 40–90 × 6–13 cm, widest ± ¼ from the base, grey-green to blue-glaucous green, with prominent imprints from the central bud on both faces, occasionally with darker cross-banding, margins straight, with a 1–2 mm wide purple band, aging to white; **marginal teeth** randomly flexed, easily detached, 5–7 mm, purple-black turning to white with age, on average 15 mm apart; **terminal Sp** proximally channelled above, 50–60 mm, purple-black, decurrent; **Inf** 2–4 m, paniculate, with triangular **Bra** 12–13.5 × 4.5–6 cm, part-**Inf** slightly ascending, 5–10, 20–30 cm, ± capitate, subtended by ± triangular purple bracts, in the upper 50–70 cm of the inflorescence; **Ped** 5–20 mm; **Fl** ± erect, densely crowded, 37.5–56 mm; **Tep** yellow-green to yellow, tube crateriform, 2–5.5 × 7–9 mm, lobes ascending, lanceolate, subequal, apex with tufted hairs and beaked tip, occasionally red, 18–24 × 5–9.5 mm,

inner keeled, outer smooth, both gibbous; **Fil** slender, 29–41 mm, subequally inserted, decurrent on the tube inside; **Ov** fusiform, 15–29 × 3–6.5 mm, light glossy green, neck sulcate, 3–6 × 2.5–6 mm, scarcely constricted; **Sty** 15–49 mm; **Sti** bulbous, rugose, vaguely 3-lobed, cream-coloured; **Fr** oblong, smooth, brown when dry, beaked, 36–45 mm, stipitate; **Se** ± crescent-shaped, flat-convex, compressed, 5–8 mm, black, shiny.

According to the protologue already photographed back in 1905, and with affinities to *A. moranii* and *A. deserti* var. *simplex*. Both these taxa share the strictly solitary habit, but differ esp. in having larger inflorescences. In its semi-compact inflorescences and grey leaves, it resembles *A. azurea* and *A. vizcainoensis* (Sect. *Intermediae*), but the flower characteristics are closer to *A. avellanidens*, *A. gigantensis* and *A. moranii* of Sect. *Conicae* where it is placed by Webb & Starr (2015). *A. turneri* is only known from 8 localities and appears critically endangered due to its restricted occurrence on a specific soil type and increasing aridity (annual rainfall possibly <100 mm), but also threatened because of the proximity to the Mexicali metropolitan area (Webb & Salazar-Ceseña 2011, Webb & Starr 2015).

**A. umbrophila** (García-Mendoza) Thiede (Haseltonia 17: 94, 2012). **Type**: Mexico, Oaxaca (García-Mendoza & al. 8524 [MEXU, ENCB, IEB, K, MO, OAX, UAMIZ]). — **Lit**: García-Mendoza (2011b: with ill., as *Manfreda*). **Distr**: Mexico (Guerrero, Oaxaca); at shaded, humid brooksides, in muddy soils of calcareous origin, in pine-oak or montane cloud forests, 1600–2500 m; flowers June to August. **I**: Hochstätter (2016: I: 44, as *Manfreda*).

≡ *Manfreda umbrophila* García-Mendoza (2011).

[3a1] Plants herbaceous; corm 4–8 (–10) × (1.5–) 2–3.5 cm, cylindrical, bulb (4–) 7–12 × 3–4 cm, ovoid, covered with membranous dry leaf bases; **R** fleshy and thickened, with filiform ramifications, contractile; **L** evergreen, 3–8, large, spreading, spatulate or elliptic, brittle, glabrous

on both faces, tip acute, (25–) 35–45 × (5–) 7–10 cm, narrowed at the base to 0.7–1 cm, dark green with large, greenish-red to reddish dots, glabrous on both faces, margins minutely denticulate on a hyaline band, often wavy; **Inf** erect to slightly curved, (1.2–) 1.4–1.8 m, ‘spicate’, peduncle greenish with purple tinge, with 5–7 (–11) **Bra** that are abruptly much shorter than the leaves, fertile part 7–15 (–20) cm, with (8–) 11–20 solitary lax to slightly congested flowers; floral **Bra** 1 × 0.3 cm; **Fl** 25–30 (–35) mm, sessile, ascending, campanulate or sometimes urceolate, slightly zygomorphic, with a lemon-like scent; **Tep** greenish-glaucous to green-brownish, with purple tinge, tube 6–10 (–12) × 6–10 mm, greenish, lobes oblong, revolute, 10–14 (–17) × 3–6 mm, purple to green-brownish; **Fil** (45–) 70–80 (–85) mm, ± curved downwards at anthesis, by far exceeding the tube, inserted ± at mid-tube all on the same level, purple; **Ov** cylindrical, (5–) 10–13 × 3–5 (–7) mm, greenish-glaucous, constricted at the apex; **Sty** 75–85 (–100) mm, greenish with purple dots; **Sti** 3-lobed, papillose; **Fr** subglobose or ellipsoid, 15–20 (–25) × 15–20 mm, slightly rostrate; **Se** crescent-shaped, 6–7 × 4–5 mm, black, shiny.

According to the protologue morphologically most similar to *A. variegata* (as *Manfreda*) and the unpublished *Manfreda huetamensis* (Castillejos-Cruz 2009). *A. variegata* differs in its much shorter corms and bulbs, linear-lanceolate, light green to glaucous leaves with denticulate margins, peduncular bracts similar to the leaves, and a much larger spike with much more flowers. The unpublished *M. huetamensis* differs in its light green leaves with prominent veins and an easily flaking cuticle, and a much larger spike with more flowers with a longer tube (Castillejos-Cruz 2009).

**A. underwoodii** Trelease (Mem. Nation. Acad. Sci. 11: 37, tt. 67–71, 1913). **Type** [syn]: Cuba (*Trelease* 2 & 3 [MO [4 sheets], B]). — **Lit**: Berger (1915: 212); León (1946); Richter (2010: with ill.); Acevedo-Rodríguez & Strong (2012: 87); Greuter & Rankin Rodríguez (2017: 36). **Distr**: SE Cuba; on rocky hills and hillsides in

coastal and near-coastal xerophytic scrub, and on karstic dome hills (mogotes); flowers February to March. **I:** Delanoy (2002: 30); Heller (2006: 142); Richter (2011: 88, 91); Kattermann (2012: 14); Pilbeam (2013: 223); Hochstätter (2015: VII: 63, 76).

**Incl.** *Agave morrisii* Worsley (1895) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave americana* Millspaugh (1900) (*nom. illeg.*, ICN Art. 53.1).

[2p] Acaulescent; **Ros** to 2 × 2 m, solitary; **L** ± narrowly lanceolate, gradually or in the broader forms acuminate pointed, concave, 100–200 × 20–25 cm, green, margins straight or somewhat concave; **marginal teeth** straight or somewhat curved or occasionally hooked (mostly downwards), rather strongly triangular from lenticular bases, 2–5 mm, brown or chestnut-brown, ±10 (–20 or even 30) mm apart, exceptionally on green prominences; **terminal Sp** triquetrously conical or somewhat subulate, straight or slightly upcurved, openly grooved to or beyond the middle or involute, smooth or a little roughened, 15–25 × 4–6 mm, brown, rather dull, decurrent and somewhat dorsally intruded into the green leaf tissue; **Inf** 4–8 m, paniculate, broad, part-**Inf** on sharply recurved to nearly straight **Br** in the upper ¾ or more of the inflorescence, ±40–50, not known to be bulbiferous; **Ped** slender, 15–20 mm; **Fl** 50–55 mm; **Tep** golden-yellow, tube conical, ±8 mm, lobes 15–20 × 5 mm; **Fil** 30–35 mm, inserted somewhat below the tube throat; **Ov** 25–35 mm; **Fr** narrowly oblong, 40–45 × 15 mm, beaked and stipitate; **Se** 5–6 × 3–4 mm.

According to the protologue rather variable (colour of terminal spine and marginal teeth, shape of the groove of the terminal spine, length of the tepal lobes, degree of exertion of the filaments). May form natural hybrids with *A. albescens* (Richter 2010: 41).

**A. undulata** Klotzsch (Allg. Gartenzeitung 8: 274, 1840). **Type:** Cult. BG Berlin (*Anonymous* 3 [B]). — **Lit:** Jacobi (1865: 560); Jacobi (1871: 89–90); Baker (1877b: 808); Rose (1903c: as *Manfreda*); Berger (1915: 37); Verhoek-Williams (1975: 310–312, as *Manfreda*). **Distr:** Known from cultivation only.

≡ *Manfreda undulata* (Klotzsch) Rose (1903); **incl.** *Agave undulata* var. *strictior* Jacobi & C. D. Bouché (1865); **incl.** *Agave drimiifolia* Hort. Petropol. ex Baker (1877) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Agave undulata* [?] *glauca* Hort. Richter (2007) (*nom. illeg.*, ICN Art. 36.1c).

[3a3] Herbaceous; rhizome (corm and bulb) short, thick, covered with dry membranous whitish leaf bases, **L** linear-lanceolate, strongly revolute, flaccid, flat, wavy, acuminate, markedly conduplicate, below with a prominent unarmed mid-rib, scabrous, 15.2–20.3 × 3.18 cm, glaucous dull green, at the base reddish on the lower face, margins minutely toothed, tip a round, convolute point, apex terete, margins entire, narrowly whitish-horny or somewhat reddish, decurrent along the leaf below the apex; **Inf** ±1.2 m, ‘spicate’, dense, tall, bracteate, glaucous; **Ped** short, thick; **Fl** ±40 mm, solitary, curved downwards; **Tep** 30 mm, tube shallowly funnel-shaped, 6-furrowed, 11 × 4 mm, light green, pruinose, with small black dots, lobes lanceolate, erect after anthesis, outer 17 × 4 mm, dorsally convex, with slightly involute margins, 7-veined, papillate, dark reddish-brown, pruinose, tip cucullate, yellowish-brown, inner somewhat broader, keeled; **St** widely exerted; **Fil** subulate, 35 mm, inserted all at the same level, green, densely dotted with reddish-brown, tip light green; **Anth** 11 mm, brownish-green; **Ov** oblong-ovate, inconspicuously 6-angled, 11 × 6 mm, pruinose-green, prolonged into the tube; **Sty** erect, robust, reddish-brown with greenish dots; **Sti** capitate, 3-lobate, papillate; **Fr** and **Se** not known.

An uncertain species, only known from the type specimen at Berlin upon which Klotzsch based his rather brief description. A plant labelled *A. undulata* flowered at the BG Berlin in 1869, from which Jacobi (1871) added, from memory, the description of its flowers. All descriptions from Jacobi to Berger indicate similarities with *A. guttata* (Verhoek-Williams 1975: 311). The erose leaf margins of the type specimen and the undulate leaves with minutely toothed margins of the protologue point towards *A. guttata* or *A. debilis*, but it cannot be assigned with confidence to either, and thus remains of uncertain

**Fig. 60** *Agave utahensis* ssp. *kaibabensis* (Etter & Kristen 295: USA; Arizona, Coconino County, Grand Canyon East Rim Drive, 2280 m). (Copyright: J. Etter & M. Kristen)

application (Verhoek-Williams 1975: 312; as *Manfreda guttata* and *M. pringlei*).

Cultivated plants labelled as “*Manfreda undulata*” have narrow, conduplicate green leaves without dots and slightly wavy erose margins (Richter 2007: 43–44, with ill.), and merit further study. *Manfreda undulata* ‘Chocolate Chips’, ‘Mint Chocolate Chip’ and ‘Cherry Chocolate Chip’, all refer to cultivars with conduplicate leaves with strongly wavy margins and large purplish to reddish dots, and are therefore misplaced in *M. undulata*, which has plain green leaves; they might represent selections or hybrids of *A. maculosa*, *A. guttata* or *A. variegata* (all Subgen. *Manfreda*).

**A. utahensis** Engelmann (in S. Watson, Bot. US Geol. Expl. 40. Parallel 5: 497, 1871). **Type** [lecto]: USA, Utah (*Palmer* s.n. [MO, US]). — **Lit**: Gentry (1982: 257–262, with ills.); Reveal & Hodgson (2002); Janeba (2010: ill. synopsis). **Distr**: USA (California, Utah, Nevada, Arizona).

≡ *Agave haynaldii* var. *utahensis* (Engelmann) A. Terracciano (1885) (*incorrect name*, ICN Art. 11.4, 25.1).

Plants from N and/or high altitude populations of ssp. *utahensis*, ssp. *kaibabensis* and var. *eborispina* may tolerate temperatures down to  $-21\text{ }^{\circ}\text{C}$  to  $-29\text{ }^{\circ}\text{C}$  and may survive outdoors in C Europe nearly without rain protection (Boeuf 2007: 134).

**A. utahensis** ssp. *kaibabensis* (McKelvey) Gentry (Agaves Cont. North Amer., 259, ill. (p. 260), 1982). **Type**: USA, Arizona (McKelvey 4381 [A]). — **Lit**: Breitung (1960: 21–22); Reveal (1977: 537–538); both with ills., as var.; Gentry (1982: 259–260, with ills.); Hodgson (1999a: 11); Reveal & Hodgson (2002); Janeba (2010: 14–17, with ills.); Starr (2012: 274, 276, 279). **Distr**: USA (N Arizona); calcareous or sandstone outcrops in desert scrub, pinyon-juniper, or conifer woodlands, 700–2500 m; flowers May to July and December. **I**: Heller (2006: 143); Pilbeam (2013: 225); Hochstätter (2015: IX: 17, as *A. utahensis*). — Fig. 60.

≡ *Agave kaibabensis* McKelvey (1949) ≡ *Agave utahensis* var. *kaibabensis* (McKelvey) Breitung (1960).

[1h] Differs from ssp. *utahensis*: **Ros** solitary or sparingly caespitose, larger, (20–) 30–60 × 40–100 cm; **L** larger, lanceolate, (25–) 27–50 × 3–5.5 cm; **marginal teeth** shorter, (2–) 3–5 mm, more distant, 20–40 mm apart; **terminal Sp** shorter, stout, subulate, 20–40 mm; **Inf** larger, 3.5–5 m, narrowly paniculate, longer part-**Inf** (1–) 4–10 cm long, with 4–12 flowers; **Fl** larger, (26–) 29–43 mm; **Ov** larger, 15–29 mm. — **Cytology**: n = 30 (Baker & al. 2009: as var.).

Distributed along the N Grand Canyon rim. Habitat temperatures may drop down to  $-18\text{ }^{\circ}\text{C}$ .

**A. utahensis** ssp. *utahensis* — **Lit**: Breitung (1960: 21–22, with ills.); Reveal (1977: 537–538,

with illis.); Gentry (1982: 257–260, with illis.); Hodgson (1999a: 10–11); Reveal & Hodgson (2002); Janeba (2010: 9–13, with illis.); Starr (2012: 274–279); Parker (2017: 262, 264–265, with illis.). **Distr:** USA (SE California, SW Nevada, S Utah, NW Arizona); calcareous outcrops with desert scrub, 600–1400 m; flowers late winter to early summer. **I:** Heller (2006: 143); Janeba (2008: 302, as *A. utahensis*); Richter (2011: 126); Pilbeam (2013: 224); Hochstätter (2015: IX: 16, as *A. utahensis*).

≡ *Agave utahensis* var. *utahensis*; **incl.** *Agave newberryi* Engelmann (1875); **incl.** *Agave scaphoidea* Greenman & Roush (1929) ≡ *Agave utahensis* var. *scaphoidea* (Greenman & Roush) M. E. Jones (1930); **incl.** *Agave utahensis* var. *discreta* M. E. Jones (1930); **incl.** *Agave utahensis* fa. *nuda* hort. ex E. & B. Lamb (1978) (*nom. inval.*, ICN Art. 39.1).

[1h] Acaulescent; **Ros** rather compact, 15–30 × (15–)25–40 cm Ø, caespitose; **L** 70–80, linear-lanceolate, stiff, straight or falcate or upcurving, convex below, flat to concave above, mostly (12–)15–30 × 1.5–3 cm, light greyish- to yellow-green, in dwarf forms also bluish-grey-glaucous; **marginal teeth** blunt, thick, detachable, larger teeth mostly 2–4 (–15) mm, brown-ringed around the bases, light grey, 10–25 mm apart; **terminal Sp** acicular, openly grooved above, 20–40 mm (to 200 mm in extreme forms), light grey or ivory-white, decurrent for 1–3 cm; **Inf** 1.7–4 m, ‘spicate’, racemose, or narrowly racemose-paniculate (then with short lateral branches 0.5–5 cm long), peduncle with caducous narrowly triangular **Bra** 4–8 cm long, fertile part lax or congested, part-**Inf** with 2–8 clustered flowers; **Ped** very short; **Fl** urceolate, 23–32 mm; **Tep** yellow, tube broadly funnel-shaped, bulging at the lobe bases, very short, 2.5–4 × 9–12 mm, lobes connivent around the filaments, persisting erect, nearly equal, 9–12 mm, outer thin, deeply concave and overlapping the inner, these strongly keeled; **Fil** 18–20 mm, inserted near the tube bottom; **Anth** small, 9–12 mm; **Ov** 12–22 mm, neck 4–6 mm, constricted; **Fr** ovoid to oblong, 10–25 × 10–12 mm, shortly beaked; **Se** crescent-shaped, thick, variable in size, 2–4 × 3–4 mm, dull or shiny black, hilar notch usually conspicuous. — **Cytology:** 2n = 60,

120 (Granick 1944 (identity uncertain), Zonneveld 2003, Simpson & al. 2011).

Ssp. *utahensis* differs from ssp. *kaibabensis* esp. in its smaller rosettes, narrower leaves and smaller flowers (Reveal & Hodgson 2002). The localities in S Utah are the second-most N *Agave* localities (only *A. virginica* of Subgen. *Manfreda* extends further N-wards).

**A. utahensis** var. **eborispina** (Hester) Breitung (Cact. Succ. J. (US) 32: 22, 1960). **Type:** USA, Nevada (Hester s.n. [CAS, G, NY, US [8 sheets]]). — **Lit:** Hester (1943: with illis.); Breitung (1960: 22–23, with illis.); Gentry (1982: 262); Reveal & Hodgson (2002); Janeba (2010: 18–21, with illis.); Starr (2012: 274–279, with illis.). **Distr:** USA (SE California, S Nevada); calcareous outcrops with desert scrub, 1100–1900 m; flowers May to July. **I:** Heller (2006: 144); Janeba (2008: 300–301, as *A. eborispina*); Pilbeam (2013: 227); Hochstätter (2015: IX: 16, as ssp.).

≡ *Agave eborispina* Hester (1943) ≡ *Agave utahensis* ssp. *eborispina* (Hester) Hochstätter (2015).

[1h] Differs from var. *utahensis*: **marginal teeth** larger, 6–12 (–15) mm; **terminal Sp** ivory-white, stout, very long, 100–200 mm.

A montane endemic in the S Mohave Desert (Gentry 1982). Specimens with esp. long terminal spines are highly attractive. The protologue illustrates rare part-inflorescences to 10 cm long and with up to 14 flowers. See also the comment for var. *nevadensis*.

**A. utahensis** var. **nevadensis** Engelmann ex Greenman & Roush (Ann. Missouri Bot. Gard. 16: 390, 1929). **Type:** USA, California (*Parish* 414 [MO, CAS]). — **Lit:** Hester (1943: with illis.); Breitung (1960: 22–23, with illis.); Gentry (1982: 261); Reveal & Hodgson (2002); Janeba (2010: 22–24, with illis.); Starr (2012: 273–276, 279, with illis.). **Distr:** USA (SE California, S Nevada); calcareous outcrops with desert scrub, 1200–1900 m; flowers May to July. **I:** Irish & Irish (2000: t. 46); Heller (2006: 144); Janeba (2008: 299, as *A. nevadensis*); Pilbeam (2013: 227).

≡ *Agave nevadensis* (Engelmann ex Greenman & Roush) Hester (1943) ≡ *Agave utahensis* ssp.

*nevadensis* (Engelmann *ex* Greenman & Roush) Hochstätter (2015).

[1h] Differs from var. *utahensis*: **marginal teeth** longer, 4–6 mm; **terminal Sp** slender, longer, 40–80 mm, brown to whitish. — **Cytology**:  $2n = 60$  (Reveal & Hodgson 2002, Zonneveld 2003).

A montane endemic in the S Mohave Desert (Gentry 1982). *A. utahensis* var. *nevadensis* and var. *eborisipina*, both accepted by Gentry (1982), were included in the synonymy of ssp. *utahensis* by Little (1981) and McKinney (1993). Gentry (1982: 261) mentions ‘transitional forms’, but since typical plants of both taxa are clearly distinct and are largely geographically separated, they are upheld here at varietal level under ssp. *utahensis* following Reveal & Hodgson (2002).

**A. valenciana** Cházaro & A. Vázquez (Novon 15(4): 525–527, ills., 2005). **Type**: Mexico, Jalisco (*Vargas-Rodríguez & al.* 436 [IEB, ENCB, GUADA, IBUG, MEXU, MO, WIS, XAL]). — **Lit**: Cházaro Basáñez & al. (2005b: with ills.); Cházaro Basáñez & al. (2006b: with ills.); Vázquez-García & al. (2007b: 74–77, t. II); Cházaro Basáñez & al. (2008a: with ills.). **Distr**: Mexico (W Jalisco); steep slopes of basaltic rock in canyons, 900–1250 m, in the ecotone of tropical deciduous forests with oak forests; flowers March to May. **I**: Richter (2011: 57); Etter & Kristen (2012: 89–90); Pilbeam (2013: 228); Hochstätter (2015: VI: 1, 24); Moore (2016: 239).

[2n] Stems short; **Ros** 1.7–2.2 × 2.7–3.3 (–4.1) m, solitary, not suckering; **L** 7–15, broadly lanceolate, ± straight or variously curved, thick, firmly concave, smooth on both faces, 150–230 × 37–46 (–53) (at mid-leaf) cm, up to 30 cm wide and up to 15 cm thick at the base, dark green, slightly glaucous, cross-banded on both faces, margins frequently repand, distinctly crenate in the middle to closely dentate at the ends, with prominences 4–6 × 5–19 mm; **marginal teeth** flattened, mostly straight, some curved towards the base, mostly 2–5 (–7) mm, 5–17 (–22) mm apart, dark brown to red-brown, tips from very broad bases 5–9 (–12) mm, intermittent teeth few or none; **terminal Sp** usually short and conical, robust, 10–15 (–20) mm, dark to red-brown, rarely shortly

decurrent; **Inf** 5–6 (–7) m, paniculate, peduncle very thick, 12–35 cm Ø at the base, with scarious triangular **Bra** variable in size, ±15 cm apart, fertile part with 25–40 part-**Inf**, straight, diffuse, flat-topped, in the upper ½ of the inflorescence; **Ped** 5–10 mm; **Fl** 50–60 (–70) mm; **Tep** brilliant yellow, tube somewhat funnel-shaped, 5–7 × 10 mm, lobes linear, fleshy, erect, 10–13 × 4–5 mm, yellow, apex galeate; **Fil** slender, 34–38 mm, yellow, inserted 2–4 mm above the tube base; **Ov** proper 18–27 × 4–5 mm, light green, neck 3–5 mm, strongly constricted; **Sty** finally longer than the filaments; **Sti** capitate; **Fr** oblong, 23–29 × 10–13 mm, slenderly stipitate, beak short; **Se** triangular, but curved to one side, flat, membranous, 3–4.5 × 2–3 mm, black.

A “gigantic” species placed in Sect. *Marmoratae*, with which it shares most of its distinctive characteristics, except the much larger size. It may be closest to *A. marmorata*, which shares a robust habit, leaves much wider in the middle than towards the tip, cross-banded on both faces, and marginal teeth >15 mm apart, but differs from the latter in its much larger size with fewer but longer and wider leaves, and smaller spines, teeth, and fruits. The authors consider *A. valenciana* to possibly have potential for the production of “raicilla” (an alcoholic tequila-like beverage), and mature “heads” (stems) of the species weigh > 350 kg, which is at least 3 × heavier than for *A. tequilana*. Magaña-González & al. (2007) found 3 species of hummingbirds and 3 perching birds as diurnal and 4 bats (3 nectarivorous, 1 insectivorous) as nocturnal flower visitors and argue that the hummingbirds are the main pollinators.

**A. variegata** Jacobi (Hamburg. Gart.- & Blumenzeit. 21: 459–462, 1865). **Type**: not typified. — **Lit**: Rose (1903c: 20–21); Small (1903: 288); Berger (1915: 34–35, with ills.); Verhoek-Williams (1975: 192–205); Piña Luján (1985: 61–62); Reveal & Hodgson (2002); Castillejos-Cruz (2009: [294]–[299], with ills.); all as *Manfreda* except Berger. **Distr**: USA (S Texas), Mexico (Nuevo León, Tamaulipas, E San Luis Potosí, N Hidalgo, C Veracruz, Puebla); dry chaparral sites, on slopes, or between rocks, and in moist oak, thorn and tropical deciduous and (semi-)

evergreen rain forests and desert scrub, 10–2000 m; flowers February to June. **I:** Refug. Bot. t. 326, 1872; Addisonia 17: t. 569, 1932; Rodríguez & Castro-Castro (2007: 7, 9); Richardson & King (2011: 19); Hochstätter (2016: I: 45); the last 4 as *Manfreda*.

≡ *Manfreda variegata* (Jacobi) Rose (1903)  
 ≡ *Polianthes variegata* (Jacobi) Shinnery (1966);  
**incl.** *Manfreda tamazunchalensis* Matuda (1966);  
**incl.** *Manfreda xilitlensis* Matuda (1966).

[3a1] Herbaceous; corm 3–6.2 (–7) × 2–3 cm, subglobose to subcylindrical, bulb (1–) 1.5–3.5 × 3–3.2 cm, subcylindrical to ovoid, apically covered with dried membranous leaf bases 6–8 cm long; **R** fleshy and thickened, with filiform ramifications, contractile; **L** drought-deciduous, 6–8 (–16), spreading to slightly ascending, lanceolate to linear-lanceolate, long-attenuate towards the apex, succulent, canaliculate, somewhat wavy, glabrous on both faces, apex acute, soft, 15–45 × 2.2–3.5 cm, light green to glaucous, with many dark green or purple round to oval dots to 1 × 0.5 cm, margins conspicuously denticulate on a cartilaginous hyaline band, denticles of various sizes, irregularly spaced, some retrorse; **Inf** 50–110 (–170) cm, erect, green-glaucous, ‘spicate’, peduncle robust, **Bra** 10–13, base truncate, lower ones similar to the leaves, decreasing in size abruptly in the fertile part, fertile part 15–20 (–30) cm, lax, with 7–40 flowers; floral **Bra** 0.6–1 × 0.4–0.6 cm; **Fl** 25–35 mm, solitary, sessile, ascending to spreading; **Tep** green-glaucous on the outer face, reddish-green to brown on the inner face, perianth as a whole broadly funnel-shaped to campanulate, tube 7–11 × 6–9 mm, constricted near the apex of the ovary, lobes oblong, reflexed to revolute, keeled on the outer face, (7–) 10–13 (–16) mm, tip slightly broadened to acute, with a bundle of short white trichomes; **Fil** 35–70 (–90) mm, ± spreading at anthesis, exceeding the tube for 30–65 (–85) mm, inserted 2–3 mm below the mouth of the tube all on the same level, greenish-red, with multiple purple dots all over the surface; **Anth** 8–12 mm, reddish to brownish; **Ov** ellipsoid to slightly obclavate, (9–) 12–15 × 4–5 mm, greenish, constricted above for ±3 mm; **Sty** 44–66 (–95) mm, elongating during anthesis, reaching the level of the anthers,

green or mahogany-brown; **Sti** capitate, 3-lobed, papillate; **Fr** cylindrical to subellipsoid, 17–26 × 13–18 mm, apiculate for 2 mm, tepals persisting; **Se** deltoid, plane-concave, 4–6 × 4 mm, dull.

Notable within Sect. *Herbaceae* for its succulent, minutely toothed and often spotted leaves, its tall inflorescence stalks, and flowers with short campanulate tubes and long-exserted stamens and styles (Verhoek-Williams 1975: 194). *A. variegata* is close to *A. sileri*, which was first treated as a variety of it (Verhoek-Williams 1975: 205), and morphologically similar to the recently published *A. umbrophila* (see there). The species is cultivated as ornamental in Yucatán (Castillejos-Cruz 2009), but previous records of the species from Yucatán may also relate to either *A. petskinil* or *A. paniculata* (see there). In Texas used against snakebites (Piña Luján 1985, Castillejos-Cruz 2009). Plants from the Cañon del Sumidero (Chiapas) referred here (Espinosa-Jimenez & al. 2011: 46) may be misidentified or represent a new record. ‘Macho Mocha’ is a hybrid with *A. mitis* (as *A. celsii*; Klein (2010), as ×*Mangave*).

**A. vazquezgarciae** Cházaro & J. A. Lomeli (Novon 16: 459–460, ills., 2006). **Type:** Mexico, Jalisco (*Cházaro-Basáñez & Vázquez-García* 8172 [IBUG, GUADA, IEB, MEXU, MO, WIS, XAL, ZEA]). — **Lit:** Hernández-Vera & al. (2007a); Cházaro Basáñez & al. (2008a: with ills.); Cuevas Guzmán & al. (2012). **Dist:** Mexico (W Jalisco: N slopes of the Sierra de Manantlán and adjacent mountain chains, N Colima); on cliffs and slopes, in pine-oak forests mixed with mesophytic elements (ecotone to cloud forests), 1550–2100 m; flowers November to February. **I:** Richter (2011: 57); Etter & Kristen (2012: 88–89); Pilbeam (2013: 229); Hochstätter (2015: VIII: 26).

[1b] Acaulescent; **Ros** open, symmetrical, (0.9–) 1.7–1.8 × (0.6–) 1–1.2 m, solitary; **L** 70–80, lanceolate or narrowly elliptic, indurate, base gradually narrowed, acuminate, with a sigmoid shape 8–9 cm below the apex, 40–91 × 9.5–16.8 cm, pale green to glaucous, margins straight; **marginal teeth** 0.5–3 × 3.5–4 (at the base) mm, brown, 2 teeth per cm; **terminal Sp** subulate, stout, 40–65 mm, reddish to dark brown or

blackened; **Inf** erect, 5–7 m, ‘spicate’, peduncle with linear coriaceous **Bra** 4.4–10.5 × 0.2 (at the base) cm, fertile part in the upper  $\frac{2}{3}$  of the inflorescence, 25–30 cm Ø; **Ped** 5–14 mm; **Fl** geminate, 52–94 mm; **Tep** greenish-yellow, tube funnel-shaped, 6–10 × 3–6 mm, lobes erect or ascending, 16–22 × 5–6 mm; **Fil** 40–72 mm, inserted at the tube apex; **Ov** 13–27 × 5–7 mm, neck slightly constricted; **Sty** 49–77 mm, equal to or longer than the stamens; **Fr** geminate or towards the inflorescence tip solitary by abortion, oblong-obovoid, 18–24 × 10–13 mm, pale brown, slightly apiculate; **Se** crescent-shaped, 3–4 × 2–3 mm.

Placed in Sect. *Inermes* (as Group *Amolae*) in the protologue due to its densely flowered ‘spike’, ascending to partly outcurving tepal lobes, and the shallow tepal tube much shorter than the lobes. It is closely related to *A. attenuata* ssp. *dentata* with which it shares the acaulescent habit and shallow tepal tube, and the repeated flowering with so-called “lateral” inflorescences which are actually likely terminal on rudimentary rosettes. Some of the material now assigned to *A. vazquezgarciae* was previously referred to *A. attenuata* ssp. *dentata* (as *A. pedunculifera*) by Gentry (1982), McVaugh (1989) and Vázquez-García & al. (1995). According to the protologue, its vernacular names are “cola de zorra” or “lechuguilla”. Fried flower buds are eaten as “bayusas” (Etter & Kristen 2012: fig. 20). Padilla Velarde & al. (2008: 68) provide a new record for N-most Colima.

**A. venustuliflora** (E. Solano & al.) Thiede & Gideon F. Smith (Bradleya 37: 263, 2019). **Type:** Mexico, Michoacán (*Solano & Ríos Gómez* 1793 [MEXU, CHAPA, FEZA, IEB, MO, UAMIZ]). — **Distr:** Mexico (N Michoacán); in disturbed pastures, farmlands or their margins, and in desert scrub, 1785–2080 m; flowers July to August; only known from 2 localities.

≡ *Polianthes venustuliflora* E. Solano & al. (2019).

[3b1] Herbaceous; corm 1.4–3 × 0.7–1.2 cm, oblong, bulb 2–4 × 1–2 cm, ovoid, covered with dried fibrous leaf bases; **R** fleshy, thickened, contractile; **L** drought-deciduous, 3–7 (–9), ±

ascending, linear, glabrous, apex acute, 12–35 (–40) × 0.2–0.4 cm, green, usually with purple dots at the base, margins papillose to regularly denticulate; **Inf** 24–65 (–68) cm, erect, ‘spicate’, greenish, peduncle with ±3 **Bra**, lowest 7–22 cm, bracts and internodes decreasing in size distally, fertile part ±2.5 cm, lax, with 3–7 remote floral nodes; floral **Bra** ovate, apex long acuminate; **Ped** none; **Fl** geminate, fragrant, 19–28 mm, ascending to diffuse; **Tep** white, pink after anthesis, the base ascending, forming a tube curved ± in the middle, narrowly infundibuliform, distal portion campanulate, tube ±15–24 × 2–4 mm at the base of the lobes, mouth irregular, lobes equal, elliptic or oblong, recurved, 4–7 × 1.5–3 mm, apex rounded or obtuse, with a bundle of inconspicuous white trichomes; **Fil** filiform, 1–3 (–7) mm, included, inserted 10 mm above the base of the tube, white; **Anth** oblong, 4–6 mm, slightly surpassing the tube; **Ov** ±5 × 2 mm; **Sty** filiform, 15–27 mm, included; **Sti** 3-lobed; **Fr** semiglobose, 11–18 × 6–10 mm, tepals persisting; **Se** semicircular, flat, 3.5–4 × 2.5–3 mm, shiny.

According to the protologue related morphologically to *A. rosei* (as *Polianthes montana*) and *A. platyphylla* (as *Polianthes*), but differing from the former esp. in having more and narrower leaves, with shorter inflorescences and ascending to diffuse flowers with smaller, reflexed lobes and shorter filaments, and larger fruits, and from the latter in its longer and narrower leaves with papillose to denticulate margins, inflorescences with fewer floral nodes, flowers with larger lobes, and longer styles. The inflorescences are locally sold on markets for ornamental and ceremonial purposes. — Classified in the IUCN Red List Category “Critically Endangered”. For the ecological niche modeling, see Solano & Feria (2007).

**A. verdensis** W. C. Hodgson & Salywon (Brittonia 65(1): 6–9, ills., 2013). **Type:** USA, Arizona (*Hodgson & Salywon* 25495 [DES, ASC, ASU, MO, NY]). — **Lit:** Parker (2018a: 22, 26, with ills.). **Distr:** USA (C Arizona); on rocky, limestone, sandstone or clayey-loamy igneous derived soils, in semi-arid desert grassland to

pinyon-juniper woodland, 1050–1350 m; flowers late June to mid-July. **I:** Hochstätter (2015: III: 8); Parker (2018b: 105).

[2h] **Ros** 50–60 × 50–60 cm, open, freely offsetting via rhizomes, forming clones of few to many rosettes; **L** numerous, short-lanceolate to short-oblongate, erect-spreading, firm, acuminate, guttered, broadest at, just below, or just above the middle, 28–42 (–47) × 5.5–10 (–13) cm, glaucous-grey, tinged with maroon distally; **marginal teeth** strongly deflexed, occasionally porrect, recurved, or upturned, esp. along the distal 1/3 of the leaf, firmly attached, grey, brown, dark mahogany to brown-black, closely set, intermittent teeth (0–) 2–8 along the distal 2/3 of the leaf; **terminal Sp** 18–34 mm, grey to dark grey-mahogany-brown, decurrent; **Inf** 4.5–6 m, narrowly paniculate, peduncle maroon-green-glaucous, part-**Inf** 17–20, horizontally spreading to ascending, 13.5–17 cm, maroon-glaucous to purplish, in the upper 2/3 of the inflorescence, with 15–49 flowers; **Fl** 42–57 mm, with a sweet-musky fragrance at anthesis; **Tep** tube thick, bulging at the base of the tepal lobes, 13–15 × 12–15 mm, light green to cream, lobes persistently erect, leathery with age, slightly unequal to subequal; **OTep** 7.8–11.5 mm, light cream-light yellow, with conspicuous brown papillose cucullate tips; **ITep** 7–10.2 mm, light cream with less cucullate and lighter tip, strongly keeled, with white ciliate hairs within the tips; **Fil** 31–49 mm, (light green-) cream to cream-yellow, subequally inserted 5.7–8.7 mm above the tube base; **Ov** 18–28 × 4–7.5 (–10) mm, light green, neck 4.5–7 mm, light green-cream; **Sty** 32–47 mm, longer than the tepals, (light green) cream-yellow; **Sti** capitate; **Fr** only produced on the uppermost part-inflorescences, linear-oblong to obovoid, (26–) 32–39 × 14–22 mm, with short beak, stipe 1–4.5 mm; **Se** only few viable per fruit, crescent-shaped, rugose, 6.5 × 5 mm, dull black, with narrow marginal wing. — **Cytology:** 2n = 60 (protologue).

According to the protologue, the species represents a pre-Columbian cultivar showing affinities with *A. chrysantha*, *A. shrevei* and *A. delamateri*, the latter representing another such cultivar.

Leaf shape and colour of *A. verdensis* suggests a small *A. delamateri*, which is difficult to distinguish as a young plant, but the latter differs in rosette and flower characters and ploidy level, and both also hybridize (Parker 2018a: 26). According to the protologue, *A. verdensis* occurs sympatrically with *A. delamateri*, *A. phillipsiana*, *A. parryi* and *A. chrysantha* and may represent a specialized, regionally domesticated plant developed by prehistoric Verde Valley farmers.

**A. verhoekiae** (García-Mendoza) Thiede (Haseltonia 17: 94, 2012). **Type:** Mexico, Oaxaca (García-Mendoza & Mérida 2551 [MEXU]). — **Lit:** García-Mendoza (2011a: 79–82); García-Mendoza (2011b: 754–756); both with ill., as *Manfreda*. **Distr:** Mexico (Oaxaca, C Veracruz); open spots in pine-oak forests and desert scrub, 2200–2400 m; flowers July to September. **I:** Hochstätter (2016: I: 46, as *Manfreda*).

≡ *Manfreda verhoekiae* García-Mendoza (2011).

[3a3] Herbaceous; corm 9–25 × 2–3 cm, cylindrical, bulb 7–12 × 4–6 cm, cylindrical, covered with fibrous dry leaf bases; **R** fleshy and thickened, contractile; **L** drought-deciduous, 4–6, erect or diffuse, linear-lanceolate, narrowing at the base, semisucculent, cartilaginous, leaf veins on the upper part of the lower face papillate, tip acute, (30–) 40–55 × 2.5–4 cm, glaucous or green-yellowish, margins minutely denticulate on a hyaline band, with papillae between the denticles; **Inf** (1.5–) 2–2.5 m, erect, ‘spicate’, peduncle greenish, with 7–10 **Bra**, the lower ones similar to the leaves, the upper deltoid, fertile part with 12–20 solitary densely arranged flowers in the uppermost 6–9 cm of the inflorescence; floral **Bra** 0.5–1 × 0.2–0.5 cm; **Fl** 30–35 mm, sessile, ascending; **Tep** greenish or green-yellowish, sometimes with purple tinge, forming a tube 13–16 × 9–10 mm, yellowish-green, lobes oblong, revolute, 7–10 × 2–4 mm; **Fil** 30–38 mm, erect or ± spreading at anthesis, exceeding the tube by far, inserted at mid-tube all on the same level, yellowish-green with purple dots; **Ov** cylindrical, 8–10 × 2–3 mm, glaucous, not constricted, apex prolonged into the tepal tube; **Sty** 50–60 mm, surpassing the filaments; **Sti** 3-lobed; **Fr** ellipsoid to oblong, 20–25 × 13–15 mm, tepals persisting;

**Se** crescent-shaped, plane-concave, 4–5 × 4–5 mm, black.

According to the protologue, the species belongs to Ser. *Guttatae* of Sect. *Herbaceae* (as *Manfreda guttata*-Group) and is morphologically most similar to *A. debilis*, which differs in much shorter corms, narrower, linear-lanceolate, dark brown and glabrous leaves without prominent veins, a shorter inflorescence with green-yellowish to purple flowers, and its stoloniferous growth. Rivera-Hernández & al. (2019, as *Manfreda*) provide a new record from C Veracruz.

**A. vicina** Trelease (Mem. Nation. Acad. Sci. 11: 19, tt. 4, 10, 1913). **Type** [syn]: Aruba (*Boldingh* 3&5 [MO]). — **Lit**: Boldingh (1913: 150–151); Boldingh (1914: 18); Hummelinck (1936: 231–236, 247–248, tt. 1–2, as *A. vivipara*); Hummelinck (1938: 16–19, tt. 2–3, as *A. vivipara*); Hummelinck (1993: 6–10, 219, 223, with ills., as *A. vivipara*); **Dist**: Leeward Antilles (Aruba, Bonaire, Curaçao); coral rocks and debris of it, limestone and igneous rocky hillsides, to 350 m; flowers March to May. **I**: Richter (2011: 97); Pilbeam (2013: 230); Thomson (2014: 176–177); Hochstätter (2016: VII: 49).

**Incl.** *Agave vivipara* var. *cabaiensis* Hummelinck (1936); **incl.** *Agave vivipara* var. *cuebensis* Hummelinck (1936).

[2u] Nearly acaulescent; **Ros** ±1–1.2 m Ø, suckering; **L** very broadly lanceolate, sub-acuminate, flatly concave, (17–) 40–80 (–100) × (5–) 12–20 cm, somewhat transiently glaucous, with age rather glossy green, margins a little concave between the teeth; **marginal teeth** commonly upcurved in the upper ½ of the lamina and recurved in the lower ½, slender from crescent-shaped bases, (2–) 4–8 (–12) mm, (4–) 10–20 mm apart, often on green prominences; **terminal Sp** triquetrously acicular, somewhat flexuous, narrowly round-grooved to the middle and involute below, smooth, polished towards the tip, (12–) 15–25 (–36) × 2–6 mm, red-brown, shortly decurrent; **Inf** (2–) 2.5–4 (–6) m, paniculate, narrowly oblong, with broadly triangular imbricate **Bra**, fertile part with part-**Inf** on ascending branches in the upper ½–½ of the inflorescence, freely bulbiferous; **Ped** 3–8 mm; **Fl**

40–60 mm; **Tep** yellow, tube open, 3–6.5 mm, greenish-yellow, lobes 12–22 × 4–6 mm; **Fil** 23–37 mm, greenish-yellow, inserted 1 mm above to 1 mm below the tube throat; **Anth** 12–21 mm, yellow; **Ov** oblong, (20–) 23–27 (–37) × 6.5–7 mm, yellowish-green; **Sty** 38–48 mm; **Fr** broadly oblong, 25–45 × 14–19 mm, usually slightly stipitate, slightly or not beaked; **Se** unknown.

Hummelinck (1936) wrongly used the name *A. vivipara* L., the earliest name for a Caribbean species in the genus, for this plant. According to Wijnands (1983: 35), *A. vivipara* represents the oldest name for the widespread continental taxon previously referred to as *A. angustifolia*, and this view was followed in the first edition of this handbook. However, García-Mendoza & Chiang (2003) showed that *A. angustifolia* and *A. vivipara* are two distinct species and re-established the former in the sense used by Gentry (1982), and the latter for the Caribbean species previously known under that name. *A. vicina* is the oldest available binomial that clearly refers to the Caribbean plants in question here. See also the note for *A. cocui*.

According to Hummelinck (1936: 243), only one (*Boldingh* 3) of the two syntypes cited in the protologue belongs here (and the other, *Boldingh* 5, is probably *A. ruteniae*). The varieties that Hummelinck published 1936 were later synonymized with the species as mere “extreme forms in the range of variability” by Hummelinck (1938: 17). Plants from Isla Margarita (Venezuela) placed here need verification as to their identity (Hummelinck 1993: 10).

**A. victoriae-reginae** T. Moore (Gard. Chron., ser. nov. 4(94): 484–485, fig. 101, 1875). **Type**: [lecto — icono] l.c. fig. 101. — **Lit**: Gentry (1982: 183–185); Ullrich (1991g); García-Mendoza (2003); Aalsemgeest & al. (2007a); González-Elizondo & al. (2011); Martínez-Palacios & Eguiarte (2011); Thiede (2011); Roosbroeck (2012); Starr (2012: 280–285); all with ills. except García-Mendoza (ill. is of *A. nickelsiae*). **Dist**: Mexico (S Coahuila, NW & W-C Nuevo León, NE Durango). **I**: Ettl (2014: 121); Hochstätter (2015: IX: 52, 53, 56, 57); Walker (2017).

**Incl.** *Agave victoriae-reginae* var. *candida* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave victoriae-reginae* var. *dentata* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave victoriae-reginae* var. *elongata* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave victoriae-reginae* var. *latifolia* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave victoriae-reginae* var. *punctata* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave victoriae-reginae* var. *striata* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a); **incl.** *Agave victoriae-reginae* var. *viridis* Hort. Besaucèle ex A. Berger (1915) (*nom. inval.*, ICN Art. 36.1c/38.1a).

The lectotype cited above was designated by Ullrich (1991e) and supersedes the neotype designated by Gentry (1982: 184), which belongs to *A. nickelsiae* and thus would have changed the application of the name. For the population genetics of the *A. victoriae-reginae*-complex, see Martínez-Palacios & al. (1999). The history and horticultural importance was summarized by Thiede (2011).

**A. victoriae-reginae** ssp. *swobodae* Halda (Acta Mus. Richnov. Sect. Nat. 7(2): 71, 2000). **Type:** Mexico, Coahuila (*Halda* 8504315 [PR]). — **Lit:** González-Elizondo & al. (2009: 132–136, as *A. victoriae-reginae* [NE Durango]); González-Elizondo & al. (2011: 76–78, figs. 1b, 2, 3b); Thiede (2011: 149–150); all with ills. **Distr:** Mexico (S Coahuila, NE Durango); calcareous slopes, rarely on plateaus, in desert scrub, 865–1550 m. **I:** Alsemgeest & al. (2007a: 63, as *A. victoriae-reginae* compacte vorm); Roosbroeck (2012: 163); Hochstätter (2015: IX: 53).

**Incl.** *Agave victoriae-reginae* ‘Compacta’ hort. (s.a.); **incl.** *Agave victoriae-reginae* fa. *compacta* hort. (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Agave victoriae-reginae* var. *compacta* hort. (s.a.) (*nom. inval.*, ICN Art. 29.1).

[lg] Differs from ssp. *victoriae-reginae*: **Ros** 20–35 × up to 35 cm, compact, oblong-globose to subcylindrical when mature; **L** 70 to ±180,

narrowly oblong to narrowly triangular, 6–12 × 1.5–4.5 cm, flat above to concave at the base, margin often separating distally in dried leaves; **Tip** inside rosy-white or reddish, tube greenish-white; **Fil** pale rose-purple; **Anth** pale yellow; **Sty** pale rose-purple; **Fr** narrowly oblong, 17–19 × 7–9 mm; **Se** 3 × 2 mm.

Plants belonging here are apparently known since Trelease (1920) indicated occurrences of “*A. victoriae-reginae*” in Nuevo León, Coahuila and Durango (see Thiede (2011)). The first specimen was not collected until 1985 by J. J. Halda who subsequently published the subspecies based on material from Parras de la Fuente, Coahuila. The protologue erroneously indicates that flowers and seeds are larger than in ssp. *victoriae-reginae*, but the flowers fall within the range of the latter and the seeds are much smaller (González-Elizondo & al. 2011: 77). Alsemgeest & al. (2007a) also recognized the plants as a distinct “compact form from Coahuila and Durango”. Plants traded as *A. victoriae-reginae* var./fa. *compacta* or ‘Compacta’ appear to belong here.

**A. victoriae-reginae** ssp. *victoriae-reginae* — **Lit:** Breitung (1960: 35–38); Gentry (1982: 183–185); Ullrich (1991g); García-Mendoza (2003); Alsemgeest & al. (2007a: as ‘vierde vorm Huasteca Canyon’); González-Elizondo & al. (2011: 73–76, figs. 1a, 2, 3a); Martínez-Palacios & Eguiarte (2011); Thiede (2011); Roosbroeck (2012); Starr (2012: 280–285); all with ills. **Distr:** Mexico (NW & W-C Nuevo León), on much inclined, often vertical, calcareous slopes, in desert and submontane scrub, 565–1685 m. **I:** Irish & Irish (2000: tt. 47, 48); Heller (2006: 145, 163); González (2008); Pilbeam (2013: 231–232, as fa. *victoriae-reginae*); Ettelt (2014: 121); Hochstätter (2015: IX: 52, 56, 57); Walker (2017). – Fig. 61.

Breitung (1960); **incl.** *Agave victoriae-reginae* fa. *longispina* Breitung (1960); **incl.** *Agave victoriae-reginae* fa. *ornata* Breitung (1960) (*nom. inval.*, ICN Art. 40.1); **incl.** *Agave victoriae-reginae* fa. *stolonifera* H. Jacobsen (1960) (*nom. inval.*, ICN Art. 40.1).

[lg] Acaulescent or with short invisible stem; **Ros** (20–) 30–65 × 60 cm, compact, globose or depressed-globose, solitary, sometimes caespitose, rarely surculose; **L** (150–) 280 to ±500, lanceolate or narrowly oblong, rigid or rarely flexible, densely imbricate, tip truncate or rounded, rarely acute, keeled or rarely rounded below, sometimes nearly triangular in cross-section, conduplicate or concave above except at the thickened base, (7–) 10–22 × 3.6–4.8 cm, green to lemon-green with conspicuous narrow white bands on both faces and along the margins, margins horny, white or grey, entire, continuous over the whole length, 1–3 mm wide; **marginal teeth** none; **terminal Sp** 1, straight or curved, from very short and mucroniform to subulate and acicular, rarely lanceolate, at the base broadened or narrow, 4–18 mm, furrowed or channelled above, coffee-brown, dark grey or nearly black, often accompanied by 1–3 small denticles; **Inf** ascending or erect, 1.6–4.3 m, ‘spicate’, with several chartaceous deltoid **Bra**, densely flowered in the upper ½, part-**Inf** with (2–) 3 flowers; **Ped** short, thick; **Fl** 39–53 mm; **Te** 26–36 mm, cream-white or greenish-white,

sometimes tinged reddish, tube funnel-shaped, 3–5 × 7–9 mm, lobes erect, subequal, broadly linear, 10–19 × 3–4 mm; **Fil** 20–48 mm, inserted above the throat of the tube; **Ov** thickly fusiform, 13–17 mm, neck short; **Fr** oblong to narrowly oblong, (13–) 17–21 × 7–11 mm, shortly beaked; **Se** 4 × 2–3.5 mm, black, dull or shiny. — **Cytology**: 2n = 60, 120 (Simpson & al. 2011).

A recent study of the *A. victoriae-reginae* complex by González-Elizondo & al. (2011) recognized 4 taxa: *A. victoriae-reginae* with 2 subspecies, the re-established *A. nickelsiae* (better known as *A. ferdinandi-regis*), and the completely new *A. pintilla*. *A. victoriae-reginae* has compact rosettes with densely imbricate, green to lemon-green leaves and a small terminal spine. In contrast, *A. nickelsiae* and *A. pintilla* both have open to subcompact rosettes with greyish-green to pale green or bluish-green leaves and larger flowers. *A. nickelsiae* is characterized by 80–170 grey-green to dull green, puberulent, oblong leaves with a strong, decurrent terminal spine, in contrast to the similar, but smaller *A. pintilla* with 60–180 green to bluish-grey-green, narrowly triangular, not puberulent leaves with a not or hardly decurrent terminal spine.

Earlier authors such as Ortgies, Engelmann, Baker, and Berger knew only the “classical” localities of ssp. *victoriae-reginae* near Monterrey, esp. at Huasteca Canyon (Thiede 2011), but the subspecies is more widespread in NW and W-C Nuevo León (González-Elizondo & al. 2011).

Previous reports of natural hybrids of *A. victoriae-reginae* relate in fact to hybrids of *A. nickelsiae* (see there). Thiede (2011) provided the first report of a putative natural hybrid of *A. victoriae-reginae* ssp. *victoriae-reginae* with *A. lechuguilla*. — ‘Kazo Bana’, ‘Snowburst’, and ‘White Rhino’ are variegated cultivars (Starr 2012: 285), and ‘Himesanoyuki’ is a miniature cultivar (Starr 2014: 221, with ill.).

**A. ×villarum** André (Rev. Hort. (Paris) 58: 465–466, 1886). **Type**: not typified. — **Lit**: Berger (1912: 365, as *A. villarum*); Trelease (1914: 237–238); Berger (1915: 74, as *A. villarum*). **Distr**: Cultivated only.

**Incl.** *Agave ×villae* Pirotti ex Baker (1892) (*nom. inval.*, ICN Art. 61.1).

[1d × 1g] According to the protologue a garden hybrid *A. filifera* × *A. xylonacantha* raised by the Villa brothers, nurserymen at Cornigliano (Italy). Apparently no longer extant in cultivation. “*A. villae* Pirotti” is placed in *A. kerchovei* by Baker (1892: 2), but is placed here by Gentry (1972: 74).

**A. vilmoriniana** A. Berger (Repert. Spec. Nov. Regni Veg. 12: 503, 1913). **Type** [neo]: Mexico, Guadalajara (*Rose & Hough* 4833 [US]). — **Lit**: Berger (1915: 127); Gentry (1942: 94–95, t. 14, as *A. mayoensis*); Gentry (1972: 62–69, with ill.); Gentry (1982: 67, 83–85, with ill.); McVaugh (1989: 145); Turner & al. (1995); Hernández-Vera & al. (2007a); Vázquez-García & al. (2007b: 41–42, t. B); González-Elizondo & al. (2009: 137–139, with ill.); Starr (2012: 286–291, with ill.). **Distr**: Mexico (S Sonora, Chihuahua, Sinaloa, Durango, Zacatecas, Aguascalientes, Jalisco); on volcanic barranca cliffs in tropical deciduous or pine-oak forests, 600–1850 m; flowers March to July. **I**: Irish & Irish (2000: t. 49); Etter & Kristen (2001: 180–183); Etter & Kristen (2003a: 3, 6); Heller (2006: 146); Richter (2011: 49); Etter & Kristen (2012: 92–93); Pilbeam (2013: 234); Hochstätter (2015: VIII: 17, 27); Moore (2016: 240–241).

**Incl.** *Agave edwardii* Trelease ms. (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Agave eduardii* Trelease (1920); **incl.** *Agave houghii* hort. ex

Trelease (1920); **incl.** *Agave mayoensis* Gentry (1942).

[1b] Stems short; **Ros** ±1 × 2 (–2.6) m, solitary; **L** linear-lanceolate, arching, pliable, deeply guttered, broadest at the base, heavily thickened towards the base, long acuminate, concave to conduplicate above, smooth, 90–180 × 6–10 cm, light green to yellowish-green, margins with a fine brown continuous border ±1 mm wide, scaly with age; **marginal teeth** none; **terminal Sp** acicular, 3–20 mm, brown to greyish-brown; **Inf** 3–5 (–6) m, ‘spicate’, peduncle 1–2 m, with scarious acicular **Bra**, lower **Bra** 10–20 cm, brownish towards the brittle tip, fertile part densely flowered, bulbiferous or not, part-**Inf** with 2–4 (–8) flowers; floral **Bra** deltoid, 2–3 mm; **Ped** 1–2 (–4) × forked, 8–20 mm; **Fl** 35–40 mm; **Tep** yellow, tube open, shallow, 4 × 8–9 mm, lobes ascending to spreading, nearly flat, clasping the filaments when drying, equal, 14–17 × 4–5 mm; **Fil** 30–40 mm, inserted at the upper edge of the tube; **Anth** 16 mm; **Ov** 15–20 mm incl. the 3–4 mm long neck; **Sty** somewhat longer than the tepals but much shorter than the filaments; **Sti** capitate; **Fr** 18–25 × 7–13 mm, beaked for 1–2 mm, somewhat glaucous; **Se** crescent-shaped, 3–4 × 2–3 mm, dull.

A cliff-dweller which may form extensive vertical colonies, distinguished by the unarmed, large, gracefully arching, deeply guttered leaves (“Octopus Agave”). The “lectotype” of Gentry (1982: 82) is in fact a neotype. Gentry (1982) and McVaugh (1989) cite a line drawing most certainly prepared by Berger from the original plant cultivated by Vilmorin and collected by Diguet (US 1023581!). The sheet is listed as “apparently genuine original material” in the US database, but the drawing, dated 20.II.1914, was prepared later than the protologue.

Related to *A. chryso glossa* and *A. ocahui* (see there). Wild populations at higher altitudes experience occasional sharp frosts (Gentry 1982), and cultivated plants may tolerate temperatures down to –9 °C (Turner & al. 1995). The species exhibits substantial diurnal CO<sub>2</sub> assimilation esp. at lower temperatures, unlike other agaves studied (Turner & al. 1995). The flowers are visited by bees, hummingbirds (documented with photographs

by Etter & Kristen (2003a) and Etter & Kristen (2012)) and perhaps bats (Turner & al. 1995). Crushed leaves are used as detergent (bath, shampoo, laundry) and also to stupefy fishes (Turner & al. 1995). — ‘Stained Glass’ is a variegated cultivar (Starr 2012: 289–291); Moore (2016: 241) illustrates an unnamed variegated form.

**A. virginica** Linné (Spec. Pl. [ed. 1], 1: 323, 1753). **Type** [neo]: USA, Virginia (*Clayton* 498 [LINN, BM]). — **Lit**: Verhoek-Williams (1975: 133–181); Diggs & al. (1999: 1079–1081, with ills.); Reveal & Hodgson (2002); Castillejos-Cruz (2009: [300]–[308]); all as *Manfreda*. **Distr**: S and E USA (from Missouri and Texas to the Atlantic), Mexico (Nuevo León, Tamaulipas); flowers June to August.

≡ *Aloe virginica* (Linné) Crantz (1766) ≡ *Manfreda virginica* (Linné) Salisbury ex Rose (1899) ≡ *Polianthes virginica* (Linné) Shinners (1966); ≡ *Agave pallida* Salisbury (1796) (*nom. illeg.*, ICN Art. 52.1).

The species is aberrant in being the only member of Subgen. *Manfreda* occurring in temperate regions, and it is the N-most species in the genus *Agave*. In addition to its distribution, the taxon is easily recognized by its slender green flowers with erect lobes and the style that is shorter than the stamens (Verhoek-Williams 1975: 170, 172). For the typification, see Reveal & Jarvis (2009: 977).

**A. virginica** ssp. **lata** (Shinners) Thiede & Eggl (Kakt. and. Sukk. 52(6): 167, 2001). **Type**: USA, Texas (*Daly* 61 [BRIT/SMU]). — **Lit**: Diggs & al. (1999: 1079–1080, 98 & 1081 ills.); Diggs & al. (2006: 412, 292 & 417: ills.); both as *Manfreda*. **Distr**: USA (S Oklahoma, N-C Texas); mainly in clay soils in the Blackland Prairie (Texas); flowers mid-June to mid-July.

≡ *Agave lata* Shinners (1951) ≡ *Polianthes lata* (Shinners) Shinners (1966) ≡ *Manfreda virginica* ssp. *lata* (Shinners) O’Kennon & al. (1999).

[3a4] Differs from ssp. *virginica*: **L** 4–10, 12–18 × (2–) 3–8 (–10) cm, 3–6 × as long as broad; **Inf** peduncle near the base 6–10 mm Ø, 3–5 mm Ø at the base of the fertile part; **Fl** 26–35 mm; **Tep** lobes 2.5–3 mm wide at the base; **Anth** 13–17 (–20) mm.

Verhoek-Williams (1975), and later Reveal & Hodgson (2002) and Castillejos-Cruz (2009: [300]) included this taxon in the synonymy of the widespread and variable *Manfreda virginica*. Diggs & al. (1999) re-emphasized the clear, albeit overlapping differences between *A. lata* and *A. virginica*, and recognized the former at subspecies rank (as *Manfreda*).

**A. virginica** ssp. **virginica** — **Lit**: Mulford (1896: 68–70, t. 26); Rose (1903c: 19); Small (1903: 287); Berger (1915: 32–33); Verhoek-Williams (1975: 133–181); Piña Luján (1985: 57–58); Diggs & al. (1999: 1079–1080, 1081, ills.); Reveal & Hodgson (2002); Diggs & al. (2006: 412–413, 417: ills.); Castillejos-Cruz (2009: [300]–[308]); all as *Manfreda* except Mulford and Berger. **Distr**: S and E USA (Missouri, Illinois, Indiana, Ohio, Kentucky, West Virginia, Virginia, Oklahoma, Arkansas, Tennessee, North Carolina, Texas, Louisiana, Mississippi, Alabama, Georgia, South Carolina, Florida), Mexico (Nuevo León, Tamaulipas); open wooded areas, on rocky and sandy soils (USA), in pine-oak, oak, and tropical (sub-)deciduous forests, desert scrub and grasslands (Mexico), 100–600 m; flowers mid-July to mid-August. **I**: Curtis’s Bot. Mag. 29: t. 1157, 1809; Hochstätter (2016: I: 6, 47, as *Manfreda*).

**Incl.** *Aloe caroliniana* Hill (1768); **incl.** *Agave conduplicata* Jacobi & C. D. Bouché (1865) ≡ *Agave virginica* var. *conduplicata* (Jacobi & C. D. Bouché) A. Terracciano (1885) ≡ *Manfreda conduplicata* (Jacobi & C. D. Bouché) Rose (1903); **incl.** *Agave virginica* var. *polyantha* Engelm. (1875); **incl.** *Agave virginica* var. *tigrina* Engelm. (1875) ≡ *Manfreda tigrina* (Engelm.) Small (1903) ≡ *Manfreda virginica* var. *tigrina* (Engelm.) Rose (1903) ≡ *Agave virginica* fa. *tigrina* (Engelm.) E. J. Palmer & Steyermark (1935) (*nom. inval.*, ICN Art. 35.1) ≡ *Agave tigrina* (Engelm.) Cory (1936) ≡ *Polianthes virginica* fa. *tigrina* (Engelm.) Shinners (1966); **incl.** *Allibertia intermedia* Marion (1882); **incl.** *Agave alibertii* Baker (1883) ≡ *Manfreda alibertii* (Baker) Rose (1903); **incl.** *Agave virginica* Baker (1883) (*nom. illeg.*, ICN Art. 53.1).

[3a4] Herbaceous; corm 3–5 × 2–2.5 cm, cylindrical, bulb 1.5–2.3 × 1.3–2 cm, ovoid, covered with dried membranous leaf bases 1.8–4.5 cm long; **R** fleshy and thickened, with filiform ramifications, contractile; **L** drought-deciduous, 8–10, spreading to slightly ascending, lanceolate to oblanceolate, somewhat wavy, succulent to semi-succulent, canaliculate, glabrous on both faces, apex acute with a soft tip, (12–) 15–45 × 1.2–4.5 (–6.5) cm, 7–15× as long as wide, light green, sometimes with reddish to purple dots, conspicuously denticulate on a hyaline cartilaginous band, denticles of various sizes and irregularly spaced; **Inf** (50–) 90–150 (–180) cm, erect, glaucous green, ‘spicate’, peduncle 4–7 mm Ø at the base, 1.5–3.5 mm Ø at the base of the fertile part, with 8–10 **Bra**, **Bra** base truncate, lower similar to leaves, the upper decreasing in size abruptly in the fertile part, fertile part 15–68 cm, lax, with 10–60 flowers; floral **Bra** 0.7–1.2 × 0.3–0.5 cm; **Fl** (17–) 22–23 mm, solitary, sessile, ascending to spreading; **Tep** glaucous-green to yellowish-green, forming a tube 11–15 × 3–4 mm, constricted near the apex of the ovary, lobes deltoid, erect, 4–8 × 1.5 mm, tip obtuse, with a bundle of short white trichomes; **Fil** 27–35 (–40) mm, erect at anthesis, exceeding the tube for 18–30 mm, inserted near the base of the tube on slightly different levels, yellowish-green, with multiple purple dots on the entire surface; **Anth** 8–12 mm, yellow with reddish to brownish dots; **Ov** ellipsoid to cylindrical, 6–10 (–12) × 3–4 mm, greenish, prolonging slightly into the tube, slightly constricted above; **Sty** 27–33 mm, elongating during anthesis, almost reaching the level of the anthers; **Sti** capitate, 3-lobed; **Fr** globose to ellipsoid, 10–14 (–17) × 10–13 (–16) mm, apiculate, tepals persisting; **Se** deltoid, plane-concave, 3–4 × 3 mm, dull. — **Cytology**: n = 30 (McKelvey & Sax 1933, Verhoek-Williams 1975).

Due to its wide distribution, the species presents great morphological variation which is mainly manifested in the shape and size of the leaves. Its most distinctive feature are the erect and short tepal lobes only 4–8 mm long, but it can also be distinguished by its fragrant banana-scented flowers (very reminiscent of the scent of

*A. singuliflora*). In addition, its perianth is tubular, thin, green and shorter than stamens and stigma (Castillejos-Cruz 2009).

Nectar and pollen production patterns indicate the species to be primarily adapted to nocturnal pollinators. Nocturnal moths and hawkmoths contribute to most of the seed set, large diurnal bees contribute much less (Groman & Pellmyr 1999). Infusions of the corms were used against snakebites by the native Americans, as is alluded by its vernacular name “rattlesnake master” (Diggs & al. 2006, Castillejos-Cruz 2009). — For the seedling establishment and outdoor cultivation in C Europe (Germany), see Richter (2011) and Werner (2016), both with ills. Lindstrom (2006) raised hybrids with *A. amica* (as *Polianthes tuberosa*) hardy down to –25 °C, subsequently published as ×*Polifreda* ‘Lindstrom’ (Ritchie & Lindstrom 2014).

**A. vivipara** Linné (Spec. Pl. [ed. 1], 1: 323, 1753). **Type**: [lecto — icono]: Commelin, Prael. Bot. 65: t. 15, 1703. — **Lit**: Trelease (1913: 18–19, tt. 1–3); Boldingh (1914: 18); Berger (1915: 223–224); Hummelinck (1936: 244); Hummelinck (1938: 21–23); Hummelinck (1993: 214–217, 223, with ills.); the last 3 all as *A. cocui*; Álvarez de Zayas (1995: 3, figs. 1, 3, 5). **Distr**: Leeward Antilles (Aruba, Bonaire, Curaçao); in secondary formations, often cultivated or naturalized, probably introduced. **I**: Pilbeam (2013: 235).

≡ *Aloe vivipara* (Linné) Crantz (1766) (*nom. illeg.*, ICN Art. 53.1).

[2u] Nearly acaulescent; **Ros** suckering; **L** very broadly lanceolate, subacuminate, flatly concave, 40–60 × 12–20 cm, somewhat transiently glaucous, with age rather glossy green; **marginal teeth** commonly upcurved in the upper ½ of the leaf and recurved in the lower ½, slender from crescent-shaped bases, 3–7 mm, 10–15 mm apart, often on green prominences, intervening margin a little concave; **terminal Sp** triquetrously acicular, somewhat flexuous, narrowly round-grooved to the middle and involute below, smooth, polished towards the tip, 15–30 × 3–5 mm, red-brown, shortly decurrent; **Inf** scarcely 3 m, paniculate, narrowly oblong,

peduncle with broadly triangular imbricate **Bra**, fertile part with part-**Inf** on ascending branches in the upper  $\frac{1}{2}$  or more of the inflorescence, freely bulbiferous; **Ped** scarcely 5 mm; **Fl** 40–45 mm; **Tep** yellow, tube open,  $\pm 4$  mm, lobes  $15\text{--}25 \times 4\text{--}7.7$  mm; **Fil** 30–43 mm, inserted usually 0.5–1 mm below the tube throat; **Ov** oblong, 20–25 mm; **Fr** broadly oblong,  $30 \times 25$  mm, beaked, very shortly stipitate; **Se** unknown. — **Cytology**:  $2n = 58, 60, 120, 180$  (Satô 1935, Simpson & al. 2011).

The concept of *A. vivipara* Linné, the earliest-named *Agave* from the Caribbean, was subject to change over time. Trelease (1913) equated it with naturally occurring plants from Curaçao with small rosettes and flowers and glaucous leaves with slender teeth on small crescent-shaped bases, separating it from his two new species *A. vicina* from Aruba (with small rosettes and flowers and dull green leaves with heavily triangular teeth on small crescent-shaped bases) and *A. cocui* from the Venezuelan coast (with rather large rosettes and flowers). Hummelinck (1936), Hummelinck (1938) and Hummelinck (1993) applied the name *A. vivipara* to Trelease's *A. vicina*, and included Trelease's *A. vivipara* in *A. cocui*, thus extending the area of the latter to Curaçao and neighbouring islands. Wijnands (1983: 35) established *A. vivipara* as oldest name for the widespread continental taxon previously referred to as *A. angustifolia*, which for reasons of priority was renamed as *A. vivipara*, and designated the lectotype cited above. However, García-Mendoza & Chiang (2003) showed that *A. angustifolia* and *A. vivipara* are two distinct species and re-established *A. angustifolia* in the sense of Gentry (1982) and *A. vivipara* in the sense of Trelease (1913). This is followed here. In this sense, *A. vivipara* includes plants from Curaçao and neighbouring islands, which can be differentiated from *A. vicina* as given above. Naturalized in RSA (Smith & al. 2008: 38–39).

**A. vizcainoensis** Gentry (Occas. Pap. Calif. Acad. Sci. 130: 67–69, ill., 1978). **Type**: Mexico, Baja California Sur (Gentry 7469 [UC, ARIZ, CAS 373726, DES, MEXU?, MICH]). — **Lit**: Gentry

(1982: 407–408, with ill.); García-Mendoza (2003); Webb & Starr (2014a: 93–95, with ill.); Webb & Starr (2015: 89–90, with ill.). **Distr**: Mexico (Baja California Sur: Vizcaino Desert); in the mountains and on alluvial fans, in succulent desert and desert scrub, 120–240 m; flowers March to April, also August. **I**: Richter (2011: 79); Pilbeam (2013: 236); Hochstätter (2015: V: 22).

[2k] **Ros** open,  $30\text{--}50 \times 50\text{--}90$  cm, surculose or solitary; **L** 16–20, linear-lanceolate to obovate-lanceolate, thickly fleshy, rather rigid, narrowed above the base, broadest in the middle, acute to attenuate,  $25\text{--}40 \times 6\text{--}10$  cm, glaucous-grey to green, sometimes reddish, with imprints from the central bud, margins repand, horny above; **marginal teeth** nearly straight or curved, slender or broadly flattened, 5–10 mm (middle of the lamina), dark brown to greyish, 10–30 mm apart, on small to distinct prominences; **terminal Sp** stoutly subulate, mostly rather straight, shallowly grooved above, 25–40 mm, brown to greyish, long-decurrent; **Inf** 1.8–3.5 m, paniculate, part-**Inf** spreading, 8–15 in the upper  $\frac{1}{2}$  of the inflorescence; **Ped** stout, 8–12 mm, with small bracteoles; **Fl** 65–75 mm; **Tep** yellow, tube funnel-shaped, bulging at the filament insertions,  $8\text{--}12 \times 15$  mm, lobes linear-lanceolate, obtuse, cucullate, strictly erect at anthesis, involute above the spreading base,  $21\text{--}26 \times 4\text{--}5$  mm; **Fil** 55–70 mm, inserted somewhat unequally 7–9 mm above the tube base; **Fil** 21–26 mm; **Anth** excentric; **Ov** 36–41 mm, green, neck 6–8 mm, in fresh flowers scarcely constricted but drying very narrow; **Sty** to 70–85 mm; **Sti** broad, lobed; **Fr** oblong, striate,  $50\text{--}70 \times 20$  mm, stipitate, rostrate, brown; **Se** drop-shaped,  $6\text{--}7 \times 4.5$  mm, black, marginal wing narrow.

The comparatively long flower tubes suggest an affinity with *A. margaritae* from the same general region, which differs in its small size and short, broad, long-toothed leaves. According to Gentry (1978) and Gentry (1982), the two species do not show close relations to other members of Sect. *Deserticolae* (as Group), but are assigned to this group for convenience only. Webb & Starr (2015) finally placed both in a separate Sect. *Intermediae*, intermediate between Sect. *Deserticolae* and Sect.

*Umbelliflorae* (Webb & Starr 2014b). Plants from Bahia Tortugas and Cerro Prieto now placed here were previously misidentified as *A. sebastiana* (Webb & Starr 2014b, Webb & Starr 2015). Plants from the region of the Pichachos de Santa Clara are more robust and less surculose than those in the Sierra Vizcaino proper, and resemble *A. giganteensis* (Gentry 1982: 407); Webb & Starr (2014a) finally published these plants as a new species, *A. azurea* (see there).

**A. wallisii** Jacobi (Nachtr. Versuch syst. Glied. Agaveen 2: 162, 1870). **Type:** Colombia (*Wallis* s.n. [not known to have been preserved]). — **Lit:** Berger (1915: 222); Bernal & al. (2015: 794); Giraldo-Cañas (2017: 47). **Distr:** Colombia (mountains of the Río Cauca region); no data on the ecology available.

[2v] Acaulescent; **L** relatively few, broadly lanceolate, at first erect, somewhat recurved, older spreading to all sides, recurved towards the tip, base thickly fleshy, becoming thin-fleshy and fibrous upwards, from the 4 cm broad base continuously broadened to 6.7 cm somewhat above the middle, lanceolate-acuminate in the upper part, below with broad rounded keel, keel more flattish in the upper part, above in the lower ½ flat or flatly convex, in the upper ½ flatly guttered, tip with several grooves, fresh green, dull, slightly glaucous, margins somewhat undulate and recurved; **marginal teeth** as very small denticles, triangular, slightly curved upwards, at first pergamentaceous with brownish tip, later horny, chestnut-brown, on flat fleshy basis; **terminal Sp** thin, corneous, subulate, on a fleshy base, horny, 6–8 mm, chestnut-brown; **Inf, Fl** and **Fr** unknown.

According to the protologue based on an undeveloped young plant 45 cm in diameter imported by Linden in Belgium in 1867 through the botanical collector Wallis from mountains of the Río Cauca region in Colombia. Trelease (1920: 135), based on the description alone, considered the species as “closely related” and “evidently allied” to *A. micracantha*, now a synonym of *A. mitis*. Munter (1981: 74) reports that the species “only rarely offsets in the wild” and must consequently have seen it in habitat. Hochstätter (2015) published a photograph of a young plant

labelled “*Agave wallisii*”, cultivated in Spain by P. van der Meer, but the plant originates from Santa Marta at the Caribbean coast of Colombia and does not belong here (P. van der Meer, pers. comm. Nov. 2018). The area in the Cauca valley is heavily urbanized now, and a search by G. Xhonneux was unsuccessful (P. van der Meer, pers. comm. Feb. 2019). See also under *A. cundinamarcensis*.

**A. warelliana** De Smet ex T. Moore & Masters (Gard. Chron., ser. nov. 5: 603, 1876). **Type:** [neo — icono]; Gard. Chron. ser. nov. 8: 265, fig. 53, 1877. — **Lit:** Berger (1915: 46–47); Gentry (1982: 230–232, with ill.); Lott & García-Mendoza (1994: online version with ills.); Cházaro Basáñez & al. (2008b: with ills.); Smith & Figueiredo (2014c: 27–29, with ills.). **Distr:** Mexico (C Veracruz, N-C Oaxaca, Chiapas), Guatemala (Huehuetenango); steep rocky limestone slopes with black soil, in pine forests, 1400–2420 m; flowers in May. **I:** Curtis’s Bot. Mag. 139: t. 8501, 1913; Richter (2011: 48); Hochstätter (2015: IX: 10).

[1f] Stems short or to 1 m; **Ros** rather robust,  $\pm 1 \times 1.7$  m, sparsely surculose, branching axillary; **L** dense, lanceolate to lanceolate-spatulate, erect or spreading, thickly fleshy, slightly constricted above the base, long acuminate, lower face convex, upper face flat, 50–70  $\times$  8–15 (6–7 at the base) cm, light pale green or shiny glaucous, margins finely serrulate, straight, brown; **marginal teeth** deltoid denticles, slightly curved, on a thin horny band not always continuous and formed by the base of the denticles, 1–2 mm, 1–3 mm apart; **terminal Sp** straight, rigid, broadly grooved above, 18–25  $\times$  3–4 mm, brown, decurrent for 5–10 cm; **Inf** erect, 4–6 m, ‘spicate’, peduncle 2–2.5 m, densely bracteate with deltoid long-acuminate appressed **Bra** 3.5 cm long (lower); floral **Bra** small, pale, lanceolate, 35 mm; **Fl** 45–55 mm, in groups of 2–4; **Te** reddish-yellow within, brownish outside, tube funnel-shaped, 6-grooved, 8–13 mm, light green, lobes linear-lanceolate, revolute,  $\pm 14$ –15  $\times$  4–6 mm, yellow within, spotted violet-brown on the back, inner 10–11 mm broad, slightly concave, with a broad thick keel; **Fil** 45–60 mm,

reddish; **Anth** 20–25 mm, reddish; **Ov** trigonous, narrowed at the base and apex, smooth, 25–30 mm, greenish-brown; **Sty** 140 mm, reddish; **Sti** 3-lobed; **Fr** somewhat obovoid, 3-grooved, narrowed at the base, 40 × 15 mm, beaked, green with some reddish dots; **Se** 5–6 × 3–5 mm, shiny black. — **Cytology**: 2n = 90, 100 (= 3×) (Simpson & al. 2011).

According to Gentry (1982), *A. warelliana* is the largest species in Sect. *Micracanthae* (as Group *Polycephalae*), esp. notable by its large flowers. Gentry relied exclusively on Baker's and Berger's descriptions and Berger's specimens at K and US; living plants or native localities were unknown to him. Lott & García-Mendoza (1994) provided the first report from nature from Mexico (Chiapas) and Guatemala (Huehuetenango) and give a description based on this new material; the later internet version (accessed Feb. 2015) omits the record from Guatemala. *A. warelliana* is now known from C Veracruz (near Pico de Orizaba, habitat photographs in Cházaro Basáñez & al. (2008b), Santos Valencia (2009: 4), Richter (2011) and Smith & Figueiredo (2014c)), from N-C Oaxaca (map in Cházaro Basáñez & Vázquez-García (2013: 59)), and from Chiapas (Pijijiapan, Motozintla, La Trinitaria, and El Triunfo, Lott & García-Mendoza (1994), Martínez-Meléndez & al. (2008: 29), Pérez-Farrera & al. (2012: 123), Portal Datos Abiertos UNAM (2018+: accessed 2018)), and from Guatemala (Huehuetenango) (specimen *Steyermark* 50940, IS 44130!, identified by A. García-Mendoza, label 2002).

According to Lott & García-Mendoza (1994) *A. warelliana* is very similar to *A. chiapensis* and differs in the size and shape of the leaves, its margins with a dark brown, almost continuous band, its decurrent terminal spine, much shorter bracts, and a much larger inflorescence. The flowers have been found to be smaller than those of *A. chiapensis*, which contrasts the data provided by Gentry (1982) and earlier authors.

Baker (1877a: 264, fig. 53), previously regarded as publication of the protologue, is antedated by the reference given above. Smith & Figueiredo (2014c) designated Fig. 53 from the former as lectotype, which thus represents a neotype. For

the in vitro-propagation, see Santos Valencia (2009). The triploid chromosome count from Simpson & al. (2011) may have been taken from a natural hybrid between *A. warelliana* and a further species with the parents being di- and tetraploid; the plant depicted by Smith & Figueiredo (2014c: fig. 7) with much broader leaves and stronger marginal teeth may be such a hybrid.

**A. weberi** J. F. Cels ex Poisson (Bull. Mus. Hist. Nat. (Paris) 7: 230–232, 1901). **Type** [neo]: USA, Texas (Gentry & al. 20003 [US [2 sheets], DES [?], MEXU [2 sheets]]). — **Lit**: Berger (1915: 259); Gentry (1982: 631–633, with ills.); Reveal & Hodgson (2002); Guillot Ortiz & al. (2008: 79–80, with ill.); Guillot Ortiz & Meer (2008b: 26–27, 31, with ill.); González-Elizondo & al. (2009: 149, with ill.); Smith & Figueiredo (2015: with ills.). **Distr**: Known from cultivation only (NE and C Mexico, introduced to Texas); flowers May to June. **I**: Irish & Irish (2000: t. 50); Heller (2006: 148); Richter (2011: 71, 117); Hochstätter (2015: VII: 21); Moore (2016: 234, 235).

**Incl.** *Agave neglecta* Small (1903).

[2a] Stems short, 0.4–1 m; **Ros** open, 1.2–1.4 × 2–3 m, freely suckering, without rhizomes; **L** lanceolate, rather softly fleshy, pliable, erect and straight to recurving, widest in the middle, narrowed below, slightly convex below, concave or guttered above at least towards the apex, 110–160 × 12–18 cm, green to greyish- or yellowish-green, or pruinose-greyish esp. when young, not cross-zoned, margins straight, finely fibrous; **marginal teeth** 1–2 mm, to 10 mm apart, usually absent along the upper 1/3–1/2 of the leaf, or completely absent; **terminal Sp** subulate, openly shallowly grooved above in the upper 1/2, 30–45 mm, brown to greyish, decurrent for several cm; **Inf** 6.5–8 m, paniculate, fertile part open, with 20–25 horizontal to slightly ascending diffuse part-**Inf** several times compound, in the upper 1/2–1/3 of the inflorescence, with 15–27 flowers, longer than 10 cm, sometimes bulbiferous; **Fl** 70–80 mm; **Te** bright yellow, tube rather urceolate, deeply grooved, 15–20 × 14–19 mm, lobes erect, involute, obtusely cucullate, subequal, 20–24 mm, inner narrower, more strongly folded; **Fil** long-

tapering, 55–60 mm, long exserted, yellow to yellow-green, inserted at mid-tube; **Anth** centric or excentric, 30–31 mm, yellow; **Ov** cylindrical, 33–40 mm, pale green, neck short, grooved, 2–4 mm, not constricted; **Sty** finally longer than the filaments; **Sti** capitate; **Fr** 55 × 30 mm, shortly stipitate but scarcely beaked; **Se** unknown.

A huge, highly attractive ornamental with gracefully arching leaves, but of unknown origin. Gentry (1982) assigned several related horticultural forms to this species which share green or glaucous-grey leaves that usually have small teeth or denticles. More distinctly grey-coloured variants might superficially be mistaken for *A. americana*, but the smooth or nearly unarmed leaf margins distinguish *A. weberi* immediately. Ullrich (1990d: 106) placed the species in Sect. *Agave* (as Group *Americanae*), which is followed here, in contrast to Gentry's placement in Group *Sisalanae*. It is perhaps a cultivar derived from *A. angustifolia* (of Sect. *Rigidae*; Govaerts (2014+)), but might also have arisen as a hybrid between *A. americana* s.l. and *A. angustifolia* s.l. The neotype at US designated by Gentry (1982: 633) consists of 2 sheets which were cross-labelled afterwards by R. Franck in 2012. *A. weberi* is cultivated for pulque and fibre and is locally naturalized in S Texas (Reveal & Hodgson 2002), Spain (Sáez & Guillot Ortiz 2015) and RSA (Smith & Figueiredo 2015). Further plants naturalized in Spain assigned here (Guillot Ortiz & al. 2008: 79–80, Guillot Ortiz & Meer 2008b: 26–27, 31) differ clearly and may represent *A. sisalana* or a relative. For a photoseries of the inflorescence development and flowering, see Bernhard (2012: accessed Dec. 2018). 'Reiner's Selection' is a cultivar with grey-green leaves, and 'Arizona Star' is a variegated cultivar with pale yellow margins.

*A. neglecta*, a local cultivate from Florida (Gentry 1982: 627–628, Reveal & Hodgson 2002), is treated as synonym by Franck (2012: 10–13). *A. franceschiana* (Berger 1912: 358, Berger 1915: 234) was related to *A. sisalana* by Berger (1915) or considered as a form of it (Ullrich 1993b: 25, 30), with which it coincides in its size and its cross-zoned leaves; this is followed here, while Gentry (1982), Smith & Figueiredo (2015: 165) and Govaerts (2014+: accessed Oct. 2018) placed

it in the synonymy of *A. weberi*, which is a much larger plant without cross-zoning of the leaves.

**A. wendtii** Cházaro (Cact. Suc. Mex. 42(4): 95, ill., 1997). **Type:** Mexico [ex cult.], Veracruz (Cházaro & Flores Macías 6645 [XAL, CHAPA, ENB, MEXU, WIS]). — **Lit:** Cházaro Basáñez (1995); Cházaro Basáñez (1997); Jimeno-Sevilla (2010: 100–102); Meer (2016a); all with ill. **Distr:** Mexico (Veracruz, Tabasco); rock faces in tropical evergreen forests with ±3000 mm rainfall, 80–350 m; flowers April to May; known only from 3 localities. **I:** Trager (2005: 93); Pilbeam (2013: 237–238); Hochstätter (2015: IX: 11, 14).

[1f] Acaulescent; **Ros** lax, to 45–60 cm Ø; **L** 25–50, lanceolate-oblong, fleshy, soft, brittle when bent, 10–25 × 1.8–3.5 cm, glaucous when young, later turning light green; **marginal teeth** small denticles, ±1–2 mm, green to coffee-brown; **terminal Sp** 8–10 mm, dark; **Inf** erect, 1–2 m, 'spicate', peduncle with narrowly-elongate **Bra**, fertile part dense, part-**Inf** with 2–3 flowers, subtended by triangular **Bra**, in the upper ½–¾ of the inflorescence, bulbiferous (in cultivation); **Fl** 20–29 mm, self-fertile; **Tep** pale yellow to yellowish-green, pale rose inside, free to the base, oblong, ±20 mm, tip roundish-acuminate; **St** 46 mm, pale yellow, long-exserted; **Anth** 11 mm, yellowish; **Ov** narrowly fusiform, ±10 × 3 mm; **Sty** ±29 mm, exserted, pale green; **Fr** nearly globose, small; **Se** not known.

According to the incomplete protologue only known from the Río Uxpanapa Gorge (Veracruz) and closely related to *A. pendula*, from which it differs in its greenish-glaucous leaves without lighter median stripe and with yellow marginal teeth, and its shorter, strictly erect inflorescence fertile in its upper half. Jimeno-Sevilla (2010) provides additional morphological data and a second locality from Veracruz at the Río Chalchijapan. *Morales Damián* 40 (MEXU 1355269!) from S Tabasco, Ejido Niños Heroes de Chapultepec, is a new state record. The record by Wendt from the Chimalapas region in Oaxaca mentioned by Cházaro Basáñez (1997: 14) needs confirmation.

**A. wercklei** F. A. C. Weber *ex* Wercklé (Monatsschr. Kakt.-kunde 17(5): 71–72, 1907).

**Type** [neo]: Cult. La Mórtoia (*Berger* s.n. [US 1023816]). — **Lit**: *Berger* (1915: 201–202); *Horich* (1973: with ill.); *Gentry* (1982: 500–502, with ill.); *Ullrich* (1992d: with ill.); *Lott & García-Mendoza* (1994: online version with ill.); *Smith & Steyn* (2002a: with ill.); *Smith & Steyn* (2003); *Grayum* (2003: 29, 30, 32, with ill.); *Walters & al.* (2011: 55–58, with ill.). **Distr**: Costa Rica (Valle del Río Grande de Candelaria/Caraigres); Pacific slopes, hot regions in sparse grasslands, 500–1700 m; flowers January to March; naturalized in South Africa. **I**: *Heller* (2006: 149); *Smith & al.* (2008: 39); *Richter* (2011: 84); *Pilbeam* (2013: 239); *Trager* (2018: 87–88).

**Incl.** *Agave costaricensis* hort. (s.a.) (*nom. inval.*, ICN Art. 29.1).

[2o] Acaulescent; **Ros** compact, 0.8–1 × 1–2 m, solitary, very rarely offsetting from rhizomes; **L** variable, ovate to lanceolate, rigidly spreading, upper ½ outcurved and deeply channelled, thick and robust, broad, thickly fleshy, narrowed towards the enlarged overlapping bases, clasping the stem, short-acuminate, tip inrolled, flat to concave in the upper ½, smooth, rough when young or rough below with age, (35–) 70–150 × 10–22 (–30) (at mid-leaf) cm, light glaucous-green to white-glaucous, with impressions from the central bud, margins smoothly rounded, straight to repand; **marginal teeth** deltoid or sinuous, slender, straight or variously curved, (1–) 3–4 mm, black to dark purplish- or greyish-brown, irregularly spaced 5–20 mm at mid-leaf, on low green prominences, smaller intermittent teeth absent or extremely rare; **terminal Sp** conical at the base tapering into an acicular point, narrowly grooved above, 16–30 mm, shiny dark purplish-brown or black, shortly decurrent; **Inf** (1–) 3–8 m, paniculate, peduncle short, surpassing the leaves, with deltoid **Bra**, fertile part large, broad, profuse, with up to 40–45 horizontally spreading, branched, dense, ‘umbellate’ part **Inf** in the upper ½ of the inflorescence, 13–20 cm long, often bulbiferous; **Ped** 4–5 mm; **Fl** 35–60 (–65 (–80)) mm, unscented to faintly fruit-scented, copiously nectariferous; **Tep** bright golden-yellow or greenish-yellow below and orange above, greenish-yellow to greenish-cream in

bud, 42–47 mm, tube openly funnel-shaped, succulent, 3–4 (–9) × 10 (at filament insertion) mm, lobes elliptic or oblong, slightly succulent, finely grooved dorsally, equal, 10–17 × 4 mm, wilting and turning brown before the female phase of anthesis; **St** 90 mm, exerted for 5–15 mm, light yellowish-green; **Fil** 28–40 mm, stout, tapered towards the apex, greenish-yellow, inserted above mid-tube; **Anth** linear, centric, 9–18 mm, golden-yellow to orange; **Ov** elongate, narrowed at both ends, terete to indistinctly grooved distally, 15–20 (–40) × 6–7 mm, light green, neck slightly constricted; **Sty** 35–40 mm, stout, terete, longer than the filaments, light yellowish-green; **Fr** ovoid-angular, chartaceous, 22–35 × 15–18 mm, dark brown mottled with light brown dots, slightly beaked; **Se** semicircular, flat, 3.5–6 × 3–4 mm, shiny.

The large, thick leaves and the flowers point towards a relationship with *A. parvidentata* (*Gentry* 1982). According to *Smith & Steyn* (2002a) similar to the Venezuelan *A. cocui*, which has a longer peduncle, somewhat longer part-inflorescences with more densely clustered flowers, and is suckering. *A. wercklei* is endemic to the region of the Valle del Río Grande de Candelaria W of San Ignacio de Acosta (*Horich* 1973, *Ullrich* 1992d, *Grayum* 2003). Populations from calcareous rocks at 1700 m near Cerro Caraigres have very dense ‘umbels’ and may represent a separate taxon (*Grayum* 2003: 32). *Smith & Steyn* (2002a) provided a detailed description and illustrations, and established the correct author citation and date and place of publication, correcting an earlier attempt by *Ullrich* (1992d). The lectotype designated by *Gentry* (1982: 501) represents in fact a neotype. The flowers on the specimen ARIZ 0004877 might represent an isoneotype. — *A. wercklei* *Trelease* (1920: 132) (*nom. illeg.*, ICN Art. 53.1) is a different species, of Sect. *Agave* (as Group *Americanae*), with more slender, white-glaucous leaves, cultivated in Costa Rica (*Gentry* 1982: 502).

**A. willdingii** *Todaro* (*Hort. Bot. Panorm.* 2: 36, t. 32, 1878). **Type**: not typified. — **Lit**: *Trelease* (1913: 42–43, tt. 93, 94); *Berger* (1915: 272); *León* (1946: 319); *Álvarez de Zayas* (1981:

37); Álvarez de Zayas (1985: 6–7); Álvarez de Zayas (1995: 41); Acevedo-Rodríguez & Strong (2012: 87); Greuter & Rankin Rodríguez (2017: 35). **Distr:** Only known from cultivation; probably originating from Hispaniola. **I:** Hochstätter (2015: VII: 94).

[2q] Acaulescent; **Ros** solitary; **L** rather few,  $\pm 15$ –30, oblanceolate or oblong-spatulate, erect-spreading, at the base flat and thick, gradually acute, upwards becoming thin and broadly guttered by the upcurved margins,  $50$ – $80 \times 12$ – $16$  cm ( $5$ – $9$  cm at the base), light green or slightly glaucous; **marginal teeth** variously curved, acuminate triangular or somewhat lenticular at the base and on green prominences,  $1$ – $4$  mm, upwards becoming smaller, at first red-brown, absent in the uppermost  $50$ – $70$  mm,  $10$ – $15$  mm apart, intervening margin slightly concave or more rarely straight; **terminal Sp** conical, slit-grooved below the middle, smooth,  $10$ – $15 \times 2$ – $3$  mm, brown, dull, becoming grey, scarcely decurrent; **Inf**  $3$ – $4$  m, paniculate, peduncle slender, with remote appressed **Bra**, fertile part in the upper  $\frac{1}{2}$ , axis slightly arching in the upper part, slightly zig-zag between the branches, **part-Inf** few, very lax, on ascending slender branches, with  $\pm$  densely congested flowers; **Ped** slender,  $5$ – $10$  mm; **Fl**  $30$  to  $<40$  mm; **Tep** yellow-orange to orange-yellow, tube openly conical,  $4 \times 12$  mm, lobes linear,  $10$ – $16 \times 4$  mm, soon fading; **Fil**  $25$ – $30$  mm, inserted nearly in the tube throat; **Anth**  $11$  mm, yellow; **Ov** cylindrical, slender,  $15$  mm, greenish; **Fr** and **Se** unknown.

Todaro's protologue is based on a plant cultivated at BG Palermo (Italy) probably originating from Mexico. According to Berger (1901), who studied the plant at Palermo, it appears to be a form of *A. kewensis*. Trelease (1913) placed it in Sect. *Antillares*, gives its origin as possibly from W Cuba, as indicated by the small, orange-yellow flowers, and on t. 94 depicts specimens from Palermo and from La Mortola where *A. willdingii* was cultivated since long (Berger 1915). *A. willdingii* specimens of Berger are extant (US 1023521 & 1023522; MO 2056808 & 2056809). Álvarez de Zayas (1981) and Álvarez de Zayas (1985) dismiss the Cuban origin of *A. willdingii* and its placement in Sect. *Antillares* due to its

“orange” flowers and the branching pattern of the inflorescence. However, the protologue and Berger (1915) give the flower colour as yellow-orange (“giallo aranciato”) and orange-yellow, respectively; such colours are also found in Sect. *Antillares*. According to Álvarez de Zayas (1995: 41), *A. willdingii* can possibly be included in the species of Sect. *Antillanae* from Hispaniola such as *A. antillarum*, which it indeed resembles. — The species is named after G. Willding, but the epithet is often misspelled ‘*wildingii*’ etc.

**A.  $\times$ winteriana** A. Berger (Agaven, 160, fig. 55 (p. 159), 1915). **Type:** not typified. — **Lit:** Guillot Ortiz & Meer (2012: with ill.); López-Pujol & al. (2015a: 58, with ill.). **Distr:** Cultivated only; naturalized in Spain.

[2a  $\times$  2c?] This is the garden hybrid *A. americana*  $\times$  *A. franzosinii*, which originated in the garden of L. Winter at Bordighera (Italy) (Berger 1915). It is still found in cultivation in Spain (Guillot Ortiz & Meer 2012, López-Pujol & al. 2015a). The involvement of *A. americana* as parent is doubtful: The hybrid is similar to *A. franzosinii*, but much smaller than both stated parents, and the first parent must have been a species which contributed the smaller habit, smaller teeth and cross-zoning to the hybrid; Guillot Ortiz & Meer (2012) suggest *A. sisalana* as possible parent. Some of the plants cultivated in the USA as *A. franzosinii* appear to belong here (see also there). Locally naturalized in Spain (López-Pujol & al. 2015a).

**A. wocomahi** Gentry (Publ. Carnegie Inst. Washington 527: 96–97, t. 17, 1942). **Type** [syn]: Mexico, Chihuahua (Gentry 1989 [CAS [2 sheets], ARIZ [2 sheets], US [2 sheets]]). — **Lit:** Breitung (1962: 142–143, with ill.); Gentry (1972: 105–109, with ills.); Gentry (1982: 456–458, with ills.); McVaugh (1989: 147); Vázquez-García & al. (2007b: 79–80, tt. O6–O7); González-Elizondo & al. (2009: 140–143, with ills.); Klopper & al. (2010: 62); Starr (2012: 292–296, with ills.). **Distr:** Mexico (SE Sonora, SW Chihuahua, N Sinaloa, S Durango, E Jalisco: Sierra Madre Occidental); rocky limestone mountain slopes in pine-oak and thorn forests,  $1350$ – $2500$  m;

flowers July to September. **I:** Bye & al. (1975: 110); Richter (2011: 54); Pilbeam (2013: 240); Hochstätter (2015: IV: 16).

[2h] **Ros** 0.8–1.3 × 1.5–2 m, eventually depressed and open at maturity, single, not suckering; **L** mostly lanceolate to linear-lanceolate, rarely ovate, ascending to depressed with age, thick-fleshy, rather rigid, somewhat narrowed towards the base, flat, smooth, 30–90 × 9–25 cm, dark to glaucous-green, margins straight to repand; **marginal teeth** large, variously curved, below the middle of the lamina frequently down-curved, with smaller irregular intermittent teeth, larger teeth 10–20 mm, dark brown to glaucous-brown; **terminal Sp** stout, usually sinuous, flattened or with a broad groove, 30–60 mm, black to bluish-grey, short- or long-decurrent; **Inf** 3–5 m, paniculate, peduncle with scarious appressed or reflexed **Bra** 15–20 (in the middle) cm long, fertile part open, part-**Inf** small, 8–15 in the upper 1/3 of the inflorescence; **Fl** erect, 65–85 mm; **Tep** yellow, tube deeply funnel-shaped, narrowly grooved below the lobe sinuses, 18–22 × 15 mm, light yellow, lobes erect, thick, linear, conduplicate, rounded and deeply hooded at the tip, dimorphic, 15–23 × 5 mm, outer with papillate pubescence well below the apex and sometimes red-tipped, inner shorter and prominently keeled, yellow; **Fil** 60–65 mm, inserted unequally 9–14 mm above the tube base; **Anth** excentric, 26–34 mm, yellow; **Ov** cylindrical, 34–40 mm incl. a 2–5 mm long neck, light green; **Sty** longer than the tepals; **Sti** capitate; **Fr** oblong, 50–60 × ≥ 15 mm, shortly stipitate; **Se** oblique, flattened on the end opposite the hilar notch, 7 × 4.5–5 mm, finely punctulate, wavy-corrugate, with a narrow margin partly upcurved, shiny black.

In the protologue, Gentry designated his collection “1989” as “type”. His later designation of a lectotype (as “holotype CAS”; Gentry 1982: 456) consists of 2 sheets which were apparently cross-labelled later.

A montane mesophyte, uncommon and with populations consisting of small colonies with widely scattered individuals. The dimorphic tepal lobes place *A. wocomahi* in Sect. *Ditepalae*. It is sometimes sympatric with the habitually similar *A. shrevei* from the same section, from which it is

usually easily distinguished by its dark green leaves and more remote teeth, and the different flowers. It is easily confused with *A. bovicornuta* (Sect. *Crenatae* (as Group)) with lighter yellowish-green leaves conspicuously narrowed just above the base, and with different flowers (Gentry 1982). Morphologically also similar to the recently published *A. temacapulinensis*. Hernández-Vera & al. (2007a) provide a new record from Jalisco. The flowers are visited by hummingbirds (photo in Starr (2012)). Baked “hearts” are used to produce mescal bread (“mesagoli”) and a fermented alcoholic beverage (“sugui”) (Bye & al. 1975: 96).

**A. xylonacantha** Salm-Dyck (Bonplandia 7: 92, 1859). **Type:** [neo — icono]: Curtis’s Bot. Mag. 93: t. 5660, 1867. — **Lit:** Berger (1915: 112–114); Breitung (1959: 116, with ill.); Gentry (1982: 186–188, with ill.); Alsemgeest & al. (2007b: with ill.); Eguiarte & Scheinvar (2008: 40–43, with ill.); Starr (2012: 297–301, with ill.). **Dist:** Mexico (Tamaulipas, San Luis Potosí, Guanajuato, Querétaro, Hidalgo); dry limestone slopes and valleys, on the desert side of the Sierra Madre Oriental, 90–1900 m; flowers February to July. **I:** Irish & Irish (2000: t. 51); Etter & Kristen (2006: 258); Heller (2006: 23, 150, 151); Spracklin (2007: 150); Zuijlen (2008: 76, 82); Pilbeam (2013: 241); Hochstätter (2015: IX: 45); Moore (2016: 276); Greulich (2016c: 152).

**Incl.** *Agave xylonacantha* var. *latifolia* Jacobi (s.a.) (*nom. inval.*, ICN Art. 29.1?); **incl.** *Agave xylonacantha* var. *macracantha* Jacobi (s.a.) (*nom. inval.*, ICN Art. 29.1?); **incl.** *Agave xylonacantha* var. *torta* Jacobi (s.a.) (*nom. inval.*, ICN Art. 29.1?); **incl.** *Agave amurensis* Jacobi (1864); **incl.** *Agave kochii* Jacobi (1866); **incl.** *Agave splendens* Jacobi (1870) ≡ *Agave heteracantha* var. *splendens* (Jacobi) A. Terracciano (1885); **incl.** *Agave vanderdonckii* hort. ex Baker (1877); **incl.** *Agave xylacantha* hort. (1877) (*nom. inval.*, ICN Art. 61.1); **incl.** *Agave carchariodonta* Pampanini (1907) ≡ *Agave univittata* var. *carchariodonta* (Pampanini) Breitung (1959); **incl.** *Agave xylonacantha* [?] *mediopicta* Trelease (1908); **incl.** *Agave xylonacantha* var. *horizontalis* hort. ex A. Berger (1915); **incl.** *Agave cornuta* Hort. Besauccèle ex A. Berger (1915) (*nom. inval.*,

[1g] Stems short; **Ros** openly spreading, to  $0.9 \times 1.2$  m, solitary or occasionally caespitose; **L** ensiform-lanceolate, rather rigid, broadest in the middle, long-acuminate, rounded below, flat to concave above,  $45\text{--}90 \times 5\text{--}10$  cm, green to yellowish-green, sometimes glaucous, with or without a pale mid-stripe, margins horny, continuous, straight between the remote conspicuous prominences but looping over the prominences; **marginal teeth** broadly flattened, thickly terminating the broad prominences, frequently 3- to 5-tipped, 8–15 mm, light grey, commonly 20–50 mm apart; **terminal Sp** trigonous-subulate, stout, flat to slightly grooved above, keeled below, 25–50 mm, light grey; **Inf** erect, 3–6 m, ‘spicate’, peduncle with very narrow chartaceous **Bra**, fertile part long-tapering, in the upper  $\frac{1}{2}\text{--}\frac{2}{3}$  of the inflorescence, part-**Inf** with 2–3 flowers; **Fl** 40–50 mm; **Tep** greenish to pale yellow, tube 3–5 mm, lobes  $3\text{--}5 \times 8\text{--}10$  mm, erect, narrowing and clasping the filaments at anthesis,  $\pm$  equal,  $15\text{--}20 \times 4\text{--}5$  mm; **Fil** slender, 38–42 mm, sometimes red or purple; **Anth** excentric, 17–22 mm; **Ov** fusiform, 4-angulate, 20–27 mm; **Sty** slender, much shorter than the filaments, yellowish-green; **Sti** small, capitate; **Fr** linear-oblong,  $20 \times 10$  mm, beak very short, shortly stipitate, brownish, pruinose; **Se** crescent-shaped,  $6 \times 3$  mm. — **Cytology**:  $2n = 60$  (Granick 1944, Simpson & al. 2011).

Related to *A. lophantha*. The highly convoluted leaf margins with large, flattened, several-tipped teeth are like an exaggeration of the forms known from *A. lophantha* (Gentry 1982: 188). Var. “*minor*” Heller (2006: 150) is a horticultural name for a small form with shorter leaves. Plants from Ezequiel Montes (Querétaro) with exceptionally strong and wildly curved horny teeth (Richter 2011: 121) may belong here. For the closely related *A. megalodonta*, see there. Gentry (1982: 188) designated the neotype cited above.

The flowers produce nectar between 22:00 and 6:00 and are mainly visited by bats and bees, also by sphingids, bumblebees and hummingbirds. The fruit and seed set belongs to the highest among the studied agaves. Populations show a moderate genetic variation. Variation is higher in the Barranca de Metztlán than outside of the barranca, suggesting that the species may have originated there. Compared to other agaves, genetic diversity and structure is low, possibly associated with a very recent origin and/or a high efficiency of its pollinators, mainly bats (Eguiarte & Scheinvar 2008). — ‘Frostbite’ is a variegated cultivar (Starr 2012).

**A. yavapaiensis** W. C. Hodgson & Salywon (Brittonia 65(1): 10, ills. (pp. 8–9), 2013). **Type**: USA, Arizona (Hodgson & Salywon 25496 [DES, ASC, ASU, MO, NY]). — **Lit**: Parker (2018a: 22, 27, with ills.). **Distr**: USA (C Arizona); rocky, clayey-loamy soils derived from igneous rocks, less frequently on limestone soils, in semi-arid desert grassland to pinyon-juniper woodland, 915–1220 m; flowers late June to early August. **I**: Hochstätter (2015: III: 10).

[2h] **Ros**  $\pm 60\text{--}70 \times 60\text{--}70$  cm, open, freely offsetting via rhizomes, forming clones of few to several rosettes; **L** numerous, narrowly elliptic to linear-oblong, erect-spreading, firm, deeply guttered, abruptly acuminate, broadest at or just above or below the middle,  $33.5\text{--}50 \times 4.2\text{--}8$  cm, blue-green, usually without maroon flush distally; **marginal teeth** porrect, upturned or recurved, firmly attached, grey, red-brown to dark mahogany, close-set, intermittent teeth 3–7 along the distal  $\frac{2}{3}$  of the leaf margin; **terminal Sp** 16–31 mm, grey to dark brown-grey, decurrent; **Inf** to 4–6 m, narrowly paniculate, peduncle dark green-maroon, glaucous, part-**Inf** 16–18, slightly ascending, 13–18 cm, in the upper  $\frac{2}{3}$  of the inflorescence; **Fl** 42–57 mm, with a sweet-musky fragrance at anthesis; **Tep** thickish, bulging at the lobe bases, tube  $13\text{--}16 \times 11\text{--}15.5$  mm, dark chartreuse-green, lobes persistently erect, leathery with age, unequal, outer 11–12 mm, cream to cream-yellow, with brown papillose-pubescent cucullate tips, inner 9–10.5 mm, cream to cream-yellow, strongly keeled, with white hairs within the

tips; **Fil** 33–43 mm, cream-yellow, subequally inserted 5–10.5 mm above the tube base; **Ov** 20–26 × 5–8.5 mm, green to dark chartreuse-green, neck 2–4 mm; **Sty** 28–39 mm, longer than the tepals, light cream; **Sti** capitate; **Fr** produced only on the uppermost part-inflorescences, linear to linear-oblong, 34–42 × 11–17 mm, apiculate, stipe 4–6 mm; **Se** only few per capsule, 5 × 4 mm, dull black. — **Cytology**: 2n = 60 (protologue).

According to the protologue a pre-Columbian cultivar species most similar to *A. verdensis*, another pre-Columbian cultivar, from which it differs in its leaf shape and colour, the orientation of the marginal teeth, the colour of the tepal lobe apices and the ovary, and its conspicuously stipitate, narrower fruits. It also shows similarities with *A. chrysantha* and *A. shrevei*. For further pre-Columbian cultivar species in Arizona, see under *A. verdensis*.

**A. zapopanensis** (E. Solano & Ríos-Gómez) Thiede (Haseltonia 17: 95, 2012). **Type**: Mexico, Jalisco (*Castillejos C. & Solano C.* 1564 [MEXU, CHAPA, ENCB, FEZA, IBUG, IEB, NY, UAMIZ]). — **Lit**: Solano & Ríos-Gómez (2011: with ill., as *Polianthes*). **Distr**: Mexico (C Jalisco); in oak forests and ecotones with tropical deciduous and pine-oak forests, 1235–1950 m; flowers July to September. **I**: Castro-Castro & al. (2015: 145); Hochstätter (2016: II: 25); Castro-Castro & al. (2016: 721); all as *Polianthes*.

≡ *Polianthes zapopanensis* E. Solano & Ríos-Gómez (2011).

[3b2] Herbaceous; corm cylindrical, 0.5–2.5 (–3) × 0.9–2 cm, with renewal buds, bulb ovoid, 3.5–5.7 × 1.7–2.5 (–4.2) cm, covered with dried leaf bases; **R** fleshy, thickened, contractile, 5–13 cm long; **L** drought-deciduous, 3–5 in sterile plants, ascending, arching over, linear, cartilaginous, lower face with lines of prominent papillae on the veins, upper face glabrous, apex acute, thickened, 43–61 × (0.17–) 0.3–0.7 (–1) cm, green, margins denticulate or papillose, scaberulous, papillae smaller than those on the veins, irregularly distributed; **Inf** (0.6–) 1–1.9 m, erect, ‘spicate’, peduncle with ±8–9 **Bra**, these similar to the leaves, base truncate, bracts and

internodes decreasing in size upwards, fertile part 41–98 cm, lax, with (12–) 16–44 floral nodes, usually with 1–2 branches 6–24 cm long, between the 5. and the 8. node; floral **Bra** 5–15 × 1–2.5 mm; **Ped** 6–19 mm, ± ascending; **Fl** geminate, 18–27 mm, diffuse to divaricate at anthesis, zygomorphic, funnel-shaped, unscented; **Tep** orange or pink, succulent, slightly curved, tube 14–20 × 2–3 mm at the base of the lobes, dorsally papillate, lobes subequal, erect, broadly ovate or transversally elliptic, succulent, papillose on both faces, much shorter than the tube, 1–3 × 1–3 mm, apex cucullate, obtuse to rounded, papillose, margin hyaline, rarely green; **Fil** filiform, 5.5–10 mm, included, inserted 5–7 mm above the ovary apex, yellow; **Anth** linear, 5–8 mm, yellow, at anthesis at the mouth of the tube; **Ov** cylindrical, 3–4 × 2–3 mm; **Sty** filiform, 10–18 mm, yellow, included; **Sti** 3-lobed, papillose; **Fr** globose, 10 × 12 mm, tepals persisting; **Se** deltoid, flat, 4–5 × 2.8–3.8 mm, dull or shiny.

Belonging to Ser. *Bravoa* (as Group) of Sect. *Polianthes* according to the protologue, and differing from the other species in its thick infundibuliform flowers and its usually branched inflorescences. The species shows morphological similarities with *A. coetocapnia*, *A. graminifolia* and *A. oaxacana*.

**A. zebra** Gentry (US Dept. Agric. Handb. 399: 126–130, ill., 1972). **Type**: Mexico, Sonora (*Gentry* 21984 [US [2 syn], ARIZ, MEXU, MICH]). — **Lit**: Gentry (1982: 516–518, with ill.); Turner & al. (1995); Velazco Macías & Alanís Flores (2002); Starr & al. (2008: 172–175, with ill.); Starr (2012: 302–307, 320–321, with ill.). **Distr**: Mexico (Sonora: Sierra del Viejo, Cerro Quituni); arid limestone slopes with desert scrub, 700–1000 m; flowers late June to August. **I**: Irish & Irish (2000: t. 52); Etter & Kristen (2001: 168); Richter (2011: 82, 129); Pilbeam (2013: 242–243); Hochstätter (2015: VI: 23); Greulich (2017a: 47). – Fig. 62.

[2n] **Ros** rather open, low-spreading, 0.4–0.6 × 1–1.6 m, solitary (in cultivation also offsetting); **L** lanceolate, arcuate, thick, rigid, narrowed above the base, broadest near the middle, deeply guttered, scabrous, 50–80 × 12–17 cm, light grey-glaucous,

**Fig. 62** *Agave zebra*  
(Etter & Kristen 539:  
Mexico; Sonora,  $\pm$  30 km S  
of Caborca, 500 m).  
(Copyright: J. Etter &  
M. Kristen)

conspicuously cross-zoned, margins strongly repand; **marginal teeth** variously curved, strong, flattened, large, mostly 10–20 mm (at mid-leaf), grey with chestnut-brown tips, 10–30 mm apart, bases broad, low, scabrous, 25–40 on each margin, on conspicuous prominences; **terminal Sp** acicular, mostly very narrowly grooved above, 35–75 mm, yellowish-brown to light grey, scabrously decurrent for 5–10 cm to the uppermost teeth; **Inf** 6–8 m, paniculate, with large **Bra** towards the base, fertile part narrow, part-**Inf** small, 7–14 in the upper  $\frac{1}{5}$ – $\frac{1}{4}$  of the inflorescence; **Ped** angled, very short; **Fl** 40–55 mm; **Tep** yellow, tube funnel-shaped, bulging, deeply sulcate, 6–7 mm, lobes lanceolate, erect to ascending, revolute, cucullate,  $\pm$  equal, 12–15  $\times$  5–6 mm, inner prominently keeled; **Fil** broad, 35–40 mm, inserted at mid-tube; **Anth** 15–18 mm; **Ov** cylindrical-angulate, slender, straight, 25–32 mm, neck slightly constricted, 6-sulcate; **Sty** longer than the tepals; **Sti** capitate; **Fr** oblong to obovate, with strong and conspicuously lined walls, mostly 40–50  $\times$  12–15 mm, stipitate, apex round, apiculate; **Se** obliquely rounded, concave on one side or both faces, 4.5–5  $\times$  4–4.5 mm, marginal wing very low, hilar notch shallow.

The attractive cross-striping of the leaves appears to be accentuated in plants exposed to full sunshine; seedlings show the banding already from a very early age (Pilbeam 2013). Velazco

Macías & Alanís Flores (2002) list it as endemic to the Sierra el Viejo, but it also occurs on nearby Cerro Quituni (Aquituni) as given by Gentry (1972), Gentry (1982) and Turner & al. (1995). The “holotype” at US consists of 2 sheets which are not cross-labelled (but both have the same identical label) and thus represent syntypes.

## Beschorneria AGAVACEAE

J. Thiede

**Beschorneria** Kunth (Enum. Pl. 5: 844, 1850). **Type:** *Furcraea tubiflora* Kunth & C. D. Bouché. — **Agavoideae—Agaveae** — **Lit:** García-Mendoza (1987: monograph); Maunder (1989: synopsis); García-Mendoza (2003: partial synopsis); Jankalski (2005: synopsis). **Distr:** Mexico, Guatemala, Belize, Honduras; dry rocky woodlands to cloud forests. **Etym:** For Friedrich W. C. Beschorner (1806–1873), German physician and botanist, director of the Institute of Public Assistance and the Lunatic Asylum at Owinsk, Poland.

Perennial rosette plants, mostly acaulescent or short-caulescent (*B. wrightii*) to caulescent-arborescent (*B. albiflora*), rhizomatous, caespitose with age; **R** fibrous to fleshy, contractile; **L** erect or recurved,  $\pm$  linear-lanceolate or oblanceolate, ascending, narrowed at the base, base broadened to form a sheath, lamina tough, carinate-canaliculate, mostly glabrous or sometimes papillose above and/or scabrous below, green to glaucous, sometimes pruinose, midrib fleshy, tip a long soft point, margins entire or minutely denticulate; **Inf** racemes or few-branched panicles, straight or arching over, peduncle greenish, rose or reddish; **Bra** red, pink or yellow, broad and long, lanceolate to ovate, conspicuous, deciduous or persistent; **Ped** articulated at the tip; **Fl** pendulous, actinomorphic,

hermaphrodite or rarely functionally unisexual (*B. yuccoides*), single or 2–5 together in remote clusters; **Tep** lanceolate, subequal, free but connivent to form a tube-like corolla, greenish, yellowish, rose or red, apical part slightly spreading and green, whitish or yellowish; **ITep** carinate on the outside, papillose or puberulous on the inside and overlapping parts; **Fil** filiform, slightly thickened at the base, papillose,  $\pm$  as long as the tepals, whitish or greenish; **Anth**  $\pm$  oblong, dorsifixed, versatile, greenish or yellowish, pollen released in monads or tetrads; **Ov** inferior, oblong, trigonous, 6-sulcate, 3-locular, glabrous or puberulent, with 3 septal nectaries; **Sty** filiform, papillose, as long as or exceeding the stamens, basally swollen into 3 ridges; **Sti** obscurely 3-lobed, papillose, occasionally ciliate; **Fr** erect or pendulous,  $\pm$  cylindrical loculicidal capsules, subglobose or subclavate, trigonous, rostrate, with persistent tepals; **Se** planoconvex, flat, shining black to blackish. — **Cytology:**  $x = 30$  (Satô 1935, Watkins 1936, Cave 1964).

With its long and soft leaves and the inflorescences with large colourful bracts, the genus is atypical for the family and might be mistaken as belonging to the *Bromeliaceae*, with some similarity to, e.g., *Billbergia*. According to recent molecular and morphological phylogenies, *Beschorneria* is closest to *Furcraea*, and they are sister groups in most analyses (Bogler & Simpson 1995, Bogler & al. 1995, Bogler & Simpson 1996, Bogler & al. 2006, Good-Avila & al. 2006), sharing the following putative synapomorphies:

---

J. Thiede (✉)  
Hamburg, Germany  
e-mail: joachim\_thiede@gmx.de

Filaments slightly to distinctly thickened, ovary basally ribbed, and pollen in monads, dyads or tetrads. *Furcraea* differs consistently from *Beschorneria* in habit and in having hard leaves mostly with denticles or teeth, inconspicuously coloured bracts, and spreading tepals.

García-Mendoza (1987) produced a full taxonomic revision of the genus, but this remained unpublished. *Beschorneria* can be divided into 2 well characterized informal species groups (Jankalski 2005):

- [1] *Beschorneria tubiflora* group: **L** linear-lanceolate to linear, 30–65 (–70) cm, relatively narrow, often rigid, rough on both faces or on the lower face only; **Inf** unbranched racemes, sometimes with 1 or few short branches at the base. — 3 spp. from Mexico. Compact-growing small plants most amenable to growing in pots.
- [2] *Beschorneria yuccoides* group: **Ros** much larger; **L** lanceolate to oblanceolate, (35–) 50–100 (–150) cm, broad, smooth on both faces or rough on the lower face only; **Inf** many-branched panicles. — 4 spp. from Mexico, Guatemala and Honduras. Very showy landscape plants, especially when in full bloom.

**Pollination ecology:** No studies are available. Hummingbirds have been suggested as the primary pollinators for most species, given the reddish colour and the tubular shape of the flowers, but at least some species may be hawkmoth-pollinated (Rocha & al. 2006). Blooming plants cultivated in the S USA indeed attract hummingbirds according to casual reports in the Web.

**Ethnobotany and uses:** Apart from the widespread use as ornamental plants the genus has little economic value. The leaves of some species are used as a soap substitute while the fresh flowers are sometimes eaten fried with egg (Matuda 1966). The leaves and flowers of *B. yuccoides* are used as drop infusion against catarrh in sheep (specimen notes for *García Mendoza* 1418, MEXU).

**Cultivation:** In warmer regions, plants in good condition may flower each year from previous years' suckers, whereas flowering of greenhouse plants in northern regions may occur at long intervals only. Seedlings grown under glass may attain flowering size in 4–6 years (Maunder 1989). For cultivation in the S USA see Irish & Irish (2000) and Symon (2005), and in C Europe Maunder (1989) and Boeuf (2007). The plants are winterhardy in the warmest parts of the British Isles such as Cornwall (Senior 1968).

The following names are of unresolved application but are referred to this genus: *Beschorneria galeottii* Jacobi (1864) (*nom. inval.*, ICN Art. 38.1); *Beschorneria pumila* Jacobi (1864) (*nom. inval.*, ICN Art. 38.1); *Beschorneria schlechtendalii* Jacobi (1864) (*nom. inval.*, ICN Art. 38.1); *Beschorneria verlindeniana* Jacobi (1864) (*nom. inval.*, ICN Art. 38.1).

**B. albiflora** Matuda (Anales Inst. Biol. UNAM, Ser. Bot. 43(1): 52–54, 1974). **Type:** Mexico, Oaxaca (*MacDougall* 359-A [MEXU, IEB]). — **Lit:** Maunder (1989); Lott & García-Mendoza (1994); García-Mendoza (2003: online version with ill.); Jankalski (2006). **Distr:** Mexico (Oaxaca, Chiapas), Guatemala, Honduras, Belize?; sclerophyllous scrub, pine-oak and cloud forests, moist and shaded places in rich soils derived from limestone, 1900–3000 m; flowers March to June or November to February. **I:** Anonymus (2005); Symon (2005: as *B. yuccoides*).

**Incl.** *Beschorneria chiapensis* Matuda (1986) (*nom. inval.*, ICN Art. 32.1c).

[2] Caulescent-arborescent, stems 0.5–3 (–8) m, 10–12 cm Ø, erect, sometimes prostrate, single in habitat, clustering in cultivation; **Ros** 1–3 (–5) at the stem tip, dense, with 15–50 leaves; **L** erect, elliptic-lanceolate or lanceolate to linear-lanceolate, chartaceous, canaliculate, gradually narrowed towards the broadened base, smooth, (35–) 50–80 (–125) × 5.5–7 (–10) cm, green to glaucous, tip acuminate, not hardened, margins entire with a yellowish or cartilaginous band, rarely denticulate; **Inf** paniculate or rarely racemose, 1.5–3 (–3.5) m, peduncle and **Bra** reddish (brilliant green according to Matuda (1974)),

glabrous, fertile part with (20–) 50–200 flowers; **Ped** 10–35 mm, reddish, glabrous, with ovate bracteoles 10–22 × 5–7 mm; **Fl** (50–) 60–70 (–85) mm, single or in clusters of up to 4 (–7); **Tep** connivent, nearly equal, 25–35 (–45) × 2–5 mm; **OTep** white with green midstripe, linear-spatulate, slightly broader than the inner tepals; **ITep** white on both faces, linear-oblong, all tepals turning bright pink at anthesis and red in age, tips yellowish or cream, glabrous outside, papillose inside; **St** erect, equal, as long as the tepals or slightly longer; **Fil** dilated, 1.7 mm broad, apex subulate, white; **Anth** oblong-elliptic, 5–7 mm; **Ov** oblong-cylindrical to semicylindrical, 25–40 × 3–6 mm, intensely red or rose, glabrous; **Sty** filiform, 27 mm; **Sti** 1–1.2 mm Ø, papillose; **Fr** pendent, oblong, 45–70 × 20–30 mm, bright pink or reddish when young; **Se** plano-convex, 9–12 × 5–8 mm.

This is the S-most and the only arborescent species. The protologue gives the flowers as white only, but these turn bright pink at anthesis and red in age. Originally described from Oaxaca (Cerro Azul) but more recently found to be widespread in Chiapas, Guatemala and Honduras (Lott & García-Mendoza 1994, Jankalski 2006). The report of *B. tonelii* for Chiapas by Breedlove (1986) most probably represents a misidentification of *B. albiflora*. The online version (accessed 2013) of Lott & García-Mendoza (1994) depicts a sterile specimen (*Davidse & al.* 36471) from S Belize that might belong here. Plants may survive temperatures down to –7 (to –9) °C.

**B. calcicola** García-Mendoza (Herbertia [ser. 3], 42: 28–30, ills., 1986). **Type:** Mexico, Oaxaca (*García-Mendoza & Lorence* 720 [MEXU, ENCB, GJ]). — **Lit:** Maunder (1989); García-Mendoza (2003: with ill.); García-Mendoza (2011: with ills.). **Distr:** Mexico (C Veracruz, SE Puebla, NW Oaxaca); sclerophyllous scrub and ecotones with pine-oak forests, in rich organic soils derived from limestone, 1900–2600 m; flowers April to September.

[1] Acaulescent; **Ros** dense, in groups of 10–15 from a short rhizome; **L** erect or sometimes ± recurved, linear, rigid, conduplicate, keeled

below, scabrous below, scabridulous above, 30–60 × 0.3–0.6 cm (0.8–1.6 cm wide at the base), glaucous (drying greenish-yellow), **L** sheath triangular, 4–6 × 1.5–2 cm, yellowish, **L** margins denticulate; **Inf** racemose, 1.15–2.3 m, peduncle 0.8–1 m, 0.5–0.8 cm Ø, pinkish or yellowish, with 7–13 pink, aristate **Bra** 3–10 × 1–1.5 cm, fertile part (20–) 40–60 cm, with 16–30 flowers; floral **Bra** deltoid, 1–2.5 × 0.3–0.6 cm; **Ped** 7–20 mm, longer than the floral bracts, glabrescent, bracteolate; **Fl** (35–) 40–50 × 6–10 mm, single or in clusters of 2 (–3); **Tep** linear to linear-spatulate, connivent to form a tubular corolla with only the tips spreading, (20–) 25–33 mm, pink or yellowish outside, white at the apex and within; **OTep** linear, 2–3 mm broad, swollen at the base; **ITep** linear-spatulate, 4–5 mm broad, with dorsal midrib, outside puberulent, within papillose; **St** as long as or slightly shorter than the tepals; **Fil** subulate, dilated at the base for 1–1.5 mm, papillose, white; **Anth** linear, 3–6 mm, pale green or greenish-yellow; **Ov** cylindrical to subglobose, 6-angled, puberulous, 13–20 × 2–4 mm, pinkish or yellowish; **Sty** dilated and trisulcate at the base, with 1 nectary per sulcus, exceeding the stamens, sometimes exceeding the tepals by 1–3 mm, papillose, white; **Sti** capitate, 0.8–1.2 mm Ø, sometimes ciliate and papillose; **Fr** erect, subglobose, 20–28 × 15–18 mm, pinkish when young, stipitate, stipe thickened, 2–3 mm Ø; **Se** crescent-shaped, plano-convex, 5–7 × 4–5 mm, shiny.

Characterized by its narrow linear and conduplicate leaves (Maunder 1989). Most closely allied to *B. tubiflora* according to the protologue, but differing in leaf, inflorescence and flower characters, and with a different habitat. First discovered E of Ciudad Oaxaca in 1973 (Lau 1993). The occurrence in Veracruz was reported by Castillo Campos & al. (1999). This is the most drought-resistant species in the genus (Jankalski 2005).

**B. rigida** Rose (Contr. US Nation. Herb. 12: 262, 1909). **Type:** Mexico, San Luis Potosí (*Palmer* 593 [US 570098]). — **Lit:** Maunder (1989). **Distr:** Mexico (Tamaulipas, San Luis Potosí, Guanajuato, Querétaro, Puebla); mountain scrub, pine-oak forests, 1800–2400 m. **I:** Curtis's

Bot. Mag. 78: t. 4642, 1852, as *B. tubiflora*; Jardin Fleuriste 4: t. 334, 1854, as *B. tubiflora*; López Martínez (2015); Nájera Quezada & al. (2015).

**Incl.** *Beschorneria roseana* Ploem (1923).

[1] Acaulescent; **L** numerous, erect, rather rigid, roughened on both faces,  $30 \times \leq 2$  cm, glaucous-green, narrowing into a long-acuminate tip; **Inf** 0.7–3 m with 24–90 flowers; peduncle 0.5–1.5 cm  $\varnothing$  at the base, pink to red; floral **Bra** large, 15–20 cm, scarious, light purple to purplish; **Ped** as long as or longer than the floral bracts; **Fl** 45 mm, in clusters of 2–4; **Tep** somewhat scabrous, dull, yellow mottled green-brown, tips green; **St** shorter than the tepals; **Fr** globose to oblong, 30 mm; **Se** black.

Insufficiently known. According to the protologue, this taxon was first regarded as belonging to *B. tubiflora*, but differs in its narrower erect and notably acuminate leaves, which are rough on both faces, pedicel length, and more numerous duller flowers (Maunder 1989). Magallán Hernández & Hernández Sandoval (2001) recorded the taxon (and genus) for the first time for Querétaro, and Hernández-Sandoval & al. (2005) provided a new record for Tamaulipas, which is corroborated by several specimens at MEXU.

**B. septentrionalis** García-Mendoza (Cact. Suc. Mex. 33(1): 3–5, ills. (2): 52 [erratum], 1988). **Type:** Mexico, Tamaulipas (*García-Mendoza & Ramos* 2903 [MEXU]). — **Distr:** Mexico (Tamaulipas, Nuevo León); cloud and pine-oak forests, rich organic soil on stony slopes, >1400 m.

[2] Acaulescent, rhizomatous; **Ros** caespitose; **L** 10–20, recurved, oblanceolate, basis dilated, smooth on both faces,  $70\text{--}90$  ( $-105$ )  $\times$   $(5\text{--})$   $6\text{--}9$  ( $-13$ ) cm,  $1.8\text{--}2.5$  ( $-3.3$ ) cm broad at the basal constriction, brilliant green, tip shortly acuminate, margins finely denticulate with 1–3 ( $-4$ ) denticles per mm; **Inf** cymose-paniculate, 1.5–2.5 m, with 4–7 part-**Inf** 9–25 ( $-50$ ) cm long, overall with 90–130 flowers, peduncle carmine-red, peduncular **Bra** 4–5, oblanceolate, to 30 cm, carmine-red; floral **Bra** 12–30, 1.5–4 cm, lanceolate to deltoid, reddish to translucent; **Ped** (10–) 35–45 ( $-60$ ) mm, longer than the floral bracts; **Fl** (50–) 55–60 ( $-65$ ) mm, in clusters of 2–4; **Tep**  $25\text{--}30 \times 2\text{--}8$  mm, carmine-red, tip and margins

yellowish, inside papillose, outside glabrous; **OTep** linear-oblong, 2–5 mm broad; **ITep** oblong to oblong-spatulate, 4–8 mm broad; **St** 2–4 mm shorter than the tepals; **Fil** subulate, papillose; **Anth** oblong, 5–7 mm; **Ov** slightly 6-sulcate,  $25\text{--}30$  ( $-33$ )  $\times$   $2\text{--}8$  mm, carmine-red; **Sty** as long as or slightly longer than the stamens, papillose; **Sti** slightly 3-lobate; **Fr** ovoid,  $35\text{--}50$  ( $-65$ )  $\times$   $25\text{--}35$  mm, green (?), stipitate for 7 cm; **Se** (8–)  $9\text{--}11 \times (5\text{--})$   $6\text{--}8$  mm, shining.

This is the N-most species of the genus, easily recognized by its glossy green leaves and showy deep red flowers on very long pedicels. It is closest to *B. yuccoides* according to the protologue.

The species is fairly tolerant to short periods of freezing (Jankalski 2005). It was hybridized with *B. yuccoides* ssp. *dekosteriana* in the 1990s, and selections were marketed under several cultivar names (Jankalski 2005, Guillot Ortiz 2010).

**B. tubiflora** (Kunth & C. D. Bouché) Kunth (Enum. Pl. 5: 844, 1850). **Type:** B. — **Lit:** Regel (1875: with ill.); Maunder (1989); García-Mendoza (2003: with ills.). **Distr:** Mexico (San Luis Potosí, Querétaro, Hidalgo, Veracruz); pine-oak and cloud forests, shady or semi-open mountain tops and rocky slopes, in wet, deep soils rich in organic matter, 1830–2440 m; flowers April to May. **I:** Curtis's Bot. Mag. 100: t. 6091, 1874, as *B. tonelii*.

≡ *Furcroya tubiflora* Kunth & C. D. Bouché (1845); **incl.** *Beschorneria cohniana* Jacobi (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Beschorneria tonelii* Jacobi *ex* Hooker *fil.* (1874); **incl.** *Beschorneria toneliana* Baker (1888) (*nom. inval.*, ICN Art. 61.1).

[1] Acaulescent to very shortly caulescent, with short conical caudex; **L** 18–30, semi-erect, arcuate-recurved, narrowly-linear to linear-lanceolate, carinate-canaliculate, base much broadened, semi-amplexicaul, triangular, above the base soon narrowing and contracted into a flat thick pseudo-petiole to 2.5 cm broad, with fine longitudinal stripes, keeled below towards the tip, apex narrowly acuminate, rough below, with very small denticles not visible to the naked eye, smooth above,  $45\text{--}65$  ( $-70$ )  $\times$   $(0.6\text{--})$   $0.9\text{--}1.6$

(–3) (in the middle) cm, green (yellow-green in dry specimens), waxy, tip sharp, obtuse, long narrowly-subulate, soon drying, margins rigid, opaque, bright green, finely papillose to denticulate, denticles not visible to the naked eye, texture papery; **Inf** racemose, (0.7–) 1–1.5 (–1.8) m, slightly inclined, brownish-red to reddish-purple, glabrous, peduncle to 2.5 cm  $\varnothing$  at the base, with membranous, lanceolate to ovate-lanceolate, remote, pendent **Bra**, fertile part  $\pm$  80 cm, lax, in strong specimens sometimes with a short branch with 2 or more flowers at the base, unbranched above, inclined or pendent above, with 23–80 (–150) flowers; **Ped** 6–25 mm, ascending-erect, with reddish-brown bracteoles 18–25  $\times$  6 mm; **Fl** 35–45 (–50)  $\times$   $\pm$  38 mm, single or in clusters of 2–3; **Tep**  $\pm$  33 mm, narrowly linear, slightly dilated at the spreading acute tip, tubularly connivent, greenish to light red in the lower  $\frac{3}{4}$ , yellow-green to green at the apex, obtuse, dorsally with a broad midrib, puberulent or glabrous outside, papillose inside; **OTep** linear-spatulate, acutish; **ITep** much broader; **St** slightly shorter than the tepals; **Fil** subulate, as long as or much shorter than the tepals, papillose below the middle, slightly thickened at the base, white, glabrous; **Anth** linear-lanceolate, sagittate, green; **Ov** oblong to subglobose, obtusely trigonous, 6-grooved, 8–15  $\times$  4–6 mm, greenish to reddish, puberulent to glabrescent, with a conical, trilobate neck; **Sty** erect,  $\pm$  30 mm, as long as or much longer than the stamens, base thickened and 3-sulcate, white, papillose; **Sti** obscurely 3-lobed, slightly papillose, white; **Fr** globose, 12–15 (–18)  $\times$  11–15 mm, green with reddish tinge; **Se** plano-convex, 4–6  $\times$  3–5 mm, shiny. — *Cytology*:  $2n = 60$  (Satô 1935).

Closest to *B. rigida*. The report of the synonymous *B. tonellii* for Chiapas (Breedlove 1986) is most certainly a misidentification of *B. albiflora*. The occurrence in Querétaro and Veracruz is based on specimens at MEXU. In cultivation, the name is often misapplied to the much larger growing *B. yuccoides* ssp. *dekosteriana* (Jankalski 2005).

**B. wrightii** Hooker fil. (Curtis's Bot. Mag. 127: t. 7779 + text, 1901). **Type**: not typified. —

**Lit**: Berger (1906: with ill.); Berger (1907); both as *B. pubescens*; Maunder (1989); García-Mendoza (2003). **Distr**: Mexico (México: Sierra de Temascaltepec); exposed rock cracks in pine-oak forests, igneous and rocky substrates rich in organic matter; 2000–2580 m; flowers February to April.

**Incl.** *Beschorneria pubescens* A. Berger (1906).

[2] Plants to 1.5 m tall; stems to 60–90 cm, with a conical caudex to 15 cm  $\varnothing$ ; **Ros** with 18–30 leaves; **L** large, densely crowded, erect, linear-lanceolate, ensiform, carinate, fleshy, subcoriaceous, base broadened, very thick and biconvex, rather stiff and fleshy along the midrib, scabridulous on the nerves below, smooth above, 70–100 (–150)  $\times$  3–5 cm in the middle, glaucous-green, tip narrowed into a long brown stiff point, margins very narrowly scarious, finely and deeply denticulate; **Inf** paniculate, 1.7–3 m, peduncle 0.8–2 cm  $\varnothing$  at the base, waxy, bright pink or cherry- to coral-red, laxly bracteate, with deltoid-lanceolate acuminate **Bra** 8–10 cm long, upper shorter, glabrous, white streaked with red, fertile part lax, pyramidal, rather slender, with 6–27 spreading or recurved part-**Inf** with 150–180 flowers in total; **Bra** ovate, white, streaked with red; **Ped** 20–40 mm, pendent, glabrous; **Fl** 45–55 (–60) mm, in clusters of 2–3 (–4), (weakly) pubescent; **Tep** greenish, with broad yellow margins, yellow within, with tips obtuse, spreading, fading to yellow; **OTep** oblong to slightly spatulate; **ITep** oblong, canescent, papillose inside; **Fil** thickened at the base, whitish, at the beginning of the anthesis shorter but finally longer than the tepals; **Anth** linear, 12 mm, tips exerted; **Ov** cylindrical to conical-cylindrical, 17–28  $\times$  3–7 mm, green to reddish, puberulent or glabrescent in mature flowers; **Sty** as long as the filaments and slightly longer than the tepals, thickened at the base, papillose; **Sti** globose, 3-lobed, papillose, sometimes ciliate; **Fr** subglobose to somewhat conical, 35–40  $\times$  17–20 mm; **Se** plano-convex, 7–8  $\times$  5–6 mm.

The pubescent flowers are characteristic of the species (*B. calcicola* has merely puberulent flowers). Closely allied to "*B. dekosteriana*" (=

*B. yuccoides* ssp. *yuccoides*) (with glabrous flowers) according to the protologue.

**B. yuccoides** K. Koch (Wochenschr. Gärtnerei Pflanzenk. 2: 337, 1859). **Type:** not typified. — **Distr:** Mexico (Hidalgo, Puebla, Veracruz, Chiapas); 2700–3000 m.

Differs from the other members of the *B. yuccoides* group in its stemless habit (vs. caulescent, to arborescent in *B. albiflora*), its leaves scabrous below and its pedicels shorter than or about as long as the bracts (vs. leaves smooth below and pedicels longer than the bracts in *B. septentrionalis*), and its glabrous flowers (vs. pubescent flowers in *B. wrightii*).

**B. yuccoides** ssp. **dekosteriana** (K. Koch) García-Mendoza (Monocot. Mexic. Syn. Florist. 1(1): 30, 1993). **Type:** not typified. — **Lit:** Maun-der (1989); Ullrich (1991: with ill.); Irish & Irish (2000: with ill.); Calderón de Rzedowski & Rzedowski (2005); Cházaro Basáñez & Vazquez-Ramírez (2015); all as *B. yuccoides*. **Distr:** Mexico (Hidalgo, Puebla, Veracruz, Chiapas); mesic woodlands, pine, pine-oak and fir forests, 2600–3400 m; flowering April to May. **I:** Hooker (1860: as *B. yuccoides*); Baker (1884: as *B. bracteata*). — Fig. 1.

≡ *Beschorneria dekosteriana* K. Koch (1864); **incl.** *Beschorneria californica* Troubetzkoy (1877); **incl.** *Beschorneria dubia* Carrière (1877); **incl.** *Beschorneria mexicana* Troubetzkoy (1877); **incl.** *Beschorneria bracteata* Jacobi ex Baker (1882); **incl.** *Beschorneria decosteriana* Baker (1884) (*nom. inval.*, ICN Art. 61.1); **incl.** *Beschorneria superba* Hort. Hanbury ex Baker (1888) (*nom. inval.*, ICN Art. 32.1c?); **incl.** *Beschorneria argyrophylla* hort. ex W. Watson (1889) (*nom. inval.*, ICN Art. 32.1c); **incl.** *Beschorneria viridiflora* Hort. Hanbury ex Baker (1892); **incl.** *Beschorneria glauca* hort. ex Gumbleton (1898); **incl.** *Beschorneria hidalgorupicola* Matuda (1967).

[2] Overall **Ros** size not recorded; **L** (10–) 20–35, inner erect, outer arching, linear-lanceolate to lanceolate, base broadened to 4–7 cm, then narrowed above the base, broadly attenuate, (sub-) coriaceous, scabrous below, papillose on

**Fig. 1** *Beschorneria yuccoides* ssp. *dekosteriana*. (Copyright: J. Trager)

the nerves, glabrous above, (40–) 60–90 (–100) × 3.3–3.5 (–5.5, to 10 in cult.) cm, grey-green to (brilliant-) green, glaucous, tip acuminate, margins finely denticulate; **Inf** 1–1.8 (–3.2 in cult.) m, peduncle ±1–1.25 m, 1.5–3.5 cm Ø at the base, bright red, reddish to dark red, fertile part with tip overhanging at first, later erect, with up to 20 part-**Inf** in the upper ⅔, drooping, red to reddish-brown, with 130–250 flowers; **Bra** broadly ovate, 0.4–3 cm, reddish, pilose; **Ped** 4–35 mm, shorter than the subtending bracts; **Fl** 40–50 mm, glabrous to glabrescent, in clusters of (2–) 3–5 (–7), glabrous to glabrescent, (always?) functionally unisexual; **Tep** 33–40 × 3.5–7 mm, free but narrowly connivent to form a tube-like corolla, red or yellowish-green and with reddish tinge, tip green, upper ±10 mm somewhat spreading and slightly pilose; **OTep** linear-oblong to oblong, 3.5–5 mm broad, acute; **ITep** oblong to spatulate, 5–7 mm broad; **Fil** filiform, 35 mm, included; **Anth** oblong, 3.5–6 mm, greenish; **Ov**

cylindrical, 20 × 5 mm, dark red, neck slightly constricted; **Sty** filiform; **Sti** slightly pilose; **Fr** oblong to subglobose or subclavate, 30–40 × 15–25 mm; **Se** flat, 7–8 × 3.5–5 mm. — **Cytology**: 2n = 60 (Watkins 1936: as *B. superba*).

According to the protologue differing from ssp. *yuccoides* (as *B. yuccoides*) especially in its more luxuriant growth and its larger, at first overhanging inflorescences with reddish peduncles and reddish bracts (vs. straight inflorescences with greenish peduncles and reddish-greenish bracts). The long-standing confusion between the two taxa goes back to Hooker (1860), who, under the name *B. yuccoides*, figured what was subsequently published as *B. dekosteriana*, and ever since, almost all descriptions of “*B. yuccoides*” refer to the reddish peduncles and bracts of what is ssp. *dekosteriana*. To make matters worse, Baker (1884) figured plants of the true *B. yuccoides* under the misapplied name *B. dekosteriana*. — *B. superba* belongs here according to Oliver & Bailey (1927) and Berger (1906) (both under *B. yuccoides*).

This subspecies is more variable and widespread than ssp. *yuccoides* and by far the most commonly cultivated *Beschorneria* (Jankalski 2005). Its leaves are used as soap substitute for washing clothes, and the plant is used as living fence, as ornamental and for its edible flowers (Matuda 1966, Reyes & Rosado 2000; both as *B. bracteata*). Maunder (1989) provided a first record for Chiapas, based on *MacDougall*

377 from Cerro Tres Picos. The taxon is naturalized in New Zealand and N Argentina (Zimer 2014, Cantero & al. 2016; both as *B. yuccoides*).

According to Symon (2005), and based on experience in cultivation in Australia, this taxon (as *B. yuccoides*) produces flowers which are functionally unisexual: The plants (monoecious or male) produce either functionally male green flowers only, or many functionally male pink flowers as well as few functionally female pale green flowers. The plant is hardy outdoors in the Mediterranean or even in S England (Ullrich 1991). In the USA, it may survive temperatures down to –12 °C for short periods (Irish & Irish 2000). ‘Flamingo Glow’ is a variegated cultivar, and ‘Quick Silver’ a cultivar with silvery leaves; both are sold as *B. yuccoides*.

**B. yuccoides** ssp. **yuccoides** — **Lit**: Maunder (1989: with ill.). **Distr**: Mexico (Hidalgo: Sierra de Pachuca); woodland and *Abies-Juniper* forests, 2700–3000 m. **I**: Baker (1884: as *B. dekosteriana*). — Fig. 2.

**Incl.** *Beschorneria yuccoides* hort. ex Hooker (1860) (*nom. illeg.*, ICN Art. 53.1).

[2] Differs from ssp. *dekosteriana*: **L** erect, 45–65 cm, coriaceous; **Inf** peduncle 1–2 m, green(ish) to light brown, **Inf** with 100–120 flowers; **Bra** greenish to light brown; **Fl** in clusters of 2–4; **Fr** oblong. — **Cytology**: 2n = 60 (Watkins 1936, Cave 1964, both most probably referring to ssp. *dekosteriana*).

**Fig. 2** *Beschorneria yuccoides* ssp. *yuccoides*. (Copyright: U. Eggli)

The typical subspecies of *B. yuccoides* remains incompletely known, and unfortunately, no modern complete description is available. The leaves and flowers are used as drop infusion against catarrh in sheep according to the annotation of a herbarium specimen (*García-Mendoza* 1418, MEXU).

## Furcraea AGAVACEAE

J. Thiede

**Furcraea** Ventenat (Bull. Sci. Soc. Philom. Paris 1: 65–67, 1793). **Type:** *Furcraea gigantea* Ventenat [type element according to l.c. p. 65; ING (accessed Aug. 2015) incorrectly lists *Agave cubensis* Jacquin (mentioned on p. 66 of the protologue as additional species) as lectotype designated by Britton, Fl. Bermuda, 80, 1918]. — **Agavoideae - Agaveae** — **Lit:** Baker (1879: synopsis); Baker (1888: synopsis); Drummond (1907: synopsis); Trelease (1910: taxonomic notes); Trelease (1915a: synopsis); Trelease (1915b: synopsis Guatemala); Trelease (1920: Fl. Mexico); Standley & Steyermark (1952: Fl. Guatemala); McVaugh (1989: Fl. Novo-Galiciana); Lott & García-Mendoza (1994: Flora Mesoamericana); Álvarez de Zayas (1996: synopsis Cuba); García-Mendoza (1998: revision Mexico & Guatemala); García-Mendoza (2001a: revision); García-Mendoza (2001b: revision arborescent taxa); Guillot Ortiz & Meer (2010: synopsis cultivated taxa Spain); García-Mendoza (2011: Fl. Valle Tehuacán-Cuicatlán). **Distr:** C and S Mexico, C America to Panama, Caribbean Region, Colombia, Ecuador, Venezuela, French Guiana, Guayana, Suriname, Peru, Bolivia, Brazil, Paraguay (the S American range apart from Colombia, Venezuela, Ecuador, Peru and Bolivia, as well as major parts of the Caribbean distribution might be exclusively

anthropogenic). **Etym:** For Antoine F. de Fourcroy (1755–1809), French politician and chemist, 1784 director at the Jardin des Plantes in Paris.

**Incl.** *Funium* Willemet (1796). **Type:** *Funium pitiferum* Willemet.

**Incl.** *Furcroea* De Candolle (1803) (*nom. inval.*, ICN Art. 61.1).

**Incl.** *Furcroya* Rafinesque (1814) (*nom. inval.*, ICN Art. 61.1).

**Incl.** *Fourcroya* Sprengel (1817) (*nom. inval.*, ICN Art. 61.1).

**Incl.** *Fourcroea* Haworth (1819) (*nom. inval.*, ICN Art. 61.1).

**Incl.** *Codonocrinum* Willdenow ex Schultes & Schultes *fil.* (1829). **Type:** *Codonocrinum agavoides* Schultes & Schultes *fil.*

**Incl.** *Fourcraea* Steudel (1840) (*nom. inval.*, ICN Art. 61.1).

**Incl.** *Roezlia* Laurentius (1861). **Type:** *Roezlia regia* Laurentius.

**Incl.** *Roeslia* Baillon (1894) (*nom. inval.*, ICN Art. 61.1).

Plants strictly monocarpic when unbranched or without offsets; stems none or a thick short or to 6 m long trunk; **Ros** with densely crowded leaves; **L** large, erect, coriaceous, lanceolate or linear, long and narrow, thin and flexible or rather thick and stiff, concave or flattened, keeled below, surface smooth or scabrous, rough on the veins below in some taxa, green or glaucous, tip a short mucro or corneous-hardened by the involute leaf

e-mail: joachim\_thiede@gmx.de

margins, margins dentate, denticulate, entire or dentate-entire, teeth simple or bicuspidate, sometimes on elevated bases; **Inf** tall lax terminal panicles to 15 m but mostly shorter, peduncle short or up to 3.5 m, bracteate, fertile part pyramidal or rhomboidal to fusiform or oblong, part-**Inf** (= 1.-order branches) on long bracteate branches, with 2.- to 4.-order branches, glabrous or puberulent, often bulbiferous, bulbils conical to ovoid and sometimes with leafy bracts; **Fl** pendulous, bracteate, pedicellate, single or fasciculate in clusters of 2–5, often all or in part replaced by bulbils; **Tep** generally equal but **OTep** narrower and **ITep** with prominent dorsal midrib, ovate to elliptic, (almost) free to the base, greenish- or yellowish-white to white, sometimes with reddish tinge, overlapping marginally, glabrous to puberulent; **Fil** 3 + 3,  $\pm \frac{1}{2}$  as long as the tepals and affixed to their bases, dilated below the middle, subulate distally, papillose; **Anth** oblong, 2–8 mm, dorsifixed, centric or sometimes slightly excentric, introrse, versatile; **Ov** inferior, oblong, cylindrical or trigonous, with a short neck at the tip, glabrous or puberulent; **Sty** columnar, basally swollen and triquetrous with 3 basal ridges, papillose; **Sti** small, shortly 3-lobate; **Fr** woody capsules, oblong, subglobose or ovoid, 3-valvate, stipitate, rostrate, opening loculicidally; **Se**  $\pm$  deltoid, flattened, often (always?) narrowly to broadly winged, black. — **Cytology**:  $2n = 60$  (Whitaker 1934, Satô 1935, Fritsch 1970) (reports of  $2n = 44–46$  and  $48–50$  by Heitz (1926) are dismissed as doubtful).

The genus has not been completely studied up to the complete revision by García-Mendoza (2001a), which clarified the circumscriptions and taxonomy of many previously uncertain taxa; it is largely followed here with the exception of the taxa that have not yet been formally published. Some of the taxa recognized may, however, merely represent early anthropogenic selections, cultivars or hybrids. With a maximum length of 15 m in *F. cabuya* (García-Mendoza 2001a), the genus apparently has the largest inflorescences of any plant.

Ullrich (1991a) regards the publication of the generic name *Furcraea* as cited above as not effectively published but this was rejected in the

first edition of this handbook, and Ullrich's interpretation is also not accepted by reference works such as García-Mendoza (1998) and Govaerts (2014+).

According to recent molecular and morphological phylogenies, *Furcraea* is sister of *Beschorneria*, and both together are sister of *Agave* in most analyses (Hernández-Sandoval 1995, Bogler & Simpson 1995, Bogler & al. 1995, Bogler & Simpson 1996, Bogler & al. 2006, Rocha & al. 2006, Good-Avila & al. 2006). The two genera exhibit the following putative synapomorphies: Filaments papillose and slightly to distinctly thickened below, ovary basally ribbed and broadened, and pollen shed in tetrads (Álvarez de Zayas & Köhler 1987, Ojeda Revah & Ludlow Wiechers 1995, Hesse & al. 2009). *Beschorneria* differs conspicuously from *Furcraea* in habit and in having soft leaves without teeth, large coloured bracts, connivent tepals, and filaments  $\pm$  as long as the tepals.

*Furcraea* can (possibly artificially) be divided as follows (adapted from García-Mendoza 2001a: 71):

- [1] Sect. *Furcraea* (incl. Sect. *Spinosa* Drummond 1907, *nom. inval.*, ICN Art. 22.2): Stems mostly none or short, to 0.7–1.5 m, or rarely arborescent to 3 (–9) m; **L** margins with conspicuous  $\pm$  distant teeth (occasionally teeth few or absent), leaf tip corneous, mucronate; bulbils bracteate or foliose; seedlings with small cotyledons. — Possibly a paraphyletic hold-all.
- [2] Sect. *Serrulatae* Drummond 1907 (incl. subgen. *Roelia* (Laurentius) Baker 1888; incl. ser. *Flexiles* Baker 1879 = subgen. *Flexiles* (Baker) García-Mendoza 2001, *nom. inval.* ICN Art. 29.1): Plants mostly arborescent and stems conspicuous, 1–9 m; **L** margins closely minutely denticulate, leaf tip corneous; bulbils foliose, with chartaceous outer leaves; seedlings with large cotyledons.

Hochstätter (2016) published 3 infrageneric taxa which each includes species of both sections as recognized above; Hochstätter's names are untypified and invalidly published under ICN Art. 29.1.

**Ethnobotany:** The leaves of many species are used as source of fibres on local household or industrial scale in major parts of its area, but also outside the Americas esp. in India, Madagascar and Mauritius (García-Mendoza 1998). *Furcraea* species are also planted as hedges and living fences, and to prevent soil erosion. The flowers are eaten and used as religious Easter decoration, the inflorescences as fodder, the leaf juice as soap or to stupefy fishes, to cure gastritis, prostata inflammation, hepatitis, and for liver cleansing and increasing bile secretion (see comments for the individual species). Many species are cultivated as ornamentals worldwide in (sub-) tropical and Mediterranean climates.

For species cultivated in the open mainly in Mediterranean climates or for naturalized species, see Irish & Irish (2000) for the USA, David (2009) for Great Britain, Guillot Ortiz & Meer (2010) for Spain, Wilcox (2005) for New Zealand, and Crouch & Smith (2011) and Smith & Figueiredo (2012) for South Africa.

The following names are of unresolved application but are referred to this genus: *Agave stenophylla* Jacobi (1866); *Agave vivipara* Miller (1768) (*nom. illeg.*, ICN Art. 53.1); *Agave vivipara* Willdenow (1799) (*nom. illeg.*, ICN Art. 53.1); *Agave vivipara* Arruda (1810) (*nom. illeg.*, ICN Art. 53.1); *Furcraea cubensis* Haworth (1819) (*nom. illeg.*, ICN Art. 53.1)  $\equiv$  *Agave cubensis* (Haworth) Sprengel (1825) (*nom. illeg.*, ICN Art. 53.1); *Furcraea demouliniana* Jacobi (1867); *Furcraea rigida* Landry ex Jacobi (1867) (*nom. inval.*, ICN Art. 36.1c); *Furcraea roezlii* Eichler (1881); *Furcraea roezlii* var. *atropurpurea* Hort. De Smet (1876); *Furcraea sobolifera* Hort. J. F. Cels ex Jacobi (1867) (*nom. inval.*, ICN Art. 36.1c).

**F. acaulis** (Kunth) B. Ullrich (Quepo 6: 69, ills., 1992). **Type:** Venezuela (*Bonpland & Humboldt* 633 [†]). — **Lit:** Lott & García-Mendoza (1994: as *F. stratiotes*). **Distr:** N Colombia (César, Guajira, N Santander); N Venezuela (Carabobo, Cumaná, Distrito Federal, Falcón, Lara, Miranda, Sucre, Yaracuy, Zulia); Ecuador (La Loja); chiefly in well-drained limestone soils,

coastal plains, thorn scrub, montane and cloud forests, 0–1330 m; flowers July to September. **I:** Hoyos (1982: as *F. humboldtiana*).

$\equiv$  *Yucca acaulis* Kunth (1816); **incl.** *Codonocrinum agavoides* Willdenow ex Schultes & Schultes fil. (1829); **incl.** *Furcraea altissima* Todaro (1889); **incl.** *Furcraea humboldtiana* Trelease (1910); **incl.** *Furcraea stratiotes* J. B. Petersen (1922).

[1] Stems simple, arborescent to subcaulescent, to 1–3.5 m, dry leaves persisting; **Ros** 3.5 m  $\varnothing$ ; **L** 70–100, at first erect, later spreading, lanceolate to broadly lanceolate, coriaceous, at the base 3.5–5 (–9.5) cm broad and 4 cm thick, plane-concave in cross-section, almost flat, concave towards the apex, acute, rough below, smooth above, or also rough on the lower part of the upper face (Dewey 1943), (1–) 1.2–1.75 (–2) m  $\times$  (9–) 11–18 (–20) cm (in the middle), glaucous or yellowish-green to dark green or greyish, margins dentate, sometimes corneous-dentate to the base; **marginal teeth** geminate or doubly geminate, reflexed in opposite directions near the leaf base, further up sometimes single and upcurved, intervening margin concave, or rarely teeth nearly all simple and mostly upcurved and intervening margin nearly straight, teeth strong, 3–10 mm, 4–6 (–7) mm broad at the base, reddish to orange, becoming garnet-red with darkened tips, or at last dark chestnut-brown, on broadly deltoid or semi-circular herbaceous decurrent bases, or sometimes decurrent along the intervening margin, (1.5–) 2–4.5 (–6 (–8)) cm apart at mid-leaf, 1–3 cm at the base; **terminal Sp** acute, partially involute, mucronate, small, robust, channelled below, 3–7 (–10)  $\times$  2 mm, dark reddish to garnet-red or chestnut-brown, slightly decurrent; **Inf** 7–9 (–12) m, peduncle 5–6 m, green, with short bracts, fertile part in the upper  $\frac{1}{2}$  or  $\frac{1}{3}$ , with  $\pm 40$  part-**Inf**, 40–70 (–100) cm, glabrous, with 20–30 2.-order branches, 5–17 cm, green, glabrous or pilose, bulbiferous, bulbils conical, 23–30  $\times$  7–8 mm, bracteate, green, covered with 2 scarious bracts; **Ped** 3–5 mm, glabrous; **Fl** 37–40 mm, geminate; **Te** 20–23 mm,  $\pm$  obtuse, yellowish-green to light yellow, with white margins, glabrous; **OTep** narrowly elliptic, (4–) 5–7 mm broad; **ITep** elliptic, (6–) 8–10 mm broad; **Fil** subulate, 12–14 mm,

1–2 mm wide at the broadened base; **Anth** oblong, 2 mm, yellow; **Ov** cylindrical, triquetrous, 17–20 × 3–4 mm; **Sty** triquetrous, (15–) 18–20 mm, 2–3 mm wide at the broadened base; **Sti** trifid; **Fr** subsphaerical, 35–40 × 30–40 mm, stipitate for 10 mm; **Se** winged for 2–3 mm, 13–15 × 8–9 mm, shiny.

Insufficiently known before the first full description was published by García-Mendoza (2001a). The type collection does not seem to be extant (Stauffer & al. 2012).

After Trelease (1915a) wrongly listed the much older *Yucca acaulis* in the synonymy of his *F. humboldtiana*, Ullrich (1992) was the first to notice the error, which he rectified by publishing the necessary new combination.

First collected by Bonpland and Humboldt in Venezuela where the species is native. The distribution in Colombia appears to be natural, and several fragmentary specimens from Grenada, the Virgin Islands and Trinidad may belong here (García-Mendoza 2001a). Spineless plants placed here by Hoyos (1982) appear to belong to *F. foetida*. *F. stratiotes* (described from material collected in Nicaragua in 1848 that flowered in cultivation in Copenhagen in 1921; never recollected in Nicaragua and the only known occurrence is in the Virgin Islands according to Proctor & Acevedo-Rodríguez 2005) differs in having smaller flowers and compressed bulbils.

Olivares & Medina (1984) argue that the flowers are sterile and that the plants propagate only through bulbils, but the description of fruits and seeds by García-Mendoza (2001a) shows that this is not universally true.

*F. acaulis* is widely cultivated in Venezuela for fibre (Dewey 1943), and Giraldo & al. (2009) report that the leaves are used against various illnesses.

**F. antillana** A. Álvarez (Anales Inst. Biol. UNAM, Ser. Bot. 67(2): 331–335, ill., 1996). **Type:** Cuba, La Habana (Álvarez 63654 [HJJB, MEXU]). — **Lit:** Proctor & Acevedo-Rodríguez (2005). **Distr:** Greater Antilles: Cuba, Hispaniola, Puerto Rico (cultivated); mainly semideciduous forests or dry coastal scrub or thornscrub, also in pine forests and secondary formations, on

limestone or serpentine, 0–200 m; flowers July to September. **I:** García-Mendoza (2001a).

[1] Stems none or short, to 0.5 m, not rhizomatous; **L** 90–110, erect, straight, coriaceous, narrowly lanceolate or narrowly elliptic, base narrowed to 2–3 cm, nearly flat to slightly canaliculate, long-acuminate, slightly folded towards the tip, rigidly coriaceous, often asperous on both faces, (0.6–) 0.9–1.2 (–2) m × (3–) 5–8 (–10) cm, light green to somewhat yellowish, opaque, margins straight between the teeth; **marginal teeth** triangular, straight or normally somewhat upcurved, 1.5–5 (–7) mm, 1–3 mm broad at the base, chestnut-brown to nearly black, on small deltoid bases, decurrent, 0.8–2 (–5) cm (0.4–1 (–1.5) cm at the leaf base) apart, lacking in the upper  $\frac{1}{3}$  –  $\frac{1}{4}$  of the leaf, **L** tip acute, not or inconspicuously mucronate for 1 mm; **Inf** 4–6 (–8) m, peduncle 3–4 m, glabrous, green, with triangular green **Bra** 20–30 cm long, fertile part narrowly fusiform, part-**Inf** 50–80, (20–) 40–70 (–120) cm, glabrous or pilose, ascending, in the upper  $\frac{1}{2}$  –  $\frac{2}{3}$  of the inflorescence, with 5–10 2.-order branches 10–25 (–30) cm long, rarely with 3.-order branches to 5 cm long, bulbiferous, bulbils conical, narrowly fusiform, bracteate to somewhat leafy, with leaves to 25–35 (–50) × 5–8 (–12) mm; **Ped** 2–6 (–10) mm; **Fl** single or 2–3 grouped together, campanulate, (25–) 32–40 (–47) mm; **Tep** elliptic, (12–) 14–20 (–27) mm, glabrous, whitish-green; **OTep** 3–7 mm broad; **ITep** 5–10 mm broad; **Fil** 8–12 (–20) mm, 1.5–2 mm broad at the base; **Anth** oblong, 2–4 mm, yellowish; **Ov** cylindrical, triquetrous, (13–) 18–20 × 3–4 mm; **Sty** (10–) 12–15 (–20) mm, 4–5 mm wide at the broadened base; **Sti** 3-lobate; **Fr** oblong, (25–) 30–35 (–50) × (16–) 25–30 mm, rostrate, base constricted, stipitate for 10 mm; **Se** winged for 1–2 mm, (8–) 9–11 (–12) × 5–7 (–9) mm, shiny.

Often confused with *F. hexapetala* and similar to the Mexican *F. cahum*, but differing from the latter in being smaller in all parts, including more and shorter leaves with smaller and fewer marginal spines, as well as glabrous inflorescence branches and flowers (Álvarez de Zayas 1996, García-Mendoza 2001a). Variable in leaf and flower characters, caused mainly by different

edaphic conditions. Reproduction is mainly asexual by bulbils (Álvarez de Zayas 1996).

**F. boliviensis** Ravenna (Pl. Life (Stanford) 34: 151–153, ill., 1978). **Type:** Bolivia, Cochabamba (Ravenna 2305 [Herb. Ravenna]). — **Lit:** Ullrich (1992). **Distr:** W & C Bolivia (Cochabamba, La Paz, Santa Cruz); infrequent on open rocky slopes in arid woodland, xeromorphic forests, and anthropogenic savannas, in partial shade, 1100–3500 m; flowers March to June.

[1] Stems short, stout, sometimes prostrate, 30–40 × 10–15 cm; **Ros** 0.9–1 (incl. stem) × 1–1.4 m; **L** numerous, linear-lanceolate, erect, often spreading, thick, rigid, narrowed near the base to 3.5–5.5 cm, moderately channelled, smooth, (45–) 60–95 × 8–9 (–11) cm, opaquely ash-green, margins dentate throughout; **marginal teeth** small, simple, uncinat, upcurved, fragile, 2–4 mm, 1–3 mm broad at the base, reddish, on small deltoid bases, 1.5–2 (–2.5) cm apart, near the base 1 cm; **terminal Sp** none, with weak, acute, reddish mucro 1–1.5 mm long; **Inf** 4–7.5 m, peduncle pale green to yellowish-green, velutinous, fertile part with velutinous part-**Inf** 30–40 cm long, with 1–3 green, velutinous 2.-order branches 10–15 cm long, bulbilliferous, bulbils conical, leafy, (20–) 40–50 × (8–) 12–18 mm, with 4–6 dentate small leaves; **Ped** 3–7 mm, velutinous; **Fl** single or geminate, 45–55 mm; **Tep** 25–30 mm, velutinous, whitish-green; **OTep** narrowly elliptic, 7–8 mm broad; **ITep** elliptic, 9–11 mm broad; **Fil** 13–14 mm, 3–4 mm wide at the broadened base; **Anth** oblong, 4 mm, yellow; **Ov** 20–25 × 3–5 mm; **Sty** 18 mm, 4 mm wide at the broadened base; **Fr** and **Se** unknown.

For long known from the sterile type specimen only, but meanwhile documented by further collections. The first complete description was provided by García-Mendoza (2001a). The species is characterized by leaves with small teeth, and velutinous peduncles, inflorescence branches and flowers, and leafy bulbils with dentate small leaves.

According to the protologue related to the Mexican *F. pubescens* and the Peruvian *F. andina* (here treated as synonym of *F. hexapetala*). Apart from *F. occidentalis* (with much smaller teeth)

*F. boliviensis* is the only native Bolivian species. Pino (2006) speculates that the species might also occur on the Peruvian altiplano.

**F. cabuya** Trelease (Ann. Jard. Bot. Buitenzorg 3(Suppl. 2): 906, tt. 36–37, 1910). **Type:** Costa Rica (Worthen & Dewey s.n. [MO]). — **Lit:** Lott & García-Mendoza (1994: online version with ills.); García-Mendoza (1998); Robbins (2001: online version with ills.). **Distr:** Honduras, W Nicaragua, Costa Rica, Panama; cultivated or naturalized in Mexico (Yucatán), Colombia and Venezuela; disturbed thorn forests, savannas and pine forests, (50–) 300–1800 m; flowers July to October.

[1] Stems none or to 0.5 (–1) m, covered with old leaves; **Ros** 2–3.5 m Ø; **L** 40, lanceolate, erect, coriaceous, semisucculent, abruptly narrowed above the base to ±5–8 cm, 4–6 cm thick at the base, openly concave, long acuminate, rough below, smooth above, (1–) 1.5–2 (–3) m × (10–) 15–20 (–22) cm, green, glaucous when young, above slightly glossy and rather pale-lined, margins often subrevolute, crenate, nearly straight between the teeth, sometimes with a corneous band from mid-leaf towards the base, **marginal teeth** deltoid, strong, upcurved, straight or recurved, 5–8 (–11) mm, 3–5 mm broad at the base, reddish chestnut-brown to blackish, decurrent on distinct deltoid herbaceous bases nearly 10 mm wide, (2.5–) 3–5 (–6) cm apart (2–4 cm near the leaf base), along the whole margin; **terminal Sp** conical, minute, 1–3 (–5) × 1–1.3 mm, chestnut- or dark brown; **Inf** 4–8 (–10 (–15)) m, peduncle much shorter than the fertile part, glabrous, green, with triangular or rhomboidal **Bra** 20–50 (–70) cm long, fertile part open, with part-**Inf** 45–70 (–100) cm long, with 8–13 2.-order branches (4–) 10–25 cm long, both glabrous or puberulent, rarely with 3.-order branches <2.5 cm long, sometimes bulbilliferous, bulbils ovoid to ovoid-conical, (20–) 60 × (15–) 50 mm, with 2–3 scarios green bracts; floral **Bra** 2–3 mm, puberulent; **Ped** glabrous, 3–7 (–12) mm, glabrous or pilose; **Fl** (37–) 40–55 (–62) mm, single or 2–3 (–6) grouped together; **Tep** (20–) 25–30 (–35) mm, whitish- to yellowish-green to white, glabrous, overlapping parts papillose; **OTep**

narrowly elliptic, 7–10 (–15) mm broad; **ITep** elliptic, 10–15 (–18) mm broad; **Fil** 11–16 mm, 1.5–3 mm wide at the broadened base; **Anth** oblong, 3–4.5 mm, yellowish; **Ov** cylindrical, 20–25 (–30) × 3–5 mm, glabrous, with a neck 9–10 mm long; **Sty** 15–22 mm, 4–5 mm wide at the broadened base; **Sti** papillose, 3-lobate; **Fr** oblong, shortly stipitate, 55–60 (–75) × (35–) 40–45 mm; **Se** winged for 3 mm, 15–17 × 9–10 mm, shiny.

Characterized by (20–) 30–50 widely separated teeth along the whole leaf margin, and flowers with an ovary 3–10 mm shorter than the tepal lobes. Similar to *F. hexapetala* in leaf size, the number of the widely separated teeth, and the diffusely branched inflorescence, but differing in its larger flowers, fruits and seeds (García-Mendoza 2001a). *F. cabuya* var. *integra* is placed in the synonymy of *F. foetida*.

The widely cultivated plant and its fibre are called “cabuya”, “cabuia”, or “cabulla”. Propagation is especially by rhizomatous offsets, and also by bulbils. In Costa Rica, the fibres were used to make twines, ropes, saddlebags, cinches, halters, and hammocks, often as household industry (Dewey 1943). Its inflorescence is the largest of any flowering plant.

**F. cahum** Trelease (Ann. Jard. Bot. Buitenzorg 3(Suppl. 2): 908, t. 39, 1910). **Type** [lecto]: Mexico, Yucatán (*Schott* 809 [F, BM, ILT, MO, US]). — **Lit**: Lott & García-Mendoza (1994: online version with ills.); García-Mendoza (1998). **Distr**: Mexico (Yucatán peninsula: Campeche, Quintana Róo, Yucatán); tropical semideciduous forests, to 150 m.

[1] Stems none or short, to 0.5 (–1) m; **Ros** 2–4 m Ø; **L** 60–80, erect, linear-lanceolate, coriaceous, narrowed to 2.5–3.5 cm above the base and 1.5–2.5 cm thick, long acuminate, flat below, concave, keeled, with prominent venation, smooth, (1.3–) 1.6–2.2 (–2.5) m × (5–) 6–10 (–11.5) cm, bright to brilliant green, margins ± straight between the teeth, dentate to dentate-corneous below, yellowish to dark reddish; **marginal teeth** rather strong, upcurved or straight, rarely geminate, 2–4 (–5) mm, 2–3 (–4) mm wide at the base, reddish, brown or dark brown to black,

decurent on small deltoid bases, 1.5–3 (–4 (–6)) cm apart at mid-leaf, 0.5–1 (–2) cm near the base, absent for the upper ¼ – ½; **terminal Sp** conical, corneous, acute, 1.5–6 × 1.5–2.5 mm, blackish chestnut-brown or reddish; **Inf** (4–) 5–8 (–11) m, peduncle to (3.5–) 5–8 m, green, glabrous, with long triangular, green, puberulent to pilose **Bra** 30–65 cm long, fertile part oblong, in the upper ¼ – ½, with 40–50 part-**Inf** 50–80 cm long, with 5–8 2.-order branches 5–30 cm long, lower rarely with 3.-order branches to 12 cm long, all puberulent to pilose, freely bulbiferous, bulbils bracteate to somewhat foliose, conical, (15–) 20–28 (–40) × 4–8 (–13) mm, with (2–) 3 deltoid green bracts, small leaves 1–3 cm; floral **Bra** deltoid, 3 mm, puberulent, brown; **Ped** 4–6 (–10) mm, puberulent; **FI** (35–) 40–45 (–52) mm, single or 2–3 (–4) grouped together, minutely papillose-puberulent; **Tep** 17–20 (–25) mm; **OTep** lanceolate-elliptic, (3–) 7–9 mm broad, glabrescent to glabrous; **ITep** elliptic, (4–) 8–12 mm broad, pilose to glabrescent on the midrib, papillose in the area of overlap, yellowish-green on the outer face, whitish within; **Fil** 10–14 mm, 2.5–4 mm wide at the broadened base, somewhat papillose; **Anth** oblong, centric, sagittate, 3.5–3.7 mm, yellow; **Ov** cylindrical, 20–27 × 3–6 mm, puberulent, neck 5–10 mm; **Sty** 14–19 mm, 7–8 mm wide at the broadened base, 3-sulcate, somewhat papillose; **Sti** 3-lobate; **Fr** oblong, stipitate for 10–13 mm, beaked for 5–8 mm, pilose, (35–) 40–50 × (25–) 30–35 mm; **Se** broadly winged for 2–4 mm, 9–12 (–13) × 5–8 mm, shiny.

The species (vernacular names: “cahum”, “cajum”, “cahun” and “cajum-ci”) was widely cultivated for fibre, but has now apparently been abandoned (García-Mendoza 2001a). It is characterized by large, linear-lanceolate leaves, small and closely spaced teeth absent in the upper ¼ or ½ of the leaves, oblong inflorescences with long peduncles occupying ⅔ of its length, and flowers which are puberulent when young, becoming glabrescent when maturing (García-Mendoza 1998, García-Mendoza 2001a).

**F. depauperata** Jacobi (Hamburg. Gart.- & Blumenzeit. 22: 411, 1866). **Type**: not typified. — **Distr**: Cultivated only.

**Incl.** *Furcraea macra* Hort. Parmentier ex Jacobi (1866) (*nom. inval.*, ICN Art. 36.1, 38.1).

[1] Stems none; **L** 15–20, lanceolate, apparently ascending, thin, coriaceous, moderately firm, 33–46 × 5–5.7 cm, dull green, much narrowed towards the base and there ±1.3 cm broad, narrowed towards the apex into a terete, fleshy tip later drying off, both faces smooth or also scabrous, lower ½ longitudinally grooved and below angularly arched and roundly keeled, towards the apex slightly arched, with several keels, with imprints of the next older leaves, margins wavy curved in the lower part, straight in the upper part, continuous, very thin and somewhat remotely toothed; **marginal teeth** small, on deltoid cartilaginous whitish-green bases, with chestnut-brown upcurved tip, 1–1.5 cm apart; **Inf** with peduncle 0.9–1.5 m, smooth, fertile part rhomboid, with spreading, somewhat flattened, 10 cm long part-**Inf**, bulbiferous; **Ped** short, articulated; **Fl** (25–) 30–35 × 32 mm, single; **OTep** lanceolate, 35 × 9–10 mm, tip nearly cucullate and with a tuft of white hairs within, finely puberulent on both faces, whitish-green; **ITep** ovate-elliptic, 38 × 12–16 mm, finely puberulent on both faces, light green turning whitish towards the margins; **Fil** 15–18 mm, 4 mm wide at the broadened base; **Ov** cylindrical, inconspicuously trigonous, with 6 flat furrows, 25 mm, whitish-puberulent, pale green; **Fr** and **Se** unknown.

This long-forgotten name was re-established by Govaerts (2014+), while García-Mendoza (2001a) lists it among the insufficiently known species. Jacobi obtained his material from the Belgian nurseryman Bedinghaus as *F. tuberosa* and noted that it was cultivated in gardens under the unpublished name *F. macra*. *F. depauperata* is only known from its protologue but appears well characterized, and cannot be reliably equated with any other presently known species. It might, however, represent a depauperate pot-cultivated *F. undulata* which likewise has wavy leaf margins and pubescent tepals and ovaries. Depauperate cultivated *F. undulata* are indeed similar in their dimensions (Baker 1892: as *F. pubescens*).

**F. foetida** (Linné) Haworth (Synops. Pl. Succ., 73, 1812). **Type:** [lecto — icono]: Commelin,

Hort. Med. Amstelod. Pl. Rar. 2: 35, t. 18, 1701. — **Lit:** Verhoek & Hess (2002); Guillot Ortiz & Meer (2010); Crouch & Smith (2011); all with ills. **Distr:** USA (Florida), Mexico (Yucatán), C America (Costa Rica, Panama?), Greater and Lesser Antilles, Trinidad, N South America (Colombia, Venezuela, Bolivia, French Guiana, Guyana, Suriname, Brazil); cultivated or naturalized; widely cultivated and naturalized in Africa, Asia and the Pacific and Indian Ocean Islands, to 2000 m; flowers any time but mainly July to September. **I:** Curtis's Bot. Mag. 48: t. 2250, 1821, as *F. gigantea*; Curtis's Bot. Mag. 107: t. 6543, 1881, as *F. cubensis* var. *inermis*; Trelease (1910: tt. 35, 46–48); Irish & Irish (2000: tt. 61–62); Wilcox (2005).

Trelease *ex* L. H. Bailey & E. Z. Bailey (1976); **incl.** *Furcraea foetida* ‘Striata’ Piens (1996).

[1] Stems none or short, to 0.5–1 m × 20–30 cm; **Ros** 2.5–3.5 m Ø; **L** to 50 cm (75–150 cm in aged plants), broadly lanceolate or linear-lanceolate to oblanceolate, erect, outermost sometimes recurving, thick, rigid, firm, narrowing distinctly in the lower ½ to about 10 cm near the base, ± flat, keeled, concave towards the base, at the base (4–) 6–10 cm broad, smooth or obsolescently striate, 1.5–2 (–2.5) m × (9–) 14–21 (–25) cm, shiny to verdant green to yellow-green, apex channelled dorsally, hardened, flattened and folded, sometimes corneous, conical, 1–2 (–3) mm, reddish, margins hard, smooth, usually entire at least in the distal ½, straight or somewhat wavy, sometimes basally with 4–7 trigonous upcurved teeth 1–3 mm long, otherwise unarmed; **Inf** (4–) 8–10 (–12) m, peduncle 1–1.5 m, green, glabrous, with rhomboidal **Bra** 30–40 cm long, fertile part ± rhomboidal to broadly pyramidal, rather narrow, lax, occupying most of the inflorescence, with 40–60 part-**Inf** 1–2 m long, the lower richly branched, glabrous, with 4–13 2.-order branches 15–30 cm long, glabrous or somewhat pilose, scarcely to freely bulbiferous, bulbils foliose, ovoid, sometimes conical, 25–30 (–45) × 5–10 (–15) mm, with 3–5 papyraceous or chartaceous bracts and 3–4 (–5) small leaves; **Ped** 3–7 (–12) mm, glabrous; **Fl** (35–) 40–45 (–50 (–57)) mm, single or 2–3 (–5) grouped together, scented; **Tep** 20–25 (–30) mm, glabrous, whitish-green, yellowish-green, or pale blue-green; **OTep** narrowly elliptic, 5–10 mm broad; **ITep** broadly elliptic, (8–) 10–15 mm broad; **Fil** 11–14 mm, 2–4 mm wide at the broadened base; **Anth** oblong, 2–3 mm; **Ov** cylindrical, glabrous, (12–) 15–25 (–30) × 2–3 (–5) mm; **Sty** 15–16 mm, 2–4 mm wide at the broadened base, 3-lobed up to the middle; **Sti** 3-lobed; **Fr** and **Se** not described (but “infrequently produced” according to Crouch & Smith 2011); **Se** “usually not formed” (l.c.). — **Cytology**: 2n = 60 (Whitaker 1934, Satô 1935: as *F. gigantea*).

Cultivated worldwide in (sub-) tropical regions for fibre (Dewey 1943) and often naturalized. Vernacular names: “cañamo” (Bolivia), “piteira”

(Brazil), “cabuya cimarrona” (Colombia), “cabuya blanca”, “cabuya olancho”, “cabuya sin espinas”, “cabulla” (Costa Rica), “cocuiza”, “cocuiza mansa” (Venezuela) (García-Mendoza 2001a). Characterized by solid green, slightly glossy leaves with a smooth, unarmed and often wavy margin, and a soft tip. It differs from *F. selloana* in its smooth leaves with margins unarmed or only armed up to mid-leaf. According to Lott & García-Mendoza (1994) not reliably known from Mesoamerica, but García-Mendoza (2001a) later cited specimens from the Mesoamerican countries as given above.

The synonym *F. viridis* is a spelling error for *F. atroviridis*. *F. cubensis* var. *inermis* and *F. cabuya* var. *integra* refer to variants with (nearly) completely toothless leaf margins placed here by García-Mendoza (2001a). *Furcraea* ‘Castilla’, a cultivar with toothless leaf margins cultivated in Colombia esp. around Antioquia (Pérez Mejía 1974), likewise appears to belong here. *F. watsoniana*, *F. variegata*, ‘Mediopicta’, and ‘Striata’ are variegated forms grown as ornamentals.

*F. nana* (Hochstätter 2016) is an invalidly published species that appears closely related to *F. foetida*, differing by smaller size and entire leaf margins.

**F. geminispina** Jacobi (Hamburg. Gart.- & Blumenzeit. 22: 358–359, 1866). **Type**: not typified. — **Lit**: Álvarez de Zayas (1996: with ill., as *F. tuberosa*). **Dist**: Bahamas (Acklins, Cat Island, Inagua), Turks and Caicos Islands (South Caicos), Cuba (Camagüey, Holguín, Guantánamo), C & N Haiti, Dominican Republic (?); frequent in secondary habitats near roads or settlements, 700–900 m (Cuba); flowers July to September.

≡ *Furcraea tuberosa* var. *geminispina* (Jacobi) Trelease (1927); **incl.** *Agave tuberosa* var. *β spinis duplicibus* Aiton (1789) (*nom. inval.*, ICN Art. 23.1).

[1] Stems none or short, to 0.3 m; **L** up to 60, lanceolate, erect, subcoriaceous, moderately flat, 2.5 cm broad at the base, scabrous below, smooth above, 1–1.6 (–1.8) m × (7–) 10–15 (–17) cm, shiny green, margins straight, dentate, sometimes corneous towards the base; **marginal teeth** simple, upcurved, 5–10 of them geminate, uncinat,

large, strong, 5–8 (–10) mm, 3–5 (–7) mm broad at the base, on small bases, 3.5–6 cm apart, reddish, **L** tip an acute mucro 2–5 mm long, chestnut-brown; **Inf** 5–7 m, peduncle short, green, **Bra** unknown, fertile part fusiform, lax, in the upper  $\frac{3}{4}$  of the inflorescence, part-**Inf** 30, 50–80 cm, with 2–4 2.-order branches (6–) 15–30 cm long, both pilose, green, bulbiferous, bulbils ovoid, bracteate or rarely foliose, 20–30 (–45)  $\times$  10–15 (–20) mm, with 2–3 scarious green bracts; **Ped** 5–10 mm, somewhat pilose; **Fl** 45–55 (–60) mm, single or 2 grouped together; **Tep** 25–30 (–33) mm, glabrous, whitish-greenish; **OTep** narrowly elliptic, (6–) 8–10 mm; **ITep** (9–) 11–13 mm; **Fil** 11–13 mm, 1.5–2 mm wide at the broadened base; **Anth** oblong, 2.5–3 mm, yellow; **Ov** cylindrical, 20–25  $\times$  3–4 mm; **Sty** 16–18 mm, 4–5 mm wide at the broadened base; **Fr** and **Se** unknown.

The first edition of this handbook and many authors placed this name in the synonymy of *F. tuberosa* (Drummond 1907, Álvarez de Zayas 1996, Smith & Figueiredo 2012), or *F. acaulis* (Dewey 1943, Pérez Mejía 1974, Ullrich 1992), while García-Mendoza (2001a) choose to re-establish the taxon as separate species for Caribbean material with geminate leaf margin teeth (as opposed to *F. tuberosa* with single teeth). *F. geminispina* is similar to *F. hexapetala* in size and armature of the leaves as well as the size of flowers and bulbils.

**F. guatemalensis** Trelease (Trans. Acad. Sci. St. Louis 23(3): 149, t. 32, 1915b). **Type:** Guatemala (Trelease 23 [ILL]). — **Lit:** Trelease (1915b: t. 35, as *F. melanodonta*); Standley & Steyermark (1952: with ill., as *F. melanodonta*); Lott & García-Mendoza (1994: online version with ill.); García-Mendoza (1998). **Dist:** Guatemala (Alta Verapaz, Baja Verapaz, Guatemala, El Progreso, Quetzaltenango, Sololá), Honduras (Comayagua, El Paraíso, Intibucá, Morazán), Nicaragua, El Salvador (Ahuachapán, Santa Ana, San Salvador, San Vicente); open hillsides, dry rocky hills and slopes, in ecotones of pine-oak forests to tropical deciduous forests, commonly planted in hedges or fence rows, 700–2750 m; flowers late June to August. **I:** Meer (2014a).

**Incl.** *Furcraea melanodonta* Trelease (1915).

[1] Stems short, 0.7–1.2  $\times$  0.3–0.6 m, simple; **Ros** 2–3 m  $\varnothing$ ; **L** 60–100, lanceolate, erect, coriaceous, narrowed at the base to 6.5–8.5 cm, base 5–10 cm thick, tip acute, moderately concave, keeled, rough below, mostly smooth or occasionally rough above, (1.5–) 2–2.5 m  $\times$  15–20 (–25) cm, dark green, margins dentate, crenate, sometimes forming a corneous band towards the base; **marginal teeth** simple, upcurved or straight, strong, (4–) 6–10 mm, 3–6 mm broad at the base, chestnut-brown, dark reddish or blackish, 1.5–3 (–5) cm apart (1–2 (–4) cm low down), uppermost 10–30 cm toothless, decurrent on deltoid bases; **terminal Sp** conical, mucronate, 0.5–1 (–4) mm, chestnut-brown; **Inf** 5–8 m, peduncle 1–2 m, green, glabrous, with narrowly triangular, toothed, mucronate, green **Bra** 40–80 cm long, fertile part dense, pyramidal to rhomboidal, glabrous, in the upper  $\frac{3}{4}$  of the inflorescence, part-**Inf** 40–90, 1.5–2 m, 2.-order branches (15–) 20–40 (–60) cm, sometimes with 3.-order branches 3–19 cm long, all with rapidly deciduous bracts, bulbiferous, bulbils broadly ovate, 25–30  $\times$  20–25 (–30) mm, green, covered with 3–5 bracts; fertile **Bra** much shorter than the pedicels; **Ped** 4–10 mm, glabrous; **Fl** (40–) 45–50 (–55) mm, single or 2–3 grouped together; **Tep** elliptic, yellowish-green with whitish margins, glabrous; **OTep** 22–25 (–30)  $\times$  6–9 (–12) mm; **ITep** 24–30 (–35)  $\times$  10–15 (–20) mm; **Fil** 10–15 mm, 3–4 mm wide at the broadened base, papillose, yellowish; **Anth** oblong, base sagittate, 2–4 mm, yellow; **Ov** cylindrical, 20–25  $\times$  3–5 mm, greenish, glabrous, neck not mentioned; **Sty** 17–20 mm, 4–6 mm wide at the broadened base, 3-sulcate; **Sti** papillose, 3-lobate; **Fr** pear-shaped, stipitate for 12–15 mm, beaked, (40–) 50–70  $\times$  35–50 mm; **Se** winged for 4–6 mm, 16–18  $\times$  8–10 mm, shiny.

The species is characterized by its stems <1.2 m high, its large leaves which are rough below, its large, massive, dense, glabrous inflorescences with glabrous flowers and broadly ovate bulbils (García-Mendoza 1998, García-Mendoza 2001a). Vernacular names: “ikaj”, “kaq ik’e”, “maguey rojo”, “maguey”, “churr”, “pita”, or “kima” (Guatemala), “maguey” or “magueyón

macho" (El Salvador), "maguey" (Honduras) (García-Mendoza 2001a). More widely used in the past when it was planted as hedges for harvesting fibres for making ropes and backpacks. Currently, plants survive near houses where they are used apparently at low levels.

Standley & Steyermark (1952) expressed doubts whether *F. melanodonta* can be separated from *F. guatemalensis*, and Lott & García-Mendoza (1994) and subsequent authors treat the name as a straightforward synonym. Material from Mexico (Chiapas) is no longer thought to belong here by García-Mendoza (2001a) but was tentatively assigned to 2 species new to describe.

**F. hexapetala** (Jacquin) Urban (Symb. Antill., 4: 152, 1903). **Type** [neo]: Cuba, La Habana (Jacquin s.n. [BM]). — **Lit**: Britton & Millspaugh (1920: as *F. macrophylla*); Correll & Correll (1982: with ills., as *F. macrophylla*); Álvarez de Zayas (1996: with ills.); Proctor (2012). **Distr**: Bermuda, Bahamas, W Cuba (Cienfuegos, Ciudad Habana, Habana, Matanzas, Pinar del Río), Jamaica, Cayman Islands, Peru; on Cuba in semi-deciduous forests and xeromorphic scrub on serpentine, esp. abundant at anthropogenic sites, to 750 (–1250) m; flowers any time of the year but mainly August to January. **I**: Hooker's Icon. Pl. 26: t. 2501, 1899, as *F. macrophylla*; Trelease (1910: t. 37, as *F. macrophylla*; t. 41, as *F. cubensis*); Curtis's Bot. Mag. 138: t. 8461, 1912, as *F. elegans*.

≡ *Agave hexapetala* Jacquin (1760); **incl.** *Agave aspera* Jacquin (1762) ≡ *Furcraea aspera* (Jacquin) M. Roemer (1847); **incl.** *Agave cubensis* Jacquin (1763) ≡ *Furcraea cubensis* (Jacquin) Ventenat (1793) ≡ *Furcroya cubensis* (Jacquin) Ventenat (1796) (*incorrect name*, ICN Art. 11.4); **incl.** *Agave odorata* Persoon (1805); **incl.** *Furcraea agavephylla* Brotero ex Schultes (1829); **incl.** *Furcraea valleculeata* Jacobi (1867); **incl.** *Furcraea elegans* Todaro (1876); **incl.** *Furcraea ghiesbreghtii* Hort. Verschaffelt ex Todaro (1876) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Furcraea pugioniformis* Hort. Verschaffelt ex Todaro (1876) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Furcraea macrophylla* Baker (1899); **incl.** *Furcraea deledevantii* Rivière (1902); **incl.**

*Furcraea deledevantii* Rivière (1902) (*nom. inval.*, ICN Art. 61.1); **incl.** *Furcraea altissima* Todaro ex Borzi (1909) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Furcraea andina* Trelease (1915); **incl.** *Furcraea altissima* hort. ex Trelease (1915) (*nom. illeg.*, ICN Art. 53.1).

[1] Stems none or short, to 0.5 m; **L** 60–80, lanceolate, erect, straight, coriaceous, gradually narrowed to 2–7 cm above the broadened base, flat or slightly canaliculate, slightly scabrous below, smooth above, 1–1.6 (–2) m × (5.5–) 8–12 (–20) cm, bright green, lustrous, margins dentate, crenate, sometimes corneous towards the base; **marginal teeth** simple, straight or upcurved, sometimes with some recurved smaller teeth near the base, 5–8 (–11) mm, (3–) 4–7 mm broad at the base, decurrent on small deltoid bases, 3–6 (–10) cm apart, blackish to reddish, **terminal Sp** canaliculate, acute, mucronate, 2–3 mm, sometimes lacking, chestnut-brown; **Inf** 6–8 m, peduncle 1–1.5 (–2) m, glabrous, green, with triangular, green **Bra** 15 cm long, fertile part rhomboidal, diffusely branched, open, in the upper  $\frac{3}{4}$  to nearly the whole inflorescence, with 30–40 part-**Inf** (0.5–) 1–1.5 (–2) m long, pilose or glabrous, with 3–9 (–15) 2.-order branches 10–40 cm long, pilose, green, rarely with 3.-order branches <1 cm long, glabrous, bulbiferous, bulbils ovoid, 20–35 (–50) × 15–20 (–25) mm, green, with 2–3 scarious bracts; **Ped** 3–7 mm, pilose; **Fl** 40–50 (–55) mm, single or 2–3 grouped together; **Tep** 25–30 mm, glabrous, whitish or whitish-greenish; **OTep** narrowly elliptic, 7–10 mm broad; **ITep** elliptic, 9–13 mm broad; **Fil** 10–13 mm, 1.5–2 mm wide at the broadened base; **Anth** oblong, 2–3 mm, yellow; **Ov** cylindrical, 17–20 × 3–4 mm; **Sty** 15–18 mm, 4–5 mm wide at the broadened base; **Sti** minute, 3-lobate; **Fr** ovoid to oblong, 30–50 × 25–40 mm, base constricted and deeply sulcate, tip beaked; **Se** flat, winged for 2 mm, 11–13 × 6–7 mm, shiny. — **Cytology**: 2n = 60 (Cave 1964: as *F. andina*, Fritsch 1970).

Characterized by large and remote teeth along the whole leaf margin, rhomboidal inflorescences with few part-inflorescences in the upper  $\frac{3}{4}$  to nearly the whole inflorescence, flowers with very narrow tepals and a very short ovary much shorter

than the tepals (García-Mendoza 2001a). Older literature mostly uses the names *F. cubensis* (described from Cuba) or *F. macrophylla* (described from the Bahamas). The occurrence in places not given above, e.g. Colombia, needs verification. *F. andina* from Peru is considered to be native to that country by the majority of authors, and is cultivated for fibre as “Fique” in Ecuador, Peru and Colombia, where it represents the Colombian national fibre (Kluge 2016). It is here included in the synonymy by García-Mendoza (2001a) due to the lack of clear morphological differences. ‘Marginata’ is a cultivar with yellow-margined variegated leaves (Meer 2014b).

**F. longaeva** Karwinsky & Zuccarini (Flora 15: 2 (Beiblatt 2): 94–95, 1832). **Type:** [neo — icono]: Acta Acad. Leop.-Carol. Nat. Cur. 16(2): t. 48, 1833. — **Lit:** Ullrich (1991b); García-Mendoza (2001b); David (2009); Guillot Ortiz & Meer (2010); García-Mendoza (2011); all with ills. **Distr:** Mexico (S Puebla, Oaxaca); open mountain slopes in rosette scrub on stony igneous soils, 2200–3100 m; flowers February to May, but also August. **I:** Curtis’s Bot. Mag. 91: t. 5519, 1865; Trelease (1915b: t. 28); Phillips (2013).

**Incl.** *Furcraea longa* J. J. Smith (1897) (*nom. inval.*, ICN Art. 61.1?).

[2] Arborescent, stems erect, thick, simple, 3–6 (–9) × 0.4–0.7 m, bark violet-red, with a single terminal **Ros** with 150–300 leaves; spent leaves forming a dry skirt below the rosette, other **L** erect, linear-lanceolate, concave, keeled below, long acuminate, narrowed at the base to 5–8 (–11) cm, base 5–7 cm thick, smooth on both faces or below at the apex slightly scabrous, 1.2–1.6 m × 10–14 (–17) cm, dark green, margin finely denticulate, 12–27 denticles per cm, on a yellowish-green band, leaf tip hardened from the involute leaf margin, dry, deciduous; **Inf** erect, 3–6 (–9 (–13)) m, peduncle 0.3–1 m, green, glabrous, with deltoid brown-violet **Bra** 50–90 cm long, fertile part pyramidal, part-**Inf** 60–100, horizontal, 0.8–1 m, glabrous or pilose, yellowish-green, 2.-order branches 30–50, 10–30 cm, pendent, pilose or glabrous, 3.-order branches 5–15 cm, pilose, rarely with 4.-order branches to 4 cm, without bulbils; floral **Bra** inconspicuous,

much shorter than the pedicels; **Ped** 2–5 (–10) mm, pilose or glabrous; **Fl** (25–) 30–35 mm, 3–6 grouped together; **Tep** 15–20 mm; **OTep** narrowly elliptic, 4–6 mm broad, pubescent outside; **ITep** elliptic, 5–10 mm broad, pubescent on the midrib in the area of overlap, whitish-yellowish or yellowish-orange during senescence; **Fil** 8–11 mm, 1.5–3.5 mm wide at the broadened papillose base, whitish; **Anth** linear-oblong, slightly excentric, 2.2–6 mm, yellow-orange; **Ov** cylindrical, (10–) 15–20 × 2–5 mm, green, puberulent, neck 1–2 mm; **Sty** 10–17 mm, 2.5–4.5 mm wide at the broadened base, deeply 3-lobed, papillose, whitish; **Sti** 3-lobate, ciliate; **Fr** subglobose or oblong, rostrate, (35–) 40–50 × 25–30 (–35) mm, yellowish-green, rostrate for 3–6 (–10) mm, stipitate for up to 15 mm, tepals persisting; **Se** winged for 1 mm, 9–10 × 7–8 mm, shiny.

Easy to recognize by the large, linear-lanceolate, dark green leaves and the inflorescence without bulbils and with 3.- and 4.-order branches (García-Mendoza 2001b). Differs from its closest relative *F. parmentieri* in being larger in all parts except its flowers, in having inflorescences without bulbils, and in occurring in drier habitats (García-Mendoza 1998). The place of valid publication (usually thought to be in 1833) was clarified by Ullrich (1991b) who also selected a neotype (as ‘lectotype’).

Vernacular names: “pescadillo”, “tehuizote”, “palma”, “palmita”, “palmilla”, “yacktobiyack”, “yahuindayasi”, “la-fo-má-é”, and “pita”. The foam from crushed and washed fresh leaves is used for washing clothes, the dry leaves for making ropes, the flowers as fodder, and the dry stems for bee-keeping (García-Mendoza 1998, García-Mendoza 2001a, García-Mendoza 2001b).

The species was attributed to Guatemala by Skinner in Bateman (1837–1843: t. 16), but this appears to be a confusion with *F. quicheensis* (Lott & García-Mendoza 1994). Standley & Steyermark (1952) cite a collection made from a cultivated plant in Europe by Berger with a purported origin from Guatemala. There is at present no reliable record of the species from Guatemala (Lott & García-Mendoza 1994). Records from Guerrero

(Ullrich 1991b, García-Mendoza 1998) appear to represent *F. martinezii*.

With a maximum size of 13 m, the species exhibits the largest inflorescences of any plant according to Verhoek-Williams (1998), but it is superseded by *F. cabuya*, for which Robbins (2001) mentions 15 m. An inflorescence may have more than 58'000 flowers (García-Mendoza 2001a). In habitat, according to local Indians cited in the protologue, the species needs 400 years to come into flower. A more likely time span is between 50 and 100 years (García-Mendoza 1998). In cultivation, plants may flower already after 25 (or perhaps even 7 or 8?) years (Ullrich 1991b).

**F. macdougallii** Matuda (Cact. Suc. Mex. 1 (2): 24–26, ills., 1955). **Type:** Mexico, Oaxaca (*MacDougall* 269 [MEXU, MEXU]). — **Lit:** García-Mendoza (2001b); García-Mendoza (2003b: with ill.); García-Mendoza (2011). **Distr:** Mexico (S Puebla, W & C Oaxaca); tropical deciduous and thorn forests on calcareous soils, and cultivated, 750–1800 m; flowers September to December. **I:** Irish & Irish (2000: t. 63); Meer (2014c).

[1] Arborescent, stems erect, simple but offsetting from along fallen stems or old stem bases, 6–9 m, 30–70 cm Ø, bark reddish; **Ros** single at the stem tips, 4–6 m Ø, with 80–120 leaves, with a skirt formed by dry leaves; **L** erect, linear, in young plants pointing upwards, in old plants spreading in all directions, coriaceous, keeled, narrowed at the base to 4–7 cm, base to 8 cm thick, scabrous on both faces, papillose, 1.4–1.8 (–2) m × 6–10 cm, dark green to dull olive-green or yellowish-green, tip hard, sometimes with a 1 mm long mucro, reddish or yellowish, margin dentate-corneous or dentate-denticulate; **marginal teeth** 2–4 × 3–4 mm at the base, upcurved, reddish with yellowing base or brownish, separated by (1–) 2–5 cm at mid-leaf, and by 0.5–2 cm in the lower 1/3, denticulate between the teeth; **Inf** erect, 5–9 m, peduncle 1.5–3.5 m, green, glabrous, with triangular, semi-fleshy, dentate, green **Bra** 30–65 cm long, fertile part in the upper 1/2 of the inflorescence, rhomboidal, part-**Inf** 40–70, 1–1.5 m, glabrous to somewhat puberulent, 2.-order

branches 9–20, (6–) 15–30 cm, puberulent to tomentose, rarely with 3.-order branches to 15 cm, tomentose, bulbiferous, bulbils conical, 40–70 (–85) × 12–16 mm, with 5–8 deltoid bracts, those near the base scarious and deciduous; floral **Bra** inconspicuous, scarious; **Ped** 2–6 (–10) mm, puberulent; **Fl** 35–40 mm, 2–4 grouped together; **Tep** narrowly elliptic, 15–20 mm; **OTep** 3–4 (–6) mm broad, pilose outside; **ITep** 4–6 (–8) mm broad, pilose on the midrib, papillose in the area of overlap, whitish outside, yellowish within; **Fil** 9–12 mm, 2–3 mm wide at the broadened base, papillose, yellowish; **Anth** oblong, 2–2.5 × 1.5 mm, yellow; **Ov** cylindrical, 13–23 × 2–3 mm, yellowish-green, puberulent, neck 5–8 mm, glabrescent; **Sty** 13–16 mm, 3–4 mm wide at the broadened base, 3-sulcate, papillose; **Sti** superficially 3-lobate; **Fr** oblong, stipitate for 20–23 mm, rostrate for 5 mm, 40–50 × 30–35 mm; **Se** plane-convex, winged for 1–2 mm, 11–13 × 7–9 mm, shiny.

Recognizable by linear leaves with scabrous faces and dentate-corneous or dentate-denticulate margins, and conical bulbils (García-Mendoza 2001a, García-Mendoza 2001b). The thick terminal spine mentioned in the protologue was not found in the material seen by García-Mendoza (2001a). The species is apparently extinct in nature and survives in cultivation only at the Puebla/Oaxaca border (García-Mendoza l.c.), but is also commercially available in the US-American nursery trade. García-Mendoza (2003a) reports that a single inflorescence produced >15'000 bulbils, which persisted even after the plant has died. Two sterile collections from Chiapas by Matuda first provisionally placed here by Lott & García-Mendoza (1994) and García-Mendoza (1998) were later placed in a new, apparently closely related species, *F. niquivilensis*.

**F. martinezii** García-Mendoza & L. de la Rosa (Bol. Soc. Bot. México 66: 121–123, ills., 2001b). **Type:** Mexico, Guerrero (*García-Mendoza & de la Rosa* 6526 [MEXU etc.]). — **Lit:** García-Mendoza (2003a: with ills.). **Distr:** Mexico (C Guerrero); on sandy soils derived from volcanic ash in montane pine-oak cloud forest, 2000–2650 m; flowers April to May.

[2] Arborescent, stems erect, 2–4 (–8) m, simple, 0.3–0.4 m  $\varnothing$ ; **Ros** single at the stem tip, with (100–) 150–200 leaves and a skirt formed by dry leaves; **L** linear to linear-lanceolate, narrowed at the base to 4–6 cm, base 4–5 mm thick, smooth above, below slightly scabrous at the hard deciduous tip, (0.9–) 1.2–1.6 m  $\times$  6–10 cm, dark green, margin denticulate, 15–19 denticles per cm, on a greenish-yellow band; **Inf** erect, 6–8 m, peduncle 0.5–1.5 m, green, glabrous, with deltoid, denticulate, brownish **Bra** 40  $\times$  4–7 cm, fertile part pyramidal, with 100–200 part-**Inf** 1–1.5 (–2) m long, green, glabrous, 2.-order branches 10–25 cm long, rarely with 3.-order branches 3–7 cm long, bulbiferous, bulbils leafy, ovoid, 25–45  $\times$  15–35 mm, covered with leafy reddish bracts; floral **Bra** inconspicuous, much shorter than the pedicel; **Ped** 4–6 mm, glabrous; **Fl** 25–32 mm, 3–4 grouped together; **Tep** 12–16 mm, whitish-green outside, whitish within, puberulent at the base; **OTep** narrowly elliptic, 3–4 (–6) mm broad; **ITep** elliptic, 5–7 (–8) mm broad; **Fil** 9–11 mm, 2–3 mm wide at the thickened papillose base, whitish; **Anth** oblong, 2.5–3 mm, yellow; **Ov** cylindrical, 13–15  $\times$  3–4 mm, green, puberulent, neck 1–2 mm, sometimes puberulent; **Sty** 9–12 (–16) mm, 3–4.5 mm wide at the broadened base, truncate, deeply trisulcate, papillose, whitish; **Sti** 3-lobate; **Fr** subglobose to oblong, 35–45 (–50)  $\times$  30–40 mm, yellowish-green, stipitate for up to 15 mm, rostrate for 4–6 mm; **Se** winged for 2 mm, 11–12 (–14)  $\times$  7–8 (–9) mm, shiny.

Only known from 3 populations consisting of few, mainly adult individuals (García-Mendoza 2001a). Similar to *F. longaeva* with which it shares the long stem, large rosettes and a pyramidal inflorescence with up to 3.-order branches, but differing by narrower leaves, smaller flowers, larger seeds, and leafy bulbils. Records of *F. longaeva* from Guerrero belong here. A specimen which flowered at the botanical garden of Mexico City was estimated to be 40 to 60 years old, had an annual stem growth of 4–8 cm, and the inflorescence was estimated to have  $\pm$  20'000 to 30'000 flowers (García-Mendoza 2003a).

**F. niquivilensis** Matuda ex García-Mendoza (Novon 9(1): 42–45, ills., 1999). **Type:** Mexico,

Chiapas (*García-Mendoza & al.* 6441 [MEXU, ENCB, HEM, K, MO]). — **Lit:** Lott & García-Mendoza (1994: online version with ills.); García-Mendoza (2001b). **Distr:** Mexico (SE Chiapas), probably also adjacent Guatemala; at present only known from cultivation at settlements but probably from pine-oak or montane cloud forests, 1800–2700 m; flowers April to May.

[1] Arborescent, stems 1–3  $\times$  0.3–0.4 m, unbranched, covered with old dry reflexed and persisting leaves; **Ros** 4–5 m  $\varnothing$ ; **L** 80–150, erect, lanceolate, coriaceous, narrowed at the base to 7–8.5 cm, 5–5.5 cm thick, concave, keeled, scabrous or muricate on both faces, (1.7–) 1.9–2.1 m  $\times$  12–14 cm, green, tip acuminate, mucronate, conical, 1–2 (–3)  $\times$  0.5–1 mm, dark chestnut-brown, margins straight, dentate; **marginal teeth** upcurved or straight at the base, recurved at mid-leaf, and upcurved in the upper part, 5–6 (–8)  $\times$  3–4 (at the base) mm, chestnut-brown, base yellowish, decurrent so that the margin becomes corneous, on small deltoid bases, (1.5–) 2–4 cm apart at mid-leaf, 0.6–1.5 (–2) cm at the base; **Inf** 6–9 m, peduncle 1.5 m, puberulent, green, with triangular, dentate and mucronate **Bra** 50  $\times$  5 cm, fertile part pyramidal, open, making up almost the whole inflorescence, with up to 55 puberulent part-**Inf** 2–2.3 m long, 2.-order branches 14–18, 30–60 cm, puberulent, bulbiferous, bulbils spheroidal to broadly conical, 50–70 (–110)  $\times$  (30–) 45–65 mm, bracteate, covered by 4–6 broadly ovate, brownish to green persistent bracts, sometimes tinged reddish; **Ped** 4–8 mm, puberulent; **Fl** 65–75 (–80) mm, puberulent, single or 2–3 together; **Tep** elliptic, greenish-white, tinged reddish outside, whitish inside; **OTep** (30–) 40–45  $\times$  11–13 mm, pilose, glabrescent; **ITep** 40–45  $\times$  12–14 mm, pilose, glabrescent on the prominent mid-rib, papillose in the area of overlap; **Fil** 20–25 mm, 3–5 mm wide at the broadened papillose base, greenish-yellow; **Anth** oblong, 4–6 mm, yellow; **Ov** cylindrical, 30–35 (–38)  $\times$  3–6 mm, puberulent, green; **Sty** trigonous, papillose, 20–23 mm, 4–6 mm wide at the broadened base, 3-sulcate, papillose, greenish-yellow; **Sti** entire, sometimes ciliate; **Fr** oblong, 65–70  $\times$  40 mm; **Se** winged for 4–5 mm, 18–19  $\times$  10–12 mm.

Sterile collections of this plant by Matuda were provisionally included under *F. macdougallii* (Lott & García-Mendoza 1994, García-Mendoza 1998), but the clear differences such as longer leaf marginal teeth, a pyramidal inflorescence with longer 1.- and 2.-order branches, much larger flowers, and larger and broader bulbils merit species status. According to the protologue, both species appear to be closely related and share arborescent growth, leaves with both faces scabrous or muricate, as well as puberulent primary and secondary inflorescence branches, pedicels and ovaries. Both taxa are apparently extinct in nature and only survive in cultivation (García-Mendoza 2001a). *F. niquivilensis* is commonly planted as fence and to prevent soil erosion, and the fibres of the leaves are used to make baskets and ropes; this use was more common in the past and is presently restricted to a very small scale (García-Mendoza 1998). The flowers emit a lemon-like odour during night and are visited by hummingbirds at day when no nectar is produced (García-Mendoza 2001a).

**F. occidentalis** Trelease (Bot. Jahrb. Syst. 50 (Beiblatt 111): 5, 1913). **Type:** Peru, Lima (Weberbauer 1687 [B, G, GH, MEXU, NY]). — **Lit:** Macbride (1936); Ullrich (1992); Pino (2006). **Distr:** Peru (Ancash, Cajamarca, Cuzco, Huallaga, Huánuco, Lima, Loreto); NW Bolivia (La Paz); dry rocky slopes in scrubland, 2200–3860 m; flowers April to May and November to December. **I:** Pino (1996); García-Mendoza (2001a).

[1] Stems none or short; **Ros** 2.5 m Ø; **L** erect, linear-lanceolate, coriaceous, narrowed at the base to 3–5 cm, smooth on both faces, 60–70 (–100) × (4.5–) 8–10 cm, margins crenate, ± corneous, minutely aculeate; **marginal teeth** ± deltoid, simple, straight or upcurved, 1–2 mm, 0.5–1 (–2) mm broad at the base, on small bases, absent at the leaf tip, 0.2–0.8 (–1) cm apart, 0.4–0.6 cm at the base, yellowish; **terminal Sp** mucronate, obtuse and semiglobose, minute, weak, 0.5–1 × 1 mm, reddish-brown; **Inf** 4–6 (–12) m, peduncle green, glabrous, with triangular toothless **Bra** 10–23 cm long, fertile part to 2 m broad, part-**Inf** 50–80 cm, with 8–17 2.-order

branches 10–30 cm long, both glabrous, freely bulbiferous, bulbils conical, (25–) 30–40 × 6–10 (–13) mm, green, bracteate, with 2–4 scarious bracts; **Ped** (5–) 10–18 mm, glabrous; **Fl** (50–) 55–68 mm, single or 2 (–4) grouped together; **Tep** 30–33 (–38) mm, glabrous, with apiculate apex, whitish-green, creamy-white or green with white margins; **OTep** narrowly elliptic, 8–10 mm broad; **ITep** elliptic, 10–15 mm broad; **Fil** (14–) 16–20 mm, 3–4 mm wide at the broadened base, yellow-green; **Anth** oblong, 3–4 mm, yellow; **Ov** 25–30 × 5–6 mm; **Sty** 20–25 mm, 4–5 mm wide at the broadened base, yellow-green; **Fr** and **Se** unknown.

For long insufficiently known, until García-Mendoza (2001a) provided the first complete description. It is characterized by short leaves with small teeth to 2 mm, and absent at the tip, large glabrous flowers with apiculate tepals, and conical and bracteate bulbils. With its very small teeth, this species is closest to *F. longaeva* and other species of Sect. *Serrulatae* (García-Mendoza 2001a). It differs from the second Peruvian species *F. hexapetala* by narrower, less rigid and largely toothless leaves (Pino 1996: as *F. andina*).

The vernacular name in Peru is “champa qara” (Pino 2006). The leaves are used as detergent, for fibres and for extracting chemical constituents, and the peduncles for constructions (García-Mendoza 2001a). The sap of half-roasted leaves is used for curing bronchitis by rubbing it on the chest and back during night (De-la-Cruz & al. 2007). The flowers are visited by hummingbirds (García-Mendoza 2001a).

**F. parmentieri** (Roezl ex Ortgies) García-Mendoza (Bol. Soc. Bot. México 66: 115, ill. (p. 116), 2001b). **Type** [neo]: Ex cult. BG Berlin (Koch s.n. [B]). — **Lit:** McVaugh (1989: 198–200, with ill.); Ullrich (1991b: with ill.); García-Mendoza (2001b); Guillot Ortiz & Meer (2010: with ill.); all as *F. beddinghausii*; González-Martínez (2016: neophyte in Spain). **Distr:** Mexico (Jalisco, Guanajuato, Hidalgo, Veracruz, Michoacán, México, Distrito Federal, Morelos); volcanic soils derived from andesite, basalt or lava flows, mountain slopes and summits, in pine-oak cloud forests, 2300–3500 m;

**Fig. 1** *Furcraea parmentieri*. (Copyright: U. Eggli)

flowers June to September; neophyte in Spain. **I:** Curtis's Bot. Mag. 117: t. 7170, 1891, as *F. bedinghausii*; Sánchez Mejorada (1966: as *F. bedinghausii*); Benítez B. (1986: 62, as *F. bedinghausii*); Etter & Kristen (2007). – Fig. 1.

[2] Arborescent, stems erect, thick, simple, 1.5–4 (–8) × 0.2–0.5 m; **Ros** 1 (–4) at the stem tip, 2–2.5 m Ø, with 100–150 leaves; **L** first ascending-spreading, later spreading to pendent, forming a dry skirt along the entire stem or just below the rosette, lanceolate to linear-lanceolate, stiff, ensiform, coriaceous, narrowed below the middle, base narrowed to 2–4 (–5) cm, 2–3 cm thick, long-attenuate, flat to concave or plicate, keeled, above striate and roughened by projections from the longitudinal veins, below asperous towards the tip, muricate above the veins, above scabrous, 60–90 (–120) × 5–8 (–10) cm, somewhat glaucous, margins straight, marginal teeth none, finely denticulate, denticles minute, irregularly spaced, pale, deltoid, 14–20 per cm, on a yellowish cartilaginous band, tip formed by hardened involute margins, < 1 mm; **Inf** erect, (2.5–) 4–6 (–9) m, peduncle 0.5–1 (–1.5) m, greenish, pubescent, with deltoid to lanceolate **Bra** 20–75 × 3.5–8 cm, brown or purple, fertile part narrowly pyramidal, greenish, pubescent, occupying nearly the whole inflorescence, with (50–) 80–130 part-**Inf** 1–1.5 (–2) m long, tips pendent, pubescent to glabrescent with age, 2.-order branches 0.3–0.6 (–0.9) m, pendent, pubescent, all branches with purple bracts, freely bulbiferous, bulbils leafy, conical to ovoid, 15–20 (–30) × (7–) 10–20 mm, covered with deltoid, scarious, deciduous bracts; floral **Bra** deltoid, scarious, <

10 mm, pubescent; **Ped** 5–10 (–15) mm, puberulent; **Fl** (35–) 45–55 mm, 2–4 grouped together; **Tep** elliptic or oblong-elliptic, (15–) 20–24 (–27) mm, green-white outside, whitish within, yellowish after anthesis; **OTep** narrowly elliptic, 4–6 (–8) mm broad, pubescent outside; **ITep** elliptic, 6–9 (–12) mm, pubescent on the prominent midrib, papillose in the area of overlap; **Fil** 10–14 mm, 2–4 mm wide at the broadened base, papillose, whitish; **Anth** oblong, 2–3 mm, yellow; **Ov** cylindrical, (15–) 20–25 (–30) × 2–7 mm, puberulent, in bud nearly lanate, green, neck 3–5 mm; **Sty** 13–18 mm, 2.5–5 mm wide at the broadened base, truncate, deeply 3-sulcate, somewhat papillose, yellowish; **Sti** shallowly 3-lobate; **Fr** oblong-ovoid to ovoid, 40–45 (–60) × (25–) 30–35 mm, rostrate for 4 mm, stipitate for up to 20 mm; **Se** plane-convex, winged for 2 mm, 9–11 × 6–8 mm, shiny. — **Cytology**:  $2n = 60$  (Whitaker 1934: as *F. bedinghausii*).

This is the species common in the Trans-Mexican Volcanic Belt, easy to recognize by its short glaucous leaves rough below and with minute denticles, its narrowly pyramidal inflorescence with pendent 1.- and 2.-order branches, a short trunk and puberulent branches and flowers (García-Mendoza 1998). It is closely related to *F. longaeva*, but smaller in all its parts except the flowers (García-Mendoza 1998). Vernacular names: “Shishi” (“xixi”), “large sishi”, “tacamba”, “palma”, “palmilla”, “palmito”, “magueyito”,

“izote”. The leaves and flowers are used as Easter decoration, the dried leaf fibres for binding sheaves of grain, and the whole plants as living fences (García-Mendoza 1998, García-Mendoza 2001a).

The *F. parmentieri* plant community on Pelado volcano (Mexico City) was studied by Almeida-Leñero & al. (2013), who found declining conditions due to repeated fires. According to Valverde & Hernández-Pedrero (2017), germination rate under field conditions reaches 40%, and the presence of nurse plants does not positively influence establishment rates. This is the only species of the genus at present widely grown outside in the UK (David 2009).

**F. pubescens** Todaro (Index Seminum [Palermo] 1877: 38, 1877). **Type**: not typified. — **Lit**: Todaro (1879: with ills.); McVaugh (1989: as *F. guerrensis*); García-Mendoza (1998: as *F. guerrensis*). **Distr**: México (S Nayarit, W Jalisco, Colima, Michoacán, México, Guerrero, Oaxaca); in calcareous, sandy or clayey soils or soils derived from volcanic rocks, in ecotones of tropical deciduous forests with pine-oak forests, subdeciduous tropical forests, and oak and pine-oak forests, rarely in montane cloud forests, 650–1900 m; flowers July to November, also in February, March and December. **I**: Matuda (1966: as *F. guerrensis*). — Fig. 2.

**Incl.** *Furcraea guerrensis* Matuda (1966).

**Fig. 2** *Furcraea pubescens*. (Copyright: U. Eggli)

[1] Stems mostly none, rarely short, 0.3–0.7 m, simple; **Ros** 1.5–2 × 3–4 m; **L** 40–80 (–120), lanceolate, erect, coriaceous, narrowed at the base to 3–6.5 cm, 4–5.5 cm thick, keeled, apex acuminate, nearly flat in the lower part, concave in the upper part, smooth on both faces, 1.2–1.8 (–3) m × 10–15 cm, dark green, margins crenate, somewhat corneous esp. towards the base; **marginal teeth** deltoid, upcurved or straight, sometimes hooked, strong, 3–6 (–8) mm, 2–4 (–5) mm broad at the base, brown to dark-reddish, with yellowish bases, mostly with teeth throughout, sometimes toothless for 10–15 cm below the leaf apex, (2–) 3–5 (–7) cm apart at mid-leaf, 1–2 (–4) cm at the base, decurrent on prominent deltoid bases; **terminal Sp** conical, 1–4 (–8) mm, brown; **Inf** (3–) 5–8.5 m, peduncle short, 0.5–2 m, green, puberulent, with linear-lanceolate, toothed, green **Bra** (15–) 40–70 × 4–7.5 cm, fertile part pyramidal or ellipsoid, open, in the upper  $\frac{3}{4}$  –  $\frac{1}{2}$  of the inflorescence, **part-Inf** 40–80, (60–) 100–150 cm, longest at mid-inflorescence, puberulent to tomentose, green, with 5–12 (–25) 2.-order branches 10–30 cm long, puberulent, tomentose or velutinous, green, with reddish tinge, bulbiferous, bulbils ovoid to conical-ovoid, (20–) 25–30 (–45) × 15–20 (–25) mm, green, covered with 3–4 suborbicular bracts, brownish; **Bra** at the base of the flower clusters <3 mm, deciduous; **Ped** 5–10 (–15) mm, puberulent to velutinous; **Fl** (50–) 55–65 (–70) mm, single or 2–3 (–4) grouped together; **Tep** (23–) 25–30 (–35) mm, whitish-green to yellowish, sometimes with reddish tinge outside; **OTep** narrowly elliptic to lanceolate, 6–10 (–13) mm, puberulent to glabrescent; **ITep** elliptic, 10–15 (–21) mm, puberulent on the midrib; **Fil** 15–18 mm, 3–4 mm wide at the broadened papillose base, yellowish-white; **Anth** oblong, base sagittate, 3–4 (–7) × 1–2 mm, yellow; **Ov** cylindrical, (20–) 25–30 (–35) × (2–) 3–4 mm, puberulent to tomentose, green, neck 5–7 mm; **Sty** (18–) 20–25 mm, 4–6 (–10) mm wide at the broadened base; **Sti** papillose; **Fr** ovoid to pyriform, 60–80 (–95) × 35–50 (–55) mm, rostrate, base and rostrum puberulent, stipitate for 10–20 (–25) mm, stipe glabrescent; **Se** plane-convex, with broad wing 5–6 (–8) mm, 15–20 (–22) × (7–) 8–10 (–12) mm, shiny. —

**Cytology:**  $2n = 60$  (Satô 1935: as *F. pubescens*), but uncertain whether applying to this taxon, or to *F. pubescens* Baker = *F. undulata*.

*F. pubescens* is based on material flowering 1877 at Palermo. Baker (1888) and Baker (1892) misnamed plants cultivated in the UK and attributable to *F. undulata* as *F. pubescens* (Drummond 1907). García-Mendoza (1998) attributes the name to plants from the state of México and adds *F. guerrerensis* as synonym. As now circumscribed, *F. pubescens* is characterized by its usually acaulescent habit, leaves smooth on both faces with large teeth, open pyramidal or ellipsoid inflorescences with short peduncles and puberulent flowers, peduncles and branches, ovoid to conical-ovoid bulbils, and seeds with broad wings. Vernacular names: “maguey de pita”, “maguey” (“wechi en triqui”), “maguey de ixtli”, “maguey de zopilote”, and “yú-gua oo yuwa”. Locally used (formerly more wide-spread) for fibre and as living fence, the flowers are eaten, and the leaf juice is used to stupefy fishes (García-Mendoza 1998, García-Mendoza 2001a).

**F. quicheensis** Trelease (Trans. Acad. Sci. St. Louis 23(3): 148, t. 29, 1915). **Type:** Guatemala, Quiché (Cook 421 [US]). — **Lit:** Standley & Steyermark (1952); Lott and García-Mendoza (1994: online version with ills.); García-Mendoza (2001b: with ills.). **Distr:** Mexico (E Chiapas), W Guatemala (Huehuetenango, San Marcos, Totonicapan, Quetzaltenango, Solola, Quiché), Honduras; oak forests, sometimes on exposed sites in montane pine-oak cloud forests, on soils derived from volcanic ash, cultivated or escaped from cultivation, 2000–3300 m; flowers April to August. **I:** Schröter (1992).

[2] Arborescent, stems erect, thick, naked, simple or 4–5 × branched, 1–2 × 0.2–0.4 m; **Ros** at the stem tip, 2–3 m Ø; **L** 60–100, erect, forming a dry skirt below the rosette, lanceolate, erect, spreading or reflexed, gradually narrowed towards the base, base 4–7 cm broad, 3–6 cm thick, broadly attenuate, flat or slightly channelled, subcoriaceous, smooth, below with prominent venation, 80–120 (–150) × 7–10 (–14) cm, glaucous to glaucous-green, margin narrow, minutely denticulate, denticles 8–10 per cm, yellow, on a

cartilaginous band, **L** tip hardened by the involute margins, narrowly rounded, obtuse, without terminal spine; **Inf** erect, 2–5 m, peduncle 1–2 m, green, often red, glabrous, with triangular **Bra** 20–60 × 5–12 cm, fertile part narrow, oblong, in the upper  $\frac{2}{3}$  –  $\frac{3}{4}$  of the inflorescence, part-**Inf** 50–80, (15–) 50–70 (–100) cm, sometimes with 2.-order branches to 10 cm, green, glabrous, without bulbils; **Bra** at the base of the flower clusters deltoid, 4–8 cm, much larger than the pedicels, reddish, bracteoles deltoid, scarious, <1.5 cm; **Ped** (10–) 20–35 mm, reddish, glabrous; **Fl** (50–) 55–65 (–70) mm, 3–5 grouped together; **Tep** elliptic, suberect or somewhat spreading, (20–) 25–30 (–35) mm; **OTep** 4–7 (–9) mm broad; **ITep** 6–9 (–12) mm broad, with prominent midrib, (pale) green with brownish tinge outside, greenish-whitish or greenish-yellow within, glabrous; **Fil** 10–14 mm, 2–4 mm wide at the broadened base, somewhat papillose, whitish; **Anth** oblong, 2–2.5 mm, yellow; **Ov** cylindrical, 25–30 (–39) × 3–5 (–7) mm, dark green to brown-green, glabrous, neck <2 mm; **Sty** 13–17 mm, 2–4 mm wide at the broadened base, papillose; **Sti** shallowly 3-lobate; **Fr** oblong, 50–70 (–80) × 20–30 (–35) mm, somewhat lustrous, contracted at the base, rostrate for 5 mm, stipitate for 20–30 mm; **Se** winged for 1 mm, 8–10 × 5–7 mm, shiny.

The above description largely follows García-Mendoza (2001a) and García-Mendoza (2001b); morphological measurements in Lott & García-Mendoza (1994) and García-Mendoza (1998) partly differ.

Characterized by the narrow inflorescences without bulbils, large, glabrous flowers, oblong fruits and glaucous leaves (García-Mendoza 2001b). Common on the W Guatemalan highland where it often is a conspicuous feature of the landscape (Standley & Steyermark 1952). The species apparently reproduces by seeds, since no bulbils were seen or reported. Vernacular names: “Mecate”, “mecatl”, “cheche”, “palma”, “chijute”, “maguey”, and “micato”. The plants are used as ornamentals and to prevent soil erosion, the leaves to extract fibres and as religious Easter decoration, which relates to its abundance near settlements, at the borders of agricultural land, or around houses

(García-Mendoza 1998, García-Mendoza 2001a). Nelson (2008) provides a new record for Honduras. Ullrich (1991b) placed the species in the *F. longaeva*-complex.

**F. samalana** Trelease (Trans. Acad. Sci. St. Louis 23(3): 149, tt. 30–31, 1915). **Type:** Guatemala, Quetzaltenango (Trelease 20 [ILL]). — **Lit:** Standley & Steyermark (1952); Lott & García-Mendoza (1994: online version with ills.). **Distr:** Mexico (Chiapas), Guatemala (Quetzaltenango, Retalhuleu, Suchitupéquez), El Salvador?, generally cultivated only; in flat and brown stony soils, disturbed sites on rocky slopes in scrub or pine-oak forests, often in moist thickets or more often in dry places, 400–2000 m; flowers July to September.

[1] Stems none, simple; **Ros** 2–3 × 4–6 m; **L** 150–200, broadly lanceolate, erect, cartilaginous, tapering at the base to 6–9 cm, 4–6 cm thick, apex long acuminate, convex below, channelled above, smooth on both faces, (1.3–) 1.8–2.6 m × (12–) 20–25 cm, green, margins straight to somewhat crenate; **marginal teeth** upcurved or straight, (2–) 3–5 (–7) × 2–4 mm, brownish to blackish, 2.5–4.5 (–6) cm apart at mid-leaf, 1.5–2 cm below, lacking in the upper  $\frac{1}{2}$  –  $\frac{2}{3}$  of the leaf, decurrent on low fleshy bases, sometimes forming a corneous band down to the base; **terminal Sp** normally lacking, or mucronate, conical, 1–2 mm, reddish; **Inf** 5–8 m, peduncle 2.5–3 m, green, glabrous, with deltoid, dentate, mucronate, green **Bra** 50 × 7.5 cm, margin entire or with few denticles near the constricted base, fertile part lax, narrow, oblong, with 25–35 part-**Inf** in the upper  $\frac{3}{4}$  of the inflorescence, <75 cm, glabrous, 2.-order branches (5–) 10–30 cm, glabrous, bulbiferous, bulbils 50–65 × 20 mm, leafy, with dull grey-green scales and 6–8 small leaves, green, conical-ovoid; floral **Bra** much shorter than the pedicels; **Ped** 3–9 mm, glabrous; **Fl** (45–) 50–55 (–57) mm, single or 2–3 grouped together; **Tep** 25–35 mm, greenish-white outside, yellowish-green within, glabrous; **OTep** elliptic, 10–13 mm broad; **ITep** broadly elliptic, 13–18 mm broad; **Fil** dorsiventrally flattened, 12–14 mm, 2–3 mm wide at the broadened base, papillose, yellowish; **Anth** oblong, 4–6 mm, yellow; **Ov** cylindrical, 20–25

(–27) × 2–4 mm, glabrous, greenish-white; **Sty** 19–22 mm, 4.5 mm wide at the broadened base; **Sti** papillose; **Fr** and **Se** not known.

Standley & Steyermark (1952) and Lott & García-Mendoza (1994) record the species from El Salvador (*Villacorta* 787, MO), but this view is not shared by García-Mendoza (2001a). Vernacular names: “ixtle”, “mecate”, “pita”, “jasite”, “maguey”, and “maguey ixtle”. The leaf fibres are used for making ropes for backpacks, hammocks and nets.

**F. selloana** K. Koch (Wochenschr. Vereines Beförd. Gartenbaues Königl. Preuss. Staaten 3: 22, 1860). **Type**: not typified. — **Lit**: Verhoek & Hess (2002); Wilcox (2005); Guillot Ortiz & Meer (2010); Aedo (2013); Smith & Figueiredo (2016: neophyte in RSA); Guillot Ortiz & al. (2016: neophyte in Spain); **Distr**: Colombia (Antioquia, Cauca, Cundinamarca, Huila, Magdalena, Santander, Tolima, Valle), Ecuador (Chimborazo, El Oro, Loja, Los Rios, Islas Galápagos); cultivated or as escape at anthropogenic and disturbed sites, wild possibly in dry river valleys and lowlands, 1000–2600 m; cultivated and naturalized in many parts of the world (e.g. RSA, Spain); flowers June to October. **I**: Curtis’s Bot. Mag. 86: t. 5163, 1860, as *F. flavoviridis*; Curtis’s Bot. Mag. 101: t. 6148, 1875; Irish & Irish (2000); Smith & Figueiredo (2012).

**Incl.** *Agave cubensis* var. *striata* hort. (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Furcraea selloa* hort. (s.a.) (*nom. inval.*, ICN Art. 61.1); **incl.** *Furcraea flavoviridis* Hooker (1860); **incl.** *Furcraea lindenbergii* Jacobi ex Anonymus (1869); **incl.** *Furcraea albispina* Hort. Panorm. ex Baker (1893); **incl.** *Furcraea tuberosa* Franceschi (1900) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Furcraea selloana* var. *edentata* Trelease (1915a) ≡ *Furcraea selloana* fa. *edentata* (Trelease) H. Jacobsen (1954) (*nom. inval.*, ICN Art. 41.5); **incl.** *Furcraea selloana* var. *marginata* Trelease (1915a).

[1] Stems usually none or short, to 0.3 or sometimes 0.9 (–1.5) m; **Ros** 3–4 m Ø; **L** 40–60, linear-lanceolate to oblanceolate, erect, straight, coriaceous, narrowed to 4–5 cm at the base, concave, rough below (fide protologue and various authors) or smooth (fide García-Mendoza

(2001a)), (0.7–) 1–1.7 (–2.4) m × (7–) 10–15 cm, green, margins with teeth throughout; **marginal teeth** simple, upcurved, straight or recurved, rarely 1–3 bifid, 4–7 × 3–4 mm, 2.5–5 (–7) cm apart at mid-leaf, 3–4 cm below, chestnut-brown, decurrent on prominent bases, rarely forming a corneous band up to the base, leaf tip acuminate, mucro conical, 1–3 mm, deciduous, chestnut-brown; **Inf** 6–10 m, peduncle 2–3 m, green, glabrous, with oblong to lanceolate, mucronate, green, glabrous **Bra** 11–35 (–50) cm, fertile part lax, oblong, in the upper ½ of the inflorescence, part-**Inf** 40–60, patent to pendulous, (60–) 80–130 cm, green, glabrous, with 6–12 2.-order branches (5–) 10–30 cm long, green, glabrous, freely bulbiferous, bulbils ovoid to ovoid-conical, 20–50 × 15–30 mm, bracteate to somewhat foliose, with 2–4 green bracts and 3–4 small leaves; floral **Bra** small, subulate, scarious, green; **Ped** 5–10 mm, glabrous; **Fl** (37–) 45–50 (–55) mm, 1–4 grouped together; **Tep** spreading and incurved, tip rounded, (20–) 25–30 mm; **OTep** narrowly elliptic, 7–10 (–12) mm; **ITep** elliptic, 10–15 mm broad, whitish-green to greenish-yellow; **Fil** 10–14 mm, 2–4 mm wide at the broadened base, greenish-white; **Anth** oblong, 3 mm, yellow; **Ov** cylindrical, (15–) 20–25 × 3–5 mm, glabrous; **Sty** 15–20 mm, 4–5 mm wide at the broadened base; **Sti** 3-lobate; **Fr** and **Se** unknown. — **Cytology**: 2n = 60 (Whitaker 1934).

The name was published in January 1860 and thus antedates *F. flavoviridis* (publ. February 1860) (Drummond 1907). Described from material cultivated at Potsdam (Germany) and purportedly originating from Quetzaltenango, Guatemala, but neither cultivated plants nor herbarium records are known from that country (Trelease 1915b, Lott & García-Mendoza 1994, García-Mendoza 2001a). The species is at present not certainly known from C America (Lott & García-Mendoza 1994).

*F. selloana* belongs into a group with *F. cabuya* and *F. hexapetala*, sharing flowers with an ovary much shorter than the tepals and ovoid bulbils, but is separated from both by its linear-lanceolate leaves, 23–35 (–50) teeth per leaf margin and variably sized, oblong, lax inflorescences, and oblong bracts with denticles at their apex only. Specimens with bifid teeth might indicate

hybridization with *F. acaulis* (García-Mendoza 2001a). Vernacular names: “fique”, “cabuya”, “penca” and “mión-kei-úvi” (“maguey”). Planted as fence or hedge or ornamental (esp. the variegated forms). The leaf fibres are used for making bags and sacks (García-Mendoza 2001a).

The variegated form was introduced in 1867 from the Cauca valley in Colombia by the botanical traveller Wallis and published by Jacobi (1870: 79–80) as *F. lindenii*. Several variegated or toothless horticultural variants have been described. The variegated form (var. *marginata*) with creamy-yellow stripes along the leaf margin and sometimes light creamy streaks on the lamina is much more common in cultivation than normal green forms (Irish & Irish 2000). Reported as local neophyte from C Portugal by Silva & al. (2015).

[Editorial note by U. Eggli:] The name was originally published with the spelling ‘selloa’, which is sometimes amended to ‘selloi’. Since the epithet honours Hermann Sello, the name must be corrected to ‘selloana’ under ICN (2018) Art. 60.8c (see Figueiredo & Smith (2016)).

**F. stricta** Jacobi (Abh. Schles. Ges. Vaterl. Cult., Abth. Naturwiss. 1869: 171, 1869). **Type:** not typified. — **Distr:** Not known to be extant.

[1] Acaulescent; **Ros** rather regular, 0.9 m Ø; **L** ± 30, linear-lanceolate, straight, rigid, coriaceous, spreading to all directions, narrowed to 3.8 cm above the base, gradually narrowed from mid-leaf towards the tip, convex below and subacutely keeled, above below the base flat or concave, so deeply channelled as to be almost triquetrous in section above mid-leaf, scabrous below, smooth and somewhat shiny above, 60–76 × 5–6.3 cm, vivid light green to bright green, margins straight, narrow, somewhat reddish; **marginal teeth** strong, rigid, distant, tip corneous, uncinat, reddish chestnut-brown on broad deltoid reddish bases, leaf tip straight, upper end soon drying; **Inf** erect, 2.43–2.74 m, green, glabrous, peduncle very short, ± 0.45 m, with lanceolate appressed **Bra** to 12.5 cm long below, fertile part 2 to 2.3 m, with part-**Inf** longest at mid-inflorescence, ascending-spreading, somewhat incurved above the middle, 30–35 cm, 2.-order branches very short, to 1 cm, bulbiferous,

bulbils many, partly somewhat laterally flattened, partly inconspicuously obtusely trigonous; **Ped** very short; **Fl** not known whether single or in groups, ovoid; **Tep** incurved, whitish-green; **OTep** lanceolate, tip somewhat thickened, 25 × 8 mm; **ITep** elliptic, with fleshy midrib, 25 × 10 mm; **Fl** 10 mm, 2.5 mm wide at the broadened base; **Anth** elliptic, sagittate, 4 mm, golden-yellow; **Ov** clavate, bluntly trigonous, 15 × 4 mm, papillose; **Sty** longer than the stamens, 15–17 mm, 4 mm wide at the broadened base; **Sti** slightly thickened, capitate; **Fr** and **Se** unknown.

Insufficiently known, and first described from a plant that flowered in the Demoulin garden in Mons (Belgium) in 1868, later also grown at Kew from material from the Berlin Botanical Garden (Baker 1888). Characterized by deeply channelled leaves scabrous below, inflorescences with a very short peduncle, and esp. by the laterally somewhat compressed bulbils (terete in all other species except *F. stratiotes*, here included in *F. acaulis*). The name was for long considered as unresolved (e.g. in the first edition of this handbook and in the revision of García-Mendoza (2001a), but was recently re-established by Govaerts (2014+). Govaerts places *F. elegans* in the synonymy here, whereas García-Mendoza (2001a) is followed here, to treat it as synonym of *F. hexapetala*. Modern records of *F. stricta* possibly refer to *F. hexapetala*.

**F. tuberosa** (Miller) W. T. Aiton (Hort. Kew., ed. 2, 2: 303, 1811). **Type:** [icono]: Plukenet, Almag., 19, 1700. — **Lit:** Drummond (1907); Álvarez de Zayas (1996); Proctor & Acevedo-Rodríguez (2005); Smith & Figueiredo (2012); all with ills. **Distr:** Lesser Antilles, Bahamas, Haiti, Puerto Rico, Dominican Republic, French Guiana, Guyana & Suriname (natural?), Brazil, Paraguay (?), cultivated worldwide; in Guyana and Suriname in tropical lowland forests, otherwise mostly in secondary anthropogenic habitats near roads or settlements, 50–400 m; flowers July to August in Guyana & Suriname, in the Caribbean January to October.

≡ *Agave tuberosa* Miller (1768) ≡ *Fourcroya tuberosa* (Miller) Hooker (1860) (*incorrect name*, ICN Art. 11.4); **incl.** *Agave tuberosa* Lamarck (1784) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave*

*tuberosa* Aiton (1789) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Agave tuberosa* var. *β spinis solitariis* Aiton (1789) (*nom. inval.*, ICN Art. 23.1); **incl.** *Furcraea spinosa* O. [1] Stems none or short, hardly 30 cm, moderately rhizomatous; **Ros** semiglobose in outline, 1.5–2 × 2–3 m; **L** 50–70, oblong-elliptic, erect, coriaceous or cartilaginous, semi-concave, 4.5–6 (–10) cm broad at the base, keeled below, smooth, 1–1.5 (–2) m × (10–) 15–20 cm, yellowish-green, glossy, margins between the teeth crenate, sometimes with a corneous band towards the base; **marginal teeth** simple, small, straight or recurved, 1–3 (–4) × (1–) 2–3 mm, decurrent on prominent deltoid bases, 1–2.5 (–3) cm apart at mid-leaf, 1–3 cm below, lacking in the upper ½ – ⅔, brown-reddish or blackish, with yellow base, **L** tip broadly acuminate, canaliculate, mucro thickened, flattened and folded, sometimes horny, (1–) 2–4 mm, reddish; **Inf** 4–7 m, peduncle 2–3 m, green, glabrous, with deltoid, mucronate, entire, pilose, green **Bra** 6 cm long, fertile part lax, oblong to rhomboidal, in the upper ½ of the inflorescence, part-**Inf** 30–40, 45–100 (–150) cm, glabrous, with 4–15 2.-order branches 10–30 cm long, glabrous, freely bulbiferous, bulbils conical to conical-ovoid, (20–) 30–50 (–70) × 10–20 (–25) mm, with 3–5 bracts and 3–4 broadly lanceolate small leaves 3–7 (–10) cm long; floral

**Bra** deltoid, 4–7 mm, deciduous; **Ped** 5–10 (–15) mm, glabrous; **Fl** (47–) 50–55 (–57) mm, single or 2–3 grouped together; **Tep** 25–30 mm, glabrous, whitish-green to greenish-yellow; **OTep** narrowly elliptic, 6–10 mm broad; **ITep** broadly elliptic, 10–15 mm broad; **Fil** dorsiventrally flattened, 10–15 mm, 2–4 mm wide at the broadened base, yellow; **Anth** oblong, 2–3 (–6) mm, yellow; **Ov** cylindrical, (22–) 25–30 × 3–4 mm, glabrous, “perhaps not functional” fide Proctor & Acevedo-Rodríguez (2005); **Sty** 15–20 (–22) mm, 3–4 (–5) mm wide at the broadened base; **Sti** papillose; **Fr** and **Se** unknown.

The typification of this name remains unresolved: Howard & Thompson-Mills (1979) designate a Plukenet plate (Almagestum, 19, 1700, showing an unarmed plant) as type, but this is in conflict with the protologue, which describes an armed plant. García-Mendoza (2001a) selected a neotype (Commelin, Horti Med. Amstelod. 2: 35, 5. 19, 1701), but since García-Mendoza’s thesis was not formally published, the selection remains inoperative.

Characterized by oblong-elliptic or broadly lanceolate leaves with a very narrow base, small, prominent teeth placed close together in the lower ½ or ⅔ of the leaves, a canaliculate tip with thickened and flattened mucro, and an ovary as long as the tepals (García-Mendoza 2001a). The species is cultivated since earliest times in the Americas and later worldwide as “Mauritius hemp”, esp. in the 19. and 20. century on Mauritius. The occurrence in Guyana and Suriname is natural (García-Mendoza 2001a). It reproduces entirely by bulbils (Proctor & Acevedo-Rodríguez 2005).

*F. samalana* is very close and García-Mendoza (2001a) treats it as a mere variety of *F. tuberosa*, but the combination is not validly published. *F. tuberosa* is also similar to *F. hexapetala* (Álvarez de Zayas 1996, Smith & Figueiredo 2012), but differs in its oblong-elliptic, mostly broader leaves smooth on both faces with brown-reddish teeth and larger flowers (vs. narrower, lanceolate leaves scabrous below with blackish to reddish teeth and smaller flowers).

Vernacular names: “guassu” (Brazil), “karata” or “carata” (Guadalupe), “pite” (Haiti), “maguey”, “maguey criollo” or “female karata” (Puerto

Rico), “langue boeuf” (Trinidad), “aloés créole” (“sábila criolla”) (Mauritius), and “shikwenga” (Moçambique) (García-Mendoza 2001a).

**F. undulata** Jacobi (Abh. Schles. Ges. Vaterl. Cult., Abth. Naturwiss. 1869: 170, 1869). **Type:** not typified. — **Distr:** Mexico (?). **I:** Curtis’s Bot. Mag. 100: t. 6160, 1874; Curtis’s Bot. Mag. 118: t. 7250, as *F. pubescens*;

**Incl.** *Furcraea aitonii* Jacobi (1869); **incl.** *Furcraea pubescens* Baker (1892) (*nom. illeg.*, ICN Art. 53.1).

[1] **Ros** (almost) acaulescent, small, to 0.9 m Ø; **L** few, (12–) 20–30, younger leaves somewhat erect-recurved, older leaves spreading-recurved or strict, partly nearly horizontal, (narrowly) lanceolate to ensiform, coriaceous but not rigid, narrowed towards the broadened semi-amplexicaul base, base to 10 cm broad, above the base 1.9–3.8 cm broad, at mid-leaf ±3 mm thick, long-acuminate, below sharply keeled in the lower ⅓, obscurely keeled in the middle, asperous, channelled above, at mid-leaf very shallowly grooved, smooth, 40–45 × 5–10 cm, fresh to dull dark olive-green, not glaucous, margins strongly wavyly curved; **marginal teeth** stout, triangular, upcurved, regular along the whole margin, or reduced in the upper ⅓, 2–3 mm, brown, on small deltoid bases; **terminal Sp** straight, (scarcely) pungent, 2.5 mm, obtusely conical, corneous, chestnut-brown; **Inf** ± 3 m, peduncle green, with few subulate bracts, fertile part elongate, slender, narrow, pubescent, in the upper ⅓, with ascending, more erect than spreading, simple, strict part-**Inf** to 30 cm, tips pendent, bulbils not mentioned; floral **Bra** minute; **Ped** ± 6 mm; **Fl** usually geminate, 50–63 mm Ø; **Tep** narrowly oblong to oblong-lanceolate, obtuse, obtusely keeled down the centre, 10–13 mm broad, pale green to greenish-white; **Fil** ½ as long as the tepals, subulate above, broadened base deltoid; **Anth** short, yellow; **Ov** cylindrical, ± 25 mm, green, pubescent (but glabrous according to Baker (1879)); **Sty** deeply 3-lobed below, subulate above, about as long as the filaments; **Fr** and **Se** unknown. — **Cytology:** 2n = 60 (Satô 1935), as *F. pubescens*, but undecidable whether applying to *F. pubescens* Baker (and thus belonging here), or to *F. pubescens* Todaro.

Introduced by Ghiesbreght for the nursery Verschaffelt (Gand, Belgium). Differs from all other species except *F. depauperata* in its wavyly curved leaf margins. It was published from sterile plants allegedly from Chiapas and Tabasco (Mexico) where Ghiesbreght mainly travelled the years before. *F. undulata* is at present unknown in habitat or cultivation; no material from S Mexico matches the description (Lott & García-Mendoza 1994), and records for El Salvador (Standley & Calderón 1941: 52), the Lesser Antilles or Puerto Rico and cultivated plants labelled *F. undulata* are all doubtful. A specimen from the Bahamas doubtfully placed here (Drummond 1907) is placed in *F. hexapetala* by Britton & Millspaugh (1920: 77, as *F. macrophylla*). Baker (1892) misnamed plants with a wavy margin and thus attributable here as *F. pubescens*. See also under *F. depauperata*.

## Hesperaloe AGAVACEAE

J. Thiede

**Hesperaloe** Engelmann (in S. Watson, Bot. US Geol. Expl. 40. Parallel 5: 497, 1871). **Type:** *Aloe yuccifolia* A. Gray [*nom. illeg.*, ICN Art. 52.1;  $\equiv$  *Yucca parviflora* Torrey]. — **SHH-Clade** — **Lit:** Gentry (1972: synopsis Sonora); Starr (1995: ill. synopsis); Starr (1998: monograph); Robbins (2002: flora N America); Guillot Ortiz & Meer (2006: ill. synopsis cult. spp. Spain); Hochstätter (2009: ill. synopsis); Hochstätter (2011: ill. synopsis). **Distr:** S USA (Texas), N Mexico (Sonora, Coahuila, Nuevo León, Tamaulipas, San Luis Potosí). **Etym:** Gr. ‘hespera’, evening; for the occurrence in North America (i.e. in the West, where the sun disappears in the evening); and for the superficial similarity to *Aloe* (*Asphodelaceae*).

Acaulescent perennials; main **R** thick and fleshy, contractile, with many additional fibrous roots; **Ros** monocarpic, caespitose with short to long rhizomes, either tightly packed or widely separated and forming large rings, or forming grass-like clumps with bulbous fibrous bases; **L** few to many, linear-elongate, succulent, fibrous, either thin, narrow and arching to recurved, or thick, broad and stiffly erect, canaliculate, leaf tip frayed or a hard spine, leaf margins narrow, brown or white, filiferous, fibres thin and tightly curled to thick and nearly straight, white, grey, or brown; **Inf** terminal, ascending, to 4.6 m but

mostly shorter, peduncle with dry lanceolate bracts, fertile part racemose to paniculate, then with 3–8 (–10) part-**Inf** in the upper  $\frac{1}{2}$ – $\frac{1}{3}$ ; **Fl** arising from indeterminate lateral spurs, either on the main stalk or on branches (part-inflorescences); **Ped** within a cluster unequal in length, persistent; **Fl** stipitate, not opening in sequence from bottom to top, 6-merous, diurnal or nocturnal; **Per** elements tubularly connivent for most of their length or upper part  $\pm$  spreading, then flowers broadly campanulate or rotate-campanulate; **Tep** with fleshy keel, about equal, essentially free but united on a fleshy nectariferous receptacle, coloured with combinations of green, white, and purplish-brown to red, pink, salmon, or coral-red to rarely yellow; **Fil** inserted on the receptacle or adnate to the base of the tepals, with the very slender apex abruptly curved inwards; **Anth** dorsifixed, sagittate, introrse, included to exerted; **Ov** superior, ovoid to oblong, trigonous, with 3 large flat septal nectaries, with 3 locules, each with numerous ovules in 2 rows; **Sty** elongate but mostly included in the perianth, sometimes exerted; **Sti** distinctly capitate, fringed with papillae; **Fr** septicidal woody capsules, transversely rugose, beaked or not, stipitate, persistent; **Se** large, black, flat, thin. — **Cytology:**  $x = 30$  (McKelvey & Sax 1933, Gómez-Pompa & al. 1971, Engard 1980, Pinkava & Baker 1985).

According to molecular and morphological phylogenies, *Hesperaloe* is closest to and the sister group of *Hesperoyucca* (Bogler & Simpson

---

J. Thiede (✉)  
Hamburg, Germany  
e-mail: joachim\_thiede@gmx.de

1995, Clary & Simpson 1995, Bogler & Simpson 1996, Rocha & al. 2006). Putative synapomorphies are leaves with papillate epidermal cells arranged over the veins, stamens adnate to the tepal base or lower part of the tepals, styles slender, and stigmas fringed with papillae. *Hesperaloe* differs from *Hesperoyucca* esp. in its coarsely grass-like habit, the filiferous leaf margins, and the flower colour (never purely whitish) and  $\pm$  connivent tepals. Differences from *Yucca* are flower colour (never pure whitish), the  $\pm$  connivent tepals, and the capitate stigma. Recent molecular studies (Halpin & Fishbein 2013, Archibald & al. 2015) unexpectedly found the non-succulent genus *Schoenolirion* of subfamily *Chlorogaloideae* as sister-group of *Hesperaloe*, and both together are in turn sister of *Hesperoyucca* (see also there).

The geographical range of *Hesperaloe* is remarkable: 2 species (*H. nocturna*, *H. tenuifolia*) are found on the W side of the Sierra Madre Occidental (which represents an important floristic continental divide), widely disjunct from the remaining 6 species, which occur E of the Sierra Madre Occidental (4 in the Chihuahuan Desert region, *H. malacophylla* in Tamaulipas, *H. engelmannii* in Texas).

**Pollination ecology:** The strictly diurnal flowers of *H. parviflora* are pollinated by hummingbirds and bees. The nocturnal, less brightly coloured, fragrant flowers of *H. funifera* and *H. nocturna* are pollinated by bats and hawkmoths. The flowers of the latter may occasionally remain open well into the morning when they are visited by bees, while visiting hummingbirds and bumblebees may merely represent nectar thieves. *H. campanulata* combines both syndromes and is pollinated by bats and hawkmoths during the night and by hummingbirds and bees the following day when the flowers close somewhat to form a tube (Engard 1980, Starr 1995, Pellmyr & Augenstein 1997, Starr 1998). While most species of *Agavaceae* are believed to be self-compatible, experimental hand-pollinations indicated that *H. parviflora* might be self-incompatible (Pellmyr & Augenstein 1997, see also Bolliger 2010).

**Ecology:** The carbohydrates stored in a *H. funifera* plant prior to flowering are sufficient to meet only about  $\frac{1}{3}$  of what is needed to produce an average inflorescence with 1–2% fruit set; accordingly all carbohydrates produced during growth are needed to support flowering and fruit production (McLaughlin & Williams 2000). *H. funifera* and *H. nocturna* both exhibit CAM photosynthesis, esp. in older leaves. These have weakly expressed mesophyll succulence closer to that of typical C3 species, and both species are characterized as non-succulent CAM-plants by Ravetta & McLaughlin (1993). Heyduk & al. (2016) found *H. funifera* and *H. parviflora* as CAM plants and characterize them as (weakly) succulent.

**Ethnobotany:** Wild populations of *H. funifera* were formerly a source of fibres used chiefly for twine and coarse sacking (Dewey 1943). McLaughlin (1996), McLaughlin (2000), Sanchez & al. (2010a), and Sanchez & al. (2010b) report about trials to use *H. funifera* leaves as raw material for producing paper and bioenergy.

**Cultivation:** *Hesperaloe* is cultivated since 1849 in England and since 1878 in the USA (Starr 1995). Cultivation advice is given by Starr (1995) and Irish & Irish (2000) for the USA, by Smith & Steyn (2002) for RSA and the Mediterranean, and by Boeuf (2007), Bolliger (2010) and Hochstätter (2011) for European regions. Plants are rather drought-tolerant and do equally well in desert, subtropical and mediterranean climates in direct or indirect sun and fast-draining soils. In a sunny place in fast-draining soil and with rain protection in the winter, plants may be hardy in C Europe (*H. campanulata* to  $-10^{\circ}\text{C}$ , *H. engelmannii* to  $-14^{\circ}\text{C}$ , *H. nocturna* to  $-15^{\circ}\text{C}$ , *H. parviflora* ssp. *parviflora* to  $-18$  (to  $-21$ )  $^{\circ}\text{C}$ ) (Boeuf 2007, Bolliger 2010, Hochstätter 2011).

**H. campanulata** G. D. Starr (Madroño 44(3): 285–286, ill., 1998). **Type:** Mexico, Nuevo León (Starr 93-001 [ARIZ, MEXU, MO, TEX]). — **Lit:** Starr (1995: as sp. nov. #1, with ill.). **Dist:** Mexico (C Nuevo León); open Chihuahuan Desert scrub, limestone slopes and hillsides,

100–600 m; flowers late March to November. **I:** Irish & Irish (2000); Guillot Ortiz & Meer (2006); Hochstätter (2011).

**Ros** moderately caespitose, forming clumps to 0.6–1.2 m Ø; **L** > 25, stiff and erect to slightly spreading, linear-lanceolate, tapering towards the tip, slightly canaliculate, 0.6–1.1 m × 1.5–2.6 cm (widest point 1/3 from the base), medium green, margins finely filiferous, fibres white, 5–7 cm, 6–8 cm apart, terminal **Sp** recurved, canaliculate, not pungent, light brown-grey; **Inf** to 3 m, peduncle green-purple, **Bra** purple, the lower 7–10 cm, fertile part unbranched racemes or usually panicles with 2–5 (–19) part-**Inf** in the upper 1/2–1/3; **Ped** recurved, 8–13 mm, rose; **Fl** tubular-campanulate to broadly campanulate, 20–25 × 20–22 (–28 in cult.) mm, in clusters of 3–8, buds rose; **Tep** strongly recurved; **OTep** linear to linear-lanceolate, 18–22 × 4–8 mm, inside white, outside pink with broad white margins; **St** included; **Fil** 14–16 mm, adnate to the tepal base for 3 mm, white; **Anth** sagittate, 3 mm, yellow-greenish; **Ov** 6–10 × 4–6 mm, white; **Sty** 9–13 mm, included; **Fr** globose or oblong, 20–30 (excl. beak) × 20–25 mm, with a sharp 4–11 mm long beak; **Se** 6–9 × 5–6 mm.

Known only from few localities. Vegetatively like a small *H. funifera*, but easily separated by the pink flower colour (vs. greenish-white). Distinguished from *H. parviflora* by more open flowers and lighter green and less channelled leaves (Starr 1995). Molecular sequence data (Archibald & al. 2015) place *H. campanulata* closest to *H. funifera*. F1 and F2 hybrids between the nocturnal *H. funifera* and the diurnal *H. parviflora* resemble *H. campanulata*, suggesting a putative hybrid origin for the latter (Archibald & al. 2015). The flowers open in the evening and are pollinated at night by bats and hawkmoths; the following day, they close somewhat forming a “tube” and are then visited by hummingbirds (Starr 1998).

**H. chiangii** (G. D. Starr) B. L. Turner (Lundellia 5: 39, 2002). **Type:** Mexico, San Luis Potosí (*Garcia Moya* s.n. [DES]). — **Lit:** Starr (1998: with ills.); Hochstätter (2009: with ills.). **Distr:** Mexico (San Luis Potosí, probably also S Nuevo León and SW Tamaulipas); locally

common in grassland on flat plateaux, open slopes and hills, 1350–1500 m. **I:** Gómez-Pompa & al. (1971: 221, as *H. funifera* from San Luis Potosí); Hochstätter (2011); Archibald & al. (2015: as *H. funifera* ssp.).

≡ *Hesperaloe funifera* ssp. *chiangii* G. D. Starr (1998).

**Ros** with long rhizomes >30 cm, forming broad clumps or fairy rings to >2 m Ø; **L** stiff and erect, lanceolate, not arching, deeply canaliculate, 1–1.5 m × 5–6 cm (from base to middle, when flattened), tapering above to the tip, medium to dark green, fibres coarse, 2–3 mm thick, white to grey near the point of attachment, straight to slightly curled; **Inf** 2–4 m, panicles with 6–8 spreading to ascending part-**Inf** in the upper 1/2; **Fl** tubular, 30 × 25 mm, nocturnal, in clusters of 3–4; **Tep** inside white, outside pinkish-red; **Fr** ovoid to rounded, 25–30 × 25 mm, with a short beak 3 mm long. — **Cytology:** x = 30 (Gómez-Pompa & al. 1971: as *H. funifera* from San Luis Potosí).

First published as a subspecies of *H. funifera*, but geographically isolated and morphologically clearly distinct. This is fully confirmed by molecular sequence data of Archibald & al. (2015), which place *H. chiangii* distant from *H. funifera* and closest to *H. nocturna* and *H. tenuifolia*. Material was already collected by C. G. Pringle in 1891, and identified as *H. funifera*. Reports of *H. funifera* for San Luis Potosí (Standley 1920–1926, Engard 1980) and S Nuevo León and SW Tamaulipas (Ullrich 1990) might refer to *H. chiangii*.

**H. engelmannii** Krauskopf (Notice Bot., [], 1878). **Type** [neo]: USA, Texas (Turner 99–367 [TEX]). — **Lit:** Trelease (1902: as *H. parviflora* var.); Turner & Turner (2002); Diggs & al. (2006); Guillot Ortiz & Meer (2006: as *H. parviflora* var.); Hochstätter (2009); all with ills. **Distr:** USA (C & S-C Texas: Edwards Plateau); sandy, silty, or rocky, usually calcareous soils, usually beneath oaks and associated shrubs and trees; flowers April to June. **I:** Hochstätter (2011).

≡ *Hesperaloe parviflora* var. *engelmannii* (Krauskopf) Trelease (1902).

**Ros** forming clumps to 0.5–1.2 Ø; **L** linear to linear-falcate, recurved, variable, to 1–1.5 m, dark

green to grey-green, tip with pungent grey to brown terminal spine, **L** margins lined purple, not markedly fibrous, fibres white to grey, irregular, 4–5 cm, 2.5–4 cm apart; **Inf** 1–2.5 m, panicles, peduncle sometimes salmon-coloured, with scarious **Bra** 4 × 1 cm, fertile part making up the upper ½, curved, with ascending part-**Inf**; **Ped** to 35 mm, rose, straight; **Fl** in clusters of 3–8, oblong-campanulate, tubular, 25–40 mm; **Tep** linear-oblong, tips slightly cucullate, 20–22 × 10 mm, pink or salmon-coloured, margins light rose; **OTep** rose; **ITep** tending to have white flaring tips; **St** included; **Fil** to 18 mm, rose; **Anth** 3–6 mm (longer than in *H. parviflora*), yellow; **Ov** 5 × 3 mm, white; **Sty** short and thick, mostly 1–2 (–3) × as long as the ovary proper, included and much shorter than the tepals; **Fr** unknown.

The author citation follows Turner & Turner (2002). Previously included in the synonymy of *H. parviflora* (e.g. Starr (1998)), but a distinct species according to Turner & Turner (2002), differing in larger and relatively narrower, somewhat flatter and darker green leaves not markedly fibrous, shorter and thicker styles, larger anthers, and inner tepals with white flaring tips (Hochstätter 2009). According to molecular sequence data (Archibald & al. 2015), *H. parviflora* ssp. *bechtoldii* is nested within *H. engelmannii*, and both place separate from *H. parviflora* s.s. Trelease (1902) describes and depicts a plant in which the first and later flowers had slightly exerted styles, similar to *H. parviflora* ssp. *bechtoldii*. Hybrids with *H. parviflora* ssp. *parviflora* are known in cultivation in the USA and Europe (Hochstätter 2009).

**H. funifera** (K. Koch) Trelease (Annual Rep. Missouri Bot. Gard. 13: 36, tt. 3–4, 1902). **Type** [neo]: Mexico, Coahuila (Engard & Gentry 23241 [ARIZ]). — **Lit**: Trelease (1902); Ullrich (1990); Starr (1995); Hochstätter (2009); all with ills. **Distr**: S USA (SW Texas: Val Verde County), N Mexico (Coahuila, N Nuevo León); calcareous lowlands and foothills in (semi-) arid regions, 350–1000 (–2100) m; flowers April to September. **I**: Irish & Irish (2000); Guillot Ortiz & Meer (2006); Hochstätter (2011).

≡ *Yucca funifera* K. Koch (1862) ≡ *Agave funifera* (K. Koch) Lemaire (1864); **incl.** *Hesperaloe davyi* Baker (1898).

**Ros** forming clumps to 1.5 m Ø, rhizomes short; **L** stiff and erect, linear-lanceolate or lanceolate, rigid, not arching, canaliculate, tapering from the middle towards the tip, 0.8–2 m × (2–) 3–4 (–6) cm (when flattened, from base to middle, to 1.5 cm wide at the base), light or yellowish-green, tip with a brown terminal spine, **L** margins brown, medium to coarsely fibrous, fibres loosely coiled, 8–15 cm, to 12 cm apart, to 1 mm thick, white or grey, or tinged purple at the base; **Inf** 2–4 (–4.6) m, paniculate, peduncle bluish-green, 1.5–1.8 m, with brown scarious **Bra**, fertile part 0.3–1.2 m, making up the upper ½, with 3–8 ascending or arching part-**Inf**; **Ped** slightly curved, 5–6 mm, green to purplish-green; **Fl** rotate-campanulate, 15–25 mm, in clusters of 3–4, opening in the morning, closing in the evening of the same day; **Tep** linear-oblong, 17–22 mm, tips cucullate, inside white; **OTep** outside green at the base, upper ⅓ reddish-purple, 6–7 mm wide; **ITep** outside green and white with a narrow mid-stripe tinged brownish-purple, 8–9 mm wide; **St** exerted; **Fil** 15–18 mm, white, at the base connate to the tepals; **Ov** (6–) 10–12 × 4–5 mm; **Sty** 6–7 × 4–5 mm, thick, included to scarcely exerted; **Fr** globose or broadly oblong, 25–35 × 25–35 mm, sharply beaked, beak 2–4 mm; **Se** 7–9 × 5–7 mm. — **Cytology**: 2n = 60 (Engard 1980; Pinkava & Baker 1985).

The largest species of the genus. Mature plants are easily recognizable by their stiff long leaves. Young plants are difficult to distinguish from *H. parviflora*, but the leaves are greener and stiffer in *H. funifera* (Starr 1995). Molecular sequence data place *H. funifera* closest to *H. campanulata*; the distributions of both taxa overlap in N Mexico where Starr observed a putative hybrid population of *H. funifera* with intermediate plant sizes and flower colours (Archibald & al. 2015).

The single collection from Texas (Butterwick & Poole 1980) is regarded as doubtful and possibly resulting from introduction (Turner & Turner 2002). Records of *H. funifera* from San Luis Potosí are *H. chiangii* (see there). Dewey (1943) reported the species from Chihuahua, but this

needs confirmation; the genus is not at present recorded from Chihuahua. A specimen from near Ciudad Victoria in Tamaulipas (*González M.*, MEXU 584975) labelled *H. funifera* would confirm earlier records of the species from that state (Dewey l.c.; Ullrich l.c.), but was collected not far from the sole locality of *H. malacophylla* and might represent that species. In cultivation, hybrids with *H. parviflora* ssp. *parviflora* and *H. tenuifolia* are known (Starr 1995).

**H. malacophylla** Hochstätter & Martínez-Ávalos (Plante Grasse 30(1): 20–22, ill., 2010). **Type:** Mexico, Tamaulipas (*Martínez-Ávalos* 898 [UAT]). — **Lit:** Hochstätter (2011: with ill.). **Distr:** Mexico (W-C Tamaulipas); open moist woodland, in the shade of oaks and pines, 800–1000 m; known from the type locality only; flowers April to May.

**Ros** in small clumps to 0.4 m Ø; **L** erect or arching, soft, flexible, 0.5–1.5 m, width not indicated, yellow-green, margins finely filiferous, fibres flexible; **Inf** usually branched panicles, 1–3 m, fertile part to 1 m making up the upper ½; **Fl** tubular-campanulate, 25–30 × 20 mm at anthesis; **Tep** white within, pink outside; **Fr** globose, 25 × 25 mm, sharply beaked, beak short; **Se** 8 × 4–7 mm, surface structured.

The short protologue lacks several floral features. Characterized by its soft and flexible, erect to arching leaves (vs. stiff, strong and ± erect in all other taxa), and notable for its occurrence in relatively moist habitats. See also under *H. funifera*.

**H. nocturna** Gentry (Madroño 19(3): 74–78, 1967). **Type:** Mexico, Sonora (*Gentry & Felger* 19988 [US, ARIZ, DES, MEX, NY]). — **Lit:** Gentry (1972); Starr (1995); Hochstätter (2009); all with ill. **Distr:** Mexico (N-C Sonora); talus slopes of basalt cliffs, 950–1150 m; flowers April to July. **I:** Hochstätter (2011); Guillot Ortiz & Meer (2016: 20–21).

**Ros** very dense, densely caespitose and forming clumps 1–2 m Ø; **L** upright and arching, narrowly linear, striate, tapering gradually from the base to the long-attenuate tip, flat towards the base, deeply canaliculate upwards, 1–1.5 m × 1–2 cm (at the base), dark green, tip an acicular

and pungent spine, fraying with age, **L** margins narrow, brown, white-filiferous, fibres irregularly wavy, white; **Inf** to 1.5–4 m, peduncle long, with lanceolate dry **Bra** 4–6 cm or less, fertile part slender racemes or panicles with 2–3 part-**Inf** in the upper ½; **Ped** 5–18 mm; **Fl** campanulate-rotate, 24–30 mm, nocturnal, in clusters of 4, 6 or 8; **Tep** reflexed at anthesis, 15–25 mm, whitish or greenish-white within, buds pruinose pink to lavender, greenish below; **OTep** 6–7 mm wide, outside reddish with greenish-brown midstripe (pink or lavender fide Gentry); **ITep** 8–9 mm wide, outside with broad reddish-purple mid-stripe (greenish-pink or greenish-lavender fide Gentry); **St** included; **Fil** 8–9 mm, as long as the style, attached to the base of the tepals for 3 mm; **Anth** sagittate, versatile, 8–9 mm; **Ov** oblong, trigonous, 10 × 4 mm, basis ringed with a nectary, roundly angled at the apex; **Sty** stout, 8 mm, included; **Sti** capitate, papillate; **Fr** depressed-ovoid or oblong, 25–40 × 25–45 mm, shortly beaked, apiculate; **Se** 11 × 8 mm. — **Cytology:** 2n = 60 (Engard 1980).

Easily identifiable by its long narrow leaves and the campanulate-rotate nocturnal flowers (Starr 1995). Molecular sequence data (Archibald & al. 2015) place *H. nocturna* closest to *H. tenuifolia*, suggesting that the Sierra Madre Occidental was traversed only once in the evolution of *Hesperaloe*.

The short but distinct flower tube mentioned by Gentry (1967) and Gentry (1972) is not mentioned by later authors and appears to be erroneous, and Gentry's drawings show the tepals free to the base as in all other species. The nocturnal flowers remain open well into the next morning on humid days. The predominant night-time pollinator is an unidentified species of bat, and a bee is a regular morning visitor, while hummingbirds are probably merely nectar thieves (Engard 1980). In cultivation, hybrids with *H. parviflora* ssp. *parviflora* are known (Starr 1995).

Hesdörfer (1904) reported that C. A. Purpus collected “*H. funifera*” in S Arizona back in 1903. If not in error or relating to cultivated plants, this might have been an early record of *H. nocturna* across the border, although *Hesperaloe* is not currently recorded from Arizona.

**H. parviflora** (Torrey) J. M. Coulter (Contr. US Nation. Herb. 2: 436, 1894). **Type** [lecto]: USA, Texas (*Wright* 1908 [GH, NY]). — **Distr**: USA (SW Texas), N Mexico (NW & N Coahuila).

≡ *Yucca parviflora* Torrey (1859); **incl.** *Aloe yuccifolia* A. Gray (1867) (*nom. illeg.*, ICN Art. 52.1) ≡ *Hesperaloe yuccifolia* (A. Gray) Engelm. (1871) (*nom. illeg.*, ICN Art. 52.1).

Molecular sequence data (Archibald & al. 2015) show the species to be polyphyletic, with *ssp. bechtoldii* nested within *H. engelmannii*, and both are placed separate from *H. parviflora ssp. parviflora*.

**H. parviflora ssp. bechtoldii** Hochstätter (CactusWorld 27(2): 103–105, ills., 2009). **Type**: Mexico, Coahuila (*Bechtold* 733 [HEID]). — **Lit**: Hochstätter (2011). **Distr**: N Mexico (N Coahuila); flat sandy desert area, 660 m; known only from the type locality; flowers April to May.

≡ *Hesperaloe bechtoldii* (Hochstätter) Hochstätter (2016) (*nom. inval.*, ICN Art. 29.1, Ex. 2).

Differs from *ssp. parviflora*: **Ros** smaller, forming irregular small clumps to 20–40 cm Ø; **L** stiff, erect, lanceolate, 20–40 cm, curving somewhat to the side, narrowly canaliculate; **Inf** unbranched racemes to 30–80 cm; **Fl** tubular, longer, 30–50 mm, not widely opening; **Sty** exserted, 12–18 mm; **Fr** 25–30 × 20–30 mm.

The protologue claims that the exserted style is characteristic, but this character is also sometimes present in the typical subspecies.

**H. parviflora ssp. parviflora** — **Lit**: Smith & Steyn (2002); Hochstätter (2009); both with ills. **Distr**: USA (SW Texas), N Mexico (NW Coahuila); creosote scrub, oak and chaparral zones, 500–2000 m; flowers March to September. **I**: Curtis's Bot. Mag. 126: t. 7723, 1900, as *H. yuccaefolia*; Hochstätter (2011). — Fig. 1.

**Incl.** *Hesperaloe yuccoides* hort. (s.a.) (*nom. inval.*, ICN Art. 29.1/61.1).

**Ros** densely caespitose, forming clumps to 1 m Ø or more; **L** arching, linear, narrowing towards the tip, 30–60 (–125) × 0.8–1.8 (–2.5) cm (at the base), dark, shiny or bluish-green, tip pungent,

**Fig. 1** *Hesperaloe parviflora ssp. parviflora*. (Copyright: U. Eggli)

5–20 mm, brown, **L** margins finely filiferous, fibres tightly curled, 4–6 cm, 3–5 cm apart, white or grey; **Inf** panicles to 1–2.5 m, peduncle 50–75 cm, fertile part with few part-**Inf** mainly in the upper ½, rachis and part-inflorescences rose-purple; **Ped** to 25 mm, rose-purple; **Fl** tubular or oblong-campanulate, suberect, 25–35 mm, diurnal, in indeterminate clusters; **Tep** linear-oblong, pressed together at anthesis, tip ± curved outwards, obtuse, with a minute tuft of white hair-like papillae; **OTep** 15–20 × 4–7 mm, salmon-coloured, coral-red, pink, or rosy-red (also yellow or pale cream in horticultural selections); **ITep** 17–20 × 8–9 mm; **St** included; **Fil** 7–13 mm, white or rosy, attached to the tepal base for 1 mm; **Anth** 2–3 mm; **Ov** ovoid to conical-ovoid, small, very slightly 6-grooved, 4–6 × 3–4 mm; **Sty** slender, elongate, 12–13 mm, slightly tapering, included or 1–3 mm exserted, triquetrous near the base, white; **Sti** 3-lobed, somewhat fimbriate; **Fr** woody, ovoid or oblong-ovoid, 25–40 ×

25–30 mm, beaked; **Se** 9–10 × 6–8 mm. — **Cytology:** 2n = 60 (McKelvey & Sax 1933, Engard 1980).

Distinguished by the combination of narrow, mainly salmon-coloured to reddish flowers and relatively short and dark green leaves (Starr 1995). Starr (1998) and Smith & Steyn (2002) describe the style as “included”, but Trelease (1902: 30), Powell (1988: Fig. 40), Turner & Turner (2002: 41) and Diggs & al. (2006) all report that the style may also be exerted (see also ssp. *bechtoldii*). Pollination is probably exclusively by hummingbirds, and the visiting bees appear to be non-pollinating nectar thieves (Engard 1980). Hummingbird pollination was also confirmed by Pellmyr & Augenstein (1997).

In cultivation, plants with yellow (cultivar ‘Yellow’) and pale cream flowers are known from Europe (Guillot Ortiz & Meer 2006, Hochstätter 2009), and the USA (Irish & Irish 2000). The yellow-flowered plants possibly belong to *H. engelmannii* on the base of flower morphology (Guillot Ortiz & Meer 2006). ‘Perpa’ is a cultivar with scarlet-red flowers. Hybrids of cultivated origin are known with *H. funifera* and *H. nocturna* (Starr 1998). For a micropropagation protocol see Richwine & al. (1996).

**H. tenuifolia** G. D. Starr (Madroño 44(3): 293–294, ills., 1998). **Type:** Mexico, Sonora (Jenkins & Meyer 90–63 [ARIZ]). — **Lit:** Starr (1995: as sp. nov. #2); Hochstätter (2009); Hochstätter (2011); all with ills. **Distr:** NW Mexico (S Sonora: Cerro Agujudo); dry rhyolitic hilltops in pine-oak forest or woodland, 1200–1500 m; only known from the type locality; flowers April to May.

**Ros** open, sparsely caespitose and forming small clumps to 50 cm Ø; **L** few, arching, narrowly linear, tapering towards the tip, 50–100 × 0.5–1 cm (at the base), apiculate, **L** margins thin, finely filiferous, fibres not tightly curled, white; **Inf** racemes or narrow panicles with 2–3 part-**Inf**, to 1.5–2 m; **Fl** rotate, small, 13 × 10 mm, nocturnal; **OTep** linear, 13 × 5 mm, outside dark pinkish-red, inside white with reddish margin; **ITep** ovate, 15 × 8 mm, outside dark pinkish-red with white margin, inside white; **St** included;

**Fil** 9 mm, attached to the tepal base for 2 mm; **Anth** 3 mm; **Ov** 6 × 3 mm; **Sty** 4 mm; **Fr** woody, ovoid, 20–30 × 20–25 mm, beak none or 1 mm; **Se** 10 × 5–7 mm.

Very easily recognized by its long and very thin leaves with finely textured very curly marginal fibres. The very short open flowers cannot be confused with those of any other species (Starr 1995). Molecular sequence data (Archibald & al. 2015) place *H. tenuifolia* closest to *H. nocturna* (see also there). — Hybrids of cultivated origin with *H. funifera* are known (Starr 1995).

## Hesperoyucca AGAVACEAE

J. Thiede

**Hesperoyucca** (Engelmann) Trelease (Annual Rep. Missouri Bot. Gard. 4: 208, 1893). **Type:** *Yucca whipplei* Torrey. — **SHH-Clade** — **Lit:** Turner & al. (1995: ecology); Clary (2001: classification); Hochstätter (2000: 15–23, as sect. *Hesperoyucca*, ill. synopsis); Boeuf & al. (2009: 126–129, ill. synopsis); Powell (2013: summary pollination ecology). **Distr:** W USA, NW Mexico. **Etym:** Gr. ‘hespera’, evening; for the occurrence in W North America (i.e. in the West, where the sun disappears in the evening); and for the similarity to *Yucca* (*Agavaceae*).

≡ *Yucca* [?] *Hesperoyucca* Engelmann (1871).

≡ *Yucca* subgen. *Hesperoyucca* (Engelmann) Baker (1876).

Acaulescent rosette plants, monocarpic when remaining unbranched or polycarpic otherwise; **Ros** solitary or in colonies, sessile, sometimes stem rhizomatous, single or caespitose; **L** linear or rarely narrowly lanceolate, rigid and sword-like to flexible and frequently falcate, plano-convex or subtriquetrous, or keeled on both faces, 25–115 × 0.5–4 cm, ± grey-green, finely striate, base expanded to ± 4–7 × 4–7 cm, ± white to greenish, margin thin, horny, pale yellow, without fibres, mostly denticulate, terminal spine sharp;

**Inf** terminal large panicles, 1.4–8 m with a bracteate peduncle 0.9–4.5 m long, flowering part dense, cylindrical or somewhat slenderly ellipsoid; **Fl** densely arranged, usually broadly expanding, pendent, campanulate or ± globose, 3.5–5 cm, very fragrant; **Tep** broadly lanceolate, nearly equal, 3–4.5 (–6) × 0.8–2.5 cm, white or creamy white to greenish or purple-tinged, tips generally purple, free to the base; **Fil** straight, linear below, tip angled, club-like, papillose, attached to the lower part of the tepals so that the stamens are pulled away from the ovary as the flower opens; **Anth** reniform, pollen uniquely glutinous; **Ov** superior, stout, 8–12 × 6–10 mm; **Sty** short, slender, white; **Sti** distinctly capitate, green towards the centre, fringed with elongated translucent papillae; **Fr** erect, obovoid, strictly loculicidally dehiscent, 3–5 × 1.5–4 cm; **Se** flat, thin, smooth, without marginal wing, 6–7 × 8 mm, dull black. — **Cytology:** n = 30 (Halpin & Fishbein 2013: 1007).

With the exception of Trelease (1893) and indirectly also Baker (1892), most earlier authors included *Hesperoyucca* within *Yucca*. Recent molecular studies (Bogler & Simpson 1995, Bogler & al. 1995, Bogler & Simpson 1996, Bogler & al. 2006, Smith & al. 2008) and a combined morphological/molecular study (Clary & Simpson 1995) clearly revealed a position as sister group of *Hesperaloe* and thus separate from *Yucca*. In fact, the recent molecular phylogenies of Halpin & Fishbein (2013), Archibald & al. (2015) and McKain & al. (2016) all show *Hesperoyucca*

---

J. Thiede (✉)  
Hamburg, Germany  
e-mail: joachim\_thiede@gmx.de

as sister of *Hesperaloe* + *Schoenolirion*, in an *Agavaceae* subclade completely distant to that which includes *Yucca*. A closer association with *Yucca* is only evident in the molecular phylogeny of Good-Avila & al. (2006) and in the morphology-based phylogeny of Hernández-Sandoval (1995). Consequently, *Hesperoyucca* should be treated as separate genus, morphologically clearly distinct from *Yucca*, as in the first edition of this handbook and in several modern floras and checklists, while some still retain it as synonym of *Yucca*.

*Hesperoyucca* differs clearly from *Yucca* (data in brackets) in forming a definite bulb in the seedling stage (Webber 1953: t. 53) (vs. bulb absent), its capitate bright green and densely long-papillate stigma (vs. 3-lobed, white, papillose on the inner surface), its filaments basally attached to the tepals, usually longer than the pistil, finely papillate, and  $\pm$  swollen the entire length, erect or spreading outwardly from the point of attachment at anthesis, bearing tufts of papillae at the apex (vs. filaments not attached to the tepals, usually shorter than the pistil, pubescent, distally clavate and held close to the ovary and bent outwards near the swollen apex), its cordate anthers (vs. sagittate or hastate), and its strictly loculicidally dehiscent fruits (vs. indehiscent or, if dehiscent, septicidal, occasionally also septicidal and loculicidal). The often very large inflorescences of *Hesperoyucca* by far exceed the inflorescence size in *Yucca*, and unbranched plants (“ssp. *whipplei*”) are monocarpic, whereas some branched plants (“ssp. *caespitosa*”) develop new rosettes from the leaf axils of very young plants; both features are unknown in *Yucca*.

Author citation and date and place of valid publication were differently interpreted over time and have been clarified by Greenhouse & Strother (2002).

**Pollination:** Powell (2013) published a comprehensive summary of present knowledge of the pollination of *Hesperoyucca*: The *Yucca* moth *Tegeticula maculata* appears to be the only pollinator, with 3 distinct geographical races. Male moths usually stay in the same inflorescence for their whole life, while females usually translocate to other inflorescences (average 53 m distance). The plants are predominantly self-sterile.

**Ethnobotany:** According to Hodgson (2001, 43–44, ill.), *H. whipplei* was formerly used as food by the local populations in its range. The base of the inflorescence as well as the “heads” left when the leaves are pruned were roasted or baked, and then tasted like a fibrous sweet potato. Young flowers were also roasted and eaten.

**H. newberryi** (McKelvey) Clary (Sida 19(4): 845, 2001). **Type:** USA, Arizona (McKelvey 4087 [A]). — **Distr:** USA (Arizona: Mohave & Coconino Counties: W slopes of the Colorado River Canyon); rocky granite, 400–1300 m; spring-flowering. **I:** Hochstätter (2015: 3, 12, 15, as *Yucca*).

$\equiv$  *Yucca newberryi* McKelvey (1947)  $\equiv$  *Yucca whipplei* ssp. *newberryi* (McKelvey) Hochstätter (2000); **incl.** *Yucca newberryi* ssp. *mckelveyana* Hochstätter (2015).

Monocarpic; **Ros** solitary; **L** 50–60 cm, 0.7–2 cm wide at the base in narrow-leaved forms, 2–2.5 cm in broader-leaved forms; **Inf** 2.8–3.2 m, peduncle 1.4–1.6 m  $\times$  10–14 cm, floriferous part in the upper  $\frac{1}{2}$ , in outline 4–55 cm wide at the widest point; **Fr** woody capsules, at maturity with slight or inconspicuous placental wings.

**H. whipplei** (Torrey) Trelease (Annual Rep. Missouri Bot. Gard. 4: 208, 1893). **Type** [lecto]: USA, California (Schott s.n. [NY]). — **Lit:** Schaffer & Schaffer (1977: pollination ecology); Schaffer & Schaffer (1979: pollination ecology); Aker (1982: summary pollination ecology); Turner & al. (1995: 414–416, as *Yucca*); Powell (2013: summary pollination ecology). **Distr:** SW USA (SW California), NW Mexico (N Baja California, N Baja California Sur, NW Sonora: Pinacate region); coastal sage, chaparral, desert woodland, 0–1400 (–2500) m; flowers (February to) May–June. **I:** Greulich (2012); Hochstätter (2015: 5–10). – Figs. 1 and 2.

$\equiv$  *Yucca whipplei* Torrey (1859); **incl.** *Yucca californica* Groenland (1858); **incl.** *Yucca graminifolia* Alph. Wood (1868) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca engelmannii* Masters (1880); **incl.** *Yucca ortgiesiana* Roetzl (1880); **incl.** *Yucca whipplei* var. *violacea* André (1884); **incl.** *Hesperoyucca whipplei* var. *graminifolia* Trelease (1893)  $\equiv$  *Yucca whipplei* fa. *graminifolia*

(Trelease) Voss (1895); **incl.** *Yucca nitida* C. Wright ex W. Watson (1906); **incl.** *Yucca whipplei* var. *caespitosa* M. E. Jones (1929)  $\equiv$  *Yucca whipplei* ssp. *caespitosa* (M. E. Jones) A. L. Haines (1942); **incl.** *Yucca whipplei* var. *parishii* M. E. Jones (1929)  $\equiv$  *Yucca whipplei* ssp. *parishii* (M. E. Jones) A. L. Haines (1941); **incl.** *Yucca whipplei* ssp. *intermedia* A. L. Haines (1941)  $\equiv$

*Yucca whipplei* var. *intermedia* (A. L. Haines) J. M. Webber (1953); **incl.** *Yucca whipplei* ssp. *percursa* A. L. Haines (1941)  $\equiv$  *Yucca whipplei* var. *percursa* (A. L. Haines) J. M. Webber (1953); **incl.** *Yucca whipplei* ssp. *typica* A. L. Haines (1941) (*nom. inval.*, ICN Art. 24.3); **incl.** *Yucca peninsularis* McKelvey (1947)  $\equiv$  *Hesperoyucca peninsularis* (McKelvey) Clary (2001); **incl.** *Yucca whipplei* ssp. *eremica* Epling & A. L. Haines (1957); **incl.** *Yucca whipplei* ssp. *rigata* Afferni & Drovandi ex Afferni (2004).

Monocarpic and **Ros** solitary, or polycarpic and **Ros** caespitose and forming small to large, compact or open groups, sometimes rhizomatous, sometimes with secondary rosettes at the base or stem branching after flowering to form new rosettes; **L** 20–90 (–125)  $\times$  0.7–4 cm at the base; **Inf** 3–6 (–8) m, peduncle 0.9–3 (–4.5) m, 2.5–15 cm  $\varnothing$  near the base, floriferous part 2.5–2.8 m, 1 when rosettes are solitary, 1 to many per group when rosettes form colonies; **Fr** woody capsules, at maturity with conspicuous placental wings.

*Yucca californica* is here listed as synonym with considerable doubt and would have priority if it is indeed conspecific. Within *H. whipplei*, Trelease (1893) recognized 2 varieties, Haines (1941) and Munz & Keck (1959) each recognized 5 subspecies, and Webber (1953) recognized 4 varieties based on growth form. In contrast, McKelvey (1938) and McKelvey (1947) as well as McKinney & Hickman (1993) argued that growth form is highly variable and recognition of any infraspecific taxa in *H. whipplei* is unwarranted. Moreover, wild populations often contain plants of different “varieties” (Keeley & Tufenkian 1983), and seeds from one capsule may even produce all possible growth forms (DeMason 1984). Consequently, no infraspecific taxa are recognized here.

*H. peninsularis* from Baja California is sunk here following Govaerts (2014+, accessed Sept. 2018). The Californian and Mexican populations show a continuous distribution (Turner & al. 1995), the differences in leaf size given by Clary (2001) are contiguous, and material from Baja California (e.g. *Hodgson 9577* [DES, digital image!]) exhibits the conspicuous placental

wings present in the Californian plants but absent in *H. newberryi*.

Forms of *H. whipplei* from higher altitudes may be winterhardy in protected sites outdoors in C Europe and may reach flowering size in as little as 13 years (Bolliger 1998). The frost tolerance is given as about  $-15\text{ }^{\circ}\text{C}$  in C Europe (Boeuf 2007) and to about  $-12\text{ }^{\circ}\text{C}$  for the USA (Irish & Irish 2000). Wolf (1935) (cited from Hodgson (2001)) reports that rosettes need 6–7 years to reach flowering size.

## Yucca AGAVACEAE

J. Thiede

**Yucca** Linné (Spec. Pl. [ed. 1], 319, 1753). **Type:** *Yucca aloifolia* Linné [lectotype, designated by Britton & Shafer, North Amer. Trees, 151, 1908 (fide ING)].— **Agavoideae - Yuccaceae** —**Lit:** Trelease (1902: synopsis); McKelvey (1938: monograph SW USA); McKelvey (1947: monograph SW USA); Webber (1953: synopsis SW USA); Shreve & Wiggins (1964: synopsis Sonoran Desert); Reveal (1977: Intermountain flora USA); Matuda & Piña Luján (1980: ill. synopsis Mexico); Benson & Darrow (1981: ill. synopsis SW USA); Welsh & al. (1987: synopsis Utah); Hochstätter (2000: ill. synopsis USA dehiscent fruited taxa); Irish & Irish (2000: cultivated taxa USA); Hess & Robbins (2002: flora N America); Hochstätter (2002a: ill. synopsis USA indehiscent fruited taxa); Hochstätter (2004a: ill. synopsis Mexico); Smith (2004: ill. synopsis); Pellmyr & al. (2007: molecular AFLP phylogeny); Guillot Ortiz & Meer (2008: cultivated taxa Spain); Smith & al. (2008a: molecular phylogeny, evolution); Boeuf (2007a: ill. synopsis); Boeuf & al. (2009: ill. synopsis); Hawker (2016: ill. synopsis SW USA); Ondrovic & Ondrovic (2016: ill. synopsis USA). **Distr:** S Canada, N, C and S USA, Mexico, Guatemala; cultivated worldwide. **Etym:** Name first used 1557 in a German travelogue and probably derived from a name used on

Hispaniola through Span. ‘yuca’, which is, however, used for the edible root tubers of Cassava, and that was perhaps erroneously applied to *Yucca* because of the edible flowers of some species.

**Incl.** *Iuka* Adanson (1763) (*nom. inval.*, ICN Art. 61.1). **Type:** *Yucca aloifolia* Linné.

**Incl.** *Clistoyucca* (Engelmann) Trelease (1902). **Type:** *Yucca brevifolia* Engelmann [typification by inference; only element included].

**Incl.** *Samuela* Trelease (1902). **Type:** not designated.

**Incl.** *Sarcoyucca* (Trelease) Lindinger (1933). **Type:** not designated.

Woody perennials, terrestrial (very rarely epiphytic: *Y. lacandonica*); stems none, short, or thick and arborescent, then usually  $\pm$  branched; **Ros** terminal, always monocarpic, but rosettes/stems always branched and whole plant polycarpic; **L** mostly numerous,  $\pm$  ensiform, nearly linear, thin and flexible or thicker and very rigid, margins entire or minutely denticulate, horny, often desintegrating into fibres, terminal **Sp** often present; **Inf** large panicles or racemes; **Fl** pedicellate, usually  $\pm$  pendent,  $\pm$  campanulate to globose, conspicuous, somewhat fleshy;  **Tep** 3 + 3, all similar and subequal in size, mostly white or whitish (or greenish or slightly reddish),  **Tep** tube none, short or up to  $\pm \frac{3}{10}$  of the tepal length;  **St** 3 + 3;  **Fil** fleshy, clavate, or slightly swollen beneath the small versatile  **Anth**, pubescent or at least papillose;  **Ov** superior, 3-locular;

J. Thiede (✉)  
Hamburg, Germany  
e-mail: joachim\_thiede@gmx.de

**Sty** very short or none, with 3 short branches with a 2-lobed **Sti** each; **Fr** many-seeded loculicidal capsules with  $\pm$  intruding dorsal false septa, more rarely septicidal, or baccate and indehiscent; **Se** flat and usually thin, black.—**Cytology**:  $x = 30$ .

The genus includes  $\pm 50$  species. Most are more xerophytic than succulent and would therefore fall mostly outside the scope of this Handbook. However, many species of *Yucca* are horticulturally important or represent dominant elements of arid vegetations, and in order to provide a complete treatment of the family *Agavaceae* s.s., the genus is dealt with in full here.

*Yucca* is easily recognizable by the flat and thin leaves typical of many species, often with filiferous leaf margins which are otherwise only found in *Hesperaloe* and a couple of *Agave* species. The mostly whitish wax-like and somewhat fleshy pendent flowers in usually compact inflorescences are another diagnostic feature of the genus. The inflorescences are either racemose, or paniculate, then distally sometimes racemose; the part-inflorescences are always unbranched and mostly decrease in length distally. Inflorescences of hybrids between species with racemose or paniculate inflorescences may be paniculate below, and racemose above, as in *Y. ×karlsruhensis* (for the inflorescence morphology, see Boeuf & al. 2008b).

**Classification:** *Yucca* (including the superficially similar but usually monocarpic *Hesperoyucca*) was historically placed in *Liliaceae* due to its superior ovary. Since the 1950s, the close relationship with *Agave* and closely related genera with inferior ovaries is universally accepted.

*Yucca* is “one of the most difficult” genera of the N American flora (Reveal 1977) due to the complex nomenclature with many old names of uncertain application, the presence of mostly poorly documented horticultural names, and the pronounced variability of many taxa, including possible hybridisation and introgression.

Carrière (1859: 389–390) published the first classification of the genus, subdividing it into unranked, artificial groups according to characters of stems (caulescent vs. acaulescent) and leaf margins (filiferous vs. non-filiferous), and in part

based on leaf size and shape. Baker (1870: 828; revised in Baker (1880: 220–221)) subdivided *Yucca* into 3 unranked, artificial groups with entire, serrulate, or filiferous leaf margins, respectively. Engelmann (1871) subdivided *Yucca* into two unranked major taxa, *Euyucca* (= *Yucca*) and *Hesperoyucca* (the latter today regarded as independent genus, see there). *Euyucca* was subdivided into 3 unranked second-order taxa, named *Sarcocarpa*, *Clistocarpa* and *Chaenocarpa*. These 3 unranked subdivisions of *Euyucca* s.l. were also used by Engelmann (1873) (publication year in dispute, said to be 1878 by TL2, but stated as 1873 in the biographical sketch included in the collective reprint of Engelmann’s works by Trelease & Gray 1887), who changed the names to *Sarcoyucca*, *Clistoyucca*, and *Chaenoyucca*, respectively, thus laying the base for the disparate use of both sets of names indiscriminately up to today. Later, Engelmann (1874: 210, 212) introduced the formal rank of section, treating the taxa as Sect. *Sarcoyucca* (*nom. inval.*,  $\equiv$  Sect. *Yucca*), Sect. *Clistoyucca*, and Sect. *Chaenoyucca*.

Trelease (1902) split *Yucca* into the segregate genera *Hesperoyucca*, *Clistoyucca* (corresponding to Sect. *Clistoyucca*), and *Samuela* (corresponding to the later Ser. *Faxonianae*). While *Hesperoyucca* is widely accepted today as separate genus being part of a separate evolutionary clade within *Agavaceae* s.l., *Clistoyucca* and *Samuela* were returned to *Yucca* by McKelvey (1938). Within *Yucca* (excl. *Clistoyucca*), Trelease (1902: 44–46) recognized three sections (rank of section explicitly used l.c. p. 82): Engelmann’s Sect. *Chaenoyucca* and Sect. *Sarcoyucca*, and the new Sect. *Heteroyucca*, split off from the latter.

McKelvey (1938, 1947) further subdivided Engelmann’s large sections *Sarcoyucca* (as *Sarcocarpa*) and *Chaenoyucca* (as *Chaenocarpa*) into a number of series, whose names were unfortunately published invalidly for lack of a Latin diagnosis (ICN Art. 39.1). Hochstätter (2002b) and subsequent publications validated most of these series names and added further new names at both sectional and series rank, but some of these were likewise published invalidly.

The first molecular phylogenetic study of *Yucca* was performed by Clary & Simpson

(1995) and Clary (1997), who found none of the traditionally recognized series to be monophyletic, and even concluded that the distinction into berry- and capsular-fruited taxa is artificial. In contrast, the much more deeply sampled studies of Pellmyr & al. (2007), Smith & al. (2008a) and Heyduk & al. (2016) (wrongly treating Engelmann's first-order divisions at the rank of subgenera) largely supported the traditional subdivision in three sections. The infrageneric classification applied here is largely based on Pellmyr & al. (2007: fig. 1) and recognizes few series only; for variable species, morphologically as well as geographically distinct infraspecific taxa are treated at subspecific rank, when names are available.

- [1] Sect. *Yucca* (incl. *Yucca* [unranked] *Sarcocarpa* Engelmann 1871 = Sect. *Sarcocarpa* Engelmann 1873, *nom. inval.*, ICN Art. 22.1; incl. Sect. *Heteroyucca* Trelease 1902, *nom. inval.*, ICN Art. 22.1; incl. Sect. *Endlichiana* Hochstätter 2008): **R** fibrous; adult plants usually stem-forming, rarely rhizomatous (*Y. endlichiana*); **L** of young plants (<6 years) few, broadened and generally reddish; **Fr** pendent, indehiscent, baccate, fleshy and edible, or pendent and soon drying; **Se** rough, unwinged.

Ser. *Arkansanae* McKelvey ex Hochstätter 2016, *nom. inval.* ICN Art. 10.1 & 29.1 Ex. 2).

**Evolution:** Radiation in *Yucca* started in the period 18–12 mybp (Good-Avila & al. 2006; Rocha & al. 2006), and Smith & al. (2008a) found a high diversification rate of 0.33 species/mybp (in contrast to 0.15–0.2 species/mybp in the analysis of Rocha & al. 2006). The crown group age of *Yucca* (excluding *Y. queretaroensis*) is estimated at ±6 mybp. This is younger than previous estimates such as “eocene” by Pellmyr & Leebens-Mack (1999). The oldest known fossil record of *Yucca*, the arborescent *Protoyucca sadishii* from NW Nevada, dates to 14 mybp (middle miocene) (Tidwell & Parker 1990). It should be noted that the fossil *Yuccites* Martius from the Carboniferous, superficially similar to extant *Yucca*, is regarded as belonging to the

*Lycophyta*, and *Yuccites* Schimper & Mougeot (*nom. illeg.*, ICN Art. 53.1, = *Pelourdea* Seward) refers to fossil gymnospermous leaves from the Triassic (Doweld 2013).

Interestingly, *Yucca* diversification is much younger than the diversification of its pollinators, whose origin falls into a period of roughly 40–32 mybp (Smith & al. 2008a). The extremely specialist pollination syndrome has thus not led to increased speciation, i.e. the radiation of *Yucca* is not the result of the obligate mutualistic pollination system (Smith & al. 2008a). The origin of the *Yucca*/moth system is dated at  $40 \pm 11$  mybp by Pellmyr & Leebens-Mack (1999) or to 13 mybp by Smith & al. (2008a: 2680). The likely age difference of moth and *Yucca* origins and diversifications is enigmatic. Substantial host switching must have occurred in the moths, and no congruence between plant and moth evolution has been found in the case of *Y. brevifolia* (incl. *Y. jaegeriana*) and its two pollinator species (Smith & al. 2008a, contradicting Pellmyr & Segraves (2003) and Godsoe & al. (2008)). In contrast to these interpretations, Cole & al. (2017) found “a functional basis for coevolution” between the two pollinator species and *Y. brevifolia* (incl. *Y. jaegeriana*).

The *Yucca*—moth pollination syndrome evolved twice independently, once in *Hesperoyucca*, and once in *Yucca*, well after the separation of these two lineages at 27 mybp. Pollinating yucca moths have a single origin within the *Prodoxidae* (bogus yucca moths, see below) (McKain & al. 2016). The evolution of pollinating yucca moths from bogus yucca moths only necessitated minimal trait evolution (Yoder & al. 2010) since oviposition in carpels and fruit feeding larvae pre-existed in the ancestors and only the behavioural component of actively collecting and depositing pollen had to evolve, linked to modifications in the tentacular apparatus to make pollen collection possible. Pollinating moths thus evolved from a pre-existing parasitic insect—plant interaction.

A major diversification of the moths occurred at  $3.2 \pm 1.8$  mybp, coincident with the development of arid habitats. Cheating yucca moths (see below, pollination ecology) evolved twice independently as part of this radiation (Segraves &

al. 2005). Plant and moth speciation shows significant phylogenetic congruence but is likely due to shared biogeography rather than co-evolution (Althoff & al. 2012) or cospeciation (Pellmyr & Leebens-Mack 1999, Smith & al. 2008b).

**Succulence:** Most species of *Yucca* have tough, rigid, very fibrous leaves, and well-developed voluminous water storage tissue is probably restricted to *Y. endlichiana*. Nonetheless, Walter (1931: 9, 153) treated *Y. elata* as a succulent. Thickened rhizomes are present in many species, and some (e.g. *Y. guatemalensis*) have a well-developed pachycaulous trunk, whose architecture is similar to that found in the stems of *Beaucarnea* (Fisher 1975, Stevenson 1980, Carlquist 2012: 113). A thickening meristem develops in the outer cortex and produces un lignified parenchymatous conjunctive tissue with abundant vascular strands.

**Physiology:** *Yucca* is heterogenous with respect to the photosynthetic pathways employed: Heyduk & al. (2016) found the species of Sect. *Clistoyucca* and *Chaenoyucca* to be C3, and those of Sect. *Yucca* (as “subgen. *Sarcocarpa*”, etc.) to be CAM. Some species use both CAM and C3, e.g. *Y. baccata*, which is a constitutive CAM species, but with considerable C3 photosynthesis during the day (Szarek & Troughton 1976, Kemp & Gardetto 1982).

Similar as in *Agave*, roots near the stem play an important role in the rapid uptake of water after the dry season (North & Baker 2007), likely based on the fact that the internal anatomy continues to appear more reminiscent of young roots with living cortical cells, despite the suberisation of the external root tissues (North & Baker 2007). Rapid water uptake occurs close to the stem and in the distal parts of the root system, while the mid-root sections rapidly lose water uptake abilities (North & al. 2004).

Eighty-five percent of the examined species had contractile roots close to the stem (North & Baker 2007, North & al. 2008). Contraction is achieved by radial expansion and longitudinal shortening of the cells of the inner and/or middle cortex, accompanied by a lack of suberisation

(North & al. 2008). Root contraction occurs already in young seedlings, which are pulled into the soil at an average of 34.7 mm/year in the 6 species studied (North & al. 2008).

**Flowering and fruiting ecology:** Flowering and fruit production is correlated with favourably wet winter/spring periods (Campbell & Keller 1932, Smith & Ludwig 1976): In good years (“mast years”), 67–83% of all plants in *Y. elata* populations produced fruit, but only 0–8% in a dry year. In populations of *Y. brevifolia*, 66% of the inflorescences developed fruit in a high-reproduction year, and 53% of the fruits were infested with yucca moth larvae, with 19.5% of the seeds consumed. In a low-reproduction year, the majority of the fruits were infested, and  $\pm 40\%$  of the seeds were consumed (Borchert & DeFalco 2016). For *Y. baccata*, Wallen & Ludwig (1978) found flowering to occur at intervals of three years—based on a simulation model, they propose that after flowering, several years of vegetative growth would be necessary to replenish the carbohydrate reserves.

Over-exploitation of fruits by the pollinator’s larvae is counter-balanced by selective fruit-abscission of multiply infested ovaries/developing fruits (Humphries & Addicott 2000). Overall, 80–90% of all flowers of a *Yucca* inflorescence abscise (Segraves 2008). The fate of a pollinated and oviposited flower is influenced by the size of the pollen load (i.e. pollination quality), the number of deposited eggs, the number of pollinated flowers in the inflorescence, as well as by the position of the flower within the inflorescence (Humphries & Addicott 2000, Snell & Addicott 2008a). Althoff (2014) found that the ability of *Yucca* plants to selectively abscise flowers that contain pollinator eggs probably influences ovipositor length of the pollinating moths; it appears that laying the eggs more superficially near the surface of the ovary wall or style base minimizes plant reaction.

Selective abortion of fruits with multiple yucca moth eggs were observed by Pellmyr & Huth (1994). Possibly, the depth of oviposition is critical, and abortion is probably triggered when ovules are damaged by oviposition, in comparison

with more superficial oviposition not touching the ovules (Marr & Pellmyr 2003, Segraves 2008). Abscission strategies are probably variable from species to species; *Y. baccata* retains relatively more multiply infested fruits than other species such as *Y. glauca* (Addicott & Bao 1999).

The puncturing of the ovary with the ovipositor during pollination by the yucca moths locally inhibits the development of the ovary wall and ovules, thus giving rise to specific types of fruit deformations in the developing fruits (Davis 1967): Fruits with a  $\pm$  pronounced curvature result from single punctures towards the middle part of the pistil in a single locule (e.g., *Y.  $\times$ schottii*), whereas fruits with a  $\pm$  pronounced median constriction result from several ovipositor punctures towards the middle part of the pistil in each of the locules (e.g., *Y. filifera*). In species such as *Y. brevifolia*, where oviposition does not occur in the ovary but in the style, the ovary and ovules are not affected and the fruits do not show deformations (Davis 1967: 33–34). The fruit curvature or constriction thus results from the oviposition injury and is independent from larval development (Davis 1967: 33). In *Y. filifera*, besides the common fruits with median curvature, fruits with a distal constriction are also found. These result from pollination by *Tegeticula yuccasella* females with a different genital morphology (Villavicencio & Pérez-Escandón 1995).

**Pollination ecology:** There is a closely knit symbiosis between *Yucca* species and its pollinators, the yucca moths. Indeed, the *Yucca*-moth system is a well-known text-book example of an obligate mutualism between the plant and its pollinators (called “obligate nursery pollination mutualism” by Svensson & al. (2011) and specialized “brood pollination mutualism” by Althoff (2016)). The specialized pollination system was first mentioned by Riley (1872) and described in more detail by Riley (1873). Additional observations were communicated subsequently by Riley (1874, 1878, 1880, 1881, 1892). Little additional investigations of the relationships were made for the almost 70 years that follow, but esp. in the past 20 years, interest has been revived, and numerous studies on various aspects of the mutualism were

published in recent years. Detailed information on the history of knowledge of the mutualism are found in Powell & Mackie (1966) and Davis (1967).

According to the accumulated knowledge, the *Yucca*—yucca moth pollination mutualism emerges as a delicate balance between the number of developing seeds in one season and a sufficient number of larvae completing their development in order to assure pollination in the next season. A total of 25 species of yucca moths from the 2 genera *Tegeticula* (20 species; incl. *Pronuba*) and *Parategeticula* (5 species) are known today (Pellmyr & al. 2008). They evolved from bogus yucca moths (*Prodoxus*, 22 species) (Althoff 2014) that feed on plant tissue other than flowers (Pellmyr 2003, Althoff 2008). *Parategeticula* females lay eggs into pits of the inflorescences or flower pedicels, and the larvae after emergence crawl into the flower and bore into the ovary (Pellmyr & al. 2008). Females of *Tegeticula* lay eggs directly on or into the ovary. Females of the pollinator moths actively collect pollen from one or more anthers of a flower before ovipositing an egg into one of the locules of the ovary. The pollen package collected is subsequently actively deposited on the stigma of the next flower visited. Attraction of the moths to the flowers is likely via floral scent, but scent is at least for some species groups not species-specific (Svensson & al. 2005, 2006, 2011, for *Y. elata*, *Y. filamentosa* and *Y. glauca*). In *Y. reverchonii*, some of the hydrocarbons in the floral scent were shown to be perceived by the antennae of *Tegeticula cassandra* (pollinator) and *Prodoxus decipiens* (herbivore) (Tröger & al. 2019). Both sexes are equally attracted by floral scents and use the flowers as resting sites during the day, and mating usually occurs in the flowers as well at night (Snell & Addicott 2008a, Svensson & al. 2011, for *Y. glauca* and the pollinator *Tegeticula yuccasella*). Scent quality of the flowers does not appear to change after successful pollination, so that multiple visits and ovipositions are possible (Svensson & al. 2011). When larval development is completed, the larvae burrow out of the fruit and pupate and overwinter in the ground (Pellmyr 2003).

There is no 1:1 relationship between *Yucca* species and species of pollinating moths; rather, most pollinator species are shared among several *Yucca* species. The most polyphagous pollinator is *Tegeticula yuccasella*, ovipositing on 5 different *Yucca* species across its geographical range (Althoff 2016). On the other hand, more than one moth species serves the same *Yucca* species, e.g. “*Y. schottii*”, whose inflorescences are visited by 2 pollinating moth species (with radically different behaviours and different ovipositions) as well as 2 bogus moths (Powell 1984). Pellmyr (2012) found evidence for selection of female yucca moths to gather and deposit abundant pollen to assure high pollination quality (an average of 3600 pollen grains are deposited per flower of *Y. filamentosa* with 150–200 ovules per ovary). A climatic niche modelling approach for 2 co-occurring species of *Tegeticula* moths both pollinating *Y. filamentosa* suggests that moth geographic distribution is heavily influenced by climate, but the competition among pollinating congeners restricts the populations of co-occurring moth species (Darwell & Althoff 2017).

Pollinator abundance is usually greatest before peak flowering, although year-to-year variations are large (Althoff & al. 2013). At any one locality, pollinator moths are very host specific, but it remains largely unknown whether this is caused by pollination ability, or larval feeding preferences (Althoff 2016). There are some indications that even in widespread pollinating moths such as *T. yuccasella*, local preferences for the locally native *Yucca* species have developed, and larval development is reduced in non-target *Yucca* species pollinated by the same pollinator species (Althoff 2016). Changes in moth morphology and emergence times have been described in association with shifts from native *Y. filamentosa* to introduced *Y. aloifolia* (Groman & Pellmyr 2000).

The close mutualistic moth—plant interaction is not an evolutionary dead-end for *Yucca* pollination. Rentsch & Leebens-Mack (2014) describe that European honey bees “were passively but effectively pollinating” *Y. aloifolia* flowers resulting in good fruit set when nocturnal moth pollinators were excluded.

A component largely overlooked in early studies are antagonists and commensalists participating in the plant—pollinator network (Althoff 2016): Parasitoid wasps feeding on *Yucca* moth larvae are at the same time indirect mutualists of the *Yucca* plants by reducing the number of consumed seeds (Crabb & Pellmyr 2006). In addition, moth egg mortality is increased by the presence of Tenebrionid beetles: The beetles, often present in large numbers but not influencing pollinator visitation behaviour, mate and feed within *Yucca* flowers and consume esp. stylar tissue, where most oviposition events by the pollinator occur (Segraves 2008).

Two species of *Tegeticula*, *T. intermedia* and *T. corruptrix*, have evolved independently into “cheaters” (Tyre & Addicott 1993, Addicott & Tyre 1995, Althoff 2014): Females oviposit without first collecting and/or depositing pollen and place their eggs into developing fruits, i.e. after fruit crop regulation by selective abscission is complete. Successful development of their larvae is dependent on successful pollination of the flowers by pollinating moths. No negative effects of the cheating moths on the mutualism were discovered (Pellmyr & Leebens-Mack 1999).

Cheating not only occurs on the side of the pollinators, but apparently also on the *Yucca* side of the mutualism: Bao & Addicott (1998) found that *Y. baccata* has two fruit types, which appear to be specific for an individual:  $\pm 70\%$  of all individuals produce narrow fruits that taper towards the style, while the remaining plants produce shorter and more globose fruits. Oviposition occurs at the transition of the style and the ovary, and the tapered fruits have no viable ovules near that zone, causing frequent premature death of the moth larvae. In the short rounded fruits, larval mortality is much lower, and a higher proportion of the seeds are consumed. The individuals with tapered fruits are regarded to be obligate cheaters by Bao & Addicott (1998). These authors also suggest that cheating could be present in other *Yucca* species that produce apically tapered fruits.

Bogus yucca moths (*Prodoxus*) were first so named by Riley (1880). The females oviposit during the flowering period of the hosts into

(depending on the species) the inflorescence axis, fruit wall, or leaves, and their larvae feed on non-flower tissues. It appears that they do not directly reduce plant fitness or were weakly antagonistic (“parasitic”) only (Althoff & al. 2004). *Yucca* does not appear to have a defence mechanism to control *Prodoxus* activity (Snell & Addicott 2008b). *Prodoxus* larvae diapause for up to 30 years (Powell 2001) and are parasitized by the wasp *Eusandalum* sp. (Althoff 2008).

Ants and aphids are further components of the *Yucca* interaction network. Ant presence reduces the number of oviposition events of the cheating yucca moth *Tegeticula corruptrix*. Aphid presence reduces herbivory/florivory by ants since ants prefer aphid honey dew (Perry & al. 2004, Snell & Addicott 2008a).

**Seed dispersal and establishment:** For the dehiscent-fruited *Yucca* species, wind dispersal of the light-weight seeds ( $\pm 15$  mg) seems to be the primary mechanism (Waitman & al. 2012 and references there cited). For the indehiscent fruited taxa, wind speeds are insufficient to detach the fruits and move them over the ground. For these species, dispersal by scatter-hoarding rodents is postulated (Waitman & al. 2012: 7).

Scatter-hoarding rodents appear to play a major role as dispersers. Animals were observed to harvest fruits directly from the canopy of *Y. brevifolia*, with subsequent seed caching (Waitman & al. 2012). Borchert & DeFalco (2016) found that 33% of the fruit crop of *Y. brevifolia* falls to the ground and was removed within 4 months by rodents. Rodents also exploited the fruits that remained in the canopy. Fruit exploitation is more rapid when the fruit crop is small (Borchert & DeFalco 2016). Animals involved in dispersal are the White-tailed antelope squirrel, Pinyon mouse, Merriam’s kangaroo rat, and many more sporadically occurring species (Borchert & DeFalco 2016).

Seed longevity remains poorly studied. Seeds of *Y. filifera* were still germinating after 3–4 years of storage at 5 °C (Morales-Rangel & al. 2015). Cambrón-Sandoval & al. (2013) found that seeds of *Y. filifera* still germinated for  $\pm 60\%$  after

4 years of storage, but were no longer viable after 14 years. In *Y. brevifolia*, germination decreases from 50–68% after 12 months to <3% after 40 months in the ground, and no soil seed bank is present (Reynolds & al. 2012).

Successful establishment of *Yucca* species from seeds is probably an infrequent event. For *Y. brevifolia*, establishment only occurs in above-average wet years (Brittingham & Walker 2000). Survivorship of a cohort due to a rare establishment event during 1983/1984, based on above-average summer rainfall, in a Nevada population was 19% after 22 years—most seedlings succumbed to herbivory by jackrabbits in the first 2 years. Average yearly growth over the 22-year period was  $3.12 \pm 1.96$  cm (Esque & al. 2015).

**Ethnobotany:** According to Hodgson (2001: 44–51) species of *Yucca* were significant sources of food and fibre for the indigenous people of the Sonoran Desert. Flowering stalks and flowers (usually boiled and consumed as vegetables) of most species were “valuable additions” to the diet of these people, esp. when plants were locally abundant. The fruits of the berry-fruited species were also consumed (fresh, cooked or roasted and then dried, and rehydrated, with the seeds removed) and are described as being pleasantly sweet and nutritive, although with cathartic effects when eaten in large numbers (Hodgson 2001: 45). A general overview of known uses of species of *Yucca* is found in Mitich (1977). The historical importance of *Yucca* fibres is documented by artefacts 2000 years old (Webber 1953). The same author also describes that plants were used as emergency fodder for cattle during the drought of 1916–1919 in the USA. Matuda & Piña Luján (1980) describe *Yucca* usage in Mexico and esp. stress the historical importance for fibres. Fibre extraction from the leaves of *Y. carnerosana* was an important business in Zacatecas and San Luis Potosí in the early 1960s, amounting to as much as 6000 tons/year. In addition, the trunks or stems of several species were used for wall construction in rural housing. *Yucca* species were also sometimes used as living fence in Mexico (Matuda & Piña Luján 1980: 8, ill.) as well as in India (Howes 1946).

Apart from its use for food and fibres, *Yucca* spp., esp. *Y. schidigera*, are important sources of saponins with many actual and potential applications in human and animal nutrition such as antibacterial activities (review by Cheeke 2000). *Yuccas* also have manifold therapeutic attributes with antioxidant, anti-inflammation, anti-arthritis, anticancer, antidiabetic, antimicrobial, and hypocholesterolaemic properties (review by Patel 2012). Tissue culture methods for large-scale propagations of useful *Yucca* species are reviewed by López-Ramírez & al. (2018).

**Horticulture:** Many *Yucca* species are popular in horticulture, esp. for landscaping, and are known by the vernacular name “Palm Lily”. Several species have become naturalized in different parts of the world (see Guillot Ortiz & Meer (2003) for a preliminary list of species for Spain, and Walters & al. (2011) for South Africa). House plants sold as “*Yuccas*” by the horticultural trade are usually species of the genus *Cordylina* (*Laxmanniaceae*).

In cultivation, variegated cultivars of several taxa are widespread and popular, and Boeuf & al. (2008a, 2010) and Boeuf & Heim (2014) discuss the known examples. Webber (1953: 66) found that some species are self-fertile, while other are self-sterile. The same author also reports on hybridisation trials.

*Yucca* hybridisation started with Jean-Baptiste A. Deleuil at Marseille (France) who obtained seeds from 13 hybrids (Deleuil 1880); some of these and further hybrids of Deleuil were published as the earliest *Yucca* nothospecies by André (1883) (listed here among the names of unresolved application). Leopold Graebener started hybridising at BG Karlsruhe (Germany) at  $\pm 1880$  and raised the still extant *Y. \times karlsruhensis* in 1899, later followed by further hybrids, which stimulated others to start with *Yucca* hybridisations (Weissbeck 2012b). Carl Sprenger (see Sprenger 1920a, b) at Korfu (Greece) raised and named no less than 122 *Yucca* hybrids in the period 1897–1907 (Jensen 2018), many of them published under nothospecies names (not further covered here). Further *Yucca* cultivars were

brought into the trade starting in 1958 by Karl Foerster at Potsdam-Bornim (Germany), largely restricted to selections (and not hybrids) of the *Y. filamentosa/flaccida*-complex still widespread in Germany, but leading to difficulties separating both species from each other and from *Y. gloriosa* (Boeuf 2018). Recent hybridisations are carried out by a few amateur collectors (e.g., *Y. 'Anna'*, Jensen 2015).

Hochstätter (2000) indicates the following species to be hardy outdoors in C Europe: *Y. arkansana*, *Y. angustissima*, *Y. baccata*, *Y. baileyi*, *Y. elata*, *Y. filamentosa*, *Y. glauca*, *Y. gloriosa*, *Y. harrimaniae*, *Y. pallida* and *Y. recurvifolia*. The following species need additional protection from moisture: *Y. faxoniana*, *Y. rupicola*, *Y. rostrata* and *Y. thompsoniana* (Hochstätter 2000).

The following names are of unresolved application but are referred to this genus: *Yucca ×andreaana* Deleuil ex André (1883); *Yucca antwerpensis* hort. ex Baker (1880); *Yucca atkinsii* Trelease (1894) (*nom. illeg.*, ICN Art. 53.1); *Yucca barrancasecca* hort. ex Pasquale (1867); *Yucca ×brasiliensis* Sprenger pro sp. (1903); *Yucca ×carrierei* Deleuil ex André (1883); *Yucca conspicua* hort. ex Regel (1871) (*nom. illeg.*, ICN Art. 53.1); *Yucca crinifera* Lemaire (1846); *Yucca ehrenbergii* Baker (1875); *Yucca ×ensifera* Deleuil ex André (1883); *Yucca ensifolia* Baker (1870) (*nom. illeg.*, ICN Art. 53.1); *Yucca fuauxiana* hort. (s.a.); *Yucca gloriosa* fa. *planifolia* Engelm (1873); *Yucca gracilis* Link ex Sweet (1830); *Yucca horrida* Humboldt ex Steudel (1840); *Yucca howard-smithii* Trelease (1937); *Yucca ×juncea* Deleuil ex André (1883); *Yucca ×massiliensis* Deleuil ex André (1883); *Yucca mexicana* Sessé & Moçino (1894) (*nom. illeg.*, ICN Art. 53.1); *Yucca quinnarjenii* Hochstätter (2016) (*nom. inval.*, ICN Art. 29.1, Ex. 2); *Yucca ×rigida* Deleuil ex André (1883); *Yucca rubra* hort. ex Lavallée (1877); *Yucca ×striatula* Deleuil ex André (1883); *Yucca ×sulcata* Deleuil ex André (1883); *Yucca toneliana* Lemaire (1865) (*nom. illeg.*, ICN Art. 53.1); *Yucca ×treleasei* Sprenger (1901); *Yucca ×vomerenis* Sprenger (1901).

**Y. aloifolia** Linné (Spec. Pl. [ed. 1], 1: 319, 1753). **Type:** [lecto—icono]: Dillenius, Hort. Eltham. 2: 435, t. 323: fig. 416, 1732.—**Lit:** Trelease (1902: 88–94, tt. 49–50); Matuda & Piña Luján (1980: 107–109, with ills.); Lott & García-Mendoza (1994: online version with ills.); Hess & Robbins (2002); Diggs & al. (2006: 415, ills. p. 417). **Distr:** USA (Virginia, North Carolina, South Carolina, Georgia, Alabama, Florida, Mississippi, Louisiana, Texas), sand dunes or shell mounds near the coast; Mexico (esp. Veracruz and Yucatán), plains and slopes in tropical deciduous forests, to 1800 m; flowers March to August; neophyte in many (sub-) tropical regions (e.g. RSA, Spain). **I:** Curtis's Bot. Mag. 41: t. 1700 (1814–1815); Piña Luján (1980: 280); Hochstätter (2002a: 103–104); Boeuf (2007a: 52–53); Boeuf & al. (2009: 18–19).

[Lc] Arborescent, forming colonies, stems to 8 m, slender, erect or somewhat declining, simple or sparsely branched, sometimes with offsets; **L** rigid, erect, thick, flattened or slightly canaliculate, 12–40 (–60)  $\times$  2.5–6 cm, brilliant light to dark green, tip acute (pungent), margins rather horny, sharply denticulate or entire, rarely filiferous with straight fibres; **Inf** erect, paniculate, peduncle to 30 cm, flowering part 45–61 cm, somewhat conical, lower  $\frac{1}{4}$ – $\frac{1}{2}$  within the the rosette leaves, glabrous or slightly pubescent; **Ped** stout, 25–50 mm; **Fl** pendent, globose, to 70 mm; **Tep** spreading, lanceolate, connate basally for <1 mm, 30–40  $\times$  12–22 mm, whitish with purple or green tinge towards the base; **Fil**  $\pm$  20 mm, slightly papillose; **Ov** oblong, basally constricted, 20–50 mm; **Sty** 5 mm; **Sti** distinct; **Fr** fleshy berries, indehiscent, pendent, ellipsoid, prismatic, 35–50  $\times$  20–26 mm, blackish, pulpa fleshy, purple; **Se** ovoid, thick, 5–6  $\times$  6–7 mm, dull black.—**Cytology**:  $n = 30$  (Watkins 1936),  $2n = 60$  (Sató 1935).

Introduced as garden plant to Europe no later than 1596 and described from European gardens, the plant is seen as having no known geographical origin (Pellmyr 2003: 46). The above-cited lectotype was designated by Wijnands (1983: 140). It

is aberrant in *Yucca* in being self-compatible and erratically forming fruits in the absence of any specific pollinator in the USA and in cultivation in many regions (Pellmyr 2003). In the USA, it is effectively pollinated by European honeybees contributing significantly to its fruit set (Rentsch & Leebens-Mack 2014). The species exhibits further domestication features such as elevated vegetative propagation, core loss in the fruit, and poorly synchronized flowering (Pellmyr 2003). These findings led Pellmyr (2003) to suggest that *Y. aloifolia* could represent an escaped, naturalized cultivar, possibly derived from *Y. guatemalensis* (as *Y. elephantipes*), which might also explain its disjunct distribution. Herbarium specimens from Mexico at MEXU were cultivated specimens or *Y. guatemalensis* (as *Y. elephantipes*) (Pellmyr 2003).

Molecular studies show a close relationship with *Y. gloriosa* (Clary 1997, cited by Hess & Robbins 2002) or with *Y. filifera* and *Y. periculosa* (weak support; *Y. guatemalensis* (as *Y. elephantipes*) groups more distantly, *Y. gloriosa* not sampled; Smith & al. 2008a). For the macrosporogenesis and embryo sac development, see Wolf (1940).

Vegetatively often confused with *Y. gloriosa* or *Y. guatemalensis*, but clearly recognizable by its light to dark green, slightly canaliculate, finely denticulate and more rigid leaves with very sharp tip (Boeuf 2007b: 52). Widely cultivated as foliage plant in (sub-) tropical gardens as well as indoors, esp. in the form of variegated cultivars (Guillot Ortiz & Meer 2008: 23–24, 98, Boeuf & al. 2009: 120–121, 2010: 50–53, Boeuf & Heim 2014: 18–19). Hardy down to  $-15$  °C (Boeuf 2007a: 53) or  $-18$  °C (Irish & Irish 2000: 235). For the in-vitro propagation, see Karpov (2004). Widely naturalized in the Mediterranean and other climatically suitable regions (Spain: Asensi & al. (2016); RSA: Smith & al. (2012); Caribbean: Proctor & Acevedo-Rodríguez (2005: 124); further listings: Hurrell & Delucchi (2009: 18)).

**Y. angustissima** Engelm ex Trelease (Annual Rep. Missouri Bot. Gard. 13: 58–59, t. 23: fig. 1, t. 24: fig. 1, t. 83: fig. 6, 1902). **Type** [lecto]: USA, Arizona (*Bigelow* s.n. [MO 148375]).—**Lit**: Reveal (1977: 533–536, with ill.); Hess &

Robbins (2002); Hawker (2016: 298–310, with ills.). **Distr:** USA (S Utah, N Arizona, NW New Mexico).

The protologue cites specimens of Bigelow, Toumey, Trelease, Palmer, and Jones (= syntypes). The designation of *Bigelow* s.n. in 1854 (MO 148375!) as “type” by Webber (1953: 52) represents a lectotypification. Molecular data (1–2 samples; Pellmyr & al. 2007, Smith & al. 2008a) place the species close to *Y. baileyi* and *Y. utahensis* (as *Y. elata utahensis*).

*Y. quinnarjenii* Hochstätter, invalidly published (ICN Art. 29.1 & Ex. 2), and with a lamentably incomplete protologue, might represent an aberrant population or hybrid of this species or of *Y. baileyi*.

**Y. angustissima** ssp. **angustissima** — **Lit:** Reveal (1977: 533–536, with ills., as var.); Welsh & al. (1987: 649, as *Y. angustissima*); Hess & Robbins (2002: as var.); Hawker (2016: 298–301, with ills., as var.). **Distr:** USA (SE Utah, N Arizona, NW New Mexico); desert flats or mesas, sandy places, sandstone outcrops or rocky hillsides, 900–2200 m; flowers May to June. **I:** Hochstätter (2000: 94–95, as *Y. angustissima*); Boeuf & al. (2009: 20).

[3b] Stems none to short and procumbent, 10–40 cm; **Ros** compact, solitary or in small to large colonies; **L** rigidly spreading, mostly flexible, narrow, long-tapering, primarily flat or distally canaliculate, smooth on both faces, 25–45 × 0.5–0.8 cm, pale blue-green to yellowish-green, margins entire, becoming filiferous with few fine slightly curled fibres, white, becoming brownish, grey or green, **terminal Sp** 3–7 mm; **Inf** erect, racemose, peduncle 0.3–0.5 m, flowering part 0.8–1 m, well above the rosette leaves, with few part-**Inf**, glabrous, or finely pubescent; **Ped** slender, 10–25 (–40) mm; **Fl** pendent, campanulate to globose, 45–55 mm; **OTep** elliptic to ovate, pale green, often tinged rose or rosy purple; **ITep** broader than the **OTep**, lanceolate, white to cream or greenish-white, often tinged with rose or rose-purple; **Tep** basally connate to form a tube 3–7 mm long; **Fil** 7–25 mm, glabrous; **Ov** ± 15 mm; **Sty** 10–13 mm; **Sti** lobed; **Fr** dry capsules, often with a deep constriction near the middle,

oblong-cylindrical, 35–50 (–57) × 20–30 mm; **Se** thin, 5–7 mm, dull black.—**Cytology:** 2n = 60 (McKelvey & Sax 1933).

The treatment of *Y. angustissima* follows Reveal (1977) and Hess & Robbins (2002) who considered four varieties (here treated as subspecies) that are well isolated geographically but overlap morphologically with one another. Reveal’s treatment is supported by molecular data (Clary 1997, cited from Hess & Robbins 2002) in which *Y. angustissima*, *Y. kanabensis* and *Y. toftiae* form distinct clades. However, significant intergradation among these taxa is present (Welsh & al. 1987). See also the note under ssp. *avia*. Webber (1953) regarded the variation in *Y. angustissima* as resulting from hybridisation with *Y. glauca*, *Y. baileyi*, or *Y. elata*, but no evidence for hybridisation was seen by Reveal (1977: 536).

**Y. angustissima** ssp. **avia** (Reveal) Hochstätter (Cactaceae Rev. 1(2): 21, 1999). **Type:** USA, Utah (*Jones* 5639a [US]).—**Lit:** Welsh & al. (1987: 649); Hess & Robbins (2002); Hawker (2016: 301–303, 305, with ills.); all as var. **Distr:** USA (S-C Utah); moist mountain hillsides, on loamy-rocky soils, 2100–2700 m; flowers May to July. **I:** Hochstätter (2000: 98–99); Boeuf & al. (2009: 21).

≡ *Yucca angustissima* var. *avia* Reveal (1977).

[3b] Differs from ssp. *angustissima*: Stems none or to 2 m and erect; **L** lanceolate, longer, 40–60 cm; **Inf** flowering part longer, 0.8–1.8 m; **Fl** shorter, 35–45 (–52) mm; **Sty** shorter, 7–10 mm.

This and ssp. *angustissima* share deeply constricted smaller capsules and smaller inflorescences, while ssp. *kanabensis* and ssp. *toftiae* have larger, moderately constricted capsules and larger inflorescences (Hess & Robbins 2002: as vars.). Welsh & al. (1987) consider this taxon as a N variant from high elevations at the end of a continuous cline within the species.

**Y. angustissima** ssp. **kanabensis** (McKelvey) Hochstätter (Cactaceae Rev. 1(2): 21, 1999). **Type:** USA, Utah (*McKelvey* 4347A [A]).—**Lit:** Welsh & al. (1987: 650, as *Y. kanabensis*); Hess &

Robbins (2002: as var.); Hawker (2016: 303–307, with *ills.*, as var.). **Distr:** USA (SW Utah, N Arizona); sandy places in juniper-pinyon or pine-oak woodlands, desert canyon hillsides, 1400–1900 m; flowers May to June. **I:** Hochstätter (2000: 97); Boeuf & al. (2009: 20).

≡ *Yucca kanabensis* McKelvey (1947) ≡ *Yucca angustissima* var. *kanabensis* (McKelvey) Reveal (1977).

[3b] Differs from var. *angustissima*: Forming small to extremely large colonies; **L** plano-convex or flat and keeled, stiff but somewhat flexible, slightly roughened on the lower face, longer, 45–80 (–150) × 1.2–2 cm; **Inf** peduncle longer, 1–1.5 m, flowering part longer, 1–2 m; **Fl** longer, 55–65 mm; **Tep** elliptic to orbiculate, often tinged pink or brown; **Fil** longer, 25–28 mm; **Ov** longer, 25–27 mm; **Sty** shorter, 5–8 mm; **Fr** moderately constricted, larger, 65–75 mm.

Differs from ssp. *toftiae* in longer flowers, mostly longer leaves, longer ovaries and a mostly lower height at flowering time (Hess & Robbins 2002). See ssp. *avia* for differences from that and ssp. *angustissima*. Most, but not all of the molecular trees in Pellmyr & al. (2007) and Smith & al. (2008a) place this taxon separate from ssp. *angustissima*.

The study by Humphries & Addicott (2000) showed that the taxon is able to regulate the flower pollination mutualism with yucca moths by selectively abscising flowers with low pollen load or without oviposition.

**Y. angustissima** ssp. *toftiae* (S. L. Welsh) Hochstätter (Cactaceae Rev. 1(2): 21, 1999). **Type:** USA, Utah (*Welsh* 11935a [BRY, NY, US]).—**Lit:** Welsh (1975: with *ills.*, as *Y. toftiae*); Welsh & al. (1987: 650, as *Y. toftiae*); Hess & Robbins (2002: as var.); Hawker (2016: 306–310, with *ills.*, as var.). **Distr:** USA (SE Utah); sandy alluvium and sandstone outcrops and mesas, 2000 m; flowers May to June. **I:** Hochstätter (2000: 96).

≡ *Yucca toftiae* S. L. Welsh (1975) ≡ *Yucca angustissima* var. *toftiae* (S. L. Welsh) Reveal (1977).

[3b] Differs from ssp. *angustissima*: Stems none or erect, to 1 m; **L** linear, rigid, longer, 25–75 × 0.4–1.7 cm; **Inf** mostly racemose,

sometimes paniculate proximally, peduncle longer, 1.2–2.5 m, flowering part longer, 0.4–2 m; **Fl** mostly smaller, 30–52 mm; **Tep** creamy-white; **Ov** mostly longer, 12–22 mm; **Sty** shorter, 3–10 mm; **Fr** moderately constricted, mostly larger, 45–60 mm.

See notes for ssp. *angustissima* and ssp. *kanabensis*.

**Y. arkansana** Trelease (Annual Rep. Missouri Bot. Gard. 13: 63–64, tt. 30, 31, 83: fig. 7, 92: fig. 2, 1902). **Type** [lecto]: USA, Arkansas (*Engelmann* 182 [MO]).—**Lit:** Hess & Robbins (2002); Diggs & al. (2006: 415, 421, *ills.* p. 417). **Distr:** USA (SE Kansas, SW Missouri, NE, C and SE Oklahoma, NW, W & SW Arkansas, NE, C, E & S Texas); limestone outcrops, rocky hillsides, pine-woods, and prairies, in gravelly or sandy soils, 100–1060 m; flowers March to mid-May. **I:** Hochstätter (1999: 3); Boeuf (2007a: 54); Boeuf & al. (2009: 24–25).

**Incl.** *Yucca angustifolia* var. *mollis* Engelmann (1873) ≡ *Yucca glauca* var. *mollis* (Engelmann) Branner & Coville (1888); **incl.** *Yucca arkansana* var. *paniculata* McKelvey (1947) ≡ *Yucca louisianensis* var. *paniculata* (McKelvey) Shinnors (1956).

[3c] Forming small colonies; stems none to short and decumbent, to 0.2 m; **Ros** 1 or several in small and lax colonies; **L** ascending, or sometimes somewhat recurved, base ± stiff, major part flexible and weak, widest near the middle, straight, lower face convex, upper face flat, somewhat canaliculate at the tip, 20–60 (–70) × 0.7–2 (–2.5) cm (at the base 0.3–0.7 cm), mostly yellowish-green, margins entire, whitish at first, papery, with short curled fibres, with age almost naked, **terminal Sp** acute, straw-coloured, 1.6–3.2 mm; **Inf** erect, racemose, occasionally paniculate proximally, peduncle 0.2–0.5 (–0.6) m, flowering part 0.3–0.6 (–0.8) m, within or just above the rosette leaves, lower part little-branched and with few flowers, glabrous (pubescent in “var. *paniculata*”); **Fl** pendent, globose, 30–60 mm; **Tep** elliptic to orbicular or oblong, 32–65 × 20–50 mm, tomentose, greenish-white, margins irregular, sometimes roughly dentate; **Fil** 13–25 mm; **Ov** oblong to cylindrical, thick

and robust, 15–19 mm; **Sty** dark green, 7–13 mm; **Sti** lobed; **Fr** dry capsules, erect, oblong-cylindrical to obovoid-cylindrical, constricted near the middle, 40–65 (–70) × 20–30 mm, walls thick; **Se** black, shiny, 10 × 5 mm.—**Cytology**: 2n = 60 (Watkins 1936).

Rather variable, esp. in the E part of its range (Hess & Robbins 2002). The “var. *paniculata*” may be an E extension of the species with a taller, paniculate and pubescent inflorescence (McKelvey 1947). *Y. arkansana* approaches “*Y. louisianensis*”, which is here synonymized with *Y. flaccida* (Hess & Robbins 2002). Molecular data of Clary (1997, cited by Hess & Robbins 2002) place *Y. arkansana* and “*Y. louisianensis*” closest to one another, whereas those of Pellmyr & al. (2007) place 2 samples of *Y. arkansana* (as *Y. “glaucata arkansana”*) separate from each other — one groups with *Y. glauca*, and the other with *Y. constricta* near to “*Y. louisianensis*”. — The lectotype cited above was designated (as “type”) by McKelvey (1947: 152).

**Y. baccata** Torrey (in Emory, Rep. US Mex. Bound. 2(1): 221, 1859). **Type**: USA, New Mexico (Bigelow 823 [NY 320132]).—**Lit**: Trelease (1902: 109–110, tt. 68–69); Reveal (1977: 528–529, with ills.); Hess & Robbins (2002). **Distr**: S USA, NW Mexico.

≡ *Sarcocoyucca baccata* (Torrey) Lindinger (1933).

For details of the typification see Reveal (1977). One of the most variable indehiscent-fruited yuccas (Webber 1953: 28). Samples of *Y. baccata* group with *Y. schidigera* and *Y. arizonica* (here treated as *Y. baccata* ssp. *thornberi*) in the molecular phylogenies of Pellmyr & al. (2007) and Smith & al. (2008a). An ethnobotanical study of the species was presented by Potter-Bassano (1991). Vernacular name: “Banana Yucca” (for further vernacular names, see Lenz & Hanson 2001: 167).

**Y. baccata** ssp. **baccata** — **Lit**: Reveal (1977: 528–529, with ills.); Matuda & Piña Luján (1980: 65–68, with ills.); Benson & Darrow (1981: 54–55, with ills.); Turner & al. (1995: 409–410, ecology); Hess & Robbins (2002: with ills.); Hawker (2016: 310–315, with ills.). **Distr**: SW & S USA (S California, S Nevada, SE Utah, S-C & SW Colorado, Arizona, New Mexico, SW Texas), NW Mexico (N Chihuahua, Coahuila); rocky slopes in pinyon, oak, and juniper woodlands or grasslands, 400–2500 m; flowers (March to) April to June (to October). **I**: Hochstätter (2002a: 108–120); Boeuf (2007a: 55); Boeuf & al. (2009: 26–27). – Fig. 1.

**Incl.** *Yucca filamentosa* Wood (1868) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca fragilifolia* Baker (1870) ≡ *Yucca baccata* fa. *fragilifolia* (Baker) Voss (1895); **incl.** *Yucca scabrifolia* Baker (1870) ≡ *Yucca baccata* var. *scabrifolia* (Baker)

**Fig. 1** *Yucca baccata* ssp. **baccata** (“var. *vespertina*”). (Copyright: U. Eggli)

Baker (1880); **incl.** *Yucca baccata* fa. *genuina* Engelm. (1873) (*nom. inval.*, ICN Art. 22.1); **incl.** *Yucca filifera* hort. ex Engelm. (1873) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca baccata* var. *hystrix* Baker (1880); **incl.** *Yucca hanburyi* Baker (1892); **incl.** *Yucca baccata* fa. *parviflora* McKelvey (1938); **incl.** *Yucca baccata* var. *vespertina* McKelvey (1938)  $\equiv$  *Yucca vespertina* (McKelvey) S. L. Welsh (1993)  $\equiv$  *Yucca baccata* ssp. *vespertina* (McKelvey) Hochstätter (2001).

[1b] Stems none or rarely up to 6, to 0.3 m, aerial or subterranean; **Ros** asymmetrical and rather open, mostly simple and (50–) 60–75  $\times$  130–150 cm, or forming colonies 1–5 m  $\varnothing$ ; **L** at the base spreading, inner leaves more erect, straight, deeply canaliculate, rigid, falcate and rather narrow (esp. in “var. *vespertina*”), (30–) 50–70 (–75)  $\times$  2.5–4 (flattened 3–6) cm, bluish-green, margins of the upper  $\frac{1}{2}$  forming broad coarse recurved to curly fibres, **terminal Sp** stout, stiff, 1.5–7 mm; **Inf** erect, paniculate, glabrous, mostly green (reddish-purple in “var. *vespertina*”), peduncle 0.6–0.8 m, flowering part short, 0.6–0.8 m, arising completely within or mostly extending  $\frac{1}{4}$  beyond the rosette leaves, with  $\pm 15$  part-**Inf**; **Ped** terete to slightly flattened, 7–40 mm; **Fl** pendent, campanulate; **Tep** lanceolate,  $\pm 50$ –150  $\times$  14–30 mm, dorsally red-brown, ventrally creamy-white, basally connate to form a tube 7–12 mm long; **Fil** 3.2–12 mm, connate proximally into a collar-like structure; **Ov** (30–) 50–70 (–75) mm; **Sty** 5–7 mm; **Sti** distinct; **Fr** fleshy berries, pendent, elongate, upper  $\frac{1}{3}$  constricted, (50–) 150–170 (–230)  $\times$  (30–) 40–75 mm, green, or tinged orange or tan; **Se** rugose, 7–11  $\times$  3 mm, dull black.

This is the common broad-leaved *Yucca* in much of Arizona and New Mexico. The large fleshy fruits are eaten raw, roasted or dried by the Navajos (Benson & Darrow 1981). Differs from ssp. *thornberi* in being acaulescent or short-caulescent with up to 6 aerial or subterranean stems to 0.3 m, and leaf margins with coarse and curling fibres (Hess & Robbins 2002). Variegated cultivars are mentioned by Boeuf & al. (2010: 77–79). Hardy down to  $-29$  °C (Irish & Irish 2000: 238).

**Y. baccata** ssp. **thornberi** (McKelvey) Hochstätter (Succulenta 80(4): 172, 2001). **Type:** USA, Arizona (McKelvey 1627 [A 441073]).—**Lit:** Gentry (1972: 166–169, with ills., as *Y. arizonica*); Matuda & Piña Luján (1980: 72–75, with ills., as *Y. arizonica*); Turner & al. (1995: 407–409, ecology, as *Y. arizonica*); Hess & Robbins (2002); Hawker (2016: 310–315, with ills.). **Distr:** S USA (SE Arizona, SW New Mexico), N Mexico (N Sonora); hills, mesas and flats in the Sonoran Desert, desert grasslands and oak woodlands, 350–2000 m; flowers March to May. **I:** Hochstätter (2002a: 121–131, as *Y. baccata* ssp. *thornberi* & ssp. *confinis*, *Y. arizonica*)).

$\equiv$  *Yucca thornberi* McKelvey (1935); **incl.** *Yucca brevifolia* A. Schott ex Torrey (1859) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca treleasei* J. F. Macbride (1918) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca arizonica* McKelvey (1935); **incl.** *Yucca confinis* McKelvey (1938)  $\equiv$  *Yucca baccata* ssp. *confinis* (McKelvey) Hochstätter (2002) (*nom. inval.*, ICN Art. 41.5); **incl.** *Yucca baccata* var. *brevifolia* L. D. Benson & Darrow (1943).

[1b] Differs from ssp. *baccata*: Caulescent, stems up to 24, aerial, often branched, to 2–3 m; **L** margins finely filiferous; **Inf** arising almost completely within to mostly extending beyond the rosette leaves; peduncle shorter, to 0.3 m.

Widely recognized as *Y. baccata* var. *brevifolia*, but treated here at subspecific rank due to its geographical and morphological distinctness. Lenz & Hanson (2001) include this taxon in the synonymy of *Y.  $\times$ schottii* (see there). Plants in Sonora are generally taller (to 3 m) and form smaller clumps than those in Arizona (to 2 m tall) (Gentry 1972).

**Y. baileyi** Wooton & Standley (Contr. US Nation. Herb. 16: 114–115, 1913). **Type:** USA, New Mexico (Standley 7638 [US 686602, US [iso]]).—**Lit:** Webber (1953: 49–52, tt. 44–45); Reveal (1977: 532–533, with ills.); Welsh & al. (1987: 649); Hess & Robbins (2002); Hawker (2016: 316–323, with ills.). **Distr:** SW USA (SE Utah, S Colorado, NE Arizona, E New Mexico); mountains, adjacent woodlands and grasslands, 1300–2500 m; flowers April to June. **I:**

Hochstätter (2000: 100); Boeuf (2007a: 56); Boeuf & al. (2009: 28–29).

**Incl.** *Yucca navajoa* J. M. Webber (1945) ≡ *Yucca baileyi* var. *navajoa* (J. M. Webber) J. M. Webber (1953); **incl.** *Yucca standleyi* McKelvey (1947).

[3b] Stems none to rarely short and (semi-) erect, to 0.2 (–1.2) m; **Ros** symmetrical, solitary or caespitose and forming colonies 1.3–2 m Ø; **L** somewhat crowded, divergently spreading, rigid, linear, occasionally falcate, lower face convex or keeled, upper face flat, smooth on both faces, 25–45 (–50) × 0.6–0.9 cm, pale or yellowish-green, margins entire, recurved, whitish, becoming separate and forming conspicuous fine curly fibres, tip gradually tapering towards a short **terminal Sp** to 3.2 mm; **Inf** erect, racemose, simple, peduncle 10–20 cm, flowering part 25–45 (–85) cm, arising within or just beyond the rosette leaves, glabrous; **Ped** 10–20 mm; **Fl** pendent, campanulate, 50–65 mm; **Tep** ovate to obovate or elliptic, 50–65 × 15–32 mm, greenish-white, usually tinged with deep purple esp. on the outer face, basally connate to form a tube 3–7 mm long; **Fil** to 20 mm; **Ov** 18–25 × 8 mm; **Sty** white, 7 mm; **Sti** lobed; **Fr** dry capsules, erect, oblong-cylindrical, not or only slightly constricted, 40–70 × 25–50 mm; **Se** thin, with broad marginal wing, 6–10 mm, dull black.

Populations comprising compact colonies with short, branched stems 0.4–1.2 m tall instead of

scattered, caespitose individuals were separated as var. *navajoa* by Webber (1953: 51). According to Webber (1953), *Y. baileyi* appears to hybridize with *Y. glauca* and *Y. angustissima*. Hochstätter (2000: 46) assumed that *Y. baileyi* is related to *Y. elata* and *Y. angustissima* based on its relatively small rosettes with narrow green strongly filiferous leaves, as well as on the distribution area. Molecular data of Pellmyr & al. (2007) and Smith & al. (2008a) group *Y. baileyi* close to *Y. angustissima* and to *Y. utahensis* (as *Y. elata utahensis*), whereas *Y. elata* is more distant. Following Hess & Robbins (2002), *Y. baileyi* var. *intermedia* is accepted here at species rank as *Y. intermedia*.

**Y. brevifolia** Engelmann (in S. Watson, Bot. US Geol. Expl. 40. Parallel 5: 496, 1871). **Type** [lecto]: USA, California (*Bigelow* s.n. [NY, US]).—**Lit**: Reveal (1977: 530–531, with ills.); Matuda & Piña Luján (1980: 111–114, with ills.); Benson & Darrow (1981: 51–53, ills. & t. H1, as var. *brevifolia*); Turner & al. (1995: 409–410, ecology); Hess & Robbins (2002: with ills.); Lenz (2007: with ills.); Hawker (2016: 310–315, with ills.). **Dist**: SW USA (SE California, S Nevada, SW Utah, NW Arizona); dry desert slopes and mesas, 400–2200 m; flowers April to May. **I**: Hochstätter (2002a: 139–153, 156–158); Boeuf & al. (2009: 30–31). – Figs. 2 and 3.

≡ *Clistoyucca brevifolia* (Engelmann) Rydberg (1918) ≡ *Sarcoyucca brevifolia* (Engelmann) Lindinger (1933); ≡ *Yucca draconis* var. *arborescens* Torrey (1857) ≡ *Yucca arborescens* (Torrey) Trelease ex Merriam (1893) (*nom. illeg.*, ICN Art. 52.1) ≡ *Clistoyucca arborescens* (Torrey) Trelease (1902) (*nom. illeg.*, Art. 52.1); **incl.** *Yucca brevifolia* var. *wolfei* M. E. Jones (1935) (*nom. inval.*, ICN Art. 39.1); **incl.** *Yucca brevifolia* fa. *herbertii* J. M. Webber (1953) ≡ *Yucca brevifolia* var. *herbertii* (J. M. Webber) Munz (1958) ≡ *Yucca brevifolia* ssp. *herbertii* (Munz) Hochstätter (2001); **incl.** *Yucca brevifolia* fa. *kernensis* Hochstätter (2000) (*nom. inval.*, ICN Art. 38.1a).

[2] Usually solitary, arborescent, to (3–) 5–12 (–16) m, main stem usually 1, occasionally several to many, simple or usually monopodially branched distally; **Br** usually from 1–3 m above the ground, stout, 1–3 m long; **Ros** broad, flat- or round-topped, 0.3–1 (–1.5) × 0.3–0.5 m; **L** straight, rigid, smooth, lower face convex or triquetrous, upper face plane, glabrous, (10–) 15–28 (–35) × 0.7–1.5 cm, green, base whitish, margins nearly entire, thin, horny, minutely denticulate, yellow, **terminal Sp** 7–12 mm; **Inf** erect, paniculate, flowering part (25–) 30–55 × 30–38 cm, ellipsoid-ovoid, for ± ¼–½ enclosed within the rosette leaves, with numerous part-**Inf** with crowded flowers, glabrous; **Ped** 7–12 (–25) mm; **Fl** erect, globose to depressed-globose, never opening fully, (30–) 40–70 mm; **Tep** broadly ovate, strongly incurved, fleshy, 25–70 × 11–22 mm, cream, barely connate at the base;

**Fil** 10–12 mm; **Ov** conical, tapering from the base, 25–30 mm; **Sty** 5.5–11 mm; **Sti** distinct; **Fr** pendent, dry, indehiscent, ovoid to broadly ovoid, rounded at the apex, deeply furrowed, rather spongy, 60–85 (–100) × 30–50 (–65) mm; **Se** flat, thin, smooth, 8–12 mm, dull black.

For details of the typification see Reveal (1977: 530). This taxon (vernacular name: “Western Joshua Tree”) and *Y. jaegeriana* (the “Eastern Joshua Tree”, only recently recognized as a separate species) are both characteristic elements of the Mojave Desert of the SW USA, often dominating the landscape.

A variant from the W edge of the Mojave Desert that reproduces asexually by short rhizomes producing large clusters of seemingly different individuals was described as fa. *herbertii* (variously also treated as var. or ssp.; illustrations: Webber 1953: t. 18, Hochstätter 2002a: 151–153, Hawker 2016: 330). Other forms reproduce similarly, but the rhizomes run underground for a longer distance so that the resulting plants are widely spaced (Benson & Darrow 1981).

The inflorescences grow primarily on branches oriented towards the S, or if not S-oriented, bend towards the S, thus maximizing exposure to solar radiation (Warren & al. 2016). Dispersed seeds show substantial loss by granivore removal or loss of germinability (reduced to 50–68% after 1 year; Reynolds & al. 2012). The seeds are distributed by various seed-caching rodents (Vander Wall & al. 2006). During the mast fruiting year 2013, seed production was 100× higher than in the following year, and much less infection by larvae and lower seed predation by rodents took place (Borchert & DeFalco 2016). Esque & al. (2015) studied the seedling establishment after an exceptionally high rainfall event 1983–1984 for 22 years up to 2014: 19% of a study cohort of 53 seedlings survived for 22 years, the highest mortality is in the first 2 years caused by rodents, and the annual growth rates (average of 3.12 cm) are strongly correlated with the amounts of rainfall.

**Y. campestris** McKelvey (Yuccas Southwest US, 2: 173, tt. 62–63, 1947). **Type:** USA, Texas (McKelvey 2849 [A]).—**Lit:** Hess & Robbins (2002); Hawker (2016: 332–334, with ills.).

**Distr:** USA (W Texas); in sand dunes and loose, sandy soils, 220–900 m; flowers May to June. **I:** Hochstätter (1999: 6, 9); Hochstätter (2000: 106); Boeuf & al. (2009: 32–33).

[3b/c] Stems none or short, 0.6–1 m; **Ros** lax, in dense groups, forming small to large colonies; **L** spreading, linear, rigid, widest near the middle, lower face convex, upper face flat, smooth on both faces, 40–65 × 0.3–0.7 (–1.5) (in the middle) cm, bluish-green, margins entire, white to grey, finely fibrous, later glabrous, **terminal Sp** acicular, 7 mm; **Inf** erect, paniculate, peduncle 0.5–1 m, flowering part 0.6–1 m, narrowly ellipsoid, starting between (rarely above) the rosette leaves, part-**Inf** many, thin, fragile, ascending, to 13 cm, glabrous; **Fl** pendent, globose; **Tep** 41–65 × 15–25 mm, **ITep** broader than the **OTep**, often concave, dull green, sometimes tinged pink, basally connate to form a tube ±13 mm long, upper margin irregular, toothed, slightly tomentose; **Fil** ± 13–21 mm; **Ov** oblong-ovoid, 13–20 mm; **Sty** ± 8–12 mm, bright green; **Sti** lobed; **Fr** erect dry capsules, rarely constricted, 45–55 (–63) × 30–50 mm, reddish-brown, aged grey; **Se** large, 11–14 × 8–11 mm, shiny black.

Webber (1953: 62–64) considered this species as the hybrid *Y. constricta* × *Y. elata*, but the occurrence in dense stands in a relatively small area in the plains region of W Texas (Hochstätter 1999: 126, 2000: 56) dismisses its status as a hybrid. The morphological-cladistic study of Clary & Simpson (1995) groups the species with *Y. arkansana*, *Y. glauca*, and *Y. intermedia*, and molecular chloroplast DNA sequence data (Smith & al. 2008a: fig. 2a) with *Y. pallida* and *Y. rupicola*.

Martin & Hutchins (1980: 409) include plants from sandy areas in extreme SE New Mexico (Lea County) here, and Sivinski (2008: 3) suggests that all the millions of stemless *Yuccas* with short peduncles, paniculate inflorescences and green styles widespread in E-C and SE New Mexico may belong here. Hawker (2016) reports an isolated occurrence on sand dunes SE of El Paso in W-most Texas.

**Y. capensis** L. W. Lenz (Cact. Succ. J. (US) 70 (6): 289–293, ills., 1998). **Type:** Mexico, Baja

California Sur (Lenz 4501 [RSA]).—**Distr:** Mexico (Baja California Sur: Cape region); thorn scrub, tropical deciduous forests, and oak woodlands, 100–1000 m; flowers March to July. **I:** Hochstätter (2002a: 96–99; 2003d: 212, 214); Boeuf & al. (2009: 34–35).

[1b] Stems 1–5.5 m, solitary, or plants becoming rhizomatous and group-forming with several un- or few-branched stems from the base, in age often decumbent; **L** spreading, upper leaves ± upcurved, narrowed above the expanded base, canaliculate in the middle, flat distally, rather thin, rough, 50–100 × 3–6 cm, yellowish-green, margins dark grey, smooth to somewhat scabrous, without fibres, tip sharp, brownish, but without a distinct **terminal Sp**; **Inf** erect or somewhat inclined, paniculate, peduncle shorter than the rosette leaves, fertile part 0.4–0.8 m, beginning within the rosette leaves, broadly ellipsoid, many-flowered, dense, with broad leathery **Bra** clasping the young inflorescence, densely tomentose to glabrous; **Fl** spreading to ± pendent, flat or saucer-shaped to more subglobose, to 100 mm Ø; **Tep** elliptic, abruptly attenuate to the narrow tips, to 50 × 25 mm, cream-coloured; **Fil** to 12 mm; **Ov** ± 15 mm; **Sty** short; **Sti** lobed; **Fr** fleshy berries, pendent, oblong-cylindrical, 80–120 × 50 mm, green, black when ripe; **Se** finely sculptured, 3–8 × 3–8 mm, black.

According to the protologue, plants placed here were formerly included in the widespread *Y. valida*, but differ clearly in their long, wide, flexible leaves without fibrous margins, long slender stems eventually falling down, and broad, clasping bracts, as first noted by Lenz (1992: 6). It is regarded as being related with a group of mountain-dwelling mainland *Yuccas* (*Y. ×schottii* [as *Y. schottii*], *Y. madrensis* and *Y. jaliscensis*). Molecular AFLP data (Pellmyr & al. 2007, Smith & al. 2008a) place the species closest to *Y. valida* (and separate from *Y. ×schottii* and *Y. jaliscensis*), while chloroplast DNA sequence data place one sample within *Y. ×schottii* and the other sample (in a second analysis both samples) separate from both *Y. madrensis* and *Y. jaliscensis* (Smith & al. 2008a). However, it is uncertain whether the “*Y. schottii*” samples are *Y. ×schottii* or *Y. schottii* auct. = *Y. madrensis*.

The species rarely forms fruits, esp. in more arid habitats. Birds feed on the fleshy fruits, but do not disperse the seeds (Lenz 1998: 293). Arteaga & al. (2015) studied morphological characters and flowering in 12 populations and found significant differences between sites, and a positive correlation of inflorescence production with average annual rainfall. Population genetic studies (Luna Ortiz 2018) largely separate the populations from the W slopes of the Sierra de La Laguna from those of the N and E slopes.

**Y. carnerosana** (Trelease) McKelvey (Yuccas Southwest US, 1: 24, tt. 6–7, 1938). **Type** [lecto]: Mexico, Coahuila (*Pringle* 3912 [MO, A, F, HBG, JE, K, NY, PH, PUL, S, UC, US]).—**Lit**: Matuda & Piña Luján (1980: 60–61, with ill.); Robbins (1983: 14–19, 31–32, 37–38). **Distr**: C Mexico (S Coahuila, S Nuevo León, E Durango, NE Zacatecas, N & C San Luis Potosí, SW Tamaulipas); dry calcareous hills and slopes in desert scrub or pine-oak forests, 850–2200 m; flowers March to April. **I**: Piña Luján (1980: 277); Hochstätter (2002a: 81); Boeuf & al. (2009: 36–37 & front cover).

≡ *Samuela carnerosana* Trelase (1902).

[1a] Stems generally simple (very rarely with 1 or 2 **Br** in the upper part), sometimes forming groups of stems united at the base, stems 0.6–7.5 m or more, 11–39 cm Ø below the rosette, with a long skirt of dried deflected leaves often reaching down to the ground; **L** spreading, rigid, constricted near the base, smooth on both faces, 23–130 × 2.1–9.8 cm in the middle (10–15 cm at the base), apple-green, margins with coarse recurving detaching filaments, **terminal Sp** 10–18 mm; **Inf** erect, paniculate, peduncle 23–40 cm, strong, flowering part 27–100 cm, ovoid to ellipsoid, above the rosette leaves or lowest part within the rosette leaves, with 14–40 densely branching part—**Inf**, with large persistent white **Bra**, glabrous, rarely tomentose; **Fl** pendent, campanulate, 40–84 mm; **Tep** broadly lanceolate, **OTep** 39–95 × 7–21 mm, **ITep** 39–92 × 11–26 mm, tube 6–25 mm, white to greenish-white; **Fil** 13–29 mm; **Ov** ± 15–55 × 5–11 mm; **Sty** 6–10 mm; **Sti** lobed; **Fr** fleshy berries, pendent, oblong, 31–99 × 20–33 mm, beak

5–36 mm, red-brown to nearly black; **Se** flat, rugose, 1–3 mm thick, 6–10 × 6–10 mm, dull black.

The protologue cites *Pringle* 2841 and *Pringle* 3912 as syntypes. McKelvey (1938: 25?) cites 3 specimens of *Pringle* 3912 at MO as “type”, which represents a lectotypification.

Trelase (1902: 116–122) originally separated plants from W Texas and possibly adjacent Mexico with a conical perianth tube <10 mm long as *Y. faxoniana* from plants from Carneros Pass (Coahuila, Mexico) and further S with a tube 12–25 mm long as *Y. carnerosana*. Robbins (1983) studied many leaf, inflorescence, flower and fruit characters and found a ± broad overlap in all studied characters, including tube length, distinguishing both species not consistently, but by tendency only, or not at all. Robbins considered both species as conspecific, but upheld them in the concept of Trelase pending further biochemical and genetic studies; this is followed here.

Wild populations of *Y. carnerosana* (vernacular name: “palma samandoca”) were and are intensively used especially for fibre (Sheldon 1980; see also under ethnobotany).

**Y. cernua** E. Keith (Sida 20(3): 892–893, ill., 2003). **Type**: USA, Texas (*Keith* 183 [TEX, BRIT, SHST]).—**Lit**: Diggs & al. (2006: 416, ill. p. 307, 417). **Distr**: USA (E-most Texas: Jasper and Newton Counties); open or slightly shaded areas, apparently restricted to brownish acidic clay soils. **I**: Boeuf & al. (2009: 38–39); Behan (2012).

[3a] Acaulescent; **Ros** forming large colonies, spreading from thick rhizomes 1–2 cm Ø; **L** divergently spreading, rigid, acute or slightly acuminate, becoming canaliculate and inrolled 0.7–2.5 cm below the tip, lowermost **L** usually undulate and twisting, (30–) 40–70 (–80) × (3–) 3.5–6.5 cm at the widest point, narrowed to 0.7–1.2 cm just above the base, young leaves glaucous, older leaves becoming yellowish-green to olive-green, margins corneous, yellowish and minutely denticulate, **terminal Sp** 3–10 mm, pungent, yellowish at the base and reddish-brown at the tip; **Inf** erect, paniculate, peduncle (1.2–) 1.5–3.2 m, flowering part (0.3–) 0.5– ± 1.2 m,

narrowly ellipsoid, high above the rosette leaves, part-**Inf** characteristically recurved and drooping as they lengthen, to 35 cm, moderately to densely floccose; **Ped** 10–20 mm; **Fl** pendent, campanulate; **Tep** (narrowly) elliptic or lanceolate, 34–50 (–58) × 7.5–18 mm, mostly white or slightly greenish-white, free, glabrous; **Fil** ± 15 mm; **Ov** oblong-cylindrical, slender, ± 17 × 4–8 mm Ø; **Sty** ± 10 mm; **Sti** lobed; **Fr** dry capsules, pendent, oblong-cylindrical, 32–45 × 20–25 mm, beak 0.5–1 cm; **Se** variable, obovate to D-shaped, 5–7 × 4–6 mm.

A very distinctive species due to the drooping part-inflorescences. It is known from only 7 populations, and despite usually occurring on a unique soil type, it appears tolerant of soil disturbance and also grows along roadsides, and rapidly colonizes bare ground (Keith 2003). *Y. cernua* is similar to *Y. pallida* and *Y. rupicola* in its acaulescent habit, denticulate leaves and beaked capsules, and a closer relationship is also corroborated by molecular data (Pellmyr & al. 2007). For the cultivation in the USA, see Behan (2012).

**Y. constricta** Buckley (Proc. Acad. Nat. Sci. Philadelphia 14: 8, 1863). **Type:** USA, Texas (Buckley s.n. [PH]).—**Lit:** Webber (1953: 53–55, t. 47); Diggs & al. (2006: 416, ill. pp. 307 & 419); Hess & Robbins (2002); Hawker (2016: 334–337, with ill.). **Distr:** USA (C, W-C & S Texas), NE Mexico (N Coahuila); limestone outcrops, scrub, woodland and grassland areas, 300–700 m; flowers April to June. **I:** Hochstätter (1999: 127–128); Boeuf & al. (2009: 42–43).

**Incl.** *Yucca glauca* var. *constricta* Hort. Mesa Garden (s.a.) (*nom. inval.*, ICN Art. 30.6); **incl.** *Yucca angustifolia* Carrière (1860) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca albo-spica* hort. ex van Houtte (1867) (*nom. inval.*, ICN Art. 23.6c?); **incl.** *Yucca polyphylla* Baker (1870).

[3c] Acaulescent or occasionally caulescent with procumbent or erect stems to 40 cm; **Ros** asymmetrical, with 100–200 leaves, forming small to large open colonies; **L** divergent, spreading, linear or somewhat wider near the middle, straight, grass-like, flexible, weak, sometimes appearing somewhat stiff, narrow at the base, straight, flattened or plano-convex, mostly 25–65

× (0.3–) 0.7–1.5 cm, light to dark green, margins entire, white, grey to green when old, becoming filiferous, fibres curly but soon eroding away, **terminal Sp** sharp; **Inf** erect, paniculate, racemose distally, peduncle 1–2 m, flowering part ovoid, 0.45–1.2 m, arising 20–46 cm beyond the rosette leaves, with few to many ascending-spreading part-**Inf** to 15–25 cm, glabrous; **Fl** pendent, semiglobose; **Tep** thin, acute, 25–48 × 11–26 mm, pale greenish-white; **Fil** 17–22 mm, pubescent; **Ov** oblong-cylindrical, 20 × 5–6 mm; **Sty** 8–11 mm, whitish or pale green; **Sti** lobed; **Fr** erect dry capsules, oblong-cylindrical, not, slightly or commonly deeply constricted near the middle, (35–) 46–63 × (15–) 25–43 mm; **Se** thin, 8–15 mm Ø, shiny black.—**Cytology:** 2n = 60 (McKelvey & Sax 1933).

McKelvey (1938, 1947) placed *Y. louisianensis* (here treated as synonym of *Y. flaccida*) and *Y. tenuistyla* here as synonyms, but later authors (e.g. Hess & Robbins 2002) accept both as separate species with pubescent inflorescences. The morphological-cladistic study of Clary & Simpson (1995) groups *Y. constricta* with *Y. standleyi* (here included in *Y. baileyi*) and *Y. elata*. The molecular phylogenies of Pellmyr & al. (2007) and Smith & al. (2008a) are inconclusive but suggest a relationship with *Y. glauca* and/or *Y. elata*.—Widespread in Texas (USA), but in Mexico apparently recorded only by the specimen Gentry & Engard 23696 (US). The plant with a distinct stem depicted by Hochstätter (1999: 128, 2002a: 106) might be *Y. elata*.

**Y. decipiens** Trelease (Annual Rep. Missouri Bot. Gard. 18: 228, 1907). **Type:** Mexico, San Luis Potosí (Trelease 154 [MO 3346084]).—**Lit:** Matuda & Piña Luján (1980: 93–96, with ill.); Robbins (1983: 19–22, 45–46). **Distr:** Mexico (S Coahuila, S Nuevo León, E & SE Durango, C & E Zacatecas, W & C San Luis Potosí, N Aguascalientes, NE Jalisco, NW Guanajuato); well-drained plains with deep sandy soil or rock slopes, in desert or oak scrub, 1750–2650 m; flowers January to April. **I:** Trelease (1902: tt. 62–66, as *Y. valida*); Piña Luján (1980: 280); Hochstätter (2004a: 110–115); Boeuf & al. (2009: 44–45).

≡ *Sarcoyucca decipiens* (Trelease) Lindinger (1933).

[1c] Arborescent, to 15 m, with a trunk 1–2 m Ø, or trunk branching at ground level, richly branched, **Br** to 90 or more, usually with a long skirt of deflected dried leaves below the rosettes; **Ros** often asymmetrical, 40–80 cm Ø; **L** linear-ensiform, straight, nearly flat, not very rigid, slightly scabrous on both faces, 28–66 × 1.3–3.9 cm, dark green, margins with numerous fine to coarse curled greyish to whitish fibres, easily detaching, sometimes soon naked, **terminal Sp** sharp, ± 15 mm, grey or brown; **Inf** erect, paniculate, mostly with the peduncle above the rosette leaves, flowering part 49–137 cm, broadly ovoid, mostly compact, upright in the direction of the subtending bract, hence either erect, oblique, or horizontal, glabrous; **Ped** to 25 mm, glabrous or minutely puberulous; **Fl** pendent, globose to campanulate, 25–56 mm; **Tep** 30–55 mm, **OTep** 7–18 mm wide, **ITep** 10–25 mm wide, creamy-white, sometimes tinged purple; **Fil** 9–22 mm; **Ov** 15–30 mm; **Sty** rather short; **Fr** fleshy berries, pendent, oblong, 46–91 × 16–32 mm, rostrate for 3–15 mm; **Se** rough, 6–7 × 7–8 mm.

The protologue does not cite a type, but the specimen *Trelease* 154 (MO 3346084 digital image!), labelled by Trelase as “*Yucca decipiens*, n. sp.”, is regarded as type (= holotype) at MO, thus rendering the neotypification by Hochstätter (2003b: 112) superfluous. New state records are collections from S Coahuila placed here by Robbins (1983), and several specimens from Municipio Galeana, Nuevo León, collected by Hinton & al. The similar *Y. filifera*, which occurs E-wards of the range of *Y. decipiens*, differs in its pendent inflorescences. Molecular data place *Y. decipiens* mostly near *Y. jaliscensis* (Pellmyr & al. 2007, Smith & al. 2008a: fig. 2a, 2b) or closest to *Y. carnerosana* (Smith & al. 2008a: fig. 2c). Vernacular name: “palma chino”.

**Y. declinata** Laferrière (Cact. Succ. J. (US) 67 (6): 347–348, ill., 1995). **Type:** Mexico, Sonora (*Gentry* 16615 [ARIZ 267477, ARIZ, US]).—**Lit:** Hochstätter (2004a: 21, with ill.). **Distr:** Mexico (E Sonora, W Chihuahua); rocky mountain slopes and open woodland, volcanic and

limestone soils, 700–1230 m. **I:** Gentry (1972: figs. 63 & 64, as *Y. grandiflora*); Matuda & Piña Luján (1980: 73: at least upper fig., as *Y. grandiflora*); Piña Luján (1980: fig. 4, as *Y. grandiflora*); Hochstätter (2003c: 154–155); Bechtold & Metorn (2005: 32); Boeuf & al. (2009: 46–47).

[1b] Arborescent, stems thick, robust, 3–6 m, branching above and forming a crown of few rosettes, suckering at the base when fully grown, with a long skirt of dried deflected leaves below the rosette; **L** erect or spreading, straight, stiff, strong, canaliculate, broadest in the middle, narrowed towards base and apex, glabrous on both faces, 40–140 × 3–6 (in the middle) cm, yellowish-green, margins smooth, pale (white), with age fraying into few fine threads, **terminal Sp** 10–20 mm, greyish to brownish; **Inf** usually inclined, paniculate, peduncle 5–30 cm, flowering part 0.55–1 m, lower part within the rosette leaves, part-**Inf** (slightly) ascending, ± 20–25, to 40 cm, glabrous; **Fl** small; **Tep** lanceolate, 30–50 × 8–12 mm, white; **Fil** 11–18 mm, pubescent; **Ov** elongate, 30–50 mm; **Sty** ± 4–7 mm; **Fr** fleshy indehiscent berries, oblong, tapering at the base, 100–200 × 40 mm, distinctly beaked, brownish when ripe; **Se** flat, slightly ovoid, finely sculptured, 6–15 mm Ø, black.

The type collection was previously tentatively identified as *Y. grandiflora* by Gentry (1972: 162). Since Gentry’s fieldnotes indicated that he considered the plant significantly different from its close relatives *Y. grandiflora* and *Y. arizonica*, Laferrière formally described the plant based on Gentry’s specimens and notes. According to the protologue, *Y. declinata* is most distinctive in its ± horizontally oriented inflorescences. In addition, it differs from *Y. grandiflora* in its smaller flowers and glabrous rachis, from *Y. arizonica* (here treated as synonym of *Y. baccata* ssp. *thornberi*) in its taller habit, larger leaves, and more open inflorescences with flowers with shorter tepals and shorter stamens, and from *Y. ×schottii* by its elongate ovary and glabrous inflorescence. Bechtold & Metorn (2005) provide a new photographic record from W-most Chihuahua. Vernacular name: “datil”. See also under *Y. grandiflora*.

**Y. ×desmetiana** Baker *pro sp.* (Gard. Chron. 27: 1217, 1870). **Type:** not typified.—**Lit:** Ullrich (1991). **Distr:** Cultivated only. **I:** Trelease (1902: t. 48); Guillot Ortiz & Meer (2008: 102); Boeuf & al. (2009: 118; 2010: 83, as *Y. 'De Smetiana'*).

**Incl.** *Yucca atkinis* hort. ex K. Koch (1873); **incl.** *Yucca smetiana* hort. ex K. Koch (1873); **incl.** *Yucca helkinsi* hort. ex Trelease (1902) (*nom. inval.*, ICN Art. 36.1c).

[1c × 3c?] Unique by its symmetrically arranged, flexible, elegantly down-curved leaves with conspicuous purplish- to reddish-brown colour “quite unlike any other *Yucca*” (Trelease 1902: 87). Of unknown origin and distributed by the Belgian nurseryman de Smet (Koch 1873: 212), cultivated in many gardens in 1873 (Engelmann 1873: 41). Koch (1873: 212) considered it as a form, and Sprenger (1920a: 103) as a mutation (“Sport”) of *Y. aloifolia*. Later authors added further possible parental species for its hybrid origin: *Y. gloriosa*, *Y. gloriosa* var. *tristis* (as *Y. recurvifolia*), *Y. filamentosa*, *Y. glauca*, and *Y. treculiana* (Ullrich 1991; Boeuf & al. 2009: 118). No inflorescences have ever been observed except for a published photograph of doubtful identity cited by Ullrich (1991). The specimen Baker s.n. from 1873 (K001096522) was prepared later than the protologue and thus does not represent original (type) material. Hardy down to  $-12\text{ }^{\circ}\text{C}$  (Boeuf & al. 2009).

**Y. elata** Engelmann (Bot. Gaz. 7: 17, 1882). **Type** [lecto]: USA, Arizona (Palmer 201 [MO]).—**Lit:** Webber (1953); Reveal (1977); Matuda & Piña Luján (1980); all with ills.; Hess & Robbins (2002). **Distr:** S USA, N Mexico. **I:** Piña Luján (1980: 281).

This name is treated as new name (*nom. nov.*, ICN Art. 58.1) for *Y. angustifolia* var. *elata* Engelmann 1873 (*nom. illeg.*, ICN Art. 52.1), because it is a superfluous renaming of *Y. angustifolia* var. *radiosa* Engelmann 1871). All names have thus the same type, i.e. the lectotype designated by Reveal (1977: 533).

Easily recognizable in its native range by its elegant crown of narrow flexible finely filiferous leaves with thin white margins on well-developed

trunks (Gentry 1972). Webber (1953) assumes hybridisation with *Y. glauca*, *Y. constricta* and *Y. baileyi* wherever they grow together, but Reveal (1977) believed that Webber did not provide evidence for his hybrid hypothesis. Reveal’s concept of *Y. elata* embraces all those plants from the SW USA with paniculate inflorescences with only the uppermost flowers arranged in racemes. Consequently, he reduced *Y. utahensis* and *Y. verdiensis* to varieties of *Y. elata* (Reveal 1977). This is only partly accepted here, since *Y. utahensis* is clearly separated from *Y. elata* in the molecular phylogenies of Pellmyr & al. (2007) and Smith & al. (2008a).

*Y. elata* is almost always caulescent, in contrast to *Y. angustissima* (plants generally acaulescent, inflorescences almost always strictly racemose) (Reveal 1977). The two infraspecific taxa of *Y. elata* recognized here are difficult to distinguish consistently (Hess & Robbins 2002).

**Y. elata** ssp. **elata** — **Lit:** Gentry (1972: 155–157); Reveal (1977: 533–534); Matuda & Piña Luján (1980: 130–132); Benson & Darrow (1981: 48–49); Lenz & Hanson (2001: 168–169); Hess & Robbins (2002); Hawker (2016: 336–341); all with ills. except Lenz & Hanson. **Distr:** USA (C, S & SE Arizona, C & S New Mexico, W Texas), N Mexico (NE Sonora, N & C Chihuahua, N Coahuila); desert hillsides, grassland (USA), small-leaved desert scrub and open forests (Mexico), on sandy and gravelly soils, 320–1900 m; flowers April to July. **I:** Curtis’s Bot. Mag. 125: t. 7650 (1899); Piña Luján (1980: 281); Hochstätter (2000: 101–103); Boeuf (2007a: 61–62, 113); Boeuf & al. (2009: 48–49).

**Incl.** *Yucca elata* var. *magdalenae* Hort. Mattern (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Yucca angustifolia* var. *radiosa* Engelmann (1871) ≡ *Yucca radiosa* (Engelmann) Trelease (1902); **incl.** *Yucca angustifolia* var. *elata* Engelmann (1873) (*nom. illeg.*, ICN Art. 52.1); **incl.** *Yucca constricta* Baker (1880) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca coahuilensis* Matuda & Piña Luján (1980).

[3b] In the USA arborescent, with 1–7 stems 1–1.5 (–5) m tall, often few-branched above, stems with a skirt of dried deflected leaves

below the rosettes, in Mexico (Coahuila) stems mostly none or very short and rosettes forming lax colonies; **Ros** solitary or in small colonies, symmetrical or asymmetrical; **L** numerous, divergent, narrowly linear, flexible, widest near the middle, lower face convex, upper face flat or canaliculate, striate, 30–95 × 0.2–1.3 cm, pale to yellow- or bluish-green, margins white, greenish-white or greyish, copiously finely filiferous, fibres ± curly, tip long-acuminate, **terminal Sp** short, ± 5 mm, very pungent; **Inf** erect, paniculate, sometimes distally racemose, green to reddish or yellowish, peduncle 1–2 m, flowering part 0.7–1.5 m, narrowly ovoid to ovoid, relatively slender, high above the rosette leaves, part-**Inf** 7–35 cm, glabrous; **Ped** (7–) 10–25 mm; **Fl** pendent, campanulate to somewhat globose; **Tep** narrowly to broadly elliptic or ovate, 32–57 × 13–32 mm (**ITep** broader), creamy-white, often tinged with green or pink, basally connate to form a tube 2–7 mm long; **Fil** 12–25 (–32) mm, pubescent; **Ov** oblong-cylindrical, with deep sutures, 15–20 × 6–10 mm; **Sty** 6–11 mm, white or pale green, pubescent; **Sti** lobed; **Fr** dry capsules, oblong-cylindrical, rarely constricted, rather thin-walled, 50–82 × 20–40 mm, smooth, whitish; **Se** thin, 7–11 (–14) mm Ø, dull black.—**Cytology**:  $n = 30$  (Pinkava & Baker 1985);  $2n = 60$  (McKelvey & Sax 1933, Watkins 1936, as *Y. radiosa*).

Successful pollination is effected by *Yucca* moths only and by outbreeding; the many diurnal insects visiting the flowers do not effect fruit set (James & al. 1993).

*Y. coahuilensis*, only known from ±3 collections in N Coahuila (Mexico), is acaulescent according to the protologue, but Boeuf & al. (2009: 40) depict plants with a short stem from Múzquiz, Coahuila. Hochstätter (2003a: 67–69) and Hochstätter (2004a: 52–53, 152) includes very similar plants from just across the border in Maverick and Zavala counties, Texas (USA), in *Y. coahuilensis*, and places it with *Y. elata* in his Ser. *Glaucæ*. According to Boeuf & al. (2009: 40–41) *Y. coahuilensis* is easily confused with *Y. elata* when young, but distinguished by the lack of a distinct stem and somewhat shorter inflorescences. K. H. Clary (label, 2003) identified the

type collection of *Y. coahuilensis* (Matuda & Piña Luján 38790 [MEXU, MO]) as *Y. elata*. Thus, *Y. coahuilensis* merely represents a redundant name for stemless or short-stemmed *Y. elata* populations from Coahuila (Mexico) and is here accordingly treated as synonym.

**Y. elata** ssp. **verdiensis** (McKelvey) Hochstätter (*Yucca* I, 50, ills. (p. 104), 2000). **Type** [syn]: USA, Arizona (McKelvey 2752 [A]).—**Lit**: Reveal (1977: 533–534); Hess & Robbins (2002); Hawker (2016: 342–348, with ills.). **Distr**: SW USA (C Arizona); rocky hillsides and canyons, 300–1900 m; flowers April to mid-June.

≡ *Yucca verdiensis* McKelvey (1947) ≡ *Yucca elata* var. *verdiensis* (McKelvey) Reveal (1977).

[3b] Differs from ssp. *elata*: Plants predominantly caulescent, 1.5–3.5 m tall, stems distinct but short, 1–1.5 m, rarely none; **L** shorter, 25–45 × 0.2–0.6 (–1.3) cm; **Inf** paniculate, distally racemose, peduncle 1–1.5 m; **Tep** smaller, 32–45 × 13–20 mm; **Ov** 20–25 mm; **Fr** smaller, 40–45 × 20–40 mm.

The type consists of three sheets, which are not cross-labelled, and therefore represent syntypes. McKelvey (1938, 1947) suggested that this could be a mountain variant of *Y. angustissima* but stated that the features bear “no resemblance to those of *Y. angustissima*”. Webber (1953: 63) suggested that ssp. *verdiensis* (as *Y. verdiensis*) is a hybrid between *Y. elata* and *Y. angustissima*. Lenz & Hanson (2001: 169) refer the taxon to the synonymy of *Y. elata*.

**Y. endlichiana** Trelease (Annual Rep. Missouri Bot. Gard. 18: 229–230, tt. 15–17, 1907). **Type** [syn]: Mexico, Coahuila (*Endlich* 6 [MO]).—**Lit**: Matuda & Piña Luján (1980: 68–71); Robbins (1983: 10–13, 41); Hochstätter (2008a); García-Mendoza (2003); Greulich (2015); all with ills. **Distr**: Mexico (S Coahuila); arid Chihuahuan Desert scrub in very hot and dry places, in calcareous soil, 1000–1200 (–1600) m, flowers in May. **I**: Hart (1977); Piña Luján (1980: 278); Glass & Foster (1986: 61); Hochstätter (2004a: 81–83, 2009); Mays (2005: front cover); Boeuf & al. (2009: 52–53); Ríha (2013). – Fig. 4.

**Fig. 4** *Yucca endlichiana*. (Copyright: J. Trager)

≡ *Sarcoyucca endlichiana* (Trelease) Lindinger (1933).

[1b] Acaulescent; **Ros** with strong, thick-fleshy rhizomes, surculose, forming dense colonies 30–60 (–80) cm Ø; **L** few, erect or recurving, rigid, thick, semicircular to triangular in cross-section at the base, conduplicate further up, 19.5–50 × 1.5 cm, bluish-green, brown-red-dish at the base, covered with narrow dark brown to black bands, margins chestnut-brown to black, with coarse, short, curled, recurved grey fibres, **terminal Sp** conical, strong, short, sometimes blunt at age, dark brown; **Inf** diffuse, without main axis, much shorter than the rosette leaves, to 10 cm, part-**Inf** with 3–6 flowers, glabrous; **Ped** filiform, >25 mm; **Fl** to 18 mm Ø; **Tep** ovate, tips acute, thick-fleshy, 15 × 8 mm, cream to pale yellowish inside, wine-red to brownish-red outside, **ITep** with paler margins; **Fil** short, 3–10 mm, finely papillose, pale yellowish; **Ov** oblong, wine-red; **Sty** short, slender; **Sti** white; **Fr** fleshy berries, pendent, subglobose to narrowly ellipsoid, thin-walled, 20–40 × 17–25 mm, ripe brownish; **Se** 6–8 × 5–6 mm, 1–2 mm thick.

This is possibly the most succulent species of *Yucca*. It certainly is very desirable and suitable for collections due to its small size. The highest

density with up to 200 plants/ha is found near the type locality Estación Marte (Matuda & Piña Luján 1980). In the protologue placed closest to *Y. baccata*, which shares the acaulescent habit, thick rhizome and leaves, and very small flowers. Hochstätter (2008a) argues that the species is without close relatives and sufficiently distinct to merit its own section, Sect. *Endlichiana*, but this is not followed here. In the molecular phylogeny of Pellmyr & al. (2007), *Y. endlichiana* is placed with weak support near the dry-fruited *Y. treculiana*.—Greulich (2015: 12) shows an artificial hybrid with *Y. filamentosa*. Hardy down to ± –10 to –12 °C (Boeuf 2007a; Boeuf & al. 2009).

**Y. faxoniana** (Trelease) Sargent (Man. Trees [ed. 1], 121, fig. 106, 1905). **Type:** USA, Texas (*Anonymus* s.n. [A [status?]]).—**Lit:** Matuda & Piña Luján (1980: 61–64, with ill.); Robbins (1983: 14–19, 31–32, 38–39); Hess & Robbins (2002); Hawker (2016: 348–354, with ill.). **Distr:** S USA (SW Texas), NE Mexico (E Chihuahua, N Coahuila); dry rocky slopes and flats in desert scrub, 500–2100 m; flowers March to April. **I:** Piña Luján (1980: 277); Hochstätter (2002a: 76, 78–81); Boeuf (2007a: 63); Boeuf & al. (2009: 54–55). – Fig. 5.

≡ *Samuela faxoniana* Trelease (1902); **incl.** *Yucca baccata* var. *macrocarpa* Torrey (1859) ≡ *Yucca macrocarpa* (Torrey) Coville (1893) (*nom. illeg.*, ICN Art. 53.1) ≡ *Sarcoyucca macrocarpa* (Torrey) Lindinger (1933); **incl.** *Yucca australis* Trelease (1894) (*nom. illeg.*, ICN Art. 53.1) ≡ *Sarcoyucca australis* (Trelease) Lindinger (1933); **incl.** *Yucca macrocarpa* Sargent (1895) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca australis* var. *valida* M. E. Jones (1929) (*nom. inval.*, ICN Art. 35.1).

[1a] Arborescent, stems erect, 0.6–5.9 m, simple or often with 2–4 **Br** in the upper part, 14–60 cm Ø below the rosettes, with a long skirt of dried deflected leaves often reaching down to the ground; **L** spreading, rigid, constricted near the base, smooth on both faces, 43–114 × 3.1–8.4 cm in the middle (12–18 cm at the base), apple-green, margins often with conspicuous coarse curling filaments, **terminal Sp** 15–25 mm, grey; **Inf** erect, paniculate, peduncle

**Fig. 5** *Yucca faxoniana*.  
(Copyright: U. Eggli)

15–83 cm, strong, flowering part 40–172 cm, usually broadly ovoid, above the rosette leaves or lowest part within the rosette leaves, with 30–40 densely branching part—**Inf**, with large persistent white **Bra**, glabrous; **Ped** 20 mm or more; **Fl** pendent, campanulate, 44–124 mm; **Tep** obovate, **OTep** 39–108 × 10–30 mm, **ITep** 28–98 × 13–38 mm, whitish to greenish-white, often tinged rose or purple, tube 1–32 mm; **Fil** 14–38 mm; **Ov** 23–74 × 6–12 mm; **Sty** 2–10 mm; **Sti** distinct; **Fr** fleshy berries, pendent, elongate, 36–136 × 18–36 mm, beak 9–36 mm, brownish to black; **Se** flat, 2–4 mm thick, finely sculptured, 7–9 mm Ø, dull black.—**Cytology**: 2n = 60 (McKelvey & Sax 1933: as *Samuela*).

Trelease (1902) published the segregate genus *Samuela* to accommodate *Y. faxoniana* and *Y. carnerosana*, characterized by a clearly developed perianth tube (tepals free or only basally slightly fused in all other species). Molecular data by Clary (1997) (cited by Hess & Robbins 2002) and Smith & al. (2008a: fig. 2b) confirm the close relationship, but other data place both species separate (Smith & al. 2008a: fig. 2a, c). In any case, both species are embedded within *Yucca*, and *Samuela* cannot be recognized. Both species are doubtfully distinct (see under *Y. carnerosana*). Plants from Brewster County, Texas, formerly placed in *Y. carnerosana* (McKelvey 1938, 1947, Webber 1953: 18), are placed here by

Robbins (1983) and Hess & Robbins (2002).—*Y. faxoniana* is often used for landscaping in (semi-) arid regions of the S USA (Starr 2000, Irish & Irish 2000: 244–246).

**Y. feeanoukiae** Hochstätter (Cactus & Co. 17 (1): 75, ills. (pp. 72–76), 2013). **Type** [syn]: USA, Utah (Hochstätter 1186.70 + 1190.56 [SRP]).—**Distr**: USA (N Utah); limestone hills, 2000 m; flowers in June.

[3b] Caespitose; **Ros** solitary or offsetting and forming small colonies; **L** variable, pointing upwards, curved and contorted, plano-convex, rigid, glaucous, smooth to finely rough, to 10–30 × 1.2–1.5 cm (in the middle, 0.3–0.5 cm at the base), margins finely fibrous, fibres curved and contorted, tip sharp; **Inf** erect, racemose, 30–60 cm, lowest parts of the flowering part within the rosette leaves; **Fl** pendent, 20–40 × 20–30 mm; **Tep** white, **OTep** sometimes purple; **Fr** dry capsules, flattened, 30 × 30 mm, brownish; **Se** crescent-shaped, 6 × 5 mm, dull black.

The published description is short and lamentably incomplete. The species is compared with *Y. harrimaniae* ssp. *sterilis* which is said to differ in forming colonies of many small compact rosettes with downward-pointing, barely fibrous leaves, and in propagating vegetatively only. The published description and photographs conform to *Y. harrimaniae* ssp. *sterilis* except for the

production of fruits and seeds; *Y. feeanoukiae* may represent the fertile taxon from which the former evolved.

**Y. filamentosa** Linné (Spec. Pl. [ed. 1], 1: 319, 1753). **Type** [lecto]: USA, Virginia (*Clayton* 720 [BM]).—**Lit**: Hess & Robbins (2002); Hochstätter (2002a: 274–278, ills. pp. 281–290); Ward (2011: with ills.). **Distr**: E USA (S Maryland, S West Virginia, Virginia, E Tennessee, North Carolina, C & S Mississippi, Alabama, Georgia, South Carolina, C & S Louisiana, N & C Florida); sandy soils; flowers June to July; naturalized in France, Italy, Turkey and New Zealand. **I**: Curtis's Bot. Mag. 23: t. 900 (1806); Curtis's Bot. Mag. 53: t. 2662 (1826, as *Y. glauca* Noisette ex Sims); Refug. Bot. 5: t. 315 (1872, as *Y. glauca* Noisette ex Sims); Hochstätter (2001a: 8–9); Hochstätter (2002a: 36–39); Boeuf (2007a: 64); Boeuf & al. (2009: 56–57).

**Incl.** *Yucca glauca* Noisette ex Sims (1826) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca filamentosa* var. *mexicana* S. Schauer (1847); **incl.** *Yucca filamentosa* var. *maxima* Carrière (1860); **incl.** *Yucca filamentosa* var. *media* Carrière (1860); **incl.** *Yucca filamentosa* var. *patens* Carrière (1860); **incl.** *Yucca filamentosa* var. *ramosa* Carrière (1860); **incl.** *Yucca filamentosa* var. *variegata* Carrière (1860)  $\equiv$  *Yucca filamentosa* fa. *variegata* (Carrière) Trelease (1902); **incl.** *Yucca filamentosa* var. *recurvifolia* Alph. Wood (1861); **incl.** *Yucca filamentosa* var. *bracteata* Engelm. (1873); **incl.** *Yucca filamentosa* var. *laevigata* Engelm. (1873); **incl.** *Yucca filamentosa* var. *latifolia* Engelm. (1873); **incl.** *Yucca filamentosa* fa. *genuina* Engelm. (1873) (*nom. inval.*, ICN Art. 24.3); **incl.** *Yucca filamentosa* [?] *foliis-aureovariegatis* Pynaert (1886) (*nom. inval.*, ICN Art. 23.1); **incl.** *Yucca filamentosa* var. *bicolor* hort. ex Trelease (1902); **incl.** *Yucca filamentosa* var. *elmensis* Sprenger (1906); **incl.** *Yucca filamentosa* var. *nobilis* Sprenger (1906).

[3c] Acaulescent and stems mostly (almost) none, hidden by the leaves when present, or rarely caulescent and stems to 0.5 m, stems always simple; **Ros** stoloniferous and clump-forming; **L** erect to spreading, lower ones often becoming

reflexed near the middle, lanceolate, flexible, thin, usually soft and limp, distinctly narrowed towards the base, widest near the middle, rather abruptly tapering and furrowed towards the tip, scabrous, 50–75  $\times$  2–4 cm, green or slightly glaucous, margins entire, otherwise splitting into stout, long and curled fibres, inrolled at the tip, tip occasionally somewhat pungent; **Inf** erect, paniculate, peduncle 1–3 m, <2.5 cm  $\varnothing$ , flowering part 0.75–1.5 cm, ovoid, well above the rosette leaves, glabrous; **Fl** pendent, globose, 50–70 mm; **Tep** ovate, abruptly short-mucronate, 50–70  $\times$  20–30 mm, white, sometimes tinged with cream, green or rarely brown, glabrous; **Fil** 20–22 mm; **Ov** 15–30 mm; **Sty** elongated, white; **Sti** lobed; **Fr** erect dry capsules, oblong, 38–50  $\times$  20 mm; **Se** thin, flat, winged, 6 mm  $\varnothing$ , dull black.—**Cytology**:  $n = 30$  (Watkins 1936),  $2n = 60$  (Satô 1935, McKelvey & Sax 1933).

The lectotype cited above was designated by Fernald (1944: 8, t. 808: fig. 1). Many slightly different variants have been described but are rarely recognized in recent literature. Very close to and possibly not distinct from *Y. flaccida* (see there for differences, and also Ward 2011).—Hardy outdoors in C Europe and many cultivars are widely cultivated, including variegated forms (Irish & Irish 2000: 247, Guillot Ortiz & Meer 2008: 49–55, Boeuf & al. 2009: 122–125, Boeuf & al. 2010: 58–62, Boeuf & Heim 2014: 22–24). It has become naturalized in France, Italy, Turkey (Euro+Med 2006+: accessed Dec. 2018), and New Zealand (Zimer 2014).

In 18 sampled populations, considerable genetic variation was found, and on average 83% of the total genetic variation was found within populations (Massey & Hamrick 1998). The peak flowering time is later than the peak pollinator activity, larger inflorescences attract more pollinators, and the fruit set may be impacted by the intensity of herbivory damage to the flowers (Althoff & al. 2005). The Bogus Yucca Moth larvae (*Prodoxus decipiens*) feed in the peduncle tissue, but its presence does not appear to affect the reproductive fitness negatively (Althoff & al. 2004). The floral volatiles show low variations between populations, indicating highly

selective attraction by the obligate pollinating moths (Svensson & al. 2005).

**Y. filifera** Chabaud (Rev. Hort. (Paris) 48: 432–434, fig. 97, 1876). **Type**: [lecto—icono]: l.c. fig. 97.—**Lit**: Matuda & Piña Luján (1980: 100, 102–104, with ills.); McVaugh (1989: 281–282, with ills., as *Y. australis*); Robbins (1983: 19–22, 46–48); Fontaine (2013: with ills.). **Distr**: C Mexico (S Coahuila, W & S Nuevo León, SW Tamaulipas, NE Zacatecas, Aguascalientes, N, C & SW San Luis Potosí, NE Jalisco, N & NE Guanajuato, C & S Querétaro, W Hidalgo, NE Michoacán, N México, Distrito Federal); plains with arid desert scrub, 450–2400 m; flowers April to May. **I**: Curtis's Bot. Mag. 117: t. 7197 (1891); Piña Luján (1980: 280); Boeuf & al. (2009: 58–59).

≡ *Yucca canaliculata* var. *filifera* (Chabaud) Fenzi (1889) ≡ *Yucca baccata* var. *filifera* (Chabaud) Schelle (1903); **incl.** *Yucca baccata* var. *australis* Engelm (1873) ≡ *Yucca australis* (Engelm) Trelease (1892).

[1c] Arborescent, stems to 6–10 (–13) m tall, much-branched, old plants with up to 40 **Br**, crown relatively open, trunk short, to 1.5 m Ø, first branch often at ground level, stems 7.4–25.8 cm Ø below the rosettes; **L** linear-oblancoolate, constricted near the base, rigid, generally asperous on both faces, 18–60 × 1.3–3.9 cm, margins often with numerous fine, spiralled, white detaching fibres, esp. on young leaves, **terminal Sp** stout, 10–30 mm, dark; **Inf** pendent, paniculate, peduncle 19–39 cm, flowering part 27–148 cm, ± cylindrical, nearly always beyond the rosette leaves, obscurely puberulent to glabrous; **Ped** to 27 mm; **Fl** 30–57 mm; **Per** white to cream, **OTep** 30–55 × 7–25 mm, **ITep** 30–57 × 14–28 mm; **Fil** 10–26 mm, puberulent; **Ov** 13–28 × 4–10 mm; **Sty** 1–4 mm; **Fr** fleshy berries, pendent, oblong, 27–88 × 12–33 mm, beak 2–16 mm, with the flavour and consistency of dates; **Se** somewhat rugose, 1–4 mm thick, 5–9 mm Ø.

The neotypification by Hochstätter (2003b: 110) is superfluous, since the illustration accompanying the protologue (Chabaud 1876: fig. 97) is available; it is **here formally designated as**

**lectotype**.—This is the most widely distributed Mexican species, first reported by Josiah Gregg in 1844 (Fontaine 2013: 37), and it forms an important element of the tree stratum of the Chihuahuan Desert scrub of C Mexico (Matuda & Piña Luján 1980). The characteristic pendent inflorescences distinguish it from other arborescent species in the area (except *Y. potosina*, see there). The extremely sweet fruits (Hoxey 2011) are eaten fresh, cooked or dried (Fontaine 2013: 39) and are usually curved in the middle, but may also have a distal constriction (Villavicencio & Pérez-Escandón 1995; see also introduction). In molecular phylogenies (Pellmyr & al. 2007, Smith & al. 2008a), the species groups as sister of *Y. jaliscensis* in most analyses. See also under *Y. potosina*.

The seeds remain viable for at least 4 years after harvesting with somewhat reduced germination rates, but seeds 14 years old showed no germination (Cambrón-Sandoval & al. 2013). Seeds in habitat show high germination rates independent of warming treatment and season (Aragón-Gastélum & al. 2018).

**Y. flaccida** Haworth (Suppl. Pl. Succ., 34–35, 1819). **Type** [neo]: USA, Florida (Ward 10736 [FLAS, FSU, FTG, GA, MO, NCU, NY, TEX, USF]).—**Lit**: Hess & Robbins (2002); Diggs & al. (2006: 416–417, ills. p. 419, as *Y. louisianensis*). **Distr**: Canada (S Ontario), NE, E and SE USA (Wisconsin, Michigan, Illinois, Kansas, Missouri, Indiana, Ohio, Pennsylvania, Maryland, Oklahoma, Arkansas, Tennessee, North Carolina, E Texas, Louisiana, Mississippi, Alabama, Georgia, South Carolina, Florida); (semi-) open sites in pine scrub or pine-hardwood woodland, old fields and coastal sands; flowers May to July. **I**: Curtis's Bot. Mag. 103: t. 6316 (1871); Refug. Bot. 5: t. 323 (1872); Hochstätter (2002a: 291–296); Hochstätter (2002c: 41–43); Boeuf (2007a: 65); Boeuf & al. (2009: 60–61, 74–75 as *Y. louisianensis*).

B. Ward (2004); **incl.** *Yucca freemanii* Shinnery (1951)  $\equiv$  *Yucca arkansana* ssp. *freemanii* (Shinnery) Hochstätter (2000).

[3c] Caespitose, forming small colonies, erect, acaulescent or rarely stems to 0.3 m, simple; **Ros** stoloniferous, usually small, dying slowly after flowering; **L** lanceolate, erect, thin, rigid or soft and limp, gradually tapering towards the tip, flattened, arching or curved in the middle with age,

glabrous on both faces, 40–80  $\times$  1–4 (–5) cm, widest near the middle, margins entire, filiferous, terminal **Sp** pungent; **Inf** erect, paniculate, peduncle 0.5–2.75 m, mostly pubescent, flowering part 0.4–1.5 m, narrowly ovoid, arising beyond the rosette leaves, part-**Inf** ascending, to 25 cm, mostly pubescent; **Ped** 15–30 mm; **Fl** pendent, 40–50 mm; **Tep** lanceolate to elliptic, 30–50  $\times$  10–30 mm, white, creamy-white or light greenish-white, mostly pubescent, tips obtuse; **Fil**  $\pm$  20 mm; **Ov** 15 mm, pale green; **Sty**  $\pm$  8 mm, greenish-white to white, papillate; **Sti** diverging; **Fr** erect dehiscent capsules, oblong, inversely pear-shaped or conical, to 35–40  $\times$  15–20 mm; **Se** thin, 6–8  $\times$  5–6 mm, dull black.—**Cytology**: 2n = 60 (McKelvey & Sax 1933, Watkins 1936: as *Y. louisianensis*).

The neotypification by Hochstätter (2001a: 12) was ineffectively published under ICN Art. 7.11. Ward (2006) validly designated a neotype as given above, and treats *Y. recurva* Haworth as synonym of *Y. gloriosa*, and *Y. concava* Haworth as synonym of *Y. filamentosa*.

Very close to and probably better regarded as a variety of *Y. filamentosa* from which it differs mainly in its thinner, narrower leaves, mostly pubescent inflorescences with tepals 30–50 mm (vs. thicker, rigid leaves and glabrous inflorescences with tepals 50–70 mm in the latter) (Hess & Robbins 2002). Ward (2011: 224–225) applies additional characters to distinguish both species.

The synonymous *Y. freemanii* was described for glabrous plants from NE Texas and SW Arkansas, but some plants otherwise attributable to *Y. freemanii* are mostly pubescent throughout the inflorescence and fall within the variation of *Y. flaccida* (Hess & Robbins 2002). *Y. louisianensis*, synonymized here following Hess & Robbins (2002), was considered as a possible synonym of *Y. constricta* by McKelvey (1947), whereas Hochstätter (1998) treats it as a subspecies of *Y. arkansana*. Molecular data (Clary 1997, cited by Hess & Robbins 2002) indicate that *Y. louisianensis* is genetically distinct and more closely related to *Y. filamentosa* than to *Y. flaccida*. In recent molecular studies (Pellmyr & al. 2007, Smith & al. 2008a), two samples of *Y. louisianensis* place separate from

each other and group mostly with *Y. glauca*, or with *Y. filamentosa* (*Y. flaccida* s.s. not sampled).

Variegated forms are reported from cultivation in Europe (Boeuf & al. 2010: 62–64, Guillot Ortiz & Meer 2008: 59–60, ill. p. 105, Boeuf & Heim 2014: 22–24) and the USA (Irish & Irish 2000: 251).

**Y. gigantea** Lemaire (Ill. Hort. 6 (Misc.): 91, 1859). **Type:** not typified.—**Lit:** Trelease (1898: 141–144, tt. 40–42); Trelease (1902: 71–72); Smith & Figueiredo (2016: with ills.). **Distr:** Probably cultivated only.

≡ *Yucca elephantipes* var. *gigantea* (Lemaire) Molon (1914) (*nom. inval.*, ICN Art. 35.1).

[1c] Arborescent, with massive trunk or stems 3–10 m or more, base of trunk often straight and hardly swollen, angled because of buttress-like projections, richly branched in the upper parts, branches brittle, with large, broad, arcuate-cordiform leaf scars; **L** numerous, horizontal, lower ones pendent, oblong-lanceolate, flat or slightly canaliculate, > 100–140 × 8–10 cm, brilliant green, tip acute, margins finely membranous, slightly roughened, not filiferous; **Inf** erect, paniculate, flowering part ±65 cm, 50 cm Ø, candle flame-shaped, dense, surpassing the rosette leaves with the upper ½ or more, with 12–15 part-**Inf** with 7–10 flowers each, to 25 cm; **Fl** pendent, campanulate to open-spreading, ± 90 mm, ± 180 mm Ø; **Tep** oblong, narrow, long acuminate, tip apiculate, hood-like, incurved, papillose on the outer face, ± 90 × 25 mm, white; **Fil** 8–10 mm; **Ov** oblong, ± 22 × 10 mm; **Sti** recurved, papillose; **Fr** fleshy berries, resembling those of *Y. gloriosa* but not further described; **Se** not described.

In modern treatments mostly included in *Y. guatemalensis* (as *Y. elephantipes*), but recently re-established as a species of its own right by Smith & Figueiredo (2016). It differs from the latter in its massive size, a trunk straight and hardly swollen at the base, brittle branches, leaves longer than 1 m, and a candle flame-shaped inflorescence with larger flowers (vs. medium to large size, an enlarged, fat-footed trunk, sturdy branches, leaves usually less than 1 m, and a

more open, egg-shaped inflorescence with smaller flowers (Smith & Figueiredo 2016).

Apparently known from cultivation only and possibly a hybrid of *Y. guatemalensis* (Trelease 1902: 71, as *Y. elephantipes*); fruits, flowers, and seeds resemble *Y. gloriosa* (Trelease 1898: 142). No complete description exists, and the above data were mainly taken from the protologue and Trelease (1898). The species forms ripe fruits in cultivation in the absence of yucca moths (Trelease 1898: 142) (also found in *Y. aloifolia*). Most records and photographs of wild, cultivated, and naturalized plants labelled *Y. gigantea* apparently belong to *Y. guatemalensis*.

**Y. glauca** Nuttall (Cat. Pl. Upper Louisiana no. 89, 1813). **Type** [neo]: USA, Montana (*Hochstätter* 1178.69 [SRP]).—**Lit:** Benson & Darrow (1981: 49, with ill.); Hess & Robbins (2002); Hawker (2016: 353–357, 359, with ills.). **Distr:** S Canada (SE Alberta), USA (Montana, North Dakota, South Dakota, Wyoming, Nebraska, Iowa, Colorado, Kansas, Missouri, New Mexico, Oklahoma, Texas); common in Great Plains grasslands, badlands and mountains, 500–2600 (–2800) m; flowers May to July. **I:** Curtis's Bot. Mag. 48: t. 2222 (1821, as *Y. stricta*); *Hochstätter* (1998: 76–78); *Hochstätter* (2000: 104–105); Boeuf (2007a: 66); Boeuf & al. (2009: 62–63).

M. Andrews (1937); **incl.** *Yucca glauca* var. *gurneyi* McKelvey (1947) ≡ *Yucca glauca* ssp. *gurneyi*

(McKelvey) Hochstätter (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Yucca glauca* fa. *montana* Hochstätter (1998) (*nom. inval.*, ICN Art. 38.1a); **incl.** *Yucca glauca* ssp. *albertana* Hochstätter (2000).

[3c] Stems none or short and to 40 cm, erect, occasionally branched; **Ros** first single but soon clump-forming, 1–15 per colony, colonies dense, 0.8–2.5 m Ø; **L** divergently spreading, linear to linear-lanceolate, rigid, plano-convex, widest near the middle, occasionally triquetrous or nearly flat, striate, 40–60 × 0.8–1.2 cm, pale green, margins entire, white or greenish-white, soon finely filiferous, apex blunt, or with a short acute brownish **terminal Sp**; **Inf** erect, racemose, occasionally paniculate proximally, peduncle 0.2–0.5 m, flowering part 0.5–1 m, from between or just beyond the rosette leaves, branches usually none or rarely few, abortive at the base; **Fl** pendent, globose or campanulate; **Tep** elliptic, acute, 50–53 × 26–35 mm, greenish-white to white, commonly tinged with purple and shiny; **Fil** 17–19 mm, white; **Ov** obovoid, 20 × 9–13 mm, white or rarely greenish-white, abruptly terminating into the style; **Sty** dark green, 10 mm; **Sti** lobed; **Fr** erect dry capsules, cylindrical to obovoid, rarely constricted, 50–80 (–90) × 30–45 (–50) mm, beaked; **Se** thin, with broad marginal wing, 7–9 × 8–10 mm, black, slightly glossy.—**Cytology**: 2n = 60 (Watkins 1936).

Hochstätter (1998: 74) provided a somewhat cryptic neotypification for this name. His measurements partly differ considerably from those of Webber (1953) and Hess & Robbins (2002) reproduced here. Webber (1953) suggested hybridisation of *Y. glauca* with *Y. baileyi*, *Y. elata*, *Y. constricta* and *Y. angustissima*. *Y. glauca* and *Y. arkansana* are very similar. The leaves of *Y. glauca* are uniform in size, rigid, linear or linear-lanceolate, and up to 1.2 cm wide, while mature leaves of *Y. arkansana* are generally somewhat flexible, lanceolate, and to 2.5 cm wide, and the young leaves immediately surrounding the peduncle are distinctly shorter than the outer leaves (Hess & Robbins 2002). The molecular data of Clary (1997, cited by Hess & Robbins 2002) do not confirm the close relationship between *Y. glauca* and *Y. arkansana* suggested by the morphological characters. Three accessions of *Y. glauca* variously

group together with *Y. constricta*, *Y. louisianensis* and *Y. arkansana* in the molecular AFLP phylogenies of Pellmyr & al. (2007) and Smith & al. (2008a). *Y. glauca* ssp. *albertana* from Canada differs in minor quantitative features only that fall well within the variability of the species given by Webber (1953). The inflorescences of *Y. glauca* are primarily racemose, but may occasionally be paniculate proximally, and such plants were given varietal names. *Y. glauca* is the most widely distributed North American *Yucca* and represents a characteristic element of the prairie grassland plains in the mid-western USA. It is the most cold-hardy form of any *Yucca* (Irish & Irish 2000: 253).

**Y. gloriosa** Linné (Spec. Pl. [ed. 1], 1: 319, 1753). **Type**: L 0052810: Herb. Adriaan van Royen No. 913.62–412.—**Distr**: SE USA (North Carolina, Mississippi, Alabama, Georgia, South Carolina, Louisiana, Florida).

**Incl.** *Yucca gloriosa* fa. *genuina* Engelmänn (1873) (*nom. inval.*, ICN Art. 24.3).

The lectotype cited above was designated by Ferrer-Gallego & al. (2015). The earlier designation of a type (lectotype) by Hochstätter (2002d: 90) is ineffectively published under ICN Art. 7.11. *Y. gloriosa*, usually placed in Sect. *Yucca*, differs from all other species in that section in its indehiscent fruits which are corky-leathery rather than fleshy. Based on morphology, Trelease (1902: 87) suggested that the species may be a hybrid between *Y. aloifolia* and *Y. filamentosa*. Recent molecular data of Rentsch & Leebens-Mack (2012) indeed provide strong support that *Y. gloriosa* originated as homoploid intersectional hybrid *Y. aloifolia* × *Y. filamentosa* (also explaining its intermediate fruit type), but leave it unclear whether it is of single or multiple origins.—Vernacular name: “Mound Lily Yucca” (Ward 2004).

Probably the most widely grown *Yucca* species with many cultivars, hybrids and selections, including variegated forms. For the cultivation in Europe, see Heim & Lorek (2008), and in the USA, see Irish & Irish (2000: 254–257).

**Y. gloriosa** var. **gloriosa** — **Lit**: Trelease (1902: 72–76, tt. 43–46); Hess & Robbins

(2002: with ills.); Hochstätter (2002a: 35–38, ills. pp. 134, 136). **Distr:** SE USA (North Carolina, South Carolina, Georgia); coastal dunes near sea-level, uncommon; flowers July to September; locally naturalized in Spain, Portugal, France, Italy, Turkey and India. **I:** Curtis's Bot. Mag. 31–32: t. 1260 (1810); Refug. Bot. 5: t. 320 (1872); Hochstätter (2002d: 90).

K. Koch (1873); **incl.** *Yucca gloriosa* var. *plicata* Engelmann (1873) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca gloriosa* var. *mediopicta* Carrière (1880); **incl.** *Yucca gloriosa* var. *mediostriata* Planchon (1880) ≡ *Yucca gloriosa* fa. *mediostriata* (Planchon) Trelease (1902); **incl.** *Yucca gloriosa* var. *superba* Baker (1880) ≡ *Yucca gloriosa* fa. *superba* (Baker) Trelease (1902).

[1c × 3e] Caulescent to arborescent, simple or more often branching near the stem tips and forming colonies, stems erect, to 5 m; **L** mostly erect, ascending, straight, rigid, becoming more flexible with age, thin, lanceolate, somewhat narrowed towards the base, plano-convex, smooth on both faces, 40–70 × 4–6 cm, glaucous, margins entire or roughly and minutely denticulate, often becoming filiferous, fibres straight, brown, opaque; **Inf** erect, paniculate, peduncle 0.9–1.5 m, flowering part ovoid to ellipsoid, 0.75–1.2 m, to 45 cm broad, extending 0.4–0.5 m beyond the rosette leaves, glabrous or occasionally pubescent; **Ped** to 20 mm; **Fl** pendent, globose to campanulate; **Tep** oblong-lanceolate, 40–50 × 20–25 mm, white to creamy-white; **Fil** ± 26 mm, granular or powdery, pubescent; **Ov** ± 28 mm, light green; **Sty** ± 9 mm; **Sti** separate; **Fr** berry-like, indhiscent-leathery and not fleshy, pendent, elongate, 6-winged or 6-ribbed, 55–80 mm; **Se** ovate, thin, 5–8 mm Ø, shiny black.—**Cytology:** 2n = 60 (Bhattacharya & Dutta 1978).

Many forms now sunk in synonymy have been named based on slight differences in habit and leaf morphology. Var. *gloriosa* differs from var. *tristis* in its mostly erect, rigid leaves (vs. mostly recurving, flexible), its inflorescences extending well beyond the rosettes (vs. inflorescences barely extending), and its pendent larger fruits 55–80 mm (vs. mostly erect fruits 25–45 mm) (Hess & Robbins 2002). Ward (2004) records the taxon from Virginia (as *Y. gloriosa*), but later (Ward 2011: 223) gives the plants as cultivated only. Variegated cultivars are shown by Boeuf & al. (2010: 65–70) and Boeuf & Heim (2014: 24–27). *Y. ellacombei* hort. ex Baker (1870) represents another name for the horticultural selection *Y. gloriosa* ‘Nobilis’.

Locally established as neophyte in Spain (López-Pujol & Guillot Ortiz 2014a, Aymerich 2015), Portugal (Verloove & Alves 2016, Almeida 2018: 272), France, Italy, Turkey (Euro+Med 2006+: accessed Dec. 2018), and India (Howes 1946), where it is used as hedge plant.

**Y. gloriosa** var. **tristis** Carrière (Rev. Hort. (Paris) 1859: 363–364, 1859). **Type:** not typified.—**Lit:** Trelease (1902: 76–78, tt. 46–47, as *Y. recurvifolia*; 78–81, t. 47, as *Y. flexilis*); Hess & Robbins (2002); Hochstätter (2002a: 38–40, ill. pp. 132, 135, 137, as *Y. recurvifolia*); **Distr:** SE USA (SE Louisiana, S Mississippi, S Alabama, S Georgia, NW & N Florida); coastal dunes of Gulf coast plains, in sandy soils, 0–100 m; flowers April to May; locally naturalized in Texas (USA), Spain and Italy. **I:** Hochstätter (2002d: 92, as *Y. recurvifolia*).

[1c × 3c] Differs from var. *gloriosa*: **L** mostly recurved, flexible; **Inf** barely extending beyond the rosettes; **Fr** mostly erect, 25–45 mm.—**Cytology:** 2n = 60 (Satô 1935: as *Y. recurvifolia*).

Insufficiently known and probably not distinct from var. *gloriosa* (Hess & Robbins 2002). The taxon has also been treated at the rank of species or forma based on the name *Y. recurvifolia*. The record of “*Yucca gloriosa*” from Pinellas County (Sorrie & LeBlond 2008: 1354), the third county record from Florida and the only one from the W coast of the peninsula, may belong here. Variegated cultivars are presented by Sprenger (1920b), Irish & Irish (2000: 261–262), Boeuf & al. (2010: 70–77), and Boeuf & Heim (2014: 24–27) (all as *Y. recurvifolia*). See also under *Y. thompsoniana*.

The taxon is locally naturalized in Texas (Diggs & al. 2006: 416, as *Y. gloriosa* var. *recurvifolia*), Spain (López-Pujol & Guillot Ortiz 2014a: as *Y. recurvifolia*), and Italy (Afferni 2003: as *Y. recurvifolia*).

**Y. grandiflora** Gentry (Madroño 14: 51–53, 1957). **Type:** Mexico, Sonora (Gentry 11601 [US, ARIZ, MEXU]).—**Lit:** Gentry (1972: 162–165); Matuda & Piña Luján (1980: 71–73); Hochstätter (2004a: 20, 86); all with ills. **Distr:** N Mexico (E & SE Sonora, W-most Chihuahua); grassy slopes in open woodland, on volcanic or limestone rocks, 600–1350 m; flowers February to May. **I:** Hochstätter (2003c: 153); Boeuf & al. (2009: 66–67).

[1b] Arborescent, stems branched at the base and above into few rosettes, 4–6 m, with a long skirt of dried deflected leaves often reaching down to the ground; **L** ascending to descending, rather flexible, slightly narrowed above the base, smooth on both faces, 70–100 (–140) × 4–5 (in the middle) cm, dark green, margins narrow, brown, filiferous with long fine brittle fibres, **terminal Sp** stout, broadly grooved, (chestnut-) brown; **Inf** erect, peduncle 10–30 cm, glabrous below, flowering part 0.5–1 m, open, part-**Inf** horizontal or slightly ascending, densely white-tomentose, with dull white scarious **Bra**; **Ped** short to nearly none; **Fl** erect or divergent; **Tep** spreading, ovate, thin, bluntly mucronate, connate at the base, 60–100 × 18–27 mm, **OTep** slightly smaller and thicker than the **ITep**, creamy-white; **Fil** 45–48 mm, hyaline-pubescent; **Ov** elongate, slender, deeply sutured, 45–60 mm; **Sty** ± 5 mm, forming a short beak below the stigma; **Sti** deeply lobed; **Fr** fleshy berries, cylindrical, large, 100–200 × 30–50 mm, with a short beak, brown when ripe; **Se** variable, 3–8 mm.

The holotype consists of two sheets which are not cross-labelled. According to the protologue the species differs from all other species in its large, nearly sessile flowers on tomentose part-inflorescences. It resembles *Y. madrensis* (as *Y. schottii*) in its arborescent habit, long, flexible, broad leaves and its pubescent inflorescences, but has otherwise little similarity with the latter (Gentry 1972: 162). The species shows a close

relationship with *Y. arizonica* (here treated as *Y. baccata* ssp. *thornberi*) in its arborescent habit and large flowers and fruits (Gentry 1972: 162). Martin & al. (1998: 471) provide a new record from W-most Chihuahua and report that the fruits are eaten raw or roasted. Plants from Bacanora previously assigned here (Gentry 1972: figs. 63 & 64, Matuda & Piña Luján 1980: 73, at least upper fig., Piña Luján 1980: fig. 4) are *Y. declinata*.

**Y. guatemalensis** Baker (Refug. Bot. 6: t. 313 + text, 1872). **Type:** sine loco (*Ehrenberg* s.n. [HAL [ex cult. England]]).—**Lit:** Trelease (1902: 94–96, tt. 51, 82, as *Y. elephantipes*); Matuda & Piña Luján (1980: 104–107, with ills., as *Y. elephantipes*); Lott & García-Mendoza (1994: online version with ills.); Robbins (2001: online version with ills.); Hammel & al. (2003: 34); Smith & Figueiredo (2016: with ills.). **Distr:** Native: Mexico (Chiapas) and possibly Guatemala; probably cultivated only: Mexico (Veracruz, Yucatán), Belize, Guatemala, El Salvador, Honduras, Nicaragua, Costa Rica, Panama; in tropical deciduous forests, 0–2700 m; flowering February to July; locally naturalized in Portugal, Spain, the Balears, and New Zealand. **I:** Curtis's Bot. Mag. 131: t. 7997 (1905); Piña Luján (1980: 280, as *Y. elephantipes*); Hochstätter (2003e: 267–268, as *Y. elephantipes*); Boeuf & al. (2009: 50–51, as *Y. elephantipes*); Ondrovic (2018: as *Y. elephantipes*).

**Incl.** *Yucca elephantipes* hort. ex Regel (1859) (*nom. inval.*, ICN Art. 36.1b) ≡ *Sarcococca elephantipes* (hort. ex Regel) Lindinger (1933) (*nom. inval.*, ICN Art. 36.1b); **incl.** *Dracaena ehrenbergii* hort. ex Baker (1875) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Dracaena lenneana* hort. ex Baker (1875) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca mooreana* Hort. *ghiesbreghtii* (Baker) Molon (1914) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca roezlii* hort. ex Baker (1880) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca mazellii* Hort. Dognin ex André (1883); **incl.** *Yucca eleana* Hort. Dognin ex W. Watson (1889) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca elephantipes* Regel ex Trelease (1902) (*nom. illeg.*, ICN Art. 52.1).

[1c] Arborescent, stems 3–10 m, usually numerous from a thickened-inflated trunk-like base, slender and densely branched in the upper parts, bark rough; **L** patent, narrowed to 1.5–2 cm above the base, flat or slightly canaliculate, lower face sometimes rough, upper face smooth, (35–) 50–100 × 5–7 cm, brilliant dark green, margins finely denticulate, with a yellow border, not filiferous, tip acute, soft, green; **Inf** erect, paniculate, peduncle short, flowering part dense, surpassing the rosette leaves with ± the upper  $\frac{3}{4}$ , glabrous; **Fl** pendent, globose; **Tep** narrowly ovate, **ITep** somewhat broader than the **OTep**, 30–50 × (10–) 15–20 mm, white to whitish; **Fil** 8–10 mm; **Ov** oblong, not constricted at the base, 10–15 mm; **Sty** short, oblong; **Fr** fleshy berries, ellipsoid, 70–80 × 45 mm, pulp greenish to whitish; **Se** nearly circular, 8–10 mm Ø.

Unfortunately, the widely used name *Y. elephantipes* was not validly published (Smith & Figueiredo 2016). Lott & García-Mendoza (1994) instead use the homotypic replacement name *Y. guatemalensis* Baker.—Widely cultivated as an ornamental in (sub-) tropical gardens, esp. also as variegated cultivars (Boeuf & al. 2010: 53–58, Guillot Ortiz & Meer 2008: 42–45, Boeuf & Heim 2014: 20–22, all as *Y. elephantipes*). The flowers are reportedly edible. *Y. gigantea*, in modern treatments mostly included in *Y. guatemalensis*, was recently re-established as a species of its own right (for differences see there). Most records and photographs of wild, cultivated, and naturalized plants apparently belong here and not to *Y. gigantea*. It has become locally naturalized in Portugal (Almeida 2018: 272, as *Y. gigantea* (*Y. elephantipes*)), Spain (López-Pujol & Guillot Ortiz 2014b: as *Y. gigantea* (*Y. elephantipes*)), the Balears (Sáez & al. 2016: 126), and New Zealand (Zimer 2014: as *Y. gigantea* (*Y. elephantipes*)).

**Y. harrimaniae** Trelease (Annual Rep. Missouri Bot. Gard. 13: 59, tt. 28–29, 83: fig. 10, 93: fig. 1, 1902). **Type** [lecto]: USA, Utah (*Trelease* s.n. [MO]).—**Lit**: Reveal (1977: 530–532, with ills.); Hochstätter (2000: 31–38, ills. pp. 84–92, p.p. as *Y. nana*); Schönherr (2017: p.p. as *Y. nana*); all with ills. **Distr**: SW USA.

The protologue cites specimens collected by Parry, Jones, Trelease and Baker. McKelvey (1947: 141) designated a range of specimens at MO (“148567–148572”) of an unnumbered collection by Trelease from 1901 as “type”.

**Y. harrimaniae** ssp. **harrimaniae** — **Lit**: Reveal (1977: 530–532, with ills.); Welsh & al. (1987: 649–650); Hochstätter (2000: 32–33, 36, ills. pp. 84, 86–88, 91, p.p. as ssp. *gilbertiana*); Hess & Robbins (2002: as *Y. harrimaniae*); Hawker (2016: 357–365, with ills., as *Y. harrimaniae*). **Distr**: W USA (E-C Nevada, N & C Utah, W & SW Colorado, N Arizona, NW New Mexico); desert slopes, foothills and plateaus, limestone and volcanic outcrops, usually 1000–2500 m; flowers April to July. **I**: Hochstätter (1998: 223, as *Y. harrimaniae*); Boeuf (2007a: 68, as *Y. harrimaniae*); Boeuf & al. (2009: 68); Schönherr (2017: 38, 39, 41, 45, as *Y. harrimaniae*).

**Incl.** *Yucca harrimaniae* var. *gilbertiana* Trelease (1907) ≡ *Yucca gilbertiana* (Trelease) Rydberg (1918) ≡ *Yucca harrimaniae* ssp. *gilbertiana* (Trelease) Hochstätter (2000); **incl.** *Yucca coloma* Andrews (1926); **incl.** *Yucca nana* Hochstätter (1998).

[3b] Stems none or short, to 0.3 m; **Ros** asymmetrical or symmetrical, 30–80 cm Ø, caespitose, forming dense to open colonies of 3–20 rosettes and 0.25–1.5 m Ø, rhizomes short; **L** linear or spatulate-lanceolate, straight, canaliculate, rigid, widest near the middle, (7.5–) 30–50 × (0.6–) 1.8–4.3 cm, pale green, margins entire, soon separating into long fine to coarse curly fibres, white or brown, tip tapering gradually to a short pungent ivory-coloured **terminal Sp**; **Inf** erect, racemose or rarely paniculate and proximally with few short part-**Inf**, peduncle 10–20 cm, flowering part 35–70 cm, arising within or just beyond the rosette leaves, glabrous; **Ped** 10–20 mm; **Fl** pendent, broadly campanulate; **Tep** broadly lanceolate,

40–50 (–53) × 16–34 mm, **ITep** broader than the **OTep**, yellow or greenish-yellow, usually tinged purple, basally connate to form a tube 2–4 mm long; **Fil** 16–28 mm; **Ov** 15–20 mm, pale green; **Sty** pale to bright green, 9–13 mm; **Sti** lobed; **Fr** erect dry capsules, cylindrical, usually deeply constricted towards the middle, 30–50 (–55) × 20–30 mm; **Se** thin, 5–8 × (3.5–) 4–8 mm, dull black.

No *Yucca* in the SW USA is more diverse in form (Hawker 2016: 357). *Y. neomexicana* was included in *Y. harrimaniae* by McKelvey (1947: 139) and Reveal (1977: 530), who gave it varietal status. According to the early molecular data of Clary (1997; cited by Hess & Robbins 2002), *Y. harrimaniae* and *Y. neomexicana* are not related at all, and *Y. neomexicana* was re-established as a species of its own (Hess & Robbins 2002). *Y. nana*, popular in horticulture as the smallest of all yuccas (Hochstätter 1998, Mattern 1999, Boeuf & al. 2009: 80–81, Schönherr 2017, all as *Y. nana*), is dismissed by most botanists as a small-growing local variant from the upper altitudinal and lower size range within this variable taxon (Hawker 2016: 364–365).

**Y. harrimaniae** ssp. **sterilis** (Neese & S. L. Welsh) Hochstätter (Cactaceae Rev. 1(2): 21, 1999). **Type:** USA, Utah (*Welsh* 18461 [BRY, ASU, NY]).—**Lit:** Neese & Welsh (1986); Hochstätter (1998: 225–226, as var.); Hochstätter (2000: 35, ill. pp. 86, 90); the latter two with ill. **Distr:** SW USA (NE Utah: Uintah Basin); salt desert shrub communities, 1470 m. **I:** Boeuf & al. (2009: 69); Utah Native Plant Society (2003–2016: accessed Dec. 2018).

≡ *Yucca harrimaniae* var. *sterilis* Neese & S. L. Welsh (1986) ≡ *Yucca sterilis* (Neese & S. L. Welsh) S. L. Welsh & L. C. Higgins (2008).

[3b] Differs from ssp. *harrimaniae*: Rhizomes long and **Ros** often widely spaced; **L** flaccid, often reclining on the ground, typically curved, margins sparingly or not filiferous; **Fr** not known to be formed.

A geographically isolated subspecies not known to produce fruits and reproducing exclusively vegetatively by rhizomes. Its status is much disputed: Hess & Robbins (2002) do not

recognize it as separate entity, Welsh & al. (1987: 650), Hochstätter (1998: 225–226, 2000: 35) and the first edition of this handbook recognize it at infraspecific rank (variety or subspecies), while Welsh & al. (2008: 779) and Govaerts (2014+: accessed Dec. 2018) treat it at species rank. See also under *Y. feeanoukia*.

**Y. intermedia** McKelvey (*Yuccas* Southwest US, 2: 116, tt. 44–46, 1947). **Type:** USA, New Mexico (*McKelvey* 4902 [A [2 syn]]).—**Lit:** Webber (1953: 56–59, sub *Y. glauca*); Reveal (1977: 532–533, as *Y. baileyi* var.); Hess & Robbins (2002); Sivinski (2008: 2, as *Y. baileyi* var.); Hawker (2016: 371–373). **Distr:** USA (C & NE New Mexico); juniper-pinyon pine woodlands and adjacent grasslands, 1100–2100 m; flowers May to June. **I:** Earle (1968); Hochstätter (1998: 81, as *Y. baileyi* var.); Hochstätter (2000: 45, as *Y. baileyi* ssp.).

≡ *Yucca baileyi* var. *intermedia* (McKelvey) Reveal (1977) ≡ *Yucca baileyi* ssp. *intermedia* (McKelvey) Hochstätter (1999); **incl.** *Yucca intermedia* var. *ramosa* McKelvey (1947).

[3b] Stems none or occasionally with erect simple stems <1 m; **Ros** caespitose, forming widely separated colonies of 1–5 rosettes; **L** linear, somewhat flexible, plano-convex or lower face keeled, widest near the middle, 33–65 × 0.5–0.8 cm, margins entire, white to greyish; **Inf** erect, racemose, sometimes paniculate proximally, occasionally paniculate and long-racemose distally, peduncle 10–50 cm, flowering part (50–) 70–130 cm, arising within the rosette leaves, glabrous; **Fl** pendent, campanulate or rarely globose; **Tep** narrowly to broadly elliptic, 55–70 × 20–32 mm, cream or greenish, often tinged rose or rosy-brown; **Fil** to 25 mm; **Ov** oblong-cylindrical, to 25 mm; **Sty** 7 mm, white or pale yellowish-green; **Sti** lobed; **Fr** erect dry capsules, oblong-cylindrical, often constricted near the middle, 50–57 × 20–25 mm; **Se** thin, 6–10 mm, glossy or dull black.

The type consists of two sheets which are not cross-labelled. According to the protologue intermediate between *Y. glauca*, *Y. angustissima* and *Y. baileyi* (as *Y. standleyi*), and considered as a hybrid between *Y. glauca* and the 2. or 3. species

listed (Webber 1953). This is rejected by Reveal (1977) because of the high pollen viability and regular fruit production, and because the putative parents are not present in the range of *Y. intermedia*. Species rank (vs. varietal rank under *Y. baileyi*) is strongly supported by the molecular data of Pellmyr & al. (2007), where *Y. intermedia* is shown as sister of *Y. harrimaniae* and separate from *Y. baileyi*. McKelvey (1947) based var. *ramosa* on populations in the SE area of the total range with paniculate inflorescences, but populations only with paniculate inflorescences as well as populations with racemose and paniculate inflorescences exist (Hess & Robbins 2002).

**Y. jaegeriana** (McKelvey) L. W. Lenz (Aliso 24(1): 99, 2007). **Type:** USA, California (McKelvey 2732 [A]).—**Lit:** Webber (1953: 31–32, t. 16); Benson & Darrow (1981: 52–53, with ill.); Hawker (2016: 328–331, with ill.), all as *Y. brevifolia* var. **Distr:** SW USA (S California, S Nevada, SW Utah, NW & W Arizona); hills and alluvial fans of the Upper Mojave Desert, 760–1500 m; flowers April to May. **I:** Hochstätter (2002a: 148–150, as *Y. brevifolia* ssp.).

≡ *Yucca brevifolia* var. *jaegeriana* McKelvey (1935) ≡ *Yucca brevifolia* ssp. *jaegeriana* (McKelvey) Hochstätter (2001).

[2] Plants ±3–6 (–9) m, stemless or with short main stem, branching dichotomously until flowering, irregularly thereafter; lowest **Br** 0.25–2.3 m, usually <1 m above the ground, relatively numerous, somewhat slender, short, nearly erect, forming an extremely dense compact crown; **Ros** symmetrical, crowded, 0.3–0.6 × ± 0.2–0.4 m; **L** straight, rigid, smooth, 9.5–22 (–27) × 0.6–1.2 (–1.5) cm, green to yellowish-green, margins nearly entire, thin, horny, minutely denticulate, **terminal Sp** ± 5–8 mm; **Inf** erect, paniculate, peduncle 2.5–5 cm, flowering part 22.5–40 cm, ovoid, for ¼–½ enclosed within the rosette leaves, with short stout part **Inf** 2.5–6.25 cm long with densely crowded flowers, glabrous; **Ped** 4–22 mm; **Fl** erect, narrowly campanulate, conspicuously expanded at the base, narrowed above, ± 45–60 mm; **Tep** narrowly oblong, apex recurving, ± 26–53 × 7–12 mm, greenish to cream, barely connate at the base; **Fil** ± 10 mm;

**Ov** lanceolate-ovoid, ± 10–16 × 4–10 mm; **Sti** 4–9 (–12) mm; **Sti** distinct; **Fr** pendent, dry, indehiscent capsules, ellipsoid, tapering at the apex, deeply furrowed, rather spongy, ± 67–86 × 30–38 mm; **Se** not described.

Occurring to the E of *Y. brevifolia*, and first separated at the rank of variety (McKelvey 1935: 269–270, t. 139). Reveal (1977: 530) did not recognize it as separate taxon as he considered it not clearly separable; this view was shared by Webber (1953: 31–32), McKinney & Hickman (1993), Hess & Robbins (2002), and Govaerts (2014+: accessed Dec. 2018), but not by Benson & Darrow (1981), Kartesz (1996), USDA (2001) and Hochstätter (2002a). Lenz (2007) treated it at species rank, arguing that differences in branching patterns, leaves, flowers and fruits, the allopatric distribution, and different pollinating moths provide a sufficiently clear and important base for such a decision. The detailed population genetic studies by Yoder & al. (2013) found that the two taxa are only weakly isolated despite the significant correlation between floral morphology and pollinator ovipositor length, indicating that substantial gene flow exists between the two taxa. Gene flow is largely asymmetric and unidirectional from *Y. jaegeriana* to *Y. brevifolia* due to different degrees of host specificity of the pollinating moths (Starr & al. 2013). However, population genomic studies by Royer & al. (2016) showed that both species are genetically highly differentiated and strongly diverged and rarely form hybrids in the hybrid zone at Tikaboo Valley (S Nevada), with selection maintaining the differences and separation between both species. The annual growth rate of young plants is 8–16 cm (Webber 1953: 92). Vernacular name: “Eastern Joshua Tree”.

**Y. jaliscensis** Trelease (Contr. US Nation. Herb. 23(1): 92–93, 1920). **Type** [lecto]: Mexico, Jalisco (*Pringle* 4392 [US [lecto, 2 sheets], BR, HBG, JE, KFTA, MO, NDG, S, VT]).—**Lit:** Matuda & Piña Luján (1980: 88–90, with ill.); McVaugh (1989: 282–283, with ill.); Hochstätter (2004a: 26–27, ill. pp. 100–103). **Distr:** Mexico (S Nayarit, W & C Jalisco, W Guanajuato, N Colima); plains with deeper soils or moderate

slopes, wooded ravines, barrancas near streams, pine or tropical deciduous forests, 1000–2200 m; flowers June to September (McVaugh 1989: September to May or almost throughout the year). **I:** Trelease (1902: t. 56, as *Y. schottii* var.); Piña Luján (1980: 279); Hochstätter (2003c: 152); Boeuf & al. (2009: 70–71).

**Incl.** *Yucca* × *schottii* var. *jaliscensis* Trelease (1902).

[1c] Arborescent, stems to 2–10 m, in cultivation to 12–15 m, trunk short, 20–60 (–150) cm Ø, often with 5–8 long upright and often much branched **Br**; **L** diverging, flexible, concave, glabrous, (30–) 50–100 × (3–) 6–7.5 (–8) cm, glaucous-green, persistent, margins hardly fibrous, pale grey to brown, occasionally with few fine fibres, tip sharp-pointed but scarcely differentiated as spine, brownish; **Inf** erect, or drooping at fruiting time, paniculate, peduncle short, flowering part 0.4–1 m, narrowly ellipsoid, dense, largely enclosed within the rosette leaves, densely tomentose to canescent with thick blunt hairs; **Ped** pubescent; **Fl** pendent, subglobose, 30–40 mm; **Te**p narrowly lanceolate, 22–40 × 8–16 mm; **Fil** 12–15 mm, pilose; **Ov** 15–22 × 5–7 mm Ø; **Sty** 3 mm; **Fr** fleshy berries, ellipsoid, narrowed at the base, asymmetrical, conical at the apex, 60–120 × 25–50 mm, brownish when ripe; **Se** flat, rugose, 5–7 × 7–10 mm.

The designation “type from Zapotlán” in the protologue refers to *Pringle* 4392 (see Gentry 1972: 161). Espejo Serna & López Ferrari (1993: 40) designated “US” as lectotype where 2 specimens are present. According to McVaugh (1989), it is often cultivated and spreading around settlements, but seldom found in the wild. In the molecular phylogenies of Pellmyr & al. (2007), the taxon groups in most analyses as sister to *Y. filifera*.

The rather short protologue of *Y. barrancasecca* hort. (1867) is based on a plant cultivated at BG Naples, Italy (esp. “foliis ... 1 meter long ad basim. 3–4 cent. lat, ad apicem fibrilloso-sphacelatis”), and the species was even thought to probably represent a species of *Dasylyrion* due to the “fibrillate” leaves, but they are much too broad for that genus (Trelease 1902: 114). According to Sprenger (1920b: 145–146), he

sold the original plant to BG Naples, where it was published as *Y. barrancasecca*; earlier it was listed by him as *Y. brasiliensis*, and it is neither “*Y. australis*” nor “*Y. schotti jaliscensis*” nor *Y. decipiens*. Govaerts (2014+: accessed Dec. 2018) lists *Y. barrancasecca* in the synonymy of *Y. jaliscensis* (which it would have to replace due to priority), but Sprenger’s comments cited above contradicts this placement, and the name should be treated as of uncertain application.

**Y. × karlsruhensis** Graebener (Gartenwelt 8(1): 7–9, ills., 1903). **Type:** not typified.—**Lit:** Weissbeck (2012b: with ills.). **Distr:** Cultivated only. **I:** Hochstätter (2000: 122); Smith (2004: 60); Boeuf & al. (2010: 33, 42).

[3c] This hybrid *Y. glauca* × *Y. filamentosa* is the earliest *Yucca* hybrid in Germany, raised by Leopold Graebener at Karlsruhe in 1899 (the earliest *Yucca* hybrids were raised by Deleuil (1880) and the earliest nothospecies were named by André (1883), see introduction). Propagations of the original plant are still cultivated at BG Karlsruhe and elsewhere (Weissbeck 2012a), so that it represents the oldest extant hybrid.

**Y. lacandonica** Gómez-Pompa & Valdés (Bol. Soc. Bot. México 27: 43–44, ills., 1962). **Type:** Mexico, Chiapas (*Gómez Pompa* 353 [MEXU, GH]).—**Lit:** Matuda & Piña Luján (1980: 109–111, with ills.); Lott & García-Mendoza (1994: online version with ills.); García-Mendoza (2003); Hochstätter (2004a: 39–40, ills. pp. 135–136); Véliz Pérez & Archila Morales (2015: with ills.). **Distr:** Mexico (Veracruz, Tabasco, Campeche, Yucatán, Oaxaca, Chiapas), Belize (Toledo), Guatemala (Alto Verapaz, El Petén); humid tropical evergreen forests, mostly epiphytic, also epilithic, 150–1030 m; flowers April to June. **I:** Gómez-Pompa & al. (1971: 220); Piña Luján (1980: 281); Hochstätter (2004b: 39–40); Roosbroeck (2017).

[1c] Terrestrial or epiphytic, stems 2.5–4 m, to 25 cm Ø at the base, 12 cm at mid-stem, 8 cm in the upper part, branching at the base, stems variably curving or twisting, partly horizontal, upcurving apically; **L** long lanceolate, narrowed towards the base (1–1.5 cm broad) and towards

the tip, weak, thin, fleshy, rigid, smooth on both faces, 30–85 × 3–7 cm, green, margins denticulate, 0.5 cm broad, with a yellowish band 0.5 mm broad, tip short, very acute, pungent, flexible, brownish; **Inf** paniculate, erect, peduncle short, ± 40 cm, flowering part 40–100 cm, arising within the rosette leaves, part-**Inf** flexible, ascending, to 20 cm, glabrous; **Fl** pendent, campanulate; **Tep** oblong-linear, very narrow, membranous-fleshy, 30–45 × 8–10 mm, white or whitish; **Fil** 7 mm; **Ov** oblong, 10–15 × 4–6 mm; **Fr** fleshy berries, indehiscent, cylindrical, subtrigonal, 40–100 × 20–45 mm, immature fruits conical, 40 × 20 mm; **Se** flattened to globose, unwinged, 5–7 × 4–6 mm.—**Cytology**: 2n = 60 (Gómez-Pompa & al. 1971).

This species was for long considered as the only strictly epiphytic taxon in the *Agavaceae* (a few species of *Agave* may rarely occur as facultative epiphytes under humid conditions), but was recently also found to occur terrestrially (Hochstätter 2004a, Roosbroeck 2017). It was first collected in Belize in 1935 (*Schipp* 1324, MO; Tropicos accessed 2015) and recently also found in N-C Guatemala (Véliz Pérez & Archila Morales 2015). The inflated stem-base, the leaves with narrowed base and yellow margins, and the short inflorescence emerging from within the leaves indicate a relationship with *Y. guatemalensis*. Such a placement is corroborated by the AFLP data (Pellmyr & al. 2007, Smith & al. 2008a: fig. 2c), but chloroplast sequence data (Smith & al. 2008a: fig. 2a, 2b) show a weakly supported grouping with *Y. periculosa* and thus distant from *Y. guatemalensis* (as *Y. elephantipes*).

**Y. linearifolia** Clary (Brittonia 47(4): 394–396, ills., 1995). **Type**: Mexico, Nuevo León (*Clary* 364 [MEXU, ANSM, CAS, GH, MO, TEX, US]).—**Lit**: Ferguson (1996: as *Y. linearis*); Hochstätter (2004a: 37–38, ills. pp. 126, 131–133); Boeuf (2007b); Heim (2011); all with ills. **Distr**: Mexico (S Coahuila, W Nuevo León); desert scrub on shale in shaded canyons, 1100–1300 m; flowers April to June. **I**: Hochstätter (2003e: 266); Boeuf (2007a: 69); Guillot Ortiz & Meer (2008: 108); Boeuf & al. (2009: 72–73).

**Incl.** *Yucca rostrata* var. *linearis* Trelease (1907) ≡ *Yucca linearis* (Trelease) D. J. Ferguson (1996).

[1c] Stems 2–3.5 m, mostly unbranched, 30–50 cm Ø at breast height, forming isolated colonies of 3–15 stems from rhizomes or fallen plants; **Ros** radially symmetrical, with somewhat flattened top; **L** numerous, linear, distally twisting slightly outwards, rounded to quadrangulate towards the base, persistent when old and then reflexing and completely covering the trunk, lower face very scabrous, upper face smooth, 34–38 (–50) × 0.4–0.5 (in the middle) cm, greyish-green to glaucous (esp. in new growth), later also green, margins thin, horny, pale yellow, with many minute denticles, **terminal Sp** 3–8 mm, dark reddish-brown to black; **Inf** erect, paniculate, peduncle short, flowering part 60–80 cm, pyramidal, basally enclosed within the rosette leaves, moderately to richly branched, lower (= largest) part-**Inf** 11 – ±17 cm, with 4–6 or more flowers, glabrous; **Fl** pendent, campanulate; **OTep** elliptic, 30–33 × 15 mm; **ITep** obovate, 30 × 20 mm, creamy-white, tube none; **Fil** 16–17 mm; **Ov** oblong-cylindrical, 17–20 × 9–10 mm; **Sty** white, 6–7 mm; **Sti** lobed, papillose; **Fr** fleshy berries, indehiscent, asymmetrical, narrowly ovoid, tip constricted, 40–70 × 23–25 mm, green; **Se** polymorphic, to 5–7 × 4–6 mm, dull, black.

*Y. linearifolia* is, besides *Y. queretaroensis*, the only fleshy-fruited *Yucca* with narrow denticulate leaves, resembling *Dasylyrion* in habit. The protologue places it with the dry-fruited *Y. rostrata*, and with *Y. queretaroensis*, which was first published with unknown fruits. Molecular data place *Y. linearifolia* within Sect. *Yucca* (as *Sarcocarpa*) and separate from *Y. queretaroensis* (Pellmyr & al. 2007, Smith & al. 2008a). In habitat, no remains of flowers, fruits or seeds can be found, since all young flowers are harvested for food so that the generative reproduction fails (Heim 2011: 99).

*Y. rostrata* var. *linearis*, wrongly synonymized under *Y. rostrata* by Hess & Robbins (2002) and Govaerts (2014+), and later elevated to species rank as *Y. linearis* (Ferguson 1996), belongs here according to its narrow leaves (label of K. H. Clary 2002/2003 on the holotype *Purpus* s.n.,

MO 148706!). An original plant collected by C. A. Purpus at about 1905 is still cultivated at BG Darmstadt, Germany (Schneckenburger 2001: 67–69). Heim (2011) reports a putative natural hybrid with *Y. torreyi* (here treated as synonym of *Y. treculiana*) needing further study. Apart from the typical form with green leaves, plants with glaucous leaves also occur (Boeuf 2007b, Heim 2011) which need additional study as to possible further differences. For the cultivation, see Boeuf (2007b) and Heim (2011). ‘Line Dance’ is a rare variegated cultivar with white margins (Boeuf & Heim 2014: 25–26).

**Y. madrensis** Gentry (US Dept. Agric. Handb. 399: 159–161, ills., 1972). **Type:** Mexico, Sonora (Gentry 21209 [US 2557499, ARIZ, DES, MEXU, MICH]).—**Lit:** Matuda & Piña Luján (1980: 85–87, with ills.); Lenz & Hanson (2001: 168); Hess & Robbins (2002); Hawker (2016: 372–376, with ills.). **Distr:** S USA (SE Arizona, NW New Mexico), N Mexico (N & E Sonora, W Chihuahua); on rocky volcanic and limestone slopes in oak woodlands and pine-oak forests, 1200–2200 m; flowers June to July. **I:** Piña Luján (1980: 279); Hochstätter (2000: 128–130; 2003d: 214); Hochstätter (2003e: 264–265); Boeuf & al. (2009: 76–77).

[1c] Caulescent, stems short or up to 3.5 m, simple or eventually few-branched from the base, usually with a long skirt of dried deflected leaves; **L** numerous, spreading to ascending, rarely recurving, linear-lanceolate, thin, flexible, nearly flat to slightly conduplicate, smooth and striate on both faces, mostly 50–80 (–100) × (2–) 3.5–6.5 cm, bluish-glaucous or green (to yellowish-green), margins thin, brown, friable, serrulate, detaching with age, rarely sparingly filiferous, brown to greyish, **terminal Sp** weak, 5–15 mm, reddish-brown to grey; **Inf** erect, paniculate, peduncle short, flowering part 30–80 cm, elongate-ovoid, somewhat open, arising  $\frac{1}{4}$ – $\frac{1}{2}$  within the rosette leaves, part-**Inf** ascending, short, 6 – ±12 cm or more, densely to sparsely tomentose; **Fl** pendent, globose, ±35 mm, broader than long, basally truncate; **Tep** ovate-lanceolate to lanceolate, 20–40 × 10–20 mm, cream or tinged with purple, free or barely connate

basally; **OTep** brownish, mucronate; **ITep** broader than the outer tepals; **Fil** 15 mm; **Ov** thick, ±20 mm; **Sty** abruptly tapering into the stigma; **Sti** lobed, papillate; **Fr** fleshy berries, becoming pendent, rounded at the base, tapering at the tip, frequently irregularly constricted, with irregular warts to 20 mm Ø, 60–130 × 25–50 mm, green; **Se** unwinged, 7–10 mm Ø, 5–9 mm thick, rough, grey.

*Y. madrensis* is characterized by its pliable, light bluish-green leaves, short inflorescences with small flowers, and a summer-flowering habit (Gentry 1972). The fruits, unknown at the time of the protologue, were later found to be fleshy and the species was placed in Ser. *Treculianae* (= Ser. *Yucca*) of Sect. *Yucca* (as *Sarcocarpa*) (Matuda & Piña Luján 1980, Laferrière 1990).

According to Lenz & Hanson (2000: 98), the plants with long, broad, flexible, bluish leaves in S Arizona commonly misnamed as *Y. schottii* sensu Trelease (1902: 98) *non* Engelmann actually belong here (e.g., Benson & Darrow 1981: 54, Irish & Irish 2000: 207–271, Hochstätter 2001b: 131–132, Hochstätter 2002a: 25–26, ills. pp. 100–102, Guillot Ortiz & Meer 2008: 88–89, 111, Faber 2015, all as *Y. schottii* auct., all with ills.).

The notion of Lenz & Hanson (2001: 168) that *Y. madrensis* may have hybridized with *Y. treculiana* in Chihuahua is unlikely, since both species occur clearly separated. The plants are intensively used by the Warihio (Guarijío) and Pima for soap (roots), cordage (leaves) and food (fruits) (Laferrière 1990).

**Y. mixtecana** García-Mendoza (Acta Bot. Mex. 42: 1–4, ills., 1998). **Type:** Mexico, Oaxaca (García-Mendoza & al. 6198 [MEXU, BM, ENCB, MO, NY, OAX, TEX]).—**Lit:** Hochstätter (2004a: 29, ills. pp. 106–109); García-Mendoza (2011: 87–89, with ills.). **Distr:** Mexico (S Puebla, NW Oaxaca); xerophytic scrub and transition to tropical deciduous forests, 1370–2200 m; flowers March to July. **I:** Hochstätter (2003b: 115–116); Boeuf & al. (2009: 78–79).

[1c] Arborescent, stems 2.5–5 m, ± conical, simple or with 2–4 branches in the upper 1–3 m, at the base forming rhizomatous colonies of 10–25 stems; **L** erect, linear-lanceolate or linear, flexible,

narrowed at the base to 1–2 cm, broadest in the middle, rough on the lower face, glabrous on the upper face, 40–65 (–80) × 1–3 cm, glaucous to greenish-yellowish, deciduous when dry, margins entire, with a brown or grey border, filiferous with fine and soft, white or grey threads, **terminal Sp** 5–10 mm, dark brown, canaliculate; **Inf** erect, paniculate, peduncle 20–30 cm, flowering part 50–80 cm, moderately branched, lower part within the rosette leaves, pilose; part-**Inf** 10–20 cm, with 15–20 flowers each; **Ped** (10–) 15–20 mm, pilose; **Fl** pendent, campanulate, (15–) 20–25 (–30) mm; **Tep** elliptic, glabrous, 20–25 (–30) mm; **OTep** 4–7 (–10) mm broad; **ITep** 6–10 (–13) mm broad, whitish to yellowish; **Fil** 10–15 (–20) mm; **Ov** cylindrical, ± 13–17 (–27) × 6–8 mm; **Sty** short; **Sti** lobed; **Fr** fleshy berries, pendent, sometimes constricted, cylindrical, (30–) 50–80 × 20–25 mm, brownish when ripe; **Se** flat, drop-shaped, 5 mm Ø, black.

According to the protologue closest to *Y. periculosa* and *Y. jaliscensis*, from both of which it differs by its shorter, conical, slender, sparsely branched stems, narrower caducous leaves and much smaller flowers and fruits. The molecular data of Pellmyr & al. (2007) shows 2 samples of *Y. mixtecana* nested within 3 accessions of *Y. periculosa*, and both well separate from *Y. jaliscensis*. The fruits, not currently used as food, have great dietary potential (Barriada-Bernal & al. 2018).

**Y. necopina** Shimmers (Spring Fl. Dallas-Fort Worth Area, 408, 1958). **Type:** USA, Texas (*Shimmers* 20102 [BRIT, BRIT]).—**Lit:** Diggs & al. (1999: 1083–1084, ills. pp. 108, 1085); Hess & Robbins (2002); Diggs & al. (2006: 418, ills. pp. 308, 419); Boeuf (2016: with ills.). **Distr:** USA (N Texas); river terraces in deep sandy soils, 200–300 m; flowers May to June.

[3c] Stems none or short and erect, to 0.4 m; **Ros** with ±50–85 leaves, caespitose, forming small colonies; **L** erect, slightly twisted, flexible but firm, plano-convex, widest near the middle, 50–80 × (1.5–) 2–4 cm, margins entire, filiferous with curly fibres, white, tip acicular; **Inf** erect, paniculate and racemose distally or entirely racemose, peduncle 0.8–1.6 m, flowering part

0.5–1.2 m, ovoid, beginning mostly beyond the rosette leaves, part-**Inf** ascending, to 15 cm, glabrous; **Fl** pendent, globose; **Tep** 40–45 × 15–30 mm, greenish-white; **Fil** 12–20 mm; **Ov** 15–38 mm, 2× as long as style and stigma; **Sti** lobed; **Fr** erect dry capsules, not conspicuously constricted, 40–70 × ± 20–35 mm; **Se** not described.

Originally known from a single locality only, but several new locations were reported by Diggs & al. (1999). It was compared with *Y. arkansana* in the protologue, and suggested to represent a hybrid between that species and *Y. pallida*. However, *Y. necopina* occurs in many rather uniform individuals in widely separated localities where neither *Y. arkansana* nor *Y. pallida* typically occur. Recognition of the taxon as separate species is also supported by molecular data which relate it to *Y. elata* and its ssp. *verdiensis* (as *Y. verdiensis*) (Clary 1997, cited by Boeuf 2016: 58). Morphologically, it appears to be closest to *Y. flaccida*, which is distinguished by its usually narrower leaves and pubescent inflorescences (Diggs & al. 1999: as *Y. louisianensis*).

**Y. neomexicana** Wooton & Standley (Contr. US Nation. Herb. 16: 115, 1913). **Type:** USA, New Mexico (*Standley* 6208 [US 685238, GH, K, MO, NY, UC, US]).—**Lit:** Webber (1953: 43–44, tt. 24, 25); Reveal (1977: 530, 532, as *Y. harrimaniae* var.); Hochstätter (2000: 34, ills. pp. 89–90, as *Y. harrimaniae* ssp.); Hess & Robbins (2002); Hawker (2016: 376–379, with ills.). **Distr:** SW USA (S Colorado, N & NE New Mexico, W Oklahoma), exposed rocky ledges in open woodlands and grasslands, 1300–2700 m; flowers May to July. **I:** Hochstätter (1998: 224, as *Y. harrimaniae* var.).

≡ *Yucca harrimaniae* var. *neomexicana* (Wooton & Standley) Reveal (1977) ≡ *Yucca harrimaniae* ssp. *neomexicana* (Wooton & Standley) Hochstätter (1999).

[3b] Stems none or rarely short, < 1 m, and primarily rhizomatous; **Ros** mostly asymmetrical, solitary or usually caespitose, in open colonies and separated by 35–60 cm; **L** spreading, spatulate-lanceolate, thin, flexible, canaliculate, widest near the middle, 15–46 × 0.7–2 cm, rather glaucous, margins entire, filiferous, brown or

straw-coloured, tapering to the pungent apex; **Inf** erect, racemose, rarely paniculate proximally, peduncle 10–40 cm, flowering part 40–70 cm, arising within or more often to 20 cm beyond the rosette leaves, part-**Inf** few, short, glabrous, with purplish **Bra** to 10 cm; **Ped** 12–20 mm, stout; **Fl** pendent, campanulate; **Tep** broadly lanceolate, 30–47 × 15–30 mm, white to somewhat greenish-white, usually tinged pink or purple; **Fil** 13–17 mm; **Ov** ± 15–20 mm; **Sty** pale green or rarely white, 9–13 mm; **Sti** lobed; **Fr** erect dry capsules, cylindrical, deeply constricted near the middle, 30–42 × 20–27 mm; **Se** thin, 6–8 × 5–8 mm, dull black.

Included in *Y. harrimaniae* by McKelvey (1947), Reveal (1977), and Hochstätter (2002a, 2004a), but morphologically distinct and allopatric, separated by the San Juan Mountains of Colorado. Hess & Robbins (2002) reinstated the taxon at species rank, supported by earlier molecular data (Clary 1997, cited in Hess & Robbins 2002). Main differences from *Y. harrimaniae* are its usually white flowers held mainly above the leaves (vs. yellow or greenish-yellow flowers, the lowest usually arising within the leaves) (Hochstätter 2004a).

**Y. pallida** McKelvey (Yuccas Southwest US, 2: 57, tt. 13–14, 1947). **Type:** USA, Texas (McKelvey 2862 [A]).—**Lit:** Diggs & al. (1999: 1084–1085, with ills.); Hochstätter (2000: 25–26, ills. pp. 24, 80); Hess & Robbins (2002); Diggs & al. (2006: 418–420, with ills.); Hawker (2016: 378–383, with ills.). **Distr:** USA (N-C Texas); rocky blackland prairies and uplands, rarely limestone outcrops, 100–400 m; flowers April to June. **I:** Hochstätter (1999: 209); Boeuf (2007a: 70); Boeuf & al. (2009: 84–85).

≡ *Yucca rupicola* fa. *pallida* (McKelvey) hort. (s.a.) (*nom. inval.*, ICN Art. 29.1); **incl.** *Yucca rupicola* Trelease (1902) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca rupicola* var. *edentata* Trelease (1912) (*incorrect name*, ICN Art. 11.4) ≡ *Yucca pallida* var. *edentata* (Trelease) Cory (1952).

[3a] Acaulescent; **Ros** with <100 leaves, usually distinctly separate from one another, forming loose rhizomatous colonies of usually 10–30 rosettes; **L** lanceolate, thin, flexible, straight when mature, acuminate, flat but concave for

1.3–2.5 cm below the tip, widest at or usually above the middle, 20–60 × 1–4.5 cm, blue- to grey-green, margins flat, bright yellow, finely denticulate or sometimes wavy, apex acute or less often acuminate; **Inf** erect, paniculate, often distally racemose, peduncle 0.6–1.3 m, flowering part 0.7–1.2 m, arising beyond the rosette leaves, part-**Inf** widely spreading, 15–23 cm, glabrous; **Fl** pendent, campanulate, 50–65 mm; **Tep** narrowly to broadly elliptic to ovate, 50–65 × 20–32 mm, greenish-white, margins white, somewhat serrate; **Fil** 18–32 mm; **Ov** oblong-cylindrical, 30–40 mm, pale blue or yellow-green; **Sty** 13–20 mm, white; **Sti** lobed; **Fr** erect dry capsules, oblong-cylindrical, 45–55 × 13–20 mm, yellowish-brown, later dark brown to black; **Se** small, rough, surface sculptured, 4–7 × 2–3 mm, dull black.

Webber (1953) reports difficulties to distinguish *Y. pallida* from *Y. rupicola* and indirectly includes the former as synonym of the latter, but most authors (Kartesz 1996, USDA 2001, Diggs & al. 1999, Hochstätter 2000, Hess & Robbins 2002, Diggs & al. 2006, Hawker 2016) keep the species separate from its close relative *Y. rupicola*. *Y. pallida* differs from *Y. rupicola* in its leaves straight or nearly so, flat, pale bluish to green and conspicuously glaucous, ± smooth on both faces, and with yellow margins (vs. leaves twisted and with margins inrolled most of their length, dark green and not glaucous, ± scabrous on both faces, and margins dark orangish or yellowish-brown or occasionally yellowish) (Diggs & al. 2006: 414–415).

Plants with leaves with entire margins are occasionally found, and were named var. *edentata*, but the protologue suggested that they are hybrids of *Y. pallida* with *Y. arkansana*. According to Keith (2003), *Y. pallida*, *Y. rupicola* and *Y. cernua* are closely related to each other within Sect. *Rupicolae*, and share an acaulescent habit, denticulate leaves, and beaked capsules. This assumed close relationship is strongly supported by molecular data (Pellmyr & al. 2007), which place the three species in a well-supported clade. *Y. cernua* differs by solitary growth, glaucous young leaves becoming olive or yellowish-green with age, and by its puberulent inflorescence with recurved and drooping branches.

**Y. periculosa** Baker (Gard. Chron. 1870: 1088, 1870). **Type:** not typified.—**Lit:** Trelease (1907: 228–229, tt. 13–14); Matuda & Piña Luján (1980: 89–93, with ills.); Hochstätter (2004a: 27–28, ills. pp. 104–105); García-Mendoza (2011: 89–93, with ills.). **Distr:** Mexico (W-C Veracruz, Tlaxcala, E Puebla, N Oaxaca); desert scrub, tropical deciduous forests, on plains with deeper soil or on moderate slopes, 1300–2200 m; flowers March to July. **I:** Piña Luján (1980: 280); Hochstätter (2003b: 114–115); Boeuf & al. (2009: 86–87).

≡ *Yucca baccata* var. *periculosa* (Baker) Baker (1880) ≡ *Yucca baccata* fa. *periculosa* (Baker) Voss (1895) ≡ *Sarcocoyucca periculosa* (Baker) Lindinger (1933); **incl.** *Yucca circinata* Baker (1870) ≡ *Yucca baccata* var. *circinata* (Baker) Baker (1880) ≡ *Yucca baccata* fa. *circinata* (Baker) Voss (1895).

[1c] Arborescent, stems to 10 m (in cultivation to 15 m), cylindrical, much-branched in age, **Br** ascending, 1–2 m, ± cylindrical, leaves persisting as dry skirt below the rosette; **L** erect, lanceolate or linear-lanceolate, rigid, (35–) 50–70 × (2–) 3–3.5 cm, green, margins with a fine dark brown band, finely fibrous, **terminal Sp** (5–) 10–15 mm, dark brown; **Inf** erect to somewhat inclined, paniculate, peduncle 30–40 cm, flowering part 0.7–0.9 (–1.2) m, ovoid, compact, peduncle enclosed within the rosette leaves, with 60–70 part-**Inf** to 15–30 cm, glabrous to pilose; **Ped** 10–20 mm, glabrous or pilose; **Fl** pendent, campanulate, expanded, (25–) 35–40 mm; **Tep** lanceolate, (20–) 25–35 mm, **OTep** 7–10 mm broad, **ITep** 10–15 mm broad, whitish, occasionally with purple tinge, glabrous to pubescent; **Fil** 10–15 (–20) mm; **Ov** cylindrical, 15–20 mm; **Sty** short; **Sti** lobed; **Fr** fleshy berries, pendent, cylindrical, (65–) 80–100 (–120) × 25–30 (–50) mm, green; **Se** 8–10 × 7–9 mm, dull black.

Two specimens apparently from the original plant cultivated by Saunders were both prepared later than the protologue and thus do not represent original material (K 001096505, 4/[18]73; MO 3346126, 1871). The neotypification by Hochstätter (2003b: 114) is ineffective under ICN Art. 7.11. *Y. mixtecana* is imbedded within *Y. periculosa* in the molecular phylogeny of Pellmyr & al. (2007)

(see also there); García-Mendoza (2011) mentions possible hybrids between both species. *Y. mixtecana* differs in its smaller and less branched stems, its narrower, glaucous leaves not persisting on the stems and with a shorter terminal spine, and its shorter inflorescences with smaller flowers and fruits (García-Mendoza 2011).

**Y. potosina** Rzedowski (Ciencia (Mexico) 55 (4–5): 90–91, ill., 1955). **Type:** Mexico, San Luis Potosí (*Rzedowski* 5924 [MEXU, ENCB]).—**Lit:** Matuda & Piña Luján (1980: 99–102, with ills.); Hochstätter (2004a: 32–33, ills. pp. 119–121). **Distr:** Mexico (San Luis Potosí: mainly Mun. Guadalcázar); slopes with shallow soil, desert scrub, submontane scrub or oak scrub, 1500–1800 m; flowers May to July. **I:** Hochstätter (2003c: 151); Boeuf & al. (2009: 88–89).

[1c] Arborescent, stems 2–7 m, to 25 cm Ø, mostly single or rarely poorly branched; **L** stiff, scabrous, flat or somewhat canaliculate, somewhat rough on both faces, 30–100 × 2–6 cm, margins with thin band, dark brown in the lower and grey in the upper part, with thin and curled grey fibres, **terminal Sp** acute, 20–30 mm, grey; **Inf** pendent, paniculate, flowering part 0.8–1.2 m, much extending beyond the rosette leaves, with very dense part-**Inf**, glabrous to pubescent; **Ped** 15–25 mm; **Fl** subglobose; **Tep** white; **OTep** elliptic-oblong, truncate at the base, acute, 25–45 × 8–13 mm; **ITep** obovate, rounded at the base, acute to acuminate, 25–50 × 10–20 mm, pubescent on the margins near the tip; **Fil** 8–15 mm, pubescent; **Ov** 15–20 mm; **Sty** very short; **Sti** finely pubescent; **Fr** fleshy berries, oblong, 40–80 × 20–35 mm, brownish when ripe; **Se** obovate, unwinged, 6–8 × 5–6 mm, 3–5 mm thick, black.

In the protologue compared with the co-occurring, rather different *Y. treculiana*, with typical unbranched plants growing in sparse soil on slopes, whereas plants on alluvial soils show tendencies towards branching and resemble *Y. filifera*. All features of *Y. potosina*, including the pendent inflorescences, fall within the range of character expressions of the widespread *Y. filifera*, and *Y. potosina* may represent nothing more than a habitat modification of *Y. filifera* with smaller growth and less branching induced by the arid

calcareous soil, as already hinted upon in the protologue. Sparsely branched plants of *Y. potosina* (Hochstätter 2004a: 119) are indistinguishable from finally sparsely branched plants identified as *Y. filifera* (Hochstätter 2004a: 122–123). Magallán Hernández & al. (2013b: 17) mention a hybrid with *Y. queretaroensis*.

**Y. queretaroensis** Piña Luján (Cact. Suc. Mex. 34(3): 51–56, ills., 1989). **Type:** Mexico, Querétaro (*Piña Luján* s.n. [MEXU 472851, ASU, ENCB, IEB, IZTA, MEXU]).—**Lit:** García-Mendoza (2003); Hochstätter (2008b: with ills.); Weissbeck (2010: with ills.); Weissbeck (2011: with ills.); Magallán Hernández & al. (2013a: with ills.); Magallán Hernández & al. (2013b: with ills.); Magallán Hernández & al. (2014); Spracklin (2015: with ills.). **Dist:** Mexico (NE Guanajuato, C Querétaro, W Hidalgo); broad valleys enclosed by high mountains, steep mountain slopes, in stony soil, in desert scrub and pine-oak forests, 800–1500 m; flowers April to June. **I:** Hochstätter (2003a: 19, 66); Boeuf & al. (2009: 90–91).

[1c] Caulescent, stems nearly always unbranched, (2–) 3–6 m, 20–40 (–60) cm Ø, often forming small rhizomatous colonies of up to 30 stems of different lengths; **L** very numerous, ±1500, linear, straight, flexible, broadened at the base to 1.5–2.5 cm, both faces convex and with a slight keel and 2 furrows between keel and margins, papillose on the keels but smooth to the touch, 40–75 (–115) × 0.2–0.5 cm, light to dull green, persistent, with age reflexed and covering the stems, margins horny, yellowish, finely denticulate, **terminal Sp** angled, 2–5 (–8) mm, coffee-brown; **Inf** erect, paniculate, peduncle short, ±6–10 cm, flowering part 0.6–0.9 m, ellipsoid, much-branched, densely flowered, above the rosette leaves; part-**Inf** 120–140, to 14–16 cm, finely tomentose; **Ped** 13–20 mm, tomentose; **Fl** pendent, campanulate to globose, 22–36 mm; **Tep** glabrous; **OTep** lanceolate, apex obtuse to truncate, 28–36 × 10–12 mm; **ITep** elliptic, apex acute, 23–30 × 12–14 mm, white to whitish-cream, tube none; **Fil** 13–15 mm, papillose; **Ov** narrowly ellipsoid to conical, 14–20 × 6–8 mm, pale green; **Sty** cylindrical, 3 mm; **Sti** lobed; **Fr**

fleshy berries, pendent, 70–98 (–115) × 25–39 (–45) mm, green; **Se** of various shapes, flat, 6–9 (–11) × 5–10 mm, 2–3 (–6) mm thick, black.

The fruits were unknown in the protologue, and *Y. queretaroensis* was at that time considered to be closest to the capsular-fruited *Y. thompsoniana* and to *Y. rostrata*, from which it differs in its taller and unbranched stems, biconvex and more slender leaves and smaller flowers. Piña Luján (1990) added a description of the baccate fruits and details of the typification. Hochstätter (2008b) placed *Y. queretaroensis* together with the similar *Y. linearifolia* in a separate, baccate-fruited section *Gracilifoliae*, but this was not accepted by others. *Y. queretaroensis* differs from the similar *Y. linearifolia* by leaves that are more rhomboid in transverse section, and its leaves break when bent into a knot, whereas those of *Y. linearifolia* neatly bend (Weissbeck 2010, 2011). Magallán Hernández & al. (2013a, b) describe habitats and distribution, and the threat by the horticultural trade of wild-collected plants. Magallán Hernández & al. (2014) provide a full description incl. leaf anatomy, and place the species in Ser. *Treculianae* (= Ser. *Yucca*). In the molecular phylogeny of Smith & al. (2008a), *Y. queretaroensis* appears to be closest to *Y. filifera*, but its position remains enigmatic, as some DNA data available from GenBank places it as basal sister to all other species of the genus. Zamudio & Galván Villanueva (2011: 10, 87) provide a new record from N Guanajuato, and Spracklin (2015) reports suspected natural hybrids with *Y. filifera*. Vernacular name: “estoquillo”. For winter-hardiness in cultivation, see Weissbeck (2010, 2011).

**Y. reverchonii** Trelease (Annual Rep. Missouri Bot. Gard. 22: 102, t. 108, 1912). **Type** [lecto]: USA, Texas (*Reverchon* 4030 [MO 148679, BRIT-SMU, MO]).—**Lit:** Webber (1953: 41–43, t. 23); Matuda & Piña Luján (1980: 118–120); Hess & Robbins (2002); Hawker (2016: 383–385); all with ills. **Dist:** USA (Texas), Mexico (Coahuila); usually on rocky limestone ledges and gravelly plains in dense bush, 300–900 m; flowers May to mid-June. **I:** Boeuf & al. (2009: 94–95).

[3a] Acaulescent, solitary or forming dense colonies, with branching subterranean rhizomes;

**Ros** single but in age forming small dense clumps with 2–10 **Ros** 0.3–1 m Ø; **L** < 100, lanceolate, straight, slightly concave, nearly flattened, quite rigid, straight, 25–60 × 1–2 (–2.5) cm, widest in the middle, light glaucous-green, margins hyaline, yellow or reddish-brown, minutely denticulate; **Inf** erect, paniculate, peduncle 46–110 cm, glabrous to heavily floccose, flowering part 35–100 cm, narrowly ovoid to narrowly pyramidal, arising 25–42 cm beyond the rosette, part-**Inf** few-flowered, densely pubescent; **Fl** pendent, campanulate to somewhat globose, hardly opening at anthesis; **Tep** ovate, sharply acuminate, 38–60 × 15–29 mm, white or greenish-white; **Fil** 18–32 mm; **Ov** ± 20–25 × 4–6 mm, tapering or rarely abruptly narrowed into the style; **Sty** 10–20 mm, white or greenish; **Fr** erect dry capsules, ellipsoid, rarely constricted, with an attenuate beak, 38–59 × 18–32 mm; **Se** flat, thin, unwinged, 5–6 × 6–7 mm, dull black.

Webber (1953: 42) designated the lectotype (as “Type”) cited above. This species is similar to *Y. rupicola* in its tall upright inflorescences, but distinguished by its straight, rigid, slightly concave and narrower leaves with yellow or reddish-brown margins (vs. leaves twisted, flexible, strongly concave, broader, and with orange or reddish-brown margins in *Y. rupicola*) (Hess & Robbins 2002). The protologue indicated that the distribution of *Y. reverchonii* on the Edwards Plateau (Texas) lies between *Y. rupicola* and *Y. thompsoniana*, and Webber (1953) reported apparent hybrids of *Y. reverchonii* with both species. The available molecular data is inconclusive about the relationships of *Y. reverchonii*: Clary (1997) (cited by Hess & Robbins 2002) found it close to *Y. thompsoniana* and *Y. rupicola*, while Pellmyr & al. (2007) and Smith & al. (2008a) found a position close to *Y. rostrata* (AFLP data), or to *Y. constricta* or *Y. intermedia* (chloroplast DNA sequence data), and *Y. rupicola* is well separated from *Y. reverchonii* in both datasets (*Y. thompsoniana* not sampled). The distribution in N Coahuila, Mexico, reported by Matuda & Piña Luján (1980: 120), is omitted by Hess & Robbins (2002) and Hawker (2016) and needs verification. Bolliger (2010) shows an artificial hybrid with *Y. filamentosa*.

**Fig. 6** *Yucca rigida*. (Copyright: U. Eggli)

**Y. rigida** (Engelmann) Trelease (Annual Rep. Missouri Bot. Gard. 13: 65, tt. 35, 36: fig. 1, 84: fig. 1, 1902). **Nom. illeg.**, ICN Art. 53.1. **Type:** Mexico, Durango (*Gregg* 477 [MO 148683]).—**Lit:** Matuda & Piña Luján (1980: 122–125, with ills.); Hochstätter (2004a: 47–49, ills. pp. 142, 144–146); Flores-Hernández & al. (2011: with ills.). **Distr:** Mexico (C & SE Chihuahua, SW Coahuila, E Durango); stony ravines and slopes in desert scrub, 1100–1600 m; flowers March to May. **I:** Earle (1964); Piña Luján (1980: 281); Starr (2000: 13); Irish & Irish (2000: t. 91); Johnson (2000: 19); Hochstätter (2003a: 20–22); Guillot Ortiz & Meer (2008: 110). – Fig. 6.

≡ *Yucca rupicola* var. *rigida* Engelmann (1873); **incl.** *Yucca luminosa* Govaerts (2014) (*nom. inval.*, ICN Art. 29.1).

[3a] Caulescent, stems to 3–5 m, 20–45 cm Ø, **Br** none or few, 3–5 or more, stems usually with a long skirt of dried deflected leaves often reaching down to the ground; **Ros** asymmetrical, 0.5–1 m Ø; **L** spreading, linear, slightly broadened in the middle, slightly canaliculate, thin, 30–60 × 2–3 cm, yellowish-green and glaucous to nearly pale blue, margins yellowish, finely denticulate, tip slender but very pungent, brown or grey; **Inf** erect, paniculate, peduncle 30–70 cm, flowering

part 0.6–1.2 m, with its base within the rosette leaves, ovoid, dense; part-**Inf** 28–40, glabrous; **Fl** globose to campanulate; **Tep** narrowly oblong, acuminate, 40–50 × 16–22 mm, creamy-white or greenish-white; **Fil** 16–22 mm; **Ov** ± 13 × 5 mm; **Sty** short, ± 2 mm; **Sti** lobed; **Fr** erect dry capsules, oblong, not constricted, rough, 35–70 × 18–25 mm, strongly beaked; **Se** 4–5 × 5–7 mm, dull black.

The protologue of the basionym cites Gregg, “scape . . . 5-10 feet high” as type. The Engelmann herbarium at MO “contains two specimens” (Trelease 1902: 65), *Gregg A* (= MO 148684) and *Gregg 477* (= MO 148683), which represent different gatherings with different collection numbers, but were nevertheless cross-labelled later. The specimen *Gregg 477* with the hand-written label “5 to 10 +” is the holotype. The neotypification by Hochstätter (2004a: 47) is thus superfluous, and moreover ineffective under ICN Art. 7.11.

The established name *Y. rigida* (Engelmann) Trelease is unfortunately a later homonym of *Y. ×rigida* Deleuil ex André 1883, and therefore illegitimate. Govaerts (2014+) used the replacement name *Y. luminosa*, but the name was not formally published and is therefore invalid. In order to stabilize current use, a proposal to conserve Trelease’s name is in progress.

Molecular AFLP data (Pellmyr & al. 2007; Smith & al. 2008a) show the species as well-supported sister to the other species of Sect. *Rupicolae* sampled in those studies; chloroplast sequence data (Smith & al. 2008a) show various different placements. A habitat study in the municipio of Mapimí, Durango, revealed a population density of 980 plants/ha, and that stem height and diameter increase with increasing altitude (Flores-Hernández & al. 2011).—The species becomes increasingly popular as landscape plant in the SW USA and is “perhaps the most beautiful and elegant of all yuccas” (Johnson 2000: 16).

**Y. rostrata** Engelmann ex Trelease (Annual Rep. Missouri Bot. Gard. 13: 68, tt. 40–42, 84: fig. 3, 93: fig. 2, 1902). **Type** [lecto]: Mexico, Coahuila (*Palmer* s.n. in 1880 [MO 148694,

GH]).—**Lit**: Matuda & Piña Luján (1980: 125–127, with ill.); Hochstätter (2000: 29–30, ill. pp. 82–83); Hess & Robbins (2002). **Dist**: USA (SW Texas: Brewster County), Mexico (C, E & S Chihuahua, N, C, W & S Coahuila, E Durango?); rocky mountain slopes, canyon bottoms, plains and moderate slopes with desert scrub, 300–800 m; flowers March to May. **I**: Hochstätter (1999: 215–218); Irish & Irish (2000: t. 92); Starr (2000: 13), Boeuf (2007a: 75); Guillot Ortiz & Meer (2008: 110); Boeuf & al. (2009: 98–99).

[3a] Arborescent, stems erect, 1.8–3.6 (–4.5) m, 18–32 cm Ø, mostly simple or occasionally with up to 3 branches; **Ros** frequently asymmetrical, with >100 leaves, solitary or forming colonies; **L** linear, often twisted, flat to canaliculate, broadest considerably above the middle, smooth on both faces, 25–60 × 1.2–1.7 cm, glaucous, margins lemon-yellow, hyaline, finely denticulate, **terminal Sp** very pungent; **Inf** erect, paniculate, peduncle 0.3–1 m, glabrous or glabrescent, flowering part 0.6–2 m, ellipsoid to ovoid, arising just within or beyond the rosette leaves, densely many-flowered; part-**Inf** 28–40, up to 38 cm, sparsely pubescent; **Fl** pendent, globose to campanulate; **Tep** narrowly ovate, sharply acuminate, 42–52 × 11–20 mm, white; **Fil** 17–20 mm; **Ov** ± 19–20 × 4–6 mm; **Sty** 6–14 mm, white; **Sti** lobed; **Fr** erect, ovoid to ellipsoid, rarely constricted, 40–70 × 18–25 mm, tip with a strong and curved beak; **Se** 4–5 × 6–7 mm, rather dull black.

The protologue cited material from Bigelow and Palmer. McKelvey (1947: 78) designated *Palmer* s.n. (MO 148694) as “Type”, which represents a lectotypification. The same selection was also made by Webber (1953: 38).

Closely related to *Y. thompsoniana*, which may represent just a N dwarfer variant (Webber 1953, Hess & Robbins 2002). It is best distinguished by its ± larger habit with larger inflorescences and longer and broader leaves with the widest part considerably above the middle, and smooth on both faces (vs. smaller-growing with smaller inflorescences and shorter and narrower leaves widest at or above the middle and ± scabrous on both faces in *Y. thompsoniana*). Specimens from Durango placed here need verification.

With early molecular data (chloroplast DNA restriction sites, Clary & Simpson 1995), *Y. rostrata* groups in an unresolved polytomy together with *Y. reverchonii*, *Y. rigida* and *Y. thompsoniana*. In recent molecular phylogenies (Pellmyr & al. 2007, Smith & al. 2008a), *Y. rostrata* is closest to *Y. reverchonii* (AFLP data), or to *Y. elata* (chloroplast DNA sequence data; *Y. thompsoniana* not sampled).

Recently, green-leaved populations from NE Coahuila placed in *Y. rostrata* (Boeuf & al. 2009: 99, Weissmüller 2017) and similar plants from N of the Big Bend National Park, Texas, placed in *Y. thompsoniana* (Boeuf 2007a: 118–119) became known and are also offered commercially in Europe. For the outdoor cultivation (hardy down to  $-15$  to  $-20$  °C) see Boeuf (2007a). Boeuf & al. (2010: 80) report variegated forms from European collections.

**Y. rupicola** Scheele (Linnaea 23: 143–144, 1850). **Type:** USA, Texas (*Lindheimer* 709 [MO 148731]).—**Lit:** Trelease (1902: 67–68, tt. 3–39); Matuda & Piña Luján (1980: 116, 119); Hochstätter (2000: 26–27, ills. p. 81); Hess & Robbins (2002); Diggs & al. (2006: 420–421, ill. p. 308); Hawker (2016: 386–391, with ills.). **Distr:** USA (S-C Texas: SE Edwards Plateau); rocky hillsides, limestone ledges and grassy plains, dense bush and open woodland, 400–900 m; flowers May to June. **I:** Curtis's Bot. Mag. 117: t. 7172 (1891); Hochstätter (1999: 209–210); Guillot Ortiz & Meer (2008: 111); Boeuf & al. (2009: 100–101).

**Incl.** *Yucca contorta* Regel (1858); **incl.** *Yucca lutescens* Carrière (1858); **incl.** *Yucca contorta* Carrière (1858) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca tortilis* hort. ex Carrière (1858) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca rupicola* var. *tortifolia* Engelmann (1873); **incl.** *Yucca tortifolia* Lindheimer ex Engelmann (1873) (*nom. inval.*, ICN Art. 36.1c).

[3a] Acaulescent, with branching subterranean rhizomes; **Ros** soon developing open colonies with 2–15 large heads; **L** < 100 per rosette, lanceolate, twisted, flaccid, flexible, strongly concave or flat but oblique or undulate, slightly striate, distinctly narrowing towards the

base, widest in the middle, (20–) 35–58 × 2–4 cm, dark green, margins hyaline dark orange or reddish-brown or occasionally yellow, minutely denticulate or wavy, tip pungent; **Inf** erect, paniculate, peduncle 30–150 cm, flowering part 25–100 cm, narrowly ovoid to narrowly pyramidal, 24–48 cm above the rosette leaves; part-**Inf** 8–16, 7–20 cm, glabrous to slightly floccose; **Fl** few, pendent, mainly campanulate, expanding but little, rarely somewhat globose and open; **Tep** ovate, sharply acuminate, 38–69 × 15–30 mm, white or greenish-white; **Fil** 18–32 mm; **Ov** 17–25 × 4–6 mm, tapering or somewhat abruptly terminating into the style; **Sty** 12–20 mm, white or greenish; **Sti** lobed; **Fr** erect dry capsules, ellipsoid or somewhat cylindrical, rarely constricted, 38–55 × 20–30 mm, beaked; **Se** thin, 6–8 × 7–8 mm, dull black.—**Cytology:** 2n = 60 (McKelvey & Sax 1933).

The protologue cites material of Lindheimer from a rocky plateau near New Braunfels, June, which, among the 14 *Y. rupicola* specimens of Lindheimer at MO, is only matched by MO 148731, as also indicated by a label of K. H. Clary (2003). The neotypification by Hochstätter (1999: 209) is thus superfluous.

This is the only species with twisted adult leaves (Hochstätter 2000, Hess & Robbins 2002, Boeuf 2009). For a discussion of the relationships of this species with *Y. pallida* and *Y. cernua*, see under *Y. pallida*.

**Y. schidigera** Roehl ex Ortgies (Gartenflora 20: 110, 1871). **Type** [neo]: USA, California (*Nuttall* s.n. [GH]).—**Lit:** Shreve & Wiggins (1964: 354); Benson & Darrow (1981: 56, figs. 3.18–3.22); Matuda & Piña Luján (1980: 81–83, with ills.); Turner & al. (1995: 411–412); Hess & Robbins (2002); Hawker (2016: 391–398, with ills.). **Distr:** S USA (S California, S Nevada, W Arizona), Mexico (adjacent N Baja California); gravelly mountain and valley slopes, desert or chaparral vegetation, 300–2050 m; flowers March to May. **I:** Hochstätter (1999: 81–85); Irish & Irish (2000: t. 94); Guillot Ortiz & Meer (2008: 111); Boeuf & al. (2009: 102–103). – Fig. 7.

**Incl.** *Yucca californica* Nuttall ex Baker (1880) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca*

**Fig. 7** *Yucca schidigera*. (Copyright: U. Eggli)

*mohavensis* Sargent (1896)  $\equiv$  *Sarcoyucca mohavensis* (Sargent) Lindinger (1933).

[1b] Stems caulescent, 1–8, erect, simple or sparingly branched, to 2.5–5 m, forming colonies of several rosettes; **L** numerous, erect, sword-shaped, thick, very rigid, for the greater part rather deeply canaliculate, broadest near the middle, glabrous, 33–130  $\times$  3–5 cm, yellowish-green, margins thick, with coarse somewhat curled fibres, apex stout-pungent; **Inf** erect, paniculate, peduncle to 40 cm, flowering part 30–60 cm, obovoid or ellipsoid and with flattened tip, entirely within or scarcely beyond the rosette leaves; part-**Inf** many, with numerous densely arranged flowers, glabrous or pubescent; **Fl** pendent, globose; **Tep** (broadly) lanceolate, spreading, 30–50 (–75)  $\times$  10–18 mm, white or cream-coloured, commonly tinged with lavender or purple; **Fil** 20–25 mm; **Ov** rather stout, apex abruptly tapered, 17–27  $\times$  7–12 mm; **Sty** 1–2 mm; **Sti** distinct; **Fr** pendent fleshy berries, variable, long and cylindrical, mostly constricted in the middle, 50–115  $\times$

30–40 mm, usually tapering from the swollen base to a rather blunt tip 60–85 mm long, first green, turning dark brown to nearly black; **Se** unwinged, rugose, 8–11 mm  $\varnothing$ , 6–9 mm thick, grey.

The protologue does not cite a type. The designation of *Nuttall* s.n. (GH), the type of *Y. californica*, as “Type” by Webber (1953: 25), represents a neotypification. In the molecular phylogeny of Pellmyr & al. (2007), the single sample analyzed of *Y. schidigera* groups within 7 samples of *Y. baccata*.

*Y. schidigera* dominates the Mohave Desert of the SW USA, and is often associated with *Y. brevifolia* (Boeuf & al. 2009: 103). It is frequently used for landscaping in the SW USA (Irish & Irish 2000). Boeuf & al. (2010: 82) report rare cases of spontaneous variegations originating in cultivation. In historical times, *Y. schidigera* was used by Native Americans as a source of fibre, food, and soap (Benson & Darrow 1981, Hess & Robbins 2002).

**Y.  $\times$ schottii** Engelm *pro sp.* (Trans. Acad. Sci. St. Louis 3: 46, 1873). **Type** [lecto]: USA, Arizona (*Schott* s.n. [NY]).—**Lit**: Lenz & Hanson (2000); Lenz & Hanson (2001); both with ill. **Distr**: S USA (Arizona, SW New Mexico?), N Mexico (N, E & SE Sonora, W-most Chihuahua); rocky slopes (volcanic and limestone) in oak woodland and pine-oak forests, 350–1500 m; flowers February to May. – Fig. 8.

$\equiv$  *Sarcoyucca schottii* (Engelm) Lindinger (1933); **incl.** *Yucca  $\times$ puberula* Torrey *pro sp.* (1858) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca brevifolia* A. Schott *ex* Engelm (1873) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca  $\times$ macrocarpa* Engelm *pro sp.* (1881); **incl.** *Yucca brevifolia* A. Schott *ex* Trelease (1902) (*nom. illeg.*, ICN Art. 53.1).

[1b  $\times$  1c  $\times$  3b] Lenz & Hanson (2000, 2001) clarified the nomenclatural and taxonomic confusion surrounding *Y. schottii*, and designated the above-cited lectotype (Lenz & Hanson 2000: 97). According to their interpretation, the name *Y. schottii* Engelm represents the earliest applicable name for hybrids and backcrosses between the fleshy-fruited *Y. baccata* and *Y. madrensis* and

**Fig. 8** ×*Yucca schottii*.  
(Copyright: U. Eggli)

the capsular-fruited *Y. elata*, and it is thus recognized as name for a collective hybrid species.

Hess & Robbins (2002) express doubts, however, on the possibility for crosses between baccate and capsular-fruited species. The common fleshy-fruited *Yucca* with long wide flexible blue-green leaves from the mountains of S Arizona, previously wrongly named *Y. schottii* auct. non Engelmann, is regarded as pertaining to *Y. madrensis*, where most treatments and published photographs named *Y. schottii* belong. In the molecular phylogeny of Pellmyr & al. (2007) 3 samples of *Y. schottii* are sister to a clade that consists of 7 samples of *Y. baccata* plus 1 sample of *Y. schidigera*, but the *Y. schottii* samples may belong to *Y. schottii* auct. = *Y. madrensis*.

Lenz & Hanson (2001) also include the widely recognized taxa *Y. baccata* var. *brevifolia* (here treated as *Y. baccata* ssp. *thornberi*) and most of its synonyms as well as *Y. grandiflora* in *Y. ×schottii*, but since their study covers a small area in S Arizony only and neither the full geographical range also including Mexico, nor a broader specimen set, both are upheld here pending more detailed studies.

**Y. tenuistyla** Trelease (Annual Rep. Missouri Bot. Gard. 13: 53–54, tt. 17: fig. 2, 18–19, 83: fig. 3, 92: fig. 1, 1902). **Type** [lecto]: USA, Texas (*Lindheimer* s.n. [MO 148758]).—**Lit**: Hess & Robbins (2002); Diggs & al. (2006: 422). **Distr**: USA (SE Texas); scrubland at the coast, brushland

in the Edwards Plateau and the South Texas Plains, in dry soil, 0–200 m; flowers May to June.

[3c] Stems none or short and erect, to 0.5 m; **Ros** forming open colonies; **L** lanceolate, mostly recurving, rigid, lower face convex, upper face flat, widest near the middle, long attenuate, lower face often somewhat scabrid, 40–70 × 1–2 cm, dark green, margins entire but filiferous, whitish, apex scarcely pungent; **Inf** erect, paniculate, peduncle 1–1.7 m, flowering part to 1 m, ovoid, arising beyond the rosette leaves, distance from the rosette leaf tips to the lowest inflorescence branches >2× the leaf length at full anthesis, glabrous or slightly pubescent; **Fl** pendent; **Tep** narrow, apex acute, ± 27–30 × 7–10 mm; **Fil** < 19 mm; **Ov** ± 12 × 4 mm, white; **Sty** oblong, often deeply lobed, ± 7 mm, white or green; **Sti** lobed; **Fr** erect dry capsules, cylindrical, stout, not constricted, 50–65 × 25–30 mm; **Se** thin, 8–10 × 7–8 mm, shiny black.

The protologue cites specimens of Lindheimer, Trelease, and Harvey, which constitute syntypes. McKelvey (1947: 133) designated the above-cited lectotype.

Very insufficiently known. *Y. tenuistyla* and *Y. louisianensis* were both regarded as possible synonyms of *Y. constricta* by McKelvey (1947), and the three taxa differ only tenuously. According to Hess & Robbins (2002) *Y. tenuistyla* is probably just a variant of *Y. flaccida*, and also includes *Y. louisianensis*. According to Diggs & al. (2006), *Y. constricta* is usually easily

distinguished in the field in being typically much taller with very numerous, straight, narrower leaves and constricted capsules.

**Y. thompsoniana** Trelease (Annual Rep. Missouri Bot. Gard. 22: 101–102, tt. 104–107, 1912). **Type:** USA, Texas (*Bigelow* s.n. [NY 688485, MO, NY]).—**Lit:** Webber (1953: 39–40, t. 21); Matuda & Piña Luján (1980: 127–130, with ills.); Hochstätter (2000: 28–29, ills. p. 82); Hess & Robbins (2002); Hawker (2016: 397–401, with ills.). **Distr:** USA (SW Texas), Mexico (NE Chihuahua, N & C Coahuila, C Nuevo León), usually on exposed rocky knolls and slopes, 200–1400 m; flowers April to May. **I:** Piña Luján (1980: 281); Hochstätter (1999: 212–214); Boeuf (2007a: 77, 118–119); Guillot Ortiz & Meer (2008: 111); Boeuf & al. (2009: 106–107).

**Incl.** *Yucca rostrata* fa. *integra* Trelease (1911); **incl.** *Yucca thompsoniana* fa. *viridis* Weissbeck & Boeuf (2007) (*nom. inval.*, ICN Art. 29.1 & Ex. 2).

[3a] Caulescent, stems erect, 0.7–2.5 m, to 30 cm Ø, single, with 1–5 comparatively long ascending or diffusive branches; **Ros** with >100 leaves, frequently asymmetrical, rather small, solitary or forming colonies; **L** linear, thin and flexible, flat or canaliculate to flat above and keeled below, striate, widest at or above the middle, ± scabrous on both faces, 20–30 (–45) × 0.7–1.2 cm, margins horny, minutely denticulate, yellow or orangish-red, apex sharply pointed; **Inf** erect, paniculate, racemose at the tip, peduncle (30–) 40–70 cm, flowering part 52–82 cm, narrowly ellipsoid to somewhat ovoid, arising 11–19 cm above the rosette leaves; part-**Inf** 20–34, 2–22 cm, glabrous or glabrescent; **Fl** pendent, globose to campanulate; **Tep** narrowly elliptic, sharply acuminate, conspicuously veined, glossy, 35–67 × 12–35 mm, white; **Fil** 17–33 mm; **Ov** slender, 4–6 mm Ø, usually tapering into the style; **Sty** 6–18 mm, white; **Sti** lobed; **Fr** erect dry capsules, ellipsoid or somewhat ovoid, rarely constricted, 35–70 × 20–25 mm, with a long beak; **Se** flat, thin, unwinged, 5–6 × 6–7 mm, dull black.

The protologue cites *Bigelow* August 10, 1852, as “type”, and according to the captions to the plates, t. 105 illustrates the type sheet at NY (=

NY 688485, confirmed by K. H. Clary (label in 2003)). Webber (1953) characterized *Y. thompsoniana* as a dwarfish form of *Y. rostrata*, perhaps not worthy of recognition at species rank. He also suggested that it may hybridize with *Y. reverchonii*. In the molecular chloroplast DNA restriction site phylogeny of Clary & Simpson (1995), *Y. thompsoniana* groups in an unresolved polytomy together with *Y. reverchonii*, *Y. rigida*, and *Y. rostrata*. For differences to *Y. rostrata*, see there. Heim (2012) raised an artificial hybrid with *Y. recurvifolia* (here treated as *Y. gloriosa* var. *tristis*).

**Y. treculiana** Carrière (Rev. Hort. (Paris) 1858: 580, 1858). **Type** [neo]: USA/Mexico (*Trécul* 1496 [P 02161277]).—**Lit:** Trelease (1902: 96–97, tt. 52–54); Webber (1953: 21–22, t. 6); Matuda & Piña Luján (1980: 75–79, with ills.); Robbins (1983: 22–28, 41–45); Hess & Robbins (2002); Diggs & al. (2006: 420–421, ills. pp. 308, 425); Hawker (2016: 401–403, with ills.). **Distr:** SE USA (W Texas), N Mexico (Chihuahua, Coahuila, Nuevo León, Tamaulipas, Durango, Zacatecas); grassy or rocky slopes or mesas, brushland, chaparral vegetation, 0–1600 m; flowers March to April. **I:** Curtis’s Bot. Mag. 86: t. 5201 (1860, as *Y. canaliculata*); Irish & Irish (2000: tt. 97–98); Johnson (2000: 19); Starr (2000: 13); Hochstätter (2001b: 78–81); Boeuf (2007a: 85); Boeuf & al. (2009: 110–111).

≡ *Sarcocoyucca treculiana* (Carrière) Lindinger (1933); **incl.** *Yucca spinosa* Kunth (1816); **incl.** *Yucca agavoides* hort. ex Carrière (1858); **incl.** *Yucca recurvata* hort. ex Carrière (1858) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca revoluta* hort. ex Carrière (1858) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca undulata* hort. ex Carrière (1858) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca aspera* Regel (1859); **incl.** *Yucca canaliculata* Hooker (1860) ≡ *Yucca treculiana* var. *canaliculata* (Hooker) Trelease (1902); **incl.** *Yucca canaliculata* var. *pendula* K. Koch (1862); **incl.** *Yucca undulata* K. Koch (1862) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca longifolia* Buckley (1863) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca argospatha* Verlot (1868); **incl.** *Yucca crassifila* Engelman (1873) (*nom. inval.*, ICN Art. 36.1c);

**incl.** *Yucca longifolia* Engelm (1873) (*nom. inval.*, ICN Art. 36.1c); **incl.** *Yucca cornuta* hort. ex Baker (1880); **incl.** *Yucca concava* hort. ex Baker (1880) (*nom. illeg.*, ICN Art. 53.1); **incl.** *Yucca treculiana* var. *glauca* Sprenger (1901); **incl.** *Yucca torreyi* Shafer (1908); **incl.** *Yucca torreyi* fa. *parviflora* McKelvey (1938); **incl.** *Yucca treculiana* var. *succulenta* McKelvey (1938).

[1c] Arborescent, stems 1–8, forming groups of variable height, simple or occasionally with 2–5 branches, to 7 m, 14–15 cm Ø, often forming colonies of several rosettes; **L** erect, rigid, canaliculate, thick, usually U- or V-shaped in cross-section, rather scabrous, 36–128 × 1.6–7 cm, yellowish- to bluish-green, old leaves hanging at various angles, giving an overall ragged appearance, margins entire, with sparse thin and straight coarse fibres, light brown, **terminal Sp** very acute; **Inf** erect, paniculate, peduncle 30 cm or more, flowering part 1.8 m, variable in shape, usually ovoid, arising mostly within the rosette leaves, exceeding the leaves for ½–¾ of its length, densely many-flowered, glabrous, rarely slightly pubescent; **Bra** large in the lower inflorescence parts; **Fl** pendent, globose; **Tep** ovate, apex rounded or acute, 27–81 × 10–34 mm, cream-coloured, occasionally tinged with purple; **Fil** 10–27 mm; **Ov** 13–33 × 4–10 mm; **Sty** 2–8 mm; **Sti** distinct; **Fr** pendent fleshy berries, cylindrical, terminal part conical, 44–187 × 18–46 mm; **Se** rough, 5–14 mm Ø, 1–5 mm thick.

The protologue does not cite a type. The designation of *Trecul* 1496 (P) as “Type” by Webber (1953: 21) represents a neotypification. The epithet is usually written ‘treculeana’, but the taxon is named for the French botanist A. A. L. Trécul.

*Y. spinosa* Kunth (1816), listed here as provisional synonym following Govaerts (2014+: accessed Jan. 2019) would have priority over the younger name *Y. treculiana* if it should definitely belong here, and a proposal to conserve the latter name would be necessary.

*Y. torreyi*, shown as closely related with *Y. treculiana* in the early molecular study of Clary & Simpson (1995), is the E entity within a broader concept of *Y. treculiana*, and included in the synonymy here following Robbins (1983) and Hess & Robbins (2002), whereas Matuda & Piña

Luján (1980), Benson & Darrow (1981), and Diggs & al. (2006) recognize it as distinct.

**Y. utahensis** McKelvey (Yuccas Southwest US, 2: 94, tt. 32–34, 1947). **Type:** USA, Utah (McKelvey 4167 [A]).—**Lit:** Webber (1953: 62–65); Reveal (1977: 533–534, as *Y. elata* var.); Welsh & al. (1987: 650); Hess & Robbins (2002); Hawker (2016: 403–408). **Dist:** SW USA (SE Nevada, SW Utah, NW Arizona); desert and desert hillsides, woodlands, and canyons, often on sandy places, 700–2200 m; flowers late April to June. **I:** Hochstätter (1999: 24, 26, as *Y. elata* var.); Boeuf & al. (2009: 112–113).

≡ *Yucca elata* var. *utahensis* (McKelvey) Reveal (1977) ≡ *Yucca elata* ssp. *utahensis* (McKelvey) Hochstätter (1999).

[3b] Caulescent or appearing acaulescent, not distinctly arborescent, stems often procumbent, usually 7 or more per colony, thick, 1.2–2.8 m; **Ros** forming large colonies with up to 10–15 rosettes; **L** numerous, linear-lanceolate, divergent, flexible, plano-convex or plano-keeled, widest near the middle, 20–70 × 0.7–2.2 cm, yellow-green, margins whitish, entire but finely filiferous, tip acuminate with a short spine; **Inf** erect, paniculate, sometimes distally racemose, peduncle 1–1.6 m, flowering part 1–1.5 m, narrowly ellipsoid, arising beyond the rosette leaves; part-**Inf** 10–20 cm, glabrous; **Bra** erect; **Ped** 13–25 mm; **Fl** pendent, campanulate; **Tep** broadly elliptic or ovate, 40–50 × 20–25 mm, creamy-white; **Fil** 20–25 mm; **Ov** 20–25 mm; **Sty** 5–10 mm, white; **Sti** lobed; **Fr** erect dry capsules, oblong-cylindrical, 50–60 × 20–25 mm; **Se** thin, dull black.

The taxon is treated very differently by different authors. The protologue suggested a close relationship with *Y. elata*, from which it differs primarily in growth habit, fruit size, and leaf width, although with some overlap. Webber (1953) regarded *Y. utahensis* as a hybrid population, but this view was rejected as unjustified by Reveal (1977: 534) who reduced the taxon to varietal rank under *Y. elata*, assigning (sub-) caulescent plants to *Y. elata* var. *utahensis* and acaulescent or infrequently caulescent plants with racemose inflorescences to *Y. angustissima*.

Welsh & al. (1987) recognized the taxon at species rank, noting that it is disjunct from *Y. elata*, and closer to *Y. (angustissima var.) kanabensis*. DNA evidence of Clary (1997) (cited by Hess & Robbins 2002) suggested a close relationship with *Y. elata*. Lenz & Hanson (2001: 169) referred the taxon to the synonymy of *Y. elata*. However, species rank for *Y. utahensis* is strongly supported by molecular data (Pellmyr & al. 2007, Smith & al. 2008a: fig. 2b, c) where the sample of *Y. utahensis* (as *Y. elata utahensis*) is sister to *Y. angustissima* [var.] *kanabensis* (thus confirming Welsh) and clearly separate from six samples of *Y. elata*, which form a distinct clade.

**Y. valida** Brandegee (Proc. Calif. Acad. Sci., Ser. 2, 2: 208, t. 11., 1889). **Type:** Mexico, Baja California (Brandegee s.n. [UC]).—**Lit:** Shreve & Wiggins (1964: 354); Matuda & Piña Luján (1980: 96–99, with ills.); Turner & al. (1995: 413–414); Hochstätter (2004a: 31–32, ills. pp. 116–118). **Distr:** Mexico (Baja California, Baja California Sur); Pacific coastal plains and gentle slopes, to 850 m; flowers March to April. **I:** Piña Luján (1980: 280); Hochstätter (2003d: 211); Boeuf & al. (2009: 114–115).

≡ *Yucca ×schottii* var. *valida* (Brandegee) M. E. Jones (1930) ≡ *Sarcocoyucca valida* (Brandegee) Lindinger (1933).

[1b] Arborescent and stems 3–12 m tall, 50–60 cm Ø, ± branched upwards, or shrub-forming and branched nearly from the base, surculose, stems with a skirt of dried deflected leaves for 1–2 m below the rosettes; **L** many, spreading, lanceolate, rigid, thin, smooth, 15–35 (–50) × 1.5–2.5 (–3) cm, yellowish-green, margins grey to brownish, strongly filiferous, fibres thick, curved, tip stout-pungent; **Inf** erect, paniculate, peduncle short, flowering part short, 30–60 cm, hidden within the leaves for ¼–½; **part-Inf** ascending-spreading, 10–20 cm, puberulent to glabrous; **Ped** 15–20 mm; **Fl** pendent, broadly campanulate, scented; **Tep** elliptic-lanceolate, acute to obtuse, 25–30 mm, creamy-white; **Fil** 10–12 mm, densely papillate-puberulent; **Ov** oblong, ± 13 × 4 mm, tip abruptly conical; **Sty** short, ± 2 mm; **Sti** nearly sessile; **Fr** fleshy berries, oblong, 25–45 mm, turning black upon

drying; **Se** with rugose margin, 3–7 mm Ø, 1–1.5 mm thick.

An important and characteristic constituent of the fog-influenced Pacific coastal desert scrub formations of the Baja California Peninsula, occurring from near El Rosario in the N to the vicinity of Ciudad Constitución in the S (Rebman & al. 2016: 272). Plants from the Cape region formerly included here were described as a distinct separate species, *Y. capensis* (see there). The close relationship between the two taxa is supported by AFLP molecular data, but not by chloroplast DNA sequence data (Pellmyr & al. 2007, Smith & al. 2008a).

**Part II**

**The Family Amaryllidaceae**

## Amaryllidaceae

U. Eggli, E. Van Jaarsveld, and S. Arroyo-Leuenberger

**Including** *Brunsvigiaceae* Horaninow.

**Including** *Cyrtanthaceae* Salisbury.

**Including** *Galanthaceae* G. Meyer.

**Including** *Gethyllidaceae* Rafinesque.

**Including** *Haemanthaceae* Salisbury.

**Including** *Leucojaceae* Batsch ex Borkhausen.

**Including** *Narcissaceae* Jussieu.

**Including** *Oporanthaceae* Salisbury.

**Including** *Pancratiaceae* Horaninow.

**Including** *Zephyranthaceae* Salisbury.

Perennial or biennial bulbous herbs with fleshy tunics, rarely rhizomatous (*Clivia*, *Scadoxus*); **R** contractile; **L** linear to oblong, sometimes ovate or tapering, slightly to rarely distinctly succulent; **Inf** umbellate with a usually well-developed scape, or rarely **Fl** solitary, with an involucre (= spathe) of 2 (–8) **Bra**; **Fl** bisexual, actinomorphic to zygomorphic; **Tep** 6 in 2 series; **St** 6 (rarely more); **Fil** free or united at the base, filiform; **Anth** dorsifixed or basifixed; **Ov** inferior,

3-locular, each with 1 to many ovules, placentation axile (rarely parietal); **Sty** terete; **Sti** capitate or tricuspidate or 3-branched; **Fr** 3-valved capsules, rarely fleshy; **Se** few to many, voluminous or flattish, angled or winged; endosperm fleshy.

**Order:** Asparagales

**Important Literature:** Meerow & Snijman (1998: synopsis); Meerow & al. (1999: molecular systematics); Meerow & al. (2000a: phylogeny American taxa); Meerow & al. (2000b: phylogeny); Meerow & Clayton (2004: phylogeny *Haemantheae*); Meerow & Snijman (2006: molecular phylogeny); Meerow (2010: evolution American taxa); Duncan & al. (2016: illustrated monograph S African taxa).

**Distribution:** Cosmopolitan, confined mainly to temperate, subtropical and tropical regions, more common in Mediterranean and Savanna regions.

A family with 59 genera and ±870 species, of which many are frequently cultivated. *Amaryllidaceae* is part of the lower core Asparagales. It has invariably been found to form a clade with *Alliaceae* and *Agapanthaceae*, and APG (2009) advocated a wide circumscription of the group (accepting the traditional families at the rank of subfamilies). A super-conservation proposal was published by Meerow & al. (2007) to allow the continued usage of the name *Amaryllidaceae* (vs. the prioritable *Alliaceae*). Recent molecular

**Fig. 1** Summary phylogeny of *Amaryllidaceae* based on Meerow & Snijman (2006); species numbers based on own counts, Stevens (2001+) and Nicolás García (pers. comm.) (870 species total). A = *Amaryllidinae*, Andean TP =

Andean Tetraploid Clade, B = *Boophoninae*, C = *Calostemateae*, Cri = *Crininae*, Cyrt = *Cyrtantheae*, Stru = *Strumarinae*. (Copyright: U. Eggli)

phylogenies found reasonable support for *Agapanthaceae* as sister to a clade formed by *Alliaceae* plus *Amaryllidaceae* s.s. (Seberg & al. 2012, Steele & al. 2012).

Meerow & al. (2000a) and Meerow & al. (2000b) divide the *Amaryllidaceae* s.s. into 14 tribes and imply an African origin with a derived Eurasian clade. The American genera form a well-defined sister group relative to the Eurasian genera, and fall in 2 subclades, the “Andean clade” (here belongs tribe *Stenomesseae*) and a Hippeastroid clade. – Fig. 1.

The underground organs of most clades are bulbs, but bulb and rhizome geophytes can occur in close systematic neighbourhood, e.g. in the African tribe *Haemantheae* (*Clivia* with rhizomes and *Haemanthus* with bulbs) (Meerow & Clayton 2004). Many species contain toxic norbelladine alkaloids which are unique for the family.

**Succulence:** Undisputed leaf succulence is found in the S American genus *Rauhia*, but varying degrees of weak leaf succulence occur also in scattered species of the genera *Boophone*, *Brunsvigia*, *Cyrtanthus* and *Haemanthus* from

the savanna regions of RSA (Eastern Cape, KwaZulu-Natal and Mpumalanga) with mainly epigeous bulbs. However, most bulbous species from seasonally arid regions could be interpreted as being succulent to some extent, esp. when they produce flowers during the dry season. The bat-pollinated epiphytic *Hippeastrum calyptratum* is sometimes also regarded as succulent, but the leaves are merely slightly fleshy, and the plants are not specifically adapted to cope with water stress.

In addition, many species have somewhat fleshy roots. Distinctly succulent and thick (to 2 cm Ø) roots are described for the S African *Clivia mirabilis* by Duncan & al. (2016: 129–130), and they are thought to “provide water storage capacity enabling plants to survive summer drought”.

**Horticultural Importance:** *Amaryllidaceae* have a fairly pronounced horticultural importance, esp. because the many spring-flowering bulbs of *Galanthus*, *Leucojum* or *Narcissus*, while hybrids and cultivars of *Hippeastrum* (= the “Amaryllis” of the horticultural trade) or *Clivia* are widely cultivated as indoor plants.

## Key to genera with succulents

<b>1a</b>	<b>L</b> usually 2, opposite, hairy or glabrous; <b>Fr</b> fleshy berries	<i>Haemanthus</i>
<b>1b</b>	<b>L</b> 2 or more, glabrous; <b>Fr</b> dry capsules	2
<b>2a</b>	<b>Spathe</b> valves 2–4; <b>Se</b> flattened, usually appearing winged	<i>Cyrtanthus</i>
<b>2b</b>	<b>Spathe</b> valves 2 (rarely more); <b>Se</b> globose	3
<b>3a</b>	<b>Fl</b> ± 100 per <b>Inf</b> ; <b>Per</b> 1–2 (–3) cm, actinomorphic	<i>Boophane</i>
<b>3b</b>	<b>Fl</b> ≤ 30 per <b>Inf</b> ; <b>Per</b> 4–15 cm	4
<b>4a</b>	<b>L</b> tongue-shaped; <b>Per</b> pink or red; <b>Inf</b> caducous at fruiting time	<i>Brunsvigia</i>
<b>4b</b>	<b>L</b> oval to oblong, very fleshy, pseudopetiolate; <b>Per</b> greenish-whitish; <b>Inf</b> persistent at fruiting time	<i>Rauhia</i>

## Boophone AMARYLLIDACEAE

E. Van Jaarsveld

**Boophone** Herbert (Appendix, 18, 1821). **Type:** *Haemanthus toxicarius* Aiton [*nom. illeg.*; = *Amaryllis disticha* Linné *fil.* (ICBN 2006: 256)]. — **Amaryllideae** — **Boophoninae** — **Lit:** Duncan & al. (2016: 48–63, 662 [key] (S African taxa)). **Distr:** Widespread in Africa from Sudan to RSA. **Etym:** Gr. ‘bouphonos’, killing cattle; for the poisonous nature of the plants.

**Incl.** *Boophane* Herbert (1821) (*nom. inval.*, Art. 61.1). **Type:** *Haemanthus toxicarius* Aiton [*nom. illeg.*; = *Amaryllis disticha* Linné *fil.* (ICBN 2006: 256)].

**Incl.** *Buphane* Herbert (1825) (*nom. inval.*, Art. 61.1). **Type:** *Amaryllis disticha* Linné *fil.*

**Incl.** *Buphone* Herbert (1825) (*nom. inval.*, Art. 61.1). **Type:** *Amaryllis disticha* Linné *fil.*

Perennials with thickly tunicated bulbs to 30 cm Ø, mainly above-ground; **L** distichous, erect when young becoming spreading with age, variable in shape, narrowly lanceolate, ensiform, strap-shaped or tongue-shaped, leathery, sometimes undulate, glaucous-green to green; **Inf** densely umbellate, many-flowered; scape short, firm, somewhat laterally compressed; **Bra** 2, triangular; **Per** consisting of a short subcylindrical

tube and spreading slender **Tep** lobes; **St** from the throat of the perianth tube; **Fil** straight, filiform; **Anth** oblong, dorsifixed, versatile; **Ov** inferior, turbinate, 3-locular, each locule with 1 to few ovules; **Sty** simple, obscurely 3-lobed; **Fr** dry capsules, triquetrous, obtriangular, indehiscent or loculicidally 3-valved; **Se** globose.

A small genus of only 2 species. The spelling of the generic name was much in dispute and various spellings are encountered in the literature. The spelling as here used has been conserved (Barrie 2006: 798). Both species of the genus are sometimes referred to as succulents. The inflorescences easily detach when the fruits are ripe, dispersing the seeds when blown away as a whole by wind. The seeds are recalcitrant and should be sown fresh.

**B. disticha** (Linné *fil.*) Herbert (Appendix, 18, 1821). **Type:** UPS. — **Distr:** SE Sudan to RSA; widespread in grassland, Karoo vegetation and dry savanna. **I:** Wyk & al. (1997: 60) Duncan & al. (2016: 54–57). – Fig. 1

≡ *Amaryllis disticha* Linné *fil.* (1782) ≡ *Brunsvigia disticha* (Linné *fil.*) Sweet (1826) ≡ *Haemanthus distichus* (Linné *fil.*) Linné *fil. ex* Savage (1937); **incl.** *Haemanthus ciliaris* Linné (1762) ≡ *Brunsvigia ciliaris* (Linné) Ker-Gawler (1817); **incl.** *Haemanthus toxicarius* Linné *fil. ex* Aiton (1789) (*nom. illeg.*, Art. 52.1) ≡ *Brunsvigia toxicaria* (Linné *fil. ex* Aiton) Ker-Gawler (1821) (*nom. illeg.*, Art. 52.1) ≡ *Boophone toxicaria*

**Fig. 1** *Boophone disticha* (Copyright: E. J. Van Jaarsveld)

(Linné *fil. ex* Aiton) Herbert (1825) (*nom. illeg.*, Art. 52.1)  $\equiv$  *Amaryllis toxicaria* (Linné *fil. ex* Aiton) D. Dietrich (1840) (*nom. illeg.*, Art. 52.1); **incl.** *Haemanthus sinuatus* Schultes & Schultes *fil.* (1830) (*nom. inval.*, Art. 32.1d); **incl.** *Boophone intermedia* M. Roemer (1847); **incl.** *Boophone longipedicellata* Pax (1889); **incl.** *Haemanthus robustus* Pax (1892); **incl.** *Brunsvigia rautanenii* Baker (1903); **incl.** *Haemanthus lemairei* De Wildeman (1921).

Bulb solitary, above-ground, subglobose, to 30 cm  $\varnothing$ , thickly tunicated, outer tunics brown and firm; **R** terete, fleshy; **L** 15–30  $\times$  5–10 cm, green, oblong, coriaceous, margin straight, tip obtuse; scape firm, to 25 cm, to 3 cm  $\varnothing$ ; **Fl** numerous, in dense umbels, creamy-yellow becoming reddish with age; **Bra** suberect, pink or red, to 14  $\times$  8.5 cm; **Ped** 5–10 cm; **Per** tube 5–7 mm, 6-angled with deep grooves between the angles, free parts of the tepals to 3.5 cm, cucullate, to 4 mm wide near the tips narrowed to 2 mm at the base; **St**  $\pm$  as long as the tepals; **St** exerted to 1 cm beyond the perianth; **Fil** slender, erect, attached to the tepals; **Sty** to 1 cm longer than the stamens; **Ov** obconical, sharply angled.

The synonymous *Haemanthus ciliaris* Linné 1762 would have nomenclatural priority, but the combination under *Boophone* is pre-occupied by *B. ciliaris* (Linné) Herbert, now regarded as a synonym of the non-succulent *Crossyne guttata* (Linné) D. & U. Müller-Doblies. The taxon is widely used in traditional popular medicine as treatment for painful wounds, headaches, skin disorders, inflammations, rheumatism, and anxiety, and of the 8 known alkaloids, 4 have been shown to be biologically active (Neergaard & al. 2009). In addition, the bulbs have also been used to prepare arrow poison (Roberts & Wink 1998: 64), and were widely used as such by Bushmen as one of several ingredients (Smith 1966). Animals suffering poisoning show a mad and confused behaviour, resembling acute drunkenness. A complete overview of traditional usage, phytochemistry and pharmacology is given by Nair & van Staden (2014).

**B. haemanthoides** F. M. Leighton (J. South Afr. Bot. 13: 59–61, fig. 4, 1947). **Type:** RSA, Western Cape (*Leighton* 2361 [BOL]). — **Lit:** Duncan & al. (2016: 58–63, with ill.). **Dist:** SW Namibia, RSA (Northern Cape, Western Cape); coastal regions, autumn-flowering.

**Incl.** *Boophone disticha* var. *ernesti-ruschii* Dinter & G. M. Schulze (1941)  $\equiv$  *Boophone haemanthoides* ssp. *ernesti-ruschii* (Dinter & G. M. Schulze) G. D. Duncan & C. C. Tsang (2016); **incl.** *Boophone ernesti-ruschii* Dinter ex Sölch (1960) (*nom. inval.*, Art. 32.1d).

Bulb solitary, glabrous, above-ground, ovoid to globose, to 18 cm  $\varnothing$ , thickly tunicated, outer tunics brown and firm; **R** terete, fleshy; **L** 15–30  $\times$  5–10 cm, green, oblong, coriaceous, margin straight, tip obtuse; scape firm, to 25 cm, to 3 cm  $\varnothing$ ; **Fl** numerous, in dense umbels, creamy-yellow becoming reddish with age; **Bra** suberect, pink or red, to 14  $\times$  8.5 cm; **Ped** 5–10 cm; **Per** tube 5–7 mm, 6-angled with deep grooves between the angles, free parts of the tepals to 3.5 cm, cucullate, to 4 mm wide near the tips narrowed to 2 mm at the base; **St**  $\pm$  as long as the tepals; **St** exerted to 1 cm beyond the perianth; **Fil** slender, erect, attached to the tepals; **Sty** to 1 cm longer than the stamens; **Ov** obconical, sharply angled.

## Brunsvigia AMARYLLIDACEAE

E. Van Jaarsveld

**Brunsvigia** Heister (Beschr. neu. Geschl., 3, 1755). **Type:** *Brunsvigia orientalis* Aiton ex Ecklon. — **Amaryllideae** — **Strumariinae** — **Lit:** Dyer (1950: revision); Dyer (1951: revision); Duncan & al. (2016: 64–107, 662–663 [key] (S African taxa)). **Distr:** Tanzania, Malawi, Botswana, Namibia, Lesotho, Swaziland, RSA. **Etym:** Honouring the House of Braunschweig [Brunswick]-Lüneburg.

Perennial herbs with underground or above-ground bulbs to 20 cm Ø, usually thickly tunicated; **L** 2 to many per season, variously shaped, usually broad, appearing after the flowers; **Inf** few- to many-flowered umbels; scape firm, to 35 cm, deciduous at fruiting time; spathe valves 2 (= **Bra**); **Ped** elongating and spreading after anthesis; **Per** zygomorphic or almost actinomorphic with short tube, segments spreading-recurved; **St** arising from the perianth tube, ± declinate or erect; **Ov** turbinate, with many superposed ovules in each locule; **Sty** filiform, declinate; **Sti** capitate; **Fr** dry capsules, obtuse or acute, 3-angled, dehiscent loculicidally or breaking unevenly; **Se** subglobose.

A genus of ±20 species in S and SE Africa. The species with above-ground fleshy bulbs are considered succulent and are treated below. They

are all from arid winter rainfall regions and occur in Succulent Karoo vegetation.

**B. herrei** F. M. Leighton ex W. F. Barker (J. South Afr. Bot. 29: 165, t. 32, 1963). **Type:** RSA, Northern Cape (*Herre* 3368 [NBG]). — **Lit:** Duncan & al. (2016: 84–85, with ills.). **Distr:** S Namibia, RSA (Northern Cape); Succulent Karoo, mountains in Namaqualand Blomveld vegetation, autumn-flowering.

Bulb to ±15 cm Ø, above-ground to partly underground, globose and covered with brownish cartilaginous tunics; **L** 6, to 20 × 9 cm, erect at first becoming spreading, oblong, smooth, glaucous, margins narrowly reddish, tip obtuse; scape green, slightly laterally compressed, to 23 cm, 15 mm Ø; **Bra** ovate, pale greenish-fawn, to 6 × 2.5 cm; umbel to 40-flowered, globose and head-like; **Ped** pale green, to 18 cm, 5 mm Ø at the base; **Per** pale pink, actinomorphic; **Tep** to 5.5 × 1.2 cm, oblong, obtuse, tube 3 mm long, deep pink; **St** declinate, the longest somewhat shorter than the perianth, the others ½ as long; **Fil** adnate to the perianth tube; **Sty** becoming longer than the stamens; **Ov** to 6 mm Ø, obtusely angled when young; **Fr** and **Se** not seen.

**B. radula** (Jacquin) W. T. Aiton (Hort. Kew., ed. 2, 2: 230, 1811). **Type:** [lecto — icono]: Jacquin, Hort. Schönbr. 1: 35, t. 68, 1797. — **Lit:** Snijman (2012); Duncan & al. (2016: 100–101, with ills.). **Distr:** RSA (Northern Cape, Western Cape); Succulent Karoo,

## Cyrtanthus AMARYLLIDACEAE

E. Van Jaarsveld

**Cyrtanthus** Aiton (Hort. Kew. 1: 414, 1789). **Type:** *Crinum angustifolium* Linné *fil.* — **Cyrtantheae** — **Lit:** Dyer (1939: synopsis); Nordal (1979: revision E Africa); Reid & Dyer (1984: synopsis S Africa); Snijman & Meerow (2010: molecular phylogeny & evolution); Duncan & al. (2016: 196–315, 665–668 [key] (S African taxa)). **Distr:** S Africa extending to E Africa (Kenya); mainly summer-rainfall regions. **Etym:** Gr. ‘kyrtos’, curved; and Gr. ‘anthos’, flower; for the curved flower tube.

**Incl.** *Vallota* Salisbury *ex* Herbert (1821). **Type:** *Vallota purpurea* Herbert [*nom. illeg.*, ≡ *Crinum speciosum* Linné *fil.*].

**Incl.** *Anoiganthus* Baker (1878). **Type:** *Cyrtanthus breviflorus* Harvey.

Plants bulbous, evergreen or deciduous; bulbs tunicate, above-ground or underground, solitary, dividing or offsetting to form dense groups; **L** ascending, straight or curved, oblong, lorate or linear, green to glaucous; **Inf** umbellate, 1- to many-flowered with up to 4 spathe valves; scape ascending, usually hollow; **Fl** tube narrow, shorter or longer than the lobes, widening towards the mouth; **St** inserted in the throat of the tube; **Anth**

dorsifixed, versatile; **Ov** 3-locular, with numerous ovules in each locule; **Sty** filiform; **Sti** 3-lobed; **Fr** oblong loculicidal capsules; **Se** flat.

A mainly S African genus with ±55 species, some of them frequently cultivated. The genus was found to be monophyletic by Snijman & Meerow (2010), and consists of 3 poorly to well-supported major lineages (recognized as informal groups) which agree with cytological findings, but not with morphological data. 10 taxa from arid to semi-arid sheer cliff-faces or rocky habitats have succulent above-ground or semi-underground bulbs. The flowers are mainly red but also yellow or mottled, depending on the species. Of the species treated below, those with tubular flowers (red or yellow) are pollinated by sunbirds. *C. flammosus* and *C. montanus* have a flower construction that makes it likely that the butterfly *Meneris* (*Aeropetes*) *tulbaghia* (Table Mountain Beauty) is involved (Johnson & Bond 1994). Switches between floral syndromes have likely played an important role in the evolution of the genus, and ornithophily likely evolved in parallel in all primary clades (Snijman & Meerow 2010).

Several species of *Cyrtanthus* are valued horticulturally.

**C. falcatus** R. A. Dyer (Herbertia 6: 75, t. 138: Fig. 1, 1939). **Type:** RSA, KwaZulu-Natal (*Carter* s.n. [NH 30339]). — **Distr:** RSA (KwaZulu-Natal: Drakensberg); sheer cliff-faces in Foothill Moist Grassland vegetation, 1500–2000 m,

**Fig. 1** *Cyrtanthus flammosus* (Copyright: E. Van Jaarsveld)

spring-flowering and summer-growing. **I:** Dyer (1971); Duncan & al. (2016: 232–233).

Deciduous, cluster-forming; bulbs above-ground, ovoid to globose, to 8 cm Ø, offsetting from the base, tapering to a neck to 12 cm long; tunics densely arranged, brown to grey, membranous; **L** to 4, linear, falcate, 35 × 3 cm, leathery, green, apex acute; **Inf** to 30 cm, scape glaucous, 15 mm Ø near the base and ±10 mm distally, characteristically recurved at the top with a pendent umbel of up to 10 flowers; spathe valves 4–5 × 1.25 cm, linear-lanceolate, soon withering; **Ped** to 14 mm; **Fl** 6–10, pendulous, greenish to red, zygomorphic, 7 cm long, **Per** tube to 4 cm, gradually dilated to 1 cm Ø at the throat, outer face greenish, buff, lobes reddish, obovate-oblong, the outer 2.5 × 1.2 cm, shortly cucullate at the throat, inner lobes 1.3 cm broad, slightly retuse at the apex; **St** arising from the base of the perianth lobes; **Anth** yellow; **Ov** to 1 cm.

Easily cultivated in containers or hanging baskets; propagation by seed or division.

**C. flammosus** Snijman & Van Jaarsveld (Flow. Pl. Afr. 54: 100–103, t. 2120, 1995). **Type:** RSA, Eastern Cape (*Van Jaarsveld & al.* 13803 [NGB, PRE]). — **Distr:** RSA (Eastern Cape); sheer cliff-faces in Gamtoos Thicket vegetation, all-year rainfall region. **I:** Duncan & al. (2016: 236–237). – Fig. 1

Evergreen, to 25 cm; bulb solitary, ovoid, partly exposed or completely above-ground, to 4 cm Ø; tunics fleshy, withering papery, brown;

**L** 2–4, ascending, 13–29 × 1.5–2 cm, glaucous, fleshy; **Inf** 1-flowered, scape erect, to 17 cm; spathe valves suberect, lanceolate, 5.5 × 1 cm; **Per** tube 4–5 cm; **Tep** spreading, broadly obovate, 4–5 × 3–3.5 cm, fire-red; **Fil** free for 2–2.5 cm, cream to pale green; **Anth** 1.5 cm, yellow, pollen yellow; **Ov** 1–1.5 × 0.6 cm; **Sty** declinate; **Sti** branches 5 mm; **Fr** not seen.

**C. flanagani** Baker (in Thiselton-Dyer, Fl. Cap. 6: 532, 1897). **Type:** RSA, KwaZulu-Natal (*Flanagan* 1824 [K, BOL, PRE]). — **Distr:** RSA (Eastern Cape, KwaZulu-Natal, Free State), Lesotho; sheer cliff faces in Ukahlamba Basalt Grassland vegetation, 2750–3000 m. **I:** Duncan & al. (2016: 238–239).

Deciduous, cluster-forming; bulbs halfway above-ground, ovoid to globose, to 3 cm Ø, offsetting from the base, tapering to a neck to 11 cm long; tunics densely arranged, brown, membranous; **L** up to 4, linear, 20 × 1.9 cm, leathery, lorate, falcate, green, obtuse; **Inf** to 20 cm, scape compressed; spathe valves white with red veins, 5 × 1.1 cm at the base; **Bra** white, 2 cm, linear-filiform; **Ped** to 2.5 cm; **Per** yellow, ascending, trumpet-shaped, tube 4.6 × 0.6 cm Ø at the throat, lobes ascending, 1.5 cm, the outer 0.9 cm broad and slightly hooded, the inner 0.8 cm broad, not hooded; **St** not exerted; **Ov** 0.8 cm, cylindrical-oblong, faintly 3-lobed; **Sty** shortly 3-lobed.

**C. herrei** (F. M. Leighton) R. A. Dyer (Flow. Pl. Afr. 33: t. 1281 + text, 1959). **Type:** RSA, Northern Cape (*Herre* s.n. [BOL]). — **Distr:** Extreme S Namibia, RSA (Northern Cape); sheer cliffs in Succulent Karoo vegetation, winter-rainfall region. **I:** Duncan & al. (2016: 250–251). – Fig. 2

≡ *Cryptostephanus herrei* F. M. Leighton (1932).

Bulbs large, above-ground, clustering, obclavate, to 6 cm Ø; **R** succulent, terete; **L** synanthous, distichous, lorate, to 45 × 5 cm, leathery, glaucous, apex obtuse; **Inf** to 40 cm, to 28-flowered; scape glaucous; spathe valves to 8 × 1.3 cm, linear-lanceolate, soon withering; **Ped** to 4 cm; **Fl** pendulous; **Per** zygomorphic, to 5.5 cm, tube to 4 cm, red,

**Fig. 2** *Cyrтанthus herrei* (Copyright: U. Eggli)

lobes yellowish-green; **St** fused to the perianth, free part of **Fil** to 6 mm; **Anth** yellow; **Ov** to 8 mm; **Se** black, winged.

**C. inaequalis** O'Brien (Gard. Chron., ser. 3, 37: 261, ill., 1905). **Type:** RSA, Western Cape (*Anonymus* s.n. [[lecto — icono]: l.c., fig. 110: part 1]). — **Distr:** RSA (Western Cape, Eastern Cape); sheer quartzitic sandstone cliffs in Gamka Thicket vegetation, summer- and winter-rainfall region. **I:** Duncan & al. (2016: 254–255).

Bulb above-ground, globose, 4–7 × 6–8 cm, purplish-green, solitary or forming groups, bulbiferous from the base; tunics withering papery, brown; **L** 2–3, evergreen, glaucous, linear-oblancoate, leathery, 30–40 × 1 cm, upper face channelled, apex subacute; **Inf** 40–45 cm, 3- to 5-flowered, scape glaucous; **Bra** 6.5 × 0.8 cm, triangular-lanceolate, acuminate, soon withering; **Ped** 3.5–4.8 cm; **Per** orange-red, zygomorphic, labiate, 6.5–9 cm long, tubular, curved, tube 2–3.5 mm Ø at the base expanding to 7–10 mm at the throat, infundibuliform, the 4 upper lobes linear-lanceolate, together forming

a hood, the 2 lower lobes lanceolate, 25 × 6 mm; **St** basally fused to the perianth, free part 1.3 cm; **Anth** yellow, 7 mm, oblong; **Sty** 7.2–7.8 cm, 3-lobed; **Ov** oblong-triangular, 0.6 × 0.4 cm.

The **lectotype** given above is formally **designated here**.

**C. junodii** Beauverd (Bull. Herb. Boissier, sér. 2, 7: 437, 1907). **Type:** RSA, Limpopo (*Junod* s.n. [G?]). — **Distr:** RSA (Limpopo: Wolkberg); S-facing sandstone cliffs in Strydpoort Summit Sourveld vegetation, 1500–2000 m, summer-flowering. **I:** Duncan & al. (2016: 256–257).

Deciduous, forming clumps 20–45 cm Ø; bulbs halfway to completely above-ground, ovoid, 3–7 × 3–6 cm, sprouting from the base, tapering to a neck; tunics densely arranged, reddish-brown, membranous, becoming papery and greyish-brown; **L** 1–6, lorate, to 25–38 × 2–2.8 cm, leathery, purplish at the base, green above, gently recurved, sometimes somewhat twisted sideways near the apex, surface smooth, obscurely striate, apex acute; **Inf** 22–50 cm, 6- to 9-flowered; scape green; spathe valves 2, erect, ovate-lanceolate, 3–5 × 1.5–1.9 cm, yellowish-brown; **Ped** variable in length, 1.5–4 cm, shorter than the spathe valves, ascending, reddish-brown; **Fl** horizontally spreading, secund, somewhat pendulous; **Per** tubular, curved, dilating towards the throat, 3.5–5.5 cm, tube 4 mm wide at the base, dilating to 10–12 mm, red, yellow at the tip of the lobes, lobes 8–12 × 4–6 mm; **St** biseriate, arising from the throat, not exerted; **Sty** yellowish, exerted; **Sti** trifid, lobes ±2 mm.

**C. labiatus** R. A. Dyer (Bothalia 13(1–2): 135, ill., 1980). **Type:** RSA, Eastern Cape (*Bayliss* 5660 [PRE]). — **Distr:** RSA (Eastern Cape); sheer cliff-faces in Gamka Thicket vegetation, all-year rainfall region, summer-flowering. **I:** Duncan & al. (2016: 258–259).

Bulb above-ground, globose, 4–7.5 × 6–7.5 cm, purplish-green, solitary or forming groups, bulbiferous from the base, withering with papery brown tunics; **L** 2–4, evergreen, lorate-elliptic to strap-shaped, 18–30 × 1.4–2 cm, apex obtuse; **Inf** 12–30 cm, up to 8-flowered, scape to 2.3 cm Ø, glaucous; **Bra** 5 × 0.5 cm, triangular-lanceolate,

soon withering; **Ped** 2–2.5 cm; **Per** red, zygomorphic, bilabiate, 5–6 cm, tubular-curved, tube 1 cm, infundibuliform, with 4 upper linear-oblong lobes forming a hood and 2 lower lobes; **St** fused to the perianth, free for the last 1 cm; **Anth** yellow, 3 mm, oblong; **Sty** 4 cm, **Sti** 3-lobed; **Ov** oblong-triangular, 6 × 4 mm.

Easily propagated from bulbils.

**C. montanus** R. A. Dyer (Flow. Pl. Afr. 44: t. 1756 + text, 1977). **Type:** RSA, Eastern Cape (*Skinner* s.n. [PRE 37061]). — **Distr:** RSA (Eastern Cape); sheer cliff-faces in Gamka Thicket vegetation, rainfall all year, summer-flowering. **I:** Duncan & al. (2016: 276–277).

Bulb above-ground, globose, 6.5 × 7 cm, purplish-greenish, solitary or forming groups, bulbiferous from the base; tunics withering grey-brown, papery; **L** 2–4, evergreen, lorate-elliptic, to 30 × 2 cm, ascending, glaucous; **Inf** to 10 cm, to 10-flowered; **Bra** 2, linear-lanceolate, to 5 cm, with smaller bracteoles subtending the flowers; **Ped** to 3 cm; **Per** red, erect, to 5 cm, tube infundibuliform, to 1.5 cm; **OTep** linear-lanceolate, to 0.9 cm wide; **ITep** to 1.1 cm wide; **St** biseriate; **Fil** 9–11 mm; **Ov** oblong, to 6 mm; **Sty** filiform; **Sti** tricuspiate; **Fr** oblong; **Se** compressed, black.

Easily propagated from bulbils.

**C. obliquus** Aiton (Hort. Kew. 1: 414, 1789). **Type:** RSA (*Masson?* s.n. [not located]). — **Distr:** RSA (Western Cape, Eastern Cape, KwaZulu-Natal); coastal areas in Fynbos and Indian Ocean Coastal Belt vegetation; summer-flowering. **I:** Phillips & Pole Evans (1921b); Duncan & al. (2016: 280–281).

**Incl.** *Crinum obliquum*. Linné *fil.* (1782); **incl.** *Amaryllis umbella*. L'Heritier (1789); **incl.** *Timmia obliqua*. J. F. Gmelin (1791).

Bulb above-ground, globose, 8–10 cm Ø, solitary or dividing to form small groups; tunics withering dark brown, papery; **L** 6–12, evergreen, ascending, distichous, lorate, semi-fleshy and twisted, 18–48 × 3.5–5 cm, grey-green, apex obtuse; **Inf** 28–77 cm, 6- to 12-flowered, scape cylindrical but slightly flattened, 1.3–2.5 cm Ø; spathe valves 3–4 × 1–1.2 cm, ovate to

acuminate; **Ped** 2 cm; **Fl** pendent, funnel-shaped, mottled green, yellowish and red; **Per** tube 4.5 cm long and 2.4 cm Ø at the throat; **OTep** 2.5 cm long, oblong; **ITep** 2.4 cm, obovate; **St** from near the base of the perianth tube; **Fil** 3 cm; **Anth** 4 mm; **Ov** subglobose, 5 mm; **Sti** faintly 3-lobed; **Fr** oblong, 2.7–3 cm; **Se** oblong, flattened, 1.2–1.3 cm, black.

Easily propagated from seed or division.

**C. sanguineus** (Lindley) Hooker *fil.* (Curtis's Bot. Mag. 86: t. 5218 + text, 1860). **Type** [neo]: RSA, Eastern Cape (*Ryder* 105 [K]). — **Lit:** Nordal (1979); Duncan & al. (2016: 292–293, with ills.). **Distr:** Sudan, Kenya, Tanzania, Zimbabwe, Moçambique, RSA (Eastern Cape, KwaZulu-Natal); sheer cliffs in Eastern Valley Bushveld vegetation or rocky regions in savannas, summer-flowering.

≡ *Gastronema sanguineum* Lindley (1848).

Easily grown from seed or division.

**C. sanguineus** ssp. **ballyi** Nordal (Norweg. J. Bot. 26: 190, 1979). **Type:** Kenya (*Bally* B5135 [EA, K]). — **Distr:** Kenya (Nairobi National Park); open grassy *Acacia* savanna, 1650 m.

Differs from ssp. *sanguineus*: **L** appearing after flowering, 0.4–1.2 cm broad; **Ped** 2–4.4 cm; **Per** bright red, or crimson to scarlet, 5–10 cm; **St** uniseriate.

**C. sanguineus** ssp. **minor** Nordal (Norweg. J. Bot. 26: 190, 1979). **Type:** Kenya (*Champion* s.n. [K]). — **Distr:** S Sudan, N Kenya, W Tanzania; grassy regions among boulders.

Differs from ssp. *sanguineus*: **Ped** 0.4–1.2 cm; **Per** pinkish-mauve, 3.5–4 cm; **St** biseriate.

**C. sanguineus** ssp. **salmonoides** (P. R. O. Bally & Carter) Nordal (Norweg. J. Bot. 26: 190, 1979). **Type:** Kenya (*Bally* 8482 [K, G]). — **Distr:** Kenya (Nairobi area: Ngong Hills); grassland, 2100 m.

≡ *Cyrtanthus salmonoides* P. R. O. Bally & Carter (1962).

Differs from ssp. *sanguineus*: Bulb 4 cm Ø; **L** absent or present at anthesis, to 30 cm;

**Ped** 0.3–1.5 cm; **Per** pink to salmon-pink, 6.5–9.5 cm; **St** uniseriate or biseriate.

**C. sanguineus** ssp. **sanguineus** — **Distr:** Sudan, Kenya, Tanzania, Zimbabwe, Moçambique, RSA (Eastern Cape, KwaZulu-Natal); sheer cliffs in Eastern Valley Bushveld vegetation or rocky regions in savannas, summer-flowering. **I:** Phillips & Pole Evans (1921a); Duncan & al. (2016: 292–293).

Bulb halfway above-ground, ovoid, 2–7 cm Ø, solitary or dividing to form small groups, evergreen; tunics brown to grey, scarious, forming a distinct neck with parchment-like scales; **L** 1–4, lanceolate, 30–35 × 0.9–1.7 cm, green, with a prominent midrib on the lower face and a distinct petiole 1–6 cm long; **Inf** 1–2 per plant, to 28 cm, 1- to 4-flowered, scape terete, to 1 cm Ø at the base; spathe valves 2, 4. 4–8.5 cm, lanceolate; **Ped** 2–5 cm; **Fl** ascending-spreading, bright red or pink; **Per** tube 3.5–12.5 cm, campanulate in the upper ½, 2.5 cm Ø at the throat, cylindrical in the lower ½; **Tep** lobes 4–5 × 1.8 cm; **St** included or slightly exserted; **Fil** 2.5 cm; **Anth** 5 mm; **Ov** oblong-triangular; **Sty** overtopping the anthers; **Sti** 3, slender, recurved.

**C. sanguineus** ssp. **wakefieldii** (Sealy) Nordal (Norweg. J. Bot. 26: 189, 1979). **Type:** Tanzania, Songea Distr. (*Milne-Redhead & Taylor* 10735 [K, BR, EA]). — **Distr:** Kenya, Tanzania; *Brachystegia* woodland (savanna), rocky slopes, coast to 1300 m. **I:** Nordal (1979: 187).

≡ *Cyrтанthus sanguineus* var. *wakefieldii* Sealy (1965).

Differs from ssp. *sanguineus*: Bulb 3–4 cm Ø; **L** 10–40 cm; **Ped** 0.3–2.5 cm; **Per** pink or salmon-pink to rose-vermillion, 8–10.5 cm.

## Haemanthus AMARYLLIDACEAE

E. Van Jaarsveld

**Haemanthus** Linné (Spec. Pl. [ed. 1], 325, 1753). **Type:** *Haemanthus coccineus* Linné [lectotype, designated by Hitchcock & Green, Stand. Spec. Linnean Gen., 1929]. — **Haemantheae** — **Lit:** Snijman (1984: monograph); Conrad & al. (2006: molecular phylogeny); Bay-Smidt & al. (2011: molecular phylogeny); Duncan & al. (2016: 398–463, 671–672, ill. synopsis). **Distr:** Namibia, RSA, Lesotho, Swaziland. **Etym:** Gr. ‘haima, haimatos’, blood; and Gr. ‘anthos’, flower; for the dark red flowers of some species.

**Incl.** *Leucodesmis* Rafinesque (1838). **Type:** *Haemanthus pubescens sensu* Rafinesque.

**Incl.** *Perihema* Rafinesque (1838). **Type:** *Haemanthus coarctatus* Jacquin.

**Incl.** *Serena* Rafinesque (1838). **Type:** *Haemanthus carneus* Ker Gawler [lectotype, designated by Snijman, J. South Afr. Bot. 12 (Suppl.): 17, 1984].

**Incl.** *Diacles* Salisbury (1866). **Type:** *Haemanthus pubescens sensu* Ker Gawler [lectotype, designated by Snijman, J. South Afr. Bot. 12(Suppl.): 17, 1984].

**Incl.** *Melicho* Salisbury (1866). **Type:** *Haemanthus amarylloides* Jacquin [lectotype,

designated by Bjørnstad & Friis, Norweg. J. Bot. 19: 187–206, 1972].

Deciduous or rarely evergreen bulbous geophytes; bulbs usually underground, rarely above-ground or half exposed, variable, usually ovoid to pyriform with fleshy tunics in successive horizontal layers; **L** few, often 2, distichous, fleshy, strap-shaped, patent to ascending; **Fl** in dense umbels to 10 cm Ø; scape compressed; spathe valves firm, fleshy, white to red, broadly ovate; **Per** with short cylindrical tube, lobes spreading to ascending, longer than the tube; **St** 6, fused to the throat of the tube; **Fil** filiform; **Anth** oblong, dorsifixed; **Ov** inferior, globose; **Sty** filiform, **Sti** tricuspidate; **Fr** soft fleshy globose berries; **Se** ovoid, fleshy, wine-red to green.

A genus of 22 species confined mainly to the winter rainfall regions in S Africa with a concentration in Namaqualand.

*Haemanthus* has been found to be monophyletic in recent molecular phylogenetic studies, and is sister to *Scadoxus* (Bay-Smidt & al. 2011). The same study found the genus to consist of 2 well defined clades, corresponding to summer-rainfall taxa with white to pale pink flowers mainly in the Eastern Cape, and, respectively, to winter-rainfall taxa with red to pale pink flowers, mainly in the Western Cape. The summer-rainfall species *H. montanus* is sister to the winter-rainfall group (Bay-Smidt & al. 2011).

**Fig. 1** *Haemanthus albiflos*. (Copyright: U. Eggli)

Only a few taxa are somewhat succulent. They are native to the summer rainfall region in E RSA and are easily cultivated in containers, but only *H. albiflos* is seen frequently in cultivation.

**H. albiflos** Jacquin (Pl. Hort. Schoenbr. 1: 31, t. 59, 1797). **Type**: [icono]: l.c., t. 59. — **Distr**: RSA (Western Cape, Eastern Cape, KwaZulu-Natal); Albany Thicket vegetation and dry Eastern Valley Bushveld vegetation (savanna biome), autumn- to spring-flowering. **I**: Duncan & al. (2016: 404–405). – Fig. 1.

≡ *Haemanthus pubescens* var. *albiflos* (Jacquin) Ker Gawler (1826) ≡ *Haemanthus virescens* var. *albiflos* (Jacquin) Herbert (1837); **incl.** *Haemanthus pubescens* auct. pl. (s.a.) (*nom. illeg.*, Art. 53.1); **incl.** *Haemanthus virescens* var. *intermedius* Herbert (1837) ≡ *Haemanthus intermedius* (Herbert) M. Roemer (1847); **incl.** *Haemanthus leucanthus* Miquel (1861); **incl.** *Haemanthus ciliaris* Salisbury (1866) (*nom. inval.*, Art. 32.1c); **incl.** *Haemanthus albo-maculatus* Baker (1878); **incl.** *Haemanthus albiflos* var. *brachyphyllus* Baker (1888); **incl.** *Haemanthus albiflos* var. *burchellii* Baker (1888).

Evergreen; bulbs ovoid, to 8 cm broad, clustering, above-ground to halfway underground; tunics truncate at the top, green when exposed to light; **L** strap-shaped to elliptic, appressed to the ground or spreading, flat or canaliculate, smooth or slightly pubescent, apex obtuse to acute; **Inf** 5–35 cm; scape compressed, to 14 mm wide; umbel compact, laterally compressed, to 7 cm wide with 4–8 semi-erect spathe valves; **Fl** to 50,

white; **Ped** to 1 cm; **Per** funnel-shaped, to 23 mm, tube to 7 mm with spreading oblong segments 10–18 × 1–2.5 mm; **Ov** globose, to 3 mm Ø; **Fr** ovoid, to 1 cm Ø, white to red.

**H. avasimontanus** Dinter (Repert. Spec. Nov. Regni Veg. 19(11–13): 186, 1923). **Type** [syn]: Namibia (*Dinter* 4465 [B]). — **Lit**: Craib (2010: with ill.). **Distr**: C Namibia (Auas Mts.); dry savanna, mainly S-facing cliffs on schist ledges, flowering in February. **I**: Duncan & al. (2016: 414–415).

Bulbs winter-deciduous, medianly compressed, to 4.5 cm broad, proliferating from the base by bulblets and forming clusters in rock crevices, usually underground but occasionally exposed, outer tunics becoming brownish and papery; **L** 2, ascending, synanthous, lorate, 35–40 × 4–4.5 cm, glabrous, soft in texture, margin smooth, apex acute; scape 25–35 cm, 7 mm Ø; **Inf** narrowly obconical, ±4.5 cm diam; spathe valves 4–5, spreading, as long as the flowers, lanceolate, ±25–30 × 6 mm, brownish-white, membranous, tips acute; **Fl** 15–20, white; **Ped** 7–10 mm; **Per** ± 20 mm, tube 2.5–3 mm long, segments slightly spreading, linear to lanceolate, ±17 × 1–2 mm, tips acute; **Fil** exerted for up to 3 mm, white; **Anth** 1 mm long, yellow; **Ov** ovoid, 2–3.5 mm; **Sty** as long as the stamens.

The specific epithet is frequently mis-spelled ‘avasmontanus’.

**H. deformis** Hooker *fil.* (Curtis’s Bot. Mag. 97: t. 5903 + text, 1871). **Type**: RSA, KwaZulu-Natal (*McKen* s.n. [[lecto — icono]: l.c., t. 5903]). — **Distr**: RSA (E-most Eastern Cape, KwaZulu-Natal); Eastern Valley Bushveld vegetation, coastal sheltered rocky regions to 1000 m. **I**: Snijman (1984: 65); Duncan & al. (2016: 428–429).

**Incl.** *Haemanthus baurii* Baker (1885); **incl.** *Haemanthus mackenii* Baker (1888).

Evergreen; bulbs solitary or in small clusters, above-ground to halfway underground, laterally compressed, to 16 × 10 cm, tunics truncate at the top, green when exposed; **L** 2–4, broadly oblong, often broader than long, to 24 × 30 cm, appressed to the ground, glabrous to pubescent, margin ciliate, tip obtuse; **Inf** 1–3, almost sessile to 6 cm,

umbel compact, with 6–7 semi-spreading spathe valves; **Fl** to 45, white; **Ped** to 7 mm; **Per** funnel-shaped, to 31 mm, tube 7–9 mm, segments to 23 mm; **Fr** ovoid, to 15 mm  $\varnothing$ , orange to red.

Closely related to *H. albiflos*.

**H. pauculifolius** Snijman & A. E. van Wyk (South Afr. J. Bot. 59(2): 247–250, ill., 1993).

**Type:** RSA, Mpumalanga (*Matthews* 624 [NBG, K, MO, PRE]). —**Distr:** RSA (Mpumalanga), Swaziland; Bushveld (savanna biome), mountainous rocky terrain. **I:** Duncan & al. (2016: 446–447).

Evergreen; bulbs ovoid, 4–5 cm  $\varnothing$ , clustering, above-ground to halfway underground, green, smooth; **L** 1–2, fleshy, strap-shaped to linear-lanceolate, canaliculate, tomentose, 7–10 (–30)  $\times$  2–4.5 cm, apex acute; **Inf** 5–19 cm; scape compressed, to 7 mm wide; umbel compact, compressed, to 3 cm wide, with 4 spathe valves; **Fl** to 19, white; **Ped** to 3 mm; **Per** funnel-shaped, to 35 mm, tube to 13 mm with spreading lanceolate segments 17–20  $\times$  3–4 mm; **Fr** globose, to 15 mm  $\varnothing$ , orange.

## Rauhia AMARYLLIDACEAE

### S. Arroyo-Leuenberger

**Rauhia** Traub (Pl. Life (Stanford) 13: 73, 1957).  
**Type:** *Rauhia peruviana* Traub. — **Andean Clade**  
— **Stenomesseae** — **Lit:** Ravenna (1969: synopsis).  
**Distr:** Peru; Andean rocky slopes. **Etym:** For  
Werner Rauh (1913–2000), German botanist in  
Heidelberg, and specialist of Madagascan succu-  
lents and bromeliads.

Bulbous perennials; bulbs tunicate, under-  
ground, solitary; **L** ascending, hysteranthous  
(in cultivation usually evergreen), distichous,  
oval to oblong, glaucous, fleshy, pseudopetiolate;  
**Inf** lateral, umbellate; scape erect, solid; **Bra** sub-  
erect, lanceolate; **Fl** declinate or horizontal,  
greenish-whitish, tube funnel-shaped; **Tep** oblan-  
ceolate, spreading; **St** inserted in the throat of the  
perianth tube, without staminal cup; **Anth**  
dorsifixed; **Ov** with numerous ovules in each locu-  
le; **Sty** slightly declinate; **Sti** capitate; **Fr** loculi-  
cidal capsules.

This small genus consists of 3 species and is  
known only from Peru. Only *R. multiflora* is  
encountered in cultivation; the other 2 are insuffi-  
ciently known and perhaps conspecific. All  
appear to be evergreen in cultivation.

**R. decora** Ravenna (Pl. Life (Stanford) 37:  
77, 1981). **Type:** Peru, Amazonas (*Ravenna*

3060 [Herb. Ravenna, K]). — **Distr:** Peru (Ama-  
zonas); 500–1000 m.

Bulb ovoid  $\pm 5.5$  cm  $\varnothing$ , tunics fleshy, withering  
papery, brown; **L** 2–6, 20–30  $\times$  8–12 cm; **Inf** 8-  
to 25-flowered; scape to 20–34 cm; **Bra** 2, free to the  
base, broadly ovate,  $\pm 3.8$  cm; **Ped** 6.5–7.5 cm;  
**Per** tube  $\pm 2.2$  cm; **Tep** 4–5 cm, greenish-whitish;  
shorter **Fil**  $\pm 6.2$  cm, longer  $\pm 6.7$  cm; **Ov**  
0.9–1.5  $\times$  0.5 cm; **Sty** declinate, longer than the  
stamens; **Sti** capitate-trilobate.

**R. multiflora** (Kunth) Ravenna (Pl. Life  
(Stanford) 25: 61, 1969). **Type:** Peru, Cajamarca  
(*Herb. Humboldt* 3582 [B]). — **Lit:** Leuenberger  
& Arroyo-Leuenberger (2006: typification).  
**Distr:** Peru (Cajamarca: Jaén); rocky slopes,  
500–1500 m. – Fig. 1.

$\equiv$  *Phaedranassa multiflora* Kunth (1850); **incl.**  
*Phaedranassa megistophylla* Kraenzlin (1917)  
 $\equiv$  *Rauhia megistophylla* (Kraenzlin) Traub (1966);  
**incl.** *Rauhia peruviana* Traub (1957); **incl.** *Rauhia*  
*occidentalis* Ravenna (2002).

Bulb ovoid,  $\pm 10$ –15 cm  $\varnothing$ , tunics fleshy,  
withering papery, brown; **L** 2–4, 20–30  $\times$   
9–15 cm, spreading; **Inf** 8- to 25-flowered; scape  
to 50–120 cm; **Bra** 2 (–3), free to the base,  
broadly ovate,  $\pm 3$  cm; **Ped** 3–9 cm; **Per**  
tube  $\pm 2.2$  cm; **Tep** 4–5 cm, greenish-whitish;  
**Fil** 2 shorter  $\pm 3.1$  cm, 4 longer  $\pm 3.6$  cm; **Sty**  
declinate, as long as or longer than the stamens;  
**Sti** capitate; **Ov** 0.5–1.2  $\times$  0.5 cm.

**Part III**

**The Family Anthericaceae**

## Anthericaceae

E. Van Jaarsveld and U. Eggli

Perennial evergreen or geophytic herbs, rarely small shrubs; **R** variable, fibrous or more commonly thickened and succulent, sometimes tuberous or moniliform; rhizome creeping, often covered with old leaf bases, or rarely stems (semi-) erect and succulent; **L** spiral and rosulate, rarely reduced to 1, or distichous, with sheathing base, lamina flat, terete or trigonous, oblong, linear, glabrous to hairy, rarely succulent and xeromorphic, rigid to softly flaccid, margin often fimbriate; **Inf** lateral racemes or panicles, or condensed into clusters; peduncle bracteate; **Fl** 3-merous, hermaphroditic, actinomorphic or rarely slightly zygomorphic, usually small but conspicuous; **Per** stellate, rarely urceolate or campanulate; **Tep** 3 + 3, oblong, often white or yellowish; **St** 6; **Fil** free or connate basally, glabrous or papillate; **Anth** basifixed or dorsifixed-epipeltate, dehiscing longitudinally; **Ov** superior, 3-locular; **Sty** simple, terete, smooth; **Sti** 3-lobed; placentation axile; **Fr** loculicidal dry capsules; **Se** black, flat to angular or rounded, sometimes with an elaiosome.

**Order:** Asparagales

**Important Literature:** Conran (1998: synopsis).

**Distribution:** Worldwide except Antarctica, mainly tropics and subtropics.

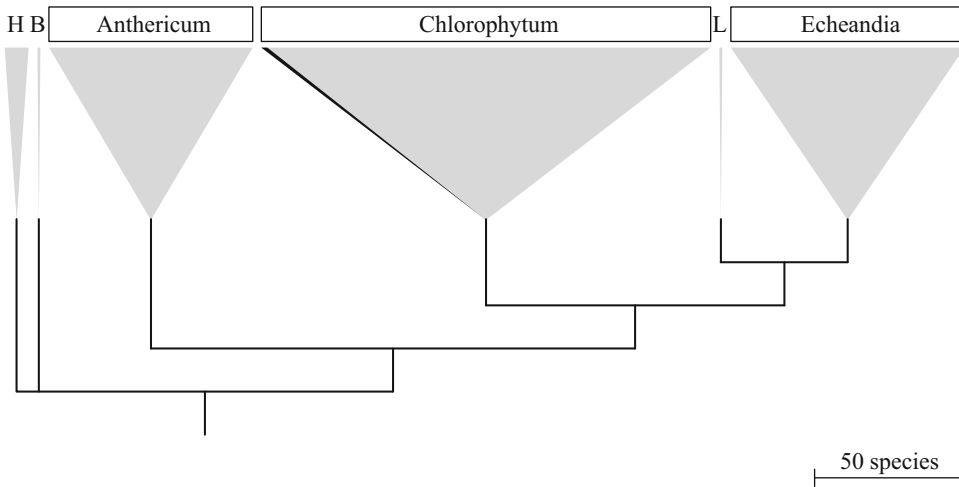

A small family of 8–9 genera and  $\pm 285$  species with a worldwide but mainly subtropical and tropical distribution with centres of diversity in Africa, SE Asia and S America. *Chlorophytum* is the largest genus with  $\pm 100$  (–150) species, followed by the closely related *Anthericum* with  $\pm 65$  species.

In traditional classifications, the family was included within *Liliaceae* s.l., but Bogler & al. (2006), Good-Avila & al. (2006) and Seberg & al. (2012) all found that the family represents a well-circumscribed lineage in sister-group position to the *Agavaceae*. APG (2009) favours a broad concept and includes *Anthericaceae* (together with *Agavaceae*) in *Asparagaceae* s.l., where the family would be placed in subfam. *Agavoideae* (Chase & al. 2009). Here, we follow the concept of Nyffeler & Eggli (2010), and accept *Anthericaceae* at family rank. Other workers have advocated a placement of *Anthericaceae* within a broadly circumscribed *Agavaceae* (e.g. Graham & al. (2006) or Pires & al. (2006)). – Fig. 1.

## Chlorophytum ANTHERICACEAE

E. Van Jaarsveld

**Chlorophytum** Ker Gawler (Curtis's Bot. Mag. 27: t. 1071 + text, 1807). **Type:** *Chlorophytum inornatum* Ker Gawler. — **Lit:** Obermeyer (1962: 690–711 [monograph S Africa]); Nordal & al. (1997: Fl. Tropical E Africa); Kativu & al. (2008: Fl. Zambesiaca); Lebrun and Stork (2014: 25–62, synopsis tropical Africa). **Distr:** Africa, Madagascar, Asia; forests, savanna and Karoo region. **Etym:** Gr. 'chloros', yellowish-green, pale green; and Gr. 'phyton', plant; for the leaves of some taxa.

**Incl.** *Hartwegia* Nees (1831). **Type:** *Hartwegia comosa* Nees [*nom. illeg.*, = *Anthericum sternbergianum* J. A. & J. H. Schultes].

**Incl.** *Hollia* Heynhold (1846) (*nom. illeg.*, Art. 53.1). **Type:** *Anthericum comosum* Thunberg.

**Incl.** *Asphodelopsis* Steudel *ex* Baker (1876). **Type:** not typified.

**Incl.** *Acrospira* Welwitsch *ex* Baker (1878) (*nom. illeg.*, Art. 53.1). **Type:** *Acrospira asphodeloides* Welwitsch *ex* Baker.

**Incl.** *Dasystachys* Baker (1878) (*nom. illeg.*, Art. 53.1). **Type:** *Dasystachys colubrina* Baker [lectotype, designated by Kativu & Nordal, Nordic J. Bot. 13(1): 62, 1993].

**Incl.** *Debesia* Kuntze (1891). **Type:** *Acrospira asphodeloides* Welwitsch *ex* Baker.

**Incl.** *Verdickia* De Wildemann (1902). **Type:** *Verdickia katangensis* De Wildemann.

Perennial evergreen or deciduous and geophytic herbs; **R** variable, mostly succulent, sometimes tuberous; rhizome creeping, often covered with old leaf bases; **L** rosulate, tufted, rarely reduced to 1, or subdistichous, lamina flat, oblong to linear, glabrous to hairy, margin often fimbriate; **Inf** terminal, racemose or paniculate; peduncle bracteate; **Ped** articulated near the middle; **Per** stellate, rarely urceolate or campanulate, white to blue; **Tep** 6, oblong, marcescent, midrib darkening, **OTep** narrower than **ITep**; **St** 6; **Fil** glabrous or papillate; **Anth** basifixed, introrse; **Ov** sessile or shortly stipitate, trigonous, with 6–30 biseriate ovules; **Sty** terete, smooth; **Sti** apical, minute; **Fr** loculicidal trilobate or 3-angled capsules; **Se** flat, rounded, black, shiny.

A large genus with  $\pm$  100 (–150) species occurring mainly in Africa, Madagascar and Asia. *C. comosum* s.l. ("Spider Plant") from South Africa is amongst the World's most commonly cultivated house plants. The genus is traditionally separated from *Anthericum* by its angled capsules (rounded in *Anthericum*) and flat (vs. angular) seeds. Kativu & Nordal (1993) have argued that *Anthericum* should be limited to species with unibracteate nodes and compact seeds, while *Chlorophytum* species have multi-bracteate nodes and thin seeds.

E. Van Jaarsveld (✉)  
Department of Biodiversity and Conservation, University  
of the Western Cape, Bellville, South Africa  
e-mail: [Ernst@babylonstoren.com](mailto:Ernst@babylonstoren.com)

Several taxa can be regarded as weakly developed succulents due to their fusiformly thickened roots (incl. *C. comosum*). Some have somewhat succulent rhizomes, or slightly fleshy leaves, but none of the latter appears to be in cultivation. The peculiar *C. suffruticosum* is notable for its stem succulence, and has been found to belong to a basal grade of species within the genus (Bjorå & al. 2008b).

**C. bulbinifolium** Hoell & Nordal (Bot. J. Linn. Soc. 157: 228, ill. (p. 229, 236), 2008). **Type:** Zambia, Northern Region (Hoell & Nordal 62 [O, K, SRGH]). — **Distr:** N Zambia (Northern Region); *Brachystegia* woodland, sandy soils, 1200 m; only known from the type locality.

Rhizomes to 10 cm, with a crown of fibres, with fusiform **R** 5–7 mm Ø; **L** in a basal **Ros**, to 12 cm × 0.5–1 mm, glabrous, filiform-semiterete, succulent, canaliculate; **Inf** to 35 cm, peduncle to 20 cm, naked, raceme to 15 cm; **Bra** green, ± 5 × 1 mm; **Fl** 1–2 (–4) per node; **Ped** ± 6 mm, articulated near the middle, green above and pale brown below the articulation; **Tep** white, persistent after anthesis; **OTep** 5–7 × 2 mm; **ITep** 4–5 mm, with 1–3 brownish veins; **Fil** ± 5 mm; **Anth** 2–3 mm; **Fr** trigonous, transversely ridged, to ± 4 × 5 mm, covered by the persistent **Per**; **Se** black, irregularly folded, ± 2 mm. — [U. Eggl].

**C. comosum** (Thunberg) Jacques (J. Soc. Imp. Centr. Hort. 8: 345, 1862). **Type:** RSA, Eastern Cape (Thunberg s.n. [UPS]). — **Lit:** Bjorå & al. (2008a). **Distr:** Widespread in Africa S of the Sahara, from W, C and E Africa (incl. Ethiopia) down to S RSA; in various habitats from coastal forest and thickets to rocks in more open areas, rarely even epiphytic, 0–2450 m; naturalized elsewhere in frost-free climates (e.g. Italy, Spain).

Poellnitz (1946); **incl.** *Chlorophytum usambarense* Poellnitz (1946).

Perennial evergreen herbs to 80 cm tall and 1 m Ø; **R** fusiform, succulent, to 1 cm Ø; rhizome creeping, 1–1.5 cm Ø, often covered with old leaf bases; **L** 21–65 × 1–3.2 cm, in a dense basal **Ros**, lamina flat, linear, slightly fleshy, glabrous, canaliculate, bright green, margins entire, base sheathing, tips acute; **Inf** terminal spreading lax racemes, 30–100 cm; peduncle bracteate, 2–4 mm Ø; **Bra** linear-lanceolate, 2–4 cm, acuminate; **Fl** often replaced by propagules, which root and serve for vegetative reproduction; **Fil** in axillary fascicles; **Per** stellate, white; **Tep** oblong, to 10 mm, becoming reflexed; **St** 6; **Fil** glabrous;

**Sty** terete, smooth; **Sti** minute; **Fr** 3-angled emarginate capsules; **Se** flat, rounded, black, shiny.

*C. comosum* in its broad sense is a very variable complex of plants, and Nordal & al. (1997: 57–58) opt for a broad definition of the species. Traditionally, the complex was thought to consist of 2 species, *C. comosum* s.s. and *C. sparsiflorum* s.l. *C. comosum* was diagnostically circumscribed by inflorescences producing small plantlets (propagules for vegetative reproduction, making the plants esp. popular in horticulture), while *C. sparsiflorum* is lacking such plantlets. However, populations with both forms occurring together are known. In addition, considerable variation in many vegetative traits is known. The recent study of BJORÅ & al. (2008a) has shown that *C. comosum* s.l. has a polyphyletic origin, and that its delimitation is problematic — it appears likely that several segregates will have to be recognized. One such segregate is described as *C. rhizopendulum* by BJORÅ & al. (2008a) and it differs ecologically as well as morphologically (no tubers but long and thick rhizomes with green aerial roots).

The species is popular in horticulture as undemanding house plant, but is also used as garden plant in frost-free climates. Variegated plants are esp. frequently cultivated, either the cultivar ‘Variegatum’ with white margins, or ‘Vittatum’ with a white mid-stripe. ‘Mboyeti’ has leaves with undulating margins. Aymerich & Gustamante (2015) report that the species is rarely locally naturalized in Spain and Italy. — [E. Van Jaarsveld & U. Eggli]

**C. cremnophilum** Van Jaarsveld (Bradleya 32: 23–24, ill. (pp. 20–23), 2014). **Type:** RSA, Eastern Cape (*Van Jaarsveld* 25,079 [NMG]). — **Distr:** RSA (S Eastern Cape); pendent from E-facing sandstone cliffs.

Evergreen, slow growing, shrubby, to 1.5 m; rhizome to 25 mm Ø at the base, **R** fleshy, white, to 7 mm Ø, slightly tapering to both ends; **Bra** sparingly dichotomously branched, tips upcurving, 30–120 cm, 1.5–2.5 cm Ø, succulent, bare along the lower 1/3, green, leaf bases persistent for some time, finally leaving light coloured rings, sometimes with aerial roots; **L** 30–40 × 1.1–1.6 cm, spirally

in an apical rosette, amplexicaul, long-lived, leathery, linear-lanceolate and the lower part distinctly canaliculate, ascending-spreading, sometimes drooping, green, tip acuminate; **Inf** ascending to ascending-spreading, 90–137 cm; peduncle 7 mm Ø at the base, angular, 72 cm, panicle 69 cm, with 5–7 branches; lower **Bra** linear-triangular, 7.5 × 0.8 cm, acuminate, becoming smaller upwards and more triangular; **Fl** diurnal, 2–3 open together; **Per** stellate, 3 cm Ø, white; **OTep** sometimes slightly reflexed, linear-lanceolate, 15 × 4 mm, acute; **ITep** 16 × 7 mm, linear-obovate; **Fil** white, 10 mm; **Anth** 3 × 1 mm, the upper 1/3 coiled; **Ov** green, globose-trigonal, 2–2.5 mm Ø; **Sty** 15 mm, curved upwards; **Sti** minute, penicillate; **Fr** 3-lobed, 6.5 × ± 8 mm, globose in outline; **Se** black, flattened, 3–4 mm Ø with a pointed hilum, testa minutely granulate.

Similarly succulent stems are found in *C. suffruticosum*.

**C. suffruticosum** Baker (Gard. Chron., ser. nov. 24: 230, 1885). **Type:** Kenya (*Wakefield* s.n. [K]). — **Distr:** S Kenya, NE Tanzania; soil-pockets on rocks, 0–1150 m. **I:** Nordal & al. (1997: 41) – Fig. 1.

≡ *Anthericum suffruticosum* (Baker) Milne-Redhead (1936); **incl.** *Chlorophytum rhizomatosum* Baker (1885); **incl.** *Anthericum acuminatum* Rendle (1895); **incl.** *Anthericum campestre* Engler (1895); **incl.** *Dasystachys polyphylla* Baker (1898) ≡ *Chlorophytum polyphyllum* (Baker) Von Poellnitz (1946); **incl.** *Anthericum inexpectatum* Von Poellnitz (1942); **incl.** *Anthericum longisetosum* Von Poellnitz (1942).

**R**stock fleshy; stems solitary or little-branched, to 1.5 cm Ø, with semicircular ± horizontal but often irregularly arranged **L** scars, dull greenish, sometimes partly covered by fibrous remains of old **L** bases; **L** 45–60 × 1.5–2 cm, in apical **Ros**, ascending to erect, basally sheathing, linear, firm, glabrous, pale greyish-green, slightly succulent and canaliculate; **Inf** erect to drooping or irregular, normally unbranched, to 60 cm; peduncle terete, glabrous, to 30 cm; **Ped** short, ascending, articulate near the middle; **Bra** lanceolate, acuminate, lowermost to 1.3 cm; **Per** to 2 cm Ø, stellate; **Tep** white, outside with green midvein, 3-veined;

**Fig. 1** *Chlorophytum suffruticosum*. (Copyright: U. Eggli)

**Fil** much shorter than the tepals, **Anth** narrowly oblong, yellow; **Fr** and **Se** not described.

This peculiar and interesting stem-succulent is almost without parallel in the family, reminiscent of some species of *Velloziaceae* in vegetative appearance. The only other species with succulent conspicuous stems is the recently described *C. cremnophilum*. Nordal & al. (1997: 40) placed *C. suffruticosum* in the relationship of the stemless

*C. subpetiolatum*, and this position was recently corroborated by BJORÅ & al. (2008b).

**Part IV**

**The Family Araceae**

## Araceae

J. Bogner

**Including** *Arisaraceae* Rafinesque.  
**Including** *Caladiaceae* Salisbury.  
**Including** *Callaceae* Bartling.  
**Including** *Colocasiaceae* Vines.  
**Including** *Cryptocorynaceae* J. Agardh.  
**Including** *Dracontiaceae* Salisbury.  
**Including** *Lasiaceae* Vines.  
**Including** *Lemnaceae* Gray.  
**Including** *Monsteraceae* Vines.  
**Including** *Orontiaceae* Bartling.  
**Including** *Philodendraceae* Vines.  
**Including** *Pistiaceae* C. Agardh.  
**Including** *Pothaceae* Rafinesque.  
**Including** *Wolffiaceae* Bubani.

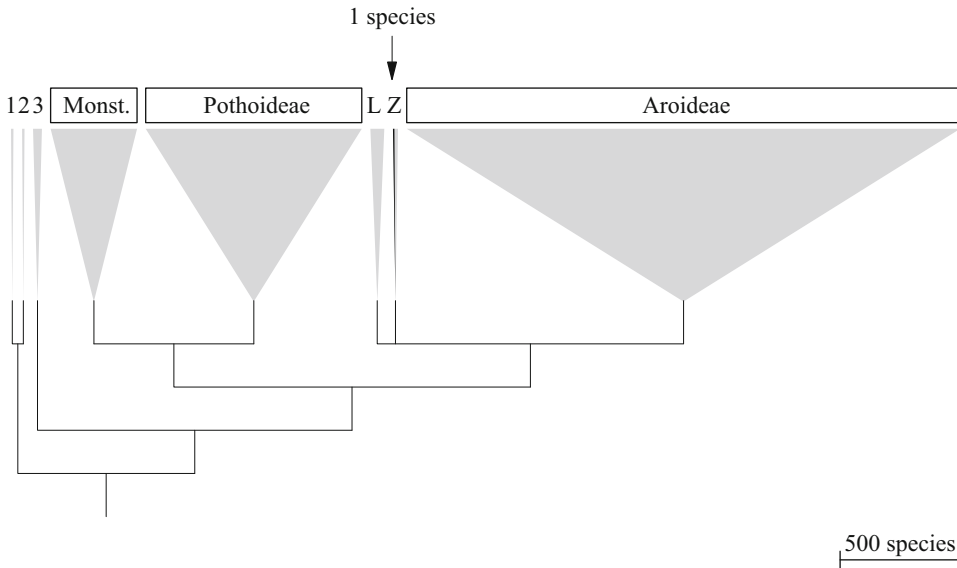

Dwarf to gigantic herbs, terrestrial, hemi-epiphytic or epiphytic, often geophytes or lithophytes, rarely floating (*Lemna*, *Pistia*) or submerged aquatic (*Jasarum*, *Cryptocoryne*); stems climbing, arborescent, erect, repent or subterranean, varying from subglobose tubers to very long rhizomes with elongate internodes; all tissues always with raphides, laticifers commonly present but absent in certain groups; **L** flat with petiole and lamina of very variable shape (except *Gymnostachys* with linear leaves), sometimes pinnatifid to pinnatisect, rarely pinnate, venation reticulate or parallel-pinnate (rarely strictly parallel); **Inf** pseudanthia consisting of

a spadix subtended and/or enveloped or surrounded by a spathe (= last leaf of the shoot, usually specialized in form and colour); spadix usually a dense fleshy spike with sessile (except *Pedicellarum*) minute ebracteate flowers; **Fl** bisexual or unisexual, when unisexual the female **Fl** forming the basal part and the male **Fl** the intermediate or apical part of the spadix (except *Spathicarpa*); **Fl** with or without perianth; **St** opposite to the tepals, free or connate into a synandrium; **Anth** extrorse (except *Zamioculcas*, *Pedicellarum*); **Ov** syncarpous, usually 1- to 3-locular (1- to 8-locular in *Spathicarpeae*, 2- to 47-locular in *Philodendron*), ovules anatropous to orthotropous or intermediate; **Sty** present or absent, often inconspicuous; **Sti** various, discoid to capitate, or  $\pm$  distinctly lobed, always wet at anthesis; **Fr** berries (basally dehiscent in *Lagenandra*), usually free and borne in  $\pm$  cylindrical dense infructescences (rarely syncarpous, *Syngonium*, *Cryptocoryne*); **Se** small to very large, globose to ellipsoid, sometimes reniform, testa very thin to very thick, smooth, ribbed, warty or rarely spiny; embryo minute to large, endosperm present or absent.

**Order:** Alismatales

**Important Literature:** Engler (1905: partial synopsis); Grayum (1990: evolution & phylogeny); Mayo & al. (1997: synopsis); Mayo & al. (1998: synopsis); Keating (2004: anatomy & classification); Tam & al. (2004: partial

J. Bogner (✉)  
Gersthofen, Germany

**Fig. 1** Summary phylogeny of Araceae (4150 species total, data from Stevens (2001 onwards, accessed May 2016). 1 = Gymnostachydoideae, 2 = Orontioideae, 3 =

Lemnoideae, L = Lasioideae, Monst. = Monsteroideae, Z = Zamioculcadoideae. (Copyright: U. Egli)

phylogeny); Cabrera & al. (2008: phylogeny); Nauheimer & al. (2012: phylogeny and evolution); Mayo & al. (2013: evolution); Henriquez & al. (2014: molecular phylogeny).

**Distribution:** Worldwide (except Antarctica), but mostly (>90%) in the tropics, especially in rainforests.

**Classification and History:** A family of 120 genera with  $\pm$  4150 species, representing a basal or near-basal lineage within the order Alismatales (Petersen & al. 2016). The circumscription of the family has remained largely uncontested, apart from the recent inclusion of the *Lemnaceae* on molecular grounds (Cabrera & al. 2008). The traditional *Araceae* can be divided in two large groups on the basis of flower morphology, i.e. all basal clades with hermaphroditic flowers on the one hand, and *Aroideae* s.l. with unisexual flowers on the other hand (Mayo & al. 1997, Mayo & al. 1998). Keating (2004) divides the family into 9 subfamilies, while Tam & al. (2004) found 5 major clades in their molecular phylogeny, and Cabrera & al. (2008) recognize 8 subfamilies – Fig. 1.

**Ethnobotany:** Several genera such as *Alocasia*, *Amorphophallus*, *Colocasia* (“Taro”), *Cyrtosperma* and *Xanthosoma* produce edible underground tubers or stems and have great importance as food plants in the tropics. *Monstera deliciosa* produces edible fruits, and some species are valued as houseplants, together with species from several other genera (*Anthurium*, *Dieffenbachia*, *Philodendron*, *Zantedeschia*, etc.).

**Succulence:** Succulence is uncommon in the family, and the only taxon with undisputed succulence is *Zamioculcas*. Several species of *Anthurium* have leathery leaves, and many tuberous (e.g. *Amorphophallus*, *Biarum*, *Eminium*) or rhizomatous members (e.g. *Stylochaeton* [some of its species with very fleshy roots], *Gonatopus* or *Synandropsadix*) have adaptations to seasonally dry conditions. The stems of *Philodendron warszewiczii* K. Koch & C. D. Bouché have been described as water-storing (Schulze & al. 1988), but are more fleshy-juicy without adaptations to water conservation.

The genera *Zamioculcas* and *Gonatopus* together form the subfamily *Zamioculcadoideae* (Bogner and Hesse 2005), which is distributed in

tropical E and SE Africa. It has an isolated position and is sister to subfamily *Aroideae* (Henriquez & al. 2014 and references cited there). *Zamioculcadoideae* (including tribe *Stylochaetoneae* with the only genus *Stylochaeton*, not succulent) are the only *Araceae* with unisexual flowers with a perigone.

## Zamioculcas ARACEAE

J. Bogner

**Zamioculcas** Schott (Syn. Aroid., 71, 1856).  
**Type:** *Zamioculcas loddigesii* Schott [*nom. illeg.*, = *Z. zamiifolia*]. — **Zamioculcadoideae** — **Lit:** Haigh and Boyce (2012: 22–24). **Distr:** Tropical E and SE Africa. **Etym:** For the genus *Zamia* (*Zamiaceae*); and from Arab. ‘qolqas’, ‘kulkas’, the name of the Taro plant (*Colocasia*); for the leaves, which resemble those of *Zamia*, and the placement in the same family as *Colocasia*.

Seasonally dormant or evergreen herbs with a short very thick rhizome 2–4 cm Ø; **L** few to many, erect, 40–80 cm, pinnate, leaflets deciduous leaving the persistent succulent petiole, petiole 10–35 cm, terete, basally thickened, 1–2 cm Ø, geniculate at the apex, sheath ligulate, free almost to the base, very short and inconspicuous, leaflets ± opposite, oblong-elliptic, 5–12 × 1.5–6 cm, coriaceous and thickish, dark glossy green, midvein thick, primary lateral veins pinnate, higher order venation reticulate; **Inf** 1–2 in each floral sympodium at ground-level; peduncle 3–20 cm, erect but recurved at fruiting time; spathe entirely persistent to fruiting stage, 5–10 cm, coriaceous, slightly constricted between tube and lamina, outside greenish, inside whitish, tube convolute, lamina longer than the tube, first expanded horizontally, later reflexed; spadix sessile, 5–8 cm, female zone subcylindrical, 1–2 × 0.7–1.5 cm Ø, separate from the male zone by a

short constriction with sterile flowers; male zone cylindrical, ellipsoid to clavate, fertile to apex, 4–6 × 1–1.5 cm Ø, falling off after anthesis; **Fl** unisexual; **Tep** 4 in 2 series, ± 3 mm, whitish, decussate, thickish; **male Fl** with 4 **St** shorter than the tepals; **Fl** free, oblong, thick, somewhat flattened; **Anth** introrse, pollen extruded in strands, pollen grains hamburger-shaped, large (c. 60 µm), fully zonate, exine fossulate-foveolate; pistillode clavate, as long as the tepals; **sterile Fl** with 4 **Tep** surrounding a clavate pistillode; **female Fl:** **Gy** equalling the tepals; **Ov** ovoid, 2-locular with 1 hemianatropous ovule per locule, placentation axile near the base of the septum; **Sti** large, discoid-capitate, ± 1.5 mm Ø; staminodes lacking; **Fr** a subglobose to ellipsoid infructescence at ground-level, to 3 cm Ø, berries depressed-globose, white, to 1.2 cm Ø, furrowed at the septum, 1- to 2-seeded, surrounded by the persistent tepals; **Se** ellipsoid, ± 8 × 4–5 mm, testa smooth, brown, raphe conspicuous, embryo large, endosperm almost absent. — **Cytology:** 2n = 34.

The only species of this monotypic genus is highly variable and is notable for the pronounced development of ‘leaf petiole succulence’. The upper part of the leaf abscises at a pre-formed layer at the top of the petiole. Crassulacean Acid Metabolism was reported by Holtum & al. (2007), and *Zamioculcas* is a flexible CAM-plant, with significant CAM appearing only during water stress conditions. It is the only taxon of the whole order Alismatales for which this mode of photosynthesis has been recorded so far. Its floral

Gersthofen, Germany

**Fig. 1** *Zamioculcas zamiifolia*. (Copyright: U. Eggli)

anatomy was studied by Barabé and Forget (1989), the palynology by Hesse & al. (2001).

The leaves are reported to be poisonous to goats (P. R. O. Bally, pers. comm.). The plants are used in the traditional medicine in Tanzania and Malawi.

**Z. zamiifolia** (Loddiges) Engler (Pflanzenr. IV. 23B: 305, Figs. 85, 1905). **Type:** [icono]: Bot. Cab. 15: t. 1408, 1829. — **Distr:** Kenya, Tanzania (incl. Pemba and Zanzibar), Malawi, Zimbabwe, Moçambique, RSA (KwaZulu-Natal); tropical moist lowland to submontane forests or savannas, often on stony ground, to 600 m. **I:** Obermeyer and Strey (1969) – Fig. 1.

≡ *Caladium zamiifolium* Loddiges (1829); **incl.** *Zamioculcas loddigesii* Schott (1856) (*nom. illeg.*, Art. 52.1); **incl.** *Zamioculcas lanceolata* Peter (1930).

Description as for the genus.

*Z. zamiifolia* is a common house-plant today in Europe and the USA, and it is produced in enormous numbers each year (Chen and Henny 2003) and sometimes marketed under the vernacular name “ZZ plant”. Plants can readily be propagated by detaching individual leaflets, which rapidly root. A variegated cultivar is also sometimes seen in cultivation.

**Part V**

**The Family Asparagaceae**

# Asparagaceae

E. Van Jaarsveld and U. Eggli

Perennial shrubs or subshrubs, often scrambling or climbing, with herbaceous to woody perennial or annual shoots; rhizome short, sympodial, **R** sometimes succulent and fusiform; stems wiry and tough, rarely twining, sometimes spiny, and **Sp** derived from modified lateral branches or leaves, usually with lateral branches transformed into leaf-like phylloclades, or modified stems (assimilatory structures) fasciculate, green, slender and needle-like; **L** often reduced to scale-like structures, spurred; **Fl** small, actinomorphic, solitary or in umbellate or racemose **Inf**, hermaphrodite or unisexual (then plants dioecious); **Te** 3 + 3, white, yellow or green, free and spreading or basally fused to form a campanulate perigone; male and hermaphrodite flowers with 3 + 3 **St**, **Fi** free or fused with the tepals; **Anth** introrse, dorsifixed; **Ov** superior, 3-locular, placentation axile with 2–12 ovules per locule; **Sty** short; **Sti** capitate or lobed; **Fr** globose red, blue or white berries; **Se** globose, black.

**Order:** Asparagales

**Important Literature:** Kubitzki & Rudall (1998: synopsis).

**Distribution:** Widely distributed in the Old World, rare in the New World (only *Hemiphylacus* in Mexico).

The *Asparagaceae* s.s., in old traditional classifications included in the *Liliaceae*, are widely distributed in the Old World. They occur mainly in semi-arid to arid Mediterranean climates, and taxa with xeromorphic adaptations such as succulent tuberous roots are common. Photosynthesis occurs mainly with green branches and branchlets (phylloclades), and true leaves are reduced to scales. The small family embraces only 2 genera, *Asparagus* and *Hemiphylacus* (Kubitzki & Rudall 1998). *Hemiphylacus* (native to Mexico) counts 5 species (none succulent) and *Asparagus* embraces the majority of the ±200 (–290?) species of the family. Older treatments of the family recognized *Protasparagus* and *Myrsiphyllum* as separate genera (e.g. Obermeyer & al. (1992)), but the differences between them and *Asparagus* are only minor (Malcomber & Demissew 1993; Fellingham & Meyer 1995).

Recent years saw a movement towards expanding the circumscription of the family, and APG (2009) as well as Chase & al. (2009) proposed to subsume *Agavaceae*, *Anthericaceae*, *Eriospermaceae*, *Hyacinthaceae* and *Ruscaceae* (including *Dracaenaceae* and *Nolinaceae*) under a vastly expanded family *Asparagaceae*. Here we

follow Nyffeler & Eggli (2010) and Judd & al. (2016) and accept a narrow circumscription of *Asparagaceae*. A broadened *Asparagaceae* is phylogenetically not more correct than the traditional family concepts, which are therefore retained.

Economically important plants include *Asparagus officinalis* Linné (“Garden Asparagus”, used as vegetable) as well as *A. setaceus* (Kunth) Jessop (“Fern Asparagus”, used by florists for decoration). Only a few species of *Asparagus* can be considered succulent due to their succulent roots.

## Asparagus ASPARAGACEAE

E. Van Jaarsveld and U. Egli

**Asparagus** Linné (Spec. Pl. [ed. 1], 1: 313, 1753). **Type:** *Asparagus officinalis* Linné. — **Lit:** Jessop (1966: synopsis S Africa); Obermeyer (1984: revision S Africa, as *Myrsiphyllum*); Obermeyer & al. (1992: flora S Africa); Malcomber & Sebsebe Demissew (1993: classification); Norup & al. (2015: phylogeny). **Distr:** Old World excluding Australasia; invasive neophytes elsewhere (e.g. Australia, New Zealand). **Etym:** Lat., asparagus, cultivated asparagus.

**Incl.** *Myrsiphyllum* Willdenow (1808). **Type:** *Medeola asparagoides* Linné.

**Incl.** *Asparagopsis* (Kunth) Kunth (1850) (*nom. illeg.*, Art. 53.1). **Type:** *Asparagus aethiopicus* Linné.

**Incl.** *Hecatrix* Salisbury (1866) (*nom. illeg.*, Art. 52.1). **Type:** *Medeola asparagoides* Linné.

**Incl.** *Protasparagus* Obermeyer (1983). **Type:** *Asparagus aethiopicus* Linné.

Shrubs, soft to woody sometimes spiny subshrubs, or scramblers, from a usually multi-stemmed tuberous base; stems often annual;

rhizome short, sympodial, mostly covered with persistent ascending cataphylls; **R** often swollen, fusiform and succulent, radiating from the rhizome, sometimes exposed but usually underground; stems ascending, sometimes with assimilating branchlets, sometimes modified into flat leaf-like phylloclades; phylloclades solitary or fascicled, deciduous to persistent, linear to ovate; **L** reduced and scale-like; **Inf** 1- to few-flowered, raceme-like; **Fl** small, white, yellowish or green, often inconspicuous, uni- or bisexual; **Tep** 3 + 3, all of similar shape, usually free or fused at the base into a campanulate perigone; male **Fl** with 3 + 3 **St**; **Fil** free; **Anth** dorsifixed, introrse, sterile in unisexual female flowers; **Ov** superior, trilocular; **Sty** short; **Sti** capitate or lobed; **Fr** globose berries, red, brown, blue or black, **Se** 1 to several, globose, black.

*Asparagus* is a large genus of  $\pm 200$  (–290?) species (Kubota & al. 2012), restricted to the Old World, and many are native to semiarid to arid climates, and xeromorphic in nature. The diversification hotspot is S Africa. (Norup & al. 2015). Many species have fleshy, succulent tubers disposed along their rhizomes, and are geophytic succulents. Seedlings of many species first develop rather weak above-ground growth, but have a comparatively huge succulent main root. Leaves are reduced to scales, and the photosynthetic organs are fascicled phylloclades of various shape (flattened and leaf like, terete, or angled). The spines, where present, are of different origins, and either represent the hardened spurs of the primary leaves, hardened phylloclades, or sterile

spur branches (Kubitzki & Rudall 1998). The phylloclades are modified axillary shoots where genes usually associated with leaf development are co-opted into phylloclade development (Nakayama & al. 2012a, Nakayama & al. 2012b).

**Classification:** In earlier classifications (e.g. Obermeyer & al. 1992) 3 separate three genera *Asparagus*, *Protasparagus* and *Myrsiphyllum* were recognized, following Dahlgren & al. (1985). Later authors found this division untenable (Malcomber & Sebsebe Demissew 1993). All 3 genera are today subsumed under an expanded *Asparagus* s.l. but — contrary to Malcomber & Sebsebe Demissew (1993) who accepted only 2 subgenera — represent separate clades in the molecular phylogeny presented by Kubota & al. (2012):

- [1] Subgen. *Asparagus*: Flowers unisexual and plants dioecious, ovary locules with 2 ovules, phylloclades terete.
- [2] Subgen. *Protasparagus*: Flowers bisexual, tepals free, ovary locules with 4 to many ovules; spines usually present; phylloclades usually dorsiventrally flattened.
- [3] Subgen. *Myrsiphyllum*: Flowers bisexual, tepals fused in the lower  $\frac{1}{2}$ , ovary locules with 4 to many ovules; spines absent; phylloclades usually dorsiventrally flattened.

The phylogeny of Kubota & al. (2012) is not supported by the results of the more detailed study of Norup & al. (2015), which found 6 clades which can also be diagnosed morphologically. Since the re-classification based on this research has not yet been published, we continue to use the traditional classification as given above for the time being. Norup & al. (2015) moreover found that about  $\frac{1}{3}$  of the studied species are not monophyletic in their analyses, supporting earlier suggestions from other sources. Species delimitations in several groups are in need of further research as to variability and suitable defining traits.

The origin of the genus is likely S Africa, with subsequent dispersal throughout the Old World (Kubota & al. 2012). This biogeographic scenario is also supported by Norup & al. (2015).

**Terminology:** Depending on the literature consulted, the term “cladode” is used for the leaf-like photosynthetic structures. The terms “cladode” and “phylloclade” are frequently used indiscriminately, esp. in English-language publications, but for *Asparagus*, the term “phylloclade” should be used, since these structures represent modified short shoots, while “cladode” refers to a modified long shoot. [U. Eggli].

**Use and cultivation:** Some species are edible such as *A. officinalis* (“Garden Asparagus”, young shoots), *A. abyssinicus*, *A. lucidus* or *A. densiflorus* (tubers). Only a small selection of tuberous-rooted species is covered below as succulents. These are becoming more popular, and esp. those with exposed tuberous roots are attractive. Most are easily grown from seed and make attractive long-lived container and garden plants.

**A. asparagoides** (Linné) W. Wight (Century Dict. 11: 854, 1909). **Type:** [lecto — icono]: Tilli, Cat. Pl. Horti Pisani, 17, t. 12: fig. 1–2, 1723. — **Distr:** Tropical Africa to Namibia, Malawi, Zimbabwe and RSA; Succulent Karoo, thickets, savanna, flowers mid-winter to spring; invasive alien in Australia. **I:** Obermeyer & al. (1992: 72, fig. 14: 2, sub *Myrsiphyllum*).

≡ *Medeola asparagoides* Linné (1753) ≡ *Myrsiphyllum asparagoides* (Linné) Willdenow (1808) ≡ *Hecatris asparagoides* (Linné) Salisbury (1866); **incl.** *Medeola angustifolia* Miller (1768) (*nom. illeg.*, Art. 52.1) ≡ *Myrsiphyllum angustifolium* (Miller) Willdenow (1808) (*nom. illeg.*, Art. 52.1) ≡ *Asparagus medeoloides* var. *angustifolius* (Miller) Baker (1896) (*nom. illeg.*, Art. 52.1); **incl.** *Dracaena medeoloides* Linné fil. [3] Scandent much-branched perennials with wiry twisted stems and shiny green ovate phylloclades, deciduous or semideciduous; rhizome cylindrical, with numerous lateral, fusiform, radially arranged **R** tubers, these to 6 × 2 cm but variable in size, close to the rhizome but not

overlapping; stems wiry, twisting, smooth or ridged, to 2 m; **Br** short, with beaded ridges; phylloclades variable in size and shape, ovate-acuminate, to 4 × 2 cm, flat or folded and curved, many-veined but mostly with 3 more pronounced veins on each face, margin smooth or minutely denticulate; **Ped** to 10 mm, articulated below the perianth; **Tep** to 10 mm, forming a tube in the lower ½, reflexed above; **St** erect, connivent; **Fil** expanded below into 2 small spreading teeth; **Anth** red; **Ov** pear-shaped, stipitate, narrowed into a **Sty** as long as the ovary, ovules to ± 6 in each locule; **Sti** short, spreading, ciliate; **Fr** globose, ± 1 cm Ø, usually many-seeded. — [E. Van Jaarsveld]

**A. crassicladius** Jessop (Bothalia 9: 75, 1966). **Type:** RSA, Eastern Cape (*Esterhuysen* 4670 [BOL]). — **Distr:** RSA (North-West, Eastern Cape: Uniondale to Somerset East); mainly in Albany Thicket vegetation and savanna.

≡ *Protasparagus crassicladius* (Jessop) Obermeyer (1983).

[2] Ascending scandent to spreading tufted shrubs to 2 m tall; rhizome broad and woody with fleshy roots, lateral roots producing fusiform tubers; stem woody, tortuous, slightly pubescent, becoming glabrous, with short recurved spines; phylloclades somewhat succulent, oval, acuminate, 1- to 12-nate, 1.2–2.5 cm long; **Inf** racemes, paired, to 6 cm; **Fl** 2–6 in fascicles; **Ped** 3–4 mm; **Tep** oblong, sometime slightly obovate, 3 mm long, cream-coloured; **St** 2.3 mm; **Anth** minute; **Ov** with 4 ovules per locule; **Sty** 1.5 mm, with short spreading **Sti**; **Fr** unknown. — [E. Van Jaarsveld]

**A. densiflorus** (Kunth) Jessop (Bothalia 9(1): 65, 1966). — **Distr:** RSA (Eastern Cape, KwaZulu-Natal, Limpopo, Mpumalanga), Swaziland, Moçambique; mainly along the coast of the Indian Ocean, on dunes and rocks, spring- to autumn-flowering.

**Incl.** *Asparagopsis densiflora* Kunth (1850) ≡ *Asparagus sarmentosus* var. *densiflorus* (Kunth) Baker (1875) ≡ *Protasparagus densiflorus* (Kunth) Obermeyer (1992); **incl.** *Asparagus meyersii* hort. (s.a.) (*nom. inval.*, Art. 29.1); **incl.**

*Asparagus aethiopicus* var. *ternifolius* Baker (1871) ≡ *Asparagus ternifolius* (Baker) Hooker fil. (1900); **incl.** *Asparagus sarmentosus* var. *comatus* Baker (1875); **incl.** *Asparagus myriocladus* Baker (1889); **incl.** *Asparagus sprengeri* Regel (1890).

[2] Many-stemmed spreading shrublets, sometimes scrambling and ascending; tubers on the rhizome or laterally on the roots; stems spreading or ascending, to 60 cm, usually straight or slightly tortuous, finely ridged, glabrous; branchlets numerous, to 10 cm, grooved, spreading or ascending; phylloclades flattened or rarely 3-angled, slightly arcuate, 5–15 mm, mucronate, sometimes ternate or numerous, with distinct midrib when flattened; **Sp** well-developed but often not pungent; **Inf** peduncles shorter than the branchlets, sometimes not differentiated; **Fl** solitary; **Ped** articulated near the middle; **Tep** oblong-obovate, obtuse, spreading, white or pale pink, 2–5 mm; **St** ¾ as long as the tepals; **Sty** divided for ± ½ of the length; **Fr** globose, red, ± 5–10 mm Ø, 1-seeded.

Very variable with several local forms. Popular in cultivation, esp. in coastal gardens. Commonly encountered cultivars in Europe are:

‘Sprengeri’: Medley-Wood sent seeds to Sprenger who became its main distributor in Europe at that time (Obermeyer et al. 1992).

‘Meyersii’: A very distinct form with ascending compact cylindrical branches and decorative red berries within the “cylinder”. This form was recently discovered in the wild by the present author along the lower Kei River (S of Gaika Ford), and this seems to be its main distribution range. — [E. Van Jaarsveld]

**A. juniperoides** Engler (Bot. Jahrb. Syst. 10: 3, 1889). **Type:** Namibia (*Marloth* 1538 [B]). — **Distr:** Namibia, RSA (Northern Cape, Western Cape); winter-rainfall regions, in Succulent Karoo and Fynbos, autumn- to mid-winter-flowering.

≡ *Myrsiphyllum juniperoides* (Engler) Obermeyer (1984).

[3] Ascending shrublets, 60–100 cm tall, from a tuberous horizontally creeping rootstock; tubers sessile to shortly stalked, fusiform; stems erect,

annual, glabrous, grooved; branchlets narrow, numerous, to 3 cm, borne directly on the stems; branchlets and phylloclades together forming a cylindrical tapering outline almost like a juniper tree; phylloclades solitary, to 1 cm, flattened, linear, with ciliate margins; **Sp** absent; **Inf** axillary, 1-flowered; **Ped**  $\pm$  2 mm, distally articulated; **Tep** oblong, to 6 mm, white with a green streak and ciliate margins; **St** almost as long as tepals; **Fil** not spurred; **Anth** minute, yellow; **Ov** globose, 1–1.5 mm; **Fr** globose, 1- to 3-seeded,  $\pm$  5 mm  $\varnothing$ , red. — [E. Van Jaarsveld].

**A. mucronatus** Jessop (Bothalia 9(1): 56, 1966). **Type:** RSA, Northern Cape (*Theron* 551 [PRE]). — **Distr:** RSA (Northern Cape, Western Cape, Eastern Cape); in Nama Karoo, Succulent Karoo and Albany Thicket vegetations, usually in brackish soil, mid-summer-flowering.

$\equiv$  *Protasparagus mucronatus* (Jessop) Obermeyer (1992).

[2] Many-stemmed shrubs to  $\pm$  1 m (rarely 2 m) tall, from a distinct tuberous **R**stock; tubers horizontally spreading, often exposed, greyish-brown, to 2 cm  $\varnothing$ ; stems erect, biennial, straight, becoming zigzag higher up, grey to brown, branches acute, to 2 cm; branchlets fascicled and up to 6-nate, pubescent or scabrid, to 6 cm with **Bra** to 5 mm; phylloclades to 10-nate, straight to arcuate, 3–8 mm, terete with non-pungent mucro; **Inf** axillary, 1- or 2-flowered, 4–7 mm; **Ped** articulated below the middle; **Tep** oblong-obovate, 3–4 mm; **St** slightly shorter than the tepals; **Anth** globose; **Ov**  $\pm$  1 mm; **Sty** shortly divided, slightly  $<$  1 mm; **Fr** globose, fleshy, red and wrinkled when ripe,  $\pm$  5 mm  $\varnothing$ , 1- to 2-seeded. — [E. Van Jaarsveld]

**A. multituberosus** R. A. Dyer (Bothalia 6: 442, 1954). **Type:** RSA, Western Cape (*Marloth* 9006 [PRE, STE]). — **Distr:** RSA (Northern Cape, Western Cape); Renosterveld and Fynbos vegetations, flowers winter and spring. **I:** Obermeyer & al. (1992: 72, fig. 14: 1, as *Myrsiphyllum*).

$\equiv$  *Myrsiphyllum multituberosum* (R. A. Dyer) Obermeyer (1984).

[3] Scandent much-branched perennials to 40 cm tall; rhizome thin, horizontal, to 50 cm, with densely overlapping small fusiform tubers 10  $\times$  3 mm; phylloclades ovate to cordate, to 2.5 cm, many-veined, tip apiculate, margin papillate; **Fl** 1–3, axillary from membranous scale-leaves; **Ped** 5 mm, curved, articulated below the flower; **Tep**  $\pm$  7 mm, forming a wide tube below, spreading above; **St** as long as the tepals; **Fil** basally broadened, flat; **Ov** ovoid, with up to 12 ovules per locule; **Sty** 3, curved outwards; **Sti** apical, papillate; **Fr** not seen. — [E. Van Jaarsveld]

**A. ovatus** Salter (J. South Afr. Bot. 6: 167, 1940). **Type:** RSA, Western Cape (*Salter* 8214 [BOL, NBG, PRE]). — **Distr:** RSA (Northern Cape, Western Cape, Eastern Cape); mainly along the coast in Fynbos, Succulent Karoo and thickets. **I:** Obermeyer & al. (1992: 72, fig. 14: 3, 5, as *Myrsiphyllum*).

$\equiv$  *Myrsiphyllum ovatum* (Salter) Obermeyer (1984).

[3] Scandent deciduous twiners to 1.5 m tall; rhizome compact, scaly, woody, with long spreading **R**, tubers numerous, hard, swollen, fusiform, 5–10  $\times$  2–4 mm, developing at some distance from the rhizome; phylloclades deciduous, ovate, 3  $\times$  1.5 cm, many-veined, shiny; **Fl** 2–3, behind the base of the phylloclades; **Ped** 10 mm, articulated near the base of the flower; **Tep**  $\pm$  6 mm, reflexed; **Fil** flattened, erect, with small basal spur on each side; **Ov** oblong, with up to 10 ovules per locule; **Sty** and **Sti** just exerted from the staminal column; **Fr** 10 mm  $\varnothing$ , globose, red when ripe. — [E. Van Jaarsveld]

**A. oxyacanthus** Baker (J. Linn. Soc., Bot. 14: 625, 1875). **Type:** RSA, Eastern Cape (*Bowker* s.n. [K, PRE [photo]]). — **Distr:** RSA (Eastern Cape); in Albany Thicket vegetation; flowering spring to summer.

$\equiv$  *Protasparagus oxyacanthus* (Baker) Obermeyer (1983).

[2] Tufted with tuberous **R**, tubers distant,  $\pm$  6 cm long; stems unbranched, ascending to spreading, 50 cm, pubescent, with numerous narrow, softly spine-like leaf spurs; **Br** solitary,

lacking branchlets; phylloclades solitary, oblong, to 4 cm, with a median vein and thickened margin, mucronate; **Fl** solitary from the axils of the phylloclades; **Ped** 2 mm, articulated distally; **Tep** obovate, obtuse, white, 2–3 mm long, spreading to ascending; **Anth** large, to 0.7 mm; **Ov** globose; **Sty** branches free, short; **Fr** fleshy and red when ripe. — [E. Van Jaarsveld]

**A. striatus** (Linné *fil.*) Thunberg (Prodr. Fl. Cap., 65, 1794). **Type:** RSA, “Cape Prov.” (*Thunberg* s.n. [UPS]). — **Distr:** RSA (Northern Cape, Western Cape, Eastern Cape, Free State); Nama Karoo, Succulent Karoo, Albany Thicket vegetation, on dry stony outcrops, flowering spring to summer.

≡ *Dracaena striata* Linné *fil.* (1781) ≡ *Myrsiphyllum striatum* (Linné *fil.*) Kunth (1850) ≡ *Protasparagus striatus* (Linné *fil.*) Obermeyer (1983); **incl.** *Dracaena erecta* Linné *fil.* (1782) ≡ *Asparagus erectus* (Linné *fil.*) Thunberg (1794); **incl.** *Dracaena stricta* Schultes (1828) (*nom. inval.*, Art. 61.1).

[2] Rhizomes with laterally placed **R** tubers; stems erect, glabrous to minutely pubescent, woody, grooved, branches ascending, similar to the stem, often zig-zag, not further branched; phylloclades terminal and 2- to 3-nate, variable, linear to lanceolate 10–40 × 1–5 mm, rarely almost terete; **Sp** not well developed, small, reflexed; **Fl** in terminal fascicles of 1–2 to up to 15 or more; **Ped** ± 5 mm, articulated below the middle; **Tep** 3–4 mm long, oblong-obovate with a serrate apex; **St** not spurred, almost as long as the tepals; **Anth** ± 0.5 mm; **Sty** ± 1 mm; **Fr** fleshy, red when ripe, ± 5 mm Ø, 1- to 2-seeded. — [E. Van Jaarsveld]

**A. undulatus** (Linné *fil.*) Thunberg (Prodr. Fl. Cap., 66, 1794). **Type:** RSA, Western Cape (*Thunberg* s.n. [UPS 8446]). — **Distr:** S Namibia, RSA (Northern Cape, Western Cape); sandy flats in Fynbos or Succulent Karoo, flowers mid-winter to spring.

≡ *Dracaena undulata* Linné *fil.* (1781) ≡ *Myrsiphyllum undulatum* (Linné *fil.*) Kunth (1850); **incl.** *Asparagus klinghardtianus* Dinter (1931).

[3] Ascending shrublets to 60 cm tall, from a tuberous base; tubers 2.5–5 × 0.8–1.5 cm; stems erect, annual, angled, the edes often winged in the upper parts, green, branches ascending; phylloclades 8–40 mm, solitary, sessile, ovate to lanceolate, undulate, tips sometimes folded, veins prominent; **L** deltoid, not forming a spine; **Fl** 1–3 per node; **Ped** 5–10 mm, articulated in the distal part; **Tep** linear oblong, spreading to reflexed, 6 mm, purplish to greenish; **St** as long as the tepals; **Fil** spurred; **Ov** 2 mm; **Sty** 2.5 mm; **Fr** fleshy and red when ripe, 5–6 mm Ø, 1- to 3-seeded. — [E. Van Jaarsveld]

[epnfigueiredo@gmail.com](mailto:epnfigueiredo@gmail.com)

karyotype of 4 long and 3 short chromosomes, with  $x = 7$ . Most species are diploid, but some polyploidy and aneuploidy occur, especially in *Aloe* and *Haworthia*, as summarized by Riley & Majumdar (1979), Brandham (1983) and Smith (1991). In the *Asphodeloideae*, *Kniphofia* has a basic set of 6 chromosomes ( $2n = 12$ ), while some genera (*Bulbinella*, *Eremurus* [both non-succulent, except *Bulbinella calcicola*] and *Trachyandra* [some spp. weakly succulent]) share a basic chromosome number of  $x = 7$  with the *Aloioideae*, but  $x = 14$  in the case of *Asphodelus* and *Asphodeline*.

**Order:** Asparagales.

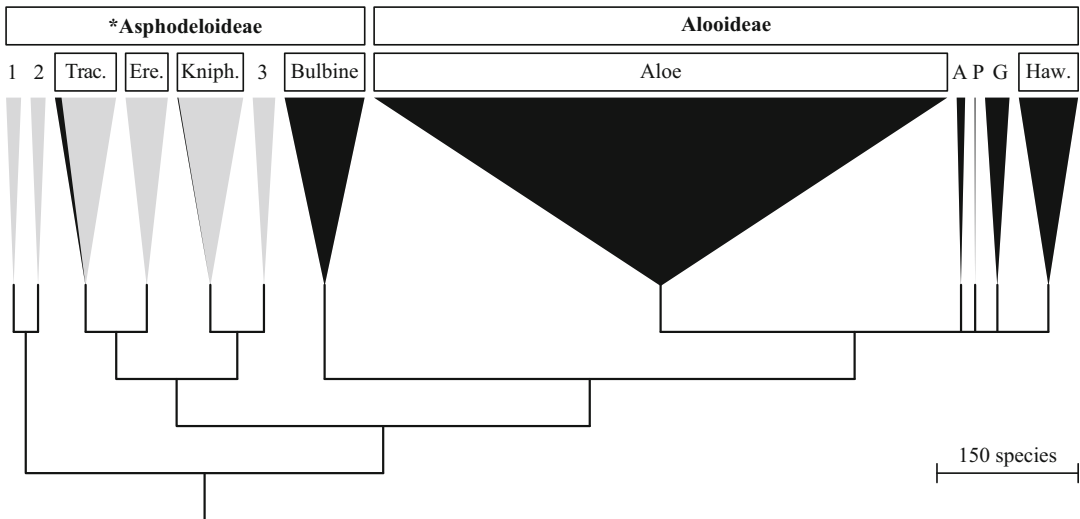

**Important Literature:** Dahlgren & al. (1985: synopsis), Smith & Wyk (1991: systematics); Smith & Wyk (1998: synopsis); Jaarsveld (2001: synopsis, as *Asphodelaceae* s.s.); Smith & Newton (2001: synopsis, as *Aloaceae*); Smith & Steyn (2004: systematics, as *Aloaceae*); Klopper & al. (2010: synopsis phylogeny); Grace & al. (2013: generic classification); Daru & al. (2013: molecular phylogeny).

**Distribution:** Africa, Madagascar, Arabian Peninsula, Mascarene Islands, Socotra, Europe, Asia, Australia, New Zealand.

**Classification and History:** The *Asphodelaceae*, here treated as consisting of two subfamilies, *Aloioideae* and *Asphodeloideae*, is a monophyletic monocot family in the order Asparagales (Smith & Wyk 1998; Klopper & al. 2010). To support the monophyly of the family, the presence of hemitropous ovules and arillate seeds has been used as evidence (Dahlgren & al. 1985; Smith & Wyk 1998; Steyn & Smith 1998; Steyn & Smith 2001; Treutlein & al. 2003).

The *Asphodelaceae* consists of 12 genera (but see below) and  $\pm 1050$  species and is widespread in dry and climatically mild parts of the tropical, subtropical and temperate Old World. Southern Africa is the main present-day centre of diversity of the family, at both genus and species ranks. The subfamily *Aloioideae*, which is widely considered monophyletic, has fairly uniform vegetative and

reproductive morphologies, is a virtually exclusively leaf-succulent group, and has definite present-day centres of diversity in southern African and Madagascar. The *Aloioideae* (as *Aloaceae*, see Cronquist (1981) and Smith & Newton (2001)) is sometimes retained as distinct from the *Asphodelaceae* s.s., from which it differs inconsistently by having succulent leaves, tubular flowers, a basic bimodal chromosome complement of 4 long and 3 short chromosomes and the presence of a parenchymatous cap at the phloem pole. In contrast, the subfamily *Asphodeloideae* is often regarded as paraphyletic, is morphologically varied, leaf succulence is inconsistently found across generic boundaries, and has a wide distribution in continental Europe, W Asia, and S and tropical Africa. Dahlgren & Clifford (1982) proposed a circumscription of the *Asphodelaceae* that included the *Aloaceae* as a subfamily, along with the families *Asteliaceae* and *Anthericaceae*, also as subfamilies. A subsequent refinement of their 1982 work (Dahlgren & al. 1985) recognised the *Asphodelaceae* as a family with only two subfamilies: *Asphodeloideae* and *Aloioideae*, i.e. the classification followed here and also supported by Chase & al. (2000: 949) (Fig. 1). Over the past 15 years APG (2003) has proposed that the *Asphodelaceae* (and *Hemerocallidaceae*) be included in the *Xanthorrhoeaceae*—this name has priority over the older *Asphodelaceae* by virtue of conservation, and must therefore be used, but Klopper & al. (2013) proposed the conservation of the name *Asphodelaceae* to rectify the nomenclatural situation. The proposal was debated by the Nomenclature Committee for Vascular Plants (NCVP), and they strongly recommended the name *Asphodelaceae* for conservation (Applequist 2014: 1362). Recently the General Committee (GC) voted to accept the report of the NCVP (Wilson 2016: 1150), and this was duly accepted by the 19. International Botanical Congress in July 2017 (Turland & al. 2017: 5). The strictly phylogenetic classificatory approach of the APG at that time expanded the *Xanthorrhoeaceae* to about 27 genera and  $\pm 1,500$  species. We here prefer to maintain the *Asphodelaceae* as a separate family (Klopper & al. 2010), a view also advocated by Nyffeler &

**Fig. 1** Summary phylogeny of *Asphodelaceae* based on Devey & al. (2006) (1050 species total, data from Mabberley (2009) and own counts). 1 = *Asphodelus*, 2 = *Asphodeline*, 3 = *Bulbinella*; A = *Astroloba*, Ere =

*Eremurus*, G = *Gasteria*, Haw. = *Haworthia*, Kniph. = *Kniphofia*, P = *Poellnitzia*, Trac. = *Trachyandra*. (Copyright: U. Eggli)

Eggli (2010) and supported by the data of Seberg & al. (2012).

While the *Asphodelaceae* have no obvious gross morphological synapomorphies, it is distinguished from other lilioid monocots by the following combination of characters: A general presence of anthraquinones, the presence of chrysophanol in the roots, a general lack of steroidal saponins, presence of parenchymatous (often secretory) cells in the inner bundle sheath adjacent to the phloem, simultaneous microsporogenesis, predominantly hemitropous ovules and the presence of an appendage (aril) on the seed (Smith & Wyk 1998; Chase & al. 2000).

**Subfamily Alooideae:** Succulent rosette plants to small pachycaul trees: *Aloe* (including *Chortolirion* and *Lomatophyllum*), *Astroloba*, *Gasteria*, *Haworthia* and *Poellnitzia*.

The subfamily *Alooideae* has in the past been treated as tribe *Aloaeae* (often erroneously as ‘*Aloineae*’) of the family *Liliaceae* (Hutchinson 1959), or as a separate family, the *Aloaceae*, by some authors (Cronquist 1981 and Brummitt 1992; see Smith (1993) for clarification on the correct spelling of the family name as *Aloaceae*

rather than *Aloaceae*). *Alooideae* numbers  $\pm$  730 species in 5 genera, all of which occur in or are restricted to southern Africa. While the circumscription of the *Alooideae* is non-contentious, exact genus boundaries in the subfamily remain a topic of much discussion, as the status of genera like *Astroloba*, *Chortolirion*, *Lomatophyllum* and *Poellnitzia* and the monophyly of *Aloe* and *Haworthia* are questioned. Essentially, the current classification system for the subfamily weakly reflects phylogenetic affinities, being rather more indicative of evolutionary diversification. In this respect the likely presence of reticulate evolution caused by frequent historical and recent hybridization is a complicating factor. Subfamily *Alooideae* has a pronounced southern African centre of generic and species diversity, with outliers of *Aloe* in the Arabian Peninsula, Madagascar and the Mascarene Islands (Smith & Wyk 1998; Treutlein & al. 2003).

Based on extensive molecular phylogenetic studies, it has become amply clear that *Aloe* in its current circumscription is paraphyletic relative to *Astroloba*, *Chortolirion*, *Gasteria*, *Haworthia* and *Poellnitzia*, and that *Haworthia* itself is not

monophyletic. Grace & al. (2013) started to formalize a revised classification by recognizing several early-diverging clades of *Aloe* as segregate genera (*Aloidendron*, *Aloiampelos*, *Kumara*) and included *Chortolirion* within the concept of *Aloe* s.s. Manning & al. (2014) went one step further and erected the genera *Aristaloe* and *Gonialoe* for a couple of anomalous taxa in the clade that embraces the part of *Haworthia* that was segregated as *Haworthiopsis* and *Tulista* by Rowley (2013), and *Gasteria*. For the present handbook the conventional circumscriptions of *Aloe* (but with *Chortolirion* included) and *Haworthia* are maintained, partly because the backbone topology of the Alooids still suffers from inadequate statistical support in a number of cases, and partly because the full diversity of *Aloe* has still not been sampled. The only exception is *Chortolirion*, which is now included in *Aloe*. Another option to arrive at a fully phylogenetic classification would be to enlarge *Aloe* to cover all traditionally accepted segregate genera of the subfamily, but this option is at least for the time being considered as impractical and not helpful.

Members of this subfamily share several apomorphies: Consistently hemitropous ovules, a distinctly bimodal basic karyotype consisting of 4 long and 3 short chromosomes, the presence of a parenchymatous, cap-like inner bundle sheath at the phloem poles (Smith & Wyk 1992), the presence of anthrone-C-glycosides in the leaves, and 1-methyl-8-hydroxyanthraquinones in the roots. Steroidal saponins are generally absent. To this may be added the succulent leaf consistency and the widespread occurrence of secondary growth via a secondary thickening meristem, although not all members of the subfamily exhibit the latter character (Smith & Wyk 1998; Chase & al. 2000; Treutlein & al. 2003; Klopper & al. 2010). In gross morphological terms it differs from subfamily *Asphodeloideae*, though not entirely consistently, by invariably having succulent leaves and tubular flowers.

Numerous taxa of *Aloe*, *Gasteria* and *Haworthia* are cultivated by succulent plant enthusiasts, and *Aloe* species are also often planted as conspicuous garden plants in warmer

climates. Apart from limited medicinal and other traditional uses of several taxa of *Haworthia* and *Gasteria*, *Aloe vera* and *A. ferox* are widely used medicinally as purgatives, as ingredients in cosmetic and health products, and to treat skin irritations and burns. The industries based on these two taxa are worth millions of dollars per year alone in RSA.

Numerous bigeneric and some trigenic hybrids have been created and formally named (see Rowley (2006) for a list of accepted and synonymous nothogeneric names; and Rowley (2014) for an updated list reflecting the re-classification of *Aloe* and *Haworthia*). However, Smith & al. (2017) and Smith & al. (2018) do not follow the expanded interpretation of *Tulista* and have published the nothogenus names  $\times$ *Astrolista* Molteno & Figueiredo and  $\times$ *Gonimara* Gideon F.Sm. & Molteno.

**Subfamily *Asphodeloideae*:** Perennial, rarely annual herbs to subshrubs: *Asphodeline* (non-succulent), *Asphodelus* (non-succulent), *Eremurus* (non-succulent), *Bulbine* (including *Jodrellia*), *Bulbinella* (1 species succulent), *Kniphofia* (1 succulent species), *Trachyandra*.

The subfamily *Asphodeloideae* comprises about 320 species. The group has a broad Old World distribution and is found from S and tropical Africa, through, especially Mediterranean Europe to W Asia. The Mediterranean region and the winter rainfall region of the Cape Provinces of South Africa in particular are present-day centres of diversity. In this regard, 2 genera, *Bulbine* and *Bulbinella*, occur predominantly in southern Africa, but with outliers in Australia and New Zealand, respectively.

In both reproductive and vegetative morphology, members of the *Asphodeloideae* vary greatly, with some taxa (e.g. *Trachyandra*) having the general appearance of members of the *Anthericaceae*, and others (e.g. *Kniphofia*) of members of the subfamily *Alooideae*. In the absence of convincing macro- and micro-morphological, and other synapomorphies, this subfamily is generally regarded as being para- or even polyphyletic (Smith & Wyk 1998; Chase

## Key to genera with succulents

1a	<b>Per</b> stellate to campanulate, segments free	2
1b	<b>Per</b> tubular, usually with short, erect or erecto-patent lobes, segments at least partly fused towards the base	4
2a	<b>Fil</b> densely and softly bearded, also in the case of the species formerly included in <i>Jodrellia</i>	<i>Bulbine</i>
2b	<b>Fil</b> glabrous or scabrid	3
3a	<b>Fl</b> white, rarely yellow, pink, or mauve, segments usually dark-keeled; <b>L</b> thickly leathery to succulent	<i>Trachyandra</i>
3b	<b>Fl</b> yellow, orange, white or cream, segments lacking dark keel; <b>L</b> mesophytic to softly succulent ( <i>Bulbinella calcicola</i> )	<i>Bulbinella</i>
4a	<b>L</b> distinctly V-shaped in cross section, soft (mesophytic), not succulent (except <i>Kniphofia typhoides</i> ), in basal rosettes, lacking spines, immaculate; <b>Inf</b> usually a simple, dense raceme or spike	<i>Kniphofia</i>
4b	<b>L</b> cymbi- or crescentiform in cross section, ± succulent, in basal or apical rosettes or cauline, hard, often spiny and/or distinctly to indistinctly maculate with spots or tubercles	5
5a	<b>Fr</b> capsules apically acute; <b>L</b> narrowly linear, margin with dense, small, retrorse teeth; underground parts bulbous; <b>Fl</b> usually <15 mm long, irregular	<i>Aloe</i> sect. <i>Chortolirion</i>
5b	<b>Fr</b> capsules apically rounded or obtuse; <b>L</b> usually thickly succulent, deltoid to lanceolate, margin mostly variously armed with soft or pungent spines; underground parts rhizomatous or stoloniferous (if rarely bulbous then <b>Fl</b> >15 mm long, regular)	6
6a	<b>Fl</b> pendulous at anthesis, <b>Per</b> tube curved upwards at apex	<i>Gasteria</i>
6b	<b>Fl</b> erect, suberect or spreading at anthesis; <b>Per</b> tube straight or curved downwards at apex	7
7a	<b>Per</b> bilabiate, <15 mm long, mouth declined	<i>Haworthia</i>
7b	<b>Per</b> regular (if rarely weakly bilabiate then flowers >15 mm long), mouth upturned	8
8a	<b>Fl</b> usually brightly coloured, fleshy	9
8b	<b>Fl</b> white or dull-coloured, flimsy	<i>Astroloba</i>
9a	<b>Tep</b> spreading; <b>St</b> as long as or longer than the perianth	<i>Aloe</i>
9b	<b>Tep</b> apically connivent; <b>St</b> shorter than the perianth	<i>Poellnitzia</i>

& al. 2000; Klopper & al. 2010). Most taxa in this subfamily are non-succulent, an obvious exception being the genus *Bulbine*, some species of *Trachyandra*, one species of *Bulbinella*, *B. calcicola*, and one species of *Kniphofia*, *K. typhoides*. Although species of *Asphodelus* are generally regarded as bulbous or tuberous rather than succulent, data presented by Sawidis & al. (2005) indicate that the perennial geophyte *A. aestivus* from the European Mediterranean basin behaves like a real succulent, based on the morphology of its subterranean storage organs and the efficiency with which water is stored. It is not unlikely that succulence occurs more widely in the genus.

The subfamily *Asphodeloideae* has no recognized economic importance except that many species are of horticultural interest, and some are locally used in various ways. Amongst the succulents, a small number of species of

*Bulbine* and *Trachyandra* have local importance as food items or for their medicinal properties.

- Incl.** ×*Aloiampaloe* G. D. Rowley (2014).
- Incl.** ×*Altulista* G. D. Rowley (2014).
- Incl.** *Aristaloe* Boatwright & J. C. Manning (2014). **Type:** *Aloe aristata* Haworth.
- Incl.** *Gonialoe* Boatwright & J. C. Manning (2014). **Type:** *Aloe variegata* Linné.
- Incl.** ×*Kumalista* G. D. Rowley (2014).
- Incl.** ×*Gonimara* Gideon F. Smith & Molteno (2018).
- Incl.** *Aloestrela* Molteno & Gideon F. Smith (2019). **Type:** *Aloe suzannae* Decary.

Perennial leaf succulents, acaulescent, shrubby, or arborescent, simple or branching; **L** rosulate, distichous or scattered along the stem, usually ± triangular, lanceolate or falcate, sometimes linear, amplexicaul, the margins usually armed with soft or pungent deltoid teeth, the teeth usually more crowded near the leaf base, glabrous, sometimes with short prickles on the surface, uniformly coloured or with whitish or pale green spots, surface smooth or rough, usually with a bitter tasting yellow or brown exudate when broken, rarely containing fibres; **Inf** lateral, usually ± erect, simple or branching, with cylindrical or capitate racemes, sometimes with flowers secund; **Fl** bracteate, pedicellate or rarely sessile, protandrous, usually erect in bud and pendulous at anthesis; **Ped** often lengthening in fruit; **Per** base rounded, truncate or attenuate, zygomorphic, cylindrical at the base, usually becoming trigonous and slightly compressed laterally above, usually curved, usually red or yellow, rarely white, usually glabrous, rarely puberulent; **OTep** 3, usually marginally fused at the base, tips free; **ITep** 3, usually with margins free but dorsally adnate to the tube formed by the outer tepals, tips free; **St** 6, usually with **Anth** exerted partly or just clear of the perianth (1–6 mm), each group of 3 elongating and exerted, and then retracted in turn during anthesis; **Sty** simple with small capitate **Sti**; **Fr** usually capsules, sometimes berries; **Se** angular or flattened, black or brown, usually with narrow membranous wings. — **Cytology:** The majority of species investigated are diploid, with a somatic number of  $2n = 14$ . One hexaploid

and several tetraploids are also known. Known chromosome counts were summarised by Riley & Majumdar (1979), and some later authors have provided chromosome numbers when describing new taxa.

**Classification and History:** In 1753, at the nomenclatural starting point for flowering plants, Linnaeus included the genus *Aloe* with 9 species, some of which had varieties listed, totalling 35 taxa. Only 5 of these taxa are still in the genus *Aloe* today, the rest having been transferred later to the genera *Astroloba* (1947), *Gasteria* (1809), *Haworthia* (1809), *Kniphofia* (1794) and *Sansevieria* (1794).

Many segregate genera have been proposed, as seen in the generic synonymy above, but few have been generally accepted. The genus *Lomatophyllum* was proposed in 1811 for a species with fleshy fruits, later added to by several other species, and was recognised for 185 years until the species were transferred to *Aloe* by Rowley (1996). Early in the twentieth century, Berger described the genus *Chamaealoe* (1905) and later Stapf described the genus *Leptaloe* (1933), but their species are now included in *Aloe*. Much later the monotypic genus *Guillauminia* was proposed for *Aloe albiflora* in 1956, but this was not recognised by Reynolds (1966). Heath (1994) later recognised *Guillauminia* and added 5 other species, but without any explanatory text to justify his action. In the same paper Heath added 2 more species to his genus *Lemeea*, proposed in 1993 for *Aloe* sect. *Aloinella* A. Berger, again without explanatory text.

More recent proposals for taxonomic change are based on molecular taxonomy, which aims to elucidate phylogeny. Grace & al. (2013) proposed the reinstatement of the genus *Kumara*, and the establishment of two new segregate genera, *Aloidendron* and *Aloiampelos*, and the sinking of *Chortolirion* into *Aloe*. However, mostly South African species were mentioned and included in the new combinations, and it is not entirely clear how the rest of the genus might be affected. Rowley (2013a) supported recognition of the segregate genera proposed by Grace & al. (2013), and

goes further by proposing two new genera, one of which, *Tulista*, includes a species of *Aloe* (*A. aristata*) (Rowley 2013b). Daru & al. (2013) also proposed a re-circumscription of the genus, but their findings are not completely congruent with those of Grace & al. (2013). Manning & al. (2014a) (summarized by Manning & al. (2014b)) went further, proposing two other new segregate genera, *Aristaloe* and *Gonialoe*. Manning & al. (2014a) recognised 6 clades, 5 of which were to be considered as separate genera. These are: Sect. *Aloidendron* + sect. *Dracoaloe* (= genus *Aloidendron*), sect. *Aristatae* (= genus *Aristaloe*), sect. *Kumara* + sect. *Haemanthifoliae* (= genus *Kumara*), sect. *Macrifoliae* (= genus *Aloiampelos*), and sect. *Serrulatae* (= genus *Gonialoe*); and the rest of the genus remaining as *Aloe*. As the whole situation is still in a state of flux (as witnessed by the recent paper of Rowley (2014b), where these plus *Astroloba* are treated as subgenera of *Tulista*), the new names are included here as synonyms until consensus has been reached. The same option, i.e. continuing to recognize *Aloe* in its traditional circumscription, was also chosen by Wyk & Smith (2014). An exception is made regarding the synonymization of *Chortolirion*, which is now included into *Aloe* in all recent studies. Grace & al. (2013) and Daru & al. (2013) independently transferred its species to *Aloe*, and the correct names to be used when treated as *Aloe* were explained by Klopper & al. (2013), where 4 species were recognised, and again by Manning & al. (2014a). As we go to press a new paper has appeared (Meer 2019) with many proposed nothogeneric names for various hybrids between the new genera suggested by recent molecular studies, together with new combinations. As there is not yet a generally accepted consensus on these new genera the new nothogeneric names are not listed here.

**Infrageneric relationships as shown in recent molecular studies:** Even though the recent study of Grace & al. (2015) includes a good number (197 species) of the diversity of the genus, and covers all major groups, not even the backbone of their cladogram is statistically well-supported.

**Fig. 1** Approximate phylogeny of *Aloe* s.s. derived from the molecular phylogeny of Grace & al. (2015), based on DNA sequencing of 197 species. Minor clades and grades

are collapsed into single items; triangle widths are arbitrary and only give a very rough indication of the number of species per clade. (Copyright: U. Eggli)

Based on the main topology and major clades (Fig. 1), the following conclusions are emerging:

- The placement of several species raises pronounced doubt, either concerning the correctness of the identification of the studied material, or concerning possible statistical artefacts in the interpretation of the sequence data. For instance, the Madagascan *A. acutissima* and *A. bakeri* occupy a position deeply embedded in a clade of species from the Arabian Peninsula. Another such example is the Madagascan *A. propagulifera*, shown as sister to the Somalian *A. eminens* and a clade made up of the South African *A. albida* and *A. chortolirioides*. Similar suspected mis-placings (e.g. *A. propagulifera* or *A. anivoranoensis* next to South African taxa) are also evident in the cladogram of Manning & al. (2014a).
- All basal clades are of African origin. Grace & al. (2015) show *A. comptonii* as basal sister to the rest of *Aloe* s.s. (i.e. excluding *Aloidendron*, *Aloiampelos*, *Kumara*), and as next higher clade a rather well-supported group embracing *A. melanacantha*, *A. pearsonii*, *A. arenicola*, *A. distans* and *A. perfoliata*. Most of these species are also shown as relatively basal in the cladogram of Manning & al. (2014a).
- The “Maculate Aloes” of S and E Africa, i.e. ser. *Saponariae*, form a coherent species group.

- Species from the Arabian Peninsula also form a coherent group (that includes *A. vera*), in sister-position to a similarly supported clade of E African and Arabian species.
- A further reasonably well-supported clade is formed by a group of species from E Africa and the Horn of Africa (esp. Ethiopia).
- The analysed species of the former genus *Lomatophyllum* form the sister group to a reasonably well-supported clade of Madagascan species, which is, however, morphologically very heterogeneous and includes, inter alia, *A. haworthioides* in close proximity to *A. vaombe*.
- A phylogenetic study of species of Madagascar and other Indian Ocean islands (Dee & al. 2018) suggests that they are not a phylogenetic unit. Some are more closely related to species on the African continent, suggesting that there were several dispersal events in the development of the Madagascan *Aloe* flora.
- The so-called “Grass Aloes” also form a reasonably well-supported clade (also shown in the phylogeny of Manning & al. (2014a)) which includes the former genus *Chortolirion*. “Grass Aloes” are thus a relatively highly derived group that diversified in a special habitat.
- The final clade, and sister to the “Grass Aloes”, is made up entirely by South African species. It is another morphologically disparate clade, including a diversity of growth forms as exhibited, e.g., by *A. arborescens*, *A. ferox*, *A. humilis* and *A. bowiea*.
- If the placement of species in the phylogeny is correct, neither the E African/Arabian Aloes nor the Madagascan Aloes form single clades, so multiple migrations to these regions have to be assumed. There is also the likelihood of neoendemic groups, such as the species with hairy flowers and the *A. archeri* group (Newton 1980).
- With the exception of the “Maculate Aloes” and the “Grass Aloes”, the molecularly defined clades appear to lack diagnostic characters, and many are (as indicated above) morphologically highly diverse. If the relationships shown in the cladogram of Grace & al. (2015) are correct,

growth form is a highly plastic character that changes rapidly during evolution.

- Only about 33% of all *Aloe* species have so far been analyzed molecularly. With the inclusion of more species, the relative relationships even in the reasonably supported sections of the cladogram are likely to change. The present state of knowledge is thus still to be considered as very provisional.

**Pollination:** Typically, aloes are ornithophilous, with nectar-feeding sunbirds (*Nectariniidae*) as the principal pollen vectors. Bees also visit the flowers but are not efficient pollinators, except in some species with short flowers (Hargreaves & al. 2012). One species, *A. inconspicua*, has been shown to be exclusively pollinated by bees (Hargreaves & al. 2008). Those bees collecting pollen for their own use are regarded as “nectar thieves”, and those seeking nectar only may contribute to pollination. The nectar of a few species, including *A. vryheidensis*, contains phenolic compounds, giving it a dark colour and bitter taste. Experiments suggest that this deters visits by bees (Johnson & al. 2006). Detailed field studies of pollination showed that nocturnal visits by some small mammals also contributed to seed production in *A. peglerae* (Payne & al. 2016) and *A. reitzii* (Symes 2017), though not as efficiently as birds. Arena (2018) reports visits by Elephant Shrews to the flowers of *A. claviflora*.

**Ethnobotany:** *Aloe vera* has been used as a medicinal plant for centuries, having featured in early herbals, and today it is the basis of a thriving industry in the production and world-wide marketing of skin creams, “health drinks”, and many cosmetic products (Upton & al. 2012). *A. ferox* has also become an important commercial plant in South Africa (Newton & Vaughan 1996). Apart from this large-scale commercial use of aloes, many species are used locally throughout the range of the genus (Grace & al. 2009, Grace 2011, Wyk 2013, BJORÅ & al. 2015). Whilst medicinal uses predominate, for both humans and domestic animals, other local uses for aloes range from hedging around farms to using the

roots in brewing beer. Chinchilla & al. (2013) provide a full review of chemistry studies and biological activities, and report baked clay tablets from Sumeria from 2100 BCE as first account of the use of *Aloe*.

**Hybrids:** Some intergeneric hybrids are known, especially between *Aloe* and *Gasteria* (=  $\times$ *Gasteraloe*). Many early intergeneric hybrids were documented by Rowley (1982), and Rowley (2014a) presents an update reflecting the proposed re-classification of *Aloe* and *Haworthia*. This reclassification has led to a number of new nothogeneric names, summarized by Rowley (2017: 192).

Interspecific hybrids have occurred spontaneously in the wild, and many were recorded by Reynolds (1950), Reynolds (1966), and Newton (1998a). There has also been some artificial hybridization with the aim of producing worthwhile cultivars, the greatest number of named ones being in southern Africa (described in *Aloe*, Journal of the South African Succulent Society, between 1971 and 1978), and in the USA (Riley 1993), with a few in England (Brandham 1973). Naturally occurring named hybrids are treated in their appropriate alphabetical sequence.

The following names refer to intrageneric hybrids obtained in cultivation: *A. \times antoninii*, *A. \times heteracantha*, *A. \times jacobseniana*, *A. \times pallancae*, *A. \times panormitana*, and *A. \times principis* (incl. *A. \times salm-dyckiana*).

**Infrageneric Classification:** No satisfactory infrageneric classification has been proposed since that of Berger (1908), since which time numerous new species have been described. The diversity of character combinations in the genus has, so far, obscured the phylogenetic relationships. For species of southern Africa Reynolds (1950) enlarged Berger's scheme somewhat, but when dealing with tropical species, he (Reynolds 1966) created new groups without formal names or ranks, some of them clearly artificial. These groups were mainly based on growth habit, starting with smaller plants and leading to trees.

This system was followed, with modification, in several later publications (Wyk & Smith 2004, Carter & al. 2011). The development of a new infrageneric classification for the genus is a long way off and so for the present a completely artificial synopsis is presented below, based on growth habit and inflorescence form. Some very variable species appear in more than one group:

#### Artificial Groups:

**A.** Plants acaulescent or with stems shorter than the  $\emptyset$  of the rosette; **L** broad (>2 cm) unless otherwise stated:

- [1] Plants with linear or very narrow **L** (usually <2 cm wide), solitary or forming groups.
- [2] Plants always solitary; **Inf** usually unbranched or with 1 **Br**.
- [3] Plants always solitary; **Inf** usually with 2 or more **Br**.
- [4] Plants solitary or forming small groups; **Inf** usually unbranched or with 1 **Br**.
- [5] Plants solitary or forming small groups; **Inf** usually with 2 or more **Br**.
- [6] Plants suckering to form groups; **Inf** unbranched or with 1 **Br**.
- [7] Plants suckering to form groups; **Inf** with 2 or more **Br**.

**B.** Plants with obvious stems; **L** broad (>2 cm) unless otherwise stated:

- [8] **Ros** on unbranched stems to 2 m tall.
- [9] Trees with usually unbranched trunks to >2 m tall; in some taxa suckering or branching at the base to produce 2 or more trunks.
- [10] Plants with linear or very narrow **L**, solitary or branching, sometimes pendulous.
- [11] Plants forming low clumps, often dense.
- [12] Plants forming large clumps (at least 1 m tall).
- [13] Plants with decumbent, sprawling or pendulous stems.
- [14] Plants with stems scrambling in or supported by surrounding vegetation.
- [15] Plants forming shrubs to 1 m tall.
- [16] Plants forming shrubs >1 m tall.

[17] Trees with basal trunks and branching above.

C. [18] Plants of unknown or uncertain growth habit.

In the descriptions below, width of leaf or bract is width at the widest point, at or near the base; details of marginal teeth refer to the middle of the leaf; and diameter of flowers is as seen from the side. Character states that are common to the majority of taxa are not stated, only the exceptions being given. For example, unless otherwise stated, leaves are erect or slightly spreading, flat or slightly canalicate above and convex below, inflorescences are erect, floral bracts are scarious, whitish with darker veins, flowers are glabrous, with cylindrical base and laterally compressed with trigonous shape above, and fruits are capsules.

The following names are of unresolved application but are referred to this genus: *Agave armata* Anonymous (1878); *Aloe abyssinica* Lamarck (1783); *Aloe agavefolia* Todaro (1878); *Aloe albispina* Haworth (1804)  $\equiv$  *Aloe mitriformis* var. *albispina* (Haworth) A. Berger (1908); *Aloe ankabeensis* Hort. W. Sterk (1988) (*nom. inval.*, ICN Art. 36.1b, 39.1); *Aloe arabica* Salm-Dyck (1817) (*nom. illeg.*, ICN Art. 53.1); *Aloe arborea* Forsskål (1775); *Aloe chloroleuca* Baker (1877); *Aloe cinnabarina* Diels & A. Berger (1905); *Aloe commelinii* Willdenow (1811)  $\equiv$  *Aloe mitriformis* var. *commelinii* (Willdenow) Baker (1880); *Aloe congolensis* De Wildeman & T. Durand (1899); *Aloe consobrina* Salm-Dyck (1863); *Aloe defalcata* Chiovenda (1932); *Aloe deflexidens* Pillans (1935); *Aloe dorsalis* Haworth (1821); *Aloe drepanophylla* Baker (1875); *Aloe elizae* A. Berger (1910); *Aloe flavispina* Haworth (1804)  $\equiv$  *Aloe mitriformis* var. *flavispina* (Haworth) Baker (1880); *Aloe fraskii* Croucher (1874); *Aloe gasterioides* Baker (1880); *Aloe grahamii* Schönland (1903); *Aloe greenii* Green ex Robinson (1875); *Aloe hexapetala* Salm-Dyck (1817); *Aloe horrida* Haworth (1804); *Aloe humilis* var. *macilentata* Baker (1880); *Aloe leucantha* A.

Berger (1905); *Aloe longiflora* Baker (1888); *Aloe macracantha* Baker (1880); *Aloe mitis* A. Berger (1908); *Aloe mitriformis* var. *humiliior* Willdenow (1811); *Aloe mitriformis* var. *pachyphylla* Baker (1880); *Aloe nobilis* Baker (1880) (*nom. illeg.*, ICN Art. 53.1); *Aloe nobilis* var. *densifolia* Baker (1880); *Aloe obscura* A. Berger ex Schönland (1905) (*nom. illeg.*, ICN Art. 53.1); *Aloe pallescens* Haworth (1821)  $\equiv$  *Aloe serrulata* var. *pallescens* (Haworth) Baker (1880); *Aloe perfoliata* var. *obscura* Aiton (1789); *Aloe perfoliata* var. *serrulata* Aiton (1789)  $\equiv$  *Aloe serrulata* (Aiton) Haworth (1804); *Aloe platylepis* Baker (1877); *Aloe pungens* A. Berger (1908); *Aloe rossii* Todaro (1891); *Aloe rubescens* De Candolle (1799); *Aloe runcinata* A. Berger (1908); *Aloe saponaria* var. *obscura* Haworth (1804); *Aloe sororia* A. Berger (1908); *Aloe spinulosa* Salm-Dyck (1822)  $\equiv$  *Aloe mitriformis* var. *spinulosa* (Salm-Dyck) Baker (1880); *Aloe spuria* A. Berger (1908); *Aloe stans* A. Berger (1908); *Aloe straussii* A. Berger (1912); *Aloe tenuifolia* Lamarck (1783); *Aloe xucraiae* A. Terraciano (1897)  $\equiv$  *Aloe arborescens* var. *ucraiae* (A. Terraciano) A. Berger (1908); *Aloe venenosa* Engler (1893); *Aloe virens* Haworth (1804); *Aloe virens* var. *macilentata* Baker (1880); *Aloe xanthacantha* Willdenow (1811)  $\equiv$  *Aloe mitriformis* var. *xanthacantha* (Willdenow) Baker (1880).

**A. aaata** T. A. McCoy & Lavranos (Cact. Succ. J. (US) 86(6): 259–260, ill. (pp. 258–260), 2014). **Type:** Saudi Arabia, Asir Prov. (McCoy 3861 [FT]). — **Distr:** Saudi Arabia (Asir Prov.); granite outcrops, 2000 m.
